MySQL 6.0 Reference Manual

MySQL 6.0 Reference Manual

Abstract

This is the MySQL Reference Manual. It documents MySQL 6.0 through 6.0.12.

MySQL Cluster is currently not supported in MySQL 6.0. For information about MySQL Cluster, please see MySQL Cluster NDB 6.X/7.X.

MySQL 6.0 features. This manual describes features that are not included in every edition of MySQL 6.0; such features may not be included in the edition of MySQL 6.0 licensed to you. If you have any questions about the features included in your edition of MySQL 6.0, refer to your MySQL 6.0 license agreement or contact your Sun Microsystems sales representative.

Document generated on: 2009-06-03 (revision: 15169)

The following table provides direct links into areas of the manual according to different topics. Links marked with » link to online guides and other manuals for more information.

Table 1. Topic Quick Reference

Getting Started	Platforms	Administrators	Developers	Functionality	Connectors	HA/Scalability
Tutorial	» Linux/Unix	Server Option/ Variable Reference	Server Option/ Variable Reference	SQL Syntax	Connector/J	» HA/ Scalability Guide
Installation	» Mac OS X	MySQL Change History	» MySQL Version Reference	Views	Connector/ ODBC	MySQL and DRBD
Upgrading	» Windows	» MySQL Version Reference	SQL Syntax	Stored Routines	Connector/ NET	MySQL and Virtualization
Server Administration	» Solaris	» Security	Optimization	Replication	Connector/C++	Memcached
FAQs	» Building from Source	» Startup/ Shutdown	Connectors & APIs	Spatial Extensions	Connector/ OOo	MySQL Proxy
		» Backup and Recovery	Functions and Operators	Precision Math	PHP	Replication
		Partitioning		I18N & L18N	C API	
		Information Schema		Partitioning		

If you want help with using MySQL, please visit either the MySQL Forums or MySQL Mailing Lists where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML, CHM, and PDF formats, see MySQL Documentation Library.

Preface, Notes, Licenses

This is the Reference Manual for the MySQL Database System, version 6.0, through release 6.0.12. It is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 6.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the *MySQL 5.1 Reference Manual*, which covers the 5.1 series of MySQL software releases, *MySQL 5.0 Manual*, which covers MySQL 5.0 releases, or to *MySQL 3.23, 4.0, 4.1 Reference Manual*, which covers the 3.23, 4.0, and 4.1 series of MySQL software releases. Differences between minor versions of MySQL 6.0 are noted in the present text with reference to release numbers (6.0.*x*).

1. MySQL Copyright Notice

2. `regex` Library License

The `regex` library used for the `REGEXP` operator is covered by this license:

```
   misrepresented as being the original software.  Since few users
   ever read sources, credits must appear in the documentation.

4. This notice may not be removed or altered.
```

3. `libedit` License

Each file in the `libedit` library is covered by one of the following three licenses:

```
/*-

5. Unicode Terms of Use

```
            Unicode Terms of Use
For the general privacy policy governing access to this
site, see the Unicode Privacy Policy. For trademark
usage, see the Unicode Consortium® Trademarks and
Logo Policy.

   A. Unicode Copyright.
      1. Copyright © 1991-2008 Unicode, Inc.
        All rights reserved.
      2. Certain documents and files on this
        website contain a legend indicating that
        "Modification is permitted." Any person
        is hereby authorized, without fee, to modify
        such documents and files to create derivative
        works conforming to the Unicode© Standard,
        subject to Terms and Conditions herein.
      3. Any person is hereby authorized, without fee, to
        view, use, reproduce, and distribute all
        documents and files solely for informational
        purposes in the creation of products
        supporting the Unicode Standard, subject to
        the Terms and Conditions herein.
      4. Further specifications of rights and restrictions
        pertaining to the use of the particular set of
        data files known as the "Unicode Character
        Database" can be found in Exhibit 1.
      5. Each version of the Unicode Standard has
        further specifications of rights and restrictions
        of use. For the book editions, these are found
        on the back of the title page. For the online
        edition, certain files (such as the PDF files for
        book chapters and code charts) carry specific
        restrictions. All other files are covered under
        these general Terms of Use. To request a
        permission to reproduce any part of the
        Unicode Standard, please contact the Unicode
        Consortium.
      6. No license is granted to "mirror" the Unicode
        website where a fee is charged for access to
        the "mirror" site.
      7. Modification is not permitted with respect to this
        document. All copies of this document must be
        verbatim.

B. Restricted Rights Legend. Any technical data or
   software which is licensed to the United States of
   America, its agencies and/or instrumentalities under
   this Agreement is commercial technical data or
   commercial computer software developed
   exclusively at private expense as defined in
   FAR 2.101, or DFARS 252.227-7014 (June 1995), as
   applicable. For technical data, use, duplication, or
   disclosure by the Government is subject to
   restrictions as set forth in DFARS 202.227-7015
   Technical Data, Commercial and Items (Nov 1995)
   and this Agreement. For Software, in accordance
   with FAR 12-212 or DFARS 227-7202, as applicable,
   use, duplication or disclosure by the Government is
   subject to the restrictions set forth in this Agreement.
```

```
C. Warranties and Disclaimers.
      1. This publication and/or website may include
        technical or typographical errors or other
        inaccuracies . Changes are periodically added
        to the information herein; these changes will
        be incorporated in new editions of the
        publication and/or website. Unicode may make
        improvements and/or changes in the
        product(s) and/or program(s) described in this
        publication and/or website at any time.
      2. If this file has been purchased on magnetic or
        optical media from Unicode, Inc. the sole and
        exclusive remedy for any claim will be
        exchange of the defective media within ninety
        (90) days of original purchase.
      3. EXCEPT AS PROVIDED IN SECTION C.2, THIS
        PUBLICATION AND/OR SOFTWARE IS
        PROVIDED "AS IS" WITHOUT WARRANTY OF
        ANY KIND EITHER EXPRESS, IMPLIED, OR
        STATUTORY, INCLUDING, BUT NOT LIMITED
        TO, ANY WARRANTIES OF
        MERCHANTABILITY, FITNESS FOR A
        PARTICULAR PURPOSE, OR
        NON-INFRINGEMENT. UNICODE AND ITS
        LICENSORS ASSUME NO RESPONSIBILITY
        FOR ERRORS OR OMISSIONS IN THIS
        PUBLICATION AND/OR SOFTWARE OR
        OTHER DOCUMENTS WHICH ARE
        REFERENCED BY OR LINKED TO THIS
        PUBLICATION OR THE UNICODE WEBSITE.

D. Waiver of Damages. In no event shall Unicode or its
   licensors be liable for any special, incidental, indirect
   or consequential damages of any kind, or any
   damages whatsoever, whether or not Unicode was
   advised of the possibility of the damage, including,
   without limitation, those resulting from the following:
   loss of use, data or profits, in connection with the
   use, modification or distribution of this information or
   its derivatives.

E. Trademarks.
    1. Unicode and the Unicode logo are registered
      trademarks of Unicode, Inc.
    2. This site contains product names and
      corporate names of other companies. All
      product names and company names and
      logos mentioned herein are the trademarks or
      registered trademarks of their respective
      owners. Other products and corporate names
      mentioned herein which are trademarks of a
      third party are used only for explanation and for
      the owners' benefit and with no intent to
      infringe.
    3. Use of third party products or information
      referred to herein is at the user's risk.

F. Miscellaneous.
    1. Jurisdiction and Venue. This server is operated
      from a location in the State of California, United
      States of America. Unicode makes no
      representation that the materials are
      appropriate for use in other locations. If you
      access this server from other locations, you are
      responsible for compliance with local laws.
      This Agreement, all use of this site and any
      claims and damages resulting from use of this
      site are governed solely by the laws of the State
      of California without regard to any principles
      which would apply the laws of a different
      jurisdiction. The user agrees that any disputes
      regarding this site shall be resolved solely in
      the courts located in Santa Clara County,
      California. The user agrees said courts have
      personal jurisdiction and agree to waive any
      right to transfer the dispute to any other forum.
    2. Modification by Unicode. Unicode shall have the
      right to modify this Agreement at any time by
      posting it to this site. The user may not assign
      any part of this Agreement without Unicode's
      prior written consent.
    3. Taxes. The user agrees to pay any taxes
      arising from access to this website or use of
      the information herein, except for those based
      on Unicode's net income.
    4. Severability. If any provision of this Agreement
      is declared invalid or unenforceable, the
      remaining provisions of this Agreement shall
      remain in effect.
    5. Entire Agreement. This Agreement constitutes
      the entire agreement between the parties.

                              EXHIBIT 1
UNICODE, INC. LICENSE AGREEMENT - DATA FILES AND SOFTWARE

  Unicode Data Files include all data files under the
  directories http://www.unicode.org/Public/,
```

```
  http://www.unicode.org/reports/, and
  http://www.unicode.org/cldr/data/ . Unicode Software
  includes any source code published in the Unicode
  Standard or under the directories http://www.unicode.org
  /Public/, http://www.unicode.org/reports/, and
  http://www.unicode.org/cldr/data/.

  NOTICE TO USER: Carefully read the following legal
  agreement. BY DOWNLOADING, INSTALLING, COPYING
  OR OTHERWISE USING UNICODE INC.'S DATA FILES
  ("DATA FILES"), AND/OR SOFTWARE ("SOFTWARE"),
  YOU UNEQUIVOCALLY ACCEPT, AND AGREE TO BE
  BOUND BY, ALL OF THE TERMS AND CONDITIONS OF
  THIS AGREEMENT. IF YOU DO NOT AGREE, DO NOT
  DOWNLOAD, INSTALL, COPY, DISTRIBUTE OR USE THE
  DATA FILES OR SOFTWARE.

Chapter 1. General Information

The MySQL® software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. MySQL is a registered trademark of MySQL AB.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from MySQL AB. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion about the capabilities of the MySQL Database Server, see Section 1.3.3, “The Main Features of MySQL”.
- For future plans, see Section 1.4, “MySQL Development Roadmap”.
- For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*. For information about upgrading MySQL, see Section 2.11.1, “Upgrading MySQL”.
- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *Tutorial*.
- For information about configuring and administering MySQL Server, see Chapter 5, *MySQL Server Administration*.
- For information about setting up replication servers, see Chapter 16, *Replication*.
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see Appendix A, *MySQL 6.0 Frequently Asked Questions*.
- For a list of currently known bugs and misfeatures, see Section B.1.8, “Known Issues in MySQL”.
- For a list of all the contributors to this project, see Section 1.8, “Credits”.
- For a history of new features and bugfixes, see Appendix C, *MySQL Change History*.
- For tips on porting the MySQL Database Software to new architectures or operating systems, see MySQL Internals: Porting.
- For benchmarking information, see the `sql-bench` benchmarking directory in your MySQL distribution.

> **Important**
>
> To report errors (often called “bugs”), please use the instructions at Section 1.6, “How to Report Bugs or Problems”.
>
> If you have found a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to `<security@mysql.com>`.

1.1. About This Manual

This is the Reference Manual for the MySQL Database System, version 6.0, through release 6.0.12. It is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 6.0 and previous versions. If you are using an earlier release of the MySQL software, please refer to the *MySQL 5.1 Reference Manual*, which covers the 5.1 series of MySQL software releases, *MySQL 5.0 Manual*, which covers MySQL 5.0 releases, or to *MySQL 3.23, 4.0, 4.1 Reference Manual*, which covers the 3.23, 4.0, and 4.1 series of MySQL software releases. Differences between minor versions of MySQL 6.0 are noted in the present text with reference to release numbers (6.0.*x*).

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at http://dev.mysql.com/doc/. Other formats also are available there, including HTML, PDF, and Windows CHM versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see http://docbook.org/

The DocBook XML sources of this manual are available from http://dev.mysql.com/tech-resources/sources.html. You can check out a copy of the documentation repository with this command:

```
svn checkout http://svn.mysql.com/svnpublic/mysqldoc/
```

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See Section 1.5.1, “MySQL Mailing Lists”, and Section 1.5.2, “MySQL Community Support at the MySQL Forums”. If you have suggestions concerning additions or corrections to the manual itself, please send them to the Documentation Team.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Jon Stephens, Martin MC Brown, and Tony Bedford.

1.2. Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- `Text in this style` is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **`Text in this style`** indicates input that you type in examples.
- `Text in this style` indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- *`Text in this style`* is used for variable input for which you should substitute a value of your own choosing.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *`db_name`*, *`tbl_name`*, and *`col_name`*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“`[`” and “`]`”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“`|`”). When one member

from a set of choices *may* be chosen, the alternatives are listed within square brackets ("[" and "]"):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces ("{" and "}"):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (`...`) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *`reset_option`* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

1.3. Overview of the MySQL Database Management System

1.3.1. What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by MySQL AB. MySQL AB is a commercial company, founded by the MySQL developers. It is a second generation Open Source company that unites Open Source values and methodology with a successful business model.

The MySQL Web site (http://www.mysql.com/) provides the latest information about MySQL software and MySQL AB.

- MySQL is a database management system.

  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- MySQL is a relational database management system.

  A relational database stores data in separate tables rather than putting all the data in one big storeroom. This adds speed and flexibility. The SQL part of "MySQL" stands for "Structured Query Language." SQL is the most common standardized language used to access databases and is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, "SQL-92" refers to the standard released in 1992, "SQL:1999" refers to the standard released in 1999, and "SQL:2003" refers to the current version of the standard. We use the phrase "the SQL standard" to mean the current version of the SQL Standard at any time.

- MySQL software is Open Source.

  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- The MySQL Database Server is very fast, reliable, and easy to use.

  If that is what you are looking for, you should give it a try. MySQL Server also has a practical set of features developed in close cooperation with our users. You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See Section 7.1.4, "The MySQL Benchmark Suite".

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- MySQL Server works in client/server or embedded systems.

  The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

  We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- A large amount of contributed MySQL software is available.

  It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2. History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to allow third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen by the founders of MySQL AB from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.3.3. The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also Section 1.4, “MySQL Development Roadmap”, for more information about current and upcoming features. In most respects, it applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 4.0 and 4.1: MySQL 4.0 in a Nutshell, and MySQL 4.1 in a Nutshell.
- MySQL 5.0: MySQL 5.0 in a Nutshell.
- MySQL 5.1: MySQL 5.1 in a Nutshell.
- MySQL 6.0: MySQL 6.0 in a Nutshell.

Internals and Portability:

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See Section 2.1.1, “Operating Systems Supported by MySQL Community Server”.
- Uses GNU Automake, Autoconf, and Libtool for portability.
- The MySQL Server design is multi-layered with independent modules.
- Fully multi-threaded using kernel threads. It can easily use multiple CPUs if they are available.
- Provides transactional and non-transactional storage engines.

- Uses very fast B-tree disk tables (`MyISAM`) with index compression.
- Relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- A very fast thread-based memory allocation system.
- Very fast joins using an optimized one-sweep multi-join.
- In-memory hash tables, which are used as temporary tables.
- SQL functions are implemented using a highly optimized class library and should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- The MySQL code is tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~sewardj/).
- The server is available as a separate program for use in a client/server networked environment. It is also available as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types:

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, `FLOAT`, `DOUBLE`, `CHAR`, `VARCHAR`, `TEXT`, `BLOB`, `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, `YEAR`, `SET`, `ENUM`, and OpenGIS spatial types. See Chapter 10, *Data Types*.
- Fixed-length and variable-length records.

Statements and Functions:

- Full operator and function support in the `SELECT` list and `WHERE` clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
    -> FROM citizen
    -> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL `GROUP BY` and `ORDER BY` clauses. Support for group functions (`COUNT()`, `COUNT(DISTINCT ...)`, `AVG()`, `STD()`, `SUM()`, `MAX()`, `MIN()`, and `GROUP_CONCAT()`).
- Support for `LEFT OUTER JOIN` and `RIGHT OUTER JOIN` with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` return the number of rows that were changed (affected). It is possible to return the number of rows matched instead by setting a flag when connecting to the server.
- The MySQL-specific `SHOW` statement can be used to retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the `INFORMATION_SCHEMA` database, implemented according to standard SQL.
- The `EXPLAIN` statement can be used to determine how the optimizer resolves a query.
- Function names do not clash with table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are allowed between the function name and the "`(`" that follows it. See Section 8.3, "Reserved Words".
- You can refer to tables from different databases in the same statement.

Security:

- A privilege and password system that is very flexible and secure, and that allows host-based verification.
- Passwords are secure because all password traffic is encrypted when you connect to a server.

Scalability and Limits:

- Handles large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 60,000 tables and about 5,000,000,000 rows.
- Up to 64 indexes per table are allowed (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 1000 bytes (767 for `InnoDB`); before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity:

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the `--enable-named-pipe` option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, allowing MySQL clients to be written in many languages. See Chapter 20, *Connectors and APIs*.
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. MyODBC source is available. All ODBC 2.5 functions are supported, as are many others. See Section 20.1, “MySQL Connector/ODBC”.
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See Section 20.4, “MySQL Connector/J”.
- MySQL Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/NET is a fully managed ADO.NET driver written in 100% pure C#. See Section 20.2, “MySQL Connector/NET”.

Localization:

- The server can provide error messages to clients in many languages. See Section 9.3, “Setting the Error Message Language”.
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters “`å`”, “`ä`” and “`ö`” are allowed in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone. Section 9.7, “MySQL Server Time Zone Support”.

Clients and Tools:

- MySQL AB provides several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as MySQL Administrator and MySQL Query Browser.

- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See Chapter 4, *MySQL Programs*.
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.4. MySQL Development Roadmap

This section describes the general MySQL development roadmap, provides an overview about features that have been implemented in previous series and that are new in this current release series (6.0), and an overview about upcoming additions or changes in the next release series (6.1).

The maturity level of the release series covered in this manual (6.0) is alpha. Information about maturity levels can be found in Section 2.1.2.1, "Choosing Which Version of MySQL to Install".

Before upgrading from one release series to the next, please see the notes in Section 2.11.1, "Upgrading MySQL".

The most requested features and the versions in which they were implemented or are scheduled for implementation are summarized in the following table.

Feature	MySQL Series
Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the `MyISAM` storage engine)
Stored procedures	5.0
Views	5.0
Cursors	5.0
XA transactions	5.0
Triggers	5.0 and 5.1
Event scheduler	5.1
Partitioning	5.1
Pluggable storage engine API	5.1
Plugin API	5.1
Row-based replication	5.1
Server log tables	5.1
Foreign keys	6.x (implemented in 3.23 for `InnoDB`)

1.4.1. What Is New in MySQL 6.0

> **Note**
>
> This section remains subject to change as long as MySQL 6.0 development is in its early stages.

The following features have been or are expected to be added to MySQL 6.0:

- The new `Falcon` transactional storage engine (see Section 13.8, "The `Falcon` Storage Engine").
- Support for additional Unicode character sets: `utf16`, `utf32`, and 4-byte `utf8`. These character sets support supplementary Unicode characters; that is, characters outside the Basic Multilingual Plane (BMP).
- `BACKUP DATABASE` and `RESTORE` statements for backup and restore operations. See Section 6.3, "Using MySQL Backup".
- Improvements in the `INFORMATION_SCHEMA` database, with the addition of the `INFORMATION_SCHEMA.PARAMETERS` table, and new columns added to `INFORMATION_SCHEMA.ROUTINES` (see Section 19.27, "The `INFORMATION_SCHEMA PARAMETERS` Table", and Section 19.14, "The `INFORMATION_SCHEMA ROUTINES` Table").
- Optimizer enhancements for faster subqueries and joins, including batched index access of table rows for sequences of disjoint ranges by the `MyISAM` and `InnoDB` storage engines.

- The syntax for the `LOCK TABLES` statement has been extended to support transactional table locks that do not commit transactions automatically. Following `LOCK TABLES ... IN SHARE MODE` or `LOCK TABLES ... IN EXCLUSIVE MODE`, you can access tables not mentioned in the `LOCK TABLES` statement. You can also issue `LOCK TABLES` statements that acquire transactional locks many times in succession, adding additional tables to the locked set, and without unlocking any tables that were locked previously. When using `LOCK TABLES` with `IN SHARE MODE` or `IN EXCLUSIVE MODE`, tables are not unlocked until the transaction ends.

  Transactional locks acquired with `LOCK TABLES` are released when the transaction ends, either explicitly with `COMMIT` or `ROLLBACK`, or implicitly due to a statement that causes implicit commit or because the connection ends. Section 12.4.3, "Statements That Cause an Implicit Commit", lists those statements that cause implicit commit.

  The behavior of `LOCK TABLES` remains unchanged for `READ` or `WRITE` locks (that is, when not using `IN SHARE MODE` or `IN EXCLUSIVE MODE`).

- Enhancements to XML functionality, including a new `LOAD XML` statement (see Section 12.2.7, "`LOAD XML` Syntax").

- Supports for an interface for semisynchronous replication: A commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowleges that it has received and logged the events for the transaction. Semisynchronous replication is implemented through an optional plugin component. See Section 16.2.9, "Semisynchronous Replication"

- Support for the SQL standard `SIGNAL` and `RESIGNAL` statements. See Section 12.8.8, "`SIGNAL` and `RESIGNAL`".

- `RESET SLAVE` no longer changes replication connection parameters; previously, it reset them to the values specified on the command line (see Section 12.6.2.3, "`RESET SLAVE` Syntax").

- Support for extended comments for tables, columns, and indexes.

The following constructs are deprecated and have been removed in MySQL 6.0. Where alternatives are shown, applications should be updated to use them.

- The `table_type` system variable (use `storage_engine`).

- The `TYPE` table option to specify the storage engine for `CREATE TABLE` or `ALTER TABLE` (use `ENGINE`).

- The `SHOW TABLE TYPES` SQL statement (use `SHOW ENGINES`).

- The `log_bin_trust_routine_creators` variable (use `log_bin_trust_function_creators`).

- `TIMESTAMP(N)`: The ability to specify a display width of *`N`* (use without *`N`*).

- The `SHOW INNODB STATUS` and `SHOW MUTEX STATUS` SQL statements (use `SHOW ENGINE INNODB STATUS` for both of these).

- The `LOAD TABLE ... FROM MASTER` and `LOAD DATA FROM MASTER` SQL statements.

- The `SHOW PLUGIN` SQL statement (use `SHOW PLUGINS`).

- The `BACKUP TABLE` and The `RESTORE TABLE` SQL statements.

- The `--master-`*`xxx`* server options to set replication parameters (use the `CHANGE MASTER TO` statement instead): `--master-host`, `--master-user`, `--master-password` , `--master-port`, `--master-connect-retry`, `--master-ssl`, `--master-ssl-ca`, `--master-ssl-capath`, `--master-ssl-cert`, `--master-ssl-cipher`, `--master-ssl-key`.

1.5. MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

1.5.1. MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit http://lists.mysql.com/. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large

message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from `lists.mysql.com` to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

If you wish to have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- `announce`

  This list is for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- `mysql`

  This is the main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- `bugs`

  This list is for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See Section 1.6, “How to Report Bugs or Problems”.

- `internals`

  This list is for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- `mysqldoc`

  This list is for people who work on the MySQL documentation: people from MySQL AB, translators, and other community members.

- `benchmarks`

  This list is for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- `packagers`

  This list is for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- `java`

  This list is for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- `win32`

  This list is for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- `myodbc`

  This list is for all topics concerning connecting to the MySQL server with ODBC.

- `gui-tools`

  This list is for all topics concerning MySQL graphical user interface tools such as `MySQL Administrator` and `MySQL Query Browser`.

- `cluster`

  This list is for discussion of MySQL Cluster.

- `dotnet`

  This list is for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- `plusplus`

  This list is for all topics concerning programming with the C++ API for MySQL.

- `perl`

  This list is for all topics concerning Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Sun Microsystems, Inc. This puts you in direct contact with MySQL developers.

The following table shows some MySQL mailing lists in languages other than English. These lists are not operated by Sun Microsystems, Inc.

- `<mysql-france-subscribe@yahoogroups.com>`

  A French mailing list.

- `<list@tinc.net>`

  A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- `<mysql-de-request@lists.4t2.com>`

  A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at http://www.4t2.com/mysql/.

- `<mysql-br-request@listas.linkway.com.br>`

  A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- `<mysql-alta@elistas.net>`

  A Spanish mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

1.5.1.1. Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.5.2. MySQL Community Support at the MySQL Forums

The forums at http://forums.mysql.com are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages

- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.5.3. MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

freenode (see http://www.freenode.net/ for servers)

- `#mysql` is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at `xChat` (http://www.xchat.org/). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at http://www.silverex.org/download/).

1.5.4. MySQL Enterprise

Sun Microsystems, Inc. offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see MySQL Enterprise.

1.6. How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at http://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. The change history (http://dev.mysql.com/doc/mysql/en/news.html) can be particularly useful since it is quite possible that a newer version contains a solution to your problem.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement. In this case, your options are to implement the syntax yourself or email `<licensing@mysql.com>` and ask for an offer to implement it.

  If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.
- For solutions to some common problems, see Section B.1, “Problems and Common Errors”.
- Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

- Search the MySQL mailing list archives at http://lists.mysql.com/. See Section 1.5.1, “MySQL Mailing Lists”.
- You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script described at the end of this section.

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the change history.

If you have found a sensitive security bug in MySQL, you can send email to `<security@mysql.com>`.

To discuss problems with other users, you can use one of the MySQL mailing lists. Section 1.5.1, “MySQL Mailing Lists”.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See MySQL Internals: Porting.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See the MyODBC section of Chapter 20, *Connectors and APIs*.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.

- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See MySQL Internals: Porting.
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

  ```
  SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
  FROM INFORMATION_SCHEMA.ROUTINES;
  ```

  For triggers, you can use this statement:

  ```
  SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
  FROM INFORMATION_SCHEMA.TRIGGERS;
  ```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

  The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

  ```
  mysql> SHOW VARIABLES;
  mysql> SHOW COLUMNS FROM ...\G
         <output from SHOW COLUMNS>
  mysql> EXPLAIN SELECT ...\G
         <output from EXPLAIN>
  mysql> FLUSH STATUS;
  mysql> SELECT ...;
         <A short version of the output from SELECT,
         including the time taken to run the query>
  mysql> SHOW STATUS;
         <output from SHOW STATUS>
  ```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

  If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.
- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`, and use FTP to transfer the archive to ftp://ftp.mysql.com/pub/mysql/upload/. Then enter the problem into our bugs database at http://bugs.mysql.com/.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can use FTP to transfer it to ftp://ftp.mysql.com/pub/mysql/upload/. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.

- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

  If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

- If the problem is that your data appears corrupt or you get errors when you access a particular table, you should first check your tables and then try to repair them with `CHECK TABLE` and `REPAIR TABLE` or with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

  If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 8.2.2, “Identifier Case Sensitivity”.

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.2.2, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See Section B.1.1, “How to Determine What Is Causing a Problem”.

- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

If you have no Web access and cannot report a bug by visiting http://bugs.mysql.com/, you can use the `mysqlbug` script to generate a bug report (or a report about any problem). `mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

1.7. MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 12.2.4, “`HANDLER` Syntax”.

We continue to support transactional and non-transactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

High-availability database clustering is available using the `NDBCLUSTER` storage engine. However, the `NDBCLUSTER` storage engine is currently not supported in MySQL 6.0. Instead, you should use MySQL Cluster NDB 6.2 or 6.3, which are based on MySQL 5.1 but contain the latest improvements and fixes for `NDBCLUSTER`. See MySQL Cluster NDB 6.X/7.X, for more information.

We are implementing XML functionality beginning in MySQL 5.1, which supports most of the W3C XPath standard. We plan to increase support for XML as part of future MySQL development. See Section 11.10, “XML Functions”.

1.7.1. What Standards MySQL Follows

Our aim is to support the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0-3.51.

1.7.2. Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

SQL modes control aspects of server operation such as what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="`*`mode_value`*`"` option. You can also change the mode at runtime by setting the `sql_mode` system variable with a `SET [GLOBAL|SESSION] sql_mode='`*`mode_value`*`'` statement.

For more information on setting the SQL mode, see Section 5.1.7, “Server SQL Modes”.

1.7.3. Running MySQL in ANSI Mode

You can tell `mysqld` to run in ANSI mode with the `--ansi` startup option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

You can achieve the same effect at runtime by executing these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
        -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Note that running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'`. The `--ansi` option affects the SQL mode and also sets the transaction isolation level. Setting the SQL mode to `'ANSI'` has no effect on the isolation level.

See Section 5.1.2, “Server Command Options”, and Section 1.7.2, “Selecting SQL Modes”.

1.7.4. MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the "`!`" character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

  MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

  - Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 8.2.2, "Identifier Case Sensitivity".
  - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax

  - By default, strings can be enclosed by either "`"`" or "`'`", not just by "`'`". (If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by "`'`" and the server interprets strings enclosed by "`"`" as identifiers.)
  - "`\`" is the escape character in strings.
  - In SQL statements, you can access tables from different databases with the *`db_name.tbl_name`* syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- SQL statement syntax

  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
  - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See Section 12.1.8, "`CREATE DATABASE` Syntax", Section 12.1.17, "`DROP DATABASE` Syntax", and Section 12.1.1, "`ALTER DATABASE` Syntax".
  - The `DO` statement.
  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
  - The `FLUSH` and `RESET` statements.
  - The `SET` statement. See Section 12.5.5, "`SET` Syntax".
  - The `SHOW` statement. See Section 12.5.6, "`SHOW` Syntax". As of MySQL 5.0, the information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See Chapter 19, *`INFORMATION_SCHEMA` Tables*.
  - Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See Section 12.2.6, "`LOAD DATA INFILE` Syntax".
  - Use of `RENAME TABLE`. See Section 12.1.26, "`RENAME TABLE` Syntax".
  - Use of `REPLACE` instead of `DELETE` plus `INSERT`. See Section 12.2.8, "`REPLACE` Syntax".
  - Use of `CHANGE` *`col_name`*, `DROP` *`col_name`*, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See Section 12.1.6, "`ALTER TABLE` Syntax".
  - Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See Sec-

tion 12.1.14, “CREATE TABLE Syntax”.

- Use of TEMPORARY or IF NOT EXISTS with CREATE TABLE.
- Use of IF EXISTS with DROP TABLE and DROP DATABASE.
- The capability of dropping multiple tables with a single DROP TABLE statement.
- The ORDER BY and LIMIT clauses of the UPDATE and DELETE statements.
- INSERT INTO *tbl_name* SET *col_name* = ... syntax.
- The DELAYED clause of the INSERT and REPLACE statements.
- The LOW_PRIORITY clause of the INSERT, REPLACE, DELETE, and UPDATE statements.
- Use of INTO OUTFILE or INTO DUMPFILE in SELECT statements. See Section 12.2.9, “SELECT Syntax”.
- Options such as STRAIGHT_JOIN or SQL_SMALL_RESULT in SELECT statements.
- You don't need to name all selected columns in the GROUP BY clause. This gives better performance for some very specific, but quite normal queries. See Section 11.12, “Functions and Modifiers for Use with GROUP BY Clauses”.
- You can specify ASC and DESC with GROUP BY, not just with ORDER BY.
- The ability to set variables in a statement with the := assignment operator:

```
mysql> SELECT @a:=SUM(total),@b:=COUNT(*),@a/@b AS avg
    -> FROM test_table;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
```

- Data types
  - The MEDIUMINT, SET, and ENUM data types, and the various BLOB and TEXT data types.
  - The AUTO_INCREMENT, BINARY, NULL, UNSIGNED, and ZEROFILL data type attributes.
- Functions and operators
  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
  - MySQL Server understands the || and && operators to mean logical OR and AND, as in the C programming language. In MySQL Server, || and OR are synonyms, as are && and AND. Because of this nice syntax, MySQL Server doesn't support the standard SQL || operator for string concatenation; use CONCAT() instead. Because CONCAT() takes any number of arguments, it is easy to convert use of the || operator to MySQL Server.
  - Use of COUNT(DISTINCT *value_list*) where *value_list* has more than one element.
  - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is latin1 (cp1252 West European) by default. If you don't like this, you should declare your columns with the BINARY attribute or use the BINARY cast, which causes comparisons to be done using the underlying character code values rather then a lexical ordering.
  - The % operator is a synonym for MOD(). That is, *N* % *M* is equivalent to MOD(*N*,*M*). % is supported for C programmers and for compatibility with PostgreSQL.
  - The =, <>, <=, <, >=, >, <<, >>, <=>, AND, OR, or LIKE operators may be used in expressions in the output column list (to the left of the FROM) in SELECT statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

  - The LAST_INSERT_ID() function returns the most recent AUTO_INCREMENT value. See Section 11.11.3, “Information Functions”.
  - LIKE is allowed on numeric values.
  - The REGEXP and NOT REGEXP extended regular expression operators.
  - CONCAT() or CHAR() with one argument or more than two arguments. (In MySQL Server, these functions can take a

variable number of arguments.)

- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See Section 11.12, "Functions and Modifiers for Use with `GROUP BY` Clauses".

For a prioritized list indicating when new extensions are added to MySQL Server, you should consult the online MySQL development roadmap at http://dev.mysql.com/doc/mysql/en/roadmap.html.

1.7.5. MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 12.5.1.5, "`REVOKE` Syntax".
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See Section 11.9, "Cast Functions and Operators".

1.7.5.1. `SELECT INTO TABLE`

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 12.2.5.1, "`INSERT ... SELECT` Syntax". For example:

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

As of MySQL 5.0, you can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 12.8.3.3, "`SELECT ... INTO` Statement".

1.7.5.2. Transactions and Atomic Operations

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` transactional storage engine. `InnoDB` provides *full* ACID compliance. See Chapter 13, *Storage Engines*. For information about `InnoDB` differences from standard SQL with regard to treatment of transaction errors, see Section 13.7.12, "`InnoDB` Error Handling".

The other non-transactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called "atomic operations." In transactional terms, `MyISAM` tables effectively always operate in `autocommit = 1` mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the tradeoff for transactional versus non-transactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as `InnoDB` also offer many significant features. MySQL Server's modular design allows the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

But how do you use the features of MySQL Server to maintain rigorous integrity even with the non-transactional `MyISAM` tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call `ROLLBACK` rather than `COMMIT` in critical situ-

ations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use non-transactional tables, MySQL Server in almost all cases allows you to resolve potential problems by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. Note that just by using the MySQL log or even adding one extra log, you can normally fix tables perfectly with no data integrity loss.

- More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with `LOCK TABLES` or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.
- To be safe with MySQL Server, regardless of whether you use transactional tables, you only need to have backups and have binary logging turned on. When that is true, you can recover from any situation that you could with any other transactional database system. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its advantages and disadvantages. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that non-transactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for non-transactional tables. If you lock tables with `LOCK TABLES`, all updates stall until integrity checks are made. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that allows concurrent inserts at the end of the table, reads are allowed, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See Section 7.3.3, “Concurrent Inserts”, and Section 12.2.5.2, “`INSERT DELAYED` Syntax”.

“Atomic,” in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with non-transactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.
- To avoid using `ROLLBACK`, you can employ the following strategy:

  1. Use `LOCK TABLES` to lock all the tables you want to access.
  2. Test the conditions that must be true before performing the update.
  3. Update if the conditions are satisfied.
  4. Use `UNLOCK TABLES` to release your locks.

  This is usually a much faster method than using transactions with possible rollbacks, although not always. The only situation this solution doesn't handle is when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.
- You can also use functions to update records in a single operation. You can get a very efficient application by using the following techniques:

  - Modify columns relative to their current value.
  - Update only those columns that actually have changed.

  For example, when we are updating customer information, we update only the customer data that has changed and test only that none of the changed data, or data that depends on the changed data, has changed compared to the original row. The test for changed data is done with the `WHERE` clause in the `UPDATE` statement. If the record wasn't updated, we give the client a message: “Some of the data you have changed has been changed by another user.” Then we show the old row versus the new row in a window so that the user can decide which version of the customer record to use.

  This gives us something that is similar to column locking but is actually even better because we only update some of the columns, using values that are relative to their current values. This means that typical `UPDATE` statements look something like these:

```
UPDATE tablename SET pay_back=pay_back+125;
```

```
UPDATE customer
  SET
    customer_date='current_date',
    address='new address',
    phone='new phone',
    money_owed_to_us=money_owed_to_us-125
  WHERE
    customer_id=id AND address='old address' AND phone='old phone';
```

This is very efficient and works even if another client has changed the values in the `pay_back` or `money_owed_to_us` columns.

- In many cases, users have wanted `LOCK TABLES` or `ROLLBACK` for the purpose of managing unique identifiers. This can be handled much more efficiently without locking or rolling back by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 11.11.3, "Information Functions", and Section 20.10.3.37, "`mysql_insert_id()`".

  You can generally code around the need for row-level locking. Some situations really do need it, and `InnoDB` tables support row-level locking. Otherwise, with `MyISAM` tables, you can use a flag column in the table and do something like the following:

  ```
  UPDATE tbl_name SET row_flag=1 WHERE id=ID;
  ```

  MySQL returns `1` for the number of affected rows if the row was found and `row_flag` wasn't `1` in the original row. You can think of this as though MySQL Server changed the preceding statement to:

  ```
  UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
  ```

1.7.5.3. Stored Routines and Triggers

Stored procedures and functions are implemented beginning with MySQL 5.0. See Section 18.2, "Using Stored Routines (Procedures and Functions)".

Basic trigger functionality is implemented beginning with MySQL 5.0.2, with further development planned for MySQL 5.1. See Section 18.3, "Using Triggers".

1.7.5.4. Foreign Keys

The `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See Section 13.7.4.4, "`FOREIGN KEY` Constraints".

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysqldump` and ODBC. At a later stage, foreign key constraints will be implemented for `MyISAM` tables as well.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another storage engine instead, such as `MyISAM`. (For example, the `MyISAM` storage engine offers very fast performance for applications that perform only `INSERT` and `SELECT` operations. In this case, the table has no holes in the middle and the inserts can be performed concurrently with retrievals. See Section 7.3.3, "Concurrent Inserts".)

If you choose not to take advantage of referential integrity checks, keep the following considerations in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.
- If `ON DELETE` is the only referential integrity capability an application needs, you can achieve a similar effect as of MySQL Server 4.0 by using multiple-table `DELETE` statements to delete rows from many tables with a single statement. See Section 12.2.2, "`DELETE` Syntax".
- A workaround for the lack of `ON DELETE` is to add the appropriate `DELETE` statements to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys and is more portable.

Be aware that the use of foreign keys can sometimes lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.
- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by allowing you to temporarily disable foreign key checks when reloading a table that depends on other tables. See Section 13.7.4.4, "`FOREIGN KEY` Constraints". As of MySQL 4.1.1, `mysqldump` generates dump files that take advantage of this capability automatically when they are reloaded.)

Note that foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See Section 12.2.9.1, "`JOIN` Syntax", and Section 3.6.6, "Using Foreign Keys".

The `FOREIGN KEY` syntax without `ON DELETE ...` is often used by ODBC applications to produce automatic `WHERE` clauses.

1.7.5.5. Views

Views (including updatable views) are implemented beginning with MySQL Server 5.0.1. See Section 18.5, "Using Views".

Views are useful for allowing users to access a set of relations (tables) as if it were a single table, and limiting their access to just that. Views can also be used to restrict access to rows (a subset of a particular table). For access control to columns, you can also use the sophisticated privilege system in MySQL Server. See Section 5.4, "The MySQL Access Privilege System".

In designing an implementation of views, our ambitious goal, as much as is possible within the confines of SQL, has been full compliance with "Codd's Rule #6" for relational database systems: "All views that are theoretically updatable, should in practice also be updatable."

1.7.5.6. '`--`' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that allow MySQL-specific SQL to be embedded in the comment, as described in Section 8.5, "Comment Syntax".

Standard SQL uses "`--`" as a start-comment sequence. MySQL Server uses "#" as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the "`--`" comment style. That is, the "`--`" start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a legal expression in SQL, but "`--`" is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that allowing comments to start with "`--`" can have serious consequences.

Using our implementation requires a space following the "`--`" in order for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with "`--`".

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains "`--`" comments, you should use the `replace` utility as follows to convert the comments to use "#" characters before executing the script:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \
        | mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file "in place" to change the "`--`" comments to "#" comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See Section 4.8.2, "`replace` — A String-Replacement Utility".

1.7.6. How MySQL Deals with Constraints

MySQL allows you to work both with transactional tables that allow rollback and with non-transactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a non-transactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce illegal values to the closest legal values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.1.7, "Server SQL Modes".

> **MySQL Enterprise**
> To be alerted when there is no form of server-enforced data integrity, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

The following sections describe how MySQL Server handles different types of constraints.

1.7.6.1. `PRIMARY KEY` and `UNIQUE` Index Constraints

Normally, errors occurs for data-change statements (such as `INSERT` or `UPDATE`) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as `InnoDB`, MySQL automatically rolls back the statement. If you are using a non-transactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an `IGNORE` keyword for `INSERT`, `UPDATE`, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 12.2.5, "`INSERT` Syntax", Section 12.2.12, "`UPDATE` Syntax", and so forth).

You can get information about the number of rows actually inserted or updated with the `mysql_info()` C API function. You can also use the `SHOW WARNINGS` statement. See Section 20.10.3.35, "`mysql_info()`", and Section 12.5.6.40, "`SHOW`

WARNINGS Syntax”.

Currently, only InnoDB tables support foreign keys. See Section 13.7.4.4, “FOREIGN KEY Constraints”. We plan to add foreign key support by other storage engines in a future MySQL release. See Section 1.4, “MySQL Development Roadmap”.

1.7.6.2. Constraints on Invalid Data

By default, MySQL is forgiving of illegal or improper data values and coerces them to legal values for data entry. However, you can change the server SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See Section 5.1.7, “Server SQL Modes”.

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a NULL into a NOT NULL column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for ENUM and SET columns are handled as described in Section 1.7.6.3, “ENUM and SET Constraints”.
- MySQL allows you to store certain incorrect date values into DATE and DATETIME columns (such as '2000-02-31' or '2000-02-00'). The idea is that it is not the job of the SQL server to validate dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.
- If you try to store NULL into a column that doesn't take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 10.1.4, “Data Type Default Values”.
- If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in non-strict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the STRICT_TRANS_TABLES or STRICT_ALL_TABLES SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

STRICT_TRANS_TABLES enables strict mode for transactional storage engines, and also to some extent for non-transactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For non-transactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with STRICT_TRANS_TABLES, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable STRICT_ALL_TABLES. This is the same as STRICT_TRANS_TABLES except that for non-transactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a non-transactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for non-transactional tables, either use single-row

statements or else use STRICT_TRANS_TABLES if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only legal values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using INSERT IGNORE or UPDATE IGNORE rather than INSERT or UPDATE without IGNORE.

1.7.6.3. ENUM and SET Constraints

ENUM and SET columns provide an efficient way to define columns that can contain only a given set of values. See Section 10.4.4, "The ENUM Type", and Section 10.4.5, "The SET Type". However, before MySQL 5.0.2, ENUM and SET columns do not provide true constraints on entry of invalid data:

- ENUM columns always have a default value. If you specify no default value, then it is NULL for columns that can have NULL, otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an ENUM column or if you force a value into an ENUM column with IGNORE, it is set to the reserved enumeration value of 0, which is displayed as an empty string in string context.
- If you insert an incorrect value into a SET column, the incorrect value is ignored. For example, if the column can contain the values 'a', 'b', and 'c', an attempt to assign 'a,x,b,y' results in a value of 'a,b'.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See Section 5.1.7, "Server SQL Modes". With strict mode enabled, the definition of a ENUM or SET column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An ENUM value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as ENUM('a','b','c'), values such as '', 'd', or 'ax' are illegal and are rejected.
- A SET value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as SET('a','b','c'), values such as 'd' or 'a,b,c,d' are illegal and are rejected.

Errors for invalid values can be suppressed in strict mode if you use INSERT IGNORE or UPDATE IGNORE. In this case, a warning is generated rather than an error. For ENUM, the value is inserted as the error member (0). For SET, the value is inserted as given except that any invalid substrings are deleted. For example, 'a,x,b,y' results in a value of 'a,b'.

1.8. Credits

This appendix lists the developers, contributors, and supporters that have helped to make MySQL what it is today.

1.8.1. Contributors to MySQL

Although Sun Microsystems, Inc. owns all copyrights in the MySQL server and the MySQL manual, we wish to recognize those who have made contributions of one kind or another to the MySQL distribution. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwerg@mbox.vol.it> or <qwerg@tin.it>

  The initial port to Win32/NT.

- Per Eric Olsson

  For more or less constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <irena@mail.yacc.it>

  Win32 port with Borland compiler. mysqlshutdown.exe and mysqlwatch.exe

- David J. Hughes

  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with mSQL, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. mysqladmin and mysql client are programs that were largely influenced by their mSQL counterparts. We have put a lot of effort into making the MySQL syntax a superset of mSQL. Many of the API's ideas are borrowed from mSQL to make it easy to port free mSQL programs to the MySQL API. The MySQL software doesn't contain any code from mSQL. Two files in the distribution (client/

`insert_test.c` and `client/select_test.c`) are based on the corresponding (non-copyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

  For helping us acquire http://www.mysql.com/.

- Fred Lindberg

  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko `<igor@frog.kiev.ua>`

  `mysqldump` (previously `msqldump`, but ported and enhanced by Monty).

- Yuri Dario

  For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

  Author of `mysqlhotcopy`.

- Zarko Mocnik `<zarko.mocnik@dem.si>`

  Sorting for Slovenian language.

- "TAMITO" `<tommy@valley.ne.jp>`

  The `_MB` character set macros and the ujis and sjis character sets.

- Joshua Chamas `<joshua@chamas.com>`

  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier `<Yves.Carlier@rug.ac.be>`

  `mysqlaccess`, a program to show the access rights for a user.

- Rhys Jones `<rhys@wales.com>` (And GWE Technologies Limited)

  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU `<X.Zhu@brad.ac.uk>`

  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper `<pixel@organic.com>`

  For setting up a searchable mailing list archive at his site.

- Rick Mehalick `<Rick_Mehalick@i-o.com>`

  For `xmysql`, a graphical X client for MySQL Server.

- Doug Sisk `<sisk@wix.com>`

  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. `<axeld@vial.ethz.ch>`

  For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive `<toni@readysoft.es>`

  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth `<jay@pathways.sde.state.sc.us>`

  For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>

  Ideas for secure checking of DNS host names.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>

  Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>

  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>

  Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>

  FROM_UNIXTIME() time formatting, ENCRYPT() functions, and bison advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>

  Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The mysql_setpermission script.

- Alexis Mikhailov <root@medinf.chuvashia.su>

  User-defined functions (UDFs); CREATE FUNCTION and DROP FUNCTION.

- Andreas F. Bobak <bobak@relog.ch>

  The AGGREGATE extension to user-defined functions.

- Ross Wakelin <R.Wakelin@march.co.uk>

  Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <jetman@li.net>

  The libmysql.dll library.

- James Pereria <jpereira@iafrica.com>

  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson <cjs@portal.ca>

  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch <m.ramsch@computer.org>

  Examples in the MySQL Tutorial.

- Steve Harvey

  For making mysqlaccess more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited

  http://www.pspl.co.in/konark/. Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

  Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

  Emulation of pthread_mutex() for OS/2.

- Benjamin Pflugmann

  Extended MERGE tables to handle INSERTS. Active member on the MySQL mailing lists.

- Jocelyn Fournier

  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

  Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X PKGs.

- Robert Rutherford

  Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

  We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>

  Irix setup.

- Luuk de Boer <luuk@wxs.nl>

  Benchmark questions.

- Tim Sailer <tps@users.buoy.com>

  DBD::mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>

  SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>

  xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>

  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>

  General questions.

- Jonathan J Smith <jsmith@wtp.net>

  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>

  Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>

  Is flexible and can handle Linux and perhaps HP-UX. Tries to get users to use `mysqlbug`.

- John Lyon <jlyon@imag.net>

  Questions about installing MySQL on Linux systems, using either `.rpm` files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

  Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

  ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

  `DBD`, Linux, some SQL syntax questions.

1.8.2. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

  Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

  Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (http://mysql.hitstar.com/) versions were based. Personal home page at linuxdb.yeah.net.

- Jay Flaherty <fty@mediapulse.com>

  Big parts of the Perl `DBI`/`DBD` section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

  Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

  French error messages.

- Petr Snajdr, <snajdr@pvt.net>

  Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

  Polish error messages.

- Miguel Angel Fernandez Roiz

  Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

  Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

  Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

  German error messages.

- Billik Stefan <billik@sun.uniag.sk>

  Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

  Romanian error messages.

- Peter Feher

  Hungarian error messages.

- Roberto M. Serqueira

  Portuguese error messages.

- Carsten H. Pedersen

  Danish error messages.

- Arjen Lentz

  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

1.8.3. Libraries used by and included with MySQL

The following is a list of the creators of the libraries we have included with the MySQL server source to make it easy to compile and install MySQL. We are very thankfully to all individuals that have created these and it has made our life much easier.

- Fred Fish

  For his excellent C debugging and trace library. Monty has made a number of smaller improvements to the library (speed and additional options).

- Richard A. O'Keefe

  For his public domain string library.

- Henry Spencer

  For his regex library, used in `WHERE column REGEXP regexp`.

- Jean-loup Gailly and Mark Adler

  For the zlib library (used on MySQL on Windows).

- Bjorn Benson

  For his safe_malloc (memory checker) package which is used in when you build MySQL using one of the `BUILD/compile-*-debug` scripts, or manually set the `-DSAFE_MALLOC`.

- Free Software Foundation

  The `readline` library (used by the `mysql` command-line client).

- The NetBSD foundation

  The `libedit` package (optionally used by the `mysql` command-line client).

- www.netlib.org

  MySQL incorporates work covered by the following copyright and permission notice:

  The author of this software is David M. Gay.

  Copyright (c) 1991, 2000, 2001 by Lucent Technologies.

  Permission to use, copy, modify, and distribute this software for any purpose without fee is hereby granted, provided that this entire notice is included in all copies of any software which is or includes a copy or modification of this software and in all copies of the supporting documentation for such software.

  THIS SOFTWARE IS BEING PROVIDED "AS IS", WITHOUT ANY EXPRESS OR IMPLIED WARRANTY. IN PARTICULAR, NEITHER THE AUTHOR NOR LUCENT MAKES ANY REPRESENTATION OR WARRANTY OF ANY KIND CONCERNING THE MERCHANTABILITY OF THIS SOFTWARE OR ITS FITNESS FOR ANY PARTICULAR PURPOSE.

1.8.4. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- Tim Bunce, Alligator Descartes

  For the `DBD` (Perl) interface.

- Andreas Koenig `<a.koenig@mind.de>`

  For the Perl interface for MySQL Server.

- Jochen Wiedmann `<wiedmann@neckar-alb.de>`

  For maintaining the Perl `DBD::mysql` module.

- Eugene Chan `<eugene@acenet.com.sg>`

  For porting PHP for MySQL Server.

- Georg Richter

  MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli `<maruzz@matrice.it>`

  For porting iODBC (Unix ODBC).

- Xavier Leroy `<Xavier.Leroy@inria.fr>`

  The author of LinuxThreads (used by the MySQL Server on Linux).

1.8.5. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

  From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb` and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

  For a really great editor/environment.

- Julian Seward

  Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

  For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`).

1.8.6. Supporters of MySQL

Although Sun Microsystems, Inc. owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

  Funded replication.

- NuSphere

  Editing of the MySQL manual.

- Stork Design studio

  The MySQL Web site in use between 1998-2000.

- Intel

  Contributed to development on Windows and Linux platforms.

- Compaq

  Contributed to Development on Linux/Alpha.

- SWSoft

  Development on the embedded `mysqld` version.

- FutureQuest

  `--skip-show-database`

Chapter 2. Installing and Upgrading MySQL

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11.1, “Upgrading MySQL”, for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, you may wish to read Section A.8, “MySQL 6.0 FAQ — Migration”, which contains answers to some common questions concerning migration issues.

1. **Determine whether MySQL runs and is supported on your platform.** Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Sun Microsystems, Inc.:

   - For MySQL Enterprise Server, the officially supported platforms are listed at http://www.mysql.com/support/supportedplatforms.html.
   - MySQL Community Server runs on the platforms listed at Section 2.1.1, “Operating Systems Supported by MySQL Community Server”.

2. **Choose which distribution to install.** Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

3. **Download the distribution that you want to install.** For instructions, see Section 2.1.3, “How to Get MySQL”. To verify the integrity of the distribution, use the instructions in Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

4. **Install the distribution.** To install MySQL from a binary distribution, use the instructions in Section 2.2, “Standard MySQL Installation Using a Binary Distribution”. To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, “MySQL Installation Using a Source Distribution”.

   If you encounter installation difficulties, see Section 2.12, “Operating System-Specific Notes”, for information on solving problems for particular platforms.

5. **Perform any necessary post-installation setup.** After installing MySQL, read Section 2.10, “Post-Installation Setup and Testing”. This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.14, “Perl Installation Notes”.

2.1. General Installation Issues

The MySQL installation procedure depends on whether you will install MySQL Enterprise Server or MySQL Community Server. The set of applicable platforms depends on which distribution you will install:

- For MySQL Enterprise Server, the officially supported platforms are listed at http://www.mysql.com/support/supportedplatforms.html.
- MySQL Community Server runs on the platforms listed at Section 2.1.1, “Operating Systems Supported by MySQL Community Server”.

For MySQL Enterprise Server, install the main distribution plus any service packs or hotfixes that you wish to apply using the Enterprise Installer. For platforms that do not yet have an Enterprise Installer, use the Community Server instructions.

For MySQL Community Server, install the main distribution plus any hotfixes and updates:

- Download a binary release, or download a source release and build MySQL yourself from the source code.
- Retrieve MySQL from the Bazaar tree and build it from source. The Bazaar tree contains the latest developer code.

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at Section 2.2, “Standard MySQL Installation Using a Binary Distribution”. To build MySQL from source, use the instructions at Section 2.9, “MySQL Installation Using a Source Distribution”.

2.1.1. Operating Systems Supported by MySQL Community Server

This section lists the operating systems on which MySQL Community Server is known to run.

> **Important**
>
> Sun Microsystems, Inc. does not necessarily provide official support for all the platforms listed in this section. For information about those platforms that are officially supported, see MySQL Server Supported Platforms on the MySQL Web site.

We use GNU Autoconf, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.)

MySQL has been reported to compile successfully on the following combinations of operating system and thread package.

- AIX 4.x, 5.x with native threads. See Section 2.12.5.3, “IBM-AIX notes”.
- Amiga.
- FreeBSD 5.x and up with native threads.
- HP-UX 11.x with the native threads. See Section 2.12.5.2, “HP-UX Version 11.x Notes”.
- Linux, builds on all fairly recent Linux distributions with `glibc` 2.3. See Section 2.12.1, “Linux Notes”.
- Mac OS X. See Section 2.12.2, “Mac OS X Notes”.
- NetBSD 1.3/1.4 Intel and NetBSD 1.3 Alpha. See Section 2.12.4.2, “NetBSD Notes”.
- Novell NetWare 6.0 and 6.5. See Section 2.7, “Installing MySQL on NetWare”.
- OpenBSD 2.5 and with native threads. OpenBSD earlier than 2.5 with the MIT-pthreads package. See Section 2.12.4.3, “OpenBSD 2.5 Notes”.
- SCO OpenServer 5.0.X with a recent port of the FSU Pthreads package. See Section 2.12.5.8, “SCO UNIX and OpenServer 5.0.x Notes”.
- SCO Openserver 6.0.x. See Section 2.12.5.9, “SCO OpenServer 6.0.x Notes”.
- SCO UnixWare 7.1.x. See Section 2.12.5.10, “SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes”.
- SGI Irix 6.x with native threads. See Section 2.12.5.7, “SGI Irix Notes”.
- Solaris 2.5 and above with native threads on SPARC and x86. See Section 2.12.3, “Solaris Notes”.
- Tru64 Unix. See Section 2.12.5.5, “Alpha-DEC-UNIX Notes (Tru64)”.
- Windows 2000, Windows XP, Windows Vista, Windows Server 2003, and Windows Server 2008. See Section 2.3, “Installing MySQL on Windows”.

MySQL has also been known to run on other systems in the past. See Section 2.12, “Operating System-Specific Notes”. Some porting effort might be required for current versions of MySQL on these systems.

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.
- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a CPU different from the original process.

- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.
- General file system stability and performance.
- If your tables are large, performance is affected by the ability of the file system to deal with large files at all and to deal with them efficiently.
- Our level of expertise here at Sun Microsystems, Inc. with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.
- The amount of testing we have done internally for similar configurations.
- The number of users that have run MySQL successfully on the platform in similar configurations. If this number is high, the likelihood of encountering platform-specific surprises is much smaller.

2.1.2. Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

2.1.2.1. Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity:

- MySQL 5.4 and 6.0 are the current development release series.
- MySQL 5.1 is the current General Availability (Production) release series. New releases are issued for bugfixes only; no new features are being added that could affect stability.
- MySQL 5.0 is the previous stable (production-quality) release series.
- MySQL 4.1, 4.0, and 3.23 are old stable (production-quality) release series. MySQL 4.1 is now at the end of the product lifecycle. Active development and support for these versions has ended.

  Extended support for MySQL 4.1 remains available. According to the MySQL Lifecycle Policy, only Security and Severity Level 1 issues are still being fixed for MySQL 4.1.

We do not believe in a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. By “somewhat frozen” we mean that we may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, we recommend going with the General Availability release series. Currently, this is MySQL 5.1. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a non-seamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Note that development releases are not as stable as production releases.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our Bazaar repositories. These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The MySQL naming scheme uses release names that consist of three numbers and a suffix; for example, **mysql-5.0.12-beta**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version and describes the file format. All MySQL 5 releases have the same file format.
- The second number (**0**) is the release level. Taken together, the major version and release level constitute the release series

number.

- The third number (**12**) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **alpha** indicates that the release is for preview purposes only. Known bugs should be documented in the News section (see Appendix C, *MySQL Change History*). Most alpha releases implement new commands and extensions. Active development that may involve major code changes can occur in an alpha release. However, we do conduct testing before issuing a release.
- **beta** indicates that the release is appropriate for use with new development. Within beta releases, the features and compatibility should remain consistent. However, beta releases may contain numerous and major unaddressed bugs.

  All APIs, externally visible structures, and columns for SQL statements will not change during future beta, release candidate, or production releases.
- **rc** indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL's internal testing, and with all known fatal runtime bugs fixed. However, the release has not been in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added. (A release candidate is what formerly was known as a gamma release.)
- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

MySQL uses a naming scheme that is slightly different from most other products. In general, it is usually safe to use any version that has been out for a couple of weeks without being replaced by a new version within the same release series.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- An internal test suite

  The `mysql-test` directory contains an extensive set of test cases. We run these tests for every server binary. See Section 21.1.2, “MySQL Test Suite”, for more information about this test suite.
- The MySQL benchmark suite

  This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See Section 7.1.4, “The MySQL Benchmark Suite”.
- The `crash-me` test

  This test tries to determine what features the database supports and what its capabilities and limitations are. See Section 7.1.4, “The MySQL Benchmark Suite”.

We also test the newest MySQL version in our internal production environment, on at least one machine. We have more than 100GB of data to work with.

2.1.2.2. Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM files for Linux or PKG package installers for Mac OS X or Solaris. Distributions also are available as Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide several servers in binary distributions. `mysqld` is an optimized server that is a smaller, faster binary. `mysqld-debug` is compiled with debugging support.

  Each of these servers is compiled from the same source distribution, though with different configuration options. All native MySQL clients can connect to servers from either MySQL version.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:
  - `--with-libwrap`
  - `--with-named-z-libs` (this is done for some of the binaries)
  - `--with-debug[=full]`
- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You have a special compiler (such as `pgcc`) or want to use compiler options that are better optimized for your processor. Binary distributions are compiled with options that should work on a variety of processors from the same processor family.
- You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

2.1.2.3. How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The News section helps you determine whether the new release has something you really want. See Appendix C, *MySQL Change History*.

We use the following policy when updating MySQL:

- Enterprise Server releases are meant to appear every 18 months, supplemented by quarterly service packs and monthly rapid updates. Community Server releases are meant to appear 2–3 times per year.
- Releases are issued within each series. Enterprise Server releases are numbered using even numbers (for example, 6.0.20). Community Server releases are numbered using odd numbers (for example, 6.0.21).
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or non-critical but annoying bugs. The fixes are available in source form immediately from our public Bazaar repositories, and are included in the next release.
- If by any chance a security vulnerability or critical bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

2.1.2.4. MySQL Binaries Compiled by Sun Microsystems, Inc.

As a service of Sun Microsystems, Inc., we provide a set of binary distributions of MySQL that are compiled on systems at our site or on systems where supporters of MySQL kindly have given us access to their machines.

In addition to the binaries provided in platform-specific package formats, we offer binary distributions for a number of platforms in the form of compressed `tar` files (`.tar.gz` files). See Section 2.2, “Standard MySQL Installation Using a Binary Distribution”.

The RPM distributions for MySQL 6.0 releases that we make available through our Web site are generated by MySQL AB.

For Windows distributions, see Section 2.3, “Installing MySQL on Windows”.

These distributions are generated using the script `Build-tools/Do-compile`, which compiles the source code and creates the binary `tar.gz` archive using `scripts/make_binary_distribution`.

These binaries are configured and built with the following compilers and options. This information can also be obtained by looking at the variables `COMP_ENV_INFO` and `CONFIGURE_LINE` inside the script `bin/mysqlbug` of every binary `tar` file distribution.

Anyone who has more optimal options for any of the following `configure` commands can mail them to the MySQL `internals` mailing list. See Section 1.5.1, “MySQL Mailing Lists”.

If you want to compile a debug version of MySQL, you should add `--with-debug` or `--with-debug=full` to the following `configure` commands and remove any `-fomit-frame-pointer` options.

The following binaries are built on our own development systems:

- Linux 2.4.xx x86 with `gcc` 2.95.3:

```
CFLAGS="-O2 -mcpu=pentiumpro" CXX=gcc CXXFLAGS="-O2 -mcpu=pentiumpro
-felide-constructors" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --disable-shared
--with-client-ldflags=-all-static --with-mysqld-ldflags=-all-static
```

- Linux 2.4.x x86 with `icc` (Intel C++ Compiler 8.1 or later releases):

```
CC=icc CXX=icpc CFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict"
CXXFLAGS="-O3 -unroll2 -ip -mp -no-gcc -restrict" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --enable-assembler
--disable-shared --with-client-ldflags=-all-static
--with-mysqld-ldflags=-all-static --with-embedded-server --with-innodb
```

  Note that versions 8.1 and newer of the Intel compiler have separate drivers for 'pure' C (`icc`) and C++ (`icpc`); if you use `icc` version 8.0 or older for building MySQL, you will need to set `CXX=icc`.

- Linux 2.4.xx Intel Itanium 2 with `ecc` (Intel C++ Itanium Compiler 7.0):

```
CC=ecc CFLAGS="-O2 -tpp2 -ip -nolib_inline" CXX=ecc CXXFLAGS="-O2
-tpp2 -ip -nolib_inline" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile
```

- Linux 2.4.xx Intel Itanium with `ecc` (Intel C++ Itanium Compiler 7.0):

```
CC=ecc CFLAGS=-tpp1 CXX=ecc CXXFLAGS=-tpp1 ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile
```

- Linux 2.4.xx alpha with `ccc` (Compaq C V6.2-505 / Compaq C++ V6.3-006):

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx CXXFLAGS="-fast -arch
generic -noexceptions -nortti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-mysqld-ldflags=-non_shared
--with-client-ldflags=-non_shared --disable-shared
```

- Linux 2.x.xx ppc with `gcc` 2.95.4:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
```

```
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared --with-embedded-server
--with-innodb
```

- Linux 2.4.xx s390 with `gcc` 2.95.3:

```
CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-client-ldflags=-all-static --with-mysqld-ldflags=-all-static
```

- Linux 2.4.xx x86_64 (AMD64) with `gcc` 3.2.1:

```
CXX=gcc ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

- Sun Solaris 8 x86 with `gcc` 3.2.3:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared --with-innodb
```

- Sun Solaris 8 SPARC with `gcc` 3.2:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --with-named-z-libs=no
--with-named-curses-libs=-lcurses --disable-shared
```

- Sun Solaris 8 SPARC 64-bit with `gcc` 3.2:

```
CC=gcc CFLAGS="-O3 -m64 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-m64 -fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no
--with-named-curses-libs=-lcurses --disable-shared
```

- Sun Solaris 9 SPARC with `gcc` 2.95.3:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --with-named-curses-libs=-lcurses
--disable-shared
```

- Sun Solaris 9 SPARC with `cc-5.0` (Sun Forte 5.0):

```
CC=cc-5.0 CXX=CC ASFLAGS="-xarch=v9" CFLAGS="-Xa -xstrconst -mt
-D_FORTEC_ -xarch=v9" CXXFLAGS="-noex -mt -D_FORTEC_ -xarch=v9"
./configure --prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --enable-assembler
--with-named-z-libs=no --enable-thread-safe-client --disable-shared
```

- IBM AIX 4.3.2 ppc with `gcc` 3.2.3:

```
CFLAGS="-O2 -mcpu=powerpc -Wa,-many " CXX=gcc CXXFLAGS="-O2
-mcpu=powerpc -Wa,-many -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --disable-shared
```

- IBM AIX 4.3.3 ppc with `xlC_r` (IBM Visual Age C/C++ 6.0):

```
CC=xlc_r CFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
CXX=xlC_r CXXFLAGS ="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared --with-innodb
```

- IBM AIX 5.1.0 ppc with `gcc` 3.3:

```
CFLAGS="-O2 -mcpu=powerpc -Wa,-many" CXX=gcc CXXFLAGS="-O2 -mcpu=powerpc
-Wa,-many -felide-constructors -fno-exceptions -fno-rtti" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared
```

- IBM AIX 5.2.0 ppc with `xlC_r` (IBM Visual Age C/C++ 6.0):

```
CC=xlc_r CFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
CXX=xlC_r CXXFLAGS="-ma -O2 -qstrict -qoptimize=2 -qmaxmem=8192"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --with-named-z-libs=no
--disable-shared --with-embedded-server --with-innodb
```

- HP-UX 10.20 pa-risc1.1 with `gcc` 3.1:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc CXXFLAGS="-DHPUX
-I/opt/dce /include -felide-constructors -fno-exceptions -fno-rtti
-O3 -fPIC" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-pthread --with-named-thread-libs=-ldce
--with-lib-ccflags=-fPIC --disable-shared
```

- HP-UX 11.00 pa-risc with `aCC` (HP ANSI C++ B3910B A.03.50):

```
CC=cc CXX=aCC CFLAGS=+DAportable CXXFLAGS=+DAportable ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-embedded-server --with-innodb
```

- HP-UX 11.11 pa-risc2.0 64bit with `aCC` (HP ANSI C++ B3910B A.03.33):

```
CC=cc CXX=aCC CFLAGS=+DD64 CXXFLAGS=+DD64 ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
```

- HP-UX 11.11 pa-risc2.0 32bit with `aCC` (HP ANSI C++ B3910B A.03.33):

```
CC=cc CXX=aCC CFLAGS="+DAportable" CXXFLAGS="+DAportable" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-innodb
```

- HP-UX 11.22 ia64 64bit with `aCC` (HP aC++/ANSI C B3910B A.05.50):

```
CC=cc CXX=aCC CFLAGS="+DD64 +DSitanium2" CXXFLAGS="+DD64 +DSitanium2"
./configure --prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile --disable-shared
--with-embedded-server --with-innodb
```

- Apple Mac OS X 10.2 powerpc with `gcc` 3.1:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

- FreeBSD 4.7 i386 with `gcc` 2.95.4:

```
CFLAGS=-DHAVE_BROKEN_REALPATH ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --with-named-z-libs=not-used
--disable-shared
```

- FreeBSD 4.7 i386 using LinuxThreads with `gcc` 2.95.4:

```
CFLAGS="-DHAVE_BROKEN_REALPATH -D__USE_UNIX98 -D_REENTRANT
-D_THREAD_SAFE -I/usr/local/include/pthread/linuxthreads"
```

```
CXXFLAGS="-DHAVE_BROKEN_REALPATH -D__USE_UNIX98 -D_REENTRANT
-D_THREAD_SAFE -I/usr/local/include/pthread/linuxthreads" ./configure
--prefix=/usr/local/mysql --localstatedir=/usr/local/mysql/data
--libexecdir=/usr/local/mysql/bin --enable-thread-safe-client
--enable-local-infile --enable-assembler
--with-named-thread-libs="-DHAVE_GLIBC2_STYLE_GETHOSTBYNAME_R
-D_THREAD_SAFE -I /usr/local/include/pthread/linuxthreads
-L/usr/local/lib -llthread -llgcc_r" --disable-shared
--with-embedded-server --with-innodb
```

- QNX Neutrino 6.2.1 i386 with `gcc` 2.95.3qnx-nto 20010315:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

The following binaries are built on third-party systems kindly provided to Sun Microsystems, Inc. by other users. These are provided only as a courtesy; we do not have full control over these systems, so we can provide only limited support for the binaries built on them.

- SCO Unix 3.2v5.0.7 i386 with `gcc` 2.95.3:

```
CFLAGS="-O3 -mpentium" LDFLAGS=-static CXX=gcc CXXFLAGS="-O3 -mpentium
-felide-constructors" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared
```

- SCO UnixWare 7.1.4 i386 with `CC` 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared --with-readline
```

- SCO OpenServer 6.0.0 i386 with `CC` 3.2:

```
CC=cc CFLAGS="-O" CXX=CC ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --with-named-z-libs=no --enable-thread-safe-client
--disable-shared --with-readline
```

- Compaq Tru64 OSF/1 V5.1 732 alpha with `cc/cxx` (Compaq C V6.3-029i / DIGITAL C++ V6.1-027):

```
CC="cc -pthread" CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline
speed -speculate all" CXX="cxx -pthread" CXXFLAGS="-O4 -ansi_alias
-fast -inline speed -speculate all -noexceptions -nortti" ./configure
--prefix=/usr/local/mysql --with-extra-charsets=complex
--enable-thread-safe-client --enable-local-infile
--with-named-thread-libs="-lpthread -lmach -lexc -lc" --disable-shared
--with-mysqld-ldflags=-all-static
```

- SGI Irix 6.5 IP32 with `gcc` 3.0.1:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared
```

- FreeBSD/sparc64 5.0 with `gcc` 3.2.1:

```
CFLAGS=-DHAVE_BROKEN_REALPATH ./configure --prefix=/usr/local/mysql
--localstatedir=/usr/local/mysql/data --libexecdir=/usr/local/mysql/bin
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --disable-shared --with-innodb
```

The following compile options have been used for binary packages that we have provided in the past. These binaries no longer are being updated, but the compile options are listed here for reference purposes.

- Linux 2.2.xx SPARC with egcs 1.1.2:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc CXXFLAGS="-O3
-fno-omit-frame-pointer -felide-constructors -fno-exceptions
-fno-rtti" ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex --enable-thread-safe-client
--enable-local-infile --enable-assembler --disable-shared
```

- Linux 2.2.x with x686 with gcc 2.95.2:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro
-felide-constructors -fno-exceptions -fno-rtti" ./configure
--prefix=/usr/local/mysql --enable-assembler
--with-mysqld-ldflags=-all-static --disable-shared
--with-extra-charsets=complex
```

- SunOS 4.1.4 2 sun4c with gcc 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors" ./configure
--prefix=/usr/local/mysql --disable-shared --with-extra-charsets=complex
--enable-assembler
```

- SunOS 5.5.1 (and above) sun4u with egcs 1.0.3a or 2.90.27 or gcc 2.95.2 and newer:

```
CC=gcc CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql
--with-low-memory --with-extra-charsets=complex --enable-assembler
```

- SunOS 5.6 i86pc with gcc 2.8.1:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-low-memory --with-extra-charsets=complex
```

- BSDI BSD/OS 3.1 i386 with gcc 2.7.2.1:

```
CC=gcc CXX=gcc CXXFLAGS=-O ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

- BSDI BSD/OS 2.1 i386 with gcc 2.7.2:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

- AIX 4.2 with gcc 2.7.2.2:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
--with-extra-charsets=complex
```

2.1.3. How to Get MySQL

Check our downloads page at http://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see http://dev.mysql.com/downloads/mirrors.html. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

Our main mirror is located at http://mirrors.sunsite.dk/mysql/.

2.1.4. Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using GnuPG, the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site. If you repeatedly cannot successfully verify the integrity of the package, please notify us about such incidents, including the full package name and the download site you have been using, at <webmaster@mysql.com> or <build@mysql.com>. Do not report downloading problems using the bug-reporting system.

2.1.4.1. Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify with the following command, where *package_name* is the name of the package you downloaded:

```
shell> md5sum package_name
```

Example:

```
shell> md5sum mysql-standard-6.0.12-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-6.0.12-linux-i686.tar.gz
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

> **Note**
>
> Make sure to verify the checksum of the *archive file* (for example, the .zip or .tar.gz file) and not of the files that are contained inside of the archive.

Note that not all operating systems support the md5sum command. On some, it is simply called md5, and others do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can download the source code from http://www.gnu.org/software/textutils/ as well. If you have OpenSSL installed, you can use the command openssl md5 *package_name* instead. A Windows implementation of the md5 command line utility is available from http://www.fourmilab.ch/md5/. winMd5Sum is a graphical MD5 checking tool that can be obtained from http://www.nullriver.com/index/products/winmd5sum.

2.1.4.2. Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the well-known Pretty Good Privacy (PGP) by Phil Zimmermann. See http://www.gnupg.org/ for more information about GnuPG and how to obtain and install it on your system. Most Linux distributions ship with GnuPG installed by default. For more information about GnuPG, see http://www.openpgp.org/.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://keyserver.pgp.com/. The key that you want to obtain is named build@mysql.com. Alternatively, you can cut and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.0.6 (GNU/Linux)
Comment: For info see http://www.gnupg.org

=Xquv
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Package signing key (www.mysql.com) <build@mysql.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server subkeys.pgp.net
gpg: key 5072E1F5: "MySQL Package signing key (www.mysql.com) <build@mysql.com>" 2 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:         new signatures: 2
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems, try exporting the key from `gpg` and importing:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you cas use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/6.0/en/checking-gpg-signature.html
```

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

Distribution file	`mysql-standard-6.0.12-linux-i686.tar.gz`
Signature file	`mysql-standard-6.0.12-linux-i686.tar.gz.asc`

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

Example:

```
shell> gpg --verify mysql-standard-6.0.12-linux-i686.tar.gz.asc
gpg: Signature made Tue 12 Jul 2005 23:35:41 EST using DSA key ID 5072E1F5
gpg: Good signature from "MySQL Package signing key (www.mysql.com) <build@mysql.com>"
```

The `Good signature` message indicates that everything is all right. You can ignore any `insecure memory` warning you might obtain.

See the GPG documentation for more information on how to work with public keys.

2.1.4.3. Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-6.0.12-0.glibc23.i386.rpm
MySQL-server-6.0.12-0.glibc23.i386.rpm: md5 gpg OK
```

> **Note**
>
> If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, it maintains its own keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key as described in Section 2.1.4.2, “Signature Checking Using GnuPG”. Then use `rpm --import` to import the key. For example, if you have saved the public key in a file named `mysql_pubkey.asc`, import it using this command:

```
shell> rpm --import mysql_pubkey.asc
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, “Signature Checking Using GnuPG”.

2.1.5. Installation Layouts

This section describes the default layout of the directories created by installing binary or source distributions provided by Sun Microsystems, Inc. A distribution provided by another vendor might use a layout different from those shown here.

For MySQL 6.0 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 6.0`. (Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.) The installation directory has the following subdirectories.

Directory	Contents of Directory

`bin`	Client programs and the `mysqld` server
`data`	Log files, databases
`Docs`	Manual in CHM format
`examples`	Example programs and scripts
`include`	Include (header) files
`lib`	Libraries
`scripts`	Utility scripts
`share`	Error message files

Installations created from our Linux RPM distributions result in files under the following system directories.

Directory	Contents of Directory
`/usr/bin`	Client programs and scripts
`/usr/sbin`	The `mysqld` server
`/var/lib/mysql`	Log files, databases
`/usr/share/info`	Manual in Info format
`/usr/share/man`	Unix manual pages
`/usr/include/mysql`	Include (header) files
`/usr/lib/mysql`	Libraries
`/usr/share/mysql`	Error message and character set files
`/usr/share/sql-bench`	Benchmarks

On Unix, a `tar` file binary distribution is installed by unpacking it at the installation location you choose (typically `/usr/local/mysql`) and creates the following directories in that location.

Directory	Contents of Directory
`bin`	Client programs and the `mysqld` server
`data`	Log files, databases
`docs`	Manual in Info format
`man`	Unix manual pages
`include`	Include (header) files
`lib`	Libraries
`scripts`	`mysql_install_db`
`share/mysql`	Error message files
`sql-bench`	Benchmarks

A source distribution is installed after you configure and compile it. By default, the installation step installs files under `/usr/local`, in the following subdirectories.

Directory	Contents of Directory
`bin`	Client programs and scripts
`include/mysql`	Include (header) files
`Docs`	Manual in Info, CHM formats
`man`	Unix manual pages
`lib/mysql`	Libraries
`libexec`	The `mysqld` server
`share/mysql`	Error message files
`sql-bench`	Benchmarks and `crash-me` test
`var`	Databases and log files

Within its installation directory, the layout of a source installation differs from that of a binary installation in the following ways:

- The `mysqld` server is installed in the `libexec` directory rather than in the `bin` directory.
- The data directory is `var` rather than `data`.
- `mysql_install_db` is installed in the `bin` directory rather than in the `scripts` directory.
- The header file and library directories are `include/mysql` and `lib/mysql` rather than `include` and `lib`.

You can create your own binary installation from a compiled source distribution by executing the `scripts/make_binary_distribution` script from the top directory of the source distribution.

2.2. Standard MySQL Installation Using a Binary Distribution

The next several sections cover the installation of MySQL on platforms where we offer packages using the native packaging format of the respective platform. (This is also known as performing a "binary install.") However, binary distributions of MySQL are available for many other platforms as well. See Section 2.8, "Installing MySQL from `tar.gz` Packages on Other Unix-Like Systems", for generic installation instructions for these packages that apply to all platforms.

See Section 2.1, "General Installation Issues", for more information on what other binary distributions are available and how to obtain them.

2.3. Installing MySQL on Windows

A native Windows distribution of MySQL has been available since version 3.21 and represents a sizable percentage of the daily downloads of MySQL. This section describes the process for installing MySQL on Windows.

> **Note**
>
> If you are upgrading MySQL from an existing installation older than MySQL 4.1.5, you must first perform the procedure described in Section 2.3.14, "Upgrading MySQL on Windows".

To run MySQL on Windows, you need the following:

- A 32-bit Windows operating system such as Windows 2000, Windows XP, Windows Vista, Windows Server 2003, or Windows Server 2008.

  A Windows operating system permits you to run the MySQL server as a service. See Section 2.3.11, "Starting MySQL as a Windows Service".

  Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`. Once installed, MySQL does not need to be executed using a user with Administrator privileges.
- TCP/IP protocol support.
- Enough space on the hard drive to unpack, install, and create the databases in accordance with your requirements (generally a minimum of 200 megabytes is recommended.)

For a list of limitations within the Windows version of MySQL, see Section D.9.3, "Windows Platform Limitations".

There may also be other requirements, depending on how you plan to use MySQL:

- If you plan to connect to the MySQL server via ODBC, you need a Connector/ODBC driver. See Section 20.1, "MySQL Connector/ODBC".
- If you plan to use MySQL server with ADO.NET applications, you need the Connector/NET driver. See Section 20.2, "MySQL Connector/NET".
- If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Don't forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 12.1.14, "`CREATE TABLE` Syntax".

MySQL for Windows is available in several distribution formats:

- Binary distributions are available that contain a setup program that installs everything you need so that you can start the server immediately. Another binary distribution format contains an archive that you simply unpack in the installation location and then configure yourself. For details, see Section 2.3.1, “Choosing An Installation Package”.
- The source distribution contains all the code and support files for building the executables using the Visual Studio compiler system.

Generally speaking, you should use a binary distribution that includes an installer. It is simpler to use than the others, and you need no additional tools to get MySQL up and running. The installer for the Windows version of MySQL, combined with a GUI Configuration Wizard, automatically installs MySQL, creates an option file, starts the server, and secures the default user accounts.

> **Caution**
>
> Using virus scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is because of the fingerprinting mechanism used by the virus scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.
>
> After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) being used to store your MySQL table data. There is usually a system built into the virus scanning software to allow certain directories to be specifically ignored during virus scanning.
>
> In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, you should configure a separate temporary directory for MySQL temporary files and add this to the virus scanning exclusion list. To do this, add a configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see Section 2.3.7, “Creating an Option File”.

The following section describes how to install MySQL on Windows using a binary distribution. To use an installation package that does not include an installer, follow the procedure described in Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”. To install using a source distribution, see Section 2.9.6, “Installing MySQL from Source on Windows”.

MySQL distributions for Windows can be downloaded from http://dev.mysql.com/downloads/. See Section 2.1.3, “How to Get MySQL”.

2.3.1. Choosing An Installation Package

For MySQL 6.0, there are three installation packages to choose from when installing MySQL on Windows:

- **The Essentials Package**: This package has a file name similar to `mysql-essential-6.0.12-win32.msi` and contains the minimum set of files needed to install MySQL on Windows, including the Configuration Wizard. This package does not include optional components such as the embedded server and benchmark suite.
- **The Complete Package**: This package has a file name similar to `mysql-6.0.12-win32.zip` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.
- **The Noinstall Archive**: This package has a file name similar to `mysql-noinstall-6.0.12-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

The Essentials package is recommended for most users. It is provided as an `.msi` file for use with the Windows Installer. The Complete and Noinstall distributions are packaged as Zip archives. To use them, you must have a tool that can unpack `.zip` files.

Your choice of install package affects the installation process you must follow. If you choose to install either the Essentials or Complete install packages, see Section 2.3.2, “Installing MySQL with the Automated Installer”. If you choose to install MySQL from the Noinstall archive, see Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”.

2.3.2. Installing MySQL with the Automated Installer

New MySQL users can use the MySQL Installation Wizard and MySQL Configuration Wizard to install MySQL on Windows. These are designed to install and configure MySQL in such a way that new users can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Essentials and Complete install packages. They are recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

2.3.3. Using the MySQL Installation Wizard

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, allows a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to shut down and remove their existing MySQL installations manually before installing MySQL with the MySQL Installation Wizard. See Section 2.3.3.6, "Upgrading MySQL with the Installation Wizard", for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation process.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference this Microsoft Knowledge Base article for information on upgrading to the latest version of the Windows Installer Engine.

In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit recently. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it allows us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in Section 1.6, "How to Report Bugs or Problems".

2.3.3.1. Downloading and Starting the MySQL Installation Wizard

The MySQL installation packages can be downloaded from http://dev.mysql.com/downloads/. If the package you download is contained within a Zip archive, you need to extract the archive first.

> **Note**
>
> If you are installing on Windows Vista it is best to open a network port before beginning the installation. To do this, first ensure that you are logged in as an Administrator, go to the `Control Panel`, and double click the `Windows Firewall` icon. Choose the `Allow a program through Windows Firewall` option and click the ADD PORT button. Enter `MySQL` into the **NAME** text box and `3306` (or the port of your choice) into the **PORT NUMBER** text box. Also ensure that the **TCP** protocol radio button is selected. If you wish, you can also limit access to the MySQL server by choosing the **CHANGE SCOPE** button. Confirm your choices by clicking the OK button. If you do not open a port prior to installation, you cannot configure the MySQL server immediately after installation. Additionally, when running the MySQL Installation Wizard on Windows Vista, ensure that you are logged in as a user with administrative rights.

The process for starting the wizard depends on the contents of the installation package you download. If there is a `setup.exe` file present, double-click it to start the installation process. If there is an `.msi` file present, double-click it to start the installation process.

Starting with MySQL 6.0.6, on starting the MySQL Installation Wizard you will be asked whether you want to run the MySQL Configuration Wizard once installation has completed and whether you want to register your installation with MySQL. If you decide to send the registration information, a small file will be uploaded to the SunConnect service. A browser window will also open and ask you to sign in to your Sun Developer Network account or to register for a new account. Your MySQL registration information will be appended to your Sun Developer Network account, and you can use the inventory management system to keep track of the pacakges you have registered. Only information about your server, version and environment is sent to the SunConnect system.

If an internet connection is not available, then the information will be stored in two files within the base directory of your MySQL installation. The files are called `register` and `svctag`. You can run then run the registration once an internet connection is available by running the **SUNINVENTORY REGISTRATION** link from the server installation folder within the **START** menu.

2.3.3.2. Choosing an Install Type

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the `mysql` command-line client, and the command-line utilities. The command-line clients and utilities include `mysqldump`, `myisamchk`, and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See Section 2.3.3.3, "The Custom Install Dialog", for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the NEXT button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation type and click the NEXT button, you advance to the custom installation dialog, described in Section 2.3.3.3, "The Custom Install Dialog".

2.3.3.3. The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the **Custom** installation type.

A tree view on the left side of the custom install dialog lists all available components. Components that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click on that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the CHANGE... button to the right of the displayed installation path.

After choosing your installation components and installation path, click the NEXT button to advance to the confirmation dialog.

2.3.3.4. The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the INSTALL button. To change your settings, click the BACK button. To exit the MySQL Installation Wizard without installing MySQL, click the CANCEL button.

After installation is complete, you have the option of registering with the MySQL web site. Registration gives you access to post in the MySQL forums at forums.mysql.com, along with the ability to report bugs at bugs.mysql.com and to subscribe to our newsletter. The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

2.3.3.5. Changes Made by MySQL Installation Wizard

Once you click the INSTALL button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 6.0`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 6.0\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 6.0.12, the key contains a value of `6.0.12`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the `noinstall` Zip archive, the registry keys are not created.

Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows START menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 6.0, the MySQL Installation Wizard creates a MySQL Server 6.0 section in the START menu.

The following entries are created within the new START menu section:

- MySQL Command Line Client: This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.
- MySQL Server Instance Config Wizard: This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.
- MySQL Documentation: This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory. This option is not available when the MySQL server is installed using the Essentials installation package.

Changes to the File System

The MySQL Installation Wizard by default installs the MySQL 6.0 server to `C:\Program Files\MySQL\MySQL Server 6.0`, where `Program Files` is the default location for applications in your system, and `6.0` is the major version of your MySQL server. This is the recommended location for the MySQL server, replacing the former default location `C:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where `Program Files` is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 6.0
C:\Program Files\MySQL\MySQL Administrator 1.0
C:\Program Files\MySQL\MySQL Query Browser 1.0
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

In MySQL 5.1.23 and earlier, the default location for the data files used by MySQL is located within the corresponding MySQL Server installation directory. For MySQL 5.1.24 and later, the default location of the data directory is the `AppData` directory configured for the user that installed the MySQL application.

2.3.3.6. Upgrading MySQL with the Installation Wizard

The MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 4.1.5 to MySQL 4.1.6, but not from MySQL 5.1 to MySQL 6.0.

See Section 2.3.14, “Upgrading MySQL on Windows”.

2.3.4. MySQL Server Instance Configuration Wizard

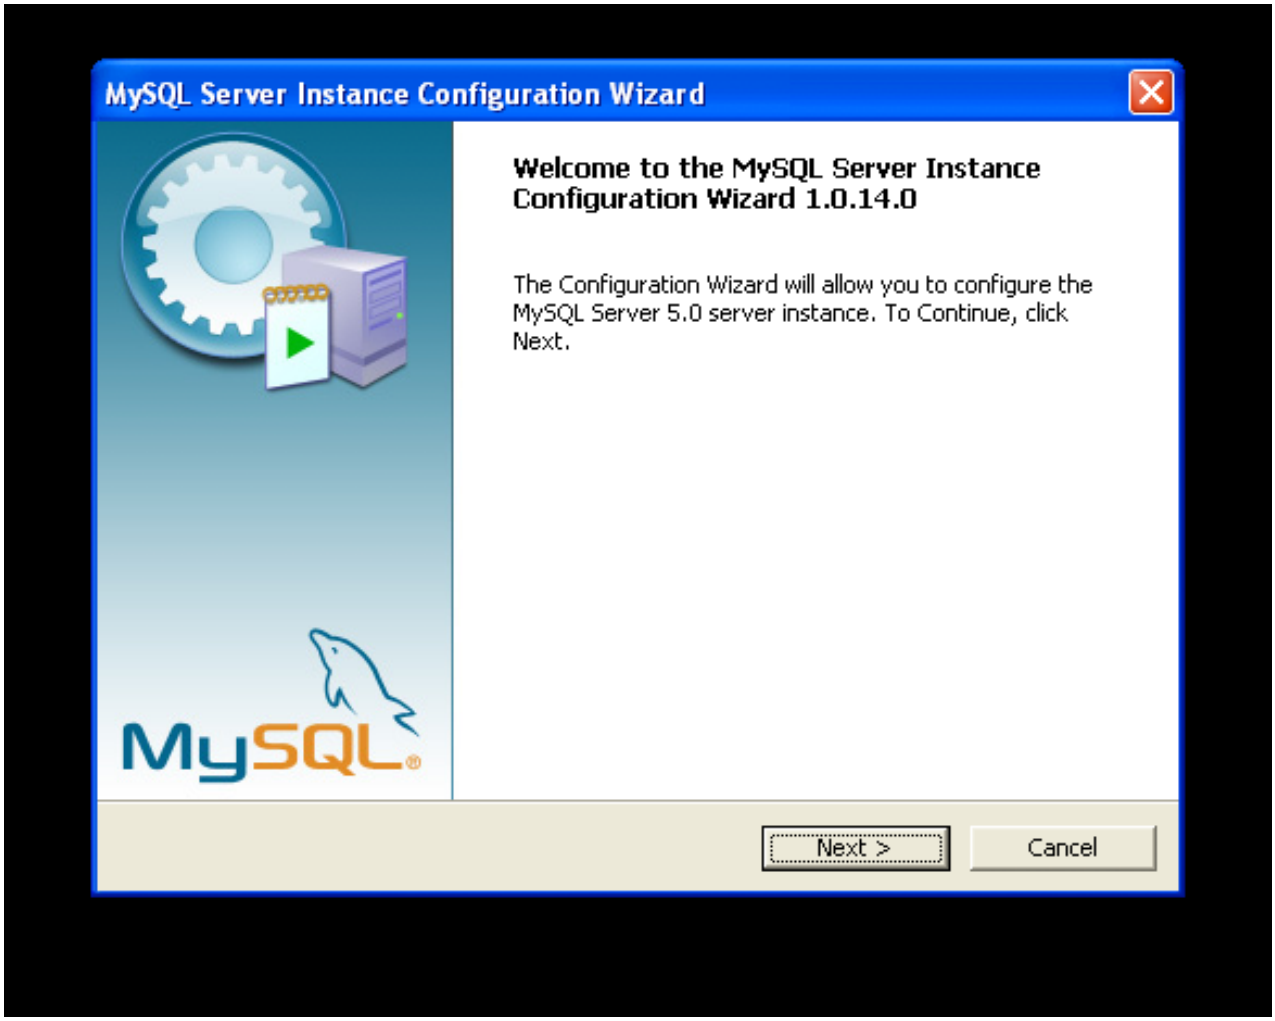
The MySQL Server Instance Configuration Wizard helps automate the process of configuring your server. It creates a custom MySQL configuration file (`my.ini` or `my.cnf`) by asking you a series of questions and then applying your responses to a template to generate the configuration file that is tuned to your installation.

The MySQL Server Instance Configuration Wizard is included with the MySQL 6.0 server. The MySQL Server Instance Configuration Wizard is only available for Windows.

2.3.4.1. Starting the MySQL Server Instance Configuration Wizard

The MySQL Server Instance Configuration Wizard is normally started as part of the installation process. You should only need to run the MySQL Server Instance Configuration Wizard again when you need to change the configuration parameters of your server.

If you chose not to open a port prior to installing MySQL on Windows Vista, you can choose to use the MySQL Server Configuration Wizard after installation. However, you must open a port in the Windows Firewall. To do this see the instructions given in Section 2.3.3.1, “Downloading and Starting the MySQL Installation Wizard”. Rather than opening a port, you also have the option of adding MySQL as a program that bypasses the Windows Firewall. One or the other option is sufficient — you need not do both. Additionally, when running the MySQL Server Configuration Wizard on Windows Vista ensure that you are logged in as a user with administrative rights.



You can launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows START menu.

Alternatively, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

The MySQL Server Instance Configuration Wizard places the `my.ini` file in the installation directory for the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 6.0\my.ini"
```

Here, *`C:\Program Files\MySQL\MySQL Server 6.0`* is replaced with the installation path to the MySQL Server. The `--defaults-file` option instructs the MySQL server to read the specified file for configuration options when it starts.

Apart from making changes to the `my.ini` file by running the MySQL Server Instance Configuration Wizard again, you can modify it by opening it with a text editor and making any necessary changes. You can also modify the server configuration with the MySQL Administrator utility. For more information about server configuration, see Section 5.1.2, “Server Command Options”.

MySQL clients and utilities such as the `mysql` and `mysqldump` command-line clients are not able to locate the `my.ini` file located in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the Windows installation directory (for example, `C:\WINDOWS`).

Under Windows Server 2003, Windows Server 2000 and Windows XP, MySQL Server Instance Configuration Wizard will configure MySQL to work as a Windows service. To start and stop MySQL you use the `Services` application that is supplied as part of the Windows Administrator Tools.

2.3.4.2. Choosing a Maintenance Option

If the MySQL Server Instance Configuration Wizard detects an existing configuration file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the configuration file and stopping and removing the MySQL service.

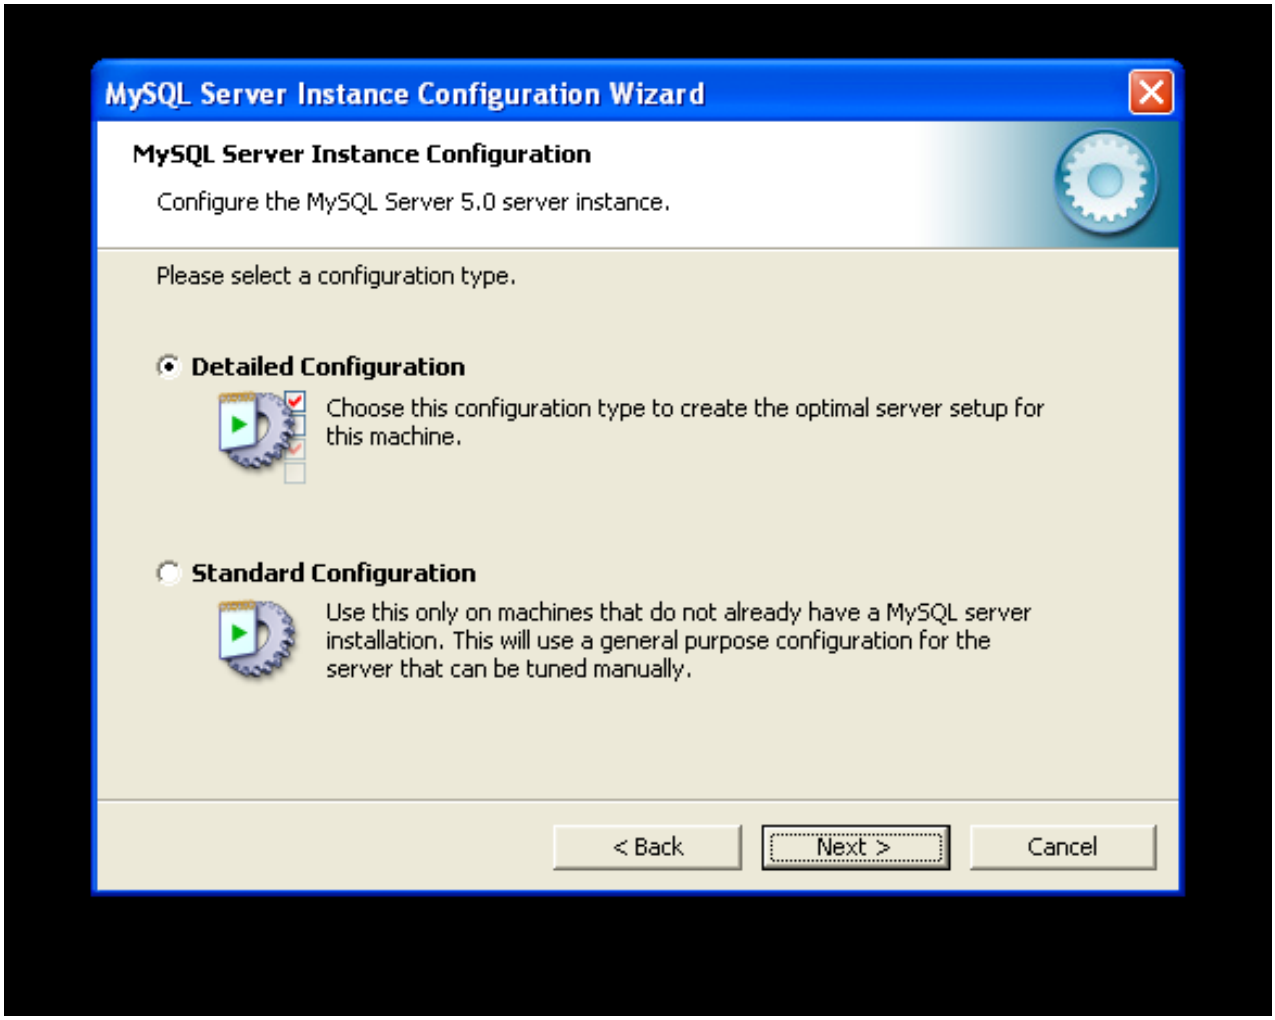
To reconfigure an existing server, choose the Re-configure Instance option and click the NEXT button. Any existing configuration file is not overwritten, but renamed (within the same directory) using a timestamp (Windows) or sequential number (Linux). To remove the existing server instance, choose the Remove Instance option and click the NEXT button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the EXECUTE button. The MySQL Server Configuration Wizard stops and removes the MySQL service, and then deletes the configuration file. The server installation and its `data` folder are not removed.

If you choose the Re-configure Instance option, you advance to the CONFIGURATION TYPE dialog where you can choose the type of installation that you wish to configure.

2.3.4.3. Choosing a Configuration Type

When you start the MySQL Server Instance Configuration Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the CONFIGURATION TYPE dialog.



There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make many decisions about server configuration. The Detailed Configuration option is intended for advanced users who want more fine-grained control over server configuration.

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Configuration Wizard to set all configuration options automatically with the exception of Service Options and Security Options.

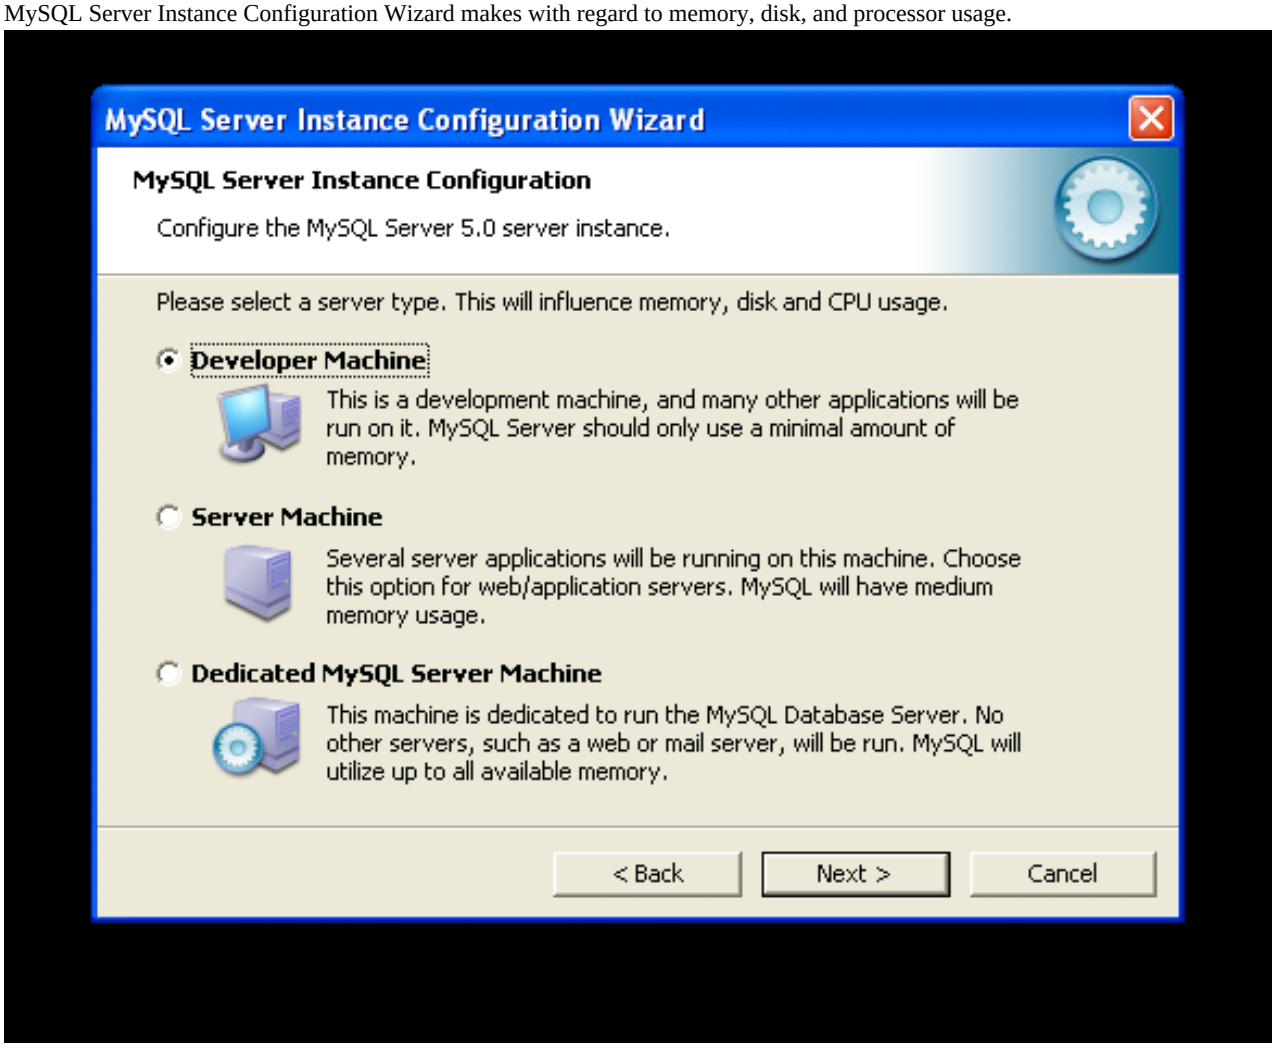
The Standard Configuration sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the Detailed Config-

uration option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in Section 2.3.4.10, "The Service Options Dialog", and Section 2.3.4.11, "The Security Options Dialog", respectively.

2.3.4.4. The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Server Instance Configuration Wizard makes with regard to memory, disk, and processor usage.



- Developer Machine: Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.
- Server Machine: Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a moderate portion of the system resources.
- Dedicated MySQL Server Machine: Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

> **Note**
>
> By selecting one of the preconfigured configurations, the values and settings of various options in your `my.cnf` or `my.ini` will be altered accordingly. The default values and options as described in the reference manual may therefore be different to the options and values that were created during the execution of the configuration wizard.

2.3.4.5. The Database Usage Dialog

The DATABASE USAGE dialog allows you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the `InnoDB` storage engine is available and what percentage of the server resources are

available to InnoDB.

- Multifunctional Database: This option enables both the InnoDB and MyISAM storage engines and divides resources evenly between the two. This option is recommended for users who use both storage engines on a regular basis.
- Transactional Database Only: This option enables both the InnoDB and MyISAM storage engines, but dedicates most server resources to the InnoDB storage engine. This option is recommended for users who use InnoDB almost exclusively and make only minimal use of MyISAM.
- Non-Transactional Database Only: This option disables the InnoDB storage engine completely and dedicates all server resources to the MyISAM storage engine. This option is recommended for users who do not use InnoDB.

The Configuration Wizard uses a template to generate the server configuration file. The DATABASE USAGE dialog sets one of the following option strings:

```
Multifunctional Database:        MIXED
Transactional Database Only:     INNODB
Non-Transactional Database Only: MYISAM
```

When these options are processed through the default template (my-template.ini) the result is:

```
Multifunctional Database:
default-storage-engine=InnoDB
_myisam_pct=50

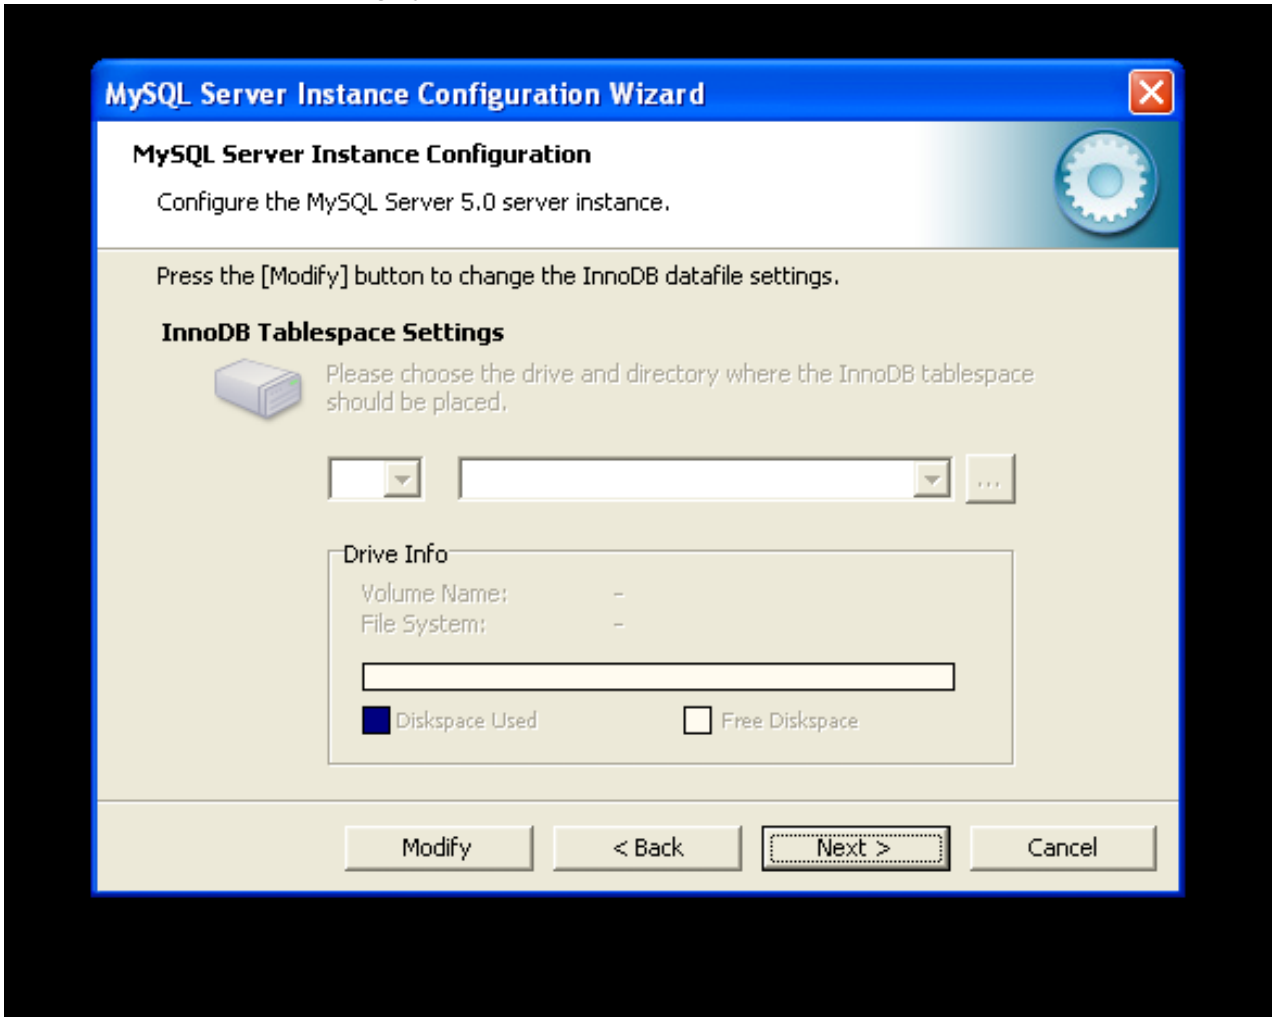
Transactional Database Only:
default-storage-engine=InnoDB
_myisam_pct=5

Non-Transactional Database Only:
default-storage-engine=MyISAM
_myisam_pct=100
skip-innodb
```

The `_myisam_pct` value is used to calculate the percentage of resources dedicated to `MyISAM`. The remaining resources are allocated to `InnoDB`.

2.3.4.6. The InnoDB Tablespace Dialog

Some users may want to locate the `InnoDB` tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.

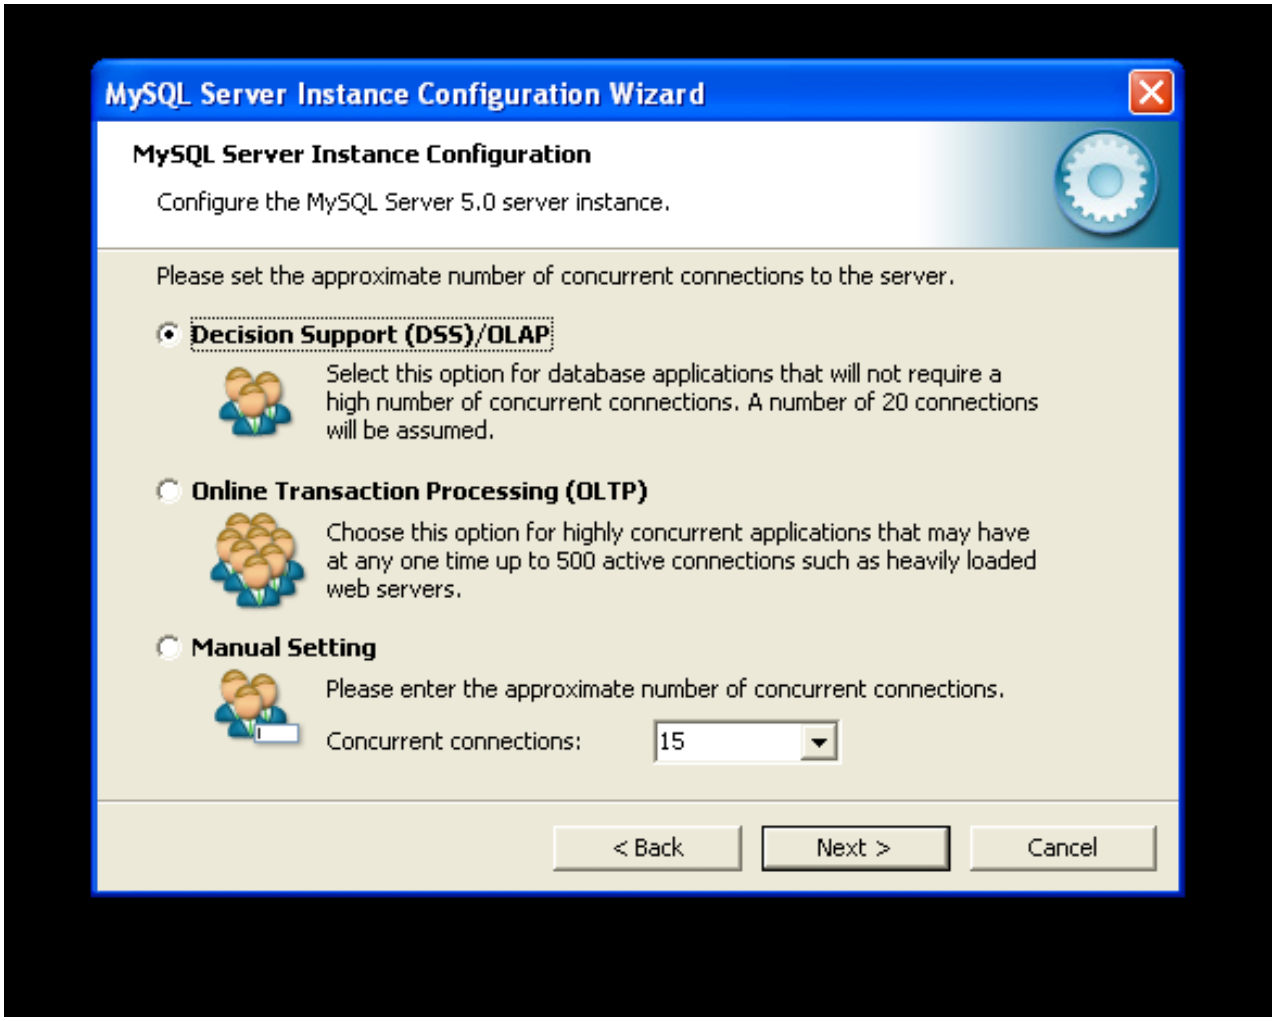


To change the default location for the `InnoDB` tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the MODIFY button before you change the path. In this situation you must move the existing tablespace files to the new location manually before starting the server.

2.3.4.7. The Concurrent Connections Dialog

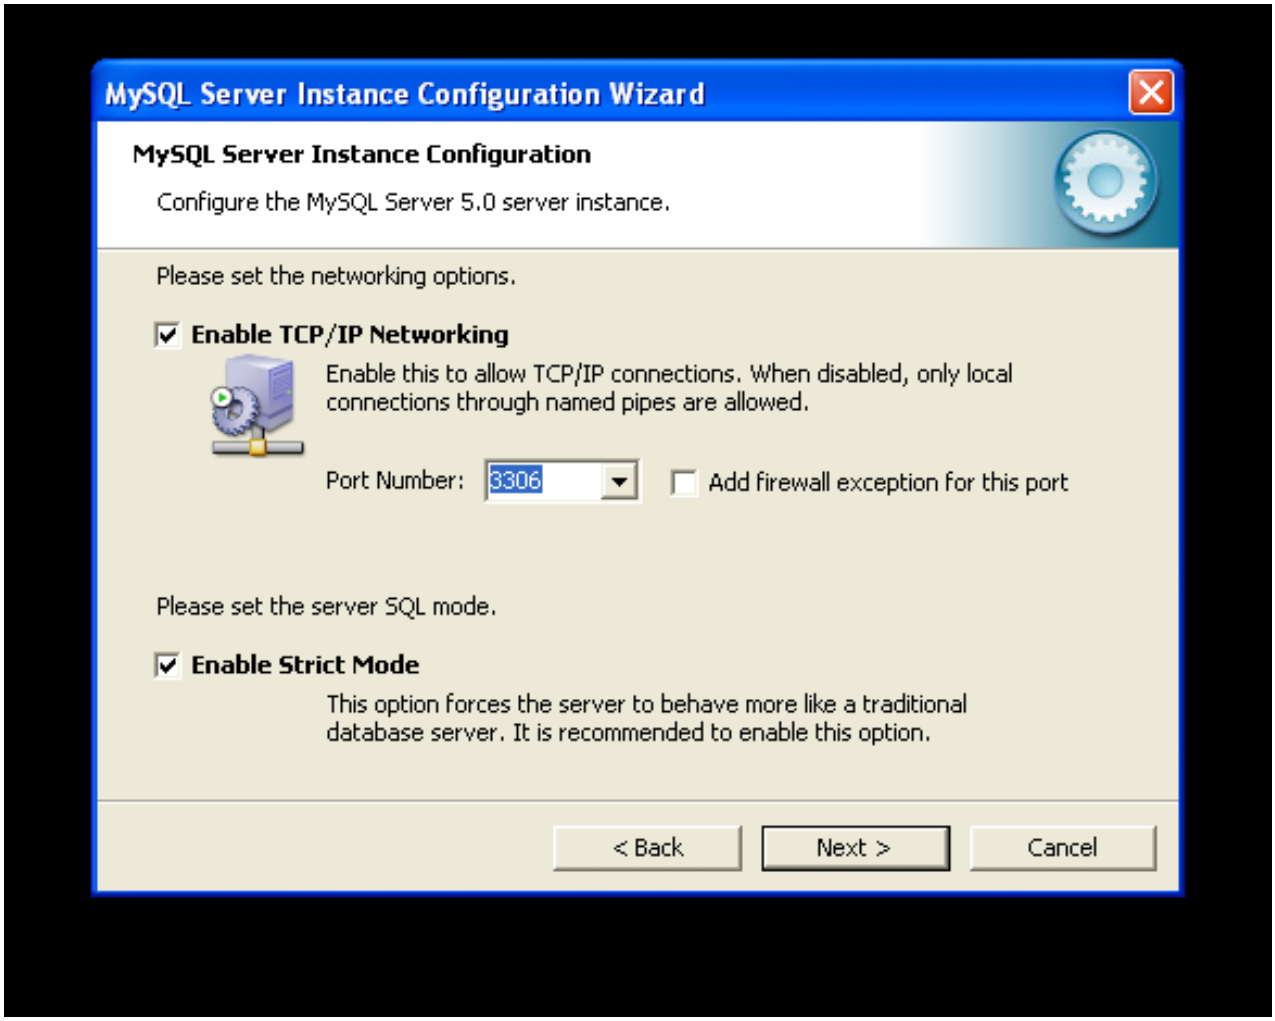
To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The CONCURRENT CONNECTIONS dialog allows you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to set the concurrent connection limit manually.



- Decision Support (DSS)/OLAP: Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.
- Online Transaction Processing (OLTP): Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.
- Manual Setting: Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or enter the maximum number of connections into the drop-down box if the number you desire is not listed.

2.3.4.8. The Networking and Strict Mode Options Dialog

Use the NETWORKING OPTIONS dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.



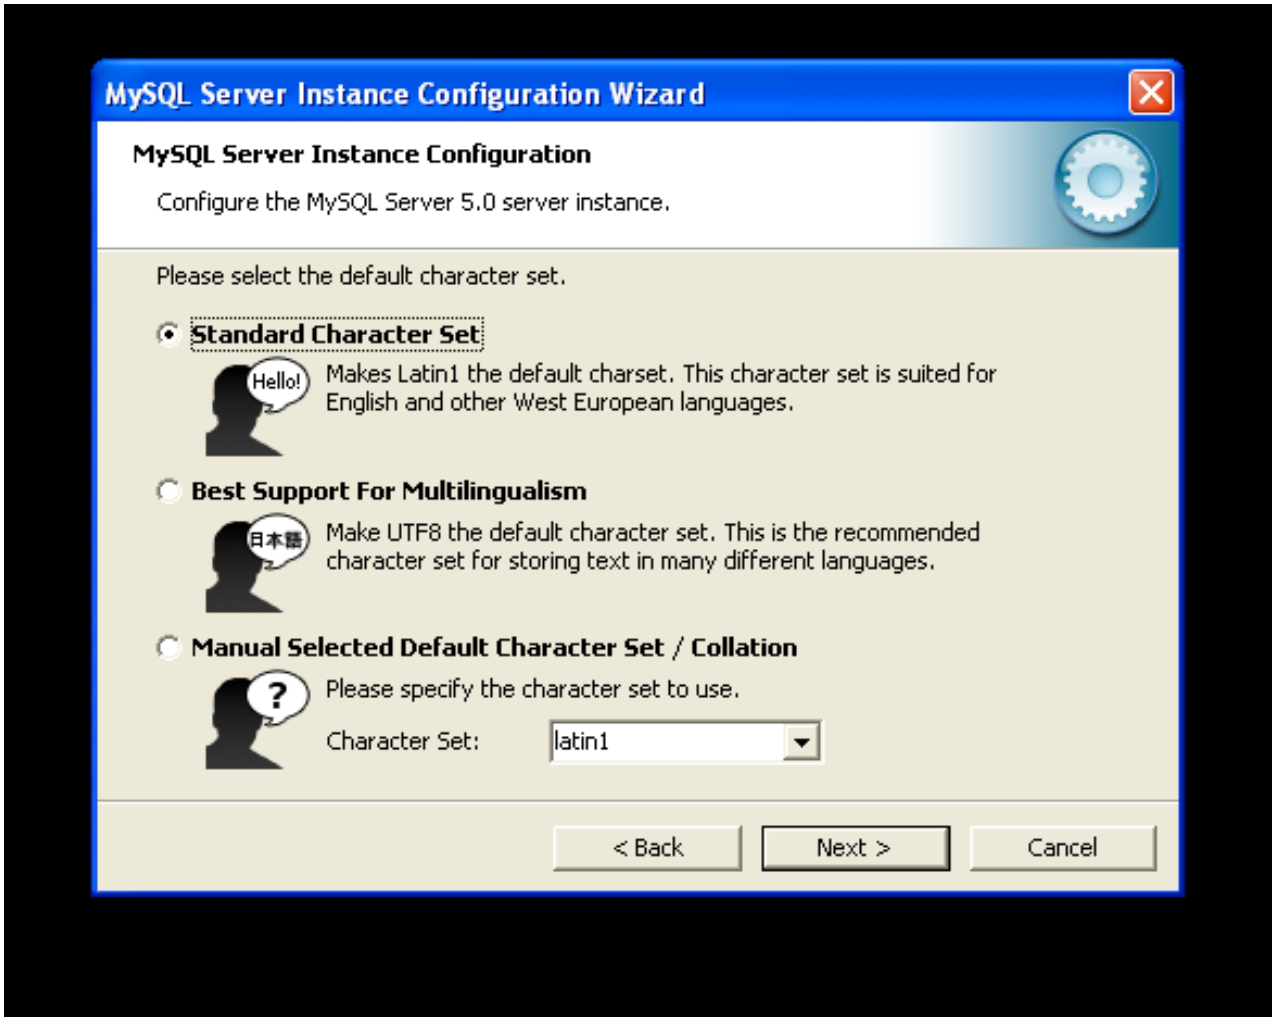
TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the SERVER SQL MODE to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. *If you run applications that rely on MySQL's old "forgiving" behavior, make sure to either adapt those applications or to disable strict mode.* For more information about strict mode, see Section 5.1.7, "Server SQL Modes".

2.3.4.9. The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the CHARACTER SET dialog to change the default character set of the MySQL server.



- Standard Character Set: Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.
- Best Support For Multilingualism: Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.
- Manual Selected Default Character Set / Collation: Choose this option if you want to pick the server's default character set manually. Choose the desired character set from the provided drop-down list.

2.3.4.10. The Service Options Dialog

On Windows platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Server Instance Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, uncheck the box next to the Install As Windows Service option. You can change the service name by picking a new service name from the drop-down box provided or by entering a new service name into the drop-down box.

> **Note**
>
> Service names can include any legal character except forward (`/`) or backward (`\`) slashes, and must be less than 256 characters long.

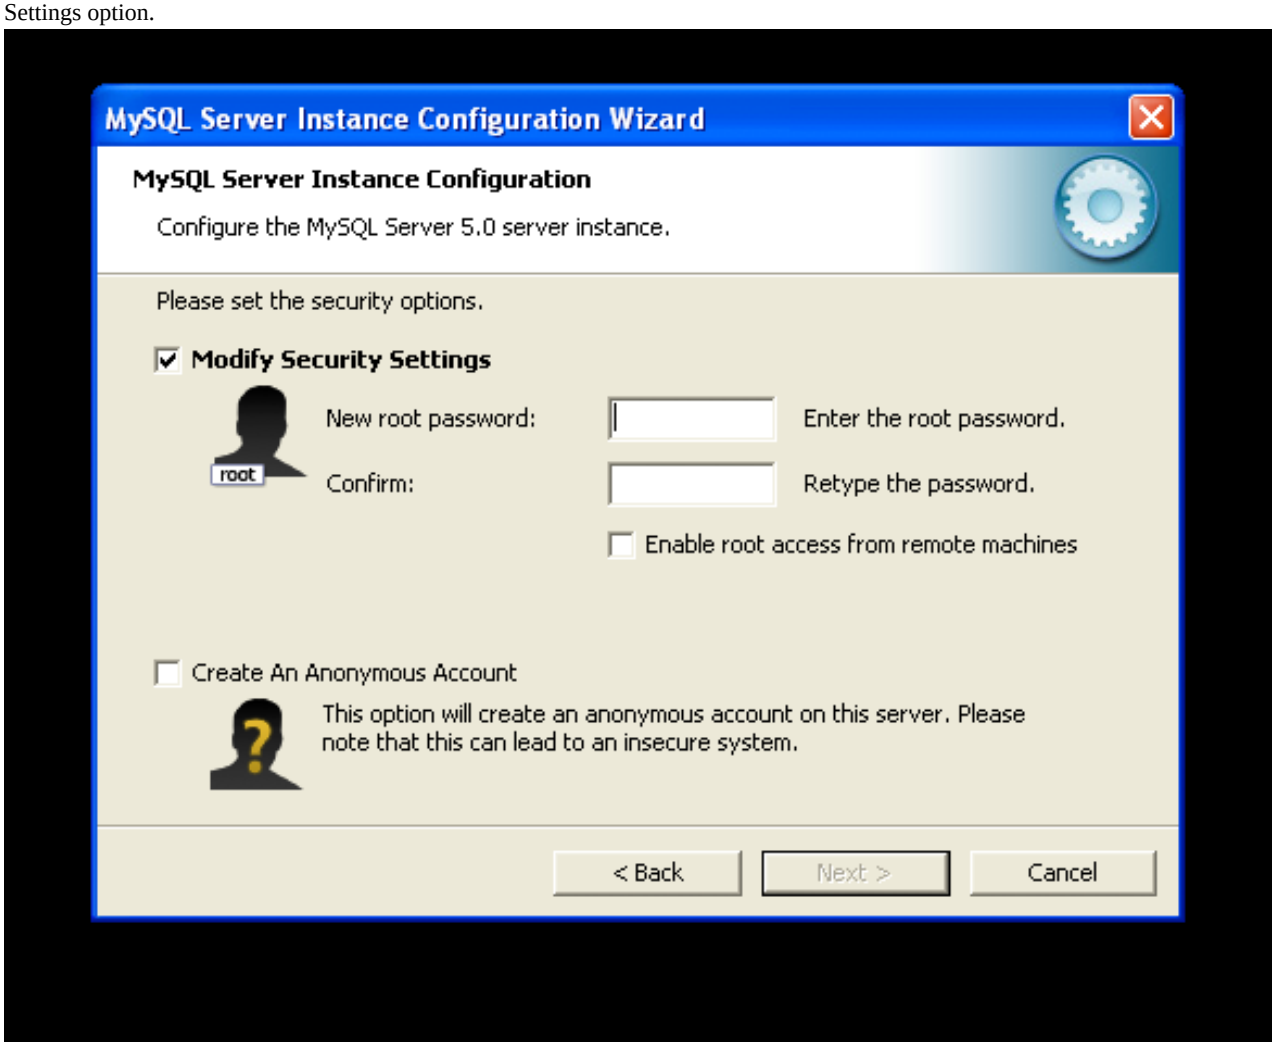
> **Warning**
>
> If you are installing multiple versions of MySQL onto the same machine, you *must* choose a different service name for each version that you install. If you do not choose a different service for each installed version then the service manager information will be inconsistent and this will cause problems when you try to uninstall a previous version.

> If you have already installed multiple versions using the same service name, you must manually edit the contents of the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services` parameters within the Windows registry to update the association of the service name with the correct server version.
>
> Typically, when installing multiple versions you create a service name based on the version information. For example, you might install MySQL 6.x as `mysql6`, or specific versions such as MySQL 6.0.8 as `mysql60008`.

To install the MySQL server as a service but not have it started automatically at startup, uncheck the box next to the Launch the MySQL Server Automatically option.

2.3.4.11. The Security Options Dialog

It is strongly recommended that you set a `root` password for your MySQL server, and the MySQL Server Instance Configuration Wizard requires by default that you do so. If you do not wish to set a `root` password, uncheck the box next to the Modify Security Settings option.



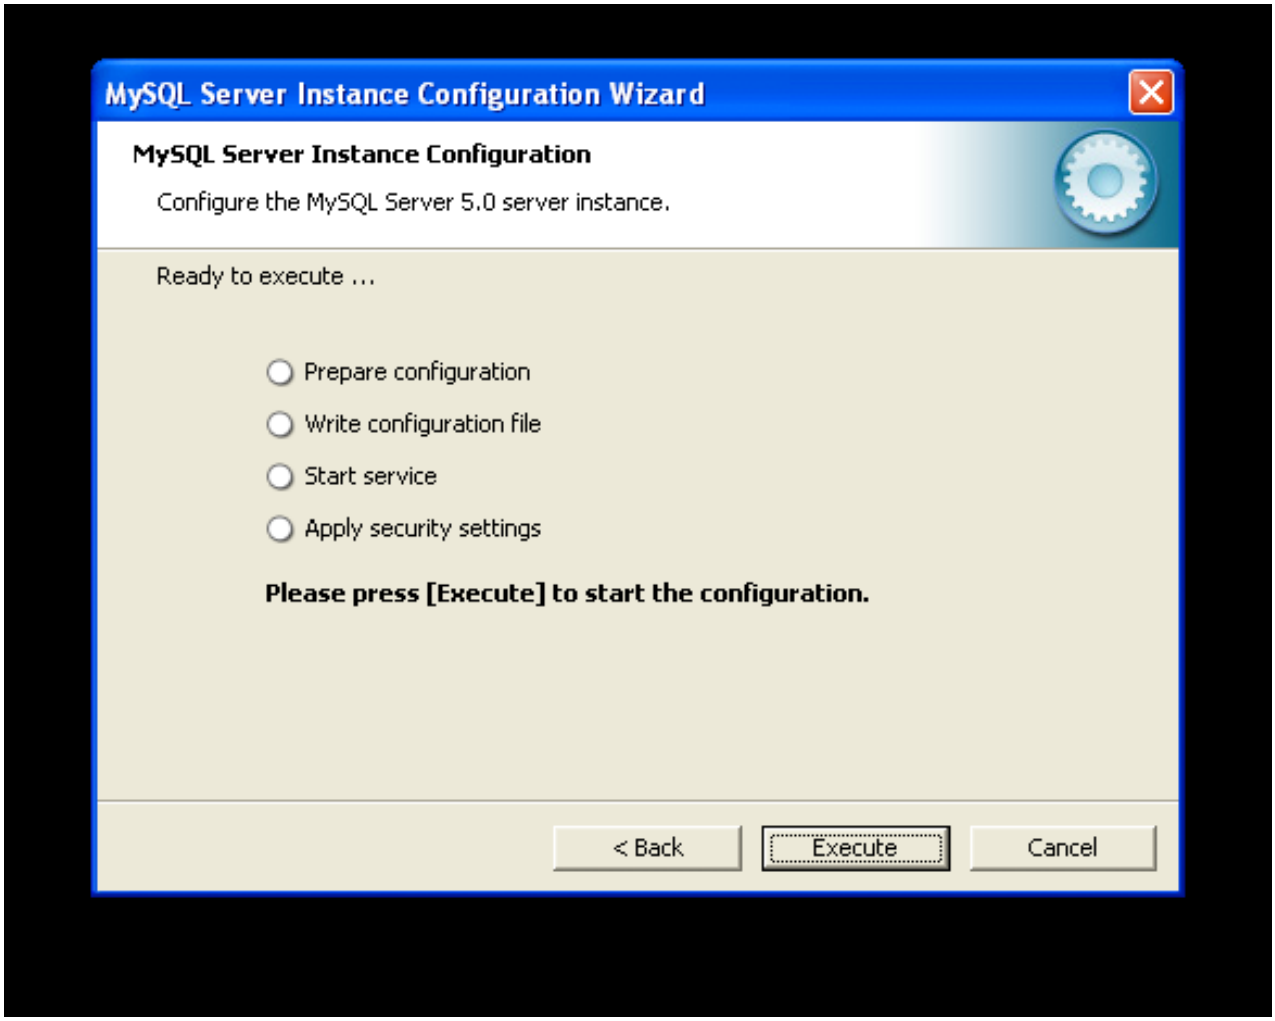
To set the `root` password, enter the desired password into both the New root password and Confirm boxes. If you are reconfiguring an existing server, you need to enter the existing `root` password into the Current root password box.

To prevent `root` logins from across the network, check the box next to the Root may only connect from localhost option. This increases the security of your `root` account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties. For this reason, it is not recommended.

2.3.4.12. The Confirmation Dialog

The final dialog in the MySQL Server Instance Configuration Wizard is the CONFIRMATION DIALOG. To start the configuration process, click the EXECUTE button. To return to a previous dialog, click the BACK button. To exit the MySQL Server Instance Configuration Wizard without configuring the server, click the CANCEL button.



After you click the EXECUTE button, the MySQL Server Instance Configuration Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Server Instance Configuration Wizard first determines configuration file options based on your choices using a template prepared by MySQL developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to the corresponding configuration file.

If you chose to create a service for the MySQL server, the MySQL Server Instance Configuration Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Server Instance Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Configuration Wizard connects to the server, sets your new `root` password, and applies any other security settings you may have selected.

After the MySQL Server Instance Configuration Wizard has completed its tasks, it displays a summary. Click the FINISH button to exit the MySQL Server Configuration Wizard.

2.3.5. Installing MySQL from a Noinstall Zip Archive

Users who are installing from the Noinstall package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type

4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

2.3.6. Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.3.14, “Upgrading MySQL on Windows”, before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.7, “Creating an Option File”.
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.7. Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 6.0` and `C:\Program Files\MySQL\MySQL Server 6.0\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for options in two files: the `my.ini` file in the Windows directory, and the `C:\my.cnf` file. The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

You can also make use of the example option files included with your MySQL distribution; see Section 4.2.3.2.2, “Preconfigured Option Files”.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

> **MySQL Enterprise**
> For expert advice on the start-up options appropriate to your circumstances, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

In MySQL 5.1.23 and earlier, the MySQL installer places the data directory directly under the directory where you install MySQL. On MySQL 5.1.24 and later, the data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\Program Files\MySQL\MySQL Server 6.0\data`) to `E:\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.8. Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 6.0.

Binary	Description
`mysqld`	Optimized binary with named-pipe support
`mysqld-debug`	Like `mysqld`, but compiled with full debugging and automatic memory allocation checking

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 6.0 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows support named pipes as indicated in the following list. However, the default is to use TCP/IP regardless of platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Named pipes are enabled only if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used.

2.3.9. Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of `C:\Program Files\MySQL\MySQL Server 6.0`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see Section 2.3.8, “Selecting a MySQL Server Type”.

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '6.0.12'  socket: ''  port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 6.0\data` by default). The error log is the file with the `.err` extension.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

2.3.10. Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqladmin" -u root shutdown
```

> **Note**
>
> If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the `C:\Program Files\MySQL\MySQL Server 6.0\data` directory. It is the file with a suffix of `.err`. You can also try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See MySQL Internals: Porting.

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

2.3.11. Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, whereby MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista, and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqladmin"
          -u root shutdown
```

> **Note**
>
> If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click on the My Computer icon, and select Properties.
- Next select the Advanced tab from the SYSTEM PROPERTIES menu that appears, and click the ENVIRONMENT VARIABLES button.
- Under **SYSTEM VARIABLES**, select Path, and then click the EDIT button. The EDIT SYSTEM VARIABLE dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **VARIABLE VALUE**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 6.0\bin`), Note that there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

  You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

> **Warning**
>
> You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used in MySQL 6.0 when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=`*`file_name`* to specify the name of an option file from which the server should read options when it starts.

  The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.
- You can also specify a `--local-service` option following the service name. This causes the server to run using the `Loc-`

alService Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options only from the `[mysqld]` group of the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld"
          --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

You can also specify options as Start parameters in the Windows `Services` utility before you start the MySQL service.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 6.0\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld" --install-manual
```

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.10, “Starting MySQL from the Windows Command Line”.

Please see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”, if you encounter difficulties during installation.

2.3.12. Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqlshow"
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP numbers in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then you must use the appropriate `-u` and `-p` options with the commands shown above in order to connect with the MySQL Server. See Section 4.2.2, "Connecting to the MySQL Server".

For more information about `mysqlshow`, see Section 4.5.6, "`mysqlshow` — Display Database, Table, and Column Information".

2.3.13. Troubleshooting a MySQL Installation Under Windows

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 6.0\data`. See Section 5.2.2, "The Error Log".

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.11, "Starting MySQL as a Windows Service".

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

  These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 6.0` and `C:\Program Files\MySQL\MySQL Server 6.0\data`, respectively).

  This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

  If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 6.0`, you need to ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
C:\> echo %WINDIR%
```

  An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

  Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, you must double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 6.0
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.7, “Creating an Option File”.

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard, you may see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This allows the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command-line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp and use the `delsrv mysql` syntax.

2.3.14. Upgrading MySQL on Windows

This section lists some of the steps you should take when upgrading MySQL on Windows.

1. Review Section 2.11.1, “Upgrading MySQL”, for additional information on upgrading MySQL that is not specific to Windows.
2. You should always back up your current MySQL installation before performing an upgrade. See Section 6.1, “Database Backups”.
3. Download the latest Windows distribution of MySQL from http://dev.mysql.com/downloads/.
4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use the following command to stop it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 6.0\bin\mysqladmin" -u root shutdown
```

> **Note**
>
> If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

5. When upgrading to MySQL 6.0 from a version previous to 4.1.5, or when upgrading from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must manually remove the previous installation and MySQL service (if the server is installed as a service).

   To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

   If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

6. If you are using the MySQL Installation Wizard, start the wizard as described in Section 2.3.3, “Using the MySQL Installation Wizard”.
7. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installa-

tion (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.

8. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See Section 2.3.11, “Starting MySQL as a Windows Service”.)

9. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.

10. If you encounter errors, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

2.3.15. MySQL on Windows Compared to MySQL on Unix

MySQL for Windows has proven itself to be very stable. The Windows version of MySQL has the same features as the corresponding Unix version, with the following exceptions:

- **Limited number of ports**

  Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Note that ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

  For more information about this problem, see http://support.microsoft.com/default.aspx?scid=kb;en-us;196271.

- **Concurrent reads**

  Before MySQL 6.0.8, the I/O subsystem depends on the `pread()` and `pwrite()` system calls to be able to mix `INSERT` and `SELECT`. The server uses mutexes to emulate `pread()` and `pwrite()`. The implementation limits the number of open files that MySQL can use to 2,048, which means that you cannot run as many concurrent threads on Windows as on Unix.

  As of MySQL 6.0.8, native Windows file I/O calls are used, so that concurrent reads are more efficiently implemented. Also, the limit of 2,048 open files is removed. The default is 16,384, but this can be increased by using the `--open-files-limit` option.

- **Blocking read**

  MySQL uses a blocking read for each connection. That has the following implications if named-pipe connections are enabled:

  - A connection is not disconnected automatically after eight hours, as happens with the Unix version of MySQL.
  - If a connection hangs, it is not possible to break it without killing MySQL.
  - `mysqladmin kill` does not work on a sleeping connection.
  - `mysqladmin shutdown` cannot abort as long as there are sleeping connections.

  We plan to fix this problem in the future.

- **`ALTER TABLE`**

  While you are executing an `ALTER TABLE` statement, the table is locked from being used by other threads. This has to do with the fact that on Windows, you can't delete a file that is in use by another thread. In the future, we may find some way to work around this problem.

- **`DROP TABLE`**

  `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` handler does the table mapping hidden from the upper layer of MySQL. Because Windows does not allow dropping files that are open, you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- **`DATA DIRECTORY` and `INDEX DIRECTORY`**

  The `DATA DIRECTORY` and `INDEX DIRECTORY` options for `CREATE TABLE` are ignored on Windows, because Windows doesn't support symbolic links. These options also are ignored on systems that have a non-functional `realpath()` call.

- **`DROP DATABASE`**

You cannot drop a database that is in use by some thread.

- **Case-insensitive names**

  File names are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 8.2.2, “Identifier Case Sensitivity”.

- **Directory and file names**

  On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name will not work in the Western locale (code page 1252):

  ```
  datadir="C:/维基百科关于中文维基百科"
  ```

  The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA INFILE`.

- **The “`\`” path name separator character**

  Path name components in Windows are separated by the “`\`” character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, use Unix-style file names with “`/`” characters:

  ```
  mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
  ```

  Alternatively, you must double the “`\`” character:

  ```
  mysql> LOAD DATA INFILE 'C:\\tmp\\skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:\\tmp\\skr.txt' FROM skr;
  ```

- **Problems with pipes**

  Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z` / `CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

  This is mainly a problem when you try to apply a binary log as follows:

  ```
  C:\> mysqlbinlog binary_log_file | mysql --user=root
  ```

  If you have a problem applying the log and suspect that it is because of a `^Z` / `CHAR(24)` character, you can use the following workaround:

  ```
  C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
  C:\> mysql --user=root --execute "source /tmp/bin.sql"
  ```

  The latter command also can be used to reliably read in any SQL file that may contain binary data.

- **`Access denied for user` error**

  If MySQL cannot resolve your host name properly, you may get the following error when you attempt to run a MySQL client program to connect to a server running on the same machine:

  ```
  Access denied for user 'some_user'@'unknown'
  to database 'mysql'
  ```

  To fix this problem, you should create a file named `\windows\hosts` containing the following information:

  ```
  127.0.0.1       localhost
  ```

Here are some open issues for anyone who might want to help us improve MySQL on Windows:

- Add macros to use the faster thread-safe increment/decrement methods provided by Windows.

2.4. Installing MySQL from RPM Packages on Linux

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use `glibc` 2.3. To obtain RPM packages, see Section 2.1.3, "How to Get MySQL".

For non-RPM Linux distributions, you can install MySQL using a `.tar.gz` package. See Section 2.8, "Installing MySQL from `tar.gz` Packages on Other Unix-Like Systems".

We do provide some platform-specific RPMs; the difference between a platform-specific RPM and a generic RPM is that a platform-specific RPM is built on the targeted platform and is linked dynamically whereas a generic RPM is linked statically with LinuxThreads.

> **Note**
>
> RPM distributions of MySQL often are provided by other vendors. Be aware that they may differ in features and capabilities from those built by us, and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

If you have problems with an RPM file (for example, if you receive the error `Sorry, the host 'xxxx' could not be looked up`), see Section 2.12.1.2, "Linux Binary Distribution Notes".

In most cases, you need to install only the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation.

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If you get a dependency failure when trying to install MySQL packages (for example, `error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`), you should also install the `MySQL-shared-compat` package, which includes both the shared libraries for backward compatibility (`libmysqlclient.so.12` for MySQL 4.0 and `libmysqlclient.so.10` for MySQL 3.23).

Some Linux distributions still ship with MySQL 3.23 and they usually link applications dynamically to save disk space. If these shared libraries are in a separate package (for example, `MySQL-shared`), it is sufficient to simply leave this package installed and just upgrade the MySQL server and client packages (which are statically linked and do not depend on the shared libraries). For distributions that include the shared libraries in the same package as the MySQL server (for example, Red Hat Linux), you could either install our 3.23 `MySQL-shared` RPM, or use the `MySQL-shared-compat` package instead. (Do not install both.)

The RPM packages shown in the following list are available. The names shown here use a suffix of `.glibc23.i386.rpm`, but particular packages can have different suffixes, as described later.

- `MySQL-server-`*`VERSION`*`.glibc23.i386.rpm`

  The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- `MySQL-client-`*`VERSION`*`.glibc23.i386.rpm`

  The standard MySQL client programs. You probably always want to install this package.

- `MySQL-devel-`*`VERSION`*`.glibc23.i386.rpm`

  The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- `MySQL-debuginfo-`*`VERSION`*`.glibc23.i386.rpm`

  This package contains debugging information. `debuginfo` RPMs are never needed to use MySQL software; this is true both for the server and for client programs. However, they contain additional information that might be needed by a debugger to analyze a crash.

- `MySQL-shared-`*`VERSION`*`.glibc23.i386.rpm`

  This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. If you install this package, do not install the `MySQL-shared-compat` package.

- `MySQL-shared-compat-`*`VERSION`*`.glibc23.i386.rpm`

  This package includes the shared libraries for MySQL 3.23, 4.0, and so on, up to the current release. It contains single-threaded and thread-safe libraries. Install this package instead of `MySQL-shared` if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies.

- `MySQL-embedded-VERSION.glibc23.i386.rpm`

  The embedded MySQL server library.

- `MySQL-test-VERSION.glibc23.i386.rpm`

  This package includes the MySQL test suite.

- `MySQL-VERSION.src.rpm`

  This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the *`VERSION`* value) has the following syntax:

```
.PLATFORM.CPU.rpm
```

The *`PLATFORM`* and *`CPU`* values indicate the type of system for which the package is built. *`PLATFORM`* indicates the platform and *`CPU`* indicates the processor type or family.

All packages are dynamically linked against `glibc` 2.3. The *`PLATFORM`* value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

`glibc23`	Platform independent, should run on any Linux distribution that supports `glibc` 2.3
`rhel3`, `rhel4`	Red Hat Enterprise Linux 3 or 4
`sles9`, `sles10`	SuSE Linux Enterprise Server 9 or 10

In MySQL 6.0, only `glibc23` packages are available currently.

The *`CPU`* value indicates the processor type or family for which the package is built.

`i386`	x86 processor, 386 and up
`i586`	x86 processor, Pentium and up
`x86_64`	64-bit x86 processor
`ia64`	Itanium (IA-64) processor

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.glibc23.i386.rpm
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you don't lose it when you install a newer RPM.) See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”, for more information on how MySQL can be started automatically on system startup.

If you want to install the MySQL RPM on older Linux distributions that do not support initialization scripts in `/etc/init.d` (directly or via a symlink), you should create a symbolic link that points to the location where your initialization scripts actually are installed. For example, if that location is `/etc/rc.d/init.d`, use these commands before installing the RPM to create `/etc/init.d` as a symbolic link that points there:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

However, all current major Linux distributions should support the new directory layout that uses `/etc/init.d`, because it is required for LSB (Linux Standard Base) compliance.

If the RPM files that you install include `MySQL-server`, the `mysqld` server should be up and running after installation. You should be able to start using MySQL.

If something goes wrong, you can find more information in the binary installation section. See Section 2.8, "Installing MySQL from `tar.gz` Packages on Other Unix-Like Systems".

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, "Post-Installation Setup and Testing".

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is ensured for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

For non-local user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user andgroup exists and manually transfers ownership following the actions in the RPM spec file.

2.5. Installing MySQL on Mac OS X

You can install MySQL on Mac OS X 10.3.x ("Panther") or newer using a Mac OS X binary package in PKG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x or 10.2.x) are **not** supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

To obtain MySQL, see Section 2.1.3, "How to Get MySQL".

> **Note**
>
> Before proceeding with the installation, be sure to shut down all running MySQL server instances by either using the MySQL Manager Application (on Mac OS X Server) or via `mysqladmin shutdown` on the command line.

To actually install the MySQL PKG file, double-click on the package icon. This launches the Mac OS X Package Installer, which guides you through the installation of MySQL.

Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, simply click the `Go Back` button once to return to the previous screen. Then click `Continue` to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

The Mac OS X PKG of MySQL installs itself into `/usr/local/mysql-`*`VERSION`* and also installs a symbolic link, `/usr/local/mysql`, that points to the new location. If a directory named `/usr/local/mysql` exists, it is renamed to `/usr/local/mysql.bak` first. Additionally, the installer creates the grant tables in the `mysql` database by executing `mysql_install_db`.

The installation layout is similar to that of a `tar` file binary distribution; all MySQL binaries are located in the directory `/usr/local/mysql/bin`. The MySQL socket file is created as `/tmp/mysql.sock` by default. See Section 2.1.5, "Installation Layouts".

MySQL installation requires a Mac OS X user account named `mysql`. A user account with this name should exist by default on Mac OS X 10.2 and up.

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

Mac OS X Server Version	MySQL Version
10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53
10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a

This manual section covers the installation of the official MySQL Mac OS X PKG only. Make sure to read Apple's help information about installing MySQL: Run the “Help View” application, select “Mac OS X Server” help, do a search for “MySQL,” and read the item entitled “Installing MySQL.”

If you previously used Marc Liyanage's MySQL packages for Mac OS X from http://www.entropy.ch, you can simply follow the update instructions for packages using the binary installation layout as given on his pages.

If you are upgrading from Marc's 3.23.x versions or from the Mac OS X Server version of MySQL to the official MySQL PKG, you also need to convert the existing MySQL privilege tables to the current format, because some new security privileges have been added. See Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

If you want MySQL to start automatically during system startup, you also need to install the MySQL Startup Item. It is part of the Mac OS X installation disk images as a separate installation package. Simply double-click the MySQLStartupItem.pkg icon and follow the instructions to install it. The Startup Item need be installed only once. There is no need to install it each time you upgrade the MySQL package later.

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. (Before MySQL 4.1.2, the location was `/Library/StartupItems/MySQL`, but that collided with the MySQL Startup Item installed by Mac OS X Server.) Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, simply change this variable to `MYSQLCOM=-NO-`.

On Mac OS X Server, the default MySQL installation uses the variable `MYSQL` in the `/etc/hostconfig` file. The MySQL Startup Item installer disables this variable by setting it to `MYSQL=-NO-`. This avoids boot time conflicts with the `MYSQLCOM` variable used by the MySQL Startup Item. However, it does not shut down a running MySQL server. You should do that yourself.

After the installation, you can start up MySQL by running the following commands in a terminal window. You must have administrator privileges to perform this task.

If you have installed the Startup Item, use this command:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
(Enter your password, if necessary)
(Press Control-D or enter "exit" to exit the shell)
```

If you don't use the Startup Item, enter the following command sequence:

```
shell> cd /usr/local/mysql
shell> sudo ./bin/mysqld_safe
(Enter your password, if necessary)
(Press Control-Z)
shell> bg
(Press Control-D or enter "exit" to exit the shell)
```

You should be able to connect to the MySQL server, for example, by running `/usr/local/mysql/bin/mysql`.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, “Invoking MySQL Programs”.

If you are upgrading an existing installation, note that installing a new MySQL PKG does not remove the directory of an older installation. Unfortunately, the Mac OS X Installer does not yet offer the functionality required to properly upgrade previously installed packages.

To use your existing databases with the new installation, you'll need to copy the contents of the old data directory to the new data directory. Make sure that neither the old server nor the new one is running when you do this. After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

2.6. Installing MySQL on Solaris

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, http://dev.mysql.com/downloads/mysql/6.0.html.

If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

You can install MySQL on Solaris using a binary package in PKG format instead of the binary tarball distribution. Before installing using the binary PKG format, you should create the `mysql` user and group, for example:

```
groupadd mysql
useradd -g mysql mysql
```

Some basic PKG-handling commands follow:

- To add a package:

  ```
  pkgadd -d package_name.pkg
  ```

- To remove a package:

  ```
  pkgrm package_name
  ```

- To get a full list of installed packages:

  ```
  pkginfo
  ```

- To get detailed information for a package:

  ```
  pkginfo -l package_name
  ```

- To list the files belonging to a package:

  ```
  pkgchk -v package_name
  ```

- To get packaging information for an arbitrary file:

  ```
  pkgchk -l -p file_name
  ```

For additional information about installing MySQL on Solaris, see Section 2.12.3, “Solaris Notes”.

2.7. Installing MySQL on NetWare

Porting MySQL to NetWare was an effort spearheaded by Novell. Novell customers should be pleased to note that NetWare 6.5 ships with bundled MySQL binaries, complete with an automatic commercial use license for all servers running that version of NetWare.

MySQL for NetWare is compiled using a combination of Metrowerks CodeWarrior for NetWare and special cross-compilation versions of the GNU autotools.

The latest binary packages for NetWare can be obtained at http://dev.mysql.com/downloads/. See Section 2.1.3, “How to Get MySQL”.

To host MySQL, the NetWare server must meet these requirements:

- The latest Support Pack of NetWare 6.5 must be installed.
- The system must meet Novell's minimum requirements to run the respective version of NetWare.
- MySQL data and the program binaries must be installed on an NSS volume; traditional volumes are not supported.

To install MySQL for NetWare, use the following procedure:

1. If you are upgrading from a prior installation, stop the MySQL server. This is done from the server console, using the following command:

   ```
   SERVER:  mysqladmin -u root shutdown
   ```

   > **Note**
   >
   > If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

2. Log on to the target server from a client machine with access to the location where you are installing MySQL.
3. Extract the binary package Zip file onto the server. Be sure to allow the paths in the Zip file to be used. It is safe to simply extract the file to `SYS:\`.

   If you are upgrading from a prior installation, you may need to copy the data directory (for example, `SYS:MYSQL\DATA`), as well as `my.cnf`, if you have customized it. You can then delete the old copy of MySQL.
4. You might want to rename the directory to something more consistent and easy to use. The examples in this manual use `SYS:MYSQL` to refer to the installation directory.

   Note that MySQL installation on NetWare does not detect if a version of MySQL is already installed outside the NetWare release. Therefore, if you have installed the latest MySQL version from the Web (for example, MySQL 4.1 or later) in `SYS:\MYSQL`, you must rename the folder before upgrading the NetWare server; otherwise, files in `SYS:\MySQL` are overwritten by the MySQL version present in NetWare Support Pack.
5. At the server console, add a search path for the directory containing the MySQL NLMs. For example:

   ```
   SERVER:  SEARCH ADD SYS:MYSQL\BIN
   ```

6. Initialize the data directory and the grant tables, if necessary, by executing `mysql_install_db` at the server console.
7. Start the MySQL server using `mysqld_safe` at the server console.
8. To finish the installation, you should also add the following commands to `autoexec.ncf`. For example, if your MySQL installation is in `SYS:MYSQL` and you want MySQL to start automatically, you could add these lines:

   ```
   #Starts the MySQL 6.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE
   ```

   If you are running MySQL on NetWare 6.0, we strongly suggest that you use the `--skip-external-locking` option on the command line:

   ```
   #Starts the MySQL 6.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE --skip-external-locking
   ```

   It is also necessary to use `CHECK TABLE` and `REPAIR TABLE` instead of `myisamchk`, because `myisamchk` makes use of external locking. External locking is known to have problems on NetWare 6.0; the problem has been eliminated in NetWare 6.5. Note that the use of MySQL on Netware 6.0 is not officially supported.

   `mysqld_safe` on NetWare provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not go away by default. Instead, it prompts for user input:

```
*<NLM has terminated; Press any key to close the screen>*
```

If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`. For example:

```
#Starts the MySQL 6.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE --autoclose
```

The behavior of `mysqld_safe` on NetWare is described further in Section 4.3.2, "`mysqld_safe` — MySQL Server Startup Script".

9. When installing MySQL, either for the first time or upgrading from a previous version, download and install the latest and appropriate Perl module and PHP extensions for NetWare:

   - Perl: http://forge.novell.com/modules/xfcontent/downloads.php/perl/Modules/
   - PHP: http://forge.novell.com/modules/xfcontent/downloads.php/php/Modules/

If there was an existing installation of MySQL on the NetWare server, be sure to check for existing MySQL startup commands in `autoexec.ncf`, and edit or delete them as necessary.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, "Post-Installation Setup and Testing".

2.8. Installing MySQL from `tar.gz` Packages on Other Unix-Like Systems

This section covers the installation of MySQL binary distributions that are provided for various platforms in the form of compressed `tar` files (files with a `.tar.gz` extension). See Section 2.1.2.4, "MySQL Binaries Compiled by Sun Microsystems, Inc.", for a detailed list.

To obtain MySQL, see Section 2.1.3, "How to Get MySQL".

MySQL `tar` file binary distributions have names of the form `mysql-`*`VERSION-OS`*`.tar.gz`, where *`VERSION`* is a number (for example, `6.0.12`), and *`OS`* indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686`).

In addition to these generic packages, we also offer binaries in platform-specific package formats for selected platforms. See Section 2.2, "Standard MySQL Installation Using a Binary Distribution", for more information on how to install these.

You need the following tools to install a MySQL `tar` file binary distribution:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a preinstalled version of `tar` that is known to have problems. For example, the `tar` provided with early versions of Mac OS X, SunOS 4.x and Solaris 8 and earlier are known to have problems with long file names. On Mac OS X, you can use the preinstalled `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.

If you run into problems and need to file a bug report, please use the instructions in Section 1.6, "How to Report Bugs or Problems".

The basic commands that you must execute to install and use a MySQL binary distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
shell> cd /usr/local
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> bin/mysqld_safe --user=mysql &
```

> **Note**
>
> This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, "Post-Installation Setup and Testing".

A more detailed version of the preceding description for installing a binary distribution follows:

1. Add a login user and group for `mysqld` to run as:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql mysql
   ```

   These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

   You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Pick the directory under which you want to unpack the distribution and change location into it. In the following example, we unpack the distribution under `/usr/local`. (The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.)

   ```
   shell> cd /usr/local
   ```

3. Obtain a distribution file using the instructions in Section 2.1.3, "How to Get MySQL". For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

4. Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory:

   ```
   shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
   shell> ln -s full-path-to-mysql-VERSION-OS mysql
   ```

   The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This lets you refer more easily to the installation directory as `/usr/local/mysql`.

   With GNU `tar`, no separate invocation of `gunzip` is necessary. You can replace the first line with the following alternative command to uncompress and extract the distribution:

   ```
   shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
   ```

5. Change location into the installation directory:

   ```
   shell> cd mysql
   ```

   You will find several files and subdirectories in the `mysql` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

   - The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See Section 2.13, "Environment Variables".
   - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.

6. Ensure that the distribution contents are accessible to `mysql`. If you unpacked the distribution as `mysql`, no further action is required. If you unpacked the distribution as `root`, its contents will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory:

   ```
   shell> chown -R mysql .
   shell> chgrp -R mysql .
   ```

   The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

7. If you have not installed MySQL before, you must create the MySQL data directory and initialize the grant tables:

   ```
   shell> scripts/mysql_install_db --user=mysql
   ```

If you run the command as `root`, include the `--user` option as shown. If you run the command while logged in as that user, you can omit the `--user` option.

The command should create the data directory and its contents with `mysql` as the owner.

After creating or updating the grant tables, you need to restart the server manually.

8. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql data
```

9. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself and in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

10. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See Section 4.6.14, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”. For Perl module installation instructions, see Section 2.14, “Perl Installation Notes”.

11. If you would like to use `mysqlaccess` and have the MySQL distribution in some non-standard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

After everything has been unpacked and installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> bin/mysqld_safe --user=mysql &
```

If you run the command as `root`, you must use the `--user` option as shown. The value of the option is the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as `mysql`, you can omit the `--user` option.

If the command fails immediately and prints `mysqld ended`, you can find some information in the *`host_name`*`.err` file in the data directory.

More information about `mysqld_safe` is given in Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

2.9. MySQL Installation Using a Source Distribution

Before you proceed with an installation from source, first check whether our binary is available for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options.

To obtain a source distribution for MySQL, Section 2.1.3, “How to Get MySQL”. If you want to build MySQL from source on Windows, see Section 2.9.6, “Installing MySQL from Source on Windows”.

MySQL source distributions are provided as compressed `tar` archives and have names of the form `mysql-`*`VERSION`*`.tar.gz`, where *`VERSION`* is a number like `6.0.12`.

You need the following tools to build and install MySQL from source:

- GNU `gunzip` to uncompress the distribution.
- A reasonable `tar` to unpack the distribution. GNU `tar` is known to work. Some operating systems come with a preinstalled version of `tar` that is known to have problems. For example, the `tar` provided with early versions of Mac OS X, SunOS 4.x

and Solaris 8 and earlier are known to have problems with long file names. On Mac OS X, you can use the preinstalled `gnutar` program. On other systems with a deficient `tar`, you should install GNU `tar` first.

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, SGI C++, and SunPro C++ are some of the compilers that are known to work. `libg++` is not needed when using `gcc`. `gcc` 2.7.x has a bug that makes it impossible to compile some perfectly legal C++ files, such as `sql/sql_base.cc`. If you have only `gcc` 2.7.x, you must upgrade your `gcc` to be able to compile MySQL. `gcc` 2.8.1 is also known to have problems on some platforms, so it should be avoided if a new compiler exists for the platform. `gcc` 2.95.2 or later is recommended.

- A good `make` program. GNU `make` is always recommended and is sometimes required. (BSD `make` fails, and vendor-provided `make` implementations may fail as well.) If you have problems, we recommend GNU `make` 3.75 or newer.

- `libtool` 1.5.24 or later is also recommended.

  This is particularly true when building 64-bit binaries on Solaris for x86_64 processors (see Bug#31268). In addition, to guarantee that the binaries are 64-bit, you should do the following:

  - Provide `--build=x86_64-pc-solaris2.10` as a `configure` argument.
  - Provide `-m64` as part of CFLAGS, CXXFLAGS and LDFLAGS
  - Run `configure` and `make` as shown here:

    ```
    % LIBRARY_PATH=/usr/local/lib/amd64 ./configure .....
    % LIBRARY_PATH=/usr/local/lib/amd64 gmake
    ```

If you are using a version of `gcc` recent enough to understand the `-fno-exceptions` option, it is *very important* that you use this option. Otherwise, you may compile a binary that crashes randomly. We also recommend that you use `-felide-constructors` and `-fno-rtti` along with `-fno-exceptions`. When in doubt, do the following:

```
CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors \
       -fno-exceptions -fno-rtti" ./configure \
       --prefix=/usr/local/mysql --enable-assembler \
       --with-mysqld-ldflags=-all-static
```

On most systems, this gives you a fast and stable binary.

If you run into problems and need to file a bug report, please use the instructions in Section 1.6, “How to Report Bugs or Problems”.

2.9.1. Source Installation Overview

The basic commands that you must execute to install a MySQL source distribution are:

```
shell> groupadd mysql
shell> useradd -g mysql mysql
shell> gunzip < mysql-VERSION.tar.gz | tar -xvf -
shell> cd mysql-VERSION
shell> ./configure --prefix=/usr/local/mysql
shell> make
shell> make install
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> bin/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql var
shell> bin/mysqld_safe --user=mysql &
```

If you start from a source RPM, do the following:

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

This makes a binary RPM that you can install. For older versions of RPM, you may have to replace the command `rpmbuild` with `rpm` instead.

> **Note**
>
> This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Post-Installation Setup and Testing”, for post-installation setup and testing.

A more detailed version of the preceding description for installing MySQL from a source distribution follows:

1. Add a login user and group for `mysqld` to run as:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql mysql
   ```

   These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

   You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Perform the following steps as the `mysql` user, except as noted.

3. Pick the directory under which you want to unpack the distribution and change location into it.

4. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.

5. Unpack the distribution into the current directory:

   ```
   shell> gunzip < /path/to/mysql-VERSION.tar.gz | tar xvf -
   ```

   This command creates a directory named `mysql-VERSION`.

   With GNU `tar`, no separate invocation of `gunzip` is necessary. You can use the following alternative command to uncompress and extract the distribution:

   ```
   shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
   ```

6. Change location into the top-level directory of the unpacked distribution:

   ```
   shell> cd mysql-VERSION
   ```

   Note that currently you must configure and build MySQL from this top-level directory. You cannot build it in a different directory.

7. Configure the release and compile everything:

   ```
   shell> ./configure --prefix=/usr/local/mysql
   shell> make
   ```

   When you run `configure`, you might want to specify other options. Run `./configure --help` for a list of options. Section 2.9.2, “Typical `configure` Options”, discusses some of the more useful options.

   If `configure` fails and you are going to send mail to a MySQL mailing list to ask for assistance, please include any lines from `config.log` that you think can help solve the problem. Also include the last couple of lines of output from `configure`. To file a bug report, please use the instructions in Section 1.6, “How to Report Bugs or Problems”.

   If the compile fails, see Section 2.9.4, “Dealing with Problems Compiling MySQL”, for help.

8. Install the distribution:

   ```
   shell> make install
   ```

   You might need to run this command as `root`.

   If you want to set up an option file, use one of those present in the `support-files` directory as a template. For example:

   ```
   shell> cp support-files/my-medium.cnf /etc/my.cnf
   ```

   You might need to run this command as `root`.

   If you want to configure support for `InnoDB` tables, you should edit the `/etc/my.cnf` file, remove the # character before the option lines that start with `innodb_...`, and modify the option values to be what you want. See Section 4.2.3.2, “Using Option Files”, and Section 13.7.2, “`InnoDB` Configuration”.

9. Change location into the installation directory:

   ```
   shell> cd /usr/local/mysql
   ```

10. If you ran the `make install` command as `root`, the installed files will be owned by `root`. Ensure that the installation is accessible to `mysql` by executing the following commands as `root` in the installation directory:

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

    The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

11. If you have not installed MySQL before, you must create the MySQL data directory and initialize the grant tables:

```
shell> bin/mysql_install_db --user=mysql
```

    If you run the command as `root`, include the `--user` option as shown. If you run the command while logged in as `mysql`, you can omit the `--user` option.

    The command should create the data directory and its contents with `mysql` as the owner.

    After using `mysql_install_db` to create the grant tables for MySQL, you must restart the server manually. The `mysqld_safe` command to do this is shown in a later step.

12. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql var
```

13. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `support-files/mysql.server` script itself; see also Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

14. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See Section 4.6.14, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”. For Perl module installation instructions, see Section 2.14, “Perl Installation Notes”.

After everything has been installed, you should test your distribution. To start the MySQL server, use the following command:

```
shell> /usr/local/mysql/bin/mysqld_safe --user=mysql &
```

If you run the command as `root`, you should use the `--user` option as shown. The value of the option is the name of the login account that you created in the first step to use for running the server. If you run the command while logged in as that user, you can omit the `--user` option.

If the command fails immediately and prints `mysqld ended`, you can find some information in the *`host_name`*`.err` file in the data directory.

More information about `mysqld_safe` is given in Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

> **Note**
>
> The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Post-Installation Setup and Testing”.

2.9.2. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure a MySQL source distribution. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. See Section 2.13, “Environment Variables”. For a full list of options supported by `configure`, run this command:

```
shell> ./configure --help
```

A list of the available `configure` options is provided in the table below.

Table 2.1. Build (`configure`) Reference

Formats	Description	Default	Introduced	Removed
--bindir=DIR	User executables	EPREFIX/bin		

Formats	Description	Default	Introduced	Removed
--build=BUILD	Configure for building on BUILD	guessed		
--cache-file=FILE	Cache test results in FILE	disabled		
-C	Alias for `--cache-file=config.cache'			
--config-cache				
--datadir=DIR	Read-only architecture-independent data	PREFIX/share		
--disable-FEATURE	Do not include FEATURE			
--disable-dependency-tracking	Disable dependency tracking			
--disable-grant-options	Disable GRANT options			
--disable-largefile	Omit support for large files			
--disable-libtool-lock	Disable libtool lock			
--disable-thread-safe-client	Compile the client without threads			
--enable-FEATURE	Enable FEATURE			
--enable-assembler	Use assembler versions of some string functions if available			
--enable-debug-sync	Compile in Debug Sync facility		6.0.6	
--enable-dependency-tracking	Do not reject slow dependency extractors			
--enable-dtrace	Compile in DTrace support		6.0.4	
--enable-fast-install	Optimize for fast installation	yes		
--enable-local-infile	Enable LOAD DATA LOCAL INFILE	disabled		
--enable-shared	Build shared libraries	yes		
--enable-static	Build static libraries	yes		
--enable-thread-safe-client	Compile the client with threads			
--exec-prefix=EPREFIX	Install architecture-dependent files in EPREFIX			
-h	Display this help and exit			
--help				
--help=short	Display options specific to this package			
--help=recursive	Display the short help of all the included packages			
--host=HOST	Cross-compile to build programs to run on HOST			
--includedir=DIR	C header files	PREFIX/include		
--infodir=DIR	Info documentation	PREFIX/info		
--libdir=DIR	Object code libraries	EPREFIX/lib		
--libexecdir=DIR	Program executables	EPREFIX/libexec		
--localstatedir=DIR	Modifiable single-machine data	PREFIX/var		
--mandir=DIR	man documentation	PREFIX/man		
-n	Do not create output files			
--no-create				
--oldincludedir=DIR	C header files for non-gcc	/usr/include		
--prefix=PREFIX	Install architecture-independent files in PREFIX			
--program-prefix=PREFIX	Prepend PREFIX to installed program names			
--program-suffix=SUFFIX	Append SUFFIX to installed program names			
- -pro-	run sed PROGRAM on installed program names			

Formats	Description	Default	Introduced	Removed
gram-transform-name=PROGRAM				
-q	Do not print `checking...' messages			
--quiet				
--sbindir=DIR	System admin executables	EPREFIX/sbin		
--sharedstatedir=DIR	Modifiable architecture-independent data	PREFIX/com		
--srcdir=DIR	Find the sources in DIR	configure directory or ..		
--sysconfdir=DIR	Read-only single-machine data	PREFIX/etc		
--target=TARGET	Configure for building compilers for TARGET			
-V	Display version information and exit			
--version				
--with-PACKAGE	Use PACKAGE			
--with-archive-storage-engine	Enable the Archive Storage Engine	no		
--with-atomic-ops	Implement atomic operations using pthread rwlocks or atomic CPU instructions for multi-processor			
--with-berkeley-db-includes	Find Berkeley DB headers in DIR			
--with-big-tables	Support tables with more than 4 G rows even on 32 bit platforms			
--with-blackhole-storage-engine	Enable the Blackhole Storage Engine	no		
--with-charset	Default character set			
--with-client-ldflags	Extra linking arguments for clients			
--with-collation	Default collation			
--with-comment	Comment about compilation environment			
--with-csv-storage-engine	Enable the CSV Storage Engine	yes		
--with-darwin-mwcc	Use Metrowerks CodeWarrior wrappers on OS X/Darwin			
--with-debug	Add debug code			
--with-debug=full	Add debug code (adds memory checker, very slow)			
--with-embedded-privilege-control	Build parts to check user's privileges (only affects embedded library)			
--with-embedded-server	Build the embedded server			
--with-error-inject	Enable error injection in MySQL Server			
--with-example-storage-engine	Enable the Example Storage Engine	no		
--with-extra-charsets	Use charsets in addition to default			
--with-fast-mutexes	Compile with fast mutexes	enabled		
--with-federated-storage-engine	Enable federated storage engine	no		
--with-gnu-ld	Assume the C compiler uses GNU ld	no		
--with-innodb	Enable innobase storage engine	no		
--with-lib-ccflags	Extra CC options for libraries			
--with-libevent	Include libevent for thread-pool support		6.0.4	
--with-low-memory	Try to use less memory to compile to avoid memory limitations			
--with-machine-type	Set the machine type, like "powerpc"			
--with-maria-temp-tables	Make the temporary tables within MySQL use the Maria storage engine		6.0.6	
--with-max-indexes=N	Sets the maximum number of indexes	64		

Formats	Description	Default	Introduced	Removed
	per table			
--with-mysqld-ldflags	Extra linking arguments for mysqld			
--with-mysqld-libs	Extra libraries to link with for mysqld			
--with-mysqld-user	What user the mysqld daemon shall be run as			
--with-named-curses-libs	Use specified curses libraries			
--with-named-thread-libs	Use specified thread libraries			
--with-ndb-ccflags	Extra CC options for ndb compile			
--with-ndb-docs	Include the NDB Cluster ndbapi and mgmapi documentation			
--with-ndb-port	Port for NDB Cluster management server			
--with-ndb-port-base	Port for NDB Cluster management server			
--with-ndb-sci=DIR	Provide MySQL with a custom location of sci library			
--with-ndb-test	Include the NDB Cluster ndbapi test programs			
--with-ndbcluster	Include the NDB Cluster table handler	no		
--with-openssl-libs	Find OpenSSL libraries in DIR			
--with-other-libc=DIR	Link against libc and other standard libraries installed in the specified nonstandard location			
--with-pic	Try to use only PIC/non-PIC objects	Use both		
--with-plugin-PLUGIN	Forces the named plugin to be linked into mysqld statically			
--with-plugins	Plugins to include in mysqld	none		
--with-pstack	Use the pstack backtrace library			
--with-pthread	Force use of pthread library			
--with-row-based-replication	Include row-based replication			
--with-server-suffix	Append value to the version string			
--with-ssl=DIR	Include SSL support			
--with-system-type	Set the system type, like "sun-solaris10"			
--with-tags	Include additional configurations	automatic		
--with-tcp-port	Which port to use for MySQL services	3306		
--with-unix-socket-path	Where to put the unix-domain socket			
--with-zlib-dir=no|bundled|DIR	Provide MySQL with a custom location of compression library			
--without-PACKAGE	Do not use PACKAGE			
--without-debug	Build a production version without debugging code			
--without-docs	Skip building of the documentation			
--without-extra-tools	Skip building utilities in the tools directory			
--without-geometry	Do not build geometry-related parts			
--without-libedit	Use system libedit instead of bundled copy			
--without-libevent	Do not include libevent for thread-pool support		6.0.4	
--without-man	Skip building of the man pages			

Formats	Description	Default	Introduced	Removed
--without-ndb-binlog	Disable ndb binlog			
--without-ndb-debug	Disable special ndb debug features			
--without-plugin-PLUGIN	Exclude PLUGIN			
--without-query-cache	Do not build query cache			
--without-readline	Use system readline instead of bundled copy			
--without-row-based-replication	Don't include row-based replication			
--without-server	Only build the client			
--without-uca	Skip building of the national Unicode collations			

Some of the `configure` options available are described here. For options that may be of use if you have difficulties building MySQL, see Section 2.9.4, “Dealing with Problems Compiling MySQL”.

- To compile just the MySQL client libraries and client programs and not the server, use the `--without-server` option:

```
shell> ./configure --without-server
```

  If you have no C++ compiler, some client programs such as `mysql` cannot be compiled because they require C++.. In this case, you can remove the code in `configure` that tests for the C++ compiler and then run `./configure` with the `--without-server` option. The compile step should still try to build all clients, but you can ignore any warnings about files such as `mysql.cc`. (If `make` stops, try `make -k` to tell it to continue with the rest of the build even if errors occur.)

- If you want to build the embedded MySQL library (`libmysqld.a`), use the `--with-embedded-server` option.

- If you don't want your log files and database directories located under `/usr/local/var`, use a `configure` command something like one of these:

```
shell> ./configure --prefix=/usr/local/mysql
shell> ./configure --prefix=/usr/local \
          --localstatedir=/usr/local/mysql/data
```

  The first command changes the installation prefix so that everything is installed under `/usr/local/mysql` rather than the default of `/usr/local`. The second command preserves the default installation prefix, but overrides the default location for database directories (normally `/usr/local/var`) and changes it to `/usr/local/mysql/data`.

  You can also specify the installation directory and data directory locations at server startup time by using the `--basedir` and `--datadir` options. These can be given on the command line or in an MySQL option file, although it is more common to use an option file. See Section 4.2.3.2, “Using Option Files”.

- If you are using Unix and you want the MySQL socket file location to be somewhere other than the default location (normally in the directory `/tmp` or `/var/run`), use a `configure` command like this:

```
shell> ./configure \
          --with-unix-socket-path=/usr/local/mysql/tmp/mysql.sock
```

  The socket file name must be an absolute path name. You can also change the location of `mysql.sock` at server startup by using a MySQL option file. See Section B.1.4.5, “How to Protect or Change the MySQL Unix Socket File”.

- If you want to compile statically linked programs (for example, to make a binary distribution, to get better performance, or to work around problems with some Red Hat Linux distributions), run `configure` like this:

```
shell> ./configure --with-client-ldflags=-all-static \
          --with-mysqld-ldflags=-all-static
```

- If you are using `gcc` and don't have `libg++` or `libstdc++` installed, you can tell `configure` to use `gcc` as your C++ compiler:

```
shell> CC=gcc CXX=gcc ./configure
```

  When you use `gcc` as your C++ compiler, it does not attempt to link in `libg++` or `libstdc++`. This may be a good thing to do even if you have those libraries installed. Some versions of them have caused strange problems for MySQL users in the past.

  The following list indicates some compilers and environment variable settings that are commonly used with each one.

- `gcc` 2.7.2:

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors"
```

- `gcc` 2.95.2:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti"
```

- `pgcc` 2.90.29 or newer:

```
CFLAGS="-O3 -mpentiumpro -mstack-align-double" CXX=gcc \
CXXFLAGS="-O3 -mpentiumpro -mstack-align-double \
-felide-constructors -fno-exceptions -fno-rtti"
```

In most cases, you can get a reasonably optimized MySQL binary by using the options from the preceding list and adding the following options to the `configure` line:

```
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The full `configure` line would, in other words, be something like the following for all recent `gcc` versions:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti" ./configure \
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The binaries we provide on the MySQL Web site at http://dev.mysql.com/downloads/ are all compiled with full optimization and should be perfect for most users. See Section 2.1.2.4, “MySQL Binaries Compiled by Sun Microsystems, Inc.”. There are some configuration settings you can tweak to build an even faster binary, but these are only for advanced users. See Section 7.5.1, “How Compiling and Linking Affects the Speed of MySQL”.

If the build fails and produces errors about your compiler or linker not being able to create the shared library `libmysqlclient.so.N` (where `N` is a version number), you can work around this problem by giving the `--disable-shared` option to `configure`. In this case, `configure` does not build a shared `libmysqlclient.so.N` library.

- By default, MySQL uses the `latin1` (cp1252 West European) character set. To change the default set, use the `--with-charset` option:

```
shell> ./configure --with-charset=CHARSET
```

`CHARSET` may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`, `sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb3`, `utf16`, `utf32`. See Section 9.2, “The Character Set Used for Data and Sorting”. (Additional character sets might be available. Check the output from `./configure --help` for the current list.)

The default collation may also be specified. MySQL uses the `latin1_swedish_ci` collation by default. To change this, use the `--with-collation` option:

```
shell> ./configure --with-collation=COLLATION
```

To change both the character set and the collation, use both the `--with-charset` and `--with-collation` options. The collation must be a legal collation for the character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.)

> **Warning**
>
> If you change character sets after having created any tables, you must run `myisamchk -r -q --set-collation=collation_name` *on every* `MyISAM` *table*. Your indexes may be sorted incorrectly otherwise. This can happen if you install MySQL, create some tables, and then reconfigure MySQL to use a different character set and reinstall it.

With the `configure` option `--with-extra-charsets=LIST`, you can define which additional character sets should be compiled into the server. `LIST` is one of the following:

- A list of character set names separated by spaces

  - `complex` to include all character sets that can't be dynamically loaded
  - `all` to include all character sets into the binaries

  Clients that want to convert characters between the server and the client should use the `SET NAMES` statement. See Section 5.1.4, “Session System Variables”, and Section 9.1.4, “Connection Character Sets and Collations”.

- To configure MySQL with debugging code, use the `--with-debug` option:

```
shell> ./configure --with-debug
```

  This causes a safe memory allocator to be included that can find some errors and that provides output about what is happening. See MySQL Internals: Porting.

  Using `--with-debug` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

- To cause the Debug Sync facility to be compiled into the server, use the `--enable-debug-sync` option. This facility is used for testing and debugging. When compiled in, Debug Sync is disabled by default. To enable it, start mysqld with the `--debug-sync-timeout=N` option, where *`N`* is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) *`N`* becomes the default timeout for individual synchronization points.

  Debug Sync is also compiled in if you configure with the `--with-debug` option (which implies `--enable-debug-sync`), unless you also use the `--disable-debug-sync` option.

  For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

  The `--enable-debug-sync` and `--disable-debug-sync` options were added in MySQL 6.0.6.

- The `--enable-dtrace` option causes support for DTrace probes to be included. Use the `--disable-dtrace` to disable DTrace probe support.

  The `--enable-dtrace` and `--disable-dtrace` options were added in MySQL 6.0.4.

- If your client programs are using threads, you must compile a thread-safe version of the MySQL client library with the `--enable-thread-safe-client` configure option. This creates a `libmysqlclient_r` library with which you should link your threaded applications. See Section 20.10.17, “How to Make a Threaded Client”.

- Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, compression of the client/server protocol, and compression by `BACKUP DATABASE`. The `--with-zlib-dir=no|bundled|DIR` option provides control for compression library support. The value `no` explicitly disables compression support. `bundled` causes the `zlib` library bundled in the MySQL sources to be used. A *`DIR`* path name specifies where to find the compression library sources.

- It is possible to build MySQL with large table support using the `--with-big-tables` option.

  This option causes the variables that store table row counts to be declared as `unsigned long long` rather than `unsigned long`. This enables tables to hold up to approximately 1.844E+19 ($(2^{32})^2$) rows rather than 2^{32} (~4.295E+09) rows. Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable this feature.

- Run `configure` with the `--disable-grant-options` option to cause the `--bootstrap`, `--skip-grant-tables`, and `--init-file` options for `mysqld` to be disabled. For Windows, the `configure.js` script recognizes the `DISABLE_GRANT_OPTIONS` flag, which has the same effect.

- As of MySQL 6.0.4, client connections can be managed by a fix-size pool of threads rather than allocating one thread per connection. Thread pooling is based on the `libevent` library. To build a server that includes the thread-pool capability, configure MySQL using the `--with-libevent` option. The `--without-libevent` option excludes the `libevent` code. For information about choosing which thread model the server uses, see Section 7.5.7, “How MySQL Uses Threads for Client Connections”.

- This option allows MySQL Community Server features to be enabled. Additional options may be required for individual features, such as `--enable-profiling` to enable statement profiling. This option was added in MySQL 6.0.5. It is enabled by default; to disable it, use `--disable-community-features`.

- When given with `--enable-community-features`, the `--enable-profiling` option enables the statement profiling capability exposed by the `SHOW PROFILE` and `SHOW PROFILES` statements. (See Section 12.5.6.32, “`SHOW PROFILES` Syntax”.) This option was added in MySQL 6.0.5. It is enabled by default; to disable it, use `-`

`-disable-profiling`.

- See Section 2.12, “Operating System-Specific Notes”, for options that pertain to particular operating systems.
- See Section 5.5.7.2, “Using SSL Connections”, for options that pertain to configuring MySQL to support secure (encrypted) connections.
- Several `configure` options apply to plugin selection and building:

```
--with-plugins=PLUGIN[,PLUGIN]...
--with-plugins=GROUP
--with-plugin-PLUGIN
--without-plugin-PLUGIN
```

  `PLUGIN` is an individual plugin name such as `csv` or `archive`.

  As shorthand, *`GROUP`* is a configuration group name such as `none` (select no plugins) or `all` (select all plugins).

  You can build a plugin as static (compiled into the server) or dynamic (built as a dynamic library that must be installed using the `INSTALL PLUGIN` statement before it can be used). Some plugins might not support static or dynamic build.

  `configure --help` shows the following information pertaining to plugins:

  - The plugin-related options
  - The names of all available plugins
  - For each plugin, a description of its purpose, which build types it supports (static or dynamic), and which plugin groups it is a part of.

  `--with-plugins` can take a list of one or more plugin names separated by commas, or a plugin group name. The named plugins are configured to be built as static plugins.

  `--with-plugin-`*`PLUGIN`* configures the given plugin to be built as a static plugin.

  `--without-plugin-`*`PLUGIN`* disables the given plugin from being built.

  If a plugin is named both with a `--with` and `--without` option, the result is undefined.

  For any plugin that is not explicitly selected or disabled, it is selected to be built dynamically if it supports dynamic build, and not built if it does not support dynamic build. (Thus, in the case that no plugin options are given, all plugins that support dynamic build are selected to be built as dynamic plugins. Plugins that do not support dynamic build are not built.)

2.9.3. Installing from the Development Source Tree

> **Caution**
>
> You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution).

To obtain the most recent development source tree, you first need to download and install Bazaar. You can obtain Bazaar from the Bazaar VCS Website. Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar website.

All MySQL projects are hosted on Launchpad. MySQL projects, including MySQL server, MySQL Workbench and others are available from the Sun/MySQL Engineering page. For the repositories related only to MySQL server, see the MySQL Server page.

To build under Unix/Linux, you must have the following tools installed:

- GNU `make`, available from http://www.gnu.org/software/make/. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make`. It may already be available on your system as `gmake`.
- `autoconf` 2.58 (or newer), available from http://www.gnu.org/software/autoconf/.
- `automake` 1.8.1, available from http://www.gnu.org/software/automake/.
- `libtool` 1.5, available from http://www.gnu.org/software/libtool/.

- `m4`, available from http://www.gnu.org/software/m4/.
- `bison`, available from http://www.gnu.org/software/bison/. You should use the latest version of bison where possible. Version 1.75 and version 2.1 are known to work. There have been reported problems with `bison` 1.875. If you experience problems, upgrade to a later, rather than earlier, version. Versions of `bison` older than 1.75 may report this error:

  ```
  sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
  ```

  The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

To build under Windows you will need a copy of Microsoft Visual C++ 2005 Express Edition, Visual Studio .Net 2003 (7.1), or Visual Studio 2005 (8.0) compiler system.

Once you have the necessary tools installed, you first need to create a local branch of the MySQL source code on your machine:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you need to initialize a new directory:

   ```
   shell> mkdir mysql-server
   shell> bzr init-repo --trees mysql-server
   ```

   Once you have an initialized directory, you can `branch` from the public MySQL server repositories. To create a branch of a specific version:

   ```
   shell> cd mysql-server
   shell> bzr branch lp:mysql-server/6.0 mysql-6.0
   ```

   The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.

   When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

   ```
   shell> bzr branch mysql-6.0 mysql-6.0-build
   ```

Once you have the local branch, you can start to build MySQL server from the source code. On Windows, the build process is different from Unix/Linux. To continue building MySQL on Windows, see Section 2.9.6, “Installing MySQL from Source on Windows”.

On Unix/Linux you need to use the `autoconf` system to create the `configure` script so that you can configure the build environment before building.

1. The following example shows the typical commands required to configure a source tree. The first `cd` command changes location into the top-level directory of the tree; replace `mysql-6.0` with the appropriate directory name.

   ```
   shell> cd mysql-6.0
   shell> autoreconf --force --install
   shell> ./configure  # Add your favorite options here
   shell> make
   ```

   Or you can use `BUILD/autorun.sh` as a shortcut for the following sequence of commands:

   ```
   shell> aclocal; autoheader
   shell> libtoolize --automake --force
   shell> automake --force --add-missing; autoconf
   ```

   The command line that changes directory into the `storage/innobase` directory is used to configure the `InnoDB` storage engine. You can omit this lines if you do not require `InnoDB` support.

   If you get some strange errors during this stage, verify that you have the correct version of the `libtool` installed.

   A collection of our standard configuration scripts is located in the `BUILD/` subdirectory. For example, you may find it more convenient to use the `BUILD/compile-pentium-debug` script than the preceding set of shell commands. To compile on a different architecture, modify the script by removing flags that are Pentium-specific, or use another script that may be more appropriate. These scripts are provided on an “as-is” basis. They are not officially maintained and their contents may change

from release to release.

2. When the build is done, run `make install`. Be careful with this on a production machine; the command may overwrite your live release installation. If you have another installation of MySQL, we recommend that you run `./configure` with different values for the `--prefix`, `--with-tcp-port`, and `--with-unix-socket-path` options than those used for your production server.

3. Play hard with your new installation and try to make the new features crash. Start by running `make test`. See Section 21.1.2, "MySQL Test Suite".

4. If you have gotten to the `make` stage, but the distribution does not compile, please enter the problem into our bugs database using the instructions given in Section 1.6, "How to Report Bugs or Problems". If you have installed the latest versions of the required GNU tools, and they crash trying to process our configuration files, please report that also. However, if you execute `aclocal` and get a `command not found` error or a similar problem, do not report it. Instead, make sure that all the necessary tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

5. After initially copying the repository with `bzr` to obtain the source tree, you should use `pull` option to periodically update your local copy. To do this any time after you have set up the repository, use this command:

   ```
   shell> bzr pull
   ```

6. You can examine the changeset comments for the tree by using the `log` option to `bzr`:

   ```
   shell> bzr log
   ```

   You can also browse changesets, comments, and source code online. To browse this information for MySQL 6.0, go to http://launchpad.net/mysql-server/.

   If you see diffs or code that you have a question about, do not hesitate to send email to the MySQL `internals` mailing list. See Section 1.5.1, "MySQL Mailing Lists". Also, if you think you have a better idea on how to do something, send an email message to the list with a patch.

2.9.4. Dealing with Problems Compiling MySQL

All MySQL programs compile cleanly for us with no warnings on Solaris or Linux using `gcc`. On other systems, warnings may occur due to differences in system include files. See Section 2.9.5, "MIT-pthreads Notes", for warnings that may occur when using MIT-pthreads. For other problems, check the following list.

The solution to many problems involves reconfiguring. If you do need to reconfigure, take note of the following:

- If `configure` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `config.cache`. When `configure` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `configure`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old configuration information or object files from being used, run these commands before re-running `configure`:

```
shell> rm config.cache
shell> make clean
```

Alternatively, you can run `make distclean`.

The following list describes some of the problems when compiling MySQL that have been found to occur most often:

- If you get errors such as the ones shown here when compiling `sql_yacc.cc`, you probably have run out of memory or swap space:

  ```
  Internal compiler error: program cc1plus got fatal signal 11
  Out of virtual memory
  Virtual memory exhausted
  ```

  The problem is that `gcc` requires a huge amount of memory to compile `sql_yacc.cc` with inline functions. Try running `configure` with the `--with-low-memory` option:

```
shell> ./configure --with-low-memory
```

This option causes `-fno-inline` to be added to the compile line if you are using `gcc` and `-O0` if you are using something else. You should try the `--with-low-memory` option even if you have so much memory and swap space that you think you can't possibly have run out. This problem has been observed to occur even on systems with generous hardware configurations, and the `--with-low-memory` option usually fixes it.

- By default, `configure` picks `c++` as the compiler name and GNU `c++` links with `-lg++`. If you are using `gcc`, that behavior can cause problems during configuration such as this:

```
configure: error: installation or configuration problem:
C++ compiler cannot create executables.
```

You might also observe problems during compilation related to `g++`, `libg++`, or `libstdc++`.

One cause of these problems is that you may not have `g++`, or you may have `g++` but not `libg++`, or `libstdc++`. Take a look at the `config.log` file. It should contain the exact reason why your C++ compiler didn't work. To work around these problems, you can use `gcc` as your C++ compiler. Try setting the environment variable `CXX` to `"gcc -O3"`. For example:

```
shell> CXX="gcc -O3" ./configure
```

This works because `gcc` compiles C++ source files as well as `g++` does, but does not link in `libg++` or `libstdc++` by default.

Another way to fix these problems is to install `g++`, `libg++`, and `libstdc++`. However, we recommend that you not use `libg++` or `libstdc++` with MySQL because this only increases the binary size of `mysqld` without providing any benefits. Some versions of these libraries have also caused strange problems for MySQL users in the past.

- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
making all in mit-pthreads
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- If you want to define flags to be used by your C or C++ compilers, do so by adding the flags to the `CFLAGS` and `CXXFLAGS` environment variables. You can also specify the compiler names this way using `CC` and `CXX`. For example:

```
shell> CC=gcc
shell> CFLAGS=-O3
shell> CXX=gcc
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

See Section 2.1.2.4, “MySQL Binaries Compiled by Sun Microsystems, Inc.”, for a list of flag definitions that have been found to be useful on various systems.

- If you get errors such as those shown here when compiling `mysqld`, `configure` did not correctly detect the type of the last argument to `accept()`, `getsockname()`, or `getpeername()`:

```
cxx: Error: mysqld.cc, line 645: In this statement, the referenced
     type of the pointer value ''length'' is ''unsigned long'',
     which is not compatible with ''int''.
new_sock = accept(sock, (struct sockaddr *)&cAddr, &length);
```

To fix this, edit the `config.h` file (which is generated by `configure`). Look for these lines:

```
/* Define as the base type of the last arg to accept */
#define SOCKET_SIZE_TYPE XXX
```

Change `XXX` to `size_t` or `int`, depending on your operating system. (You must do this each time you run `configure` because `configure` regenerates `config.h`.)

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pre-generated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

  This is a sign that your version of `yacc` is deficient. You probably need to install `bison` (the GNU version of `yacc`) and use that instead.

- On Debian Linux 3.0, you need to install `gawk` instead of the default `mawk`.

- If you need to debug `mysqld` or a MySQL client, run `configure` with the `--with-debug` option, and then recompile and link your clients with the new client library. See MySQL Internals: Porting.

- If you get a compilation error on Linux (for example, SuSE Linux 8.1 or Red Hat Linux 7.3) similar to the following one, you probably do not have `g++` installed:

```
libmysql.c:1329: warning: passing arg 5 of `gethostbyname_r' from
incompatible pointer type
libmysql.c:1329: too few arguments to function `gethostbyname_r'
libmysql.c:1329: warning: assignment makes pointer from integer
without a cast
make[2]: *** [libmysql.lo] Error 1
```

  By default, the `configure` script attempts to determine the correct number of arguments by using `g++` (the GNU C++ compiler). This test yields incorrect results if `g++` is not installed. There are two ways to work around this problem:

  - Make sure that the GNU C++ `g++` is installed. On some Linux distributions, the required package is called `gpp`; on others, it is named `gcc-c++`.

  - Use `gcc` as your C++ compiler by setting the `CXX` environment variable to `gcc`:

```
export CXX="gcc"
```

  You must run `configure` again after making either of those changes.

2.9.5. MIT-pthreads Notes

This section describes some of the issues involved in using MIT-pthreads.

On Linux, you should *not* use MIT-pthreads. Use the installed LinuxThreads implementation instead. See Section 2.12.1, “Linux Notes”.

If your system does not provide native thread support, you should build MySQL using the MIT-pthreads package. This includes older FreeBSD systems, SunOS 4.x, Solaris 2.4 and earlier, and some others. See Section 2.1.1, “Operating Systems Supported by MySQL Community Server”.

MIT-pthreads is not part of the MySQL 6.0 source distribution. If you require this package, you need to download it separately from http://dev.mysql.com/Downloads/Contrib/pthreads-1_60_beta6-mysql.tar.gz

After downloading, extract this source archive into the top level of the MySQL source directory. It creates a new subdirectory named `mit-pthreads`.

- On most systems, you can force MIT-pthreads to be used by running `configure` with the `--with-mit-threads` option:

```
shell> ./configure --with-mit-threads
```

  Building in a non-source directory is not supported when using MIT-pthreads because we want to minimize our changes to this code.

- The checks that determine whether to use MIT-pthreads occur only during the part of the configuration process that deals with the server code. If you have configured the distribution using `--without-server` to build only the client code, clients do not know whether MIT-pthreads is being used and use Unix socket file connections by default. Because Unix socket files do

not work under MIT-pthreads on some platforms, this means you need to use `-h` or `--host` with a value other than `localhost` when you run client programs.

- When MySQL is compiled using MIT-pthreads, system locking is disabled by default for performance reasons. You can tell the server to use system locking with the `--external-locking` option. This is needed only if you want to be able to run two MySQL servers against the same data files, but that is not recommended, anyway.
- Sometimes the pthread `bind()` command fails to bind to a socket without any error message (at least on Solaris). The result is that all connections to the server fail. For example:

```
shell> mysqladmin version
mysqladmin: connect to server at '' failed;
error: 'Can't connect to mysql server on localhost (146)'
```

  The solution to this problem is to kill the `mysqld` server and restart it. This has happened to us only when we have forcibly stopped the server and restarted it immediately.

- With MIT-pthreads, the `sleep()` system call isn't interruptible with `SIGINT` (break). This is noticeable only when you run `mysqladmin --sleep`. You must wait for the `sleep()` call to terminate before the interrupt is served and the process stops.
- When linking, you might receive warning messages like these (at least on Solaris); they can be ignored:

```
ld: warning: symbol `_iob' has differing sizes:
    (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
    /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
ld: warning: symbol `__iob' has differing sizes:
    (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
    /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
```

- Some other warnings also can be ignored:

```
implicit declaration of function `int strtoll(...)'
implicit declaration of function `int strtoul(...)'
```

- We have not been able to make `readline` work with MIT-pthreads. (This is not necessary, but may be of interest to some.)

2.9.6. Installing MySQL from Source on Windows

These instructions describe how to build binaries from source for MySQL 6.0 on Windows. Instructions are provided for building binaries from a standard source distribution or from the Bazaar tree that contains the latest development source.

> **Note**
>
> The instructions here are strictly for users who want to test MySQL on Microsoft Windows from the latest source distribution or from the Bazaar tree. For production use, we do not advise using a MySQL server built by yourself from source. Normally, it is best to use precompiled binary distributions of MySQL that are built specifically for optimal performance on Windows by Sun Microsystems, Inc. Instructions for installing binary distributions are available in Section 2.3, “Installing MySQL on Windows”.

To build MySQL on Windows from source, you must satisfy the following system, compiler, and resource requirements:

- Windows 2000, Windows XP, or newer version.

  Windows Vista is supported when using Visual Studio 2005 provided you have installed the following updates:

  - Microsoft Visual Studio 2005 Professional Edition - ENU Service Pack 1 (KB926601)
  - Security Update for Microsoft Visual Studio 2005 Professional Edition - ENU (KB937061)
  - Update for Microsoft Visual Studio 2005 Professional Edition - ENU (KB932232)

- CMake, which can be downloaded from http://www.cmake.org. After installing, modify your path to include the `cmake` binary.
- Microsoft Visual C++ 2005 Express Edition, Visual Studio .Net 2003 (7.1), or Visual Studio 2005 (8.0) compiler system.
- If you are using Visual C++ 2005 Express Edition, you must also install an appropriate Platform SDK. More information and

links to downloads for various Windows platforms is available from http://www.microsoft.com/downloads/details.aspx?familyid=0baf2b35-c656-4969-ace8-e4c0c0716adb.

- If you are compiling from a Bazaar tree or making changes to the parser, you need `bison` for Windows, which can be downloaded from http://gnuwin32.sourceforge.net/packages/bison.htm. Download the package labeled "Complete package, excluding sources". After installing the package, modify your path to include the `bison` binary and ensure that this binary is accessible from Visual Studio.
- Cygwin might be necessary if you want to run the test script or package the compiled binaries and support files into a Zip archive. (Cygwin is needed only to test or package the distribution, not to build it.) Cygwin is available from http://cygwin.com.
- 3GB to 5GB of disk space.

The exact system requirements can be found here: http://msdn.microsoft.com/vstudio/Previous/2003/sysreqs/default.aspx and http://msdn.microsoft.com/vstudio/products/sysreqs/default.aspx

You also need a MySQL source distribution for Windows, which can be obtained two ways:

- Obtain a source distribution packaged by Sun Microsystems, Inc. These are available from http://dev.mysql.com/downloads/.
- Package a source distribution yourself from the latest Bazaar developer source tree. For instructions on pulling the latest source files, see Section 2.9.3, "Installing from the Development Source Tree".

If you find something not working as expected, or you have suggestions about ways to improve the current build process on Windows, please send a message to the `win32` mailing list. See Section 1.5.1, "MySQL Mailing Lists".

2.9.6.1. Building MySQL from Source Using CMake and Visual Studio

You can build MySQL on Windows by using a combination of `cmake` and Microsoft Visual Studio .NET 2003 (7.1), Microsoft Visual Studio 2005 (8.0) or Microsoft Visual C++ 2005 Express Edition. You must have the appropriate Microsoft Platform SDK installed.

> **Note**
>
> To compile from the source code on Windows you must use the standard source distribution (for example, `mysql-5.0.45.tar.gz`). You build from the same distribution as used to build MySQL on Unix, Linux and other platforms. Do *not* use the Windows Source distributions as they do not contain the necessary configuration script and other files.

Follow this procedure to build MySQL:

1. If you are installing from a packaged source distribution, create a work directory (for example, `C:\workdir`), and unpack the source distribution there using `WinZip` or another Windows tool that can read `.zip` files. This directory is the work directory in the following instructions.
2. If you are installing from a Bazaar tree, the root directory of that tree is the work directory in the following instructions.
3. Using a command shell, navigate to the work directory and run the following command:

   ```
   C:\workdir>win\configure.js options
   ```

   If you have associated the `.js` file extension with an application such as a text editor, then you may need to use the following command to force `configure.js` to be executed as a script:

   ```
   C:\workdir>cscript win\configure.js options
   ```

   These options are available for `configure.js`:

   - `WITH_INNOBASE_STORAGE_ENGINE`: Enable the `InnoDB` storage engine.
   - `WITH_PARTITION_STORAGE_ENGINE`: Enable user-defined partitioning.
   - `WITH_ARCHIVE_STORAGE_ENGINE`: Enable the `ARCHIVE` storage engine.
   - `WITH_BLACKHOLE_STORAGE_ENGINE`: Enable the `BLACKHOLE` storage engine.

- `WITH_EXAMPLE_STORAGE_ENGINE`: Enable the `EXAMPLE` storage engine.
- `WITH_FEDERATED_STORAGE_ENGINE`: Enable the `FEDERATED` storage engine.
- `MYSQL_SERVER_SUFFIX=`*`suffix`*: Server suffix, default none.
- `COMPILATION_COMMENT=`*`comment`*: Server comment, default "Source distribution".
- `MYSQL_TCP_PORT=`*`port`*: Server port, default 3306.
- `DISABLE_GRANT_OPTIONS`: Disables the `--bootstrap`, `--skip-grant-tables`, and `--init-file` options for `mysqld`.

For example (type the command on one line):

```
C:\workdir>win\configure.js WITH_INNOBASE_STORAGE_ENGINE
            WITH_PARTITION_STORAGE_ENGINE MYSQL_SERVER_SUFFIX=-pro
```

4. From the work directory, execute the `win\build-vs8.bat` or `win\build-vs71.bat` file, depending on the version of Visual Studio you have installed. The script invokes CMake, which generates the `mysql.sln` solution file.

   You can also use `win\build-vs8_x64.bat` to build the 64-bit version of MySQL. However, you cannot build the 64-bit version with Visual Studio Express Edition. You must use Visual Studio 2005 (8.0) or higher.

5. From the work directory, open the generated `mysql.sln` file with Visual Studio and select the proper configuration using the CONFIGURATION menu. The menu provides Debug, Release, RelwithDebInfo, MinRelInfo options. Then select SOLUTION > Build to build the solution.

   Remember the configuration that you use in this step. It is important later when you run the test script because that script needs to know which configuration you used.

6. Test the server. The server built using the preceding instructions expects that the MySQL base directory and data directory are `C:\mysql` and `C:\mysql\data` by default. If you want to test your server using the source tree root directory and its data directory as the base directory and data directory, you need to tell the server their path names. You can either do this on the command line with the `--basedir` and `--datadir` options, or by placing appropriate options in an option file. (See Section 4.2.3.2, “Using Option Files”.) If you have an existing data directory elsewhere that you want to use, you can specify its path name instead.

   When the server is running in standalone fashion or as a service based on your configuration, try to connect to it from the `mysql` interactive command-line utility.

   You can also run the standard test script, `mysql-test-run.pl`. This script is written in Perl, so you'll need either Cygwin or ActiveState Perl to run it. You may also need to install the modules required by the script. To run the test script, change location into the `mysql-test` directory under the work directory, set the `MTR_VS_CONFIG` environment variable to the configuration you selected earlier (or use the `--vs-config` option), and invoke `mysql-test-run.pl`. For example (using Cygwin and the `bash` shell):

```
shell> cd mysql-test
shell> export MTS_VS_CONFIG=debug
shell> ./mysql-test-run.pl --force --timer
shell> ./mysql-test-run.pl --force --timer --ps-protocol
```

When you are satisfied that the programs you have built are working correctly, stop the server. Now you can install the distribution. One way to do this is to use the `make_win_bin_dist` script in the `scripts` directory of the MySQL source distribution (see Section 4.4.2, “`make_win_bin_dist` — Package MySQL Distribution as ZIP Archive”). This is a shell script, so you must have Cygwin installed if you want to use it. It creates a Zip archive of the built executables and support files that you can unpack in the location at which you want to install MySQL.

It is also possible to install MySQL by copying directories and files directly:

1. Create the directories where you want to install MySQL. For example, to install into `C:\mysql`, use these commands:

```
C:\> mkdir C:\mysql
C:\> mkdir C:\mysql\bin
C:\> mkdir C:\mysql\data
C:\> mkdir C:\mysql\share
C:\> mkdir C:\mysql\scripts
```

   If you want to compile other clients and link them to MySQL, you should also create several additional directories:

```
C:\> mkdir C:\mysql\include
C:\> mkdir C:\mysql\lib
C:\> mkdir C:\mysql\lib\debug
C:\> mkdir C:\mysql\lib\opt
```

If you want to benchmark MySQL, create this directory:

```
C:\> mkdir C:\mysql\sql-bench
```

Benchmarking requires Perl support. See Section 2.14, “Perl Installation Notes”.

2. From the work directory, copy into the `C:\mysql` directory the following directories:

```
C:\> cd \workdir
C:\workdir> copy client_release\*.exe C:\mysql\bin
C:\workdir> copy client_debug\mysqld.exe C:\mysql\bin\mysqld-debug.exe
C:\workdir> xcopy scripts\*.* C:\mysql\scripts /E
C:\workdir> xcopy share\*.* C:\mysql\share /E
```

If you want to compile other clients and link them to MySQL, you should also copy several libraries and header files:

```
C:\workdir> copy lib_debug\mysqlclient.lib C:\mysql\lib\debug
C:\workdir> copy lib_debug\libmysql.* C:\mysql\lib\debug
C:\workdir> copy lib_debug\zlib.* C:\mysql\lib\debug
C:\workdir> copy lib_release\mysqlclient.lib C:\mysql\lib\opt
C:\workdir> copy lib_release\libmysql.* C:\mysql\lib\opt
C:\workdir> copy lib_release\zlib.* C:\mysql\lib\opt
C:\workdir> copy include\*.h C:\mysql\include
C:\workdir> copy libmysql\libmysql.def C:\mysql\include
```

If you want to benchmark MySQL, you should also do this:

```
C:\workdir> xcopy sql-bench\*.* C:\mysql\bench /E
```

After installation, set up and start the server in the same way as for binary Windows distributions. See Section 2.3, “Installing MySQL on Windows”.

2.9.7. Compiling MySQL Clients on Windows

In your source files, you should include `my_global.h` before `mysql.h`:

```
#include <my_global.h>
#include <mysql.h>
```

`my_global.h` includes any other files needed for Windows compatibility (such as `windows.h`) if you compile your program on Windows.

You can either link your code with the dynamic `libmysql.lib` library, which is just a wrapper to load in `libmysql.dll` on demand, or link with the static `mysqlclient.lib` library.

The MySQL client libraries are compiled as threaded libraries, so you should also compile your code to be multi-threaded.

2.10. Post-Installation Setup and Testing

After installing MySQL, there are some issues that you should address. For example, on Unix, you should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. Optionally, you can create time zone tables to enable recognition of named time zones.

The following sections include post-installation procedures that are specific to Windows systems and to Unix systems. Another section, Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”, applies to all platforms; it describes what to do if you have trouble getting the server to start. Section 2.10.3, “Securing the Initial MySQL Accounts”, also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 5.4, “The MySQL Access Privilege System”, and Section 5.5, “MySQL User Account Management”.

2.10.1. Windows Post-Installation Procedures

On Windows, the data directory and the grant tables do not have to be created. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. It is unnecessary to run the `mysql_install_db` script that is used on Unix. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See Section 2.3.3, “Using the MySQL Installation Wizard”.) Otherwise, use the password-assignment procedure given in Section 2.10.3, “Securing the Initial MySQL Accounts”.

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.9, “Starting the Server for the First Time”), and then issue the following commands to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
C:\> C:\mysql\bin\mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| test               |
+--------------------+

C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| general_log               |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| host                      |
| plugin                    |
| proc                      |
| procs_priv                |
| servers                   |
| slow_log                  |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+

C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM db" mysql
+------+-------+------+
| host | db    | user |
+------+-------+------+
| %    | test% |      |
+------+-------+------+
```

You may need to specify a different directory from the one shown; if you used the Windows Installation Wizard, then the default directory is `C:\Program Files\MySQL\MySQL Server 6.0`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 6.0\bin`. See Section 2.3.3, “Using the MySQL Installation Wizard”, for more information.

If you have already secured the initial MySQL accounts, you may need to use the `-u` and `-p` options to supply a user name and password to the `mysqlshow` and `mysql` client programs; otherwise the programs may fail with an error, or you may not be able to view all databases. For example, if you have assigned the password “secretpass” to the MySQL `root` account, then you can invoke `mysqlshow` and `mysql` as shown here:

```
C:\> C:\mysql\bin\mysqlshow -uroot -psecretpass
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| test               |
+--------------------+

C:\> C:\mysql\bin\mysqlshow -uroot -psecretpass mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| general_log               |
| help_category             |
| help_keyword              |
```

```
| help_relation             |
| help_topic                |
| host                      |
| plugin                    |
| proc                      |
| procs_priv                |
| servers                   |
| slow_log                  |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+

C:\> C:\mysql\bin\mysql -uroot -psecretpass -e "SELECT Host,Db,User FROM db" mysql
+------+-------+------+
| host | db    | user |
+------+-------+------+
| %    | test% |      |
+------+-------+------+
```

For more information about these programs, see Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”, and Section 4.5.1, “mysql — The MySQL Command-Line Tool”.

If you are running a version of Windows that supports services and you want the MySQL server to run automatically when Windows starts, see Section 2.3.11, “Starting MySQL as a Windows Service”.

2.10.2. Unix Post-Installation Procedures

After installing MySQL on Unix, you need to initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the mysql_install_db program. For some installation methods, this program is run for you automatically:

- If you install MySQL on Linux using RPM distributions, the server RPM runs mysql_install_db.
- If you install MySQL on Mac OS X using a PKG distribution, the installer runs mysql_install_db.

Otherwise, you'll need to run mysql_install_db yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and then start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

After you complete the procedure and have the server running, you should assign passwords to the accounts created by mysql_install_db. Instructions for doing so are given in Section 2.10.3, “Securing the Initial MySQL Accounts”.

In the examples shown here, the server runs under the user ID of the mysql login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location into the top-level directory of your MySQL installation, represented here by *BASEDIR*:

   ```
   shell> cd BASEDIR
   ```

   BASEDIR is likely to be something like /usr/local/mysql or /usr/local. The following steps assume that you are located in this directory.

2. If necessary, run the mysql_install_db program to set up the initial MySQL grant tables containing the privileges that determine how users are allowed to connect to the server. You'll need to do this if you used a distribution type for which the installation procedure doesn't run the program for you.

   Typically, mysql_install_db needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation, However, mysql_install_db does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

   To initialize the grant tables, use one of the following commands, depending on whether mysql_install_db is located in the bin or scripts directory:

   ```
   shell> bin/mysql_install_db --user=mysql
   ```

```
shell> scripts/mysql_install_db --user=mysql
```

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> bin/mysql_install_db --user=mysql \
         --basedir=/opt/mysql/mysql \
         --datadir=/opt/mysql/mysql/data
```

The `mysql_install_db` script creates the server's data directory. Under the data directory, it creates directories for the `mysql` database that holds all database privileges and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. A description of their initial privileges is given in Section 2.10.3, "Securing the Initial MySQL Accounts". Briefly, these privileges allow the MySQL `root` user to do anything, and allow anybody to create or use databases with a name of `test` or starting with `test_`.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, the `--user` option should be used as shown if you run `mysql_install_db` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

`mysql_install_db` creates several tables in the `mysql` database, including `user`, `db`, `host`, `tables_priv`, `columns_priv`, `func`, and others. See Section 5.4, "The MySQL Access Privilege System", for a complete listing and description of these tables.

If you don't want to have the `test` database, you can remove it with `mysqladmin -u root drop test` after starting the server.

If you have trouble with `mysql_install_db` at this point, see Section 2.10.2.1, "Problems Running `mysql_install_db`".

3. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, the `--user` option should be used as shown if you run `mysqld_safe` as system `root`. Otherwise, you should execute the script while logged in to the system as `mysql`, in which case you can omit the `--user` option from the command.

Further instructions for running MySQL as an unprivileged user are given in Section 5.3.5, "How to Run MySQL as a Normal User".

If you neglected to create the grant tables before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

If you have other problems starting the server, see Section 2.10.2.3, "Starting and Troubleshooting the MySQL Server".

4. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin  Ver 14.12 Distrib 6.0.12, for pc-linux-gnu on i686
...

Server version          6.0.12
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

5. Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

6. Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql --log &
```

If `mysqld_safe` fails, see Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”.

7. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----------+
| Databases |
+-----------+
| mysql     |
| test      |
+-----------+

shell> bin/mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| func                      |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| host                      |
| proc                      |
| procs_priv                |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+

shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
+------+--------+------+
| host | db     | user |
+------+--------+------+
| %    | test   |      |
| %    | test_% |      |
+------+--------+------+
```

8. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```
DBI
DBD::mysql
Data::Dumper
Data::ShowTable
```

These modules can be obtained from CPAN (http://www.cpan.org/). See also Section 2.14.1, “Installing Perl on Unix”.

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you don't have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate benchmark RPM files named `mysql-bench-`*`VERSION`*`.i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vvf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

9. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, so you should assign passwords using the instructions found in Section 2.10.3, “Securing the Initial MySQL Accounts”.

The MySQL 6.0 installation procedure creates time zone tables in the `mysql` database. However, you must populate the tables manually using the instructions in Section 9.7, “MySQL Server Time Zone Support”.

2.10.2.1. Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> bin/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

  You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

  ```
  Starting mysqld daemon with databases from XXXXXX
  mysqld ended
  ```

  In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` didn't start. If you do not understand what happened, include the log when you post a bug report. See Section 1.6, “How to Report Bugs or Problems”.

- **There is a `mysqld` process running**

  This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

  This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

  ```
  Can't start server: Bind on TCP/IP port:
  Address already in use
  Can't start server: Bind on unix socket...
  ```

  For instructions on setting up multiple servers, see Section 5.6, “Running Multiple MySQL Servers on the Same Machine”.

- **You do not have write access to the `/tmp` directory**

  If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory), an error occurs when you run `mysql_install_db` or the `mysqld` server.

  You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *`some_tmp_dir`* is the full path name to some directory for which you have write permission:

  ```
  shell> TMPDIR=/some_tmp_dir/
  shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
  shell> export TMPDIR MYSQL_UNIX_PORT
  ```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> bin/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See Section B.1.4.5, "How to Protect or Change the MySQL Unix Socket File", and Section 2.13, "Environment Variables".

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

  If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

  ```
  shell> bin/mysql_install_db --user=mysql
  shell> bin/mysql -u root < your_script_file
  ```

  By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you're just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

  To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

- You can start `mysqld` manually using the `--skip-grant-tables` option and add the privilege information yourself using `mysql`:

  ```
  shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
  shell> bin/mysql mysql
  ```

  From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

  Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

2.10.2.2. Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- By invoking `mysqld` directly. This works on any platform.
- By running the MySQL server as a Windows service. The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see Section 2.3.11, "Starting MySQL as a Windows Service".
- By invoking `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See Section 4.3.2, "`mysqld_safe` — MySQL Server Startup Script".
- By invoking `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories, where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 4.3.3, "`mysql.server` — MySQL Server Startup Script".
- On Mac OS X, you can install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See Section 2.5, "Installing MySQL on Mac OS X", for details.

The `mysqld_safe` and `mysql.server` scripts and the Mac OS X Startup Item can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a non-standard location. Modify it to `cd` into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-`*`VERSION`*`.rpm`), the `mysql.server` script is installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
```

```
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

Script	Option Groups
`mysqld`	`[mysqld]`, `[server]`, `[mysqld-major_version]`
`mysqld_safe`	`[mysqld]`, `[server]`, `[mysqld_safe]`
`mysql.server`	`[mysqld]`, `[mysql.server]`, `[server]`

`[mysqld-major_version]` means that groups with names like `[mysqld-5.1]` and `[mysqld-6.0]` are read by servers having versions 5.1.x, 6.0.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 6.0.

See Section 4.2.3.2, “Using Option Files”.

2.10.2.3. Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on Unix. If you are using Windows, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.
- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `NDB`), be sure that you have them configured the way you want before starting the server:

> **MySQL Enterprise**
> For expert advice on start-up options appropriate to your circumstances, subscribe to The MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- If you are using `InnoDB` tables, see Section 13.7.2, “`InnoDB` Configuration”.

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options.

If the default locations don't match the MySQL installation layout on your system, you can override them by specifying options to

`mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not allow the server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 6.0\data` on Windows, `/usr/local/mysql/data` for a Unix binary distribution, and `/usr/local/var` for a Unix source distribution). Look in the data directory for files with names of the form *`host_name`*`.err` and *`host_name`*`.log`, where *`host_name`* is the name of your server host. Then examine the last few lines of these files. On Unix, you can use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server couldn't start.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.6, “Running Multiple MySQL Servers on the Same Machine”.)

If no other server is running, try to execute the command `telnet` *`your_host_name tcp_ip_port_number`*. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you don't get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You'll need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` option. In this case, you'll also need to specify the port number for client programs when connecting to the server via TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to allow access to the port.

If the server starts but you can't connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1       localhost
```

This problem occurs only on systems that do not have a working thread library and for which MySQL must be configured to use MIT-pthreads.

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See MySQL Internals: Porting.

2.10.3. Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables that are installed automatically.
- On Unix, the grant tables are populated by the `mysql_install_db` program. Some installation methods run this program for you. Others require that you execute it manually. For details, see Section 2.10.2, “Unix Post-Installation Procedures”.

The grant tables define the initial MySQL user accounts and their access privileges. These accounts are set up as follows:

- Accounts with the user name `root` are created. These are superuser accounts that can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` — *without a password* — and be granted all privileges.
  - On Windows, one `root` account is created; this account allows connecting from the local host only. The Windows installer will optionally create an account allowing for connections from any host only if the user selects the **ENABLE ROOT ACCESS FROM REMOTE MACHINES** option during installation.
  - On Unix, both `root` accounts are for connections from the local host. Connections must be made from the local host by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP number for the other.
- Two anonymous-user accounts are created, each with an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
  - On Windows, one anonymous account is for connections from the local host. It has no global privileges. The other is for connections from any host and has all privileges for the `test` database and for other databases with names that start with `test`.
  - On Unix, both anonymous accounts are for connections from the local host. Connections must be made from the local host by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP number for the other. These accounts have all privileges for the `test` database and for other databases with names that start with `test_`.

As noted, none of the initial accounts have passwords. This means that your MySQL installation is unprotected until you do something about it:

- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.
- You should assign a password to each MySQL `root` account.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the anonymous accounts and then for the `root` accounts. Replace “*newpwd*” in the examples with the actual password that you want to use. The instructions also cover how to remove the anonymous accounts, should you prefer not to allow anonymous access at all.

You might want to defer setting the passwords until later, so that you don't need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

Anonymous Account Password Assignment

To assign passwords to the anonymous accounts, connect to the server as `root` and then use either `SET PASSWORD` or `UPDATE`.

In either case, be sure to encrypt the password using the `PASSWORD()` function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'%' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

In the second `SET PASSWORD` statement, replace *`host_name`* with the name of the server host. This is the name that is specified in the `Host` column of the non-`localhost` record for `root` in the `user` table. If you don't know what host name this is, issue the following statement before using `SET PASSWORD`:

```
mysql> SELECT Host, User FROM mysql.user;
```

Look for the record that has `root` in the `User` column and something other than `localhost` in the `Host` column. Then use that `Host` value in the second `SET PASSWORD` statement.

Anonymous Account Removal

If you prefer to remove the anonymous accounts instead, do so as follows:

```
shell> mysql -u root
mysql> DROP USER '';
```

The `DROP` statement applies both to Windows and to Unix. On Windows, if you want to remove only the anonymous account that has the same privileges as `root`, do this instead:

```
shell> mysql -u root
mysql> DROP USER ''@'localhost';
```

That account allows anonymous access but has full privileges, so removing it improves security.

`root` Account Password Assignment

You can assign passwords to the `root` accounts in several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `mysqladmin` command-line client program
- Use the `UPDATE` statement

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue `SET PASSWORD` statements. Be sure to encrypt the password using the `PASSWORD()` function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

In the second `SET PASSWORD` statement, replace *`host_name`* with the name of the server host. This is the same host name that you used when you assigned the anonymous account passwords.

If the `user` table contains an account with `User` and `Host` values of `'root'` and `'127.0.0.1'`, use an additional `SET PASSWORD` statement to set that account's password:

```
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
```

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

These commands apply both to Windows and to Unix. In the second command, replace *`host_name`* with the name of the server host. The double quotes around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not set the password for the `'root'@'127.0.0.1'` account. To do so, use `SET PASSWORD` as shown earlier.

You can also use `UPDATE` to modify the `user` table directly. The following `UPDATE` statement assigns a password to all `root` accounts:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
    ->     WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `UPDATE` statement applies both to Windows and to Unix.

After the passwords have been set, you must supply the appropriate password whenever you connect to the server. For example, if you want to use `mysqladmin` to shut down the server, you can do so using this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

> **Note**
>
> If you forget your `root` password after setting it up, Section B.1.4.1, “How to Reset the Root Password”, covers the procedure for resetting it.

To set up additional accounts, you can use the `GRANT` statement. For instructions, see Section 5.5.2, “Adding User Accounts”.

2.11. Upgrading or Downgrading MySQL

2.11.1. Upgrading MySQL

As a general rule, to upgrade from one release series to another, you should go to the next series rather than skipping a series. To upgrade from a release series previous to MySQL 5.1, upgrade to each successive release series in turn until you have reached MySQL 5.1, and then proceed with the upgrade to MySQL 6.0. For example, if you currently are running MySQL 4.1 and wish to upgrade to a newer series, upgrade to MySQL 5.0 first before upgrading to 5.1, and so forth. For information on upgrading to MySQL 5.1, see the *MySQL 5.1 Reference Manual*.

To upgrade from MySQL 5.1 to 6.0, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables. See Section 6.1, “Database Backups”.
- Read *all* the notes in Section 2.11.1.1, “Upgrading from MySQL 5.1 to 6.0”. These notes enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed in that section require your attention *before* upgrading. Others should be dealt with *after* upgrading.
- Read Appendix C, *MySQL Change History* as well, which provides information about features that are new in MySQL 6.0 or differ from those found in MySQL 5.1.
- After you upgrade to a new version of MySQL, run `mysql_upgrade` (see Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)
- If you are running MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- If you are using replication, see Section 16.3.3, “Upgrading a Replication Setup”, for information on upgrading your replication setup.
- If you are upgrading an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different non-conflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 8.2.4, "Function Name Parsing and Resolution", for the rules describing how the server interprets references to different kinds of functions.

You can always move the MySQL format files and data files between different versions on systems with the same architecture as long as you stay within versions for the same release series of MySQL.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using MySQL 5.1.13 and want to upgrade to 6.0.10, rename your current server from `mysqld` to `mysqld-5.1.13`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If, after an upgrade, you experience problems with recompiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries.

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` extensions and the Python `MySQLdb` module.

2.11.1.1. Upgrading from MySQL 5.1 to 6.0

> **Note**
>
> It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.
>
> To upgrade to 6.0 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading.

In general, you should do the following when upgrading from MySQL 5.1 to 6.0:

- Read *all* the items in the following sections to see whether any of them might affect your applications:
  - Section 2.11.1, "Upgrading MySQL", has general update information.
  - The items in the change lists found later in this section enable you to identify upgrade issues that apply to your current MySQL installation.
  - The MySQL 6.0 change history describes significant new features you can use in 6.0 or that differ from those found in MySQL 5.1. Some of these changes may result in incompatibilities. See Section C.1, "Changes in release 6.0.x (Development)".
- Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*.

  Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Often this will involve a dump and reload, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

  For dump and reload instructions, see Section 2.11.4, "Rebuilding or Repairing Tables or Indexes". Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See Section 12.5.2.5, "`REPAIR TABLE` Syntax".
- After you upgrade to a new version of MySQL, run `mysql_upgrade` (see Section 4.4.8, "`mysql_upgrade` — Check Tables for MySQL Upgrade"). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)
- Check Section 2.11.3, "Checking Whether Table Indexes Must Be Rebuilt", to see whether changes to character sets or colla-

tions were made that affect your table indexes. If so, you will need to rebuild the affected indexes using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

- If you are running MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- If you are using replication, see Section 16.3.3, “Upgrading a Replication Setup”, for information on upgrading your replication setup.

The following lists describe changes that may affect applications and that you should watch out for when upgrading to MySQL 6.0.

Server Changes:

- **Known issue**: MySQL introduces encoding for table names that have non-ASCII characters (see Section 8.2.3, “Mapping of Identifiers to File Names”). After a binary upgrade from MySQL 5.0 to 5.1 or higher, the server recognizes names that have non-ASCII characters and adds a `#mysql50#` prefix to them.

  As of MySQL 6.0.10, `mysql_upgrade` encodes these names by executing the following command:

  ```
  mysqlcheck --all-databases --check-upgrade --fix-db-names --fix-table-names
  ```

  Prior to MySQL 6.0.10, `mysql_upgrade` does not execute this command, so you should execute it manually if you have database or table names that contain non-alphanumeric characters.

  `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 6.0, and then reload the dump file after upgrading.

- **Known issue**: Before MySQL 6.0.8, the `CHECK TABLE ... FOR UPGRADE` statement did not check for incompatible collation changes made in MySQL 5.1.24. (This also affects `mysqlcheck` and `mysql_upgrade`, which cause that statement to be executed.)

  Prior to the fix made in 6.0.8, a binary upgrade (performed without dumping tables with `mysqldump` before the upgrade and reloading the dump file after the upgrade) would corrupt tables. After the fix, `CHECK TABLE ... FOR UPGRADE` properly detects the problem and warns about tables that need repair.

  However, the fix is not backward compatible and can result in a downgrading problem under these circumstances:

  1. Perform a binary upgrade to a version of MySQL that includes the fix.
  2. Run `CHECK TABLE ... FOR UPGRADE` (or `mysqlcheck` or `mysql_upgrade`) to upgrade tables.
  3. Perform a binary downgrade to a version of MySQL that does not include the fix.

  The solution is to dump tables with `mysqldump` before the downgrade and reload the dump file after the downgrade. Alternatively, drop and recreate affected indexes after upgrading.

- **Known issue**: In connection with view creation, the server created `arc` directories inside database directories and maintained useless copies of `.frm` files there. Creation and renaming procedures of those copies as well as creation of `arc` directories has been discontinued in MySQL 6.0.8.

  This change does cause a problem when downgrading to older server versions which manifests itself under these circumstances:

  1. Create a view `v_orig` in MySQL 6.0.8 or higher.
  2. Rename the view to `v_new` and then back to `v_orig`.
  3. Downgrade to an older 6.0.x server and run `mysql_upgrade`.
  4. Try to rename `v_orig` to `v_new` again. This operation fails.

  As a workaround to avoid this problem, use either of these approaches:

  - Dump your data using `mysqldump` before downgrading and reload the dump file after downgrading.

  - Instead of renaming a view after the downgrade, drop it and recreate it.

- **Incompatible change**: Character set or collation changes were made in MySQL 6.0.1, 6.0.5, and 6.0.6 that may require table indexes to be rebuilt. For details, see Section 2.11.3, "Checking Whether Table Indexes Must Be Rebuilt".

- **Incompatible change**: From MySQL 6.0.5 to 6.0.9, the `UPDATE` statement was changed such that assigning `NULL` to a `NOT NULL` column caused an error even when strict SQL mode was not enabled. The original behavior before MySQL 6.0.5 was that such assignments caused an error only in strict SQL mode, and otherwise set the column to the implicit default value for the column data type and generated a warning. (For information about implicit default values, see Section 10.1.4, "Data Type Default Values".)

  The change caused compatibility problems for applications that relied on the original behavior. It also caused replication problems between servers that had the original behavior and those that did not, for applications that assigned `NULL` to `NOT NULL` columns in `UPDATE` statements without strict SQL mode enabled. The change was reverted in MySQL 6.0.10 so that `UPDATE` again had the original behavior. Problems can still occur if you replicate between servers that have the modified `UPDATE` behavior and those that do not.

- **Incompatible change**: In MySQL 6.0.6, a change was made to the way that the server handles prepared statements. This affects prepared statements processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client-server protocol (using the `mysql_stmt_prepare()` C API function).

  Previously, changes to metadata of tables or views referred to in a prepared statement could cause a server crash when the statement was next executed, or perhaps an error at execute time with a crash occurring later. For example, this could happen after dropping a table and recreating it with a different definition.

  Now metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Repreparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

  Repreparation is automatic, but to the extent that it occurs, performance of prepared statements is diminished.

  Table content changes (for example, with `INSERT` or `UPDATE`) do not cause repreparation, nor do `SELECT` statements.

  An incompatibility with previous versions of MySQL is that a prepared statement may now return a different set of columns or different column types from one execution to the next. For example, if the prepared statement is `SELECT * FROM t1`, altering `t1` to contain a different number of columns causes the next execution to return a number of columns different from the previous execution.

  Older versions of the client library cannot handle this change in behavior. For applications that use prepared statements with the new server, an upgrade to the new client library is strongly recommended.

  Along with this change to statement repreparation, the default value of the `table_definition_cache` system variable has been increased from 128 to 256. The purpose of this increase is to lessen the chance that prepared statements will need repreparation due to referred-to tables/views having been flushed from the cache to make room for new entries.

  A new status variable, `Com_stmt_reprepare`, has been introduced to track the number of repreparations.

- **Incompatible change**: As of MySQL 6.0.5, the server includes `dtoa`, a library for conversion between strings and numbers by David M. Gay. In MySQL, this library provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT`/`DOUBLE`) numbers.

  Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

  For additional information about the properties of `dtoa` conversions, see Section 11.2.2, "Type Conversion in Expression Evaluation".

- **Incompatible change:** `SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. As of MySQL 6.0.4, aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems for replication or loading dump files. For additional information and workarounds, see Section D.5, "Restrictions on Views".

- **Incompatible change:** As of MySQL 6.0.4, the Unicode implementation has been extended to provide support for supplementary characters that lie outside the Basic Multilingual Plane (BMP). Noteworthy features:

- `utf16` and `utf32` character sets have been added. These correspond to the UTF-16 and UTF-32 encodings of the Unicode character set, and they both support supplementary characters.
- The `utf8` character set from previous versions of MySQL has been renamed to `utf8mb3`, to reflect that its encoding uses a maximum of three bytes for multi-byte characters. (Old tables that previously used `utf8` will be reported as using `utf8mb3` after an in-place upgrade to MySQL 6.0, but otherwise work as before.)
- The new `utf8` character set in MySQL 6.0 is similar to `utf8mb3`, but its encoding allows up to four bytes per character to enable support for supplementary characters.
- The `ucs2` character set is essentially unchanged except for the inclusion of some newer BMP characters.

In most respects, upgrading from MySQL 5.1 to 6.0 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. Some examples:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum length in characters for `utf8` columns is less in MySQL 6.0 than previously.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters for `utf8` columns that can be indexed is less in MySQL 6.0 than previously.

Consequently, if you want to upgrade tables from the old `utf8` (now `utf8mb3`) to the current `utf8`, it may be necessary to change some column or index definitions.

For additional details about the new Unicode character sets and potential incompatibilities, see Section 9.1.9, “Unicode Support”, and Section 9.1.10, “Upgrading from Previous to Current Unicode Support”.

If you use events, a known issue is that if you upgrade from MySQL 5.1 to 6.0.4 though 6.0.6, the event scheduler will not work, even after you run `mysql_upgrade`. (This is an issue only for an upgrade, not for a new installation of MySQL 6.0.x.) As of MySQL 6.0.7, `mysql_upgrade` handles upgrading the system tables properly. For this reason, avoid upgrading to MySQL 6.0.4 through 6.0.6.

- **Incompatible change**: As of MySQL 6.0.3, `DROP TABLE` is allowed only if you have acquired a `WRITE` lock with `LOCK TABLES`, or if you hold no locks, or if the table is a `TEMPORARY` table.

  Previously, if other tables were locked, you could drop a table with a read lock or no lock, which could lead to deadlocks between clients. The new stricter behavior means that some usage scenarios will fail when previously they did not.

SQL Changes:

- **Incompatible change:** Several changes were made to the processing of multiple-table `DELETE` statements:
  - Statements could not perform cross-database deletes unless the tables were referred to without using aliases. This limitation has been lifted and table aliases now are allowed.
  - Previously, alias declarations could be given for tables elsewhere than in the *`table_references`* part of the syntax. This could lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table. Example:

    ```
    DELETE FROM t1 AS a2 USING t1 AS a1 INNER JOIN t2 AS a2;
    ```

    Now alias declarations can be declared only in the *`table_references`* part. Elsewhere in the statement, alias references are allowed but not alias declarations.
  - Alias resolution was improved so that it is no longer possible to have inconsistent or ambiguous aliases for tables.

  Statements containing alias constructs that are no longer allowed must be rewritten.
- Some keywords are reserved in MySQL 6.0 that were not reserved in MySQL 5.1. See Section 8.3, “Reserved Words”.

2.11.2. Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

If you are downgrading within the same release series (for example, from 5.1.13 to 5.1.12) the general rule is that you just have to install the new binaries on top of the old ones. There is no need to do anything with the databases. As always, however, it is always

a good idea to make a backup.

The following items form a checklist of things you should do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See Section 2.11.1, “Upgrading MySQL”.
- If there is a downgrading section for that version, you should read that as well.
- To see which new features were added between the version to which you are downgrading and your current version, see the change logs (Appendix C, *MySQL Change History*).
- Check Section 2.11.3, “Checking Whether Table Indexes Must Be Rebuilt”, to see whether changes to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes affect your table indexes, you will need to rebuild the affected indexes using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

In most cases, you can move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see Section 2.11.5, “Copying MySQL Databases to Another Machine”.

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

It might also be the case that the structure of the system tables in the `mysql` database has changed and that downgrading introduces some loss of functionality or requires some adjustments. Here are some examples:

- Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.
- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.

2.11.2.1. Downgrading to MySQL 5.0

When downgrading to MySQL 5.0 from MySQL 5.1 or a later version, you should keep in mind the following issues relating to features found in MySQL 5.1 and later, but not in MySQL 5.0:

- **Event Scheduler.** MySQL 5.0 does not support scheduled events. If your databases contain scheduled event definitions, you should prevent them from being dumped when you use `mysqldump` by using the `--skip-events` option. (See Section 4.5.4, “`mysqldump` — A Database Backup Program”.)
- **Partitioning.** MySQL 5.0 does not support user-defined partitioning. If a table was created as a partitioned table in 5.1 (or if an table created in a previous version of MySQL was altered to include partitions after an upgrade to 5.1), the table is accessible after downgrade only if you do one of the following:
  - Export the table using `mysqldump` and then drop it in MySQL 5.1; import the table again following the downgrade to MySQL 5.0.
  - Prior to the downgrade, remove the table's partitioning using `ALTER TABLE table_name REMOVE PARTITIONING`.

2.11.3. Checking Whether Table Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without change by the new version. However, sometimes modifications are made to the handling of character sets or collations that change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results
- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. For information about rebuilding indexes, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug#29461 was fixed in MySQL 5.0.48, so it applies to upgrades from versions older than 5.0.48 to 5.0.48 or newer, and also to downgrades from 5.0.48 or newer to versions older than 5.0.58.

If you have tables with indexes that are affected, rebuild the indexes using the instructions given in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. (It will report: `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!`) In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see Section 12.5.2.2, “`CHECK TABLE` Syntax”.

Changes that cause index rebuilding to be necessary:

- MySQL 5.0.48 (Bug#29461)

  Affects indexes for columns that use any of these character sets: `eucjpms`, `euc_kr`, `gb2312`, `latin7`, `macce`, `ujis`

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 6.0.8 (see Bug#39585).

- MySQL 5.0.48 (Bug#27562)

  Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: `'``'` GRAVE ACCENT, `'['` LEFT SQUARE BRACKET, `'\'` REVERSE SOLIDUS, `']'` RIGHT SQUARE BRACKET, `'~'` TILDE

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 6.0.8 (see Bug#39585).

- MySQL 5.1.21 (Bug#29461)

Affects indexes for columns that use any of these character sets: `eucjpms`, `euc_kr`, `gb2312`, `latin7`, `macce`, `ujis`

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 6.0.8 (see Bug#39585).

- MySQL 5.1.23 (Bug#27562)

  Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: `'`'` GRAVE ACCENT, `'['` LEFT SQUARE BRACKET, `'\'` REVERSE SOLIDUS, `']'` RIGHT SQUARE BRACKET, `'~'` TILDE

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29, 6.0.8 (see Bug#39585).

- MySQL 5.1.24 (Bug#27877)

  Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain `'ß'` LATIN SMALL LETTER SHARP S (German).

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30, 6.0.8 (see Bug#40053).

- * MySQL 6.0.1 (WL#3664)

  Affects indexes that use the `latin2_czech_cs collation`.

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 6.0.9 (see Bug#40054).

  MySQL 6.0.5 (Bug#33452)

  Affects indexes that use the `latin2_czech_cs collation`.

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 6.0.9 (see Bug#40054).

- MySQL 6.0.5 (Bug#27877)

  Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain `'ß'` LATIN SMALL LETTER SHARP S (German).

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 6.0.8 (see Bug#40053).

- MySQL 6.0.6 (Bug#25420)

  Affects indexes for columns that use the following collations, if the columns contain the indicated characters: `big5_chinese_ci`: `'~'` TILDE or `'`'` GRAVE ACCENT; `cp866_general_ci`: `j` LATIN SMALL LETTER J; `gb2312_chinese_ci`: `'~'` TILDE; `gbk_chinese_ci`: `'~'` TILDE

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 6.0.9 (see Bug#40054).

2.11.4. Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table. This can be necessitated by changes to MySQL such as how data types are handled or changes to character set handling. For example, an error in a collation might have been corrected, necessitating a table rebuild to rebuild the indexes for character columns that use the collation. It might also be that a table repair or upgrade should be done as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`.

> **Note**
>
> If you are rebuilding tables because a different version of MySQL will not handle them after a binary upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading (using your original version of MySQL), and reload the tables *after* upgrading or downgrading (after installing the new version).
>
> If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To re-create a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
shell> mysqldump db_name t1 > dump.sql
shell> mysql db_name < dump.sql
```

To recreate all the tables in a single database, specify the database name without any following table name:

```
shell> mysqldump db_name > dump.sql
shell> mysql db_name < dump.sql
```

To recreate all tables in all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
shell> mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a statement that "changes" the table to use the storage engine that it already has. For example, if `t1` is a `MyISAM` table, use this statement:

```
mysql> ALTER TABLE t1 ENGINE = MyISAM;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you must rebuild a table because a table checking operation indicates that the table is corrupt or needs an upgrade, you can use `REPAIR TABLE` if that statement supports the table's storage engine. For example, to repair a `MyISAM` table, use this statement:

```
mysql> REPAIR TABLE t1;
```

For storage engines such as `InnoDB` that `REPAIR TABLE` does not support, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier.

For specifics about which storage engines `REPAIR TABLE` supports, see Section 12.5.2.5, "`REPAIR TABLE` Syntax".

2.11.5. Copying MySQL Databases to Another Machine

You can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 13.5, "The `MyISAM` Storage Engine".

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, *`DUMPDIR`* represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the *DUMPDIR* directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name           # create database
shell> cat DUMPDIR/*.sql | mysql db_name   # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt   # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

2.12. Operating System-Specific Notes

2.12.1. Linux Notes

This section discusses issues that have been found to occur on Linux. The first few subsections describe general operating system-related issues, problems that can occur when using binary or source distributions, and post-installation issues. The remaining subsections discuss problems that occur with Linux on specific platforms.

Note that most of these problems occur on older versions of Linux. If you are running a recent version, you may see none of them.

2.12.1.1. Linux Operating System Notes

MySQL needs at least Linux version 2.0.

> **Warning**
>
> We have seen some strange problems with Linux 2.2.14 and MySQL on SMP systems. We also have reports from some MySQL users that they have encountered serious stability problems using MySQL with kernel 2.2.14. If you are using this kernel, you should upgrade to 2.2.19 (or newer) or to a 2.4 kernel. If you have a multiple-CPU box, you should seriously consider using 2.4 because it gives you a significant speed boost. Your system should be more stable.

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

2.12.1.2. Linux Binary Distribution Notes

The Linux-Intel binary and RPM releases of MySQL are configured for the highest possible speed. We are always trying to use the fastest stable compiler available.

The binary release is linked with `-static`, which means you do not normally need to worry about which version of the system libraries you have. You need not install LinuxThreads, either. A program linked with `-static` is slightly larger than a dynamically linked program, but also slightly faster (3-5%). However, one problem with a statically linked program is that you can't use user-defined functions (UDFs). If you are going to write or use UDFs (this is something for C or C++ programmers only), you must compile MySQL yourself using dynamic linking.

A known issue with binary distributions is that on older Linux systems that use `libc` (such as Red Hat 4.x or Slackware), you get some (non-fatal) issues with host name resolution. If your system uses `libc` rather than `glibc2`, you probably will encounter some difficulties with host name resolution and `getpwnam()`. This happens because `glibc` (unfortunately) depends on some external libraries to implement host name resolution and `getpwent()`, even when compiled with `-static`. These problems manifest themselves in two ways:

- You may see the following error message when you run `mysql_install_db`:

  ```
  Sorry, the host 'xxxx' could not be looked up
  ```

  You can deal with this by executing `mysql_install_db --force`, which does not execute the `resolveip` test in `mysql_install_db`. The downside is that you cannot use host names in the grant tables: except for `localhost`, you must use IP numbers instead. If you are using an old version of MySQL that does not support `--force`, you must manually remove the `resolveip` test in `mysql_install_db` using a text editor.

- You also may see the following error when you try to run `mysqld` with the `--user` option:

  ```
  getpwnam: No such file or directory
  ```

To work around this problem, start `mysqld` by using the `su` command rather than by specifying the `--user` option. This causes the system itself to change the user ID of the `mysqld` process so that `mysqld` need not do so.

Another solution, which solves both problems, is not to use a binary distribution. Obtain a MySQL source distribution (in RPM or `tar.gz` format) and install that instead.

On some Linux 2.2 versions, you may get the error `Resource temporarily unavailable` when clients make a great many new connections to a `mysqld` server over TCP/IP. The problem is that Linux has a delay between the time that you close a TCP/IP socket and the time that the system actually frees it. There is room for only a finite number of TCP/IP slots, so you encounter the resource-unavailable error if clients attempt too many new TCP/IP connections over a short period of time. For example, you may see the error when you run the MySQL `test-connect` benchmark over TCP/IP.

We have inquired about this problem a few times on different Linux mailing lists but have never been able to find a suitable resolution. The only known “fix” is for clients to use persistent connections, or, if you are running the database server and clients on the same machine, to use Unix socket file connections rather than TCP/IP connections.

2.12.1.3. Linux Source Distribution Notes

The following notes regarding `glibc` apply only to the situation when you build MySQL yourself. If you are running Linux on an x86 machine, in most cases it is much better for you to use our binary. We link our binaries against the best patched version of `glibc` we can find and with the best compiler options, in an attempt to make it suitable for a high-load server. For a typical user, even for setups with a lot of concurrent connections or tables exceeding the 2GB limit, our binary is the best choice in most cases. After reading the following text, if you are in doubt about what to do, try our binary first to determine whether it meets your needs. If you discover that it is not good enough, you may want to try your own build. In that case, we would appreciate a note about it so that we can build a better binary next time.

MySQL uses LinuxThreads on Linux. If you are using an old Linux version that doesn't have `glibc2`, you must install LinuxThreads before trying to compile MySQL. You can obtain LinuxThreads from http://dev.mysql.com/downloads/os-linux.html.

Note that `glibc` versions before and including version 2.1.1 have a fatal bug in `pthread_mutex_timedwait()` handling, which is used when `INSERT DELAYED` statements are issued. We recommend that you not use `INSERT DELAYED` before upgrading `glibc`.

Note that Linux kernel and the LinuxThread library can by default handle a maximum of 1,024 threads. If you plan to have more than 1,000 concurrent connections, you need to make some changes to LinuxThreads, as follows:

- Increase `PTHREAD_THREADS_MAX` in `sysdeps/unix/sysv/linux/bits/local_lim.h` to 4096 and decrease `STACK_SIZE` in `linuxthreads/internals.h` to 256KB. The paths are relative to the root of `glibc`. (Note that MySQL is not stable with 600-1000 connections if `STACK_SIZE` is the default of 2MB.)
- Recompile LinuxThreads to produce a new `libpthread.a` library, and relink MySQL against it.

There is another issue that greatly hurts MySQL performance, especially on SMP systems. The mutex implementation in LinuxThreads in `glibc` 2.1 is very poor for programs with many threads that hold the mutex only for a short time. This produces a paradoxical result: If you link MySQL against an unmodified LinuxThreads, removing processors from an SMP actually improves MySQL performance in many cases. We have made a patch available for `glibc` 2.1.3 to correct this behavior (http://dev.mysql.com/Downloads/Linux/linuxthreads-2.1-patch).

With `glibc` 2.2.2, MySQL uses the adaptive mutex, which is much better than even the patched one in `glibc` 2.1.3. Be warned, however, that under some conditions, the current mutex code in `glibc` 2.2.2 overspins, which hurts MySQL performance. The likelihood that this condition occurs can be reduced by re-nicing the `mysqld` process to the highest priority. We have also been able to correct the overspin behavior with a patch, available at http://dev.mysql.com/Downloads/Linux/linuxthreads-2.2.2.patch. It combines the correction of overspin, maximum number of threads, and stack spacing all in one. You need to apply it in the `linuxthreads` directory with `patch -p0 </tmp/linuxthreads-2.2.2.patch`. We hope it is included in some form in future releases of `glibc` 2.2. In any case, if you link against `glibc` 2.2.2, you still need to correct `STACK_SIZE` and `PTHREAD_THREADS_MAX`. We hope that the defaults is corrected to some more acceptable values for high-load MySQL setup in the future, so that the commands needed to produce your own build can be reduced to `./configure; make; make install`.

We recommend that you use these patches to build a special static version of `libpthread.a` and use it only for statically linking against MySQL. We know that these patches are safe for MySQL and significantly improve its performance, but we cannot say anything about their effects on other applications. If you link other applications that require LinuxThreads against the patched static version of the library, or build a patched shared version and install it on your system, you do so at your own risk.

If you experience any strange problems during the installation of MySQL, or with some common utilities hanging, it is very likely

that they are either library or compiler related. If this is the case, using our binary resolves them.

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`).
- Copy `libmysqclient.so` to `/usr/lib`.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you are using the Fujitsu compiler (`fcc/FCC`), you may have some problems compiling MySQL because the Linux header files are very `gcc` oriented. The following `configure` line should work with `fcc/FCC`:

```
CC=fcc CFLAGS="-O -K fast -K lib -K omitfp -Kpreex -D_GNU_SOURCE \
    -DCONST=const -DNO_STRTOLL_PROTO" \
CXX=FCC CXXFLAGS="-O -K fast -K lib \
    -K omitfp -K preex --no_exceptions --no_rtti -D_GNU_SOURCE \
    -DCONST=const -Dalloca=__builtin_alloca -DNO_STRTOLL_PROTO \
    '-D_EXTERN_INLINE=static __inline'" \
./configure \
    --prefix=/usr/local/mysql --enable-assembler \
    --with-mysqld-ldflags=-all-static --disable-shared \
    --with-low-memory
```

2.12.1.4. Linux Post-Installation Notes

`mysql.server` can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

If MySQL cannot open enough files or connections, it may be that you have not configured Linux to handle enough files.

In Linux 2.2 and onward, you can check the number of allocated file handles as follows:

```
shell> cat /proc/sys/fs/file-max
shell> cat /proc/sys/fs/dquot-max
shell> cat /proc/sys/fs/super-max
```

If you have more than 16MB of memory, you should add something like the following to your init scripts (for example, `/etc/init.d/boot.local` on SuSE Linux):

```
echo 65536 > /proc/sys/fs/file-max
echo 8192 > /proc/sys/fs/dquot-max
echo 1024 > /proc/sys/fs/super-max
```

You can also run the `echo` commands from the command line as `root`, but these settings are lost the next time your computer restarts.

Alternatively, you can set these parameters on startup by using the `sysctl` tool, which is used by many Linux distributions (including SuSE Linux 8.0 and later). Put the following values into a file named `/etc/sysctl.conf`:

```
# Increase some values for MySQL
fs.file-max = 65536
fs.dquot-max = 8192
fs.super-max = 1024
```

You should also add the following to `/etc/my.cnf`:

```
[mysqld_safe]
open-files-limit=8192
```

This should allow the server a limit of 8,192 for the combined number of connections and open files.

The `STACK_SIZE` constant in LinuxThreads controls the spacing of thread stacks in the address space. It needs to be large enough so that there is plenty of room for each individual thread stack, but small enough to keep the stack of some threads from running in-

to the global `mysqld` data. Unfortunately, as we have experimentally discovered, the Linux implementation of `mmap()` successfully unmaps a mapped region if you ask it to map out an address currently in use, zeroing out the data on the entire page instead of returning an error. So, the safety of `mysqld` or any other threaded application depends on the "gentlemanly" behavior of the code that creates threads. The user must take measures to make sure that the number of running threads at any given time is sufficiently low for thread stacks to stay away from the global heap. With `mysqld`, you should enforce this behavior by setting a reasonable value for the `max_connections` variable.

If you build MySQL yourself, you can patch LinuxThreads for better stack use. See Section 2.12.1.3, "Linux Source Distribution Notes". If you do not want to patch LinuxThreads, you should set `max_connections` to a value no higher than 500. It should be even less if you have a large key buffer, large heap tables, or some other things that make `mysqld` allocate a lot of memory, or if you are running a 2.2 kernel with a 2GB patch. If you are using our binary or RPM version, you can safely set `max_connections` at 1500, assuming no large key buffer or heap tables with lots of data. The more you reduce `STACK_SIZE` in LinuxThreads the more threads you can safely create. We recommend values between 128KB and 256KB.

If you use a lot of concurrent connections, you may suffer from a "feature" in the 2.2 kernel that attempts to prevent fork bomb attacks by penalizing a process for forking or cloning a child. This causes MySQL not to scale well as you increase the number of concurrent clients. On single-CPU systems, we have seen this manifest as very slow thread creation; it may take a long time to connect to MySQL (as long as one minute), and it may take just as long to shut it down. On multiple-CPU systems, we have observed a gradual drop in query speed as the number of clients increases. In the process of trying to find a solution, we have received a kernel patch from one of our users who claimed it helped for his site. This patch is available at http://dev.mysql.com/Downloads/Patches/linux-fork.patch. We have done rather extensive testing of this patch on both development and production systems. It has significantly improved MySQL performance without causing any problems and we recommend it to our users who still run high-load servers on 2.2 kernels.

This issue has been fixed in the 2.4 kernel, so if you are not satisfied with the current performance of your system, rather than patching your 2.2 kernel, it might be easier to upgrade to 2.4. On SMP systems, upgrading also gives you a nice SMP boost in addition to fixing the fairness bug.

We have tested MySQL on the 2.4 kernel on a two-CPU machine and found MySQL scales *much* better. There was virtually no slowdown on query throughput all the way up to 1,000 clients, and the MySQL scaling factor (computed as the ratio of maximum throughput to the throughput for one client) was 180%. We have observed similar results on a four-CPU system: Virtually no slowdown as the number of clients was increased up to 1,000, and a 300% scaling factor. Based on these results, for a high-load SMP server using a 2.2 kernel, we definitely recommend upgrading to the 2.4 kernel at this point.

We have discovered that it is essential to run the `mysqld` process with the highest possible priority on the 2.4 kernel to achieve maximum performance. This can be done by adding a `renice -20 $$` command to `mysqld_safe`. In our testing on a four-CPU machine, increasing the priority resulted in a 60% throughput increase with 400 clients.

We are currently also trying to collect more information on how well MySQL performs with a 2.4 kernel on four-way and eight-way systems. If you have access such a system and have done some benchmarks, please send an email message to `<benchmarks@mysql.com>` with the results. We will review them for inclusion in the manual.

If you see a dead `mysqld` server process with `ps`, this usually means that you have found a bug in MySQL or you have a corrupted table. See Section B.1.4.2, "What to Do If MySQL Keeps Crashing".

To get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. Note that you also probably need to raise the core file size by adding `ulimit -c 1000000` to `mysqld_safe` or starting `mysqld_safe` with `--core-file-size=1000000`. See Section 4.3.2, "`mysqld_safe` — MySQL Server Startup Script".

2.12.1.5. Linux x86 Notes

MySQL requires `libc` 5.4.12 or newer. It is known to work with `libc` 5.4.46. `glibc` 2.0.6 and later should also work. There have been some problems with the `glibc` RPMs from Red Hat, so if you have problems, check whether there are any updates. The `glibc` 2.0.7-19 and 2.0.7-29 RPMs are known to work.

If you are using Red Hat 8.0 or a new `glibc` 2.2.x library, you may see `mysqld` die in `gethostbyaddr()`. This happens because the new `glibc` library requires a stack size greater than 128KB for this call. To fix the problem, start `mysqld` with the `--thread-stack=192K` option. (Use `-O thread_stack=192K` before MySQL 4.) This stack size is the default on MySQL 4.0.10 and above, so you should not see the problem.

If you are using `gcc` 3.0 and above to compile MySQL, you must install the `libstdc++v3` library before compiling MySQL; if you don't do this, you get an error about a missing `__cxa_pure_virtual` symbol during linking.

On some older Linux distributions, `configure` may produce an error like this:

```
Syntax error in sched.h. Change _P to __P in the
/usr/include/sched.h file.
See the Installation chapter in the Reference Manual.
```

Just do what the error message says. Add an extra underscore to the `_P` macro name that has only one underscore, and then try again.

You may get some warnings when compiling. Those shown here can be ignored:

```
mysqld.cc -o objs-thread/mysqld.o
mysqld.cc: In function `void init_signals()':
mysqld.cc:315: warning: assignment of negative value `-1' to
`long unsigned int'
mysqld.cc: In function `void * signal_hand(void *)':
mysqld.cc:346: warning: assignment of negative value `-1' to
`long unsigned int'
```

If `mysqld` always dumps core when it starts, the problem may be that you have an old `/lib/libc.a`. Try renaming it, and then remove `sql/mysqld` and do a new `make install` and try again. This problem has been reported on some Slackware installations.

If you get the following error when linking `mysqld`, it means that your `libg++.a` is not installed correctly:

```
/usr/lib/libc.a(putc.o): In function `_IO_putc':
putc.o(.text+0x0): multiple definition of `_IO_putc'
```

You can avoid using `libg++.a` by running `configure` like this:

```
shell> CXX=gcc ./configure
```

2.12.1.6. Linux SPARC Notes

In some implementations, `readdir_r()` is broken. The symptom is that the `SHOW DATABASES` statement always returns an empty set. This can be fixed by removing `HAVE_READDIR_R` from `config.h` after configuring and before compiling.

2.12.1.7. Linux Alpha Notes

We have tested MySQL 6.0 on Alpha with our benchmarks and test suite, and it appears to work well.

We currently build the MySQL binary packages on SuSE Linux 7.0 for AXP, kernel 2.4.4-SMP, Compaq C compiler (V6.2-505) and Compaq C++ compiler (V6.3-006) on a Compaq DS20 machine with an Alpha EV6 processor.

You can find the preceding compilers at http://www.support.compaq.com/alpha-tools/. By using these compilers rather than `gcc`, we get about 9-14% better MySQL performance.

For MySQL on Alpha, we use the `-arch generic` flag to our compile options, which ensures that the binary runs on all Alpha processors. We also compile statically to avoid library problems. The `configure` command looks like this:

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx \
CXXFLAGS="-fast -arch generic -noexceptions -nortti" \
./configure --prefix=/usr/local/mysql --disable-shared \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --with-mysqld-ldflags=-non_shared --with-client-ldflags=-non_shared
```

Some known problems when running MySQL on Linux-Alpha:

- Debugging threaded applications like MySQL does not work with `gdb 4.18`. You should use `gdb` 5.1 instead.
- If you try linking `mysqld` statically when using `gcc`, the resulting image dumps core at startup time. In other words, *do not* use `--with-mysqld-ldflags=-all-static` with `gcc`.

2.12.1.8. Linux PowerPC Notes

MySQL should work on MkLinux with the newest `glibc` package (tested with `glibc` 2.0.7).

2.12.1.9. Linux MIPS Notes

To get MySQL to work on Qube2 (Linux Mips), you need the newest `glibc` libraries. `glibc-2.0.7-29C2` is known to work. You must also use `gcc` 2.95.2 or newer).

2.12.1.10. Linux IA-64 Notes

To get MySQL to compile on Linux IA-64, we use the following `configure` command for building with `gcc` 2.96:

```
CC=gcc \
CFLAGS="-O3 -fno-omit-frame-pointer" \
CXX=gcc \
```

```
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    "--with-comment=Official MySQL binary" \
    --with-extra-charsets=complex
```

On IA-64, the MySQL client binaries use shared libraries. This means that if you install our binary distribution at a location other than `/usr/local/mysql`, you need to add the path of the directory where you have `libmysqlclient.so` installed either to the `/etc/ld.so.conf` file or to the value of your `LD_LIBRARY_PATH` environment variable.

See Section B.1.3.1, “Problems Linking to the MySQL Client Library”.

2.12.1.11. SELinux Notes

RHEL4 comes with SELinux, which supports tighter access control for processes. If SELinux is enabled (`SELINUX` in `/etc/selinux/config` is set to `enforcing`, `SELINUXTYPE` is set to either `targeted` or `strict`), you might encounter problems installing MySQL AB RPM packages.

Red Hat has an update that solves this. It involves an update of the “security policy” specification to handle the install structure of the RPMs provided by MySQL AB. For further information, see https://bugzilla.redhat.com/bugzilla/show_bug.cgi?id=167551 and http://rhn.redhat.com/errata/RHBA-2006-0049.html.

The preceding discussion applies only to RHEL4. The patch is unnecessary for RHEL5.

2.12.2. Mac OS X Notes

On Mac OS X, `tar` cannot handle long file names. If you need to unpack a `.tar.gz` distribution, use `gnutar` instead.

2.12.2.1. Mac OS X 10.x (Darwin)

MySQL should work without major problems on Mac OS X 10.x (Darwin).

Known issues:

- If you have problems with performance under heavy load, try using the `--skip-thread-priority` option to `mysqld`. This runs all threads with the same priority. On Mac OS X, this gives better performance, at least until Apple fixes its thread scheduler.
- The connection times (`wait_timeout`, `interactive_timeout` and `net_read_timeout`) values are not honored.

  This is probably a signal handling problem in the thread library where the signal doesn't break a pending read and we hope that a future update to the thread libraries will fix this.

Our binary for Mac OS X is compiled on Darwin 6.3 with the following `configure` line:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc \
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile --disable-shared
```

See Section 2.5, “Installing MySQL on Mac OS X”.

2.12.2.2. Mac OS X Server 1.2 (Rhapsody)

For current versions of Mac OS X Server, no operating system changes are necessary before compiling MySQL. Compiling for the Server platform is the same as for the client version of Mac OS X.

For older versions (Mac OS X Server 1.2, a.k.a. Rhapsody), you must first install a pthread package before trying to configure MySQL.

See Section 2.5, “Installing MySQL on Mac OS X”.

2.12.3. Solaris Notes

For information about installing MySQL on Solaris using PKG distributions, see Section 2.6, “Installing MySQL on Solaris”.

On Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long

file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

Sun native threads work only on Solaris 2.5 and higher. For Solaris 2.4 and earlier, MySQL automatically uses MIT-pthreads. See Section 2.9.5, "MIT-pthreads Notes".

If you get the following error from `configure`, it means that you have something wrong with your compiler installation:

```
checking for restartable system calls... configure: error can not
run test programs while cross compiling
```

In this case, you should upgrade your compiler to a newer version. You may also be able to solve this problem by inserting the following row into the `config.cache` file:

```
ac_cv_sys_restartable_syscalls=${ac_cv_sys_restartable_syscalls='no'}
```

If you are using Solaris on a SPARC, the recommended compiler is `gcc` 2.95.2 or 3.2. You can find this at http://gcc.gnu.org/. Note that `gcc` 2.8.1 does not work reliably on SPARC.

The recommended `configure` line when using `gcc` 2.95.2 is:

```
CC=gcc CFLAGS="-O3" \
CXX=gcc CXXFLAGS="-O3 -felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory \
    --enable-assembler
```

If you have an UltraSPARC system, you can get 4% better performance by adding `-mcpu=v8 -Wa,-xarch=v8plusa` to the `CFLAGS` and `CXXFLAGS` environment variables.

If you have Sun's Forte 5.0 (or newer) compiler, you can run `configure` like this:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt" \
CXX=CC CXXFLAGS="-noex -mt" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit binary with Sun's Forte compiler, use the following configuration options:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt -xarch=v9" \
CXX=CC CXXFLAGS="-noex -mt -xarch=v9" ASFLAGS="-xarch=v9" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit Solaris binary using `gcc`, add `-m64` to `CFLAGS` and `CXXFLAGS` and remove `--enable-assembler` from the `configure` line.

In the MySQL benchmarks, we obtained a 4% speed increase on UltraSPARC when using Forte 5.0 in 32-bit mode, as compared to using `gcc` 3.2 with the `-mcpu` flag.

If you create a 64-bit `mysqld` binary, it is 4% slower than the 32-bit binary, but can handle more threads and memory.

When using Solaris 10 for x86_64, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.

If you get a problem with `fdatasync` or `sched_yield`, you can fix this by adding `LIBS=-lrt` to the `configure` line

For compilers older than WorkShop 5.3, you might have to edit the `configure` script. Change this line:

```
#if !defined(__STDC__) || __STDC__ != 1
```

To this:

```
#if !defined(__STDC__)
```

If you turn on `__STDC__` with the `-Xc` option, the Sun compiler can't compile with the Solaris `pthread.h` header file. This is a Sun bug (broken compiler or broken include file).

If `mysqld` issues the following error message when you run it, you have tried to compile MySQL with the Sun compiler without enabling the `-mt` multi-thread option:

```
libc internal error: _rmutex_unlock: rmutex not held
```

Add `-mt` to `CFLAGS` and `CXXFLAGS` and recompile.

If you are using the SFW version of `gcc` (which comes with Solaris 8), you must add `/opt/sfw/lib` to the environment variable `LD_LIBRARY_PATH` before running `configure`.

If you are using the `gcc` available from `sunfreeware.com`, you may have many problems. To avoid this, you should recompile `gcc` and GNU `binutils` on the machine where you are running them.

If you get the following error when compiling MySQL with `gcc`, it means that your `gcc` is not configured for your version of Solaris:

```
shell> gcc -O3 -g -O2 -DDBUG_OFF  -o thr_alarm ...
./thr_alarm.c: In function `signal_hand':
./thr_alarm.c:556: too many arguments to function `sigwait'
```

The proper thing to do in this case is to get the newest version of `gcc` and compile it with your current `gcc` compiler. At least for Solaris 2.5, almost all binary versions of `gcc` have old, unusable include files that break all programs that use threads, and possibly other programs as well.

Solaris does not provide static versions of all system libraries (`libpthreads` and `libdl`), so you cannot compile MySQL with `--static`. If you try to do so, you get one of the following errors:

```
ld: fatal: library -ldl: not found
undefined reference to `dlopen'
cannot find -lrt
```

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`).
- Copy `libmysqclient.so` to `/usr/lib`.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you have problems with `configure` trying to link with `-lz` when you don't have `zlib` installed, you have two options:

- If you want to be able to use the compressed communication protocol, you need to get and install `zlib` from `ftp.gnu.org`.
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

If you are using `gcc` and have problems with loading user-defined functions (UDFs) into MySQL, try adding `-lgcc` to the link line for the UDF.

If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this. (Use `-O back_log=50` before MySQL 4.)

Solaris doesn't support core files for `setuid()` applications, so you can't get a core file from `mysqld` if you are using the `--user` option.

2.12.3.1. Solaris 2.7/2.8 Notes

Normally, you can use a Solaris 2.6 binary on Solaris 2.7 and 2.8. Most of the Solaris 2.6 issues also apply for Solaris 2.7 and 2.8.

MySQL should be able to detect new versions of Solaris automatically and enable workarounds for the following problems.

Solaris 2.7 / 2.8 has some bugs in the include files. You may see the following error when you use `gcc`:

```
/usr/include/widec.h:42: warning: `getwc' redefined
/usr/include/wchar.h:326: warning: this is the location of the previous
definition
```

If this occurs, you can fix the problem by copying `/usr/include/widec.h` to `.../lib/gcc-lib/os/gcc-version/include` and changing line 41 from this:

```
#if     !defined(lint) && !defined(__lint)
```

To this:

```
#if     !defined(lint) && !defined(__lint) && !defined(getwc)
```

Alternatively, you can edit `/usr/include/widec.h` directly. Either way, after you make the fix, you should remove `config.cache` and run `configure` again.

If you get the following errors when you run `make`, it is because `configure` didn't detect the `curses.h` file (probably because of the error in `/usr/include/widec.h`):

```
In file included from mysql.cc:50:
/usr/include/term.h:1060: syntax error before `,'
/usr/include/term.h:1081: syntax error before `;'
```

The solution to this problem is to do one of the following:

- Configure with `CFLAGS=-DHAVE_CURSES_H CXXFLAGS=-DHAVE_CURSES_H ./configure`.
- Edit `/usr/include/widec.h` as indicated in the preceding discussion and re-run `configure`.
- Remove the `#define HAVE_TERM` line from the `config.h` file and run `make` again.

If your linker cannot find `-lz` when linking client programs, the problem is probably that your `libz.so` file is installed in `/usr/local/lib`. You can fix this problem by one of the following methods:

- Add `/usr/local/lib` to `LD_LIBRARY_PATH`.
- Add a link to `libz.so` from `/lib`.
- If you are using Solaris 8, you can install the optional `zlib` from your Solaris 8 CD distribution.
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

2.12.3.2. Solaris x86 Notes

On Solaris 8 on x86, `mysqld` dumps core if you remove the debug symbols using `strip`.

If you are using `gcc` on Solaris x86 and you experience problems with core dumps under load, you should use the following `configure` command:

```
CC=gcc CFLAGS="-O3 -fomit-frame-pointer -DHAVE_CURSES_H" \
CXX=gcc \
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti -DHAVE_CURSES_H" \
./configure --prefix=/usr/local/mysql
```

This avoids problems with the `libstdc++` library and with C++ exceptions.

If this doesn't help, you should compile a debug version and run it with a trace file or under `gdb`. See MySQL Internals: Porting.

2.12.4. BSD Notes

This section provides information about using MySQL on variants of BSD Unix.

2.12.4.1. FreeBSD Notes

FreeBSD 4.x or newer is recommended for running MySQL, because the thread package is much more integrated. To get a secure and stable system, you should use only FreeBSD kernels that are marked `-RELEASE`.

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

It is recommended you use MIT-pthreads on FreeBSD 2.x, and native threads on FreeBSD 3 and up. It is possible to run with native threads on some late 2.2.x versions, but you may encounter problems shutting down `mysqld`.

Unfortunately, certain function calls on FreeBSD are not yet fully thread-safe. Most notably, this includes the `gethostbyname()` function, which is used by MySQL to convert host names into IP addresses. Under certain circumstances, the `mysqld` process suddenly causes 100% CPU load and is unresponsive. If you encounter this problem, try to start MySQL using the `--skip-name-resolve` option.

Alternatively, you can link MySQL on FreeBSD 4.x against the LinuxThreads library, which avoids a few of the problems that the native FreeBSD thread implementation has. For a very good comparison of LinuxThreads versus native threads, see Jeremy Zawodny's article *FreeBSD or Linux for your MySQL Server?* at http://jeremy.zawodny.com/blog/archives/000697.html.

Known problem when using LinuxThreads on FreeBSD is:

- The connection times (`wait_timeout`, `interactive_timeout` and `net_read_timeout`) values are not honored. The symptom is that persistent connections can hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

  This is probably a signal handling problem in the thread library where the signal doesn't break a pending read. This is supposed to be fixed in FreeBSD 5.0

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

The recommended way to compile and install MySQL on FreeBSD with `gcc` (2.95.2 and up) is:

```
CC=gcc CFLAGS="-O2 -fno-strength-reduce" \
    CXX=gcc CXXFLAGS="-O2 -fno-rtti -fno-exceptions \
    -felide-constructors -fno-strength-reduce" \
    ./configure --prefix=/usr/local/mysql --enable-assembler
gmake
gmake install
cd /usr/local/mysql
bin/mysql_install_db --user=mysql
bin/mysqld_safe &
```

If you notice that `configure` uses MIT-pthreads, you should read the MIT-pthreads notes. See Section 2.9.5, “MIT-pthreads Notes”.

If you get an error from `make install` that it can't find `/usr/include/pthreads`, `configure` didn't detect that you need MIT-pthreads. To fix this problem, remove `config.cache`, and then re-run `configure` with the `--with-mit-threads` option.

Be sure that your name resolver setup is correct. Otherwise, you may experience resolver delays or failures when connecting to `mysqld`. Also make sure that the `localhost` entry in the `/etc/hosts` file is correct. The file should start with a line similar to this:

```
127.0.0.1       localhost localhost.your.domain
```

FreeBSD is known to have a very low default file handle limit. See Section B.1.2.18, “'*File*' Not Found and Similar Errors”. Start the server by using the `--open-files-limit` option for `mysqld_safe`, or raise the limits for the `mysqld` user in `/etc/login.conf` and rebuild it with `cap_mkdb /etc/login.conf`. Also be sure that you set the appropriate class for this user in the password file if you are not using the default (use `chpass mysqld-user-name`). See Section 4.3.2,

`mysqld_safe` — MySQL Server Startup Script".

FreeBSD limits the size of a process to 512MB, even if you have much more RAM available on the system. So you may get an error such as this:

```
Out of memory (Needed 16391 bytes)
```

In current versions of FreeBSD (at least 4.x and greater), you may increase this limit by adding the following entries to the `/boot/loader.conf` file and rebooting the machine (these are not settings that can be changed at run time with the `sysctl` command):

```
kern.maxdsiz="1073741824" # 1GB
kern.dfldsiz="1073741824" # 1GB
kern.maxssiz="134217728" # 128MB
```

For older versions of FreeBSD, you must recompile your kernel to change the maximum data segment size for a process. In this case, you should look at the `MAXDSIZ` option in the `LINT` config file for more information.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 2.13, "Environment Variables".

2.12.4.2. NetBSD Notes

To compile on NetBSD, you need GNU `make`. Otherwise, the build process fails when `make` tries to run `lint` on C++ files.

2.12.4.3. OpenBSD 2.5 Notes

On OpenBSD 2.5, you can compile MySQL with native threads with the following options:

```
CFLAGS=-pthread CXXFLAGS=-pthread ./configure --with-mit-threads=no
```

2.12.4.4. BSD/OS Version 2.x Notes

If you get the following error when compiling MySQL, your `ulimit` value for virtual memory is too low:

```
item_func.h: In method
`Item_func_ge::Item_func_ge(const Item_func_ge &)':
item_func.h:28: virtual memory exhausted
make[2]: *** [item_func.o] Error 1
```

Try using `ulimit -v 80000` and run `make` again. If this doesn't work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

If you are using `gcc`, you may also use have to use the `--with-low-memory` flag for `configure` to be able to compile `sql_yacc.cc`.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 2.13, "Environment Variables".

2.12.4.5. BSD/OS Version 3.x Notes

Upgrade to BSD/OS 3.1. If that is not possible, install BSDIpatch M300-038.

Use the following command when configuring MySQL:

```
env CXX=shlicc++ CC=shlicc2 \
./configure \
    --prefix=/usr/local/mysql \
    --localstatedir=/var/mysql \
    --without-perl \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

The following is also known to work:

```
env CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure \
    --prefix=/usr/local/mysql \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

You can change the directory locations if you wish, or just use the defaults by not specifying any locations.

If you have problems with performance under heavy load, try using the `--skip-thread-priority` option to `mysqld`. This

runs all threads with the same priority. On BSDI 3.1, this gives better performance, at least until BSDI fixes its thread scheduler.

If you get the error `virtual memory exhausted` while compiling, you should try using `ulimit -v 80000` and running `make` again. If this doesn't work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

2.12.4.6. BSD/OS Version 4.x Notes

BSDI 4.x has some thread-related bugs. If you want to use MySQL on this, you should install all thread-related patches. At least M400-023 should be installed.

On some BSDI 4.x systems, you may get problems with shared libraries. The symptom is that you can't execute any client programs, for example, `mysqladmin`. In this case, you need to reconfigure not to use shared libraries with the `--disable-shared` option to configure.

Some customers have had problems on BSDI 4.0.1 that the `mysqld` binary after a while can't open tables. This occurs because some library/system-related bug causes `mysqld` to change current directory without having asked for that to happen.

The fix is to either upgrade MySQL to at least version 3.23.34 or, after running `configure`, remove the line `#define HAVE_REALPATH` from `config.h` before running `make`.

Note that this means that you can't symbolically link a database directories to another database directory or symbolic link a table to another database on BSDI. (Making a symbolic link to another disk is okay).

2.12.5. Other Unix Notes

2.12.5.1. HP-UX Version 10.20 Notes

If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

There are a couple of small problems when compiling MySQL on HP-UX. We recommend that you use `gcc` instead of the HP-UX native compiler, because `gcc` produces better code.

We recommend using `gcc` 2.95 on HP-UX. Don't use high optimization flags (such as `-O6`) because they may not be safe on HP-UX.

The following `configure` line should work with `gcc` 2.95:

```
CFLAGS="-I/opt/dce/include -fpic" \
CXXFLAGS="-I/opt/dce/include -felide-constructors -fno-exceptions \
-fno-rtti" \
CXX=gcc \
./configure --with-pthread \
    --with-named-thread-libs='-ldce' \
    --prefix=/usr/local/mysql --disable-shared
```

The following `configure` line should work with `gcc` 3.1:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc \
CXXFLAGS="-DHPUX -I/opt/dce/include -felide-constructors \
    -fno-exceptions -fno-rtti -O3 -fPIC" \
./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile  --with-pthread \
    --with-named-thread-libs=-ldce --with-lib-ccflags=-fPIC
    --disable-shared
```

2.12.5.2. HP-UX Version 11.x Notes

If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative
PHNE_22397 ARPA cumulative
```

This solves the problem of getting `EWOULDBLOCK` from `recv()` and `EBADF` from `accept()` in threaded applications.

If you are using `gcc` 2.95.1 on an unpatched HP-UX 11.x system, you may get the following error:

```
In file included from /usr/include/unistd.h:11,
                 from ../include/global.h:125,
                 from mysql_priv.h:15,
                 from item.cc:19:
/usr/include/sys/unistd.h:184: declaration of C function ...
/usr/include/sys/pthread.h:440: previous declaration ...
In file included from item.h:306,
                 from mysql_priv.h:158,
                 from item.cc:19:
```

The problem is that HP-UX does not define `pthreads_atfork()` consistently. It has conflicting prototypes in `/usr/include/sys/unistd.h`:184 and `/usr/include/sys/pthread.h`:440.

One solution is to copy `/usr/include/sys/unistd.h` into `mysql/include` and edit `unistd.h` and change it to match the definition in `pthread.h`. Look for this line:

```
extern int pthread_atfork(void (*prepare)(), void (*parent)(),
                                          void (*child)());
```

Change it to look like this:

```
extern int pthread_atfork(void (*prepare)(void), void (*parent)(void),
                                          void (*child)(void));
```

After making the change, the following `configure` line should work:

```
CFLAGS="-fomit-frame-pointer -O3 -fpic" CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti -O3" \
./configure --prefix=/usr/local/mysql --disable-shared
```

If you are using HP-UX compiler, you can use the following command (which has been tested with `cc` B.11.11.04):

```
CC=cc CXX=aCC CFLAGS=+DD64 CXXFLAGS=+DD64 ./configure \
    --with-extra-character-set=complex
```

You can ignore any errors of the following type:

```
aCC: warning 901: unknown option: `-3': use +help for online
documentation
```

If you get the following error from `configure`, verify that you don't have the path to the K&R compiler before the path to the HP-UX C and C++ compiler:

```
checking for cc option to accept ANSI C... no
configure: error: MySQL requires an ANSI C compiler (and a C++ compiler).
Try gcc. See the Installation chapter in the Reference Manual.
```

Another reason for not being able to compile is that you didn't define the `+DD64` flags as just described.

Another possibility for HP-UX 11 is to use the MySQL binaries provided at http://dev.mysql.com/downloads/, which we have built and tested ourselves. We have also received reports that the HP-UX 10.20 binaries supplied by MySQL can be run successfully on HP-UX 11. If you encounter problems, you should be sure to check your HP-UX patch level.

2.12.5.3. IBM-AIX notes

Automatic detection of `xlC` is missing from Autoconf, so a number of variables need to be set before running `configure`. The following example uses the IBM compiler:

```
export CC="xlc_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "
export CXX="xlC_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192"
export CFLAGS="-I /usr/local/include"
export LDFLAGS="-L /usr/local/lib"
export CPPFLAGS=$CFLAGS
export CXXFLAGS=$CFLAGS

./configure --prefix=/usr/local \
               --localstatedir=/var/mysql \
               --sbindir='/usr/local/bin' \
               --libexecdir='/usr/local/bin' \
               --enable-thread-safe-client \
```

```
                --enable-large-files
```

The preceding options are used to compile the MySQL distribution that can be found at http://www-frec.bull.com/.

If you change the `-O3` to `-O2` in the preceding `configure` line, you must also remove the `-qstrict` option. This is a limitation in the IBM C compiler.

If you are using `gcc` to compile MySQL, you *must* use the `-fno-exceptions` flag, because the exception handling in `gcc` is not thread-safe! There are also some known problems with IBM's assembler that may cause it to generate bad code when used with `gcc`.

We recommend the following `configure` line with `gcc` 2.95 on AIX:

```
CC="gcc -pipe -mcpu=power -Wa,-many" \
CXX="gcc -pipe -mcpu=power -Wa,-many" \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory
```

The `-Wa,-many` option is necessary for the compile to be successful. IBM is aware of this problem but is in no hurry to fix it because of the workaround that is available. We don't know if the `-fno-exceptions` is required with `gcc` 2.95, but because MySQL doesn't use exceptions and the option generates faster code, we recommend that you should always use it with `gcc`.

If you get a problem with assembler code, try changing the `-mcpu=`*`xxx`* option to match your CPU. Typically `power2`, `power`, or `powerpc` may need to be used. Alternatively, you might need to use `604` or `604e`. We are not positive but suspect that `power` would likely be safe most of the time, even on a power2 machine.

If you don't know what your CPU is, execute a `uname -m` command. It produces a string that looks like `000514676700`, with a format of `xxyyyyyymmss` where `xx` and `ss` are always `00`, `yyyyyy` is a unique system ID and `mm` is the ID of the CPU Planar. A chart of these values can be found at http://www16.boulder.ibm.com/pseries/en_US/cmds/aixcmds5/uname.htm.

This gives you a machine type and a machine model you can use to determine what type of CPU you have.

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring as follows:

```
CFLAGS=-DDONT_USE_THR_ALARM CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti \
-DDONT_USE_THR_ALARM" \
./configure --prefix=/usr/local/mysql --with-debug \
    --with-low-memory
```

This doesn't affect the performance of MySQL, but has the side effect that you can't kill clients that are “sleeping” on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

On some versions of AIX, linking with `libbind.a` makes `getservbyname()` dump core. This is an AIX bug and should be reported to IBM.

For AIX 4.2.1 and `gcc`, you have to make the following changes.

After configuring, edit `config.h` and `include/my_config.h` and change the line that says this:

```
#define HAVE_SNPRINTF 1
```

to this:

```
#undef HAVE_SNPRINTF
```

And finally, in `mysqld.cc`, you need to add a prototype for `initgroups()`.

```
#ifdef _AIX41
extern "C" int initgroups(const char *,int);
#endif
```

For 32-bit binaries, if you need to allocate a lot of memory to the `mysqld` process, it is not enough to just use `ulimit -d unlimited`. You may also have to modify `mysqld_safe` to add a line something like this:

```
export LDR_CNTRL='MAXDATA=0x80000000'
```

You can find more information about using a lot of memory at http://publib16.boulder.ibm.com/pseries/en_US/aixprggd/genprogc/lrg_prg_support.htm.

Users of AIX 4.3 should use `gmake` instead of the `make` utility included with AIX.

As of AIX 4.1, the C compiler has been unbundled from AIX as a separate product. We recommend using `gcc` 3.3.2, which can be obtained here: ftp://ftp.software.ibm.com/aix/freeSoftware/aixtoolbox/RPMS/ppc/gcc/

The steps for compiling MySQL on AIX with `gcc` 3.3.2 are similar to those for using `gcc` 2.95 (in particular, the need to edit `config.h` and `my_config.h` after running `configure`). However, before running `configure`, you should also patch the `curses.h` file as follows:

```
/opt/freeware/lib/gcc-lib/powerpc-ibm-aix5.2.0.0/3.3.2/include/curses.h.ORIG
       Mon Dec 26 02:17:28 2005
--- /opt/freeware/lib/gcc-lib/powerpc-ibm-aix5.2.0.0/3.3.2/include/curses.h
Mon Dec 26 02:40:13 2005
***************
*** 2023,2029 ****

  #endif /* _AIX32_CURSES */
! #if defined(__USE_FIXED_PROTOTYPES__) || defined(__cplusplus) || defined
(__STRICT_ANSI__)
  extern int delwin (WINDOW *);
  extern int endwin (void);
  extern int getcurx (WINDOW *);
--- 2023,2029 ----

  #endif /* _AIX32_CURSES */
! #if 0 && (defined(__USE_FIXED_PROTOTYPES__) || defined(__cplusplus)
|| defined
(__STRICT_ANSI__))
  extern int delwin (WINDOW *);
  extern int endwin (void);
  extern int getcurx (WINDOW *);
```

2.12.5.4. SunOS 4 Notes

On SunOS 4, MIT-pthreads is needed to compile MySQL. This in turn means you need GNU `make`.

Some SunOS 4 systems have problems with dynamic libraries and `libtool`. You can use the following `configure` line to avoid this problem:

```
./configure --disable-shared --with-mysqld-ldflags=-all-static
```

When compiling `readline`, you may get warnings about duplicate defines. These can be ignored.

When compiling `mysqld`, there are some `implicit declaration of function` warnings. These can be ignored.

2.12.5.5. Alpha-DEC-UNIX Notes (Tru64)

If you are using `egcs` 1.1.2 on Digital Unix, you should upgrade to `gcc` 2.95.2, because `egcs` on DEC has some serious bugs!

When compiling threaded programs under Digital Unix, the documentation recommends using the `-pthread` option for `cc` and `cxx` and the `-lmach -lexc` libraries (in addition to `-lpthread`). You should run `configure` something like this:

```
CC="cc -pthread" CXX="cxx -pthread -O" \
./configure --with-named-thread-libs="-lpthread -lmach -lexc -lc"
```

When compiling `mysqld`, you may see a couple of warnings like this:

```
mysqld.cc: In function void handle_connections()':
mysqld.cc:626: passing long unsigned int *' as argument 3 of
accept(int,sockadddr *, int *)'
```

You can safely ignore these warnings. They occur because `configure` can detect only errors, not warnings.

If you start the server directly from the command line, you may have problems with it dying when you log out. (When you log out, your outstanding processes receive a `SIGHUP` signal.) If so, try starting the server like this:

```
nohup mysqld [options] &
```

`nohup` causes the command following it to ignore any `SIGHUP` signal sent from the terminal. Alternatively, start the server by running `mysqld_safe`, which invokes `mysqld` using `nohup` for you. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

If you get a problem when compiling `mysys/get_opt.c`, just remove the `#define _NO_PROTO` line from the start of that

file.

If you are using Compaq's CC compiler, the following `configure` line should work:

```
CC="cc -pthread"
CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed \
       -speculate all -arch host"
CXX="cxx -pthread"
CXXFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed \
         -speculate all -arch host -noexceptions -nortti"
export CC CFLAGS CXX CXXFLAGS
./configure \
    --prefix=/usr/local/mysql \
    --with-low-memory \
    --enable-large-files \
    --enable-shared=yes \
    --with-named-thread-libs="-lpthread -lmach -lexc -lc"
gnumake
```

If you get a problem with `libtool` when compiling with shared libraries as just shown, when linking `mysql`, you should be able to get around this by issuing these commands:

```
cd mysql
/bin/sh ../libtool --mode=link cxx -pthread  -O3 -DDBUG_OFF \
    -O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all \ -arch host  -DUNDEF_HAVE_GETHOSTBYNAME_R \
    -o mysql  mysql.o readline.o sql_string.o completion_hash.o \
    ../readline/libreadline.a -lcurses \
    ../libmysql/.libs/libmysqlclient.so  -lm
cd ..
gnumake
gnumake install
scripts/mysql_install_db
```

2.12.5.6. Alpha-DEC-OSF/1 Notes

If you have problems compiling and have DEC `CC` and `gcc` installed, try running `configure` like this:

```
CC=cc CFLAGS=-O CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

If you get problems with the `c_asm.h` file, you can create and use a 'dummy' `c_asm.h` file with:

```
touch include/c_asm.h
CC=gcc CFLAGS=-I./include \
CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

Note that the following problems with the `ld` program can be fixed by downloading the latest DEC (Compaq) patch kit from: http://ftp.support.compaq.com/public/unix/.

On OSF/1 V4.0D and compiler "DEC C V5.6-071 on Digital Unix V4.0 (Rev. 878)," the compiler had some strange behavior (undefined `asm` symbols). `/bin/ld` also appears to be broken (problems with `_exit undefined` errors occurring while linking `mysqld`). On this system, we have managed to compile MySQL with the following `configure` line, after replacing `/bin/ld` with the version from OSF 4.0C:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
```

With the Digital compiler "C++ V6.1-029," the following should work:

```
CC=cc -pthread
CFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
       -speculate all -arch host
CXX=cxx -pthread
CXXFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
         -speculate all -arch host -noexceptions -nortti
export CC CFLAGS CXX CXXFLAGS
./configure --prefix=/usr/mysql/mysql \
            --with-mysqld-ldflags=-all-static --disable-shared \
            --with-named-thread-libs="-lmach -lexc -lc"
```

In some versions of OSF/1, the `alloca()` function is broken. Fix this by removing the line in `config.h` that defines `'HAVE_ALLOCA'`.

The `alloca()` function also may have an incorrect prototype in `/usr/include/alloca.h`. This warning resulting from this can be ignored.

`configure` uses the following thread libraries automatically: `--with-named-thread-libs="-lpthread -lmach -`

`lexc -lc"`.

When using `gcc`, you can also try running `configure` like this:

```
CFLAGS=-D_PTHREAD_USE_D4 CXX=gcc CXXFLAGS=-O3 ./configure ...
```

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring with:

```
CFLAGS=-DDONT_USE_THR_ALARM \
CXXFLAGS=-DDONT_USE_THR_ALARM \
./configure ...
```

This does not affect the performance of MySQL, but has the side effect that you can't kill clients that are “sleeping” on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

With `gcc` 2.95.2, you may encounter the following compile error:

```
sql_acl.cc:1456: Internal compiler error in `scan_region',
at except.c:2566
Please submit a full bug report.
```

To fix this, you should change to the `sql` directory and do a cut-and-paste of the last `gcc` line, but change `-O3` to `-O0` (or add `-O0` immediately after `gcc` if you don't have any `-O` option on your compile line). After this is done, you can just change back to the top-level directory and run `make` again.

2.12.5.7. SGI Irix Notes

As of MySQL 5.0, we don't provide binaries for Irix any more.

If you are using Irix 6.5.3 or newer, `mysqld` is able to create threads only if you run it as a user that has `CAP_SCHED_MGT` privileges (such as `root`) or give the `mysqld` server this privilege with the following shell command:

```
chcap "CAP_SCHED_MGT+epi" /opt/mysql/libexec/mysqld
```

You may have to undefine some symbols in `config.h` after running `configure` and before compiling.

In some Irix implementations, the `alloca()` function is broken. If the `mysqld` server dies on some `SELECT` statements, remove the lines from `config.h` that define `HAVE_ALLOC` and `HAVE_ALLOCA_H`. If `mysqladmin create` doesn't work, remove the line from `config.h` that defines `HAVE_READDIR_R`. You may have to remove the `HAVE_TERM_H` line as well.

SGI recommends that you install all the patches on this page as a set: http://support.sgi.com/surfzone/patches/patchset/6.2_indigo.rps.html

At the very minimum, you should install the latest kernel rollup, the latest `rld` rollup, and the latest `libc` rollup.

You definitely need all the POSIX patches on this page, for pthreads support:

http://support.sgi.com/surfzone/patches/patchset/6.2_posix.rps.html

If you get the something like the following error when compiling `mysql.cc`:

```
"/usr/include/curses.h", line 82: error(1084):
invalid combination of type
```

Type the following in the top-level directory of your MySQL source tree:

```
extra/replace bool curses_bool < /usr/include/curses.h > include/curses.h
make
```

There have also been reports of scheduling problems. If only one thread is running, performance is slow. Avoid this by starting another client. This may lead to a two-to-tenfold increase in execution speed thereafter for the other thread. This is a poorly understood problem with Irix threads; you may have to improvise to find solutions until this can be fixed.

If you are compiling with `gcc`, you can use the following `configure` command:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql --enable-thread-safe-client \
    --with-named-thread-libs=-lpthread
```

On Irix 6.5.11 with native Irix C and C++ compilers ver. 7.3.1.2, the following is reported to work

```
CC=cc CXX=CC CFLAGS='-O3 -n32 -TARG:platform=IP22 -I/usr/local/include \
-L/usr/local/lib' CXXFLAGS='-O3 -n32 -TARG:platform=IP22 \
-I/usr/local/include -L/usr/local/lib' \
./configure --prefix=/usr/local/mysql --with-innodb \
    --with-libwrap=/usr/local \
    --with-named-curses-libs=/usr/local/lib/libncurses.a
```

2.12.5.8. SCO UNIX and OpenServer 5.0.x Notes

The current port is tested only on `sco3.2v5.0.5`, `sco3.2v5.0.6`, and `sco3.2v5.0.7` systems. There has also been progress on a port to `sco3.2v4.2`. Open Server 5.0.8 (Legend) has native threads and allows files greater than 2GB. The current maximum file size is 2GB.

We have been able to compile MySQL with the following `configure` command on OpenServer with `gcc` 2.95.3.

```
CC=gcc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
CXX=gcc CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-innodb \
    --with-openssl --with-vio --with-extra-charsets=complex
```

`gcc` is available at ftp://ftp.sco.com/pub/openserver5/opensrc/gnutools-5.0.7Kj.

This development system requires the OpenServer Execution Environment Supplement oss646B on OpenServer 5.0.6 and oss656B and The OpenSource libraries found in gwxlibs. All OpenSource tools are in the `opensrc` directory. They are available at ftp://ftp.sco.com/pub/openserver5/opensrc/.

We recommend using the latest production release of MySQL.

SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.[0-6] and ftp://ftp.sco.com/pub/openserverv5/507 for OpenServer 5.0.7.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer for OpenServer 5.0.x.

The maximum file size on an OpenServer 5.0.x system is 2GB.

The total memory which can be allocated for streams buffers, clists, and lock records cannot exceed 60MB on OpenServer 5.0.x.

Streams buffers are allocated in units of 4096 byte pages, clists are 70 bytes each, and lock records are 64 bytes each, so:

```
(NSTRPAGES × 4096) + (NCLIST × 70) + (MAX_FLCKREC × 64) <= 62914560
```

Follow this procedure to configure the Database Services option. If you are unsure whether an application requires this, see the documentation provided with the application.

1. Log in as `root`.
2. Enable the SUDS driver by editing the `/etc/conf/sdevice.d/suds` file. Change the `N` in the second field to a `Y`.
3. Use `mkdev aio` or the Hardware/Kernel Manager to enable support for asynchronous I/O and relink the kernel. To allow users to lock down memory for use with this type of I/O, update the aiomemlock(F) file. This file should be updated to include the names of users that can use AIO and the maximum amounts of memory they can lock down.
4. Many applications use setuid binaries so that you need to specify only a single user. See the documentation provided with the application to determine whether this is the case for your application.

After you complete this process, reboot the system to create a new kernel incorporating these changes.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

```
Value           Default         Min             Max
-----           -------         ---             ---
NBUF            0               24              450000
NHBUF           0               32              524288
NMPBUF          0               12              512
MAX_INODE       0               100             64000
MAX_FILE        0               100             64000
CTBUFSIZE       128             0               256
MAX_PROC        0               50              16000
MAX_REGION      0               500             160000
NCLIST          170             120             16640
MAXUP           100             15              16000
NOFILES         110             60              11000
NHINODE         128             64              8192
```

```
NAUTOUP         10              0               60

NUMTIM          16              1               8192
NUMTRW          16              1               8192
* Semaphore Parameters
SEMMAP          10              10              8192
SEMMNI          10              10              8192
SEMMNS          60              60              8192
SEMMNU          30              10              8192
SEMMSL          25              25              150
SEMOPM          10              10              1024
SEMUME          10              10              25
SEMVMX          32767           32767           32767
SEMAEM          16384           16384           16384
* Shared Memory Parameters
SHMMAX          524288          131072          2147483647
SHMMIN          1               1               1
SHMMNI          100             100             2000
FILE            0               100             64000
NMOUNT          0               4               256
NPROC           0               50              16000
NREGION         0               500             160000
```

We recommend setting these values as follows:

- `NOFILES` should be 4096 or 2048.
- `MAXUP` should be 2048.

To make changes to the kernel, use the `idtune` *`name parameter`* command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. For example, to change `SEMMS` to `200`, execute this command as `root`:

```
# /etc/conf/bin/idtune SEMMNS 200
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `NOFILES` and `MAXUP` should be set to at least 2048.
- `MAXPROC` should be set to at least 3000/4000 (depends on number of users) or more.
- We also recommend using the following formulas to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

  ```
  SEMMSL = 13
  ```

  13 is what has been found to be the best for both Progress and MySQL.

  ```
  SEMMNS = SEMMSL × number of db servers to be run on the system
  ```

  Set `SEMMNS` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

  ```
  SEMMNU = SEMMNS
  ```

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

You need to at least install the SCO OpenServer Linker and Application Development Libraries or the OpenServer Development System to use gcc. You cannot use the GCC Dev system without installing one of these.

You should get the FSU Pthreads package and install it first. This can be found at http://moss.csc.ncsu.edu/~mueller/ftp/pub/PART/pthreads.tar.gz. You can also get a precompiled package from ftp://ftp.zenez.com/pub/zenez/prgms/FSU-threads-3.14.tar.gz.

FSU Pthreads can be compiled with SCO Unix 4.2 with tcpip, or using OpenServer 3.0 or Open Desktop 3.0 (OS 3.0 ODT 3.0) with the SCO Development System installed using a good port of GCC 2.5.x. For ODT or OS 3.0, you need a good port of GCC 2.5.x. There are a lot of problems without a good port. The port for this product requires the SCO Unix Development system. Without it, you are missing the libraries and the linker that is needed. You also need SCO-3.2v4.2-includes.tar.gz. This file contains the changes to the SCO Development include files that are needed to get MySQL to build. You need to replace the existing system include files with these modified header files. They can be obtained from ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

To build FSU Pthreads on your system, all you should need to do is run GNU make. The Makefile in FSU-threads-3.14.tar.gz is set up to make FSU-threads.

You can run ./configure in the threads/src directory and select the SCO OpenServer option. This command copies Makefile.SCO5 to Makefile. Then run make.

To install in the default /usr/include directory, log in as root, and then cd to the thread/src directory and run make install.

Remember that you must use GNU make to build MySQL.

> **Note**
>
> If you don't start mysqld_safe as root, you should get only the default 110 open files per process. mysqld writes a note about this in the log file.

With SCO 3.2V4.2, you should use FSU Pthreads version 3.14 or newer. The following configure command should work:

```
CFLAGS="-D_XOPEN_XPG4" CXX=gcc CXXFLAGS="-D_XOPEN_XPG4" \
./configure \
    --prefix=/usr/local/mysql \
    --with-named-thread-libs="-lgthreads -lsocket -lgen -lgthreads" \
    --with-named-curses-libs="-lcurses"
```

You may have problems with some include files. In this case, you can find new SCO-specific include files at ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

You should unpack this file in the include directory of your MySQL source tree.

SCO development notes:

- MySQL should automatically detect FSU Pthreads and link mysqld with -lgthreads -lsocket -lgthreads.
- The SCO development libraries are re-entrant in FSU Pthreads. SCO claims that its library functions are re-entrant, so they must be re-entrant with FSU Pthreads. FSU Pthreads on OpenServer tries to use the SCO scheme to make re-entrant libraries.
- FSU Pthreads (at least the version at ftp://ftp.zenez.com) comes linked with GNU malloc. If you encounter problems with memory usage, make sure that gmalloc.o is included in libgthreads.a and libgthreads.so.
- In FSU Pthreads, the following system calls are pthreads-aware: read(), write(), getmsg(), connect(), accept(), select(), and wait().
- The CSSA-2001-SCO.35.2 (the patch is listed in custom as erg711905-dscr_remap security patch (version 2.0.0)) breaks FSU threads and makes mysqld unstable. You have to remove this one if you want to run mysqld on an OpenServer 5.0.6 machine.
- If you use SCO OpenServer 5, you may need to recompile FSU pthreads with -DDRAFT7 in CFLAGS. Otherwise, InnoDB may hang at a mysqld startup.
- SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.x.

- SCO provides security fixes and `libsocket.so.2` at ftp://ftp.sco.com/pub/security/OpenServer and ftp://ftp.sco.com/pub/security/sse for OpenServer 5.0.x.
- Pre-OSR506 security fixes. Also, the `telnetd` fix at ftp://stage.caldera.com/pub/security/openserver/ or ftp://stage.caldera.com/pub/security/openserver/CSSA-2001-SCO.10/ as both `libsocket.so.2` and `libresolv.so.1` with instructions for installing on pre-OSR506 systems.

  It is probably a good idea to install these patches before trying to compile/use MySQL.

Beginning with Legend/OpenServer 6.0.0, there are native threads and no 2GB file size limit.

2.12.5.9. SCO OpenServer 6.0.x Notes

OpenServer 6 includes these key improvements:

- Larger file support up to 1 TB
- Multiprocessor support increased from 4 to 32 processors
- Increased memory support up to 64GB
- Extending the power of UnixWare into OpenServer 6
- Dramatic performance improvement

OpenServer 6.0.0 commands are organized as follows:

- `/bin` is for commands that behave exactly the same as on OpenServer 5.0.x.
- `/u95/bin` is for commands that have better standards conformance, for example Large File System (LFS) support.
- `/udk/bin` is for commands that behave the same as on UnixWare 7.1.4. The default is for the LFS support.

The following is a guide to setting `PATH` on OpenServer 6. If the user wants the traditional OpenServer 5.0.x then `PATH` should be `/bin` first. If the user wants LFS support, the path should be `/u95/bin:/bin`. If the user wants UnixWare 7 support first, the path would be `/udk/bin:/u95/bin:/bin:`.

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on OpenServer 6.0.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

MySQL distribution files with names of the following form are `tar` archives of media are tar archives of media images suitable for installation with the SCO Software Manager (`/etc/custom`) on SCO OpenServer 6:

```
mysql-PRODUCT-6.0.12-sco-osr6-i686.VOLS.tar
```

A distribution where *`PRODUCT`* is `pro-cert` is the Commercially licensed MySQL Pro Certified server. A distribution where *`PRODUCT`* is `pro-gpl-cert` is the MySQL Pro Certified server licensed under the terms of the General Public License (GPL).

Select whichever distribution you wish to install and, after download, extract the `tar` archive into an empty directory. For example:

```
shell> mkdir /tmp/mysql-pro
shell> cd /tmp/mysql-pro
shell> tar xf /tmp/mysql-pro-cert-6.0.12-sco-osr6-i686.VOLS.tar
```

Prior to installation, back up your data in accordance with the procedures outlined in Section 2.11.1, “Upgrading MySQL”.

Remove any previously installed `pkgadd` version of MySQL:

```
shell> pkginfo mysql 2>&1 > /dev/null && pkgrm mysql
```

Install MySQL Pro from media images using the SCO Software Manager:

```
shell> /etc/custom -p SCO:MySQL -i -z /tmp/mysql-pro
```

Alternatively, the SCO Software Manager can be displayed graphically by clicking on the `Software Manager` icon on the desktop, selecting `Software -> Install New`, selecting the host, selecting `Media Images` for the Media Device, and entering `/tmp/mysql-pro` as the Image Directory.

After installation, run `mkdev mysql` as the `root` user to configure your newly installed MySQL Pro Certified server.

> **Note**
>
> The installation procedure for VOLS packages does not create the `mysql` user and group that the package uses by default. You should either create the `mysql` user and group, or else select a different user and group using an option in `mkdev mysql`.

If you wish to configure your MySQL Pro server to interface with the Apache Web server via PHP, download and install the PHP update from SCO at ftp://ftp.sco.com/pub/updates/OpenServer/SCOSA-2006.17/.

We have been able to compile MySQL with the following `configure` command on OpenServer 6.0.x:

```
CC=cc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
CXX=CC CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client  \
    --with-extra-charsets=complex \
    --build=i686-unknown-sysv5SCO_SV6.0.0
```

If you use `gcc`, you must use `gcc` 2.95.3 or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

SCO provides OpenServer 6 operating system patches at ftp://ftp.sco.com/pub/openserver6.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer.

By default, the maximum file size on a OpenServer 6.0.0 system is 1TB. Some operating system utilities have a limitation of 2GB. The maximum possible file size on UnixWare 7 is 1TB with VXFS or HTFS.

OpenServer 6 can be configured for large file support (file sizes greater than 2GB) by tuning the UNIX kernel.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

```
Value           Default         Min             Max
-----           -------         ---             ---
SVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
```

To make changes to the kernel, use the `idtune` *`name parameter`* command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. We recommend setting the kernel values by executing the following commands as `root`:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `SFNOLIM` and `HFNOLIM` should be at maximum 2048.
- `NPROC` should be set to at least 3000/4000 (depends on number of users).
- We also recommend using the following formulas to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

  ```
  SEMMSL = 13
  ```

13 is what has been found to be the best for both Progress and MySQL.

```
SEMMNS = SEMMSL × number of db servers to be run on the system
```

Set SEMMNS to the value of SEMMSL multiplied by the number of database servers (maximum) that you are running on the system at one time.

```
SEMMNU = SEMMNS
```

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

2.12.5.10. SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes

We recommend using the latest production release of MySQL. Should you choose to use an older release of MySQL on UnixWare 7.1.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

We have been able to compile MySQL with the following configure command on UnixWare 7.1.x:

```
CC="cc" CFLAGS="-I/usr/local/include" \
CXX="CC" CXXFLAGS="-I/usr/local/include" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client \
    --with-innodb --with-openssl --with-extra-charsets=complex
```

If you want to use gcc, you must use gcc 2.95.3 or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

SCO provides operating system patches at ftp://ftp.sco.com/pub/unixware7 for UnixWare 7.1.1, ftp://ftp.sco.com/pub/unixware7/713/ for UnixWare 7.1.3, ftp://ftp.sco.com/pub/unixware7/714/ for UnixWare 7.1.4, and ftp://ftp.sco.com/pub/openunix8 for OpenUNIX 8.0.0.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenUNIX for OpenUNIX and ftp://ftp.sco.com/pub/security/UnixWare for UnixWare.

The UnixWare 7 file size limit is 1 TB with VXFS. Some OS utilities have a limitation of 2GB.

On UnixWare 7.1.4 you do not need to do anything to get large file support, but to enable large file support on prior versions of UnixWare 7.1.x, run fsadm.

```
# fsadm -Fvxfs -o largefiles /
# fsadm /         * Note
# ulimit unlimited
# /etc/conf/bin/idtune SFSZLIM 0x7FFFFFFF     ** Note
# /etc/conf/bin/idtune HFSZLIM 0x7FFFFFFF     ** Note
# /etc/conf/bin/idbuild -B

* This should report "largefiles".
** 0x7FFFFFFF represents infinity for these values.
```

Reboot the system using shutdown.

By default, the entries in /etc/conf/cf.d/mtune are set as follows:

```
Value           Default         Min             Max
-----           -------         ---             ---
SVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
```

To make changes to the kernel, use the idtune *name parameter* command. idtune modifies the /etc/conf/cf.d/stune file for you. We recommend setting the kernel values by executing the following commands as root:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

We recommend tuning the system, but the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `SFNOLIM` and `HFNOLIM` should be at maximum 2048.
- `NPROC` should be set to at least 3000/4000 (depends on number of users).
- We also recommend using the following formulas to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

  ```
  SEMMSL = 13
  ```

  13 is what has been found to be the best for both Progress and MySQL.

  ```
  SEMMNS = SEMMSL × number of db servers to be run on the system
  ```

  Set `SEMMNS` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

  ```
  SEMMNU = SEMMNS
  ```

  Set the value of `SEMMNU` to equal the value of `SEMMNS`. You could probably set this to 75% of `SEMMNS`, but this is a conservative estimate.

2.13. Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.2.3.2, “Using Option Files”.

Variable	Description
`CXX`	The name of your C++ compiler (for running `configure`).
`CC`	The name of your C compiler (for running `configure`).
`CFLAGS`	Flags for your C compiler (for running `configure`).
`CXXFLAGS`	Flags for your C++ compiler (for running `configure`).
`DBI_USER`	The default user name for Perl DBI.
`DBI_TRACE`	Trace options for Perl DBI.
`HOME`	The default path for the `mysql` history file is `$HOME/.mysql_history`.
`LD_RUN_PATH`	Used to specify the location of `libmysqlclient.so`.
`MYSQL_DEBUG`	Debug trace options when debugging.
`MYSQL_GROUP_SUFFIX`	Option group suffix value (like specifying `--defaults-group-suffix`).
`MYSQL_HISTFILE`	The path to the `mysql` history file. If this variable is set, its value overrides the default for `$HOME/.mysql_history`.
`MYSQL_HOME`	The path to the directory in which the server-specific `my.cnf` file resides (as of MySQL 5.0.3).
`MYSQL_HOST`	The default host name used by the `mysql` command-line client.
`MYSQL_PS1`	The command prompt to use in the `mysql` command-line client.
`MYSQL_PWD`	The default password when connecting to `mysqld`. Note that using this is insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.
`MYSQL_TCP_PORT`	The default TCP/IP port number.
`MYSQL_UNIX_PORT`	The default Unix socket file name; used for connections to `localhost`.

PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See Section B.1.4.6, “Time Zone Problems”.
UMASK	The user-file creation mode when creating files. See note following table.
UMASK_DIR	The user-directory creation mode when creating directories. See note following table.
USER	The default user name on Windows and NetWare used when connecting to mysqld.

The UMASK and UMASK_DIR variables, despite their names, are used as modes, not masks:

- If UMASK is set, mysqld uses ($UMASK | 0600) as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).
- If UMASK_DIR is set, mysqld uses ($UMASK_DIR | 0700) as the base mode for directory creation, which then is AND-ed with ~(~$UMASK & 0666), so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL assumes that the value for UMASK or UMASK_DIR is in octal if it starts with a zero.

2.14. Perl Installation Notes

Perl support for MySQL is provided by means of the DBI/DBD client interface. The interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI *does not work* if you have an older version of Perl.

If you want to use transactions with Perl DBI, you need to have DBD::mysql 2.0900. If you are using the MySQL 4.1 or newer client library, you must use DBD::mysql 2.9003 or newer. Support for server-side prepared statements requires DBD::mysql 3.0009 or newer.

Perl support is not included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState ppm program on Windows. The following sections describe how to do this.

Perl support for MySQL must be installed if you want to run the MySQL benchmark scripts; see Section 7.1.4, “The MySQL Benchmark Suite”.

2.14.1. Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. However, if you installed MySQL from RPM files on Linux, be sure that you've installed the developer RPM. The client programs are in the client RPM, but client programming support is in the developer RPM.

If you want to install Perl support, the files you need can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the CPAN module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The DBD::mysql installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and ODBC on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use force install DBD::mysql to ignore the failed tests.

DBI requires the Data::Dumper module. It may be installed; if not, you should install it before installing DBI.

It is also possible to download the module distributions in the form of compressed tar archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

   ```
   shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
   ```

   This command creates a directory named DBI-*VERSION*.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL, particularly if you notice symptoms such as that all your `DBI` scripts fail after you upgrade MySQL.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://servers.digitaldaze.com/extensions/perl/modules.html#modules

Look under the heading “Installing New Modules that Require Locally Installed Modules.”

2.14.2. Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.
2. Open a console window (a “DOS window”).
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the MyODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
  die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.14.3. Problems Using the Perl `DBI`/`DBD` Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Compile the `DBD::mysql` distribution with `perl Makefile.PL -static -config` rather than `perl Makefile.PL`.
- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).

- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

You may see the following error from `DBD::mysql` when you run the tests:

```
t/00base.....install_driver(mysql) failed:
Can't load '../blib/arch/auto/DBD/mysql/mysql.so' for module DBD::mysql:
../blib/arch/auto/DBD/mysql/mysql.so: undefined symbol:
uncompress at /usr/lib/perl5/5.00503/i586-linux/DynaLoader.pm line 169.
```

This means that you need to include the `-lz` compression library on the link line. That can be done by changing the following line in the file `lib/DBD/mysql/Install.pm`:

```
$sysliblist .= " -lm";
```

Change that line to:

```
$sysliblist .= " -lm -lz";
```

After this, you *must* run `make realclean` and then proceed with the installation from the beginning.

If you want to install DBI on SCO, you have to edit the `Makefile` in DBI-*`xxx`* and each subdirectory. Note that the following assumes `gcc` 2.95.2 or newer:

```
OLD:                                    NEW:
CC = cc                                 CC = gcc
CCCDLFLAGS = -KPIC -W1,-Bexport         CCCDLFLAGS = -fpic
CCDLFLAGS = -wl,-Bexport                CCDLFLAGS =

LD = ld                                 LD = gcc -G -fpic
LDDLFLAGS = -G -L/usr/local/lib         LDDLFLAGS = -L/usr/local/lib
LDFLAGS = -belf -L/usr/local/lib        LDFLAGS = -L/usr/local/lib

LD = ld                                 LD = gcc -G -fpic
OPTIMISE = -Od                          OPTIMISE = -O1

OLD:
CCCFLAGS = -belf -dy -w0 -U M_XENIX -DPERL_SCO5 -I/usr/local/include

NEW:
CCFLAGS = -U M_XENIX -DPERL_SCO5 -I/usr/local/include
```

These changes are necessary because the Perl dynaloader does not load the `DBI` modules if they were compiled with `icc` or `cc`.

If you want to use the Perl module on a system that does not support dynamic linking (such as SCO), you can generate a static version of Perl that includes `DBI` and `DBD::mysql`. The way this works is that you generate a version of Perl with the `DBI` code linked in and install it on top of your current Perl. Then you use that to build a version of Perl that additionally has the `DBD` code linked in, and install that.

On SCO, you must have the following environment variables set:

```
LD_LIBRARY_PATH=/lib:/usr/lib:/usr/local/lib:/usr/progressive/lib
```

Or:

```
LD_LIBRARY_PATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
LIBPATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
MANPATH=scohelp:/usr/man:/usr/local1/man:/usr/local/man:\
    /usr/skunk/man:
```

First, create a Perl that includes a statically linked `DBI` module by running these commands in the directory where your `DBI` distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Then you must install the new Perl. The output of `make perl` indicates the exact `make` command you need to execute to perform the installation. On SCO, this is `make -f Makefile.aperl inst_perl MAP_TARGET=perl`.

Next, use the just-created Perl to create another Perl that also includes a statically linked `DBD::mysql` by running these commands in the directory where your `DBD::mysql` distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Finally, you should install this new Perl. Again, the output of `make perl` indicates the command to use.

Chapter 3. Tutorial

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the "terminal monitor" or just "monitor") is an interactive program that allows you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, *MySQL Server Administration*.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1. Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: ********
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `********` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: ********
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 6.0.12-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section B.1.2, "Common Errors When Using MySQL Programs".

Some MySQL installations allow users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control-D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

3.2. Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----------------+--------------+
| VERSION()       | CURRENT_DATE |
+-----------------+--------------+
| 6.0.11-alpha-log | 2009-05-04   |
+-----------------+--------------+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+------------------+---------+
| SIN(PI()/4)      | (4+1)*5 |
+------------------+---------+
| 0.70710678118655 |      25 |
+------------------+---------+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----------------+
| VERSION()       |
+-----------------+
| 6.0.11-alpha-log |
+-----------------+
1 row in set (0.00 sec)

+---------------------+
| NOW()               |
+---------------------+
| 2009-05-04 15:15:00 |
+---------------------+
1 row in set (0.00 sec)
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
+---------------+--------------+
| USER()        | CURRENT_DATE |
+---------------+--------------+
| jon@localhost | 2005-10-11   |
+---------------+--------------+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
`mysql>`	Ready for new command.
`->`	Waiting for next line of multiple-line command.
`'>`	Waiting for next line, waiting for completion of a string that began with a single quote (“'”).
`">`	Waiting for next line, waiting for completion of a string that began with a double quote (“"”).
`` `> ``	Waiting for next line, waiting for completion of an identifier that began with a backtick (“`”).
`/*>`	Waiting for next line, waiting for completion of a comment that began with `/*`.

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
    ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
    -> ;
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either “'” or “"” characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a “'” or “"” quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated

string. (Do you see the error in the statement? The string `'Smith` is missing the second single quote mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The `` `> `` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and `` `> `` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql` — including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

3.3. Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at http://dev.mysql.com/doc/.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See Section 12.5.6.15, “SHOW DATABASES Syntax”.

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

Note that `USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to

use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1. Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, our recommended best practice is always to use the same lettercase that was used when the database was created.)

> **Note**
>
> If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 5.4, "The MySQL Access Privilege System".

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: ********
```

Note that `menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

3.3.2. Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)

- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
    -> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can normally pick any length from `1` to `65535`, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+----------------------+
| Tables in menagerie |
+----------------------+
| pet                  |
+----------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 10, *Data Types*.

3.3.3. Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler        Gwen    bird    \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this command:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

Note that if you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
    -> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 5.3.4, “Security Issues with LOAD DATA LOCAL”, for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
    -> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

Note that string and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4. Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

`what_to_select` indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *`which_table`* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *`conditions_to_satisfy`* specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1. Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+----------+--------+---------+------+------------+------------+
| name     | owner  | species | sex  | birth      | death      |
+----------+--------+---------+------+------------+------------+
| Fluffy   | Harold | cat     | f    | 1993-02-04 | NULL       |
| Claws    | Gwen   | cat     | m    | 1994-03-17 | NULL       |
| Buffy    | Harold | dog     | f    | 1989-05-13 | NULL       |
| Fang     | Benny  | dog     | m    | 1990-08-27 | NULL       |
| Bowser   | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
| Chirpy   | Gwen   | bird    | f    | 1998-09-11 | NULL       |
| Whistler | Gwen   | bird    | NULL | 1997-12-09 | NULL       |
| Slim     | Benny  | snake   | m    | 1996-04-29 | NULL       |
| Puffball | Diane  | hamster | f    | 1999-03-30 | NULL       |
+----------+--------+---------+------+------------+------------+
```

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

  However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

  The `UPDATE` changes only the record in question and does not require you to reload the table.

3.3.4.2. Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL  |
| Slim     | Benny | snake   | m    | 1996-04-29 | NULL  |
+----------+-------+---------+------+------------+-------+
```

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
    -> OR (species = 'dog' AND sex = 'f');
+-------+--------+---------+------+------------+-------+
```

```
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

3.3.4.3. Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
+----------+------------+
| name     | birth      |
+----------+------------+
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Buffy    | 1989-05-13 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Puffball | 1999-03-30 |
+----------+------------+
```

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
+--------+
| owner  |
+--------+
| Harold |
| Gwen   |
| Harold |
| Benny  |
| Diane  |
| Gwen   |
| Gwen   |
| Benny  |
| Diane  |
+--------+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
| Harold |
+--------+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
    -> WHERE species = 'dog' OR species = 'cat';
+--------+---------+------------+
| name   | species | birth      |
+--------+---------+------------+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+--------+---------+------------+
```

3.3.4.4. Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
```

```
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting — like all other comparison operations — is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
    -> ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+----------+---------+------------+
```

Note that the `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

3.3.4.5. Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, compute the difference in the year part of the current date and the birth date, then subtract one if the current date occurs earlier in the calendar year than the birth date. The following query shows, for each pet, the birth date, the current date, and the age in years.

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
+----------+------------+------------+------+
```

Here, `YEAR()` pulls out the year part of a date and `RIGHT()` pulls off the rightmost five characters that represent the `MM-DD`

(calendar year) part of the date. The part of the expression that compares the `MM-DD` values evaluates to 1 or 0, which adjusts the year difference down a year if `CURDATE()` occurs earlier in the year than `birth`. The full expression is somewhat ungainly, so an *alias* (`age`) is used to make the output column label more meaningful.

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY name;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
+----------+------------+------------+------+
```

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY age;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
+----------+------------+------------+------+
```

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
    -> (YEAR(death)-YEAR(birth)) - (RIGHT(death,5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet WHERE death IS NOT NULL ORDER BY age;
+--------+------------+------------+------+
| name   | birth      | death      | age  |
+--------+------------+------------+------+
| Bowser | 1989-08-31 | 1995-07-29 |    5 |
+--------+------------+------------+------+
```

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with NULL Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
+----------+------------+--------------+
| name     | birth      | MONTH(birth) |
+----------+------------+--------------+
| Fluffy   | 1993-02-04 |            2 |
| Claws    | 1994-03-17 |            3 |
| Buffy    | 1989-05-13 |            5 |
| Fang     | 1990-08-27 |            8 |
| Bowser   | 1989-08-31 |            8 |
| Chirpy   | 1998-09-11 |            9 |
| Whistler | 1997-12-09 |           12 |
| Slim     | 1996-04-29 |            4 |
| Puffball | 1999-03-30 |            3 |
+----------+------------+--------------+
```

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month

value is 4 and you can look for animals born in May (month 5) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-------+------------+
| name  | birth      |
+-------+------------+
| Buffy | 1989-05-13 |
+-------+------------+
```

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. DATE_ADD() allows you to add a time interval to a given date. If you add a month to the value of CURDATE(), then extract the month part with MONTH(), the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (MOD) to wrap the month value to 0 if it is currently 12:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

Note that MONTH() returns a number between 1 and 12. And MOD(something,12) returns a number between 0 and 11. So the addition has to be after the MOD(), otherwise we would go from November (11) to January (1).

3.3.4.6. Working with NULL Values

The NULL value can be surprising until you get used to it. Conceptually, NULL means “a missing unknown value” and it is treated somewhat differently from other values. To test for NULL, you cannot use the arithmetic comparison operators such as =, <, or <>. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```

Clearly you get no meaningful results from these comparisons. Use the IS NULL and IS NOT NULL operators instead:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

Note that in MySQL, 0 or NULL means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of NULL is why, in the previous section, it was necessary to determine which animals are no longer alive using death IS NOT NULL instead of death <> NULL.

Two NULL values are regarded as equal in a GROUP BY.

When doing an ORDER BY, NULL values are presented first if you do ORDER BY ... ASC and last if you do ORDER BY ... DESC.

A common error when working with NULL is to assume that it is not possible to insert a zero or an empty string into a column defined as NOT NULL, but this is not the case. These are in fact values, whereas NULL means “not having a value.” You can test this easily enough by using IS [NOT] NULL as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+------------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+------------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+------------+----------------+
```

Thus it is entirely possible to insert a zero or empty string into a NOT NULL column, as these are in fact NOT NULL. See Section B.1.5.3, “Problems with NULL Values”.

3.3.4.7. Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching allows you to use "`_`" to match any single character and "`%`" to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. Note that you do not use `=` or `<>` when you use SQL patterns; use the `LIKE` or `NOT LIKE` comparison operators instead.

To find names beginning with "`b`":

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To find names ending with "`fy`":

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a "`w`":

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

To find names containing exactly five characters, use five instances of the "`_`" pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP` and `NOT REGEXP` operators (or `RLIKE` and `NOT RLIKE`, which are synonyms).

Some characteristics of extended regular expressions are:

- "`.`" matches any single character.
- A character class "`[...]`" matches any character within the brackets. For example, "`[abc]`" matches "`a`", "`b`", or "`c`". To name a range of characters, use a dash. "`[a-z]`" matches any letter, whereas "`[0-9]`" matches any digit.
- "`*`" matches zero or more instances of the thing preceding it. For example, "`x*`" matches any number of "`x`" characters, "`[0-9]*`" matches any number of digits, and "`.*`" matches any number of anything.
- A `REGEXP` pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use "`^`" at the beginning or "`$`" at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` queries shown previously are rewritten here to use `REGEXP`.

To find names beginning with "`b`", use "`^`" to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+--------+--------+---------+------+------------+------------+
```

```
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

If you really want to force a `REGEXP` comparison to be case sensitive, use the `BINARY` keyword to make one of the strings a binary string. This query matches only lowercase "`b`" at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with "`fy`", use "`$`" to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a "`w`", use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use "`^`" and "`$`" to match the beginning and end of the name, and five instances of "`.`" in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

You could also write the previous query using the `{n}` ("repeat-*n*-times") operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

Section 11.4.2, "Regular Expressions", provides more information about the syntax for regular expressions.

3.3.4.8. Counting Rows

Databases are often used to answer the question, "How often does a certain type of data occur in a table?" For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as "How many rows are in the `pet` table?" because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+----------+
| COUNT(*) |
+----------+
|        9 |
+----------+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

```
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Benny  |        2 |
| Diane  |        2 |
| Gwen   |        3 |
| Harold |        2 |
+--------+----------+
```

Note the use of `GROUP BY` to group all records for each `owner`. Without it, all you get is an error message:

```
mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

`COUNT()` and `GROUP BY` are useful for characterizing your data in various ways. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+---------+----------+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+------+----------+
| sex  | COUNT(*) |
+------+----------+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+------+----------+
```

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE species = 'dog' OR species = 'cat'
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE sex IS NOT NULL
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | f    |        1 |
```

```
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

3.3.4.9. Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs:

- To contain the pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
    -> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
    -> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
    -> remark
    -> FROM pet INNER JOIN event
    ->   ON pet.name = event.name
    -> WHERE event.type = 'litter';
+--------+------+-----------------------------+
| name   | age  | remark                      |
+--------+------+-----------------------------+
| Fluffy |    2 | 4 kittens, 3 female, 1 male |
| Buffy  |    4 | 5 puppies, 2 female, 3 male |
| Buffy  |    5 | 3 puppies, 3 female         |
+--------+------+-----------------------------+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

  The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` allows for rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.
- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
    -> FROM pet AS p1 INNER JOIN pet AS p2
    ->   ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+--------+------+--------+------+---------+
| name   | sex  | name   | sex  | species |
+--------+------+--------+------+---------+
| Fluffy | f    | Claws  | m    | cat     |
| Buffy  | f    | Fang   | m    | dog     |
| Buffy  | f    | Bowser | m    | dog     |
+--------+------+--------+------+---------+
```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4. Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
+------------+
```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
+----------------------+
| Tables_in_menagerie |
+----------------------+
| event                |
| pet                  |
+----------------------+
```

The name of the column in the output produced by this statement is always `Tables_in_`*`db_name`*, where *`db_name`* is the name of the database. See Section 12.5.6.37, “SHOW TABLES Syntax”, for more information.

If you want to find out about the structure of a table, the `DESCRIBE` command is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
```

```
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value will be `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See Section 12.3.1, “`DESCRIBE` Syntax”, for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See Section 12.5.6.12, “`SHOW CREATE TABLE` Syntax”.

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See Section 12.5.6.23, “`SHOW INDEX` Syntax”, for more about this statement.

3.5. Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script allows you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

  ```
  shell> mysql < batch-file | more
  ```

- You can catch the output in a file for further processing:

  ```
  shell> mysql < batch-file > mysql.out
  ```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+---------+
| species |
+---------+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+---------+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See Section 4.5.1.4, “Executing SQL Statements from a Text File”, for more information.

3.6. Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
    article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
    dealer  CHAR(20)                 DEFAULT ''     NOT NULL,
    price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL,
    PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
    (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
    (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | A      |  3.45 |
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | B      |  1.45 |
|    0003 | C      |  1.69 |
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

3.6.1. The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;

+---------+
| article |
```

```
+---------+
|       4 |
+---------+
```

3.6.2. The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM   shop
WHERE  price=(SELECT MAX(price) FROM shop);

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

> **Note**
>
> If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

3.6.3. Maximum of Column per Group

Task: Find the highest price per article.

```
SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article;

+---------+-------+
| article | price |
+---------+-------+
|    0001 |  3.99 |
|    0002 | 10.99 |
|    0003 |  1.69 |
|    0004 | 19.95 |
+---------+-------+
```

3.6.4. The Rows Holding the Group-wise Maximum of a Certain Field

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | C      |  1.69 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

The preceding example uses a correlated subquery, which can be inefficient (see Section 12.2.10.7, “Correlated Subqueries”). Other possibilities for solving the problem are to use a uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
  ON s1.article = s2.article AND s1.price = s2.price;

SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See Section 12.2.9.1, "`JOIN` Syntax".

3.6.5. Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 8.4, "User-Defined Variables".)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

> **Note**
>
> It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See Section 12.7, "SQL Syntax for Prepared Statements", for more information.

3.6.6. Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See Section 13.7, "The `InnoDB` Storage Engine", and Section 1.7.5.4, "Foreign Keys".

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES` *`tbl_name(col_name)`* clause, which has no actual effect, and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that *`col_name`* actually exists in *`tbl_name`* (or even that *`tbl_name`* itself exists).
- MySQL does not perform any sort of action on *`tbl_name`* such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();
```

```
INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+--------------------+
| id | name               |
+----+--------------------+
|  1 | Antonio Paz        |
|  2 | Lilliana Angelovska |
+----+--------------------+

SELECT * FROM shirt;
+----+---------+--------+-------+
| id | style   | color  | owner |
+----+---------+--------+-------+
|  1 | polo    | blue   |     1 |
|  2 | dress   | white  |     1 |
|  3 | t-shirt | blue   |     1 |
|  4 | dress   | orange |     2 |
|  5 | polo    | red    |     2 |
|  6 | dress   | blue   |     2 |
|  7 | t-shirt | white  |     2 |
+----+---------+--------+-------+

SELECT s.* FROM person p INNER JOIN shirt s
   ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
   AND s.color <> 'white';

+----+-------+--------+-------+
| id | style | color  | owner |
+----+-------+--------+-------+
|  4 | dress | orange |     2 |
|  5 | polo  | red    |     2 |
|  6 | dress | blue   |     2 |
+----+-------+--------+-------+
```

When used in this fashion, the `REFERENCES` clause is not displayed in the output of `SHOW CREATE TABLE` or `DESCRIBE`:

```
SHOW CREATE TABLE shirt\G
*************************** 1. row ***************************
Table: shirt
Create Table: CREATE TABLE `shirt` (
`id` smallint(5) unsigned NOT NULL auto_increment,
`style` enum('t-shirt','polo','dress') NOT NULL,
`color` enum('red','blue','orange','white','black') NOT NULL,
`owner` smallint(5) unsigned NOT NULL,
PRIMARY KEY  (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of `REFERENCES` in this way as a comment or “reminder” in a column definition works with `MyISAM` tables.

3.6.7. Searching on Two Keys

An `OR` using a single key is well optimized, as is the handling of `AND`.

The one tricky case is that of searching on two different keys combined with `OR`:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR  field2_index = '1'
```

This case is optimized. See Section 7.2.6, “Index Merge Optimization”.

You can also solve the problem efficiently by using a `UNION` that combines the output of two separate `SELECT` statements. See Section 12.2.9.3, “`UNION` Syntax”.

Each `SELECT` searches only one key and can be optimized:

```
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
```

3.6.8. Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
            day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
           (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
       GROUP BY year,month;
```

Which returns:

```
+------+-------+------+
| year | month | days |
+------+-------+------+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+------+-------+------+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9. Using `AUTO_INCREMENT`

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
     id MEDIUMINT NOT NULL AUTO_INCREMENT,
     name CHAR(30) NOT NULL,
     PRIMARY KEY (id)
 );

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | lax     |
|  5 | whale   |
|  6 | ostrich |
+----+---------+
```

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

> **Note**
>
> For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This allows multiple-row inserts to be reproduced correctly on other servers in a replication setup.

For `MyISAM` tables you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
    grp ENUM('fish','mammal','bird') NOT NULL,
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
```

```
    name CHAR(30) NOT NULL,
    PRIMARY KEY (grp,id)
);

INSERT INTO animals (grp,name) VALUES
    ('mammal','dog'),('mammal','cat'),
    ('bird','penguin'),('fish','lax'),('mammal','whale'),
    ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
+--------+----+---------+
```

Note that in this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL will generate sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

To start with an `AUTO_INCREMENT` value other than 1, you can set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: Section 12.1.14, “`CREATE TABLE` Syntax”, and Section 12.1.6, “`ALTER TABLE` Syntax”.
- How `AUTO_INCREMENT` behaves depending on the SQL mode: Section 5.1.7, “Server SQL Modes”.
- Find the row that contains the most recent AUTO_INCREMENT value: Section 11.2.3, “Comparison Functions and Operators”.
- Set the `AUTO_INCREMENT` value to be used: Section 5.1.4, “Session System Variables”.
- `AUTO_INCREMENT` and replication: Section 16.3.1, “Replication Features and Issues”.
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment` and `auto_increment_offset`) that can be used for replication: Section 5.1.3, “Server System Variables”.

3.7. Queries from the Twin Project

At the places the early MySQL was developed (Analytikerna and Lentus), the founders did systems and field work for a big research project. This project was a collaboration between the Institute of Environmental Medicine at Karolinska Institutet Stockholm and the Section on Clinical Research in Aging and Psychology at the University of Southern California.

The project involved lots of data collection from all twins in Sweden older than 65 Years (see http://ki.se/ki/jsp/polopoly.jsp?d=9610&l=en).

Large parts of the project were administered with a Web interface written using Perl and MySQL.

3.7.1. Find All Non-distributed Twins

The following query was used to determine what twins should be studied further after a initial screening. The time for this was around MySQL 3.19 in 1997.

```
SELECT
```

```
    CONCAT(p1.id, p1.tvab) + 0 AS tvid,
    CONCAT(p1.christian_name, ' ', p1.surname) AS Name,
    p1.postal_code AS Code,
    p1.city AS City,
    pg.abrev AS Area,
    IF(td.participation = 'Aborted', 'A', ' ') AS A,
    p1.dead AS dead1,
    l.event AS event1,
    td.suspect AS tsuspect1,
    id.suspect AS isuspect1,
    td.severe AS tsevere1,
    id.severe AS isevere1,
    p2.dead AS dead2,
    l2.event AS event2,
    h2.nurse AS nurse2,
    h2.doctor AS doctor2,
    td2.suspect AS tsuspect2,
    id2.suspect AS isuspect2,
    td2.severe AS tsevere2,
    id2.severe AS isevere2,
    l.finish_date
FROM
    twin_project AS tp
    /* For Twin 1 */
    LEFT JOIN twin_data AS td ON tp.id = td.id
              AND tp.tvab = td.tvab
    LEFT JOIN informant_data AS id ON tp.id = id.id
              AND tp.tvab = id.tvab
    LEFT JOIN harmony AS h ON tp.id = h.id
              AND tp.tvab = h.tvab
    LEFT JOIN lentus AS l ON tp.id = l.id
              AND tp.tvab = l.tvab
    /* For Twin 2 */
    LEFT JOIN twin_data AS td2 ON p2.id = td2.id
              AND p2.tvab = td2.tvab
    LEFT JOIN informant_data AS id2 ON p2.id = id2.id
              AND p2.tvab = id2.tvab
    LEFT JOIN harmony AS h2 ON p2.id = h2.id
              AND p2.tvab = h2.tvab
    LEFT JOIN lentus AS l2 ON p2.id = l2.id
              AND p2.tvab = l2.tvab,
    person_data AS p1,
    person_data AS p2,
    postal_groups AS pg
WHERE
    /* p1 gets main twin and p2 gets his/her twin. */
    /* ptvab is a field inverted from tvab */
    p1.id = tp.id AND p1.tvab = tp.tvab AND
    p2.id = p1.id AND p2.ptvab = p1.tvab AND
    /* Just the screening survey */
    tp.survey_no = 5 AND
    /* Skip if partner died before 65 but allow emigration (dead=9) */
    (p2.dead = 0 OR p2.dead = 9 OR
     (p2.dead = 1 AND
      (p2.death_date = 0 OR
       (((TO_DAYS(p2.death_date) - TO_DAYS(p2.birthday)) / 365)
        >= 65))))
    AND
    (
    /* Twin is suspect */
    (td.future_contact = 'Yes' AND td.suspect = 2) OR
    /* Twin is suspect - Informant is Blessed */
    (td.future_contact = 'Yes' AND td.suspect = 1
                               AND id.suspect = 1) OR
    /* No twin - Informant is Blessed */
    (ISNULL(td.suspect) AND id.suspect = 1
                        AND id.future_contact = 'Yes') OR
    /* Twin broken off - Informant is Blessed */
    (td.participation = 'Aborted'
     AND id.suspect = 1 AND id.future_contact = 'Yes') OR
    /* Twin broken off - No inform - Have partner */
    (td.participation = 'Aborted' AND ISNULL(id.suspect)
                                  AND p2.dead = 0))
    AND
    l.event = 'Finished'
    /* Get at area code */
    AND SUBSTRING(p1.postal_code, 1, 2) = pg.code
    /* Not already distributed */
    AND (h.nurse IS NULL OR h.nurse=00 OR h.doctor=00)
    /* Has not refused or been aborted */
    AND NOT (h.status = 'Refused' OR h.status = 'Aborted'
    OR h.status = 'Died' OR h.status = 'Other')
ORDER BY
    tvid;
```

Some explanations:

- `CONCAT(p1.id, p1.tvab) + 0 AS tvid`

  We want to sort on the concatenated `id` and `tvab` in numerical order. Adding `0` to the result causes MySQL to treat the result as a number.

- column `id`

  This identifies a pair of twins. It is an index in all tables.

- column `tvab`

  This identifies a twin in a pair. It has a value of `1` or `2`.

- column `ptvab`

  This is an inverse of `tvab`. When `tvab` is `1` this is `2`, and vice versa. It exists to save typing and to make it easier for MySQL to optimize the query.

This query demonstrates, among other things, how to do lookups on a table from the same table with a join (`p1` and `p2`). In the example, this is used to check whether a twin's partner died before the age of 65. If so, the row is not returned.

All of the above exist in all tables with twin-related information. We have an index on both `id, tvab` (all tables), and `id, ptvab` (`person_data`) to make queries faster.

When we did this work, our production machine was a 200MHz UltraSPARC, and on that old hardware this query returned about 150-200 rows in less than one second. The main table had 70k Rows.

3.7.2. Show a Table of Twin Pair Status

Each twin has a status code called `event`. The query shown here is used to select all twin pairs combined by event. This indicates in how many pairs both twins are finished, in how many pairs one twin is finished and the other refused, and so on.

```
SELECT
        t1.event,
        t2.event,
        COUNT(*)
FROM
        lentus AS t1,
        lentus AS t2,
        twin_project AS tp
WHERE
        /* We are looking at one pair at a time */
        t1.id = tp.id
        AND t1.tvab=tp.tvab
        AND t1.id = t2.id
        /* Just the screening survey */
        AND tp.survey_no = 5
        /* This makes each pair only appear once */
        AND t1.tvab='1' AND t2.tvab='2'
GROUP BY
        t1.event, t2.event;
```

3.8. Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
        "\"%h\",%{%Y%m%d%H%M%S}t,%>s,\"%b\",\"%{Content-Type}o\",  \
        \"%U\",\"%{Referer}i\",\"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

Chapter 4. MySQL Programs

This chapter provides a brief overview of the command-line programs provided by MySQL AB. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1. Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one. Each program's description indicates its invocation syntax and the options that it supports.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, *Installing and Upgrading MySQL*, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, “Using MySQL Programs”, for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

  The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, “`mysqld` — The MySQL Server”.

- `mysqld_safe`

  A server startup script. `mysqld_safe` attempts to start `mysqld`. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

- `mysql.server`

  A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See Section 4.3.3, “`mysql.server` — MySQL Server Startup Script”.

- `mysqld_multi`

  A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

  This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, “`comp_err` — Compile MySQL Error Message File”.

- `make_binary_distribution`

  This program makes a binary release of a compiled MySQL. This could be sent by FTP to `/pub/mysql/upload/` on `ftp.mysql.com` for the convenience of other MySQL users.

- `make_win_bin_dist`

  This program is used on Windows. It packages a MySQL distribution for installation after the source distribution has been built. See Section 4.4.2, “`make_win_bin_dist` — Package MySQL Distribution as ZIP Archive”.

- `mysql_install_db`

This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See Section 4.4.5, “mysql_install_db — Initialize MySQL Data Directory”, Section 2.10.2, “Unix Post-Installation Procedures”, and Section 4.4.5, “mysql_install_db — Initialize MySQL Data Directory”.

- `mysql_secure_installation`

  This program enables you to improve the security of your MySQL installation. SQL. See Section 4.4.6, “mysql_secure_installation — Improve MySQL Installation Security”.

- `mysql_tzinfo_to_sql`

  This program loads the time zone tables in the `mysql` database using the contents of the host system *zoneinfo* database (the set of files describing time zones). SQL. See Section 4.4.7, “mysql_tzinfo_to_sql — Load the Time Zone Tables”.

- `mysql_upgrade`

  This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See Section 4.4.8, “mysql_upgrade — Check Tables for MySQL Upgrade”.

MySQL client programs that connect to the MySQL server:

- `mysql`

  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 4.5.1, “mysql — The MySQL Command-Line Tool”.

- `mysqladmin`

  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

- `mysqlcheck`

  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 4.5.3, “mysqlcheck — A Table Maintenance Program”.

- `mysqldump`

  A client that dumps a MySQL database into a file as SQL, text, or XML. See Section 4.5.4, “mysqldump — A Database Backup Program”.

- `mysqlimport`

  A client that imports text files into their respective tables using `LOAD DATA INFILE`. See Section 4.5.5, “mysqlimport — A Data Import Program”.

- `mysqlshow`

  A client that displays information about databases, tables, columns, and indexes. See Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”.

- `mysqlslap`

  A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See Section 4.5.7, “mysqlslap — Load Emulation Client”.

MySQL administrative and utility programs:

- `innochecksum`

  An offline `InnoDB` offline file checksum utility. See Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”.

- `myisam_ftdump`

A utility that displays information about full-text indexes in `MyISAM` tables. See Section 4.6.2, “`myisam_ftdump` — Display Full-Text Index information”.

- `myisamchk`

  A utility to describe, check, optimize, and repair `MyISAM` tables. See Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

- `myisamlog`, `isamlog`

  A utility that processes the contents of a `MyISAM` log file. See Section 4.6.4, “`myisamlog` — Display MyISAM Log File Contents”.

- `myisampack`

  A utility that compresses `MyISAM` tables to produce smaller read-only tables. See Section 4.6.5, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”.

- `mysqlaccess`

  A script that checks the access privileges for a host name, user name, and database combination. See Section 4.6.6, “`mysqlaccess` — Client for Checking Access Privileges”.

- `mysqlbinlog`

  A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.8, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

- `mysqldumpslow`

  A utility to read and summarize the contents of a slow query log. See Section 4.6.9, “`mysqldumpslow` — Summarize Slow Query Log Files”.

- `mysqlhotcopy`

  A utility that quickly makes backups of `MyISAM` tables while the server is running. See Section 4.6.10, “`mysqlhotcopy` — A Database Backup Program”.

- `mysql_convert_table_format`

  A utility that converts tables in a database to use a given storage engine. See Section 4.6.11, “`mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine”.

- `mysql_find_rows`

  A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See Section 4.6.12, “`mysql_find_rows` — Extract SQL Statements from Files”.

- `mysql_fix_extensions`

  A utility that converts the extensions for `MyISAM` table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See Section 4.6.13, “`mysql_fix_extensions` — Normalize Table File Name Extensions”.

- `mysql_setpermission`

  A utility for interactively setting permissions in the MySQL grant tables. See Section 4.6.14, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”.

- `mysql_waitpid`

  A utility that kills the process with a given process ID. See Section 4.6.15, “`mysql_waitpid` — Kill Process and Wait for Its Termination”.

- `mysql_zap`

  A utility that kills processes that match a pattern. See Section 4.6.16, “`mysql_zap` — Kill Processes That Match a Pattern”.

MySQL program-development utilities:

- `msql2mysql`

  A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See Section 4.7.1, “`msql2mysql` — Convert mSQL Programs for Use with MySQL”.

- `mysql_config`

  A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.2, “`mysql_config` — Get Compile Options for Compiling Clients”.

- `my_print_defaults`

  A utility that shows which options are present in option groups of option files. See Section 4.7.3, “`my_print_defaults` — Display Options from Option Files”.

- `resolve_stack_dump`

  A utility program that resolves a numeric stack trace dump to symbols. See Section 4.7.4, “`resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols”.

Miscellaneous utilities:

- `perror`

  A utility that displays the meaning of system or MySQL error codes. See Section 4.8.1, “`perror` — Explain Error Codes”.

- `replace`

  A utility program that performs string replacement in the input text. See Section 4.8.2, “`replace` — A String-Replacement Utility”.

- `resolveip`

  A utility program that resolves a host name to an IP address or vice versa. See Section 4.8.3, “`resolveip` — Resolve Host name to IP Address or Vice Versa”.

MySQL AB also provides several GUI tools for administering and otherwise working with MySQL Server:

- MySQL Administrator: This tool is used for administering MySQL servers, databases, tables, and user accounts.
- MySQL Query Browser: This graphical tool is provided by MySQL AB for creating, executing, and optimizing queries on MySQL databases.
- MySQL Migration Toolkit: This tool helps you migrate schemas and data from other relational database management systems for use with MySQL.

These GUI programs are available at http://dev.mysql.com/downloads/. Each has its own manual that you can access at http://dev.mysql.com/doc/.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

`MYSQL_UNIX_PORT`	The default Unix socket file; used for connections to `localhost`
`MYSQL_TCP_PORT`	The default port number; used for TCP/IP connections
`MYSQL_PWD`	The default password
`MYSQL_DEBUG`	Debug trace options when debugging
`TMPDIR`	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see Section 2.13, “Environment Variables”.

Use of `MYSQL_PWD` is insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

4.2. Using MySQL Programs

4.2.1. Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. "`shell>`" represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh` or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash ("`-`", "`--`") specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.3, "Specifying Program Options".

Non-option arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first non-option argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional non-option arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they allow you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see Section 4.2.2, "Connecting to the MySQL Server".

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a "program not found" error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.4, "Setting Environment Variables".) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2. Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password` is given.
- For `mysql`, the first non-option argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
```

```
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` option and specify the password value, there must be *no space* between `-p` or `--password=` and the password following it.
- If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See Section 5.5.6.2, "End-User Guidelines for Password Security".

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name`, `-h host_name`

  The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

  The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` and the password following it. The default is to send no password.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server. The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--port=port_num`, `-P port_num`

  The port number to use for the connection, for connections made via TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made via a Unix socket file by default:

  ```
  shell> mysql --host=localhost
  ```

  To force a TCP/IP connection to be used instead, specify a `--protocol` option:

  ```
  shell> mysql --host=localhost --protocol=TCP
  ```

  The following table shows the allowable `--protocol` option values and indicates the platforms on which each value may be used. The values are not case sensitive.

`--protocol` Value	Connection Protocol	Allowable Operating Systems
`TCP`	TCP/IP connection to local or remote server	All
`SOCKET`	Unix socket file connection to local server	Unix only
`PIPE`	Named-pipe connection to local server	Windows only
`MEMORY`	Shared-memory connection to local server	Windows only

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use, for connections made via shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

  The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name`, `-S file_name`

  On Unix, the name of the Unix socket file to use, for connections made via a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

  On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

  The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

  Options that begin with `--ssl` are used for establishing a secure connection to the server via SSL, if the server is configured with SSL support. For details, see Section 5.5.7.3, “SSL Command Options”.

- `--user=user_name`, `-u user_name`

  The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

  ```
  [client]
  host=host_name
  user=user_name
  password=your_pass
  ```

  Section 4.2.3.2, “Using Option Files”, discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows and NetWare only). The password can be specified using `MYSQL_PWD`, although this is insecure; see Section 5.5.6.2, “End-User Guidelines for Password Security”. For a list of variables, see Section 2.13, “Environment Variables”.

4.2.3. Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is most common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see Section 4.2.4, “Setting Environment Variables”). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but Section 5.6.2, “Running Multiple Servers on Unix”, discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

Because options are processed in order, if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

You can take advantage of the way that MySQL programs process options by specifying default values for a program's options in an option file. That enables you to avoid typing them each time you run the program, but also allows you to override the defaults if necessary by using command-line options.

4.2.3.1. Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an "`=`" sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=`*`pass_val`* or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-p`*`pass_val`* or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

  ```
  shell> mysql -ptest
  shell> mysql -p test
  ```

  The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.
- Within option names, dash ("`-`") and underscore ("`_`") may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)

Another option that may occasionally be useful with `mysql` is the `--execute` or `-e` option, which can be used to pass SQL statements to the server. When this option is used, `mysql` executes the statements and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
shell> mysql -u root -p --execute="SELECT User, Host FROM user" mysql
Enter password: ******
+------+-----------+
| User | Host      |
+------+-----------+
|      | gigan     |
| root | gigan     |
|      | localhost |
| jon  | localhost |
| root | localhost |
+------+-----------+
shell>
```

Note that the long form (`--execute`) is followed by an equals sign (`=`).

If you wish to use quoted values within a statement, you will either need to escape the inner quotes, or use a different type of quotes within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotes, you can double quotes around the statement, and single quotes for any quoted values within the statement.

In the preceding example, the name of the `mysql` database was passed as a separate argument. However, the same statement could have been executed using this command, which specifies no default database:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
```

Multiple SQL statements may be passed on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: ******
+-----------------+
| VERSION()       |
+-----------------+
| 5.1.5-alpha-log |
+-----------------+
+---------------------+
| NOW()               |
+---------------------+
| 2006-01-05 21:19:04 |
```

```
+--------------------+
```

4.2.3.1.1. Program Option Modifiers

Some options control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file, An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

`mysqld` enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-query_cache_size=4M` prevents any client from making the query cache size larger than 4MB.

4.2.3.2. Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. For the MySQL server, MySQL provides a number of preconfigured option files.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

On Windows, MySQL programs read startup options from the following files.

File Name	Purpose
`WINDIR``\my.ini`, *`WINDIR`*`\my.cnf`	Global options
`C:\my.ini`, `C:\my.cnf`	Global options
`INSTALLDIR``\my.ini`, *`INSTALLDIR`*`\my.cnf`	Global options
`defaults-extra-file`	The file specified with `--defaults-extra-file=`*`path`*, if any

`WINDIR` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the MySQL installation directory. This is typically `C:\`*`PROGRAMDIR`*`\MySQL\MySQL 6.0 Server` where *`PROGRAMDIR`* represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 6.0 has been installed using the installation and configuration wizards. See The Location of the my.ini File.

On Unix, MySQL programs read startup options from the following files.

File Name	Purpose
`/etc/my.cnf`	Global options
`/etc/mysql/my.cnf`	Global options
`SYSCONFDIR``/my.cnf`	Global options
`$MYSQL_HOME/my.cnf`	Server-specific options
`defaults-extra-file`	The file specified with `--defaults-extra-file=`*`path`*, if any
`~/.my.cnf`	User-specific options

`SYSCONFDIR` represents the directory specified with the `--sysconfdir` option to `configure` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides.

If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let *`BASEDIR`* and *`DATADIR`* represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in *`DATADIR`* but not in *`BASEDIR`*, `mysqld_safe` sets `MYSQL_HOME` to *`DATADIR`*.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in *`DATADIR`*, `mysqld_safe` sets `MYSQL_HOME` to *`BASEDIR`*.

In MySQL 6.0, use of *`DATADIR`* as the location for `my.cnf` is deprecated.

Typically, *`DATADIR`* is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

> **Note**
>
> On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax, except that you omit the leading two dashes and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-`*`opt_name`* in an option file, write it as `loose-`*`opt_name`*.

Empty lines in option files are ignored. Non-empty lines can take any of the following forms:

- *`#comment`*, *`;comment`*

  Comment lines start with "`#`" or "`;`". A "`#`" comment can start in the middle of a line as well.

- `[`*`group`*`]`

  `group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given.

- *`opt_name`*

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

  This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the "`=`" character, something that is not true on the command line. You can enclose the value within single quotes or double quotes, which is useful if the value contains a "`#`" comment character or whitespace.

For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Leading and trailing blanks are automatically deleted from option names and values. You may use the escape sequences "`\b`", "`\t`", "`\n`", "`\r`", "`\\`", and "`\s`" in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters.

Because the "`\\`" escape sequence represents a single backslash, you must write each "`\`" as "`\\`". Alternatively, you can specify the value using "`/`" rather than "`\`" as the path name separator.

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This allows you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses `var_name=value` syntax for the lines that set the `key_buffer_size` and `max_allowed_packet` variables.

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

If you want to create option groups that should be read by `mysqld` servers from a specific MySQL release series only, you can do this by using groups with names of `[mysqld-5.1]`, `[mysqld-6.0]`, and so forth. The following group indicates that the `--new` option should be used only by MySQL servers with 6.0.x version numbers:

```
[mysqld-6.0]
new
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

There is no guarantee about the order in which the option files in the directory will be read.

> **Note**
>
> Currently, any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqldamin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

4.2.3.2.1. Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must immediately follow the command name, with the exception that `--print-defaults` may be used immediately after `--defaults-file` or `--defaults-extra-file`. Also, when specifying file names, you should avoid the use of the "~" shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=`*`file_name`*

  Read this option file after the global option file but (on Unix) before the user option file. *`file_name`* is the full path name to the file. If the file does not exist or is otherwise inaccessible, the program will exit with an error.

- `--defaults-file=`*`file_name`*

  Use only the given option file. *`file_name`* is the full path name to the file. If the file does not exist or is otherwise inaccessible, the program will exit with an error.

- `--defaults-group-suffix=`*`str`*

  If this option is given, the program reads not only its usual option groups, but also groups with the usual names and a suffix of *`str`*. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--no-defaults`

  Do not read any option files. If a program does not start because it is reading unknown options from an option file, `--no-defaults` can be used to prevent the program from reading them.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

4.2.3.2.2. Preconfigured Option Files

MySQL provides a number of preconfigured option files that can be used as a basis for tuning the MySQL server. Look for files such as `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample option files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf` extension.

> **Note**
>
> On Windows, the `.cnf` or `.ini` option file extension might not be displayed.

For a binary distribution, look for the files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. You can rename a copy of a sample file and place it in the appropriate location for use as a base configuration file. Regarding names and appropriate location, see the general information provided in Section 4.2.3.2, "Using Option Files".

4.2.3.3. Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 12.5.5, "`SET` Syntax", and Section 5.1.5, "Using System Variables".

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M

[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

> **Note**
>
> Before MySQL 4.0.2, the only syntax for setting program variables was `--set-variable=option=value` (or `set-variable=option=value` in option files). Underscores cannot be given as dashes, and the variable name must be specified in full. This syntax still is recognized, but is now deprecated.

4.2.3.4. Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equals sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named "tonfisk" using an account with the user name "jon".

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 6.0.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
MYSQL: OPTION '--USER' REQUIRES AN ARGUMENT
```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): UNKNOWN MYSQL SERVER HOST '--USER' (1)
```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named "--user".

Options having default values always require an equals sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value *`host_name`*`.err`, where *`host_name`* is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is "tonfisk", and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

```
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                    ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32  InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32  InnoDB: Starting shutdown...
080111 22:53:34  InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equals sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equals sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]

user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equals sign:

```
[mysql]

user=jon
```

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 6.0.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 6.0.12 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
```

```
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

Beginning with MySQL 6.0.12, specifying an option requiring a value without a value in an option file causes the server to abort with an error. For example, suppose `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &

090514 09:48:39 mysqld_safe Logging to '/home/jon/bin/mysql-6.0/var/tonfisk.err'.
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql-6.0/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql-6.0/var/tonfisk.pid ended
```

The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to *`datadir/hostname.err`*):

```
shell> tail -n 3 ../var/tonfisk.err

090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql-6.0/var
090514  9:48:39 [ERROR] /home/jon/bin/mysql-6.0/libexec/mysqld: option '--relay-log' requires an argument
090514  9:48:39 [ERROR] Aborting
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using "relay_log_index" as the basename. (Bug#25192)

4.2.4. Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. Section 2.13, "Environment Variables", lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows or NetWare, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and non-login shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for non-login shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.3. MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

4.3.1. `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, “The MySQL Server”. For information about installing MySQL and setting up the initial configuration, see Chapter 2, *Installing and Upgrading MySQL*.

4.3.2. `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix and NetWare. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. Descriptions of error logging and NetWare-specific behaviors are given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.1.2, “Server Command Options”.

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See Section 4.2.3.2, “Using Option Files”.

`mysqld_safe` reads all options from the `[mysqld]`, `[server]`, and `[mysqld_safe]` sections in option files. For example, if you specify a `[mysqld]` section like this, `mysqld_safe` will find and use the `--log-error` option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, `mysqld_safe` also reads `[safe_mysqld]` sections, although you should rename such sections to `[mysqld_safe]` in MySQL 6.0 installations.

Table 4.1. `mysqld_safe` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--autoclose	autoclose	On NetWare, mysqld_safe provides a screen presence			
--basedir=path	basedir	The path to the MySQL installation directory			
--core-file-size=size	core-file-size	The size of the core file that mysqld should be able to create			
--datadir=path	datadir	The path to the data directory			
--defaults-extra-file=path	defaults-extra-file	The name of an option file to be read in addition to the usual option files			
--defaults-file=file_name	defaults-file	The name of an option file to be read instead of the usual option files			
--help		Display a help message and exit			
--ledir=path	ledir	Use this option to indicate the path name to the directory where the server is located			
--log-error=file_name	log-error	Write the error log to the given file			
--mysqld=prog_name	mysqld	The name of the server program (in the ledir directory) that you want to start			
--mysqld-version=suffix	mysqld-version	This option is similar to the --mysqld option, but you specify only the suffix for the server program name			
--nice=priority	nice	Use the nice program to set the server's scheduling priority to the given value			
--no-defaults	no-defaults	Do not read any option files			
--open-files-limit=count	open-files-limit	The number of files that mysqld should be able to open			
--pid-file	pid-file	The path name of the process ID file			
--port=number	port	The port number that the server should use when listening for TCP/IP connections			
--skip-kill-mysqld	skip-kill-mysqld	Do not try to kill stray mysqld processes			
--skip-syslog	skip-syslog	Do not write error messages to syslog; use error log file			
--socket=path	socket	The Unix socket file that the server should use when listening for local connections			
--syslog	syslog	Write error messages to syslog			
--timezone=timezone	timezone	Set the TZ time zone environment variable to the given option value			
--user={user_name|user_id}	user	Run the mysqld server as the user having the name user_name or the numeric user ID user_id			

`mysqld_safe` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`

  Display a help message and exit.

- `--autoclose`

  (NetWare only) On NetWare, `mysqld_safe` provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input:

  ```
  *<NLM has terminated; Press any key to close the screen>*
  ```

  If you want NetWare to close the screen automatically instead, use the `--autoclose` option to `mysqld_safe`.

- `--basedir=path`

  The path to the MySQL installation directory.

- `--core-file-size=size`

  The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=path`

  The path to the data directory.

- `--defaults-extra-file=path`

  The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.

- `--defaults-file=file_name`

  The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- `--ledir=path`

  If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

- `--log-error=file_name`

  Write the error log to the given file. See Section 5.2.2, “The Error Log”.

- `--mysqld=prog_name`

  The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

- `--mysqld-version=suffix`

  This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority`

  Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

  Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count`

  The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=file_name`

The path name of the process ID file.

- `--port=port_num`

  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld`

  Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

  The Unix socket file that the server should use when listening for local connections.

- `--syslog`, `--skip-syslog`

  `--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

- `--syslog-tag=tag`

  For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

- `--timezone=timezone`

  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

  Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, “Installation Layouts”.) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).

- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (*`host_name`*`.err` in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=`*`file_name`*: Write error messages to the named error file.

If none of these options is given, the default is `--skip-syslog`.

If `--syslog` and `--log-error` are both given, a warning is issued and `--log-error` takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

On NetWare, `mysqld_safe` is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on `MyISAM` tables.
3. Provides a screen presence for the MySQL server.
4. Starts `mysqld`, monitors it, and restarts it if it terminates in error.
5. Sends error messages from `mysqld` to the *`host_name`*`.err` file in the data directory.
6. Sends `mysqld_safe` screen output to the *`host_name`*`.safe` file in the data directory.

4.3.3. `mysql.server` — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-`*`VERSION`*`.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 6.0.

`mysql.server` supports the following options:

- `--basedir=path`

  The path to the MySQL installation directory.

- `--datadir=path`

  The path to the MySQL data directory.

- `--pid-file=file_name`

  The path name of the file in which the server should write its process ID.

- `--service-startup-timeout=file_name`

  How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

- `--use-mysqld_safe`

  Use `mysqld_safe` to start the server. This is the default.

- `--user=user_name`

  The login user name to use for running `mysqld`.

4.3.4. `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--config-file` option). *`N`* can be any positive integer. This number is referred to in the following discussion as the option group number, or *`GNR`*. Group numbers distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the `[mysqld]` group used for starting `mysqld`. (See, for example, Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.6, “Running Multiple MySQL Servers on the Same Machine”.

To invoke `mysqld_multi`, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *`GNR`* list that follows the option name. If there is no list, `mysqld_multi` performs the operation for all servers in the option file.

Each *`GNR`* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *`GNR`* for a group named `[mysqld17]` is `17`. To specify a range of numbers, separate the first and last numbers by a dash. The *`GNR`* value `10-13` represents groups `[mysqld10]` through `[mysqld13]`. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *`GNR`* list; anything after a whitespace character is ignored.

This command starts a single server using option group `[mysqld17]`:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

`mysqld_multi` searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for `[mysqld_multi]` and `[mysqldN]` option groups.

`mysqld_multi` supports the following options:

- `--help`

  Display a help message and exit.

- `--config-file=file_name`

  This option is deprecated. If given, it is treated the same way as `--defaults-extra-file`, described earlier.

- `--example`

  Display a sample option file.

- `--log=file_name`

  Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

  The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

  The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.) Example:

  ```
  [mysqld38]
  mysqld = mysqld-debug
  ledir  = /opt/local/mysql/libexec
  ```

- `--no-log`

  Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

  The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

  Silent mode; disable warnings.

- `--tcp-ip`

  Connect to each MySQL server via the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only via the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

  The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

  Be more verbose.

- `--version`

  Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important**: Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See Section 5.6, "Running Multiple MySQL Servers on the Same Machine".

- **Important**

  Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix *`root`* account for this, unless you *know* what you are doing. See Section 5.3.5, "How to Run MySQL as a Normal User".

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

  ```
  shell> mysql -u root -S /tmp/mysql.sock -p
  Enter password:
  mysql> GRANT SHUTDOWN ON *.*
      -> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
  ```

  See Section 5.4, "The MySQL Access Privilege System". You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must allow you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

  ```
  ----------------------------------------------------------------
  MY_PWD=`pwd`
  # Check if we are starting this relative (for the binary release)
  if test -d $MY_PWD/data/mysql -a \
     -f ./share/mysql/english/errmsg.sys -a \
     -x ./bin/mysqld
  ----------------------------------------------------------------
  ```

  The test performed by these lines should be successful, or you might encounter problems. See Section 4.3.2, "`mysqld_safe` — MySQL Server Startup Script".

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix `root` user. Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have "gaps" in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld     = /usr/local/bin/mysqld_safe
mysqladmin = /usr/local/bin/mysqladmin
user       = multi_admin
```

```
password   = multipass

[mysqld2]
socket     = /tmp/mysql.sock2
port       = 3307
pid-file   = /usr/local/mysql/var2/hostname.pid2
datadir    = /usr/local/mysql/var2
language   = /usr/local/share/mysql/english
user       = john

[mysqld3]
socket     = /tmp/mysql.sock3
port       = 3308
pid-file   = /usr/local/mysql/var3/hostname.pid3
datadir    = /usr/local/mysql/var3
language   = /usr/local/share/mysql/swedish
user       = monty

[mysqld4]
socket     = /tmp/mysql.sock4
port       = 3309
pid-file   = /usr/local/mysql/var4/hostname.pid4
datadir    = /usr/local/mysql/var4
language   = /usr/local/share/mysql/estonia
user       = tonu

[mysqld6]
socket     = /tmp/mysql.sock6
port       = 3311
pid-file   = /usr/local/mysql/var6/hostname.pid6
datadir    = /usr/local/mysql/var6
language   = /usr/local/share/mysql/japanese
user       = jani
```

See Section 4.2.3.2, “Using Option Files”.

4.4. MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1. `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file located at `sql/share/errmsg.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ername.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the options described in the following list.

- `--help`, `-?`

  Display a help message and exit.

- `--charset=path, -C path`

  The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options, -# debug_options`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:O,file_name'`. The default is `'d:t:O,/tmp/comp_err.trace'`.

- `--debug-info`, `-T`

  Print some debugging information when the program exits.

- `--header_file=file_name, -H file_name`

  The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name, -F file_name`

  The name of the input file. The default is `../sql/share/errmsg.txt`.

- `--name_file=file_name, -N file_name`

  The name of the error name file. The default is `mysqld_ername.h`.

- `--out_dir=path, -D path`

  The name of the output base directory. The default is `../sql/share/`.

- `--out_file=file_name, -O file_name`

  The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name, -S file_name`

  The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version`, `-V`

  Display version information and exit.

4.4.2. `make_win_bin_dist` — Package MySQL Distribution as ZIP Archive

This script is used on Windows after building a MySQL distribution from source to create executable programs. It packages the binaries and support files into a ZIP archive that can be unpacked at the location where you want to install MySQL.

`make_win_bin_dist` is a shell script, so you must have Cygwin installed to use it.

This program's use is subject to change. Currently, you invoke it as follows from the root directory of your source distribution:

```
shell> make_win_bin_dist [options] package_basename [copy_def ...]
```

The *`package_basename`* argument provides the basename for the resulting ZIP archive. This name will be the name of the directory that results from unpacking the archive.

Because you might want to include files of directories from other builds, you can instruct this script do copy them in for you, via *`copy_def`* arguments, which of which is of the form *`relative_dest_name`*`=`*`source_name`*.

Example:

```
bin/mysqld-max.exe=../my-max-build/sql/release/mysqld.exe
```

If you specify a directory, the entire directory will be copied.

`make_win_bin_dist` supports the following options:

- `--debug`

  Pack the debug binaries and produce an error if they were not built.

- `--embedded`

  Pack the embedded server and produce an error if it was not built. The default is to pack it if it was built.

- `--exe-suffix=suffix`

  Add a suffix to the basename of the `mysql` binary. For example, a suffix of `-abc` produces a binary named `mysqld-abc.exe`.

- `--no-debug`

  Don't pack the debug binaries even if they were built.

- `--no-embedded`

  Don't pack the embedded server even if it was built.

- `--only-debug`

  Use this option when the target for this build was `Debug`, and you just want to replace the normal binaries with debug versions (that is, do not use separate `debug` directories).

4.4.3. `mysqlbug` — Generate Bug Report

This program enables you to generate a bug report and send it to MySQL AB. It is a shell script and runs on Unix.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script.

`mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

Invoke `mysqlbug` without arguments:

```
shell> mysqlbug
```

The script will place you in an editor with a copy of the report to be sent. Edit the lines near the beginning that indicate the nature of the problem. Then write the file to save your changes, quit the editor, and `mysqlbug` will send the report by email.

4.4.4. `mysql_fix_privilege_tables` — Upgrade MySQL System Tables

Some releases of MySQL introduce changes to the structure of the system tables in the `mysql` database to add new privileges or support new features. When you update to a new version of MySQL, you should update your system tables as well to make sure that their structure is up to date. Otherwise, there might be capabilities that you cannot take advantage of.

`mysql_fix_privilege_tables` is an older script that previously was used to uprade the system tables in the `mysql` database after a MySQL upgrade.

> **Note**
>
> As of MySQL 5.1.7, `mysql_fix_privilege_tables` is superseded by `mysql_upgrade`, which should be used instead. See Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

Before running `mysql_fix_privilege_tables`, make a backup of your `mysql` database.

On Unix or Unix-like systems, update the system tables by running the `mysql_fix_privilege_tables` script:

```
shell> mysql_fix_privilege_tables
```

You must run this script while the server is running. It attempts to connect to the server running on the local host as `root`. If your `root` account requires a password, indicate the password on the command line like this:

```
shell> mysql_fix_privilege_tables --password=root_password
```

The `mysql_fix_privilege_tables` script performs any actions necessary to convert your system tables to the current format. You might see some `Duplicate column name` warnings as it runs; you can ignore them.

After running the script, stop the server and restart it so that any changes made to the system tables take effect.

On Windows systems, MySQL distributions include a `mysql_fix_privilege_tables.sql` SQL script that you can run using the `mysql` client. For example, if your MySQL installation is located at `C:\Program Files\MySQL\MySQL Server 6.0`, the commands look like this:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 6.0"
C:\> bin\mysql -u root -p mysql
mysql> SOURCE scripts/mysql_fix_privilege_tables.sql
```

The `mysql` command will prompt you for the `root` password; enter it when prompted.

If your installation is located in some other directory, adjust the path names appropriately.

As with the Unix procedure, you might see some `Duplicate column name` warnings as `mysql` processes the statements in the `mysql_fix_privilege_tables.sql` script; you can ignore them.

After running the script, stop the server and restart it.

4.4.5. mysql_install_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist.

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, needs to access the data directory when it runs later, you should either run `mysql_install_db` from the same account that will be used for running `mysqld` or run it as `root` and use the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> bin/mysql_install_db --user=mysql \
         --basedir=/opt/mysql/mysql \
         --datadir=/opt/mysql/mysql/data
```

`mysql_install_db` needs to invoke `mysqld` with the `--bootstrap` and `--skip-grant-tables` options (see Section 2.9.2, "Typical `configure` Options"). If MySQL was configured with the `--disable-grant-options` option, `--bootstrap` and `--skip-grant-tables` will be disabled. To handle this, set the `MYSQLD_BOOTSTRAP` environment variable to the full path name of a server that has all options enabled. `mysql_install_db` will use that server.

`mysql_install_db` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, "Command-Line Options that Affect Option-File Handling".

- `--basedir=path`

  The path to the MySQL installation directory.

- `--force`

  Causes `mysql_install_db` to run even if DNS does not work. In that case, grant table entries that normally use host names will use IP addresses.

- `--datadir=path`, `--ldata=path`

  The path to the MySQL data directory.

- `--rpm`

  For internal use. This option is used by RPM files during the MySQL installation process.

- `--skip-name-resolve`

  Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=path`

  For internal use. The directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables. This option was added in MySQL 5.1.14.

- `--user=user_name`

  The login user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose`

  Verbose mode. Print more information about what the program does.

- `--windows`

  For internal use. This option is used for creating Windows distributions.

4.4.6. mysql_secure_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for root accounts.
- You can remove root accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the test database, which by default can be accessed by anonymous users.

Invoke mysql_secure_installation without arguments:

```
shell> mysql_secure_installation
```

The script will prompt you to determine which actions to perform.

4.4.7. mysql_tzinfo_to_sql — Load the Time Zone Tables

The mysql_tzinfo_to_sql program loads the time zone tables in the mysql database. It is used on systems that have a *zoneinfo* database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Sun Solaris, and Mac OS X. One likely location for these files is the /usr/share/zoneinfo directory (/usr/share/lib/zoneinfo on Solaris). If your system does not have a zoneinfo database, you can use the downloadable package described in Section 9.7, "MySQL Server Time Zone Support".

mysql_tzinfo_to_sql can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to mysql_tzinfo_to_sql and send the output into the mysql program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

mysql_tzinfo_to_sql reads your system's time zone files and generates SQL statements from them. mysql processes those statements to load the time zone tables.

The second syntax causes mysql_tzinfo_to_sql to load a single time zone file *tz_file* that corresponds to a time zone name *tz_name*:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke mysql_tzinfo_to_sql using the third syntax, which initializes the leap second information. *tz_file* is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running mysql_tzinfo_to_sql, it is best to restart the server so that it does not continue to use any previously cached time zone data.

4.4.8. mysql_upgrade — Check Tables for MySQL Upgrade

mysql_upgrade examines all tables in all databases for incompatibilities with the current version of MySQL Server. mysql_upgrade also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

mysql_upgrade should be executed each time you upgrade MySQL. It supersedes the older mysql_fix_privilege_tables script, which should no longer be used.

If a table is found to have a possible incompatibility, mysql_upgrade performs a table check. If any problems are found, a table repair is attempted. If the table cannot be repaired, see Section 2.11.4, "Rebuilding or Repairing Tables or Indexes" for manual table repair strategies.

Caution

> You should always back up your current MySQL installation *before* performing an upgrade. See Section 6.1, “Database Backups”.
>
> Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See Section 2.11.1, “Upgrading MySQL”, for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --all-databases --check-upgrade --auto-repair
mysql < fix_priv_tables
mysqlcheck --all-databases --check-upgrade --fix-db-names --fix-table-names
```

Notes about the preceding commands:

- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.
- For details about what checks the `--check-upgrade` option entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see Section 12.5.2.2, “`CHECK TABLE` Syntax”).
- *`fix_priv_tables`* represents a script generated interally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.
- Prior to MySQL 6.0.10, `mysql_upgrade` does not run the second `mysqlcheck` command, which is necessary to re-encode database or table names that contain non-alphanumeric characters. (They still appear after the upgrade with the `#mysql50#` prefix described in Section 8.2.3, “Mapping of Identifiers to File Names”.) If you have such database or table names, execute the second `mysqlcheck` command manually after executing `mysql_upgrade`.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See Section 2.4, “Installing MySQL from RPM Packages on Linux”.)

`mysql_upgrade` supports the options in the following list. It also reads option files (the `[mysql_upgrade]` and `[client]` groups) and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”. Other options are passed to `mysqlcheck`. For example, it might be necessary to specify the `--password[=password]` option.

- `--help`

  Display a short help message and exit.

- `--basedir=path`

  The path to the MySQL installation directory.

- `--datadir=path`

  The path to the data directory.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--force`

  Ignore the `mysql_upgrade_info` file and force execution of `mysqlcheck` even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--tmpdir=path`, `-t path`

  The path name of the directory to use for creating temporary files. This option was added in MySQL 6.0.6.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server. The default user name is `root`.

- `--verbose`

  Verbose mode. Print more information about what the program does.

4.5. MySQL Client Programs

4.5.1. `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell (with GNU `readline` capabilities). It supports interactive and non-interactive use. When used interactively, query results are presented in an ASCII-table format. When used non-interactively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with "`;`", `\g`, or `\G` and press Enter.

Typing Control-C causes `mysql` to attempt to kill the current statement. If this cannot be done, or Control-C is typed again before the statement is killed, `mysql` exits. Previously, Control-C caused `mysql` to exit in all cases.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

4.5.1.1. `mysql` Options

Table 4.2. `mysql` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--auto-rehash	auto-rehash	Enable automatic rehashing			
-- auto-vertical-output	auto-vertical-output	Enable automatic vertical result set display	6.0.4		
--batch	batch	Don't use history file			
-- -charac-	character-sets-dir	Set the default character set			

Format	Config File	Description	Introduction	Deprecated	Removed
ter-sets-dir=name					
--column-names	column-names	Write column names in results			
--column-type-info	column-type-info	Display result set metadata			
--comments	comments	Whether to retain or strip comments in statements sent to the server	6.0.4		
--compress	compress	Compress all information sent between the client and the server			
--connect_timeout=value	connect_timeout	The number of seconds before connection timeout			
--database=dbname	database	The database to use			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--delimiter=str	delimiter	Set the statement delimiter			
--execute=statement	execute	Execute the statement and quit			
--force	force	Continue even if an SQL error occurs			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--html	html	Produce HTML output			
--ignore-spaces	ignore-spaces	Ignore spaces after function names			
--line-numbers	line-numbers	Write line numbers for errors			
--local-infile[={0|1}]	local-infile	Enable or disable for LOCAL capability for LOAD DATA INFILE			
--max_allowed_packet=value	max_allowed_packet	The maximum packet length to send to or receive from the server			
--max_join_size=value	max_join_size	The automatic limit for rows in a join when using --safe-updates			
--named-commands	named-commands	Enable named mysql commands			
--net_buffer_length=value	net_buffer_length	The buffer size for TCP/IP and socket communication			
--no-auto-rehash		Disable automatic rehashing			

Format	Config File	Description	Introduction	Deprecated	Removed
--no-beep	no-beep	Do not beep when errors occur			
--no-named-commands	no-named-commands	Disable named mysql commands			
--no-pager	no-pager	Deprecated form of --skip-pager			
--no-tee	no-tee	Do not copy output to a file			
--one-database	one-database	Ignore statements except those for the default database named on the command line			
--pager[=command]	pager	Use the given command for paging query output			
--password[=password]	password	The password to use when connecting to the server			
--port=port_num	port	The TCP/IP port number to use for the connection			
--prompt=format_str	prompt	Set the prompt to the specified format			
--protocol=type	protocol	The connection protocol to use			
--quick	quick	Do not cache each query result			
--raw	raw	Write column values without escape conversion			
--reconnect	reconnect	If the connection to the server is lost, automatically try to reconnect			
--safe-updates	safe-updates	Allow only UPDATE and DELETE statements that specify key values			
--secure-auth	secure-auth	Do not send passwords to the server in old (pre-4.1.1) format			
--select_limit=value	select_limit	The automatic limit for SELECT statements when using --safe-updates			
--show-warnings	show-warnings	Show warnings after each statement if there are any			
--sigint-ignore	sigint-ignore	Ignore SIGINT signals (typically the result of typing Control-C)			
--silent	silent	Silent mode			
--skip-auto-rehash	skip-auto-rehash	Disable automatic rehashing			
--skip-column-names	skip-column-names	Do not write column names in results			
--skip-line-numbers	skip-line-numbers	Skip line numbers for errors			
--skip-named-commands	skip-named-commands	Disable named mysql commands			
--skip-pager	skip-pager	Disable paging			
--skip-reconnect	skip-reconnect	Disable reconnecting			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			

Format	Config File	Description	Introduction	Deprecated	Removed
ssl-capath=directory_name					
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--table	table	Display output in tabular format			
--tee=file_name	tee	Append a copy of output to the given file			
--unbuffered	unbuffered	Flush the buffer after each query			
--user=user_name	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			
--vertical	vertical	Print query output rows vertically (one line per column value)			
--wait	wait	If the connection cannot be established, wait and retry instead of aborting			
--xml	xml	Produce XML output			

`mysql` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `-?`

  Display a help message and exit.

- `--auto-rehash`

  Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command if you want to use name completion.

  To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

- `--auto-vertical-output`

  Causes result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.) This option was added in MySQL 6.0.4.

- `--batch`, `-B`

  Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

  Batch mode results in non-tabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--character-sets-dir=path`

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--column-names`

  Write column names in results.

- `--column-type-info`, `-m`

  Display result set metadata.

- `--comments`, `-c`

  Whether to preserve comments in statements sent to the server. The default is --skip-comments (discard comments), enable with --comments (preserve comments). This option was added in MySQL 6.0.4.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--database=db_name`, `-D db_name`

  The database to use. This is useful primarily in an option file.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysql.trace'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--delimiter=str`

  Set the statement delimiter. The default is the semicolon character (“`;`”).

- `--disable-named-commands`

  Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (“`;`”). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, “`mysql` Commands”.

- `--execute=statement`, `-e statement`

  Execute the statement and quit. The default output format is like that produced with `--batch`. See Section 4.2.3.1, “Using Options on the Command Line”, for some examples.

- `--force`, `-f`

  Continue even if an SQL error occurs.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--html`, `-H`

  Produce HTML output.

- `--ignore-spaces`, `-i`

  Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see

Section 5.1.7, “Server SQL Modes”).

- `--line-numbers`

  Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

  Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

  > **MySQL Enterprise**
  > For expert advice on the security implications of enabling `LOCAL`, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--named-commands`, `-G`

  Enable named `mysql` commands. Long-format commands are allowed, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See Section 4.5.1.2, “`mysql` Commands”.

- `--no-auto-rehash`, `-A`

  Deprecated form of `-skip-auto-rehash`. Use `--disable-auto-rehash` instead. See the description for `--auto-rehash`.

- `--no-beep`, `-b`

  Do not beep when errors occur.

- `--no-named-commands`, `-g`

  Deprecated, use `--disable-named-commands` instead.

- `--no-pager`

  Deprecated form of `--skip-pager`. See the `--pager` option.

- `--no-tee`

  Do not copy output to a file. Section 4.5.1.2, “`mysql` Commands”, discusses tee files further.

- `--one-database`, `-o`

  Ignore statements except those for the default database named on the command line. This is useful for skipping updates to other databases in the binary log.

- `--pager[=command]`

  Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix. It does not work in batch mode. To disable paging, use `--skip-pager`. Section 4.5.1.2, “`mysql` Commands”, discusses output paging further.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=port_num`, `-P port_num`

The TCP/IP port number to use for the connection.

- `--prompt=format_str`

  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 4.5.1.2, “`mysql` Commands”.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--quick`, `-q`

  Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw`, `-r`

  For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For non-tabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

  The following example demonstrates tabular versus non-tabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
+----------+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect`

  If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates`, `--i-am-a-dummy`, `-U`

  Allow only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See Section 4.5.1.5, “`mysql` Tips”, for more information about this option.

- `--secure-auth`

  Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format.

  MySQL Enterprise
  For expert advice on database security, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--show-warnings`

  Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

  Ignore `SIGINT` signals (typically the result of typing Control-C).

- `--silent`, `-s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in non-tabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names`, `-N`

  Do not write column names in results. The short format, `-N` is deprecated, use the long format instead.

- `--skip-line-numbers`, `-L`

  Do not write line numbers for errors. Useful when you want to compare result files that include error messages. The short format, `-L` is deprecated, use the long format instead.

- `--socket=`*`path`*, `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--table`, `-t`

  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=`*`file_name`*

  Append a copy of output to the given file. This option does not work in batch mode. Section 4.5.1.2, “`mysql` Commands”, discusses tee files further.

- `--unbuffered`, `-n`

  Flush the buffer after each query.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version`, `-V`

  Display version information and exit.

- `--vertical`, `-E`

  Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait`, `-w`

  If the connection cannot be established, wait and retry instead of aborting.

- `--xml`, `-X`

  Produce XML output.

```
<field name="column_name">NULL</field>
```

  The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See Section 4.5.4, “`mysqldump` — A Database Backup Program” for details.

  The XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>
```

```
<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<row>
<field name="Variable_name">version</field>
<field name="Value">5.0.40-debug</field>
</row>

<row>
<field name="Variable_name">version_comment</field>
<field name="Value">Source distribution</field>
</row>

<row>
<field name="Variable_name">version_compile_machine</field>
<field name="Value">i686</field>
</row>

<row>
<field name="Variable_name">version_compile_os</field>
<field name="Value">suse-linux-gnu</field>
</row>
</resultset>
```

(See Bug#25946.)

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated.

- `connect_timeout`

  The number of seconds before connection timeout. (Default value is `0`.)

- `max_allowed_packet`

  The maximum packet length to send to or receive from the server. (Default value is 16MB.)

- `max_join_size`

  The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `net_buffer_length`

  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

  The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

On Unix, the `mysql` client writes a record of executed statements to a history file. By default, this file is named `.mysql_history` and is created in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

The `.mysql_history` should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

If you do not want to maintain a history file, first remove `.mysql_history` if it exists, and then use either of the following techniques:

- Set the `MYSQL_HISTFILE` variable to `/dev/null`. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`:

  ```
  shell> ln -s /dev/null $HOME/.mysql_history
  ```

  You need do this only once.

4.5.1.2. `mysql` Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help
```

```
List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?         (\?) Synonym for `help'.
clear     (\c) Clear command.
connect   (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit      (\e) Edit command with $EDITOR.
ego       (\G) Send command to mysql server, display result vertically.
exit      (\q) Exit mysql. Same as quit.
go        (\g) Send command to mysql server.
help      (\h) Display this help.
nopager   (\n) Disable pager, print to stdout.
notee     (\t) Don't write into outfile.
pager     (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print     (\p) Print current command.
prompt    (\R) Change your mysql prompt.
quit      (\q) Quit mysql.
rehash    (\#) Rebuild completion hash.
source    (\.) Execute an SQL script file. Takes a file name as an argument.
status    (\s) Get status information from the server.
system    (\!) Execute a system shell command.
tee       (\T) Set outfile [to_outfile]. Append everything into given
               outfile.
use       (\u) Use another database. Takes database name as argument.
charset   (\C) Switch to another charset. Might be needed for processing
               binlog with multi-byte charsets.
warnings  (\W) Show warnings after every statement.
nowarning (\w) Don't show warnings after every statement.

For server side help, type 'help contents'
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line `/* ... */` comments is not supported.

- `help [arg]`, `\h [arg]`, `\? [arg]`, `? [arg]`

  Displays a help message listing the available `mysql` commands.

  If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.3, “`mysql` Server-Side Help”.

- `charset charset_name`, `\C charset_name`

  The `charset` command changes the default character set and issues a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear`, `\c`

  Clears the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]`, `\r [db_name host_name]`

  Reconnects to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str`, `\d str`

  The `delimiter` command changes the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“`;`”).

  The delimiter can be specified as an unquoted or quoted argument. Quoting can be done with either single quote (`'`) or douple quote (`"`) characters. To include a quote within a quoted string, either quote the string with the other quote character or escape the quote with a backslash (“`\`”) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delmiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

  When the delimiter recognized by `mysql` is set to something other than the default of “`;`”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “`;`” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see Section 20.10.12, “C API Support for Multiple Statement Execution”), and for parsing the body of stored procedures and functions, triggers, and events (see Section 18.1, “Defining Stored Programs”).

- `edit`, `\e`

  Edits the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine

which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego`, `\G`

  Sends the current statement to the server to be executed and displays the result using vertical format.

- `exit`, `\q`

  Exits `mysql`.

- `go`, `\g`

  Sends the current statement to the server to be executed.

- `nopager`, `\n`

  Disables output paging. See the description for `pager`.

  The `nopager` command works only in Unix.

- `notee`, `\t`

  Disables output copying to the tee file. See the description for `tee`.

- `nowarning`, `\w`

  Enables display of warnings after each statement.

- `pager [command]`, `\P [command]`

  By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that.

  Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

  Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print`, `\p`

  Prints the current input statement without executing it.

- `prompt [str]`, `\R [str]`

  Reconfigures the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

  If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit`, `\q`

  Exits `mysql`.

- `rehash`, `\#`

  Rebuilds the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `source file_name`, `\. file_name`

  Reads the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\\`.

- `status`, `\s`

  The `status` command provides some information about the connection and the server you are using. If you are running in `-`

`-safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command`, `\! command`

  Executes the given command using your default command interpreter.

  The `system` command works only in Unix.

- `tee [file_name]`, `\T [file_name]`

  By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt.

  You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name`, `\u db_name`

  Uses *db_name* as the default database.

- `warnings`, `\W`

  Enables display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

  ```
  mysql> pager cat > /tmp/log.txt
  ```

  You can also pass any options for the program that you want to use as your pager:

  ```
  mysql> pager less -n -i -S
  ```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

  ```
  shell> man less
  ```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

  ```
  mysql> pager less -n -i -S -F -X
  ```

- You can specify very complex pager commands for handling query output:

  ```
  mysql> pager cat | tee /dr1/tmp/res.txt \
            | tee /dr2/tmp/res2.txt | less -n -i -S
  ```

  In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen via `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description

`\c`	A counter that increments for each statement you issue
`\D`	The full current date
`\d`	The default database
`\h`	The server host
`\l`	The current delimiter
`\m`	Minutes of the current time
`\n`	A newline character
`\O`	The current month in three-letter format (Jan, Feb, …)
`\o`	The current month in numeric format
`\P`	am/pm
`\p`	The current TCP/IP port or socket file
`\R`	The current time, in 24-hour military time (0-23)
`\r`	The current time, standard 12-hour time (1-12)
`\S`	Semicolon
`\s`	Seconds of the current time
`\t`	A tab character
`\U`	Your full *`user_name@host_name`* account name
`\u`	Your user name
`\v`	The server version
`\w`	The current day of the week in three-letter format (Mon, Tue, …)
`\Y`	The current year, four digits
`\y`	The current year, two digits
`\_`	A space
`\ `	A space (a space follows the backslash)
`\'`	Single quote
`\"`	Double quote
`\\`	A literal "`\`" backslash character
`\x`	*`x`*, for any "*`x`*" not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\\u@\\h) [\\d]>\\_
```

  In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of allowable prompt options and the set of special escape sequences that are recognized in option files. (These sequences are listed in Section 4.2.3.2, "Using Option Files".) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

4.5.1.3. `mysql` Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.8, “Server-Side Help”).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
   Account Management
   Administration
   Data Definition
   Data Manipulation
   Data Types
   Functions
   Functions and Modifiers for Use with GROUP BY
   Geographic Features
   Language Structure
   Plugins
   Storage Engines
   Stored Routines
   Table Maintenance
   Transactions
   Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
   SHOW
   SHOW BINARY LOGS
   SHOW ENGINE
   SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 |    724935 |
| binlog.000016 |    733481 |
+---------------+-----------+
```

4.5.1.4. Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file *`text_file`* that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE` *`db_name`* statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

As of MySQL 6.0.4, `mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see Section 3.5, “Using mysql in Batch Mode”.

4.5.1.5. `mysql` Tips

This section describes some techniques that can help you use `mysql` more effectively.

4.5.1.5.1. Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
     date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
    reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
      sbj: UTF-8
      txt: >>>>> "Thimble" == Thimble Smith writes:

Thimble> Hi.  I think this is a good idea.  Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty
     file: inbox-jani-1
     hash: 190402944
1 row in set (0.09 sec)
```

4.5.1.5.2. Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM` *`tbl_name`* statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

See Section 5.1.4, “Session System Variables”.

The SET statement has the following effects:

- You are not allowed to execute an UPDATE or DELETE statement unless you specify a key constraint in the WHERE clause or provide a LIMIT clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large SELECT results to 1,000 rows unless the statement includes a LIMIT clause.
- The server aborts multiple-table SELECT statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the --select_limit and --max_join_size options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

4.5.1.5.3. Disabling mysql Auto-Reconnect

If the mysql client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if mysql succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
1 row in set (0.05 sec)
```

The @a user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have mysql terminate with an error if the connection has been lost, you can start the mysql client with the --skip-reconnect option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see Section 20.10.11, “Controlling Automatic Reconnection Behavior”.

4.5.2. mysqladmin — Client for Administering a MySQL Server

mysqladmin is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke mysqladmin like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

mysqladmin supports the commands described in the following list. Some of the commands take an argument following the command name.

- create *db_name*

  Create a new database named *db_name*.

- `debug`

  Tell the server to write debug information to the error log.

  This includes information about the Event Scheduler. See Section 18.4.5, “Event Scheduler Status”.

- `drop db_name`

  Delete the database named *db_name* and all its tables.

- `extended-status`

  Display the server status variables and their values.

  > **MySQL Enterprise**
  > For expert advice on using server status variables, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `flush-hosts`

  Flush all information in the host cache.

- `flush-logs`

  Flush all logs.

- `flush-privileges`

  Reload the grant tables (same as `reload`).

- `flush-status`

  Clear status variables.

- `flush-tables`

  Flush all tables.

- `flush-threads`

  Flush the thread cache.

- `kill id,id,...`

  Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- `old-password new-password`

  This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See Section 5.5.6.3, “Password Hashing in MySQL”.)

  > **MySQL Enterprise**
  > For expert advice on the security implications of using the `old-password` command, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `password new-password`

  Set a new password. This changes the password to *new-password* for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

  If the *new-password* value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotes. On Windows, be sure to use double quotes rather than single quotes; single quotes are not stripped from the password, but rather are interpreted as part of the password. For example:

  ```
  shell> mysqladmin password "my new password"
  ```

  > **Caution**
  >
  > Do not use this command used if the server was started with the `--skip-grant-tables` option. No password

change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

  Check whether the server is alive. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

  Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 12.5.6.30, "`SHOW PROCESSLIST` Syntax".)

- `reload`

  Reload the grant tables.

- `refresh`

  Flush all tables and close and open log files.

- `shutdown`

  Stop the server.

- `start-slave`

  Start replication on a slave server.

- `status`

  Display a short server status message.

- `stop-slave`

  Stop replication on a slave server.

- `variables`

  Display the server system variables and their values.

  MySQL Enterprise
  For expert advice on using server system variables, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `version`

  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+----+-------+-----------+----+---------+------+-------+------------------+
| Id | User  | Host      | db | Command | Time | State | Info             |
+----+-------+-----------+----+---------+------+-------+------------------+
| 51 | monty | localhost |    | Query   | 0    |       | show processlist |
+----+-------+-----------+----+---------+------+-------+------------------+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

  The number of seconds the MySQL server has been running.

- `Threads`

The number of active threads (clients).

- `Questions`

  The number of questions (queries) from clients since the server was started.

- `Slow queries`

  The number of queries that have taken more than `long_query_time` seconds. See Section 5.2.5, “The Slow Query Log”.

- `Opens`

  The number of tables the server has opened.

- `Flush tables`

  The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

  The number of tables that currently are open.

- `Memory in use`

  The amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

- `Maximum memory used`

  The maximum amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `--with-debug=full`.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

Table 4.3. `mysqladmin` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--compress	compress	Compress all information sent between the client and the server			
--connect_timeout=seconds	connect_timeout	The number of seconds before connection timeout			
--count=#	count	The number of iterations to make for repeated command execution			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--force	force	Continue even if an SQL error occurs			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--no-beep	no-beep	Do not beep when errors occur			

Format	Config File	Description	Introduction	Deprecated	Removed
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--protocol=type	protocol	The connection protocol to use			
--relative	relative	Show the difference between the current and previous values when used with the --sleep option			
--shutdown_timeout=seconds	shutdown_timeout	The maximum number of seconds to wait for server shutdown			
--silent	silent	Silent mode			
--sleep=delay	sleep	Execute commands repeatedly, sleeping for delay seconds in between			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			
--vertical	vertical	Print query output rows vertically (one line per column value)			
--wait	wait	If the connection cannot be established, wait and retry instead of aborting			

`mysqladmin` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--count=N`, `-c N`

  The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqladmin.trace'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

  Use *`charset_name`* as the default character set. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--force`, `-f`

  Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--no-beep`, `-b`

  Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--relative`, `-r`

  Show the difference between the current and previous values when used with the `--sleep` option. Currently, this option works only with the `extended-status` command.

- `--silent`, `-s`

  Exit silently if a connection to the server cannot be established.

- `--sleep=delay`, `-i delay`

Execute commands repeatedly, sleeping for *`delay`* seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=`*`path`*, `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

- `--vertical`, `-E`

  Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=`*`count`*`]`, `-w[`*`count`*`]`

  If the connection cannot be established, wait and retry instead of aborting. If a *`count`* value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--`*`var_name=value`* The `--set-variable` format is deprecated. syntax:

- `connect_timeout`

  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

  The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

4.5.3. `mysqlcheck` — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed. Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 12.5.2, “Table Maintenance Statements”.

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note     : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see Section 2.11.4, "Rebuilding or Repairing Tables or Indexes" for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

The use of `mysqlcheck` with partitioned tables is not supported before MySQL 6.0.6.

> **Caution**
>
> It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```
shell> mysqlcheck [options] db_name [tables]
shell> mysqlcheck [options] --databases db_name1 [db_name2 db_name3...]
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following *`db_name`* or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The following names can be used to change `mysqlcheck` default behavior.

`mysqlrepair`	The default option is `--repair`
`mysqlanalyze`	The default option is `--analyze`
`mysqloptimize`	The default option is `--optimize`

Table 4.4. `mysqlcheck` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--all-databases	all-databases	Check all tables in all databases			
--all-in-1	all-in-1	Execute a single statement for each database that names all the tables from that database			
--analyze	analyze	Analyze the tables			
--auto-repair	auto-repair	If a checked table is corrupted, automatically fix it			
--character-sets-dir=path	character-sets-dir	The directory where character sets are installed			
--check	check	Check the tables for errors			
--check-only-changed	check-only-changed	Check only tables that have changed since the last check			
--check-upgrade	check-upgrade	Invoke CHECK TABLE with the FOR UPGRADE option			
--compress	compress	Compress all information sent between the client and the server			
--databases	databases	Process all tables in the named databases			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			

Format	Config File	Description	Introduction	Deprecated	Removed
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--extended	extended	Check and repair tables			
--fast	fast	Check only tables that have not been closed properly			
--fix-db-names	fix-db-names	Convert database names to 5.1 format			
--fix-table-names	fix-table-names	Convert table names to 5.1 format			
--force	force	Continue even if an SQL error occurs			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--medium-check	medium-check	Do a check that is faster than an --extended operation			
--optimize	optimize	Optimize the tables			
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--protocol=type	protocol	The connection protocol to use			
--quick	quick	The fastest method of checking			
--repair	repair	Perform a repair that can fix almost anything except unique keys that are not unique			
--silent	silent	Silent mode			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--tables	tables	Overrides the --databases or -B option			
--use-frm	use-frm	For repair operations on MyISAM tables			
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			

`mysqlcheck` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, "Command-Line Options that Affect Option-File Handling".

- `--help`, `-?`

  Display a help message and exit.

- `--all-databases`, `-A`

  Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--all-in-1`, `-1`

  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze`, `-a`

  Analyze the tables.

  MySQL Enterprise
  For expert advice on optimizing tables, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--auto-repair`

  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, "The Character Set Used for Data and Sorting".

- `--check`, `-c`

  Check the tables for errors. This is the default operation.

- `--check-only-changed`, `-C`

  Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade`, `-g`

  Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options.

- `--compress`

  Compress all information sent between the client and the server if both support compression.

- `--databases`, `-B`

  Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=`*`debug_options`*`]`, `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=`*`charset_name`*

  Use *`charset_name`* as the default character set. See Section 9.2, "The Character Set Used for Data and Sorting".

- `--extended`, `-e`

  If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

  If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--fast`, `-F`

  Check only tables that have not been closed properly.

- `--fix-db-names`

  Convert database names to 5.1 format. Only database names that contain special characters are affected.

- `--fix-table-names`

  Convert table names to 5.1 format. Only table names that contain special characters are affected. As of MySQL 6.0.5, this option also applies to views.

- `--force`, `-f`

  Continue even if an SQL error occurs.

- `--host=`*`host_name`*, `-h` *`host_name`*

  Connect to the MySQL server on the given host.

- `--medium-check`, `-m`

  Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--optimize`, `-o`

  Optimize the tables.

- `--password[=`*`password`*`]`, `-p[`*`password`*`]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=`*`port_num`*, `-P` *`port_num`*

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--quick`, `-q`

  If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

  If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair`, `-r`

  Perform a repair that can fix almost anything except unique keys that are not unique.

- `--silent`, `-s`

  Silent mode. Print only error messages.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--tables`

  Overrides the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm`

  For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print information about the various stages of program operation.

- `--version`, `-V`

  Display version information and exit.

4.5.4. `mysqldump` — A Database Backup Program

The `mysqldump` client is a backup program originally written by Igor Romanenko. It can be used to dump a database or a collection of databases for backup or transfer to another SQL server (not necessarily a MySQL server). The dump typically contains SQL statements to create the table, populate it, or both. However, `mysqldump` can also be used to generate files in CSV, other delimited text, or XML format.

If you are doing a backup on the server and your tables all are `MyISAM` tables, consider using the `mysqlhotcopy` instead because it can accomplish faster backups and faster restores. See Section 4.6.10, “`mysqlhotcopy` — A Database Backup Program”.

There are three general ways to invoke `mysqldump`:

```
shell> mysqldump [options] db_name [tables]
shell> mysqldump [options] --databases db_name1 [db_name2 db_name3...]
shell> mysqldump [options] --all-databases
```

If you do not name any tables following *db_name* or if you use the `--databases` or `--all-databases` option, entire databases are dumped.

`mysqldump` does not dump the `INFORMATION_SCHEMA` database. If you name that database explicitly on the command line, `mysqldump` silently ignores it.

To get a list of the options your version of `mysqldump` supports, execute `mysqldump --help`.

Some `mysqldump` options are shorthand for groups of other options. `--opt` and `--compact` fall into this category. For example, use of `--opt` is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. Note that all of the options that `--opt` stands for also are on by default because `--opt` is on by default.

To reverse the effect of a group option, uses its `--skip-xxx` form (`--skip-opt` or `--skip-compact`). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. For example, to disable exten-

ded inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (As of MySQL 6.0, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)

- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default in MySQL 6.0; to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

Table 4.5. `mysqldump` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--add-drop-database	add-drop-database	Add a DROP DATABASE statement before each CREATE DATABASE statement			
--add-drop-table	add-drop-table	Add a DROP TABLE statement before each CREATE TABLE statement			
--add-locks	add-locks	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements			
--all-databases	all-databases	Dump all tables in all databases			
--allow-keywords	allow-keywords	Allow creation of column names that are keywords			
--apply-slave-statements	apply-slave-statements	Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output	6.0.4		
--comments	comments	Add comments to the dump file			
--compact	compact	Produce less verbose output			
--compatible=name[,name,...]	compatible	Produce output that is more compatible with other database systems or with older MySQL servers			
--complete-insert	complete-insert	Use complete INSERT statements that include column names			
--create-options	create-options	Include all MySQL-specific table options in the CREATE TABLE statements			
--databases	databases	Dump several databases			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--delayed-insert	delayed-insert	Write INSERT DELAYED statements rather than			

Format	Config File	Description	Introduction	Deprecated	Removed
		INSERT statements			
--delete-master-logs	delete-master-logs	On a master replication server, delete the binary logs after performing the dump operation			
--disable-keys	disable-keys	For each table, surround the INSERT statements with disable and enable keys statements			
--dump-date	dump-date	Include dump date in "Dump completed on" comment if --comments is given	6.0.4		
--dump-slave[=value]	dump-slave	Include CHANGE MASTER statement that lists binary log coordinates of slave's master	6.0.4		
--events	events	Dump events from the dumped databases			
--extended-insert	extended-insert	Use multiple-row INSERT syntax that include several VALUES lists			
--fields-enclosed-by=string	fields-enclosed-by	This option is used with the -T option and has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-escaped-by	fields-escaped-by	This option is used with the -T option and has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-optionally-enclosed-by=string	fields-optionally-enclosed-by	This option is used with the -T option and has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-terminated-by=string	fields-terminated-by	This option is used with the -T option and has the same meaning as the corresponding clause for LOAD DATA INFILE			
--lock-all-tables	first-slave	Deprecated. Now renamed to --lock-all-tables			
--flush-logs	flush-logs	Flush the MySQL server log files before starting the dump			
--flush-privileges	flush-privileges	Emit a FLUSH PRIVILEGES statement after dumping the mysql database			
--help		Display help message and exit			
--hex-blob	hex-blob	Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263)			
--ignore-table=db_name.tbl_name	ignore-table	Do not dump the given table			
--include-master-host-port	include-master-host-port	Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave	6.0.4		
--insert-ignore	insert-ignore	Write INSERT statements with the IGNORE option			
--lines-terminated-by=string	lines-terminated-by	This option is used with the -T option and has the same meaning as the corresponding clause for LOAD DATA INFILE			
--lock-all-tables	lock-all-tables	Lock all tables across all databases			
--lock-tables	lock-tables	Lock all tables before dumping them			
--log-error	log-error	Append warnings and errors to the named file			

Format	Config File	Description	Introduction	Deprecated	Removed
log-error=file_name					
--master-data[=value]	master-data	Write the binary log file name and position to the output			
--max_allowed_packet=value	max_allowed_packet	The maximum packet length to send to or receive from the server			
--net_buffer_length=value	net_buffer_length	The buffer size for TCP/IP and socket communication			
--no-autocommit	no-autocommit	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements			
--no-create-db	no-create-db	This option suppresses the CREATE DATABASE statements			
--no-create-info	no-create-info	Do not write CREATE TABLE statements that re-create each dumped table			
--no-data	no-data	Do not write any table row information (that is, do not dump table contents)			
--no-set-names	no-set-names	Turn off complete-insert			
--opt	opt	This option is shorthand; it is the same as specifying --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset.			
--order-by-primary	order-by-primary	Sorts each table's rows by its primary key, or by its first unique index			
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--quick	quick	Retrieve rows for a table from the server a row at a time			
--quote-names	quote-names	Quote database, table, and column names within backtick characters			
--replace	replace	Write REPLACE statements rather than INSERT statements			
--result-file=file	result-file	Direct output to a given file			
--routines	routines	Dump stored routines (procedures and functions) from the dumped databases			
--set-charset	set-charset	Add SET NAMES default_character_set to the output			
--single-transaction	single-transaction	This option issues a BEGIN SQL statement before dumping data from the server			
--skip-add-drop-table	skip-add-drop-table	Do not add			
--skip-add-locks	skip-add-locks	Do not add locks			
--skip-comments	skip-comments	Do not add comments to the dump file			
--skip-compact	skip-compact	Turn off compact			
--skip-disable-keys	skip-disable-keys	Do not disable keys			

Format	Config File	Description	Introduction	Deprecated	Removed
--skip-extended-insert	skip-extended-insert	Turn off extended-insert			
--skip-opt	skip-opt	Turn off the options set by opt			
--skip-quick	skip-quick	Do not retrieve rows for a table from the server a row at a time			
--skip-quote-names	skip-quote-names	Turn off quote names			
--skip-set-charset	skip-set-charset	Suppress the SET NAMES statement			
--skip-triggers	skip-triggers	Turn off triggers			
--skip-tz-utc	skip-tz-utc	Turn off tz-utc			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--tab=path	tab	Produce tab-separated data files			
--tables	tables	Override the --databases or -B option			
--triggers	triggers	Dump triggers for each dumped table			
--tz-utc	tz-utc	Add SET TIME_ZONE='+00:00' to the dump file			
--verbose		Verbose mode			
--version		Display version information and exit			
--where='where_condition'	where	Dump only rows selected by the given WHERE condition			
--xml	xml	Produce XML output			

`mysqldump` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `-?`

  Display a help message and exit.

- `--add-drop-database`

  Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement.

- `--add-drop-table`

  Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-locks`

  Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 7.2.25, "Speed of INSERT Statements".

- `--all-databases`, `-A`

  Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--allow-keywords`

  Allow creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--apply-slave-statements`

  For a slave dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output. This option was added in MySQL 6.0.4.

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, "The Character Set Used for Data and Sorting".

- `--comments`, `-i`

  Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--compact`

  Produce less verbose output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=`*`name`*

  Produce output that is more compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.1.7, "Server SQL Modes".

  This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

  This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.

- `--complete-insert`, `-c`

  Use complete `INSERT` statements that include column names.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--create-options`

  Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--databases`, `-B`

  Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

- `--debug[=`*`debug_options`*`]`, `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default value is `'d:t:o,/tmp/mysqldump.trace'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

  Use *`charset_name`* as the default character set. See Section 9.2, "The Character Set Used for Data and Sorting". If no character set is specified, `mysqldump` uses `utf8`, and earlier versions use `latin1`.

  This option has no effect for output data files produced by using the `--tab` option. See the description for that option.

- `--delayed-insert`

  Write `INSERT DELAYED` statements rather than `INSERT` statements.

- `--delete-master-logs`

  On a master replication server, delete the binary logs after performing the dump operation. This option automatically enables `--master-data`.

- `--disable-keys`, `-K`

  For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for non-unique indexes of `MyISAM` tables.

- `--dump-date`

  `mysqldump` produces a `-- Dump completed on DATE` comment at the end of the dump if the `--comments` option is given. However, the date causes dump files for identical data take at different times to appear to be different. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing. This option was added in MySQL 6.0.4.

- `--dump-slave[=value]`

  This option is similar to `--master-data` except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave's master (rather than the coordinates of the dumped server, as is done by the `--master-data` option). These are the master server coordinates from which the slave should start replicating. This option was added in MySQL 6.0.4.

  The option value is handled the same way as for `--master-data` and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

  In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

- `--events`, `-E`

  Dump events from the dumped databases.

- `--extended-insert`, `-e`

  Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

  These options are used with the `-T` option and have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 12.2.6, "`LOAD DATA INFILE` Syntax".

- `--first-slave`, `-x`

  Deprecated. Now renamed to `--lock-all-tables`.

- `--flush-logs`, `-F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. Note that if you use this option in combination with the `--all-databases` (or `-A`) option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables` or `--master-data`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data`.

- `--flush-privileges`

  Emit a `FLUSH PRIVILEGES` statement after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

- `--force`, `-f`

  Continue even if an SQL error occurs during a table dump.

  One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--host=`*`host_name`*, `-h` *`host_name`*

  Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--hex-blob`

  Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, `BLOB`, and `BIT`.

- `--include-master-host-port`

  For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` option, add `MASTER_PORT` and `MASTER_PORT` options for the host name and TCP/IP port number of the slave's master. This option was added in MySQL 6.0.4.

- `--ignore-table=`*`db_name.tbl_name`*

  Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--insert-ignore`

  Write `INSERT` statements with the `IGNORE` option.

- `--lines-terminated-by=...`

  This option is used with the `-T` option and has the same meaning as the corresponding clause for `LOAD DATA INFILE`. See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.

- `--lock-all-tables`, `-x`

  Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables`, `-l`

  Lock all tables before dumping them. The tables are locked with `READ LOCAL` to allow concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB` and `BDB`, `--single-transaction` is a much better option, because it does not need to lock the tables at all.

  Please note that when dumping multiple databases, `--lock-tables` locks tables for each database separately. Therefore, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

- `--log-error=`*`file_name`*

  Append warnings and errors to the named file.

- `--master-data[=`*`value`*`]`

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement takes effect when the dump file is reloaded. If the option value is not specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master. To do this, use the `--dump-slave` option instead.

- `--no-autocommit`

  Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--no-create-db`, `-n`

  This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info`, `-t`

  Do not write `CREATE TABLE` statements that re-create each dumped table.

- `--no-data`, `-d`

  Do not write any table row information (that is, do not dump table contents). This is very useful if you want to dump only the `CREATE TABLE` statement for the table.

- `--no-set-names`

  This option is deprecated. Use `--skip-set-charset`. instead.

- `--opt`

  This option is shorthand; it is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.

  The `--opt` option is enabled by default. Use `--skip-opt` to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling certain of the options affected by `--opt`.

- `--order-by-primary`

  Sorts each table's rows by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but will make the dump itself take considerably longer.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=port_num`, `-P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, "Connecting to the MySQL Server".

- `--quick`, `-q`

  This option is useful for dumping large tables. It forces `mysqldump` to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--quote-names`, `-Q`

  Quote database, table, and column names within "`" characters. If the `ANSI_QUOTES` SQL mode is enabled, names are quoted within "" characters. This option is enabled by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--replace`

  Write `REPLACE` statements rather than `INSERT` statements.

- `--result-file=`*`file_name`*, `-r` *`file_name`*

  Direct output to a given file. This option should be used on Windows to prevent newline "`\n`" characters from being converted to "`\r\n`" carriage return/newline sequences. The result file is created and its contents overwritten, even if an error occurs while generating the dump. The previous contents are lost.

- `--routines`, `-R`

  Dump stored routines (procedures and functions) from the dumped databases. Use of this option requires the `SELECT` privilege for the `mysql.proc` table. The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

  If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

- `--set-charset`

  Add `SET NAMES` *`default_character_set`* to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--single-transaction`

  This option issues a `BEGIN` SQL statement before dumping data from the server. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `BEGIN` was issued without blocking any applications.

  When using this option, you should keep in mind that only `InnoDB` and `Falcon` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

  While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log position), no other connection should use the following statements: `ALTER TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

  The `--single-transaction` option and the `--lock-tables` option are mutually exclusive, because `LOCK TABLES` causes any pending transactions to be committed implicitly.

  To dump large tables, you should combine this option with `--quick`.

- `--skip-comments`

  See the description for the `--comments` option.

- `--skip-opt`

See the description for the `--opt` option.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--tab=path`, `-T path`

  Produce tab-separated data files. For each dumped table, `mysqldump` creates a *`tbl_name`*`.sql` file that contains the `CREATE TABLE` statement that creates the table, and a *`tbl_name`*`.txt` file that contains its data. The option value is the directory in which to write the files.

  By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-`*`xxx`* and `--lines-terminated-by` options.

  Column values are dumped using the `binary` character set and the `--default-character-set` option is ignored. In effect, there is no character set conversion. If a table contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

  > **Note**
  >
  > This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

- `--tables`

  Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

  Dump triggers for each dumped table. This option is enabled by default; disable it with `--skip-triggers`.

- `--tz-utc`

  This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

- `--where='where_condition'`, `-w 'where_condition'`

  Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

  Examples:

  ```
  --where="user='jimf'"
  -w"userid>1"
  -w"userid<1"
  ```

- `--xml`, `-X`

  Write dump output as well-formed XML.

`NULL`, `'NULL'`, and Empty Values: For some column named *`column_name`*, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

Value:	**XML Representation**:
`NULL` (*unknown value*)	`<field name="column_name" xsi:nil="true" />`
`''` (*empty string*)	`<field name="column_name"></field>`
`'NULL'` (*string value*)	`<field name="column_name">NULL</field>`

The output from the `mysql` client when run using the `--xml` option also follows these rules. (See Section 4.5.1.1, "`mysql` Options".)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID" Collation="A" Cardinality="40
Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079" Avg_row_length="67" Data_length="2
3" Max_data_length="18858823439613951" Index_length="43008" Data_free="0" Auto_increment="4080" Create_time="2007-0
e_time="2007-03-31 01:47:02" Collation="latin1_swedish_ci" Create_options="" Comment="" />
</table_structure>
<table_data name="City">
<row>
<field name="ID">1</field>
<field name="Name">Kabul</field>
<field name="CountryCode">AFG</field>
<field name="District">Kabol</field>
<field name="Population">1780000</field>
</row>

...

<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mysqldump>
```

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

  The maximum size of the buffer for client/server communication. The maximum is 1GB.

- `net_buffer_length`

  The initial size of the buffer for client/server communication. When creating multiple-row-insert statements (as with option `--extended-insert` or `--opt`), `mysqldump` creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

The most common use of `mysqldump` is probably for making a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

You can read the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For `InnoDB` tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.2.4, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2
             > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for point-in-time recovery if tables are stored using the `InnoDB` storage engine.

For more information on making backups, see Section 6.1, “Database Backups”, and Section 6.2, “Example Backup and Recovery Strategy”.

If you encounter problems backing up views, please read the section that covers restrictions on views which describes a workaround for backing up views when this fails due to insufficient privileges. See Section D.5, “Restrictions on Views”.

> **MySQL Enterprise**
> MySQL Enterprise subscribers will find more information about `mysqldump` in the Knowledge Base article, How Can I Avoid Inserting Duplicate Rows From a Dump File?. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

4.5.5. `mysqlimport` — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

Table 4.6. `mysqlimport` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--columns=column_list	columns	This option takes a comma-separated list of column names as its value			
--compress	compress	Compress all information sent between the client and the server			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--delete	delete	Empty the table before importing the text file			
--fields-enclosed-by=string	fields-enclosed-by	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-escaped-by	fields-escaped-by	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-optionally-enclosed-by=string	fields-optionally-enclosed-by	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
--fields-terminated-by=string	fields-terminated-by	-- This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
--force	force	Continue even if an SQL error occurs			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--ignore	ignore	See the description for the --replace option			
--ignore-lines=#	ignore-lines	Ignore the first N lines of the data file			
--lines-terminated-by=string	lines-terminated-by	This option has the same meaning as the corresponding clause for LOAD DATA INFILE			
--local	local	Read input files locally from the client host			
--lock-tables	lock-tables	Lock all tables for writing before processing any text files			
--low-priority	low-priority	Use LOW_PRIORITY when loading the table.			
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--protocol=type	protocol	The connection protocol to use			
--replace	replace	The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values			

Format	Config File	Description	Introduction	Deprecated	Removed
--silent	silent	Produce output only when errors occur			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--use-threads=#	use-threads	The number of threads for parallel file-loading			
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			

`mysqlimport` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--columns=`*`column_list`*, `-c` *`column_list`*

  This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--debug[=`*`debug_options`*`]`, `-#` `[`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

  Use `charset_name` as the default character set. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--delete`, `-D`

  Empty the table before importing the text file.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

  These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.

- `--force`, `-f`

  Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name`, `-h host_name`

  Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore`, `-i`

  See the description for the `--replace` option.

- `--ignore-lines=N`

  Ignore the first `N` lines of the data file.

- `--lines-terminated-by=...`

  This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.

- `--local`, `-L`

  Read input files locally from the client host.

  MySQL Enterprise
  For expert advice on the security implications of enabling `LOCAL`, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--lock-tables`, `-l`

  Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority`

  Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=port_num`, `-P port_num`

The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--replace`, `-r`

  The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent`, `-s`

  Silent mode. Produce output only when errors occur.

- `--socket=`*`path`*, `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--use-threads=`*`N`*

  Load files in parallel using *`N`* threads.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100     Max Sydow
101     Count Dracula
.
w imptest.txt
32
q
shell> od -c imptest.txt
0000000   1   0   0  \t   M   a   x       S   y   d   o   w  \n   1   0
0000020   1  \t   C   o   u   n   t       D   r   a   c   u   l   a  \n
0000040
shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
+------+---------------+
|  100 | Max Sydow     |
|  101 | Count Dracula |
+------+---------------+
```

4.5.6. `mysqlshow` — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See Section 12.5.6, “`SHOW` Syntax”. The same

information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters ("`*`", "`?`", "`%`", or "`_`"), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. "`*`" and "`?`" characters are converted into SQL "`%`" and "`_`" wildcard characters. This might cause some confusion when you try to display the columns for a table with a "`_`" in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra "`%`" last on the command line as a separate argument.

Table 4.7. `mysqlshow` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--compress	compress	Compress all information sent between the client and the server			
--count	count	Show the number of rows per table			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--keys	keys	Show table indexes			
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--protocol=type	protocol	The connection protocol to use			
--show-table-type		Show a column indicating the table type			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
-	ssl-cert	The name of the SSL certificate file to use for es-			

Format	Config File	Description	Introduction	Deprecated	Removed
--ssl-cert=file_name		tablishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection			
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--status	status	Display extra information about each table			
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			

`mysqlshow` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- `--help`, `-?`

  Display a help message and exit.

- `--character-sets-dir=path`

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--count`

  Show the number of rows per table. This can be slow for non-`MyISAM` tables.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,file_name'`. The default is `'d:t:o'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

  Use *`charset_name`* as the default character set. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--keys`, `-k`

  Show table indexes.

- `--password[=password]`, `-p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, "End-User Guidelines for Password Security".

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=`*`port_num`*, `-P` *`port_num`*

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, "Connecting to the MySQL Server".

- `--show-table-type`, `-t`

  Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=`*`path`*, `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, "SSL Command Options".

- `--status`, `-i`

  Display extra information about each table.

- `--user=`*`user_name`*, `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version`, `-V`

  Display version information and exit.

4.5.7. `mysqlslap` — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data you want to using for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each:

```
mysqlslap --delimiter=";" \
  --create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)" \
  --query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20 \
  --number-int-cols=2 --number-char-cols=3 \
  --auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `';'` and multiple insert statements delimited by `';'`. The `--query` file will have multiple queries delimited by `';'`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5 \
  --iterations=5 --query=query.sql --create=create.sql \
  --delimiter=";"
```

Table 4.8. `mysqlslap` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--auto-generate-sql	auto-generate-sql	Generate SQL statements automatically when they are not supplied in files or via command options			
--auto-generate-sql-add-autoincrement	auto-generate-sql-add-autoincrement	Add AUTO_INCREMENT column to automatically generated tables			
--auto-generate-sql-execute-number=#	auto-generate-sql-execute-number	Specify how many queries to generate automatically			
--auto-generate-sql-guid-primary	auto-generate-sql-guid-primary	Add a GUID-based primary key to automatically generated tables			
--auto-generate-sql-load-type=type	auto-generate-sql-load-type	Specify how many queries to generate automatically			
--auto-generate-sql-sec-	auto-generate-sql-sec-ondary-indexes	Specify how many secondary indexes to add to automatically generated tables			

Format	Config File	Description	Introduction	Deprecated	Removed
ondary-indexes=#					
--auto-generate-sql-select-columns=str	auto-generate-sql-select-columns	The string to use for the select columns used in automatic tests	6.0.3		
--auto-generate-sql-unique-query-number=#	auto-generate-sql-unique-query-number	How many different queries to generate for automatic tests.			
--auto-generate-sql-unique-write-number=#	auto-generate-sql-unique-write-number	How many different queries to generate for --auto-generate-sql-write-number			
--auto-generate-sql-write-number=#	auto-generate-sql-write-number	How many row inserts to perform on each thread			
--burnin	burnin	Run the full test case in an infinite loop	6.0.3		
--commit=#	commit	How many statements to execute before committing.			
--compress	compress	Compress all information sent between the client and the server			
--concurrency=#	concurrency	The number of clients to simulate when issuing the SELECT statement			
--create=value	create	The file or string containing the statement to use for creating the table			
--cre-ate-schema=value	create-schema	The schema in which to run the tests			
--csv=[file]	csv	Generate output in comma-separated values format			
--de-bug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--delayed-start=#	delayed-start	Delay each thread start by random number of microseconds up to this maximum	6.0.3		
--delimiter=str	delimiter	The delimiter to use in SQL statements			
--detach=#	detach	Detach (close and reopen) each connection after each N statements			
--en-gine=engine_name	engine	The storage engine to use for creating the table			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			

Format	Config File	Description	Introduction	Deprecated	Removed
--ignore-sql-errors	ignore-sql-errors	Ignore SQL errors during the test run	6.0.4		
--iterations=#	iterations	The number of times to run the tests			
--label=str	label	The label to use in SQL statements	6.0.3		
--number-blob-cols=#	number-blob-cols	The number of BLOB columns to use if --auto-generate-sql is specified	6.0.3		
--number-char-cols=#	number-char-cols	The number of VARCHAR columns to use if --auto-generate-sql is specified			
--number-int-cols=#	number-int-cols	The number of INT columns to use if --auto-generate-sql is specified			
--number-of-queries=#	number-of-queries	Limit each client to approximately this number of queries			
--only-print	only-print	Do not connect to databases. mysqlslap only prints what it would have done			
--password[=password]	password	The password to use when connecting to the server			
--pipe		On Windows, connect to server via a named pipe			
--port=port_num	port	The TCP/IP port number to use for the connection			
--post-query=value	post-query	The file or string containing the statement to execute after the tests have completed			
--post-system=str	post-system	The string to execute via system() after the tests have completed			
--pre-query=value	pre-query	The file or string containing the statement to execute before running the tests			
--pre-system=str	pre-system	The string to execute via system()> before running the tests			
--preserve-schema	preserve-schema	Preserve the schema from the mysqlslap run			6.0.5
--protocol=type	protocol	The connection protocol to use			
--query=value	query	The file or string containg the SELECT statement to use for retrieving data			
--set-random-seed=#	set-random-seed	The seed value for the randomizer			
--silent	silent	Silent mode			
--socket=path	socket	For connections to localhost			
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs			
--ssl-capath=directory_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format			
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection			
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption			
--	ssl-key	The name of the SSL key file to use for establishing a secure connection			

Format	Config File	Description	Introduction	Deprecated	Removed
ssl-key=file_name					
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server			
--timer-length=#	timer-length	The duration in seconds to run each test	6.0.3		
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Verbose mode			
--version		Display version information and exit			

`mysqlslap` supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, "Command-Line Options that Affect Option-File Handling".

- `--help`, `-?`

  Display a help message and exit.

- `--auto-generate-sql`, `-a`

  Generate SQL statements automatically when they are not supplied in files or via command options.

- `--auto-generate-sql-add-autoincrement`

  Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=N`

  Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary`

  Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=type`

  Specify the test load type. The allowable values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=N`

  Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-select-columns=str`

  The string to use for the select columns used in automatic tests. You can use this to determine the effect on performance of selecting or excluding particular columns. This option was added in MySQL 6.0.3.

- `--auto-generate-sql-unique-query-number=N`

  How many different queries to generate for automatic tests. For example, if you run a `key` test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N`

  How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=N`

  How many row inserts to perform on each thread. The default is 100.

- `--burnin`

  Run the full test case in an infinite loop. This option was added in MySQL 6.0.3.

- `--commit=N`

  How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress`, `-C`

  Compress all information sent between the client and the server if both support compression.

- `--concurrency=N`, `-c N`

  The number of clients to simulate when issuing the `SELECT` statement.

- `--create=value`

  The file or string containing the statement to use for creating the table.

- `--create-schema=value`

  The schema in which to run the tests.

- `--csv[=file_name]`

  Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqlslap.trace'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`, `-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--delimiter=str`, `-F str`

  The delimiter to use in SQL statements supplied in files or via command options.

- `--delayed-start=N`

  The maximum delay in microseconds. Startup of each thread is delayed by a random number of microseconds up to this maximum. The default is 0. This option was added in MySQL 6.0.3.

- `--detach=N`

  Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- `--engine=engine_name`, `-e engine_name`

  The storage engine to use for creating tables.

- `--host=host_name`, `-h host_name`

  Connect to the MySQL server on the given host.

- `--ignore-sql-errors`

  Ignore SQL errors during the test run. By default, errors cause `mysqlslap` to exit. This option was added in MySQL 6.0.4.

- `--iterations=N`, `-i N`

  The number of times to run the tests.

- `--label=str`

  The label to use in printed and CSV output. This option was added in MySQL 6.0.3.

- `--number-blob-cols=str`,

The number of `BLOB` columns to use if `--auto-generate-sql` is specified. `--number-blob-cols=3:1024/2048` would give you 3 `BLOB` columns with a random size between 1024 and 2048. This option was added in MySQL 6.0.3.

- `--number-char-cols=N`, `-x N`

  The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N`, `-y N`

  The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

  Limit each client to approximately this number of queries.

- `--only-print`

  Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--pipe`, `-W`

  On Windows, connect to the server via a named pipe. This option applies only for connections to a local server, and only if the server supports named-pipe connections.

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for the connection.

- `--post-query=value`

  The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use, for connections made via shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--post-system=str`

  The string to execute via `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

  The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes. This option was added in MySQL 5.1.18.

- `--pre-system=str`

  The string to execute via `system()` before running the tests. This execution is not counted for timing purposes.

- `--preserve-schema`

  Preserve the schema from the `mysqlslap` run. The `--auto-generate-sql` and `--create` options disable this option. This option was removed in MySQL 6.0.5.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--query=value`, `-q value`

  The file or string containing the `SELECT` statement to use for retrieving data.

- `--set-random-seed=value`,

  The seed value for the randomizer.

- `--silent`, `-s`

  Silent mode. No output.

- `--slave`

  Follow master locks for other `mysqlslap` clients. Use this option if you are trying to synchronize around one master server with `--lock-directory` plus NFS.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--timer-length=N`

  The duration in seconds to run each test. Tests that run longer are terminated. This option was added in MySQL 6.0.3.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version`, `-V`

  Display version information and exit.

4.6. MySQL Administrative and Utility Programs

4.6.1. `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

`innochecksum` supports the options described in the following list. For options that refer to page numbers, the numbers are zero-based.

- `-c`

  Print a count of the number of pages in the file.

- `-d`

  Debug mode; prints checksums for each page.

- `-e num`

  End at this page number.

- `-p num`

  Check only this page number.

- `-s num`

  Start at this page number.

- `-v`

  Verbose mode; print a progress indicator every five seconds.

4.6.2. `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The *`tbl_name`* argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttablel` that has the following definition:

```
CREATE TABLE mytexttable
(
  id   INT NOT NULL,
  txt  TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
);
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

`myisam_ftdump` supports the following options:

- `--help`, `-h -?`

  Display a help message and exit.

- `--count`, `-c`

  Calculate per-word statistics (counts and global weights).

- `--dump`, `-d`

  Dump the index, including data offsets and word weights.

- `--length`, `-l`

  Report the length distribution.

- `--stats`, `-s`

  Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose`, `-v`

Verbose mode. Print more output about what the program does.

4.6.3. myisamchk — MyISAM Table-Maintenance Utility

The myisamchk utility gets information about your database tables or checks, repairs, or optimizes them. myisamchk works with MyISAM tables (tables that have .MYD and .MYI files for storing data and indexes).

The use of myisamchk with partitioned tables is not supported.

> **Caution**
>
> It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke myisamchk like this:

```
shell> myisamchk [options] tbl_name ...
```

The *options* specify what you want myisamchk to do. They are described in the following sections. You can also get a list of options by invoking myisamchk --help.

With no options, myisamchk simply checks your table as the default operation. To get more information or to tell myisamchk to take corrective action, specify options as described in the following discussion.

tbl_name is the database table you want to check or repair. If you run myisamchk somewhere other than in the database directory, you must specify the path to the database directory, because myisamchk has no idea where the database is located. In fact, myisamchk does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the myisamchk command line if you wish. You can also specify a table by naming its index file (the file with the .MYI suffix). This allows you to specify all tables in a directory by using the pattern *.MYI. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all MyISAM tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
          --key_buffer_size=64M --sort_buffer_size=64M \
          --read_buffer_size=1M --write_buffer_size=1M \
          /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with myisamchk, see Section 4.6.3.5, “myisamchk Memory Usage”.

> **MySQL Enterprise**
> For expert advice on checking and repairing tables, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

> **Important**
>
> *You must ensure that no other program is using the tables while you are running myisamchk*. The most effective means of doing so is to shut down the MySQL server while running myisamchk, or to lock all tables that myisamchk is being used on.

> Otherwise, when you run `myisamchk`, it may display the following error message:
>
> ```
> warning: clients are using or haven't closed the table properly
> ```
>
> This means that you are trying to check a table that has been updated by another program (such as the `mysqld` server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more `MyISAM` tables.
>
> If `mysqld` is running, you must force it to flush any table modifications that are still buffered in memory by using `FLUSH TABLES`. You should then ensure that no one is using the tables while you are running `myisamchk`
>
> However, the easiest way to avoid this problem is to use `CHECK TABLE` instead of `myisamchk` to check tables. See Section 12.5.2.2, "`CHECK TABLE` Syntax".

`myisamchk` supports the options in the following table. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, "Command-Line Options that Affect Option-File Handling".

Table 4.9. `myisamchk` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--analyze	analyze	Analyze the distribution of key values			
--backup	backup	Make a backup of the .MYD file as file_name-time.BAK			
--block-search=offset	block-search	Find the record that a block at the given offset belongs to			
--check	check	Check the table for errors			
--check-only-changed	check-only-changed	Check only tables that have changed since the last check			
--correct-checksum	correct-checksum	Correct the checksum information for the table			
--data-file-length=len	data-file-length	Maximum length of the data file (when re-creating data file when it is full)			
--debug[=debug_options]	debug	Write a debugging log			
decode_bits=#	decode_bits	Decode_bits			
--description	description	Print some descriptive information about the table			
--extend-check	extend-check	Do a repair that tries to recover every possible row from the data file			
--extended-check	extended-check	Check the table very thoroughly			
--fast	fast	Check only tables that haven't been closed properly			
--force	force	Do a repair operation automatically if myisamchk finds any errors in the table			
--force	force-recover	Overwrite old temporary files. For use with the -r or -o option			
ft_max_word_len=#	ft_max_word_len	Maximum word length for FULLTEXT indexes			
ft_min_word_len=#	ft_min_word_len	Minimum word length for FULLTEXT indexes			
ft_stopword_file=value	ft_stopword_file	Use stopwords from this file instead of built-in list			
--HELP		Display help message and exit			

Format	Config File	Description	Introduction	Deprecated	Removed
--help		Display help message and exit			
--information	information	Print informational statistics about the table that is checked			
key_buffer_size=#	key_buffer_size	The size of the buffer used for index blocks for MyISAM tables			
--keys-used=val	keys-used	A bit-value that indicates which indexes to update			
--max-record-length=len	max-record-length	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them			
--medium-check	medium-check	Do a check that is faster than an --extend-check operation			
myisam_block_size=#	myisam_block_size	Block size to be used for MyISAM index pages			
--parallel-recover	parallel-recover	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)			
--quick	quick	Achieve a faster repair by not modifying the data file.			
read_buffer_size=#	read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans			
--read-only	read-only	Don't mark the table as checked			
--recover	recover	Do a repair that can fix almost any problem except unique keys that aren't unique			
--safe-recover	safe-recover	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found			
--set-auto-increment[=value]	set-auto-increment	Force AUTO_INCREMENT numbering for new records to start at the given value			
--set-collation=name	set-collation	Specify the collation to use for sorting table indexes			
--silent	silent	Silent mode			
sort_buffer_size=#	sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE			
--sort-index	sort-index	Sort the index tree blocks in high-low order			
sort_key_blocks=#	sort_key_blocks	sort_key_blocks			
--sort-records=#	sort-records	Sort records according to a particular index			
--sort-recover	sort-recover	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large			
stats_method=value	stats_method	Specifies how MyISAM index statistics collection code should treat NULLs			
--tmpdir=path	tmpdir	Path of the directory to be used for storing temporary files			
--unpack	unpack	Unpack a table that was packed with myisampack			
--update-state	update-state	Store information in the .MYI file to indicate when the table was checked and whether the table crashed			
--verbose		Verbose mode			
--version		Display version information and exit			

Format	Config File	Description	Introduction	Deprecated	Removed
write_buffer_size =#	write_buffer_size	Write buffer size			

4.6.3.1. `myisamchk` General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help`, `-?`

  Display a help message and exit. Options are grouped by type of operation.

- `--HELP`, `-H`

  Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options, -# debug_options`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/myisamchk.trace'`.

- `--silent`, `-s`

  Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version`, `-V`

  Display version information and exit.

- `--wait`, `-w`

  Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
`decode_bits`	9
`ft_max_word_len`	version-dependent
`ft_min_word_len`	4
`ft_stopword_file`	built-in list
`key_buffer_size`	523264
`myisam_block_size`	1024
`read_buffer_size`	262136
`sort_buffer_size`	2097144
`sort_key_blocks`	16
`stats_method`	nulls_unequal
`write_buffer_size`	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following

cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.3, "Server System Variables", and Section 7.4.6, "`MyISAM` Index Statistics Collection". For MySQL 6.0, `stats_method` was added in MySQL 5.0.14. For older versions, the statistics collection method is equivalent to `nulls_equal`.

The `ft_min_word_len` and `ft_max_word_len` variables are available as of MySQL 4.0.0. `ft_stopword_file` is available as of MySQL 4.0.19.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.3.2. `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

- `--check`, `-c`

  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed`, `-C`

  Check only tables that have changed since the last check.

- `--extend-check`, `-e`

  Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

- `--fast`, `-F`

  Check only tables that haven't been closed properly.

- `--force`, `-f`

  Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information`, `-i`

  Print informational statistics about the table that is checked.

- `--medium-check`, `-m`

  Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only`, `-T`

  Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state`, `-U`

  Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

4.6.3.3. `myisamchk` Repair Options

`myisamchk` supports the following options for table repair operations:

- `--backup`, `-B`

  Make a backup of the `.MYD` file as *`file_name-time`*`.BAK`

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--correct-checksum`

  Correct the checksum information for the table.

- `--data-file-length=`*`len`*`, -D `*`len`*

  Maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check`, `-e`

  Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

- `--force`, `-f`

  Overwrite old intermediate files (files with names like *`tbl_name`*`.TMD`) instead of aborting.

- `--keys-used=`*`val`*, `-k `*`val`*

  For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks`, `-l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

  Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover`, `-p`

  Uses the same technique as `-r` and `-n`, but creates all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick`, `-q`

  Achieve a faster repair by not modifying the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover`, `-r`

  Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with `MyISAM` tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

  If you have lots of memory, you should increase the value of `sort_buffer_size`.

- `--safe-recover`, `-o`

  Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

  If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name`

  Change the character set used by the table indexes. This option was replaced by `--set-collation` in MySQL 5.0.3.

- `--set-collation=name`

  Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover`, `-n`

  Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=path`, `-t path`

  Path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (“`:`”) on Unix and the semicolon (“`;`”) on Windows, NetWare, and OS/2.

- `--unpack`, `-u`

  Unpack a table that was packed with `myisampack`.

4.6.3.4. Other `myisamchk` Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze`, `-a`

  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset`, `-b offset`

  Find the record that a block at the given offset belongs to.

- `--description`, `-d`

  Print some descriptive information about the table.

- `--set-auto-increment[=value]`, `-A[value]`

  Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index`, `-S`

  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N`, `-R N`

  Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

  If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

4.6.3.5. `myisamchk` Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 32MB RAM, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --sort_buffer_size=16M --key_buffer_size=16M \
           --read_buffer_size=1M --write_buffer_size=1M ...
```

Using `--sort_buffer_size=16M` should probably be enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, you may easily get out of memory errors. If this happens, run `myisamchk` with the `--tmpdir=path` option to specify some directory located on a file system that has more space.

When repairing, `myisamchk` also needs a lot of disk space:

- Double the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space for a sort buffer. The following formula yields the amount of space required:

  ```
  (largest_key + row_pointer_length) × number_of_rows × 2
  ```

  You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name`. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=path`).

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

4.6.4. `myisamlog` — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` for `myisamlog` and `isam.log` for `isamlog` if no *`log_file`* argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?`, `-I`

  Display a help message and exit.

- `-c N`

  Execute only *`N`* commands.

- `-f N`

  Specify the maximum number of open files.

- `-i`

  Display extra information before exiting.

- `-o offset`

  Specify the starting offset.

- `-p N`

  Remove *`N`* components from path.

- `-r`

  Perform a recovery operation.

- `-R record_pos_file record_pos`

  Specify record position file and record position.

- `-u`

  Perform an update operation.

- `-v`

  Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

  Specify the write file.

- `-V`

  Display version information.

4.6.5. `myisampack` — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses `MyISAM` tables. `myisampack` works by compressing each column in the table separately.

Usually, myisampack packs the data file 40%-70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses mmap() when possible to perform memory mapping on compressed tables. If mmap() does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the mysqld server was invoked with external locking disabled, it is not a good idea to invoke myisampack if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD). Allowing writes to a packed table is on our TODO list, but with low priority.

Invoke myisampack like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (.MYI) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the .MYI extension.

After you compress a table with myisampack, you should use myisamchk -rq to rebuild its indexes. Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

myisampack supports the options in the following list. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

- --help, -?

  Display a help message and exit.

- --backup, -b

  Make a backup of each table's data file using the name *tbl_name*.OLD.

- --character-sets-dir=*path*

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- --debug[=*debug_options*], -# [*debug_options*]

  Write a debugging log. A typical *debug_options* string is 'd:t:o,*file_name*'. The default is 'd:t:o'.

- --force, -f

  Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of myisampack exists. (myisampack creates an intermediate file named *tbl_name*.TMD in the database directory while it compresses the table. If you kill myisampack, the .TMD file might not be deleted.) Normally, myisampack exits with an error if it finds that *tbl_name*.TMD exists. With --force, myisampack packs the table anyway.

- --join=*big_tbl_name*, -j *big_tbl_name*

  Join all tables named on the command line into a single packed table *big_tbl_name*. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

  big_tbl_name must not exist prior to the join operation. All source tables named on the command line to be merged into *big_tbl_name* must exist. The source tables are read for the join operation but not modified. The join operation does not create a .frm file for *big_tbl_name*, so after the join operation finishes, copy the .frm file from one of the source tables and name it *big_tbl_name*.frm.

- --silent, -s

  Silent mode. Write output only when errors occur.

- --test, -t

  Do not actually pack the table, just test packing it.

- `--tmpdir=path`, `-T path`

  Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose`, `-v`

  Verbose mode. Write information about the progress of the packing operation and its result.

- `--version`, `-V`

  Display version information and exit.

- `--wait`, `-w`

  Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r--   1 monty    my         994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 monty    my          53248 Apr 17 19:00 station.MYI

13    187   35     no endspace, not_always, no empty   6     9
14    222   4      zerofill(1)                         2     9
15    226   16     no endspace, not_always, no empty   5     9
16    242   20     no endspace, not_always             8     9
17    262   20     no endspace, no empty               8     9
18    282   20     no endspace, no empty               5     9
19    302   30     no endspace, no empty               6     9
20    332   4      always zero                         2     9
21    336   4      always zero                         2     9
22    340   1                                          3     9
23    341   8      table-lookup                        9     0
24    349   8      table-lookup                       10     0
25    357   8      always zero                         2     9
26    365   2                                          2     9
27    367   2      no zeros, zerofill(1)               2     9
28    369   4      no zeros, zerofill(1)               2     9
29    373   4      table-lookup                       11     0
30    377   1                                          3     9
31    378   2      no zeros, zerofill(1)               2     9
32    380   8      no zeros                            2     9
33    388   4      always zero                         2     9
34    392   4      table-lookup                       12     0
35    396   4      no zeros, zerofill(1)              13     9
36    400   4      no zeros, zerofill(1)               2     9
37    404   1                                          2     9
38    405   4      no zeros                            2     9
39    409   4      always zero                         2     9
40    413   4      no zeros                            2     9
41    417   4      always zero                         2     9
42    421   4      no zeros                            2     9
43    425   4      always zero                         2     9
44    429   20     no empty                            3     9
45    449   30     no empty                            3     9
46    479   1                                         14     4
47    480   1                                         14     4
48    481   79     no endspace, no empty              15     9
49    560   79     no empty                            2     9
50    639   79     no empty                            2     9
51    718   79     no endspace                        16     9
```

```
52    797   8      no empty                              2     9
53    805   1                                           17     1
54    806   1                                            3     9
55    807   20     no empty                              3     9
56    827   4      no zeros, zerofill(2)                 2     9
57    831   4      no zeros, zerofill(1)                 2     9
```

`myisampack` displays the following kinds of information:

- `normal`

  The number of columns for which no extra packing is used.

- `empty-space`

  The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

  The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

  The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

  The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

  The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

  The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

  The number of columns for which all values are zero.

- `Original trees`

  The initial number of Huffman trees.

- `After join`

  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, `myisamchk -dvv` prints additional information about each column:

- `Type`

  The data type. The value may contain any of the following descriptors:

  - `constant`

    All rows have the same value.

  - `no endspace`

    Do not store endspace.

  - `no endspace, not_always`

    Do not store endspace and do not do endspace compression for all values.

  - `no endspace, no empty`

    Do not store endspace. Do not store empty values.

  - `table-lookup`

    The column was converted to an `ENUM`.

  - `zerofill(N)`

    The most significant *`N`* bytes in the value are always 0 and are not stored.

  - `no zeros`

    Do not store zeros.

  - `always zero`

    Zero values are stored using one bit.

- `Huff tree`

  The number of the Huffman tree associated with the column.

- `Bits`

  The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

4.6.6. `mysqlaccess` — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user`, `db`, and `host` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` supports the following options:

Table 4.10. `mysqlaccess` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--brief	brief	Generate reports in single-line tabular format			
--commit	commit	Copy the new access privileges from the temporary tables to the original grant tables			
--copy	copy	Reload the temporary grant tables from original ones			
--db=db_name	db	Specify the database name			
--debug=#	debug	Specify the debug level			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			

Format	Config File	Description	Introduction	Deprecated	Removed
--howto	howto	Display some examples that show how to use mysqlaccess			
--old_server	old_server	Assume that the server is an old MySQL server (prior to MySQL 3.21)			
-p --password[=password]	password	The password to use when connecting to the server			
--plan	plan	Display suggestions and ideas for future releases			
--preview	preview	Show the privilege differences after making changes to the temporary grant tables			
--relnotes	relnotes	Display the release notes			
-h --rhost=host_name	rhost	Connect to the MySQL server on the given host			
--rollback	rollback	Undo the most recent changes to the temporary grant tables.			
-P --spassword[=password]	spassword	The password to use when connecting to the server as the superuser			
-U --superuser=user_name	superuser	Specify the user name for connecting as the superuser			
--table	table	Generate reports in table format			
-u --user=user_name,	user	The MySQL user name to use when connecting			
--version		Display version information and exit			

- `--help`, `-?`

  Display a help message and exit.

- `--brief`, `-b`

  Generate reports in single-line tabular format.

- `--commit`

  Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- `--copy`

  Reload the temporary grant tables from original ones.

- `--db=db_name`, `-d db_name`

  Specify the database name.

- `--debug=N`

  Specify the debug level. *`N`* can be an integer from 0 to 3.

- `--host=host_name`, `-h host_name`

  The host name to use in the access privileges.

- `--howto`

  Display some examples that show how to use `mysqlaccess`.

- `--old_server`

  Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE`

clauses.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--plan`

  Display suggestions and ideas for future releases.

- `--preview`

  Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes`

  Display the release notes.

- `--rhost=host_name`, `-H host_name`

  Connect to the MySQL server on the given host.

- `--rollback`

  Undo the most recent changes to the temporary grant tables.

- `--spassword[=password]`, `-P[password]`

  The password to use when connecting to the server as the superuser. If you omit the *`password`* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--superuser=user_name`, `-U user_name`

  Specify the user name for connecting as the superuser.

- `--table`, `-t`

  Generate reports in table format.

- `--user=user_name`, `-u user_name`

  The user name to use in the access privileges.

- `--version`, `-v`

  Display version information and exit.

If your MySQL distribution is installed in some non-standard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

4.6.7. `mysqlbackup` — Display Backup Information

`mysqlbackup` displays information from backup images created by the `BACKUP DATABASE` statement. This program was added in MySQL 6.0.11.

`mysqlbackup` has these capabilities:

- List the objects contained in the backup image or information about the objects
- Display the metadata (SQL statements to create objects in the backup image)
- Search the backup image for a particular object

Invoke `mysqlbackup` like this:

```
shell> mysqlbackup [options] backup_image_file
```

With no options, `mysqlbackup` displays a short summary about the backup image:

```
shell> mysqlbackup /tmp/test.bak
Image path:           '/tmp/test.bak'
Image size:           12305 bytes
Image compression:    none
Image version:        1
Creation time:        2009-04-08 18:08:43 UTC
Server version:       6.0.11 (6.0.11-alpha)
Server byte order:    little-endian
```

`mysqlbackup` supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

Table 4.11. `mysqlbackup` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--all	all	Display everything except snapshots and data-chunks	6.0.11		
--catalog-details	catalog-details	Display details of the database objects catalog	6.0.11		
--catalog-summary	catalog-summary	Display summary of the database objects catalog	6.0.11		
--data-chunks	data-chunks	Display length of each data chunk contained in the backup image	6.0.11		
--data-totals	data-totals	Display length of data contained in the backup image for each object	6.0.11		
--debug[=debug_options]	debug	Write a debugging log	6.0.11		
--exact	exact	Display exact number of bytes instead of KB, MB, GB units	6.0.11		
--help		Display help message and exit	6.0.11		
--image-order	image-order	Display catalog items and metadata in the order of the backup image	6.0.11		
--metadata-extra	metadata-extra	Display extra metadata for the database objects	6.0.11		
--metadata-statements	metadata-statements	Display SQL statements that create the database objects	6.0.11		
--open_files_limit=#	open_files_limit	How many file descriptors to reserve	6.0.11		
--search=name	search	Search for object in the backup image	6.0.11		
--snapshots	snapshots	Display information about snapshots contained in the backup image	6.0.11		
--summary	summary	Display summary information from end of the backup image	6.0.11		
--verbose		Verbose mode	6.0.11		
--version		Display version information and exit	6.0.11		

- `--help`, `-?`

  Display a help message and exit.

- `--all`

  Display everything except snapshots and data-chunks.

- `--catalog-details`

  Display the details of the database objects catalog.

- `--catalog-summary`

  Display summary of the database objects catalog.

- `--data-chunks`

  Display the length of each data chunk contained in the backup image.

- `--data-totals`

  Display the data length for each object contained in the backup image.

- `--debug[=debug_options]`, `-# [debug_options]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/mysqlbackup.trace'`.

- `--exact`

  Display lengths using the exact number of bytes instead of multiplier units such as KB, MB, and GB.

- `--image-order`

  Display catalog items and metadata in the order of the backup image.

- `--metadata-extra`

  Display extra metadata for the database objects.

- `--metadata-statements`

  Display SQL statements that create the database objects in the backup image.

- `--open_files_limit=count`

  Specify how many file descriptors to reserve.

- `--search=name`

  Search for the given object in the backup image. The name can be *`object`* to find a global object or *`database.object`* to find a per-database object. Quoting of database and/or object with `"`, `'`, or `` ` `` is allowed. The wildcard characters `'%'` and `'_'` are available and have the same effect as for the `LIKE` operator. Use this option with the `--metadata-*` options to see metadata.

- `--snapshots`

  Display information about snapshots contained in the backup image.

- `--summary`

  Display a summary information from end of the backup image.

- `--verbose`, `-v`

  Verbose mode. Include more information about the backup image in program output.

- `--version`, `-V`

  Display version information and exit.

4.6.8. mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in Section 5.2.4, “The Binary Log”, and Section 16.4.2, “Replication Relay and Status Files”.

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.0000003
```

The output includes events contained in `binlog.000003`. Event information includes the statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to reapply the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section.

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. When you read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

`mysqlbinlog` supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.3.2.1, “Command-Line Options that Affect Option-File Handling”.

Table 4.12. mysqlbinlog Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--base64-output[=value]	base64-output	Print binary log entries using base-64 encoding			
--character-sets-dir=path	character-sets-dir	The directory where character sets are installed			
--database=db_name	database	List entries for just this database			
--debug[=debug_options]	debug	Write a debugging log			
--debug-check	debug-check	Print debugging information when the program exits			
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits			
--disable-log-bin	disable-log-bin	Disable binary logging			
--force-read	force-read	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning			
--help		Display help message and exit			
--hexdump	hexdump	Display a hex dump of the log in comments			
--host=host_name	host	Connect to the MySQL server on the given host			
--local-load=path	local-load	Prepare local temporary files for LOAD DATA INFILE in the specified directory			
--offset=#	offset	Skip the first N entries in the log			
-	password	The password to use when connecting to the server			

Format	Config File	Description	Introduction	Deprecated	Removed
-pass-word[=password]					
--port=port_num	port	The TCP/IP port number to use for the connection			
--protocol=type	protocol	The connection protocol to use			
--read-from-remote-server	read-from-remote-server	Read the binary log from a MySQL server rather than reading a local log file			
--result-file=name	result-file	Direct output to the given file			
--server-id=id	server-id	Extract only those events created by the server having the given server ID			
--set-charset=charset_name	set-charset	Add a SET NAMES charset_name statement to the output			
--short-form	short-form	Display only the statements contained in the log			
--socket=path	socket	For connections to localhost			
--start-datetime=datetime	start-datetime	Start reading the binary log at the first event having a timestamp equal to or later than the datetime argument			
--start-position=#	start-position	Start reading the binary log at the first event having a position equal to or greater than the argument			
--stop-datetime=datetime	stop-datetime	Stop reading the binary log at the first event having a timestamp equal to or greater than the datetime argument			
--stop-position=#	stop-position	Stop reading the binary log at the first event having a position equal to or greater than the argument			
--to-last-log	to-last-log	Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log			
--user=user_name,	user	The MySQL user name to use when connecting to the server			
--verbose		Reconstruct row events as SQL statements	6.0.7		
--version		Display version information and exit			
--write-binlog	write-binlog	Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. --skip-write-binlog adds NO_WRITE_TO_BINLOG to these statements.			

- `--help`, `-?`

  Display a help message and exit.

- `--base64-output[=value]`

  This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these allowable values (not case sensitive):

  - `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). This is the default if no `--base64-output` option is given.

    Note

    Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

  - `ALWAYS` displays `BINLOG` statements whenever possible. This is the implied value if the option is given as `--base64-output` without a value.
  - `NEVER` causes `BINLOG` statements not to be displayed. `mysqlbinlog` exits with an error if a row event is found that must be displayed using `BINLOG`.
  - `DECODE-ROWS` specifies to `mysqlbinlog` that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the `--verbose` option. Like `NEVER`, `DECODE-ROWS` suppresses display of `BINLOG` statements, but unlike `NEVER`, it does not exit with an error if a row event is found.

  Before MySQL 6.0.4, the `--base64-output` option was boolean, to be given as `--base64-output` or `--skip-base64-output` (with the sense of `AUTO` or `NEVER`). The option values described in the preceding list may be used as of MySQL 6.0.4, with the exception of `UNSPEC` and `DECODE-ROWS`, which are available as of MySQL 6.0.7.

  For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, “`mysqlbinlog` Row Event Display”.

- `--character-sets-dir=`*`path`*

  The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--database=`*`db_name`*, `-d` *`db_name`*

  List entries for just this database (local log only). You can only specify one database with this option - if you specify multiple `--database` options, only the last one is used. This option forces `mysqlbinlog` to output entries from the binary log where the default database (that is, the one selected by `USE`) is *`db_name`*. Note that this does not replicate cross-database statements such as `UPDATE` *`some_db.some_table`* `SET foo='bar'` while having selected a different database or no database.

- `--debug[=`*`debug_options`*`]`, `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o,/tmp/mysqlbinlog.trace'`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--disable-log-bin`, `-D`

  Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

  This option requires that you have the `SUPER` privilege. It causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. The `SET` statement is ineffective unless you have the `SUPER` privilege.

- `--force-read`, `-f`

  With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump`, `-H`

  Display a hex dump of the log in comments, as described in Section 4.6.8.1, “`mysqlbinlog` Hex Dump Format”. This output can be helpful for replication debugging.

- `--host=`*`host_name`*, `-h` *`host_name`*

  Get the binary log from the MySQL server on the given host.

- `--local-load=`*`path`*, `-l` *`path`*

  Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

- `--offset=`*`N`*, `-o` *`N`*

Skip the first *N* entries in the log.

- `--password[=password]`, `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, you are prompted for one.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, "End-User Guidelines for Password Security".

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use for connecting to a remote server.

- `--position=N`, `-j N`

  Deprecated. Use `--start-position` instead.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the allowable values, see Section 4.2.2, "Connecting to the MySQL Server".

- `--read-from-remote-server`, `-R`

  Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

  This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

- `--result-file=name`, `-r name`

  Direct output to the given file.

- `--server-id=id`

  Extract only those events created by the server having the given server ID.

- `--set-charset=charset_name`

  Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--short-form`, `-s`

  Display only the statements contained in the log, without any extra information.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`

  Start reading the binary log at the first event having a timestamp equal to or later than the *datetime* argument. The *datetime* value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

  ```
  shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
  ```

  This option is useful for point-in-time recovery. See Section 6.2, "Example Backup and Recovery Strategy".

- `--start-position=N`

  Start reading the binary log at the first event having a position equal to or greater than *N*. This option applies to the first log file named on the command line.

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal to or later than the *`datetime`* argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the *`datetime`* value.

- `--stop-position=N`

  Stop reading the binary log at the first event having a position equal to or greater than *`N`*. This option applies to the last log file named on the command line.

- `--to-last-log`, `-t`

  Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to a remote server.

- `--verbose`, `-v`

  Reconstruct row events and display them as commented SQL statements. If given twice, the output includes comments to indicate column data types and some metadata. This option was added in MySQL 6.0.7.

  For examples that show the effect of `--base64-output` and `--verbose` on row event output, see Section 4.6.8.2, “`mysqlbinlog` Row Event Display”.

- `--version`, `-V`

  Display version information and exit.

- `--write-binlog`

  This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause `NO_WRITE_TO_BINLOG` to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

  Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the statements contained in the binary log. This is used to recover from a crash when you have an old backup (see Section 6.1, “Database Backups”). For example:

```
shell> mysqlbinlog binlog.000001 | mysql
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql
```

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program.

`mysqlbinlog` has the `--start-position` option, which prints only those statements with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports "unknown table."

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 >  /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured to allow `LOCAL` capability. See Section 5.3.4, "Security Issues with `LOAD DATA LOCAL`".

MySQL Enterprise
For expert advice on the security implications of enabling `LOCAL`, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like *`original_file_name-#-#`*.

4.6.8.1. `mysqlbinlog` Hex Dump Format

The `--hexdump` option produces a hex dump of the log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position  Timestamp   Type   Master ID        Size      Master Pos    Flags
# 00000004 9d fc 5c 43   0f   01 00 00 00   5e 00 00 00   62 00 00 00   00 00
# 00000017 04 00 35 2e 30 2e 31 35  2d 64 65 62 75 67 2d 6c |..5.0.15.debug.l|
# 00000027 6f 67 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |og..............|
# 00000037 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |................|
# 00000047 00 00 00 00 9d fc 5c 43  13 38 0d 00 08 00 12 00 |.......C.8......|
# 00000057 04 04 04 04 12 00 00 4b  00 04 1a               |.......K...|
#       Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#       at startup
ROLLBACK;
```

Hex dump output currently contains the following elements. This format is subject to change.

- `Position`: The byte position within the log file.
- `Timestamp`: The event timestamp. In the example shown, `'9d fc 5c 43'` is the representation of `'051024 17:24:13'` in hexadecimal.
- `Type`: The event type code. In the example shown, `'0f'` indicates a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible type codes.

Type	Name	Meaning
`00`	`UNKNOWN_EVENT`	This event should never be present in the log.

01	START_EVENT_V3	This indicates the start of a log file written by MySQL 4 or earlier.
02	QUERY_EVENT	The most common type of events. These contain statements executed on the master.
03	STOP_EVENT	Indicates that master has stopped.
04	ROTATE_EVENT	Written when the master switches to a new log file.
05	INTVAR_EVENT	Used for AUTO_INCREMENT values or when the LAST_INSERT_ID() function is used in the statement.
06	LOAD_EVENT	Used for LOAD DATA INFILE in MySQL 3.23.
07	SLAVE_EVENT	Reserved for future use.
08	CREATE_FILE_EVENT	Used for LOAD DATA INFILE statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only.
09	APPEND_BLOCK_EVENT	Contains data for use in a LOAD DATA INFILE statement. The data is stored in the temporary file on the slave.
0a	EXEC_LOAD_EVENT	Used for LOAD DATA INFILE statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.
0b	DELETE_FILE_EVENT	Rollback of a LOAD DATA INFILE statement. The temporary file should be deleted on the slave.
0c	NEW_LOAD_EVENT	Used for LOAD DATA INFILE in MySQL 4 and earlier.
0d	RAND_EVENT	Used to send information about random values if the RAND() function is used in the statement.
0e	USER_VAR_EVENT	Used to replicate user variables.
0f	FORMAT_DESCRIPTION_EVENT	This indicates the start of a log file written by MySQL 5 or later.
10	XID_EVENT	Event indicating commit of an XA transaction.
11	BEGIN_LOAD_QUERY_EVENT	Used for LOAD DATA INFILE statements in MySQL 5 and later.
12	EXECUTE_LOAD_QUERY_EVENT	Used for LOAD DATA INFILE statements in MySQL 5 and later.
13	TABLE_MAP_EVENT	Information about a table definition. Used in MySQL 5.1.5 and later.
14	PRE_GA_WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17.
15	PRE_GA_UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17.
16	PRE_GA_DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.5 to 5.1.17.
17	WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.18 and later.
18	UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.18 and later.
19	DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.18 and later.
1a	INCIDENT_EVENT	Something out of the ordinary happened. Added in MySQL 5.1.18.
1b	HEARTBEAT_LOG_EVENT	Heartbeat sent by master to slave. Added in MySQL 6.0.5.

- Master ID: The server ID of the master that created the event.
- Size: The size in bytes of the event.
- Master Pos: The position of the next event in the original master log file.
- Flags: 16 flags. Currently, the following flags are used. The others are reserved for future use.

Flag	Name	Meaning
01	LOG_EVENT_BINLOG_IN_USE_F	Log file correctly closed. (Used only in FORMAT_DESCRIPTION_EVENT.) If this flag is set (if the flags are, for example, '01 00') in a FORMAT_DESCRIPTION_EVENT, the log file has not been properly closed. Most probably this is because of a master crash (for example, due to

		power failure).
02		Reserved for future use.
04	LOG_EVENT_THREAD_SPECIFIC_F	Set if the event is dependent on the connection it was executed in (for example, '04 00'), for example, if the event uses temporary tables.
08	LOG_EVENT_SUPPRESS_USE_F	Set in some circumstances when the event is not dependent on the default database.

4.6.8.2. mysqlbinlog Row Event Display

The following examples illustrate how mysqlbinlog displays row events that specify data modifications. These correspond to events with the WRITE_ROWS_EVENT, UPDATE_ROWS_EVENT, and DELETE_ROWS_EVENT type codes. The --base64-output=DECODE-ROWS and --verbose options may be used to affect row event output. These options are available as of MySQL 6.0.7.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id   INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, mysqlbinlog displays row events encoded as base-64 strings using BINLOG statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258         Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAALAAAANoAAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356         Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAALAAAAC4BAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBgBAAAANgAAAGQBAAAQABEAAAAAAAEAA////AEAAAAFYXBwbGX4AQAAAARwZWFyIbIP
'/*!*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442         Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAALAAAAJABAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAEAA//4AQAAAARwZWFyIbIP
'/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run mysqlbinlog with the --verbose or -v option. The output will contain lines beginning with ###:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258         Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAALAAAANoAAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAEAA//8AQAAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356         Update_rows: table id 17 flags: STMT_END_F
```

```
BINLOG '
fAS3SBMBAAAALAAAAC4BAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=

'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```
shell> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258         Write_rows: table id 17 flags: STMT_END_F

BINLOG '

###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442         Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAALAAAAJABAAAAABEAAAAAAAAAABHRlc3QAAXQAAwMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAEAA//4AQAAAARwZWFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```
shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258         Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356         Update_rows: table id 17 flags: STMT_END_F
```

```
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442         Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

> **Note**
>
> You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by *`@N`*, where *`N`* is a column number.
- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
  - For multi-byte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

    ```
    CHAR(4) CHARACTER SET latin1
    CHAR(2) CHARACTER SET ucs2
    ```

  - Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

4.6.9. `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see Section 5.2.5, “The Slow Query Log”). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

Table 4.13. `mysqldumpslow` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
-a		Do not abstract all numbers to N and strings to S			
-n num		Abstract numbers with at least the specified digits			
--debug	debug	Write debugging information			

Format	Config File	Description	Introduction	Deprecated	Removed
-g pattern		Only consider statements that match the pattern			
--help		Display help message and exit			
-h name		Host name of the server in the log file name			
-i name		Name of the server instance			
-l		Do not subtract lock time from total time			
-r		Reverse the sort order			
-s value		How to sort output			
-t num		Display only first num queries			
--verbose	verbose	Verbose mode			

`mysqldumpslow` supports the following options:

- `--help`

  Display a help message and exit.

- `-a`

  Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug`, `-d`

  Run in debug mode.

- `-g` *`pattern`*

  Consider only queries that match the (`grep`-style) pattern.

- `-h` *`host_name`*

  Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcare. The default is `*` (match all).

- `-i` *`name`*

  Name of server instance (if using `mysql.server` startup script).

- `-l`

  Do not subtract lock time from total time.

- `-n` *`N`*

  Abstract numbers with at least *`N`* digits within names.

- `-r`

  Reverse the sort order.

- `-s` *`sort_type`*

  How to sort the output. The value of *`sort_type`* should be chosen from the following list:

  - `t`, `at`: Sort by query time or average query time
  - `l`, `al`: Sort by lock time or average lock time
  - `s`, `as`: Sort by rows sent or average rows went
  - `c`: Sort by count

- `-t` *`N`*

  Display only the first *`N`* queries in the output.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t1 select * from t1
```

4.6.10. `mysqlhotcopy` — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `LOCK TABLES`, `FLUSH TABLES`, and `cp` or `scp` to make a database backup quickly. It is the fastest way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix and NetWare.

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“~”):

```
shell> mysqlhotcopy db_name./~regex/
```

Table 4.14. `mysqlhotcopy` Option Reference

Format	Config File	Description	Introduction	Deprecated	Removed
--addtodest	addtodest	Do not rename target directory (if it exists); merely add files to it			
--allowold	allowold	Do not abort if a target exists; rename it by adding an _old suffix			
--check-point=db_name.tbl_name	checkpoint	Insert checkpoint entries			
--chroot=path	chroot	Base directory of the chroot jail in which mysqld operates			
--debug	debug	Write a debugging log			
--dryrun	dryrun	Report actions without performing them			
--flushlog	flushlog	Flush logs after all tables are locked			
--help		Display help message and exit			
--host=host_name	host	Connect to the MySQL server on the given host			
--keepold	keepold	Do not delete previous (renamed) target when done			
--noindices	noindices	Do not include full index files in the backup			
--password[=password]	password	The password to use when connecting to the server			
--port=port_num	port	The TCP/IP port number to use for the connection			
--quiet	quiet	Be silent except for errors			

Format	Config File	Description	Introduction	Deprecated	Removed
--regexp	regexp	Copy all databases with names that match the given regular expression			
--resetmaster	resetmaster	Reset the binary log after locking all the tables			
--resetslave	resetslave	Reset the master.info file after locking all the tables			
--socket=path	socket	For connections to localhost			
--tmpdir=path	tmpdir	The temporary directory			
--user=user_name,	user	The MySQL user name to use when connecting to the server			

`mysqlhotcopy` supports the following options:

- `--help`, `-?`

  Display a help message and exit.

- `--addtodest`

  Do not rename target directory (if it exists); merely add files to it.

- `--allowold`

  Do not abort if a target exists; rename it by adding an `_old` suffix.

- `--checkpoint=`*`db_name.tbl_name`*

  Insert checkpoint entries into the specified database *`db_name`* and table *`tbl_name`*.

- `--chroot=`*`path`*

  Base directory of the `chroot` jail in which `mysqld` operates. The *`path`* value should match that of the `--chroot` option given to `mysqld`.

- `--debug`

  Enable debug output.

- `--dryrun`, `-n`

  Report actions without performing them.

- `--flushlog`

  Flush logs after all tables are locked.

- `--host=`*`host_name`*, `-h` *`host_name`*

  The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold`

  Do not delete previous (renamed) target when done.

- `--method=`*`command`*

  The method for copying files (`cp` or `scp`).

- `--noindices`

  Do not include full index files in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=`*`password`*, `-p`*`password`*

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs. You can use an option file to avoid giving the password on the command line.

Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, "End-User Guidelines for Password Security".

- `--port=port_num`, `-P port_num`

  The TCP/IP port number to use when connecting to the local server.

- `--quiet`, `-q`

  Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

  Record master and slave status in the specified database *`db_name`* and table *`tbl_name`*.

- `--regexp=expr`

  Copy all databases with names that match the given regular expression.

- `--resetmaster`

  Reset the binary log after locking all the tables.

- `--resetslave`

  Reset the `master.info` file after locking all the tables.

- `--socket=path`, `-S path`

  The Unix socket file to use for the connection.

- `--suffix=str`

  The suffix for names of copied databases.

- `--tmpdir=path`

  The temporary directory. The default is `/tmp`.

- `--user=user_name`, `-u user_name`

  The MySQL user name to use when connecting to the server.

`mysqlhotcopy` reads the `[client]` and `[mysqlhotcopy]` option groups from option files.

To execute `mysqlhotcopy`, you must have access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

> **MySQL Enterprise**
> MySQL Enterprise subscribers will find more information about `mysqlhotcopy` in the Knowledge Base article, How Does mysqlhotcopy Work?. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

4.6.11. `mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (`MyISAM` by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed

(see Section 2.14, “Perl Installation Notes”).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The *`db_name`* argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help`

  Display a help message and exit.

- `--force`

  Continue even if errors occur.

- `--host=host_name`

  Connect to the MySQL server on the given host.

- `--password=password`

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs. You can use an option file to avoid giving the password on the command line.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, “End-User Guidelines for Password Security”.

- `--port=port_num`

  The TCP/IP port number to use for the connection.

- `--socket=path`

  For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name`

  Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

  > **MySQL Enterprise**
  > For expert advice on choosing the optimum storage engine, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--user=user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose`

  Verbose mode. Print more information about what the program does.

- `--version`

  Display version information and exit.

4.6.12. `mysql_find_rows` — Extract SQL Statements from Files

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility was written for use with update log files (as used prior to MySQL 5.0) and as such expects statements to be terminated with semicolon (`;`) characters. It may be useful with other files that contain SQL statements as long as statements are terminated with semicolons.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each *`file_name`* argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table  update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help`, `--Information`

  Display a help message and exit.

- `--regexp=`*`pattern`*

  Display queries that match the pattern.

- `--rows=`*`N`*

  Quit after displaying *`N`* queries.

- `--skip-use-db`

  Do not include `USE` *`db_name`* statements in the output.

- `--start_row=`*`N`*

  Start output from this row.

4.6.13. `mysql_fix_extensions` — Normalize Table File Name Extensions

`mysql_fix_extensions` converts the extensions for `MyISAM` (or `ISAM`) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where *`data_dir`* is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

4.6.14. `mysql_setpermission` — Interactively Set Permissions in Grant Tables

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see Section 2.14, “Perl Installation Notes”).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help`

  Display a help message and exit.

- `--host=`*`host_name`*

Connect to the MySQL server on the given host.

- `--password=password`

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs. You can use an option file to avoid giving the password on the command line.

  Specifying a password on the command line should be considered insecure. See Section 5.5.6.2, "End-User Guidelines for Password Security".

- `--port=port_num`

  The TCP/IP port number to use for the connection.

- `--socket=path`

  For connections to `localhost`, the Unix socket file to use.

- `--user=user_name`

  The MySQL user name to use when connecting to the server.

4.6.15. `mysql_waitpid` — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by *`pid`* and waits up to *`wait_time`* seconds for the process to terminate. *`pid`* and *`wait_time`* must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help`, `-?`, `-I`

  Display a help message and exit.

- `--verbose`, `-v`

  Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version`, `-V`

  Display version information and exit.

4.6.16. `mysql_zap` — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?Ift] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the *-signal* option is given, it specifies the name or number of the signal to send to each process. Otherwise, mysql_zap tries first with TERM (signal 15) and then with KILL (signal 9).

mysql_zap supports the following additional options:

- --help, -?, -I

  Display a help message and exit.

- -f

  Force mode. mysql_zap attempts to kill each process without confirmation.

- -t

  Test mode. Display information about each process but do not kill it.

4.7. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the my_print_defaults program to parse option files and see what options would be used by a given program. The following example shows the output that my_print_defaults might produce when asked to show the options found in the [client] and [mysql] groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1. msql2mysql — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The msql2mysql utility performs the conversion of mSQL C API function calls to their MySQL equivalents. msql2mysql converts the input file in place, so make a copy of the original before converting it. For example, use msql2mysql like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine client-prog.c and make any post-conversion revisions that may be necessary.

msql2mysql uses the replace utility to make the function name substitutions. See Section 4.8.2, “replace — A String-Replacement Utility”.

4.7.2. mysql_config — Get Compile Options for Compiling Clients

mysql_config provides you with useful information for compiling your MySQL client and connecting it to MySQL.

mysql_config supports the following options:

- --cflags

  Compiler flags to find include files and critical compiler flags and defines used when compiling the libmysqlclient library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use --include for more portable options that contain only include paths.

- `--include`

  Compiler options to find MySQL include files.

- `--libmysqld-libs`, `--embedded`

  Libraries and options required to link with the MySQL embedded server.

- `--libs`

  Libraries and options required to link with the MySQL client library.

- `--libs_r`

  Libraries and options required to link with the thread-safe MySQL client library.

- `--plugindir`

  The default plugin directory path name, defined when configuring MySQL. This option was added in MySQL 6.0.5.

- `--port`

  The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

  The default Unix socket file, defined when configuring MySQL.

- `--version`

  Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include        [-I/usr/local/mysql/include/mysql]
  --libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
                    -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
  --libs_r         [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                    -lpthread -lz -lcrypt -lnsl -lm -lpthread]
  --socket         [/tmp/mysql.sock]
  --port           [3306]
  --version        [4.0.16]
  --libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                    -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
shell> CFG=/usr/local/mysql/bin/mysql_config
shell> sh -c "gcc -o progname `$CFG --include` progname.c `$CFG --libs`"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (“`”) characters. That tells the shell to execute it and substitute its output into the surrounding command.

4.7.3. `my_print_defaults` — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options:

- `--help`, `-?`

  Display a help message and exit.

- `--config-file=file_name`, `--defaults-file=file_name`, `-c file_name`

  Read only the given option file.

- `--debug=debug_options`, `-# debug_options`

  Write a debugging log. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/my_print_defaults.trace'`.

- `--defaults-extra-file=file_name`, `--extra-file=file_name`, `-e file_name`

  Read this option file after the global option file but (on Unix) before the user option file.

- `--defaults-group-suffix=suffix`, `-g suffix`

  In addition to the groups named on the command line, read groups that have the given suffix.

- `--no-defaults`, `-n`

  Return an empty string.

- `--verbose`, `-v`

  Verbose mode. Print more information about what the program does.

- `--version`, `-V`

  Display version information and exit.

4.7.4. `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the options described in the following list.

- `--help`, `-h`

  Display a help message and exit.

- `--numeric-dump-file=file_name`, `-n file_name`

  Read the stack trace from the given file.

- `--symbols-file=file_name`, `-s file_name`

  Use the given symbols file.

- `--version`, `-V`

  Display version information and exit.

4.8. Miscellaneous Programs

4.8.1. `perror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code  13:  Permission denied
OS error code  64:  Machine is not on the network
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options:

- `--help`, `--info`, `-I`, `-?`

  Display a help message and exit.

- `--silent`, `-s`

  Silent mode. Print only the error message.

- `--verbose`, `-v`

  Verbose mode. Print error code and message. This is the default behavior.

- `--version`, `-V`

  Display version information and exit.

4.8.2. `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for and *`to`* represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. *`replace`* prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

The `replace` program is used by `msql2mysql`. See Section 4.7.1, “`msql2mysql` — Convert mSQL Programs for Use with MySQL”.

`replace` supports the following options:

- `-?`, `-I`

  Display a help message and exit.

- *`-#debug_options`*

  Enable debugging.

- `-s`

  Silent mode. Print less information what the program does.

- `-v`

  Verbose mode. Print more information about what the program does.

- `-V`

  Display version information and exit.

4.8.3. `resolveip` — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the options described in the following list.

- `--help`, `--info`, `-?`, `-I`

  Display a help message and exit.

- `--silent`, `-s`

  Silent mode. Produce less output.

- `--version`, `-V`

  Display version information and exit.

Chapter 5. MySQL Server Administration

MySQL Server (`mysqld`) is the main program that does most of the work in a MySQL installation. This section provides an overview of MySQL Server and covers topics that deal with administering a MySQL installation:

- Server configuration
- The server log files
- Security issues and user-account management
- Management of multiple servers on a single machine

5.1. The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports
- Server system variables
- Server status variables
- How to set the server SQL mode
- The server shutdown process

> **Note**
>
> Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines are supported by your MySQL server installation, see Section 12.5.6.17, “`SHOW ENGINES` Syntax”.

5.1.1. Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

Table 5.1. `mysqld` Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
abort-slave-event-count	Yes	Yes				
Aborted_clients				Yes	Global	No
Aborted_connects				Yes	Global	No
allow-suspicious-udfs	Yes	Yes				
ansi	Yes	Yes				
auto_increment_increment	Yes	Yes	Yes		Both	Yes
auto_increment_offset	Yes	Yes	Yes		Both	Yes
autocommit			Yes		Session	Yes
automatic_sp_privileges			Yes		Global	Yes
back_log	Yes	Yes	Yes		Global	No
backup_history_log	Yes	Yes	Yes		Global	Yes

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
backup_history_log_file	Yes	Yes	Yes		Global	Yes
backup_progress_log	Yes	Yes	Yes		Global	Yes
backup_progress_log_file	Yes	Yes	Yes		Global	Yes
backup_wait_timeout			Yes		Session	Yes
backupdir	Yes	Yes	Yes		Global	Yes
basedir	Yes	Yes	Yes		Global	No
big-tables	Yes	Yes			Session	Yes
- *Variable*: big_tables			Yes		Session	Yes

[a]This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.
[b]This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.2. Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.3, "Specifying Program Options". The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.3.2, "Using Option Files".

> **MySQL Enterprise**
> For expert advice on setting command options, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where *xxxxx* is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See Section 5.3.3, “Security-Related `mysqld` Options”.
- SSL-related options: See Section 5.5.7.3, “SSL Command Options”.
- Binary log control options: See Section 5.2.4, “The Binary Log”.
- Replication-related options: See Section 16.1.3, “Replication and Binary Logging Options and Variables”.
- Options specific to particular storage engines: See Section 13.5.1, “`MyISAM` Startup Options”, and Section 13.7.3, “`InnoDB` Startup Options and System Variables”.

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

- `--help`, `-?`

Command Line Format	`-?`
Config File Format	`help`

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

Command Line Format	`--allow-suspicious-udfs`	
Config File Format	`allow-suspicious-udfs`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See Section 21.3.2.6, “User-Defined Function Security Precautions”.

- `--ansi`

Command Line Format	`--ansi`
Config File Format	`ansi`

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See Section 1.7.3, “Running MySQL in ANSI Mode”, and Section 5.1.7, “Server SQL Modes”.

- `--basedir=`*`path`*, `-b` *`path`*

Command Line Format	`--basedir=name`	
Config File Format	`basedir`	
Option Sets Variable	Yes, `basedir`	
Variable Name	`basedir`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables`

Command Line Format	`--big-tables`
Config File Format	`big-tables`
Option Sets Variable	Yes, `big_tables`

Variable Name	big-tables	
Variable Scope	Session	
Dynamic Variable	Yes	
Value Set	**Type**	boolean

Allow large result sets by saving all temporary sets in files. This option prevents most "table full" errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=IP`

Command Line Format	--bind-address=name	
Config File Format	bind-address	
Value Set	**Type**	string
	Default	0.0.0.0
	Range	0.0.0.0-255.255.255.255

The IP address to bind to. Only one address can be selected. If this option is specified multiple times, the last address given is used.

If no address or `0.0.0.0` is specified, the server listens on all interfaces.

- `--binlog-format={ROW|STATEMENT|MIXED}`

Command Line Format	--binlog-format	
Config File Format	binlog-format	
Option Sets Variable	Yes, binlog_format	
Variable Name	binlog_format	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration
	Default	STATEMENT
	Valid Values	ROW, STATEMENT, MIXED

Specify whether to use row-based, statement-based, or mixed replication (mixed is the default in MySQL 6.0). See Section 16.1.2, "Replication Formats".

- `--bootstrap`

Command Line Format	--bootstrap
Config File Format	bootstrap

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

This option is unavailable if MySQL was configured with the `--disable-grant-options` option. See Section 2.9.2, "Typical `configure` Options".

- `--character-sets-dir=path`

Command Line Format	--character-sets-dir=name
Config File Format	character-sets-dir
Option Sets Variable	Yes, character_sets_dir
Variable Name	character-sets-dir

Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The directory where character sets are installed. See Section 9.2, “The Character Set Used for Data and Sorting”.

- `--character-set-client-handshake`

Command Line Format	`--character-set-client-handshake`	
Config File Format	`character-set-client-handshake`	
Value Set	**Type**	`boolean`
	Default	`TRUE`

Don't ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=`*`charset_name`*

Command Line Format	`--character-set-filesystem=name`	
Config File Format	`character-set-filesystem`	
Option Sets Variable	Yes, `character_set_filesystem`	
Variable Name	`character_set_filesystem`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The file system character set. This option sets the `character_set_filesystem` system variable.

- `--character-set-server=`*`charset_name`*, `-C` *`charset_name`*

Command Line Format	`--character-set-server`	
Config File Format	`character-set-server`	
Option Sets Variable	Yes, `character_set_server`	
Variable Name	`character_set_server`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

Use *`charset_name`* as the default server character set. See Section 9.2, “The Character Set Used for Data and Sorting”. If you use this option to specify a non-default character set, you should also use `--collation-server` to specify the collation.

- `--chroot=`*`path`*, `-r` *`path`*

Command Line Format	`--chroot=name`	
Config File Format	`chroot`	
Value Set	**Type**	`filename`

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=`*`collation_name`*

Command Line Format	--collation-server	
Config File Format	collation-server	
Option Sets Variable	Yes, collation_server	
Variable Name	collation_server	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	string

Use *collation_name* as the default server collation. See Section 9.2, "The Character Set Used for Data and Sorting".

- --console

Command Line Format	--console
Config File Format	console
Platform Specific	windows

(Windows only.) Write error log messages to stderr and stdout even if --log-error is specified. mysqld does not close the console window if this option is used.

- --core-file

Command Line Format	--core-file	
Config File Format	core-file	
Value Set	**Type**	boolean
	Default	TRUE

Write a core file if mysqld dies. The name and location of the core file is system dependent. On Linux, a core file named core.*pid* is written to the current working directory of the process, which for mysqld is the data directory. *pid* represents the process ID of the server process. On Mac OS X, a core file named core.*pid* is written to the /cores directory. On Solaris, use the coreadm command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the --core-file-size option to mysqld_safe. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script". On some systems, such as Solaris, you do not get a core file if you are also using the --user option. There might be additional restrictions or limitations. For example, it might be necessary to execute ulimit -c unlimited before starting the server. Consult your system documentation.

- --datadir=*path*, -h *path*

Command Line Format	--datadir=name	
Config File Format	datadir	
Option Sets Variable	Yes, datadir	
Variable Name	datadir	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The path to the data directory.

- --debug[=*debug_options*], -# [*debug_options*]

Command Line Format	--debug[=debug_options]
Config File Format	debug
Variable Name	debug
Variable Scope	Both

Dynamic Variable	Yes	
Value Set	Type	string
	Default	'd:t:o,/tmp/mysqld.trace

If MySQL is configured with --with-debug, you can use this option to get a trace file of what mysqld is doing. A typical *debug_options* string is 'd:t:o,*file_name*'. The default is 'd:t:i:o,mysqld.trace'. See MySQL Internals: Porting.

Using --with-debug to configure MySQL with debugging support enables you to use the --debug="d,parser_debug" option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with + or - are added to or subtracted from the previous value. For example, --debug=T --debug=+P sets the value to P:T.

- --debug-sync-timeout[=*N*]

Version Introduced	6.0.6	
Command Line Format	--debug-sync-timeout[=#]	
Config File Format	debug-sync-timeout	
Value Set	Type	numeric

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the --enable-debug-sync option (see Section 2.9.2, "Typical configure Options"). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

This option was added in MySQL 6.0.6.

- --default-character-set=*charset_name* (*DEPRECATED*)

Command Line Format	--default-character-set=name	
Config File Format	default-character-set	
Deprecated	5.0	
Value Set	Type	string

Use *charset_name* as the default character set. This option is deprecated in favor of --character-set-server. See Section 9.2, "The Character Set Used for Data and Sorting".

- --default-collation=*collation_name*

Command Line Format	--default-collation=name	
Variable Name	default-collation	
Variable Scope		
Dynamic Variable	No	
Deprecated	4.1.3	
Value Set	Type	string

Use *collation_name* as the default collation. This option is deprecated in favor of --collation-server. See Section 9.2, "The Character Set Used for Data and Sorting".

- --default-storage-engine=*type*

Command Line Format	--default-storage-engine=name
Config File Format	default-storage-engine

Set the default storage engine (table type) for tables. See Chapter 13, *Storage Engines*.

- --default-table-type=*type*

Version Removed	6.0.8	
Command Line Format	--default-table-type=name	
Config File Format	default-table-type	
Deprecated	5.0, by default-storage-engine	
Value Set	**Type**	string

This option is a deprecated synonym for --default-storage-engine. It has been removed as of MySQL 6.0.8.

- --default-time-zone=*timezone*

Command Line Format	--default-time-zone=name	
Config File Format	default-time-zone	
Value Set	**Type**	string

Set the default server time zone. This option sets the global time_zone system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the system_time_zone system variable.

- --delay-key-write[={OFF|ON|ALL}]

Command Line Format	--delay-key-write[=name]	
Config File Format	delay-key-write	
Option Sets Variable	Yes, delay_key_write	
Variable Name	delay-key-write	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration
	Default	ON
	Valid Values	ON, OFF, ALL

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for MyISAM tables. OFF disables delayed key writes. ON enables delayed key writes for those tables that were created with the DELAY_KEY_WRITE option. ALL delays key writes for all MyISAM tables. See Section 7.5.3, “Tuning Server Parameters”, and Section 13.5.1, “MyISAM Startup Options”.

> **Note**
>
> If you set this variable to ALL, you should not use MyISAM tables from within another program (such as another MySQL server or myisamchk) when the tables are in use. Doing so leads to index corruption.

- --des-key-file=*file_name*

Command Line Format	--des-key-file=name
Config File Format	des-key-file

Read the default DES keys from this file. These keys are used by the DES_ENCRYPT() and DES_DECRYPT() functions.

- --enable-named-pipe

Enable support for named pipes. This option applies only on Windows NT, 2000, XP, and 2003 systems.

- `--enable-pstack`

Command Line Format	`--enable-pstack`	
Config File Format	`enable-pstack`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Print a symbolic stack trace on failure.

- `--engine-condition-pushdown={ON|OFF}`

Command Line Format	`--engine-condition-pushdown`	
Config File Format	`engine-condition-pushdown`	
Option Sets Variable	Yes, `engine_condition_pushdown`	
Variable Name	`engine_condition_pushdown`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`ON`

Sets the `engine_condition_pushdown` system variable. For more information, see Section 7.2.7, “Condition Pushdown Optimization”.

- `--event-scheduler[=value]`

Command Line Format	`--event-scheduler[=value]`	
Config File Format	`event-scheduler`	
Option Sets Variable	Yes, `event_scheduler`	
Variable Name	`event_scheduler`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`
	Default	`OFF`
	Valid Values	`ON`, `OFF`, `DISABLED`

Enable or disable, and start or stop, the event scheduler.

For detailed information, see The `event-scheduler` Option.

- `--exit-info[=flags]`, `-T [flags]`

Command Line Format	`--exit-info[=flags]`	
Config File Format	`exit-info`	
Value Set	**Type**	`numeric`

This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

Command Line Format	`--external-locking`

Config File Format	external-locking	
Option Sets Variable	Yes, skip_external_locking	
Disabled by	skip-external-locking	
Value Set	Type	boolean
	Default	FALSE

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which lockd does not fully work (such as Linux), it is easy for mysqld to deadlock. This option previously was named --enable-locking.

For more information about external locking, including conditions under which it can and cannot be used, see Section 7.3.5, "External Locking".

- --flush

Command Line Format	--flush	
Config File Format	flush	
Variable Name	flush	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	boolean
	Default	OFF

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.1.4.2, "What to Do If MySQL Keeps Crashing".

- --gdb

Command Line Format	--gdb	
Config File Format	gdb	
Value Set	Type	boolean
	Default	FALSE

Install an interrupt handler for SIGINT (needed to stop mysqld with ^C to set breakpoints) and disable stack tracing and core file handling. See MySQL Internals: Porting.

- --general-log[={0|1}]

Command Line Format	--general-log	
Config File Format	general-log	
Option Sets Variable	Yes, general_log	
Variable Name	general_log	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	boolean
	Default	OFF

Specify the initial general query log state. With no argument or an argument of 1, the --general-log option enables the log. If omitted or given with an argument of 0, the option disables the log.

- --init-file=*file_name*

Command Line Format	--init-file=name	
Config File Format	init-file	
Option Sets Variable	Yes, init_file	
Variable Name	init_file	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

This option is unavailable if MySQL was configured with the `--disable-grant-options` option. See Section 2.9.2, "Typical `configure` Options".

- `--innodb-xxx`

  The `InnoDB` options are listed in Section 13.7.3, "`InnoDB` Startup Options and System Variables".

- `--language=lang_name, -L lang_name`

Command Line Format	--language=name	
Config File Format	language	
Option Sets Variable	Yes, language	
Variable Name	language	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename
	Default	/usr/local/mysql/share/mysql/english/

Return client error messages in the given language. *`lang_name`* can be given as the language name or as the full path name to the directory where the language files are installed. See Section 9.3, "Setting the Error Message Language".

- `--large-pages`

Command Line Format	--large-pages	
Config File Format	large-pages	
Option Sets Variable	Yes, large_pages	
Variable Name	large_pages	
Variable Scope	Global	
Dynamic Variable	No	
Platform Specific	linux	
Value Set	**Type** (linux)	boolean
	Default	FALSE

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

Currently, MySQL supports only the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 7.5.9, "Enabling Large Page Support".

`--large-pages` is disabled by default.

- `--log[=file_name]`, `-l [file_name]`

Command Line Format	`--log[=name]`	
Config File Format	`log`	
Option Sets Variable	Yes, `log`	
Variable Name	`log`	
Variable Scope	Global	
Dynamic Variable	Yes	
Deprecated	5.1.29, by `general-log`	
Value Set	**Type**	`string`
	Default	`OFF`

This option enables logging to the general query log, which contains entries that record client connections and SQL statements received from clients. The log output destination can be selected with the `--log-output` option. See Section 5.2.1, "Selecting General Query and Slow Query Log Output Destinations", and Section 5.2.3, "The General Query Log".

As of MySQL 6.0.8, the `--log` option is deprecated and will be removed (along with the `log` system variable) in MySQL 7.0. Instead, use the `--general_log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.

- `--log-backup-output[=value,...]`

Version Introduced	6.0.8	
Command Line Format	`--log-backup-output[=name]`	
Config File Format	`log-backup-output`	
Option Sets Variable	Yes, `log_backup_output`	
Variable Name	`log_backup_output`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`
	Default	`TABLE`
	Valid Values	`TABLE`, `FILE`, `NONE`

This option determines the destination for MySQL Backup history and progress log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. If the option is given without a value, the default is `TABLE`. `TABLE` selects logging to the `backup_history` and `backup_progress` log tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--backup_history_log` and `--backup_progress_log` options. For `FILE` logging, the default log files are `backup_history.log` and `backup_progress.log` in the data directory. To change the names, set the global `backup_history_log_file` and `backup_progress_log_file` system variables. For more information, see Section 6.3.3.1, "MySQL Backup Log Control".

This option was added in MySQL 6.0.8.

- `--log-error[=file_name]`

Command Line Format	`--log-error[=name]`	
Config File Format	`log-error`	
Option Sets Variable	Yes, `log_error`	
Variable Name	`log_error`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

Log errors and startup messages to this file. See Section 5.2.2, “The Error Log”. If you omit the file name, MySQL uses *`host_name`*`.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=`*`file_name`*`]`

Command Line Format	`--log-isam[=name]`	
Config File Format	`log-isam`	
Value Set	**Type**	`filename`

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-long-format` (*DEPRECATED*)

Command Line Format	`--log-long-format`
Config File Format	`log-long-format`
Deprecated	4.1

Log extra information to the binary log and slow query log, if they have been activated. For example, the user name and timestamp are logged for all queries. This option is deprecated, as it now represents the default logging behavior. (See the description for `--log-short-format`.) The `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log.

- `--log-output[=`*`value`*`,...]`

Command Line Format	`--log-output[=name]`	
Config File Format	`log-output`	
Option Sets Variable	Yes, `log_output`	
Variable Name	`log_output`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`
	Default	`FILE`
	Valid Values	`TABLE`, `FILE`, `NONE`

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. If the option is given without a value, the default is `FILE`. `TABLE` selects logging to the `general_log` and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` and `--slow_query_log` options. For `FILE` logging, the `--general_log_file` and `-slow_query_log_file` options determine the log file location. (Before MySQL 6.0.8, enable the logs with the `--log` and `--log-slow-queries` options. The options take an optional file name argument to specify the log file name.) For more information, see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”.

- `--log-queries-not-using-indexes`

Command Line Format	`--log-queries-not-using-indexes`	
Config File Format	`log-queries-not-using-indexes`	
Option Sets Variable	Yes, `log_queries_not_using_indexes`	
Variable Name	`log_queries_not_using_indexes`	
Variable Scope	Global	
Dynamic Variable	Yes	
Deprecated	5.1.29, by `slow-query-log`	
Value Set	**Type**	`boolean`

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.2.5, “The Slow Query Log”. This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-short-format`

Command Line Format	`--log-short-format`	
Config File Format	`log-short-format`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Originally intended to log less information to the binary log and slow query log, if they have been activated. However, this option is not operational.

- `--log-slow-admin-statements`

Command Line Format	`--log-slow-admin-statements`	
Config File Format	`log-slow-admin-statements`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

- `--log-slow-queries[=`*`file_name`*`]`

Command Line Format	`--log-slow-queries[=name]`	
Config File Format	`log-slow-queries`	
Option Sets Variable	Yes, `log_slow_queries`	
Variable Name	`log_slow_queries`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`

This option enables logging to the slow query log, which contains entries for all queries that have taken more than `long_query_time` seconds to execute. See the descriptions of the `--log-long-format` and `--log-short-format` options for details.

The log output destination can be selected with the `--log-output` option. If you omit the file name, MySQL uses *`host_name`*`-slow.log` as the file name. See Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”, and Section 5.2.5, “The Slow Query Log”.

As of MySQL 6.0.8, the `--log-slow-queries` option is deprecated and will be removed (along with the `log_slow_queries` system variable) in MySQL 7.0. Instead, use the `--slow_query_log` option to enable the slow query log and the `--slow_query_log_file=`*`file_name`* option to set the slow query log file name.

- `--log-tc=`*`file_name`*

Command Line Format	`--log-tc=name`	
Config File Format	`log-tc`	
Value Set	**Type**	`filename`
	Default	`tc.log`

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. Currently, this option is unused.

- `--log-tc-size=size`

Command Line Format	`--log-tc-size=#`	
Config File Format	`log-tc-size`	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`24576`
	Max Value	`4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`24576`
	Max Value	`18446744073709547520`

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level]`, `-W [level]`

Command Line Format	`--log-warnings[=#]`	
Config File Format	`log-warnings`	
Option Sets Variable	Yes, `log_warnings`	
Variable Name	`log_warnings`	
Variable Scope	Both	
Dynamic Variable	Yes	
Disabled by	`skip-log-warnings`	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`1`
	Range	`0-18446744073709547520`

Print out warnings such as `Aborted connection...` to the error log. Enabling this option is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled (1) by default, and the default *`level`* value if omitted is 1. To disable this option, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.1.2.11, “Communication Errors and Aborted Connections”.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

- `--low-priority-updates`

Command Line Format	`--low-priority-updates`	
Config File Format	`low-priority-updates`	
Option Sets Variable	Yes, `low_priority_updates`	
Variable Name	`low_priority_updates`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done via `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only

table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See Section 7.3.2, “Table Locking Issues”.

- `--min-examined-row-limit=number`

Version Introduced	6.0.4	
Command Line Format	`--min-examined-row-limit=#`	
Config File Format	`min-examined-row-limit`	
Variable Name	`min_examined_row_limit`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`0`
	Range	`0-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`0`
	Range	`0-18446744073709547520`

When this option is set, queries which examine fewer than *`number`* rows are not written to the slow query log. The default is 0.

This option was introduced in MySQL 6.0.4.

- `--memlock`

Command Line Format	`--memlock`	
Config File Format	`memlock`	
Variable Name	`locked_in_memory`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris as well as most Linux distributions that use a 2.4 or newer kernel. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

> **Important**
>
> Using this option requires that you run the server as `root`, which, for reasons of security, is normally not a good idea. See Section 5.3.5, “How to Run MySQL as a Normal User”.
>
> You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

Command Line Format	`--myisam-block-size=#`

Config File Format	myisam-block-size	
Value Set	Type	numeric
	Default	1024
	Range	1024-16384

The block size to be used for MyISAM index pages.

- --myisam-recover[=*option*[,*option*]...]]

Command Line Format	--myisam-recover[=name]	
Config File Format	myisam-recover	
Value Set	Type	enumeration
	Default	OFF
	Valid Values	DEFAULT, BACKUP, FORCE, QUICK

Set the MyISAM storage engine recovery mode. The option value is any combination of the values of DEFAULT, BACKUP, FORCE, or QUICK. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying DEFAULT, and specifying with an explicit value of "" disables recovery (same as not giving the option). If recovery is enabled, each time mysqld opens a MyISAM table, it checks whether the table is marked as crashed or wasn't closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, mysqld runs a check on the table. If the table was corrupted, mysqld attempts to repair it.

The following options affect how the repair works.

Option	Description
DEFAULT	Recovery without backup, forcing, or quick checking.
BACKUP	If the data file was changed during recovery, save a backup of the *tbl_name*.MYD file as *tbl_name-datetime*.BAK.
FORCE	Run recovery even if we would lose more than one row from the .MYD file.
QUICK	Don't check the rows in the table if there aren't any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options BACKUP,FORCE. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

See Section 13.5.1, “MyISAM Startup Options”.

- --old-passwords

Command Line Format	--old_passwords	
Config File Format	old-passwords	
Option Sets Variable	Yes, old_passwords	
Variable Name	old_passwords	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	boolean
	Default	FALSE

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.5.6.3, “Password Hashing in MySQL”.

- --old-style-user-limits

Command Line Format	--old-style-user-limits

Config File Format	old-style-user-limits	
Value Set	Type	boolean
	Default	FALSE

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 5.5.4, “Limiting Account Resources”.

- `--one-thread`

Command Line Format	--one-thread
Config File Format	one-thread

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See MySQL Internals: Porting.

This option is deprecated; use `--thread_handling=no-threads` instead.

- `--open-files-limit=`*`count`*

Command Line Format	--open-files-limit=#	
Config File Format	open-files-limit	
Option Sets Variable	Yes, open_files_limit	
Variable Name	open_files_limit	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type	numeric
	Default	0
	Range	0-65535

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

- `--pid-file=`*`path`*

Command Line Format	--pid-file=name	
Config File Format	pid-file	
Option Sets Variable	Yes, pid_file	
Variable Name	pid_file	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Type	filename

The path name of the process ID file. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--plugin-load=`*`plugin_list`*

Command Line Format	--plugin-load=plugin_list	
Config File Format	plugin-load	
Value Set	Type	string

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. This option enables plugins to be loaded even when `--skip-grant-tables` is given (which tells the server not to read system tables). This option also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

The option value is a colon-separated list of *`name=plugin_library`* values. Each *`name`* is the name of the plugin, and *`plugin_library`* is the name of the shared library that contains the plugin code. Each library file must be located in the directory named by the `plugin_dir` system variable. For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to load them at startup:

```
shell> mysqld --plugin-load=myplug1=myplug1.so:myplug2=myplug2.so
```

All plugins to load must be named in the same `--plugin-load` option. If multiple `--plugin-load` options are given, only the last one is used.

The plugins are loaded for a single invocation of `mysqld` only. After a restart, the plugins are not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

- `--port=`*`port_num`*, `-P` *`port_num`*

Command Line Format	`--port=#`	
Config File Format	`port`	
Option Sets Variable	Yes, `port`	
Variable Name	`port`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`numeric`
	Default	`3306`

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=`*`num`*

Command Line Format	`--port-open-timeout=#`	
Config File Format	`port-open-timeout`	
Value Set	**Type**	`numeric`
	Default	`0`

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--safe-mode`

Command Line Format	`--safe-mode`
Config File Format	`safe-mode`
Deprecated	5.0

Skip some optimization stages.

- `--safe-show-database` (*DEPRECATED*)

Command Line Format	`--safe-show-database`
Config File Format	`safe-show-database`
Variable Name	`safe_show_database`
Variable Scope	Global

Dynamic Variable	Yes	
Deprecated	4.0.2	
Value Set	**Type**	`boolean`

See Section 5.4.1, “Privileges Provided by MySQL”.

- `--safe-user-create`

Command Line Format	`--safe-user-create`	
Config File Format	`safe-user-create`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

Command Line Format	`--secure-auth`	
Config File Format	`secure-auth`	
Option Sets Variable	Yes, `secure_auth`	
Variable Name	`secure_auth`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Disallow authentication by clients that attempt to use accounts that have old (pre-4.1) passwords.

- `--secure-backup-file-priv=path`

Command Line Format	`--secure-backup-file-priv`	
Config File Format	`secure-backup-file-priv`	
Option Sets Variable	Yes, `secure_backup_file_priv`	
Variable Name	`secure_backup_file_priv`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

This option limits the effect of the `BACKUP DATABASE` and `RESTORE` statements to work only with files in the specified directory. This option was added in MySQL 6.0.11; in older releases, use `--secure-file-priv` instead.

- `--secure-file-priv=path`

Command Line Format	`--secure-file-priv`
Config File Format	`secure-file-priv`
Option Sets Variable	Yes, `secure_file_priv`

Variable Name	secure_file_priv	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	string

This option limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory. Before MySQL 6.0.11, it also applies to the `BACKUP DATABASE` and `RESTORE` statements; as of 6.0.11, `--secure-backup-file-priv` applies to those statements.

- `--shared-memory`

  Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=`*name*

  The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert`

  Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See Section 7.3.3, “Concurrent Inserts”.

- `--skip-external-locking`

  Do not use external locking (system locking). For more information about external locking, including conditions under which it can and cannot be used, see Section 7.3.5, “External Locking”.

  External locking has been disabled by default since MySQL 4.0.

- `--skip-grant-tables`

  This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of plugins, user-defined functions (UDFs), and scheduled events. To cause plugins to be loaded anyway, use the `--plugin-load` option.

  `--skip-grant-tables` is unavailable if MySQL was configured with the `--disable-grant-options` option. See Section 2.9.2, “Typical `configure` Options”.

- `--skip-host-cache`

  Do not use the internal host name cache for faster name-to-IP resolution. Instead, query the DNS server every time a client connects. See Section 7.5.11, “How MySQL Uses DNS”.

- `--skip-innodb`

  Disable the `InnoDB` storage engine. This saves memory and disk space and might speed up some operations. Do not use this option if you require `InnoDB` tables.

- `--skip-name-resolve`

  Do not resolve host names when checking client connections. Use only IP numbers. If you use this option, all `Host` column values in the grant tables must be IP numbers or `localhost`. See Section 7.5.11, “How MySQL Uses DNS”.

- `--skip-networking`

  Don't listen for TCP/IP connections at all. All interaction with `mysqld` must be made via named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are allowed. See Section 7.5.11, “How MySQL Uses DNS”.

- `--ssl*`

  Options that begin with `--ssl` specify whether to allow clients to connect via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

- `--standalone`

Command Line Format	`--standalone`
Config File Format	`standalone`
Platform Specific	windows

Available on Windows NT-based systems only; instructs the MySQL server not to run as a service.

- `--symbolic-links`, `--skip-symbolic-links`

Command Line Format	`--symbolic-links`
Config File Format	`symbolic-links`

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links allows you to establish a symbolic link to a database directory by creating a *`db_name`*`.sym` file that contains the path to the real directory. See Section 7.6.1.3, “Using Symbolic Links for Databases on Windows”.
- On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”.

- `--skip-safemalloc`

Command Line Format	`--skip-safe-malloc`
Config File Format	`skip-safemalloc`

If MySQL is configured with `--with-debug=full`, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you don't need it by using the `--skip-safemalloc` option.

- `--skip-show-database`

Command Line Format	`--skip-show-database`
Config File Format	`skip-show-database`
Option Sets Variable	Yes, `skip_show_database`
Variable Name	`skip_show_database`
Variable Scope	Global
Dynamic Variable	No

With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that *any* global privilege is considered a privilege for the database.

- `--skip-stack-trace`

Command Line Format	`--skip-stack-trace`
Config File Format	`skip-stack-trace`

Don't write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See MySQL Internals: Porting.

- `--skip-thread-priority`

Version Removed	6.0.8
Command Line Format	`--skip-thread-priority`

Config File Format	skip-thread-priority
Deprecated	5.1.29

Disable using thread priorities for faster response time. This option was removed in MySQL 6.0.8

- `--slow-query-log[={0|1}]`

Command Line Format	--slow-query-log	
Config File Format	slow-query-log	
Option Sets Variable	Yes, slow_query_log	
Variable Name	slow_query_log	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	boolean
	Default	OFF

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--socket=path`

Command Line Format	--socket=name	
Config File Format	socket	
Option Sets Variable	Yes, socket	
Variable Name	socket	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename
	Default	/tmp/mysql.sock

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

Command Line Format	--sql-mode=name	
Config File Format	sql-mode	
Option Sets Variable	Yes, sql_mode	
Variable Name	sql_mode	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	set
	Default	''
	Valid Values	ALLOW_INVALID_DATES, ANSI_QUOTES, ERROR_FOR_DIVISION_BY_ZERO, HIGH_NOT_PRECEDENCE, IGNORE_SPACE, NO_AUTO_CREATE_USER, NO_AUTO_VALUE_ON_ZERO, NO_BACKSLASH_ESCAPES, NO_DIR_IN_CREATE, NO_ENGINE_SUBSTITUTION,

		NO_FIELD_OPTIONS, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_UNSIGNED_SUBTRACTION, NO_ZERO_DATE, NO_ZERO_IN_DATE, ONLY_FULL_GROUP_BY, PAD_CHAR_TO_FULL_LENGTH, PIPES_AS_CONCAT, REAL_AS_FLOAT, STRICT_ALL_TABLES, STRICT_TRANS_TABLES

Set the SQL mode. See Section 5.1.7, “Server SQL Modes”.

- `--sysdate-is-now`

Command Line Format	`--sysdate-is-now`	
Config File Format	`sysdate-is-now`	
Value Set	**Type**	`boolean`
	Default	`FALSE`

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in Section 11.6, “Date and Time Functions” and for `SET TIMESTAMP` in Section 5.1.4, “Session System Variables”.

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

Command Line Format	`--tc-heuristic-recover=name`	
Config File Format	`tc-heuristic-recover`	
Value Set	**Type**	`enumeration`
	Valid Values	`COMMIT`, `RECOVER`

The type of decision to use in the heuristic recovery process. Currently, this option is unused.

- `--temp-pool`

Command Line Format	`--temp-pool`	
Config File Format	`temp-pool`	
Value Set	**Type**	`boolean`
	Default	`TRUE`

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache. As of MySQL 6.0.10, this option is ignored except on Linux.

- `--transaction-isolation=level`

Command Line Format	`--transaction-isolation=name`	
Config File Format	`transaction-isolation`	
Value Set	**Type**	`enumeration`
	Valid Values	`READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 12.4.6, "`SET TRANSACTION` Syntax".

- `--tmpdir=path`, `-t path`

Command Line Format	`--tmpdir=name`	
Config File Format	`tmpdir`	
Option Sets Variable	Yes, `tmpdir`	
Variable Name	`tmpdir`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters ("`:`") on Unix and semicolon characters ("`;`") on Windows, NetWare, and OS/2. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see Section B.1.4.4, "Where MySQL Stores Temporary Files". A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}`, `-u {user_name|user_id}`

Command Line Format	`--user=name`	
Config File Format	`user`	
Value Set	**Type**	`string`

Run the `mysqld` server as the user having the name *`user_name`* or the numeric user ID *`user_id`*. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 5.3.1, "General Security Guidelines".

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--verbose`, `-v`

  Use this option with the `--help` option for detailed help.

- `--version`, `-V`

  Display version information and exit.

You can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest allowable value if only certain values are allowed.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

You can change the values of most system variables for a running server with the `SET` statement. See Section 12.5.5, "`SET` Syntax".

Section 5.1.3, "Server System Variables", provides a full description for all variables, and additional information for setting them at

server startup and runtime. Section 7.5.3, “Tuning Server Parameters”, includes information on optimizing the server by tuning system variables.

5.1.3. Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 6.0 releases. For historical information concerning their implementation, please see http://dev.mysql.com/doc/refman/5.1/en/, http://dev.mysql.com/doc/refman/5.0/en/, and http://dev.mysql.com/doc/refman/4.1/en/.

The following table lists all available system variables:

Table 5.2. `mysqld` System Variable Summary

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
auto_increment_increment	Yes	Yes	Yes	Both	Yes
auto_increment_offset	Yes	Yes	Yes	Both	Yes
autocommit			Yes	Session	Yes
automatic_sp_privileges			Yes	Global	Yes
back_log	Yes	Yes	Yes	Global	No
backup_history_log	Yes	Yes	Yes	Global	Yes
backup_history_log_file	Yes	Yes	Yes	Global	Yes
backup_progress_log	Yes	Yes	Yes	Global	Yes
backup_progress_log_file	Yes	Yes	Yes	Global	Yes
backup_wait_timeout			Yes	Session	Yes
backupdir	Yes	Yes	Yes	Global	Yes
basedir	Yes	Yes	Yes	Global	No
big-tables	Yes	Yes			Yes
- *Variable*: big_tables			Yes	Session	Yes
binlog_cache_size	Yes	Yes	Yes	Global	Yes
binlog-format	Yes	Yes			Yes
- *Variable*: binlog_format			Yes	Both	Yes
bulk_insert_buffer_size	Yes	Yes	Yes	Both	Yes
character_set_client			Yes	Both	Yes
character_set_connection			Yes	Both	Yes
character_set_database[a]			Yes	Both	Yes
character-set-filesystem	Yes	Yes			Yes
- *Variable*: character_set_filesystem			Yes	Both	Yes
character_set_results			Yes	Both	Yes
character-set-server	Yes	Yes			Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
- *Variable*: character_set_server			Yes	Both	Yes
character_set_system			Yes	Global	No
character-sets-dir	Yes	Yes			No
- *Variable*: character_sets_dir			Yes	Global	No
collation_connection			Yes	Both	Yes
collation_database[b]			Yes	Both	Yes
collation-server	Yes	Yes			Yes
- *Variable*: collation_server			Yes	Both	Yes
completion_type	Yes	Yes	Yes	Both	Yes
concurrent_insert	Yes	Yes	Yes	Global	Yes
connect_timeout	Yes	Yes	Yes	Global	Yes
datadir	Yes	Yes	Yes	Global	No
date_format			Yes	Both	Yes
datetime_format	Yes	Yes	Yes	Both	Yes
debug	Yes	Yes	Yes	Both	Yes
debug_sync			Yes	Both	Yes
default_week_format	Yes	Yes	Yes	Both	Yes
delay-key-write	Yes	Yes			Yes
- *Variable*: delay_key_write			Yes	Global	Yes
delayed_insert_limit	Yes	Yes	Yes	Global	Yes
delayed_insert_timeout	Yes	Yes	Yes	Global	Yes
delayed_queue_size	Yes	Yes	Yes	Global	Yes
div_precision_increment	Yes	Yes	Yes	Both	Yes
engine-condition-pushdown	Yes	Yes			Yes
- *Variable*: engine_condition_pushdown			Yes	Both	Yes
error_count			Yes	Session	No
event-scheduler	Yes	Yes			Yes
- *Variable*: event_scheduler			Yes	Global	Yes
expire_logs_days	Yes	Yes	Yes	Global	Yes

[a]This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.
[b]This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- Section 5.1.4, “Session System Variables”, describes system variables that exist only as session variables (that is, they do not have any global counterpart).
- Section 5.1.5, “Using System Variables”, discusses the syntax for setting and displaying system variable values.
- Section 5.1.5.2, “Dynamic System Variables”, lists the variables that can be set at runtime.
- Information on tuning system variables can be found in Section 7.5.3, “Tuning Server Parameters”.
- Section 13.7.3, “`InnoDB` Startup Options and System Variables”, lists `InnoDB` system variables.
- For information on server system variables specific to replication, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

> **Note**
>
> Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not

work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

- `automatic_sp_privileges`

Variable Name	`automatic_sp_privileges`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`TRUE`

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges when the creator drops the routine. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

- `backup_history_log`

Version Introduced	6.0.8	
Command Line Format	`--backup_history_log`	
Config File Format	`backup_history_log`	
Option Sets Variable	Yes, `backup_history_log`	
Variable Name	`backup_history_log`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`ON`

Whether the MySQL Backup history log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_backup_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled. This variable was added in MySQL 6.0.8.

- `backup_history_log_file`

Version Introduced	6.0.8	
Command Line Format	`--backup_history_log_file`	
Config File Format	`backup_history_log_file`	
Option Sets Variable	Yes, `backup_history_log_file`	
Variable Name	`backup_history_log_file`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`filename`
	Default	`backup_history.log`

The name of the MySQL Backup history log file. The default value is `backup_history.log`. This variable was added in MySQL 6.0.8.

- `backup_progress_log`

Version Introduced	6.0.8	
Command Line Format	`--backup_progress_log`	
Config File Format	`backup_progress_log`	
Option Sets Variable	Yes, `backup_progress_log`	
Variable Name	`backup_progress_log`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`ON`

Whether the MySQL Backup progress log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The destination for log output is controlled by the `log_backup_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled. This variable was added in MySQL 6.0.8.

- `backup_progress_log_file`

Version Introduced	6.0.8	
Command Line Format	`--backup_progress_log_file`	
Config File Format	`backup_progress_log_file`	
Option Sets Variable	Yes, `backup_progress_log_file`	
Variable Name	`backup_progress_log_file`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`filename`
	Default	`backup_progress.log`

The name of the MySQL Backup progress log file. The default value is `backup_progress.log`. This variable was added in MySQL 6.0.8.

- `back_log`

Command Line Format	`--back_log=#`	
Config File Format	`back_log`	
Option Sets Variable	Yes, `back_log`	
Variable Name	`back_log`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`numeric`
	Default	`50`
	Range	`1-65535`

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

- `backupdir`

Version Introduced	6.0.7	
Command Line Format	`--backupdir=name`	
Config File Format	`backupdir`	
Option Sets Variable	Yes, `backupdir`	
Variable Name	`backupdir`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`filename`

The path to the default image file directory for `BACKUP DATABASE` and `RESTORE` operations. If an image file is named as a relative path name, it is interpreted relative to the value of `backupdir`. If the value of `backupdir` is itself a relative path name, its value is interpreted relative to the data directory. The default value is the data directory.

If `backupdir` is set to a non-existent path, `BACKUP DATABASE` and `RESTORE` cannot be executed. The same is true if `backupdir` references a symbolic link that points at a non-existent path. Specifying the backup image file name as an absolute path name does not help.

If `backupdir` is set to an existing plain file or pipe, `BACKUP DATABASE` and `RESTORE` fail if the value is a relative path, unless it starts with a leading `../` component or unless the backup image file name is given as an absolute path. The same is true if `backupdir` references a symbolic link that points at an existent plain file or pipe.

This variable was added in MySQL 6.0.7.

- `basedir`

Command Line Format	`--basedir=name`	
Config File Format	`basedir`	
Option Sets Variable	Yes, `basedir`	
Variable Name	`basedir`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- `bulk_insert_buffer_size`

Command Line Format	`--bulk_insert_buffer_size=#`	
Config File Format	`bulk_insert_buffer_size`	
Option Sets Variable	Yes, `bulk_insert_buffer_size`	
Variable Name	`bulk_insert_buffer_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`8388608`
	Range	`0-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`8388608`
	Range	`0-18446744073709547520`

`MyISAM` uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to non-empty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client`

Variable Name	`character_set_client`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 9.1.4, "Connection Character Sets and Collations".) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

- `character_set_connection`

Variable Name	`character_set_connection`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The character set used for literals that do not have a character set introducer and for number-to-string conversion.

- `character_set_database`

Variable Name	`character_set_database`	
Variable Scope	Both	
Dynamic Variable	Yes	
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
Value Set	**Type**	`string`

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

Command Line Format	`--character-set-filesystem=name`	
Config File Format	`character-set-filesystem`	
Option Sets Variable	Yes, `character_set_filesystem`	
Variable Name	`character_set_filesystem`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte file names are allowed, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8'`.

- `character_set_results`

Variable Name	`character_set_results`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The character set used for returning query results to the client.

- `character_set_server`

Command Line Format	`--character-set-server`	
Config File Format	`character-set-server`	
Option Sets Variable	Yes, `character_set_server`	
Variable Name	`character_set_server`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The server's default character set.

- `character_set_system`

Variable Name	`character_set_system`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

Command Line Format	`--character-sets-dir=name`	
Config File Format	`character-sets-dir`	
Option Sets Variable	Yes, `character_sets_dir`	
Variable Name	`character-sets-dir`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The directory where character sets are installed.

- `collation_connection`

Variable Name	`collation_connection`
Variable Scope	Both

Dynamic Variable	Yes	
Value Set	**Type**	`string`

The collation of the connection character set.

- `collation_database`

Variable Name	`collation_database`	
Variable Scope	Both	
Dynamic Variable	Yes	
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
Value Set	**Type**	`string`

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

Command Line Format	`--collation-server`	
Config File Format	`collation-server`	
Option Sets Variable	Yes, `collation_server`	
Variable Name	`collation_server`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

The server's default collation.

- `completion_type`

Command Line Format	`--completion_type=#`	
Config File Format	`completion_type`	
Option Sets Variable	Yes, `completion_type`	
Variable Name	`competion_type`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`0`
	Valid Values	`0`, `1`, `2`

The transaction completion type:

- If the value is 0 (the default), `COMMIT` and `ROLLBACK` are unaffected.
- If the value is 1, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT AND CHAIN` and `ROLLBACK AND CHAIN`, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
- If the value is 2, `COMMIT` and `ROLLBACK` are equivalent to `COMMIT RELEASE` and `ROLLBACK RELEASE`, respectively. (The server disconnects after terminating the transaction.)

- `concurrent_insert`

Command Line Format	`--concurrent_insert[=#]`

Config File Format	concurrent_insert	
Option Sets Variable	Yes, concurrent_insert	
Variable Name	concurrent_insert	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	1
	Valid Values	0, 1, 2

If 1 (the default), MySQL allows INSERT and SELECT statements to run concurrently for MyISAM tables that have no free blocks in the middle of the data file. You can turn this option off by starting mysqld with --safe-mode or --skip-new.

This variable can take three integer values.

Value	Description
0	Off
1	(Default) Enables concurrent insert for MyISAM tables that don't have holes
2	Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

See also Section 7.3.3, “Concurrent Inserts”.

- connect_timeout

Command Line Format	--connect_timeout=#	
Config File Format	connect_timeout	
Option Sets Variable	Yes, connect_timeout	
Variable Name	connect_timeout	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	10

The number of seconds that the mysqld server waits for a connect packet before responding with Bad handshake. The default value is 10 seconds.

Increasing the connect_timeout value might help if clients frequently encounter errors of the form Lost connection to MySQL server at '*XXX*', system error: *errno*.

- datadir

Command Line Format	--datadir=name	
Config File Format	datadir	
Option Sets Variable	Yes, datadir	
Variable Name	datadir	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The MySQL data directory. This variable can be set with the --datadir option.

- `date_format`

  This variable is unused.

- `datetime_format`

  This variable is unused.

- `debug`

Command Line Format	`--debug[=debug_options]`	
Config File Format	`debug`	
Variable Name	`debug`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`
	Default	`'d:t:o,/tmp/mysqld.trace`

  This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

  Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| P:T     |
+---------+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+
```

- `debug_sync`

Version Introduced	6.0.6	
Variable Name	`debug_sync`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`string`

  This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `--enable-debug-sync` option (see Section 2.9.2, “Typical `configure` Options”). If Debug Sync is not compiled in, this system variable is not available.

  The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where *`N`* is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, *`N`* becomes the default timeout for individual synchronization points.

  The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

This variable was added in MySQL 6.0.6.

- `default_week_format`

Command Line Format	`--default_week_format=#`	
Config File Format	`default_week_format`	
Option Sets Variable	Yes, `default_week_format`	
Variable Name	`default_week_format`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`0`
	Range	`0-7`

The default mode value to use for the `WEEK()` function. See Section 11.6, “Date and Time Functions”.

- `delay_key_write`

Command Line Format	`--delay-key-write[=name]`	
Config File Format	`delay-key-write`	
Option Sets Variable	Yes, `delay_key_write`	
Variable Name	`delay-key-write`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`
	Default	`ON`
	Valid Values	`ON`, `OFF`, `ALL`

This option applies only to `MyISAM` tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
`OFF`	`DELAY_KEY_WRITE` is ignored.
`ON`	MySQL honors any `DELAY_KEY_WRITE` option specified in `CREATE TABLE` statements. This is the default value.
`ALL`	All new opened tables are treated as if they were created with the `DELAY_KEY_WRITE` option enabled.

If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all `MyISAM` tables by starting the server with the `--myisam-recover` option (for example, `--myisam-recover=BACKUP,FORCE`). See Section 5.1.2, “Server Command Options”, and Section 13.5.1, “`MyISAM` Start-up Options”.

> **Warning**
>
> If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`

Command Line Format	`--delayed_insert_limit=#`
Config File Format	`delayed_insert_limit`

Option Sets Variable	Yes, `delayed_insert_limit`	
Variable Name	`delayed_insert_limit`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`100`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`100`
	Range	`1-18446744073709547520`

After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it allows them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout`

Command Line Format	`--delayed_insert_timeout=#`	
Config File Format	`delayed_insert_timeout`	
Option Sets Variable	Yes, `delayed_insert_timeout`	
Variable Name	`delayed_insert_timeout`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`300`

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size`

Command Line Format	`--delayed_queue_size=#`	
Config File Format	`delayed_queue_size`	
Option Sets Variable	Yes, `delayed_queue_size`	
Variable Name	`delayed_queue_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`1000`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`1000`
	Range	`1-18446744073709547520`

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `div_precision_increment`

Command Line Format	`--div_precision_increment=#`	
Config File Format	`div_precision_increment`	
Option Sets Variable	Yes, `div_precision_increment`	
Variable Name	`div_precision_increment`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`4`
	Range	`0-30`

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+----------------+
| 1/7            |
+----------------+
| 0.142857142857 |
+----------------+
```

- `engine_condition_pushdown`

Command Line Format	`--engine-condition-pushdown`	
Config File Format	`engine-condition-pushdown`	
Option Sets Variable	Yes, `engine_condition_pushdown`	
Variable Name	`engine_condition_pushdown`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`ON`

When the value of this variable is 0 (`OFF`), a query such as `SELECT * FROM t WHERE mycol = 42`, where `mycol` is a non-indexed column, is executed as a full table scan. The storage engine sends every row to the MySQL server, which applies the `WHERE` condition. If `engine_condition_pushdown` is set to 1 (`ON`), the condition is "pushed down" to the storage engine, which uses the condition to perform the scan, and sends back to the MySQL server only those rows that match the condition. By default, this variable is `OFF`.

In MySQL 6.0, this variable can be used only with the `MyISAM` storage engine. It may be implemented for additional storage engines in future MySQL releases.

For more information, see Section 7.2.7, "Condition Pushdown Optimization".

- `event_scheduler`

Command Line Format	`--event-scheduler[=value]`
Config File Format	`event-scheduler`
Option Sets Variable	Yes, `event_scheduler`
Variable Name	`event_scheduler`
Variable Scope	Global
Dynamic Variable	Yes

Value Set	Type	enumeration
	Default	OFF
	Valid Values	ON, OFF, DISABLED

This variable indicates the status of the Event Scheduler; possible values are ON, OFF, and DISABLED, with the default being OFF. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the Overview section of the Events chapter.

- expire_logs_days

Command Line Format	--expire_logs_days=#	
Config File Format	expire_logs_days	
Option Sets Variable	Yes, expire_logs_days	
Variable Name	expire_logs_days	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	0
	Range	0-99

The number of days for automatic binary log removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and at binary log rotation.

- flush

Command Line Format	--flush	
Config File Format	flush	
Variable Name	flush	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	boolean
	Default	OFF

If ON, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.1.4.2, “What to Do If MySQL Keeps Crashing”. This variable is set to ON if you start mysqld with the --flush option.

- flush_time

Command Line Format	--flush_time=#	
Config File Format	flush_time	
Option Sets Variable	Yes, flush_time	
Variable Name	flush_time	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	0
	Min Value	0
Value Set	Type (windows)	numeric
	Default	1800

	Min Value	`0`

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. We recommend that this option be used only on Windows 9x or Me, or on systems with minimal resources.

- `ft_boolean_syntax`

Command Line Format	`--ft_boolean_syntax=name`	
Config File Format	`ft_boolean_syntax`	
Variable Name	`ft_boolean_syntax`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`string`
	Default	`+-><()~*:""&`

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 11.8.2, “Boolean Full-Text Searches”.

The default variable value is `'+ -><()~*:""&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII non-alphanumeric character.
- Either the first or second character must be a space.
- No duplicates are allowed except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to “`:`”, “`&`”, and “`|`”) are reserved for future extensions.

- `ft_max_word_len`

Command Line Format	`--ft_max_word_len=#`	
Config File Format	`ft_max_word_len`	
Option Sets Variable	Yes, `ft_max_word_len`	
Variable Name	`ft_max_word_len`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`numeric`
	Min Value	`10`

The maximum length of the word to be included in a `FULLTEXT` index.

> **Note**
>
> `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

Command Line Format	`--ft_min_word_len=#`
Config File Format	`ft_min_word_len`
Option Sets Variable	Yes, `ft_min_word_len`
Variable Name	`ft_min_word_len`

Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	4
	Min Value	1

The minimum length of the word to be included in a FULLTEXT index.

> **Note**
>
> FULLTEXT indexes must be rebuilt after changing this variable. Use REPAIR TABLE *tbl_name* QUICK.

- ft_query_expansion_limit

Command Line Format	--ft_query_expansion_limit=#	
Config File Format	ft_query_expansion_limit	
Option Sets Variable	Yes, ft_query_expansion_limit	
Variable Name	ft_query_expansion_limit	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	20
	Range	0-1000

The number of top matches to use for full-text searches performed using WITH QUERY EXPANSION.

- ft_stopword_file

Command Line Format	--ft_stopword_file=name	
Config File Format	ft_stopword_file	
Option Sets Variable	Yes, ft_stopword_file	
Variable Name	ft_stopword_file	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The file from which to read the list of stopwords for full-text searches. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the storage/myisam/ft_static.c file). Setting this variable to the empty string ('') disables stopword filtering.

> **Note**
>
> FULLTEXT indexes must be rebuilt after changing this variable or the contents of the stopword file. Use REPAIR TABLE *tbl_name* QUICK.

- general_log

Command Line Format	--general-log
Config File Format	general-log
Option Sets Variable	Yes, general_log
Variable Name	general_log
Variable Scope	Global
Dynamic Variable	Yes

Value Set	Type	boolean
	Default	OFF

Whether the general query log is enabled. The value can be 0 (or OFF) to disable the log or 1 (or ON) to enable the log. The default value depends on whether the --general_log option is given (--log before MySQL 6.0.8). The destination for log output is controlled by the log_output system variable; if that value is NONE, no log entries are written even if the log is enabled.

- general_log_file

Command Line Format	--general-log-file=file_name	
Config File Format	general_log_file	
Option Sets Variable	Yes, general_log_file	
Variable Name	general_log_file	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Type	filename
	Default	host_name.log

The name of the general query log file. The default value is *host_name*.log, but the initial value can be changed with the --general_log_file option (--log before MySQL 6.0.8).

- group_concat_max_len

Command Line Format	--group_concat_max_len=#	
Config File Format	group_concat_max_len	
Option Sets Variable	Yes, group_concat_max_len	
Variable Name	group_concat_max_len	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	1024
	Range	4-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	1024
	Range	4-18446744073709547520

The maximum allowed result length in bytes for the GROUP_CONCAT() function. The default is 1024.

- have_compress

  YES if the zlib compression library is available to the server, NO if not. If not, the COMPRESS() and UNCOMPRESS() functions cannot be used.

- have_crypt

  YES if the crypt() system call is available to the server, NO if not. If not, the ENCRYPT() function cannot be used.

- have_csv

  YES if mysqld supports ARCHIVE tables, NO if not.

- have_dynamic_loading

  YES if mysqld supports dynamic loading of plugins, NO if not.

- have_geometry

  YES if the server supports spatial data types, NO if not.

- have_innodb

  YES if mysqld supports InnoDB tables. DISABLED if --skip-innodb is used.

- have_openssl

  This variable is an alias for have_ssl.

- have_partitioning

  YES if mysqld supports partitioning.

- have_query_cache

  YES if mysqld supports the query cache, NO if not.

- have_rtree_keys

  YES if RTREE indexes are available, NO if not. (These are used for spatial indexes in MyISAM tables.)

- have_ssl

  YES if mysqld supports SSL connections, NO if not.

- have_symlink

  YES if symbolic link support is enabled, NO if not. This is required on Unix for support of the DATA DIRECTORY and INDEX DIRECTORY table options, and on Windows for support of data directory symlinks.

- hostname

Variable Name	hostname	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	string

  The server sets this variable to the server host name at startup.

- init_connect

Command Line Format	--init-connect=name	
Config File Format	init_connect	
Option Sets Variable	Yes, init_connect	
Variable Name	init_connect	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	string

  A string to be executed by the server for each client that connects. The string consists of one or more SQL statements. To specify multiple statements, separate them by semicolon characters. For example, each client begins by default with autocommit mode enabled. There is no global system variable to specify that autocommit should be disabled by default, but init_connect can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

This variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

Note that the content of `init_connect` is not executed for users that have the `SUPER` privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

- `init_file`

Command Line Format	`--init-file=name`	
Config File Format	`init-file`	
Option Sets Variable	Yes, `init_file`	
Variable Name	`init_file`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments.

Note that the `--init-file` option is unavailable if MySQL was configured with the `--disable-grant-options` option. See Section 2.9.2, “Typical `configure` Options”.

- `innodb_xxx`

  `InnoDB` system variables are listed in Section 13.7.3, “`InnoDB` Startup Options and System Variables”.

- `interactive_timeout`

Command Line Format	`--interactive_timeout=#`	
Config File Format	`interactive_timeout`	
Option Sets Variable	Yes, `interactive_timeout`	
Variable Name	`interactive_timeout`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`28800`
	Min Value	`1`

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `join_buffer_size`

Command Line Format	`--join_buffer_size=#`	
Config File Format	`join_buffer_size`	
Option Sets Variable	Yes, `join_buffer_size`	
Variable Name	`join_buffer_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set (<= 6.0.8)	**Platform Bit Size**	`64`

	Type	numeric
	Default	131072
	Range	8200-18446744073709547520
Value Set (>= 6.0.9)	**Platform Bit Size**	64
	Type	numeric
	Default	131072
	Range	128-18446744073709547520

The size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

The maximum allowable setting for `join_buffer_size` is 4GB. As of MySQL 5.2.6, values larger than 4GB are allowed for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- `join_cache_level`

Version Introduced	6.0.9	
Command Line Format	`--join_cache_level=#`	
Config File Format	`join_cache_level`	
Option Sets Variable	Yes, `join_cache_level`	
Variable Name	`join_cache_level`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	1
	Range	0-8

This variable is used for join buffer managment. It controls for which join operations of which types join buffers are supposed to be used. See Section 7.2.15, “Block Nested-Loop and Batched Key Access Joins”. The allowable `join_cache_level` values are shown in the following table.

Option	Description
0	No join buffer is used for any join operation. This setting can be useful for assessing baseline join performance in comparison to performance with nonzero values that enable use of join buffering.
1	This is the default value. Join buffers are employed exactly in the same cases as in versions of MySQL prior to 6.0.9: They are used only for inner joins that are executed by the original Block Nested-Loop (BNL) join algorithm. When this algorithm is applied, rows of the inner table are accessed through a table scan, a plain index scan, or a range index scan.
2	The server employs an incremental join buffer for a join operation if its first operand is produced by a join operation that uses a join buffer itself.
3	The BNL algorithm is used for an outer join and semi-join operation with one inner table, and for inner joins.
4	The BNL algorithm uses incremental buffers for inner tables. In this case, the BNL algorithm can be used for nested outer joins and semi-joins (outer joins and semi-joins with several inner tables). Such an operation can be executed only if incremental join buffers are used to join all inner tables but the first one.
5	The BKA algorithm uses regular buffers for any join operation with index access to the joined table.
6	The BKA algorithm uses incremental buffers for any join operation with index access to the joined table.
7	The BKA algorithm uses regular join buffers with a hash table.
8	The BKA algorithm uses incremental join buffers with a hash table.

This variable was added in MySQL 6.0.9.

- `keep_files_on_create`

Command Line Format	`--keep_files_on_create=#`	
Config File Format	`keep_files_on_create`	
Option Sets Variable	Yes, `keep_files_on_create`	
Variable Name	`keep_files_on_create`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`OFF`

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`

Command Line Format	`--key_buffer_size=#`	
Config File Format	`key_buffer_size`	
Option Sets Variable	Yes, `key_buffer_size`	
Variable Name	`key_buffer_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`8388608`
	Range	`8-4294967295`

Index blocks for `MyISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum allowable setting for `key_buffer_size` is 4GB on 32-bit platforms. Values larger than 4GB are allowed for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

Increase the value to get better index handling (for all reads and multiple writes) to as much as you can afford. Using a value that is 25% of total memory on a machine that mainly runs MySQL is quite common. However, if you make the value too large (for example, more than 50% of your total memory) your system might start to page and become extremely slow. MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. Consider also the memory requirements of other storage engines.

For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 7.2.25, “Speed of `INSERT` Statements”.

You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests`, `Key_reads`, `Key_write_requests`, and `Key_writes` status variables. (See Section 12.5.6, “`SHOW` Syntax”.) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

The fraction of the key buffer in use can be determined using `key_buffer_size` in conjunction with the `Key_blocks_unused` status variable and the buffer block size, which is available from the `key_cache_block_size` system variable:

```
1 - ((Key_blocks_unused × key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer may be allocated internally for administrative structures.

It is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 7.4.5, "The MyISAM Key Cache".

- `key_cache_age_threshold`

Command Line Format	`--key_cache_age_threshold=#`	
Config File Format	`key_cache_age_threshold`	
Option Sets Variable	Yes, `key_cache_age_threshold`	
Variable Name	`key_cache_age_threshold`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`300`
	Range	`100-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`300`
	Range	`100-18446744073709547520`

This value controls the demotion of buffers from the hot sub-chain of a key cache to the warm sub-chain. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 7.4.5, "The MyISAM Key Cache".

- `key_cache_block_size`

Command Line Format	`--key_cache_block_size=#`	
Config File Format	`key_cache_block_size`	
Option Sets Variable	Yes, `key_cache_block_size`	
Variable Name	`key_cache_block_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`1024`
	Range	`512-16384`

The size in bytes of blocks in the key cache. The default value is 1024. See Section 7.4.5, "The MyISAM Key Cache".

- `key_cache_division_limit`

Command Line Format	`--key_cache_division_limit=#`	
Config File Format	`key_cache_division_limit`	
Option Sets Variable	Yes, `key_cache_division_limit`	
Variable Name	`key_cache_division_limit`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`100`
	Range	`1-100`

The division point between the hot and warm sub-chains of the key cache buffer chain. The value is the percentage of the buffer chain to use for the warm sub-chain. Allowable values range from 1 to 100. The default value is 100. See Section 7.4.5, “The MyISAM Key Cache”.

- `language`

Command Line Format	`--language=name`	
Config File Format	`language`	
Option Sets Variable	Yes, `language`	
Variable Name	`language`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`
	Default	`/usr/local/mysql/share/mysql/english/`

The language used for error messages.

- `large_files_support`

Variable Name	`large_files_support`
Variable Scope	Global
Dynamic Variable	No

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

Command Line Format	`--large-pages`	
Config File Format	`large-pages`	
Option Sets Variable	Yes, `large_pages`	
Variable Name	`large_pages`	
Variable Scope	Global	
Dynamic Variable	No	
Platform Specific	linux	
Value Set	**Type** (linux)	`boolean`
	Default	`FALSE`

Whether large page support is enabled (via the `--large-pages` option). See Section 7.5.9, “Enabling Large Page Support”.

- `large_page_size`

Variable Name	`large_page_size`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type** (linux)	`numeric`
	Default	`0`

If large page support is enabled, this shows the size of memory pages. Currently, large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See Section 7.5.9, “Enabling Large Page Support”.

- `lc_time_names`

Variable Name	lc_time_names	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	string

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the DATE_FORMAT(), DAYNAME() and MONTHNAME() functions. Locale names are POSIX-style values such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting. For further information, see Section 9.8, “MySQL Server Locale Support”.

- license

Variable Name	license	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	string
	Default	GPL

The type of license the server has.

- local_infile

Variable Name	local_infile	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	

Whether LOCAL is supported for LOAD DATA INFILE statements. See Section 5.3.4, “Security Issues with LOAD DATA LOCAL”.

- locked_in_memory

Variable Name	locked_in_memory
Variable Scope	Global
Dynamic Variable	No

Whether mysqld was locked in memory with --memlock.

- log

Whether logging of all statements to the general query log is enabled. See Section 5.2.3, “The General Query Log”.

This variable is deprecated as of MySQL 6.0.8; use general_log instead.

- log_backup_output

Version Introduced	6.0.8	
Command Line Format	--log-backup-output[=name]	
Config File Format	log-backup-output	
Option Sets Variable	Yes, log_backup_output	
Variable Name	log_backup_output	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration

	Default	TABLE
	Valid Values	TABLE, FILE, NONE

The destination for MySQL Backup history and progress log output. The value can be a comma-separated list of one or more of the words TABLE (log to tables), FILE (log to files), or NONE (do not log to tables or files). The default value is TABLE. NONE, if present, takes precedence over any other specifiers. If the value is NONE log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of log_backup_output is not NONE. For more information, see Section 6.3.3.1, "MySQL Backup Log Control".

This variable was added in MySQL 6.0.8.

- log_bin

Variable Name	log_bin
Variable Scope	Global
Dynamic Variable	No

Whether the binary log is enabled. See Section 5.2.4, "The Binary Log".

- log_bin_trust_function_creators

Command Line Format	--log-bin-trust-function-creators	
Config File Format	log-bin-trust-function-creators	
Option Sets Variable	Yes, log_bin_trust_function_creators	
Variable Name	log_bin_trust_function_creators	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	boolean
	Default	FALSE

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not allowed to create or alter stored functions unless they have the SUPER privilege in addition to the CREATE ROUTINE or ALTER ROUTINE privilege. A setting of 0 also enforces the restriction that a function must be declared with the DETERMINISTIC characteristic, or with the READS SQL DATA or NO SQL characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 18.6, "Binary Logging of Stored Programs".

- log_error

Command Line Format	--log-error[=name]	
Config File Format	log-error	
Option Sets Variable	Yes, log_error	
Variable Name	log_error	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The location of the error log.

- log_output

Command Line Format	--log-output[=name]
Config File Format	log-output
Option Sets Variable	Yes, log_output

Variable Name	log_output	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration
	Default	FILE
	Valid Values	TABLE, FILE, NONE

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words TABLE (log to tables), FILE (log to files), or NONE (do not log to tables or files). The default value is TABLE. NONE, if present, takes precedence over any other specifiers. If the value is NONE log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of log_output is not NONE. For more information, see Section 5.2.1, "Selecting General Query and Slow Query Log Output Destinations".

- log_queries_not_using_indexes

Command Line Format	--log-queries-not-using-indexes	
Config File Format	log-queries-not-using-indexes	
Option Sets Variable	Yes, log_queries_not_using_indexes	
Variable Name	log_queries_not_using_indexes	
Variable Scope	Global	
Dynamic Variable	Yes	
Deprecated	5.1.29, by slow-query-log	
Value Set	**Type**	boolean

Whether queries that do not use indexes are logged to the slow query log. See Section 5.2.5, "The Slow Query Log".

- log_slave_updates

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 16.1.3, "Replication and Binary Logging Options and Variables".

- log_slow_queries

Command Line Format	--log-slow-queries[=name]	
Config File Format	log-slow-queries	
Option Sets Variable	Yes, log_slow_queries	
Variable Name	log_slow_queries	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	boolean

Whether slow queries should be logged. "Slow" is determined by the value of the long_query_time variable. See Section 5.2.5, "The Slow Query Log".

This variable is deprecated as of MySQL 6.0.8; use slow_query_log instead.

- log_warnings

Command Line Format	--log-warnings[=#]
Config File Format	log-warnings
Option Sets Variable	Yes, log_warnings
Variable Name	log_warnings
Variable Scope	Both

Dynamic Variable	Yes	
Disabled by	`skip-log-warnings`	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`1`
	Range	`0-18446744073709547520`

Whether to produce additional warning messages. It is enabled (1) by default and can be disabled by setting it to 0. Aborted connections are not logged to the error log unless the value is greater than 1.

- `long_query_time`

Command Line Format	`--long_query_time=#`	
Config File Format	`long_query_time`	
Option Sets Variable	Yes, `long_query_time`	
Variable Name	`long_query_time`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set (<= 6.0.3)	**Type**	`numeric`
	Default	`10`
	Min Value	`1`
Value Set (>= 6.0.4)	**Type**	`numeric`
	Default	`10`
	Min Value	`0`

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. Prior to MySQL 6.0.4, the minimum value is 1, and the value for this variable must be an integer. Beginning with MySQL 6.0.4, the minimum is 0, and a resolution of microseconds is supported when logging to a file. However, the microseconds part is ignored and only integer values are written when logging to tables. The default value is 10. See Section 5.2.5, “The Slow Query Log”.

- `low_priority_updates`

Command Line Format	`--low-priority-updates`	
Config File Format	`low-priority-updates`	
Option Sets Variable	Yes, `low_priority_updates`	
Variable Name	`low_priority_updates`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`FALSE`

If set to `1`, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`). This variable previously was named `sql_low_priority_updates`.

- `lower_case_file_system`

Command Line Format	`--lower_case_file_system[=#]`
Config File Format	`lower_case_file_system`
Option Sets Variable	Yes, `lower_case_file_system`

Variable Name	lower_case_file_system	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	boolean

This variable describes the case sensitivity of file names on the file system where the data directory is located. OFF means file names are case sensitive, ON means they are not case sensitive.

- lower_case_table_names

Command Line Format	--lower_case_table_names[=#]	
Config File Format	lower_case_table_names	
Option Sets Variable	Yes, lower_case_table_names	
Variable Name	lower_case_table_names	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	0
	Range	0-2

If set to 1, table names are stored in lowercase on disk and table name comparisons are not case sensitive. If set to 2 table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. See Section 8.2.2, "Identifier Case Sensitivity".

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

You should *not* set this variable to 0 if you are running MySQL on a system that does not have case-sensitive file names (such as Windows or Mac OS X). If this variable is not set at startup and the file system on which the data directory is located does not have case-sensitive file names, MySQL automatically sets lower_case_table_names to 2.

- max_allowed_packet

Command Line Format	--max_allowed_packet=#	
Config File Format	max_allowed_packet	
Option Sets Variable	Yes, max_allowed_packet	
Variable Name	max_allowed_packet	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	1048576
	Range	1024-1073741824

The maximum size of one packet or any generated/intermediate string.

The packet message buffer is initialized to net_buffer_length bytes, but can grow up to max_allowed_packet bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for max_allowed_packet is 1GB. The value should be a multiple of 1024; non-multiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the max_allowed_packet variable, you should also change the buffer size on the client side if your client program allows it. On the client side, max_allowed_packet has a default of 1GB. Some programs such as mysql and mysqldump enable you to change the client-side value by setting max_allowed_packet on the command line or in an option file.

As of MySQL 6.0.9, the session value of this variable is read only. Before 6.0.9, setting the session value is allowed but has no effect.

- `max_connect_errors`

Command Line Format	`--max_connect_errors=#`	
Config File Format	`max_connect_errors`	
Option Sets Variable	Yes, `max_connect_errors`	
Variable Name	`max_connect_errors`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`10`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`10`
	Range	`1-18446744073709547520`

If there are more than this number of interrupted connections from a host, that host is blocked from further connections. You can unblock blocked hosts with the `FLUSH HOSTS` statement.

- `max_connections`

Command Line Format	`--max_connections=#`	
Config File Format	`max_connections`	
Option Sets Variable	Yes, `max_connections`	
Variable Name	`max_connections`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`151`
	Range	`1-100000`

The number of simultaneous client connections allowed. By default, this is 151. See Section B.1.2.7, “`Too many connections`”, for more information.

> **MySQL Enterprise**
> For notification that the maximum number of connections is getting dangerously high and for advice on setting the optimum value for `max_connections` subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Increasing this value increases the number of file descriptors that `mysqld` requires. See Section 7.4.7, “How MySQL Opens and Closes Tables”, for comments on file descriptor limits.

- `max_delayed_threads`

Command Line Format	`--max_delayed_threads=#`
Config File Format	`max_delayed_threads`
Option Sets Variable	Yes, `max_delayed_threads`
Variable Name	`max_delayed_threads`
Variable Scope	Both
Dynamic Variable	Yes

Value Set	Type	numeric
	Default	20
	Range	0-16384

Do not start more than this number of threads to handle INSERT DELAYED statements. If you try to insert data into a new table after all INSERT DELAYED threads are in use, the row is inserted as if the DELAYED attribute wasn't specified. If you set this to 0, MySQL never creates a thread to handle DELAYED rows; in effect, this disables DELAYED entirely.

For the SESSION value of this variable, the only valid values are 0 or the GLOBAL value.

- max_error_count

Command Line Format	--max_error_count=#	
Config File Format	max_error_count	
Option Sets Variable	Yes, max_error_count	
Variable Name	max_error_count	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	64
	Range	0-65535

The maximum number of error, warning, and note messages to be stored for display by the SHOW ERRORS and SHOW WARNINGS statements.

- max_heap_table_size

Command Line Format	--max_heap_table_size=#	
Config File Format	max_heap_table_size	
Option Sets Variable	Yes, max_heap_table_size	
Variable Name	max_heap_table_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	numeric
	Default	16777216
	Range	16384-4294967295

This variable sets the maximum size to which MEMORY tables are allowed to grow. The value of the variable is used to calculate MEMORY table MAX_ROWS values. Setting this variable has no effect on any existing MEMORY table, unless the table is recreated with a statement such as CREATE TABLE or altered with ALTER TABLE or TRUNCATE TABLE. A server restart also sets the maximum size of existing MEMORY tables to the global max_heap_table_size value.

Note

On 64-bit platforms, the maximum value for this variable is 1844674407370954752.

MySQL Enterprise
Subscribers to the MySQL Enterprise Monitor receive recommendations for the optimum setting for max_heap_table_size. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- max_insert_delayed_threads

Variable Name	max_insert_delayed_threads
Variable Scope	Both

Dynamic Variable	Yes	
Value Set	**Type**	`numeric`

This variable is a synonym for `max_delayed_threads`.

- `max_join_size`

Command Line Format	`--max_join_size=#`	
Config File Format	`max_join_size`	
Option Sets Variable	Yes, `max_join_size`	
Variable Name	`max_join_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`4294967295`
	Range	`1-4294967295`

Do not allow `SELECT` statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch `SELECT` statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to `0`. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named `sql_max_join_size`.

- `max_length_for_sort_data`

Command Line Format	`--max_length_for_sort_data=#`	
Config File Format	`max_length_for_sort_data`	
Option Sets Variable	Yes, `max_length_for_sort_data`	
Variable Name	`max_length_for_sort_data`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`1024`
	Range	`4-8388608`

The cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 7.2.17, “`ORDER BY` Optimization”.

- `max_prepared_stmt_count`

Command Line Format	`--max_prepared_stmt_count=#`	
Config File Format	`max_prepared_stmt_count`	
Option Sets Variable	Yes, `max_prepared_stmt_count`	
Variable Name	`max_prepared_stmt_count`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`

	Default	`16382`
	Range	`0-1048576`

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The allowable range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- `max_relay_log_size`

Command Line Format	`--max_relay_log_size=#`	
Config File Format	`max_relay_log_size`	
Option Sets Variable	Yes, `max_relay_log_size`	
Variable Name	`max_relay_log_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`0`
	Range	`0-1073741824`

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 16.4.1, “Replication Implementation Details”.

- `max_seeks_for_key`

Command Line Format	`--max_seeks_for_key=#`	
Config File Format	`max_seeks_for_key`	
Option Sets Variable	Yes, `max_seeks_for_key`	
Variable Name	`max_seeks_for_key`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`4294967295`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`18446744073709547520`
	Range	`1-18446744073709547520`

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 12.5.6.23, “`SHOW INDEX` Syntax”). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

Command Line Format	`--max_sort_length=#`

Config File Format	max_sort_length	
Option Sets Variable	Yes, max_sort_length	
Variable Name	max_sort_length	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	1024
	Range	4-8388608

The number of bytes to use when sorting BLOB or TEXT values. Only the first max_sort_length bytes of each value are used; the rest are ignored.

- max_sp_recursion_depth

Command Line Format	--max_sp_recursion_depth[=#]	
Config File Format	max_sp_recursion_depth	
Option Sets Variable	Yes, max_sp_recursion_depth	
Variable Name	max_sp_recursion_depth	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	0
	Max Value	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disallows recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of max_sp_recursion_depth, it may be necessary to increase thread stack size by increasing the value of thread_stack at server startup.

- max_tmp_tables

Command Line Format	--max_tmp_tables=#	
Config File Format	max_tmp_tables	
Option Sets Variable	Yes, max_tmp_tables	
Variable Name	max_tmp_tables	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	32
	Range	1-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	32
	Range	1-18446744073709547520

The maximum number of temporary tables a client can keep open at the same time. (This option does not yet do anything.)

- max_user_connections

Command Line Format	`--max_user_connections=#`	
Config File Format	`max_user_connections`	
Option Sets Variable	Yes, `max_user_connections`	
Variable Name	`max_user_connections`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Range	`1-4294967295`

The maximum number of simultaneous connections allowed to any given MySQL account. A value of 0 means “no limit.”

This variable has both a global scope and a (read-only) session scope. The session variable has the same value as the global variable unless the current account has a nonzero `MAX_USER_CONNECTIONS` resource limit. In that case, the session value reflects the account limit.

- `max_write_lock_count`

Command Line Format	`--max_write_lock_count=#`	
Config File Format	`max_write_lock_count`	
Option Sets Variable	Yes, `max_write_lock_count`	
Variable Name	`max_write_lock_count`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`4294967295`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`18446744073709547520`
	Range	`1-18446744073709547520`

After this many write locks, allow some pending read lock requests to be processed in between.

- `min_examined_row_limit`

Version Introduced	6.0.4	
Command Line Format	`--min-examined-row-limit=#`	
Config File Format	`min-examined-row-limit`	
Variable Name	`min_examined_row_limit`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`0`
	Range	`0-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`0`
	Range	`0-18446744073709547520`

Queries that examine fewer than this number of rows are not logged to the slow query log. This variable was added in MySQL 6.0.4.

- `myisam_data_pointer_size`

Command Line Format	`--myisam_data_pointer_size=#`	
Config File Format	`myisam_data_pointer_size`	
Option Sets Variable	Yes, `myisam_data_pointer_size`	
Variable Name	`myisam_data_pointer_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`6`
	Range	`2-7`

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.1.2.12, “`The table is full`”.

- `myisam_max_sort_file_size`

Command Line Format	`--myisam_max_sort_file_size=#`	
Config File Format	`myisam_max_sort_file_size`	
Option Sets Variable	Yes, `myisam_max_sort_file_size`	
Variable Name	`myisam_max_sort_file_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`2147483648`

The maximum size of the temporary file that MySQL is allowed to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

The default value is 2GB. If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance.

- `myisam_recover_options`

Variable Name	`myisam_recover_options`
Variable Scope	Global
Dynamic Variable	No

The value of the `--myisam-recover` option. See Section 5.1.2, “Server Command Options”.

- `myisam_repair_threads`

Command Line Format	`--myisam_repair_threads=#`	
Config File Format	`myisam_repair_threads`	
Option Sets Variable	Yes, `myisam_repair_threads`	
Variable Name	`myisam_repair_threads`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`

	Default	1
	Range	1-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	1
	Range	1-18446744073709547520

If this value is greater than 1, MyISAM table indexes are created in parallel (each index in its own thread) during the Repair by sorting process. The default value is 1.

Note

Multi-threaded repair is still *beta-quality* code.

- myisam_sort_buffer_size

Command Line Format	--myisam_sort_buffer_size=#	
Config File Format	myisam_sort_buffer_size	
Option Sets Variable	Yes, myisam_sort_buffer_size	
Variable Name	myisam_sort_buffer_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	8388608
	Range	4-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	8388608
	Range	4-18446744073709547520

The size of the buffer that is allocated when sorting MyISAM indexes during a REPAIR TABLE or when creating indexes with CREATE INDEX or ALTER TABLE.

The maximum allowable setting for myisam_sort_buffer_size is 4GB. Values larger than 4GB are allowed for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- myisam_stats_method

Command Line Format	--myisam_stats_method=name	
Config File Format	myisam_stats_method	
Option Sets Variable	Yes, myisam_stats_method	
Variable Name	myisam_stats_method	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration
	Valid Values	nulls_equal, nulls_unequal, nulls_ignored

How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For

`nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 7.4.6, "`MyISAM` Index Statistics Collection".

Any unique prefix of a valid value may be used to set the value of this variable.

- `myisam_use_mmap`

Command Line Format	`--myisam_use_mmap`	
Config File Format	`myisam_use_mmap`	
Option Sets Variable	Yes, `myisam_use_mmap`	
Variable Name	`myisam_use_mmap`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`FALSE`

Use memory mapping for reading and writing `MyISAM` tables.

- `named_pipe`

Variable Name	`named_pipe`
Variable Scope	Global
Dynamic Variable	No
Platform Specific	windows

(Windows only.) Indicates whether the server supports connections over named pipes.

- `net_buffer_length`

Command Line Format	`--net_buffer_length=#`	
Config File Format	`net_buffer_length`	
Option Sets Variable	Yes, `net_buffer_length`	
Variable Name	`net_buffer_length`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`16384`
	Range	`1024-1048576`

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

As of MySQL 6.0.9, the session value of this variable is read only. Before 6.0.9, setting the session value is allowed but has no effect.

- `net_read_timeout`

Command Line Format	`--net_read_timeout=#`
Config File Format	`net_read_timeout`

Option Sets Variable	Yes, `net_read_timeout`	
Variable Name	`net_read_timeout`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`30`
	Min Value	`1`

The number of seconds to wait for more data from a connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

Command Line Format	`--net_retry_count=#`	
Config File Format	`net_retry_count`	
Option Sets Variable	Yes, `net_retry_count`	
Variable Name	`net_retry_count`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`10`
	Range	`1-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`10`
	Range	`1-18446744073709547520`

If a read on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

Command Line Format	`--net_write_timeout=#`	
Config File Format	`net_write_timeout`	
Option Sets Variable	Yes, `net_write_timeout`	
Variable Name	`net_write_timeout`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`60`
	Min Value	`1`

The number of seconds to wait for a block to be written to a connection before aborting the write. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory. See also `net_read_timeout`.

- `new`

Command Line Format	`--new`
Config File Format	`new`
Option Sets Variable	Yes, `new`
Variable Name	`new`
Variable Scope	Both
Dynamic Variable	Yes
Disabled by	`skip-new`
Value Set	**Type** `boolean` **Default** `FALSE`

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 6.0, its value is always `OFF`.

- `old`

Command Line Format	`old`
Config File Format	`old`
Variable Name	`old`
Variable Scope	Global
Dynamic Variable	No

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

Currently, when `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See Section 12.2.9.2, “Index Hint Syntax”.) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- `old_passwords`

Command Line Format	`--old_passwords`
Config File Format	`old-passwords`
Option Sets Variable	Yes, `old_passwords`
Variable Name	`old_passwords`
Variable Scope	Both
Dynamic Variable	Yes
Value Set	**Type** `boolean` **Default** `FALSE`

Whether the server should use pre-4.1-style passwords for MySQL user accounts. See Section B.1.2.4, “`Client does not support authentication protocol`”.

- `one_shot`

This is not a variable, but it can be used when setting some variables. It is described in Section 12.5.5, “`SET` Syntax”.

- `open_files_limit`

Command Line Format	`--open-files-limit=#`
Config File Format	`open-files-limit`
Option Sets Variable	Yes, `open_files_limit`
Variable Name	`open_files_limit`
Variable Scope	Global

Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	0
	Range	0-65535

The number of files that the operating system allows `mysqld` to open. This is the real value allowed by the system and might be different from the value you gave using the `--open-files-limit` option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL can't change the number of open files.

- `optimizer_prune_level`

Command Line Format	`--optimizer_prune_level[=#]`	
Config File Format	`optimizer_prune_level`	
Option Sets Variable	Yes, `optimizer_prune_level`	
Variable Name	`optimizer_prune_level`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	boolean
	Default	1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

Command Line Format	`--optimizer_search_depth[=#]`	
Config File Format	`optimizer_search_depth`	
Option Sets Variable	Yes, `optimizer_search_depth`	
Variable Name	`optimizer_search_depth`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	62

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to the maximum number of tables used in a query plus 2, the optimizer switches to the algorithm used in MySQL 5.0.0 (and previous versions) for performing searches.

- `optimizer_switch`

Command Line Format	`--optimizer_switch=value`	
Config File Format	`optimizer_switch`	
Option Sets Variable	Yes, `optimizer_switch`	
Variable Name	`optimizer_switch`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set (<= 6.0.10)	**Type**	set
	Default	''
	Valid Values	no_semijoin, no_materialization,

		no_loosescan, no_firstmatch
Value Set (>= 6.0.11)	**Type**	set
	Valid Values	index_merge={on|off}, index_merge_intersection={on|off}, index_merge_union={on|off}, semijoin={on|off}, materialization={on|off}, loosescan={on|off}, firstmatch={on|off}

The optimizer_switch system variable enables control over optimizer behavior. As of MySQL 6.0.11, the value of this variable is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: firstmatch=on,index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,index_merge_intersection=on,
                    loosescan=on,materialization=on,semijoin=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see Section 7.2.22, "Using optimizer_switch to Control the Optimizer".

Prior to MySQL 6.0.11, the syntax of optimizer_switch is like that of a SET column or the sql_mode system variable. The value can be set to a comma-separated list of flags to disable specific optimizer behaviors, chosen from no_semijoin (disable semi-join), no_materialization (disable materialization), no_loosescan (disable LooseScan, available as of MySQL 6.0.7), and no_firstmatch (disable FirstMatch, available as of MySQL 6.0.10). For example:

```
SET @optimizer_switch='no_semijoin,no_materialization';
```

Presence or absence of a no_*opt_name* keyword means that the behavior is disabled or enabled, respectively. The default value is the empty string (no optimizations disabled).

- optimizer_use_mrr

Variable Name	optimizer_use_mrr	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	enumeration
	Default	force
	Valid Values	auto, disable, force

Controls whether the optimizer uses the Multi-Range Read (MRR) access method for which a number of ranges are sent to a storage engine at once during range selects. Sending multiple ranges to a handler at once can improve the performance of certain selects dramatically.

The value can be 'force' (use MRR when possible; this is the default), 'disable' (do not use MRR), or 'auto'. (attempt to make a cost-based choice between using and not using MRR).

Any unique prefix of a valid value may be used to set the value of this variable.

The optimizer interface provided by this variable is tentative. (For example, at the moment, the cost formula is such that we do not recommend a setting of 'auto'. It is better to use 'force' or 'disable'.) Currently, this variable enables use of MRR to be turned on or off, but the syntax might change to allow control over additional capabilities.

The optimizer_use_mrr system variable replaces the multi_range_count variable from older versions of MySQL.

- pid_file

Command Line Format	--pid-file=name

Config File Format	pid-file	
Option Sets Variable	Yes, pid_file	
Variable Name	pid_file	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The path name of the process ID (PID) file. This variable can be set with the --pid-file option.

- plugin_dir

Command Line Format	--plugin_dir=name	
Config File Format	plugin_dir	
Option Sets Variable	Yes, plugin_dir	
Variable Name	plugin_dir	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename
	Default	/usr/local/mysql/lib/mysql

The path name of the plugin directory.

- port

Command Line Format	--port=#	
Config File Format	port	
Option Sets Variable	Yes, port	
Variable Name	port	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	3306

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the --port option.

- preload_buffer_size

Command Line Format	--preload_buffer_size=#	
Config File Format	preload_buffer_size	
Option Sets Variable	Yes, preload_buffer_size	
Variable Name	preload_buffer_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	32768
	Range	1024-1073741824

The size of the buffer that is allocated when preloading indexes.

- protocol_version

Variable Name	protocol_version	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric

The version of the client/server protocol used by the MySQL server.

- query_alloc_block_size

Command Line Format	--query_alloc_block_size=#	
Config File Format	query_alloc_block_size	
Option Sets Variable	Yes, query_alloc_block_size	
Variable Name	query_alloc_block_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	8192
	Range	1024-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	8192
	Range	1024-18446744073709547520

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this a bit.

- query_cache_limit

Command Line Format	--query_cache_limit=#	
Config File Format	query_cache_limit	
Option Sets Variable	Yes, query_cache_limit	
Variable Name	query_cache_limit	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	1048576
	Range	0-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	1048576
	Range	0-18446744073709547520

Don't cache results that are larger than this number of bytes. The default value is 1MB.

- query_cache_min_res_unit

Command Line Format	--query_cache_min_res_unit=#
Config File Format	query_cache_min_res_unit

Option Sets Variable	Yes, query_cache_min_res_unit	
Variable Name	query_cache_min_res_unit	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	4096
	Range	512-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	4096
	Range	512-18446744073709547520

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in Section 7.5.5.3, “Query Cache Configuration”.

- query_cache_size

Command Line Format	--query_cache_size=#	
Config File Format	query_cache_size	
Option Sets Variable	Yes, query_cache_size	
Variable Name	query_cache_size	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	0
	Range	0-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0-18446744073709547520

The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. The allowable values are multiples of 1024; other values are rounded down to the nearest multiple. Note that query_cache_size bytes of memory are allocated even if query_cache_type is set to 0. See Section 7.5.5.3, “Query Cache Configuration”, for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of query_cache_size too small, you'll get a warning, as described in Section 7.5.5.3, “Query Cache Configuration”.

- query_cache_type

Command Line Format	--query_cache_type=#	
Config File Format	query_cache_type	
Option Sets Variable	Yes, query_cache_type	
Variable Name	query_cache_type	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	Type	enumeration

	Default	1
	Valid Values	0, 1, 2

Set the query cache type. Setting the GLOBAL value sets the type for all clients that connect thereafter. Individual clients can set the SESSION value to affect their own use of the query cache. Possible values are shown in the following table.

Option	Description
0 or OFF	Don't cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set query_cache_size to 0.
1 or ON	Cache all cacheable query results except for those that begin with SELECT SQL_NO_CACHE.
2 or DEMAND	Cache results only for cacheable queries that begin with SELECT SQL_CACHE.

This variable defaults to ON.

Any unique prefix of a valid value may be used to set the value of this variable.

- query_cache_wlock_invalidate

Command Line Format	--query_cache_wlock_invalidate	
Config File Format	query_cache_wlock_invalidate	
Option Sets Variable	Yes, query_cache_wlock_invalidate	
Variable Name	query_cache_wlock_invalidate	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	boolean
	Default	FALSE

Normally, when one client acquires a WRITE lock on a MyISAM table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a WRITE lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- query_prealloc_size

Command Line Format	--query_prealloc_size=#	
Config File Format	query_prealloc_size	
Option Sets Variable	Yes, query_prealloc_size	
Variable Name	query_prealloc_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	8192
	Range	8192-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	8192
	Range	8192-18446744073709547520

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger query_prealloc_size value might be helpful in improving performance, because it

can reduce the need for the server to perform memory allocation during query execution operations.

- `range_alloc_block_size`

Command Line Format	`--range_alloc_block_size=#`	
Config File Format	`range_alloc_block_size`	
Option Sets Variable	Yes, `range_alloc_block_size`	
Variable Name	`range_alloc_block_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`4096`
	Range	`4096-18446744073709547520`

The size of blocks that are allocated when doing range optimization.

- `read_buffer_size`

Command Line Format	`--read_buffer_size=#`	
Config File Format	`read_buffer_size`	
Option Sets Variable	Yes, `read_buffer_size`	
Variable Name	`read_buffer_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`131072`
	Range	`8200-2147479552`

Each thread that does a sequential scan allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

The maximum allowable setting for `read_buffer_size` is 2GB.

`read_buffer_size` and `read_rnd_buffer_size` are not specific to any storage engine and apply in a general manner for optimization. See Section 7.5.8, “How MySQL Uses Memory”, for example.

- `read_only`

Command Line Format	`--read_only`	
Config File Format	`read_only`	
Option Sets Variable	Yes, `read_only`	
Variable Name	`read_only`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`0`

This variable is off by default. When it is enabled, the server allows no updates except from users that have the `SUPER` privilege or (on a slave server) from updates performed by slave threads. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables, nor does it prevent the server from inserting rows into the log tables (see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”).

`read_only` exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` privilege. Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

The following conditions apply:

- If you attempt to enable `read_only` while you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction, an error occurs.
- If you attempt to enable `read_only` while other clients hold explicit table locks or have pending transactions, the attempt blocks until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

As of MySQL 6.0.11, attempts to set `read_only` block for active transactions that hold metadata locks until those transactions end.

- `read_rnd_buffer_size`

Command Line Format	`--read_rnd_buffer_size=#`	
Config File Format	`read_rnd_buffer_size`	
Option Sets Variable	Yes, `read_rnd_buffer_size`	
Variable Name	`read_rnd_buffer_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`262144`
	Range	`8200-4294967295`

When reading rows in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 7.2.17, “`ORDER BY` Optimization”. Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum allowable setting for `read_rnd_buffer_size` is 2GB.

`read_buffer_size` and `read_rnd_buffer_size` are not specific to any storage engine and apply in a general manner for optimization. See Section 7.5.8, “How MySQL Uses Memory”, for example.

- `relay_log_purge`

Command Line Format	`--relay_log_purge`	
Config File Format	`relay_log_purge`	
Option Sets Variable	Yes, `relay_log_purge`	
Variable Name	`relay_log_purge`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`TRUE`

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_space_limit`

Command Line Format	`--relay_log_space_limit=#`
Config File Format	`relay_log_space_limit`
Option Sets Variable	Yes, `relay_log_space_limit`

Variable Name	relay_log_space_limit	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	Platform Bit Size	32
	Type	numeric
	Default	0
	Range	0-4294967295
Value Set	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0-18446744073709547520

The maximum amount of space to use for all relay logs.

- report_host

  The value of the --report-host option. This variable was added in MySQL 6.0.5.

- report_password

  The value of the --report-password option. This variable was added in MySQL 6.0.5.

- report_port

  The value of the --report-port option. This variable was added in MySQL 6.0.5.

- report_user

  The value of the --report-user option. This variable was added in MySQL 6.0.5.

- rpl_semi_sync_master_enabled

  Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 1.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_reply_log_file_pos

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_timeout

  A value in seconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10 seconds.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_trace_level

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_slave_enabled

  Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 1.

This variable is was added in MySQL 6.0.8. It is available only if the slave-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_trace_level`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the slave-side semisynchronous replication plugin is installed.

- `secure_auth`

Command Line Format	`--secure-auth`	
Config File Format	`secure-auth`	
Option Sets Variable	Yes, `secure_auth`	
Variable Name	`secure_auth`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`FALSE`

  If the MySQL server has been started with the `--secure-auth` option, it blocks connections from all accounts that have passwords stored in the old (pre-4.1) format. In that case, the value of this variable is `ON`, otherwise it is `OFF`.

  You should enable this option if you want to prevent all use of passwords employing the old format (and hence insecure communication over the network).

  Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See Section B.1.2.4, “`Client does not support authentication protocol`”.

- `secure_backup_file_priv`

  By default, this variable is empty. If set to the name of a directory, it limits the effect of the `BACKUP DATABASE` and `RESTORE` statements to work only with files in that directory. This variable was added in MySQL 6.0.11; in older releases, use `secure_backup_file_priv` instead.

- `secure_file_priv`

Command Line Format	`--secure-file-priv`	
Config File Format	`secure-file-priv`	
Option Sets Variable	Yes, `secure_file_priv`	
Variable Name	`secure_file_priv`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

  By default, this variable is empty. If set to the name of a directory, it limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in that directory. Before MySQL 6.0.11, it also applies to the `BACKUP DATABASE` and `RESTORE` statements; as of 6.0.11, `secure_backup_file_priv` applies to those statements.

- `server_id`

Command Line Format	`--server-id=#`	
Config File Format	`server-id`	
Option Sets Variable	Yes, `server_id`	
Variable Name	`server_id`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`

	Default	`0`
	Range	`0-4294967295`

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` option. For each server participating in replication, you should pick a positive integer in the range from 1 to $2^{32} - 1$ to act as that server's ID.

- `shared_memory`

Variable Name	`shared_memory`
Variable Scope	Global
Dynamic Variable	No
Platform Specific	windows

(Windows only.) Whether the server allows shared-memory connections.

- `shared_memory_base_name`

Variable Name	`shared_memory_base_name`
Variable Scope	Global
Dynamic Variable	No
Platform Specific	windows

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `skip_external_locking`

  This is `OFF` if `mysqld` uses external locking, `ON` if external locking is disabled.

- `skip_networking`

  This is `ON` if the server allows only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. On NetWare, only TCP/IP connections are supported, so do not set this variable to `ON`. This variable can be set to `ON` with the `--skip-networking` option.

- `skip_show_database`

  This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is allowed to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege.

- `slow_launch_time`

Command Line Format	`--slow_launch_time=#`	
Config File Format	`slow_launch_time`	
Option Sets Variable	Yes, `slow_launch_time`	
Variable Name	`slow_launch_time`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`2`

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

  Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given (`--log-slow-queries` before MySQL 6.0.8). The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `slow_query_log_file`

Command Line Format	`--slow-query-log-file=file_name`	
Config File Format	`slow_query_log_file`	
Option Sets Variable	Yes, `slow_query_log_file`	
Variable Name	`slow_query_log_file`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`filename`

  The name of the slow query log file. The default value is *`host_name`*`-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option (`--log-slow-queries` before MySQL 6.0.8).

- `socket`

Command Line Format	`--socket=name`	
Config File Format	`socket`	
Option Sets Variable	Yes, `socket`	
Variable Name	`socket`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`filename`
	Default	`/tmp/mysql.sock`

  On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

  On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

Command Line Format	`--sort_buffer_size=#`	
Config File Format	`sort_buffer_size`	
Option Sets Variable	Yes, `sort_buffer_size`	
Variable Name	`sort_buffer_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`2097144`
	Max Value	`4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`2097144`
	Max Value	`18446744073709547520`

Each thread that needs to do a sort allocates a buffer of this size. Increase this value for faster `ORDER BY` or `GROUP BY` operations. See Section B.1.4.4, "Where MySQL Stores Temporary Files".

The maximum allowable setting for `sort_buffer_size` is 4GB. As of MySQL 5.2.6, values larger than 4GB are allowed for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB with a warning).

- `sql_mode`

Command Line Format	`--sql-mode=name`	
Config File Format	`sql-mode`	
Option Sets Variable	Yes, `sql_mode`	
Variable Name	`sql_mode`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`set`
	Default	`''`
	Valid Values	`ALLOW_INVALID_DATES`, `ANSI_QUOTES`, `ERROR_FOR_DIVISION_BY_ZERO`, `HIGH_NOT_PRECEDENCE`, `IGNORE_SPACE`, `NO_AUTO_CREATE_USER`, `NO_AUTO_VALUE_ON_ZERO`, `NO_BACKSLASH_ESCAPES`, `NO_DIR_IN_CREATE`, `NO_ENGINE_SUBSTITUTION`, `NO_FIELD_OPTIONS`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_UNSIGNED_SUBTRACTION`, `NO_ZERO_DATE`, `NO_ZERO_IN_DATE`, `ONLY_FULL_GROUP_BY`, `PAD_CHAR_TO_FULL_LENGTH`, `PIPES_AS_CONCAT`, `REAL_AS_FLOAT`, `STRICT_ALL_TABLES`, `STRICT_TRANS_TABLES`

The current server SQL mode, which can be set dynamically. See Section 5.1.7, "Server SQL Modes".

- `sql_select_limit`

Variable Name	`sql_select_limit`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server allows per table, which depends on the server configuration and may be affected if the server build was configured with `--with-big-tables`. Typical default values are (2^{32})–1 or (2^{64})–1. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

`sql_select_limit` does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `ssl_ca`

Command Line Format	`--ssl-ca=name`

Config File Format	`ssl-ca`
Option Sets Variable	Yes, `ssl_ca`
Variable Name	`ssl_ca`
Variable Scope	Global
Dynamic Variable	No
Value Set	**Type** `filename`

The path to a file with a list of trusted SSL CAs.

- `ssl_capath`

Command Line Format	`--ssl-capath=name`
Config File Format	`ssl-capath`
Option Sets Variable	Yes, `ssl_capath`
Variable Name	`ssl_capath`
Variable Scope	Global
Dynamic Variable	No
Value Set	**Type** `filename`

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `ssl_cert`

Command Line Format	`--ssl-cert=name`
Config File Format	`ssl-cert`
Option Sets Variable	Yes, `ssl_cert`
Variable Name	`ssl_cert`
Variable Scope	Global
Dynamic Variable	No
Value Set	**Type** `filename`

The name of the SSL certificate file to use for establishing a secure connection.

- `ssl_cipher`

Command Line Format	`--ssl-cipher=name`
Config File Format	`ssl-cipher`
Option Sets Variable	Yes, `ssl_cipher`
Variable Name	`ssl_cipher`
Variable Scope	Global
Dynamic Variable	No
Value Set	**Type** `filename`

A list of allowable ciphers to use for SSL encryption.

- `ssl_key`

Command Line Format	`--ssl-key=name`
Config File Format	`ssl-key`
Option Sets Variable	Yes, `ssl_key`
Variable Name	`ssl_key`

Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

The name of the SSL key file to use for establishing a secure connection.

- `storage_engine`

Variable Name	`storage_engine`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` option. See Section 5.1.2, "Server Command Options".

- `sync_frm`

Command Line Format	`--sync-frm`	
Config File Format	`sync-frm`	
Option Sets Variable	Yes, `sync_frm`	
Variable Name	`sync_frm`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`TRUE`

If this variable is set to 1, when any non-temporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

Variable Name	`system_time_zone`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 9.7, "MySQL Server Time Zone Support".

- `table_definition_cache`

Command Line Format	`--table_definition_cache=#`
Config File Format	`table_definition_cache`
Option Sets Variable	Yes, `table_definition_cache`
Variable Name	`table_definition_cache`
Variable Scope	Global
Dynamic Variable	Yes

Value Set (<= 6.0.5)	**Type**	`numeric`
	Default	`128`
	Range	`1-524288`
Value Set (>= 6.0.6)	**Type**	`numeric`
	Default	`256`
	Range	`256-524288`

The number of table definitions that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum and default values are 1 and 128 before MySQL 6.0.6. The minimum and default are both 256 as of MySQL 6.0.6.

- `table_lock_wait_timeout`

Command Line Format	`--table_lock_wait_timeout=#`	
Config File Format	`table_lock_wait_timeout`	
Option Sets Variable	Yes, `table_lock_wait_timeout`	
Variable Name	`table_lock_wait_timeout`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`50`
	Range	`1-1073741824`

This variable currently is unused.

- `table_open_cache`

Command Line Format	`--table-open-cache=#`	
Config File Format	`table_open_cache`	
Variable Name	`table_open_cache`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`64`
	Range	`1-524288`

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See Section 5.1.6, “Server Status Variables”. If the value of `Opened_tables` is large and you don't do `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see Section 7.4.7, “How MySQL Opens and Closes Tables”.

- `thread_cache_size`

Command Line Format	`--thread_cache_size=#`	
Config File Format	`thread_cache_size`	
Option Sets Variable	Yes, `thread_cache_size`	
Variable Name	`thread_cache_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`

	Default	`0`
	Range	`0-16384`

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. (Normally, this doesn't provide a notable performance improvement if you have a good thread implementation.) By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see Section 5.1.6, "Server Status Variables".

- `thread_concurrency`

Command Line Format	`--thread_concurrency=#`	
Config File Format	`thread_concurrency`	
Option Sets Variable	Yes, `thread_concurrency`	
Variable Name	`thread_concurrency`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`numeric`
	Default	`10`
	Range	`1-512`

This variable is specific to Solaris systems, for which `mysqld` invokes the `thr_setconcurrency()` with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time.

- `thread_handling`

Command Line Format	`--thread_handling=name`	
Config File Format	`thread_handling`	
Option Sets Variable	Yes, `thread_handling`	
Variable Name	`thread_handling`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set (<= 6.0.3)	**Type**	`enumeration`
	Valid Values	`no-threads`, `one-thread-per-connection`
Value Set (>= 6.0.4)	**Type**	`enumeration`
	Valid Values	`no-threads`, `one-thread-per-connection`, `pool-of-threads`

The thread-handling model. The allowable values are `no-threads` (the server uses one thread), `one-thread-per-connection` (the server uses one thread to handle each client connection), `pool-of-threads` (the server does not create a thread per client connection, but uses a pool of threads for processing statements). `no-threads` is useful for debugging under Linux; see MySQL Internals: Porting. `pool-of-threads` is available as of MySQL 6.0.4. To use thread pooling, MySQL must be configured with the `--with-libevent` option when you run `configure`.

For information about choosing one thread model over the other and tuning the parameters that control thread resources, see Section 7.5.7, "How MySQL Uses Threads for Client Connections".

- `thread_pool_size`

Version Introduced	6.0.4
Command Line Format	`--thread_pool_size=#`

Config File Format	thread_pool_size	
Option Sets Variable	Yes, thread_pool_size	
Variable Name	thread_pool_size	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	numeric
	Default	20
	Range	1-16384

The size of the thread pool that is use if `thread_handling` is set to `pool-of-threads`. The default pool size is 20, and the range of values is 1 to 16,384. This variable was added in MySQL 6.0.4.

- `thread_stack`

Command Line Format	--thread_stack=#	
Config File Format	thread_stack	
Option Sets Variable	Yes, thread_stack	
Variable Name	thread_stack	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Platform Bit Size**	32
	Type	numeric
	Default	196608
	Range	131072-4294967295
Value Set	**Platform Bit Size**	64
	Type	numeric
	Default	196608
	Range	131072-18446744073709547520

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See Section 7.1.4, “The MySQL Benchmark Suite”. The default (192KB) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This variable is unused.

- `time_zone`

Command Line Format	--default_time_zone=string	
Config File Format	default_time_zone	
Variable Name	time_zone	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	string

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See Section 9.7, “MySQL Server Time Zone Support”.

- `timed_mutexes`

Command Line Format	--timed_mutexes	
Config File Format	timed_mutexes	
Option Sets Variable	Yes, timed_mutexes	
Variable Name	timed_mutexes	
Variable Scope	Global	
Dynamic Variable	Yes	
Value Set	**Type**	boolean
	Default	OFF

This variable controls whether InnoDB mutexes are timed. If this variable is set to 0 or OFF (the default), mutex timing is disabled. If the variable is set to 1 or ON, mutex timing is enabled. With timing enabled, the os_wait_times value in the output from SHOW ENGINE INNODB MUTEX indicates the amount of time (in ms) spent in operating system waits. Otherwise, the value is 0.

- tmp_table_size

Command Line Format	--tmp_table_size=#	
Config File Format	tmp_table_size	
Option Sets Variable	Yes, tmp_table_size	
Variable Name	tmp_table_size	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	numeric
	Default	system dependent
	Range	1024-4294967295

The maximum size of internal in-memory temporary tables. (The actual limit is determined as the smaller of max_heap_table_size and tmp_table_size.) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk MyISAM table. Increase the value of tmp_table_size (and max_heap_table_size if necessary) if you do many advanced GROUP BY queries and you have lots of memory. This variable does not apply to user-created MEMORY tables.

- tmpdir

Command Line Format	--tmpdir=name	
Config File Format	tmpdir	
Option Sets Variable	Yes, tmpdir	
Variable Name	tmpdir	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	filename

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows, NetWare, and OS/2.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set tmpdir to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or LOAD DATA INFILE operations. If files in the temporary file directory are lost when the server restarts, replication fails. However, if you are using MySQL 4.0.0 or later, you can set the slave's temporary directory using the slave_load_tmpdir variable. In that case, the slave won't use the general tmpdir value and you can set tmpdir to a non-permanent location.

- `transaction_alloc_block_size`

Command Line Format	`--transaction_alloc_block_size=#`	
Config File Format	`transaction_alloc_block_size`	
Option Sets Variable	Yes, `transaction_alloc_block_size`	
Variable Name	`transaction_alloc_block_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`8192`
	Range	`1024-4294967295`

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

Command Line Format	`--transaction_prealloc_size=#`	
Config File Format	`transaction_prealloc_size`	
Option Sets Variable	Yes, `transaction_prealloc_size`	
Variable Name	`transaction_prealloc_size`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Platform Bit Size**	`32`
	Type	`numeric`
	Default	`4096`
	Range	`1024-4294967295`
Value Set	**Platform Bit Size**	`64`
	Type	`numeric`
	Default	`4096`
	Range	`1024-18446744073709547520`

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

Variable Name	`tx_isolation`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`enumeration`
	Default	`REPEATABLE-READ`
	Valid Values	`READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable is set by the `SET TRANSACTION ISOLATION LEVEL` statement. See Section 12.4.6, "`SET TRANSACTION` Syntax". If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotes, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

- `updatable_views_with_limit`

Command Line Format	`--updatable_views_with_limit=#`	
Config File Format	`updatable_views_with_limit`	
Option Sets Variable	Yes, `updatable_views_with_limit`	
Variable Name	`updatable_views_with_limit`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`boolean`
	Default	`1`

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- `1` or `YES`: Issue a warning only (not an error message). This is the default value.
- `0` or `NO`: Prohibit the update.

- `version`

Command Line Format	`--version`
Config File Format	`version`
Variable Name	`version`
Variable Scope	Global
Dynamic Variable	No

The version number for the server.

- `version_comment`

The `configure` script has a `--with-comment` option that allows a comment to be specified when building MySQL. This variable contains the value of that comment.

- `version_compile_machine`

The type of machine or architecture on which MySQL was built.

- `version_compile_os`

Variable Name	`version_compile_os`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

The type of operating system on which MySQL was built.

- `wait_timeout`

Command Line Format	`--wait_timeout=#`	
Config File Format	`wait_timeout`	
Option Sets Variable	Yes, `wait_timeout`	
Variable Name	`wait_timeout`	
Variable Scope	Both	
Dynamic Variable	Yes	
Value Set	**Type**	`numeric`
	Default	`28800`
	Range	`1-31536000`
Value Set	**Type** (windows)	`numeric`
	Default	`28800`
	Range	`1-2147483`

The number of seconds the server waits for activity on a non-interactive connection before closing it. This timeout applies only to TCP/IP and Unix socket file connections, not to connections made via named pipes, or shared memory.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

5.1.4. Session System Variables

Several system variables exist only as session variables. These cannot be set at server startup but can be assigned values at runtime using the `SET` statement (except for those that are read only). Most of them are not displayed by `SHOW VARIABLES`, but you can obtain their values using `SELECT`. This section describes the session system variables. For information about setting or displaying their values, see Section 5.1.5, “Using System Variables”. For example:

```
mysql> SELECT @@autocommit;
+--------------+
| @@autocommit |
+--------------+
|            1 |
+--------------+
```

The lettercase of these variables does not matter.

The following table lists the system variables that have only session scope:

Table 5.3. `mysqld` Session System Variable Summary

Name	Cmd-Line	Option file	System Var	Dynamic
autocommit			Yes	Yes
backup_wait_timeout			Yes	Yes
big-tables	Yes	Yes		
- *Variable*: big_tables			Yes	Yes
error_count			Yes	No
foreign_key_checks			Yes	Yes
identity			Yes	Yes
insert_id			Yes	Yes
last_insert_id			Yes	Yes
profiling			Yes	Yes

Name	Cmd-Line	Option file	System Var	Dynamic
rand_seed1			Yes	Yes
rand_seed2			Yes	Yes
sql_auto_is_null			Yes	Yes
sql_big_selects			Yes	Yes
sql_big_tables			Yes	Yes
sql_buffer_result			Yes	Yes
sql_log_bin			Yes	Yes
sql_log_off			Yes	Yes
sql_log_update			Yes	Yes
sql_notes			Yes	Yes
sql_quote_show_create			Yes	Yes
sql_safe_updates			Yes	Yes
sql_warnings			Yes	Yes
timestamp			Yes	Yes
unique_checks			Yes	Yes
warning_count			Yes	No

- `autocommit`

  The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. By default, client connections begin with `autocommit` set to 1. If you change `autocommit` mode from 0 to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 12.4.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”.

- `backup_wait_timeout`

  The number of seconds DDL statements wait for a `BACKUP DATABASE` or `RESTORE` operation before aborting with an error. The default value is 50. A value of 0 means “immediate timeout.” This variable was added in MySQL 6.0.7.

- `big_tables`

  If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

  > **Note**
  >
  > This variable was formerly named `sql_big_tables`.

- `error_count`

  The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 12.5.6.18, “`SHOW ERRORS` Syntax”.

- `foreign_key_checks`

  If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See Section 13.7.4.4, “`FOREIGN KEY` Constraints”.

  Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

  > **Note**
  >
  > Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` will not be verified for consistency.

- `identity`

  This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `insert_id`

  The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `last_insert_id`

  The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `profiling`

  If set to 0 (the default), statement profiling is disabled. If set to 1, statement profiling is enabled and the `SHOW PROFILES` and `SHOW PROFILE` statements provide access to profiling information. See Section 12.5.6.32, “`SHOW PROFILES` Syntax”. This variable was added in MySQL 6.0.5.

- `profiling_history_size`

  The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 12.5.6.32, “`SHOW PROFILES` Syntax”. This variable was added in MySQL 6.0.5.

- `rand_seed1`

  The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. Beginning with MySQL 6.0.5, the variables — but not their values — are shown in the output of `SHOW VARIABLES`.

  The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

  See the description for `rand_seed1`.

- `sql_auto_is_null`

  If set to 1 (the default), you can find the last inserted row for a table that contains an `AUTO_INCREMENT` column by using the following construct:

  ```
  WHERE auto_increment_column IS NULL
  ```

  This behavior is used by some ODBC programs, such as Access.

- `sql_big_selects`

  If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which allows all `SELECT` statements.

  If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to 0.

- `sql_buffer_result`

  If set to 1, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `sql_log_bin`

  If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` privilege to set this option. The default value is 1.

- `sql_log_off`

If set to 1, no logging is done to the general query log for this client. The client must have the SUPER privilege to set this option. The default value is 0.

- sql_log_update

  This variable is deprecated, and is mapped to sql_log_bin.

- sql_notes

  If set to 1 (the default), warnings of Note level are recorded. If set to 0, Note warnings are suppressed. mysqldump includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- sql_quote_show_create

  If set to 1 (the default), the server quotes identifiers for SHOW CREATE TABLE and SHOW CREATE DATABASE statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 12.5.6.12, “SHOW CREATE TABLE Syntax”, and Section 12.5.6.8, “SHOW CREATE DATABASE Syntax”.

- sql_safe_updates

  If set to 1, MySQL aborts UPDATE or DELETE statements that do not use a key in the WHERE clause or a LIMIT clause. This makes it possible to catch UPDATE or DELETE statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- sql_warnings

  This variable controls whether single-row INSERT statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- timestamp = {*timestamp_value* | DEFAULT}

  Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. *timestamp_value* should be a Unix epoch timestamp, not a MySQL timestamp.

  SET timestamp affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the binary log have no effect on invocations of SYSDATE(). The server can be started with the --sysdate-is-now option to cause SYSDATE() to be an alias for NOW(), in which case SET timestamp affects both functions.

- unique_checks

  If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, storage engines are allowed to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB.

  Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still allowed to check for them and issue duplicate-key errors if it detects them.

- warning_count

  The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 12.5.6.40, “SHOW WARNINGS Syntax”.

5.1.5. Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. Section 5.1.3, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the SET statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.3, “Specifying Program Options”.)

- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

If you want to restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, you can specify this maximum by using an option of the form `--maximum-`*`var_name`*`=`*`value`* at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see Section 5.1.5.2, “Dynamic System Variables”. To change a system variable with `SET`, refer to it as *`var_name`*, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global.`. The `SUPER` privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session.`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session.`.
- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@`*`var_name`* syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```
SET max_join_size=DEFAULT;
```

```
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or sesson system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as *`@@var_name`* (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET` *`@@var_name = value`*, which always refers to the session value.)

> **Note**
>
> Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT` *`@@var_name`* syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE` *`'var_name'`*.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

> **Note**
>
> Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
+---------------------------------+-----------------------------------+
| Variable_name                   | Value                             |
+---------------------------------+-----------------------------------+
| auto_increment_increment        | 1                                 |
| auto_increment_offset           | 1                                 |
| automatic_sp_privileges         | ON                                |
| back_log                        | 50                                |

| innodb_data_file_path           | ibdata1:10M:autoextend            |
| innodb_data_home_dir            |                                   |
...
| version                         | 5.1.6-alpha-log                   |
| version_comment                 | Source distribution               |
| version_compile_machine         | i686                              |
| version_compile_os              | suse-linux                        |
| wait_timeout                    | 28800                             |
+---------------------------------+-----------------------------------+
```

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a

LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the "%" wildcard character in a LIKE clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because "_" is a wildcard that matches any single character, you should escape it as "_" to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a SESSION variable that has the same name as a GLOBAL variable, a client with the SUPER privilege might accidentally change the GLOBAL variable rather than just the SESSION variable for its own connection. If we add a SESSION variable with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

5.1.5.1. Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL 6.0 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- key_buffer_size
- key_cache_block_size
- key_cache_division_limit
- key_cache_age_threshold

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 7.4.5, "The MyISAM Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in *instance_name.component_name* format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of default is always predefined. If you refer to a component of a structured variable without any instance name, the default instance is used. Thus, default.key_buffer_size and key_buffer_size both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named default, so default is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, hot-cache is not legal, but `hot-cache` is.

- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to non-structured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
         --extra_cache.key_buffer_size=128K \
         --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
         --hot_cache.key_buffer_size=2M \
         --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.5.2. Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See Section 5.1.5, “Using System Variables”.

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. Section 5.1.4, “Session System Variables”, discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

Variable Name	Variable Type	Variable Scope
auto_increment_increment	numeric	GLOBAL | SESSION
auto_increment_offset	numeric	GLOBAL | SESSION

5.1.6. Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the SHOW [GLOBAL | SESSION] STATUS statement (see Section 12.5.6.35, "SHOW STATUS Syntax"). The optional GLOBAL keyword aggregates the values over all connections, and SESSION shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+----------------------------------+------------+
| Variable_name                    | Value      |
+----------------------------------+------------+
| Aborted_clients                  | 0          |
| Aborted_connects                 | 0          |
| Bytes_received                   | 155372598  |
| Bytes_sent                       | 1176560426 |
...
| Connections                      | 30023      |
| Created_tmp_disk_tables          | 0          |
| Created_tmp_files                | 3          |
```

```
| Created_tmp_tables                | 2          |
...
| Threads_created                   | 217        |
| Threads_running                   | 88         |
| Uptime                            | 1389872    |
+-----------------------------------+------------+
```

The following table lists all available server status variables:

Variable Name	Variable Type	Variable Scope
Aborted_clients	numeric	GLOBAL

Many status variables are reset to 0 by the FLUSH STATUS statement.

> **MySQL Enterprise**
> For expert advice on using status variables, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

The status variables have the following meanings. Variables with no version indicated were already present prior to MySQL 6.0. For information regarding their implementation history, see *MySQL 5.1 Reference Manual*.

- Aborted_clients

  The number of connections that were aborted because the client died without closing the connection properly. See Section B.1.2.11, “Communication Errors and Aborted Connections”.

- Aborted_connects

  The number of failed attempts to connect to the MySQL server. See Section B.1.2.11, “Communication Errors and Aborted Connections”.

- Binlog_cache_disk_use

  The number of transactions that used the temporary binary log cache but that exceeded the value of binlog_cache_size and used a temporary file to store statements from the transaction.

- Binlog_cache_use

  The number of transactions that used the temporary binary log cache.

- Bytes_received

  The number of bytes received from all clients.

- Bytes_sent

  The number of bytes sent to all clients.

- Com_*xxx*

  The Com_*xxx* statement counter variables indicate the number of times each *xxx* statement has been executed. There is one status variable for each type of statement. For example, Com_delete and Com_insert count DELETE and INSERT statements, respectively. However, if a query result is returned from query cache, the server increments the Qcache_hits status variable, not Com_select. See Section 7.5.5.4, “Query Cache Status and Maintenance”.

  All of the Com_stmt_*xxx* variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

  The Com_stmt_*xxx* status variables are as follows:

  - Com_stmt_prepare

  - `Com_stmt_execute`
  - `Com_stmt_fetch`
  - `Com_stmt_send_long_data`
  - `Com_stmt_reset`
  - `Com_stmt_close`

  Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older (available since MySQL 4.1.3) statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

  `Com_stmt_reprepare` indicated the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. This variable was added in MySQL 6.0.6. A reprepare operation increments `Com_stmt_reprepare` is incremented, and also `Com_stmt_prepare`.

- `Compression`

  Whether the client connection uses compression in the client/server protocol.

- `Connections`

  The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

  The number of temporary tables on disk created automatically by the server while executing statements.

- `Created_tmp_files`

  How many temporary files `mysqld` has created.

- `Created_tmp_tables`

  The number of in-memory temporary tables created automatically by the server while executing statements. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` value to cause temporary tables to be memory-based instead of disk-based.

- `Delayed_errors`

  The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

- `Delayed_insert_threads`

  The number of `INSERT DELAYED` handler threads in use.

- `Delayed_writes`

  The number of `INSERT DELAYED` rows written.

- `Flush_commands`

  The number of executed `FLUSH` statements.

- `Handler_commit`

  The number of internal `COMMIT` statements.

- `Handler_delete`

  The number of times that rows have been deleted from tables.

- `Handler_prepare`

  A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

  The number of times the first entry was read from an index. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- `Handler_read_key`

  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_next`

  The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

  The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

  The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that don't use keys properly.

- `Handler_read_rnd_next`

  The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

  The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

  The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

  The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

  The number of requests to update a row in a table.

- `Handler_write`

  The number of requests to insert a row in a table.

- `Innodb_buffer_pool_pages_data`

  The number of pages containing data (dirty or clean).

- `Innodb_buffer_pool_pages_dirty`

  The number of pages currently dirty.

- `Innodb_buffer_pool_pages_flushed`

  The number of buffer pool page-flush requests.

- `Innodb_buffer_pool_pages_free`

  The number of free pages.

- `Innodb_buffer_pool_pages_latched`

  The number of latched pages in `InnoDB` buffer pool. These are pages currently being read or written or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so as of MySQL 6.0.6, it is available only when the

UNIV_DEBUG system is defined at server build time.

- Innodb_buffer_pool_pages_misc

  The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as Innodb_buffer_pool_pages_total – Innodb_buffer_pool_pages_free – Innodb_buffer_pool_pages_data.

- Innodb_buffer_pool_pages_total

  The total size of the buffer pool, in pages.

- Innodb_buffer_pool_read_ahead_rnd

  The number of "random" read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order.

- Innodb_buffer_pool_read_ahead_seq

  The number of sequential read-aheads initiated by InnoDB. This happens when InnoDB does a sequential full table scan.

- Innodb_buffer_pool_read_requests

  The number of logical read requests InnoDB has done.

- Innodb_buffer_pool_reads

  The number of logical reads that InnoDB could not satisfy from the buffer pool and had to do a single-page read.

- Innodb_buffer_pool_wait_free

  Normally, writes to the InnoDB buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small.

- Innodb_buffer_pool_write_requests

  The number writes done to the InnoDB buffer pool.

- Innodb_data_fsyncs

  The number of fsync() operations so far.

- Innodb_data_pending_fsyncs

  The current number of pending fsync() operations.

- Innodb_data_pending_reads

  The current number of pending reads.

- Innodb_data_pending_writes

  The current number of pending writes.

- Innodb_data_read

  The amount of data read so far, in bytes.

- Innodb_data_reads

  The total number of data reads.

- Innodb_data_writes

  The total number of data writes.

- Innodb_data_written

  The amount of data written so far, in bytes.

- Innodb_dblwr_pages_written

The number of pages that have been written for doublewrite operations. See Section 13.7.11.1, “InnoDB Disk I/O”.

- `Innodb_dblwr_writes`

  The number of doublewrite operations that have been performed. See Section 13.7.11.1, “InnoDB Disk I/O”.

- `Innodb_log_waits`

  The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- `Innodb_log_write_requests`

  The number of log write requests.

- `Innodb_log_writes`

  The number of physical writes to the log file.

- `Innodb_os_log_fsyncs`

  The number of `fsync()` writes done to the log file.

- `Innodb_os_log_pending_fsyncs`

  The number of pending log file `fsync()` operations.

- `Innodb_os_log_pending_writes`

  The number of pending log file writes.

- `Innodb_os_log_written`

  The number of bytes written to the log file.

- `Innodb_page_size`

  The compiled-in `InnoDB` page size (default 16KB). Many values are counted in pages; the page size allows them to be easily converted to bytes.

- `Innodb_pages_created`

  The number of pages created.

- `Innodb_pages_read`

  The number of pages read.

- `Innodb_pages_written`

  The number of pages written.

- `Innodb_row_lock_current_waits`

  The number of row locks currently being waited for.

- `Innodb_row_lock_time`

  The total time spent in acquiring row locks, in milliseconds.

- `Innodb_row_lock_time_avg`

  The average time to acquire a row lock, in milliseconds.

- `Innodb_row_lock_time_max`

  The maximum time to acquire a row lock, in milliseconds.

- `Innodb_row_lock_waits`

  The number of times a row lock had to be waited for.

- `Innodb_rows_deleted`

  The number of rows deleted from `InnoDB` tables.

- `Innodb_rows_inserted`

  The number of rows inserted into `InnoDB` tables.

- `Innodb_rows_read`

  The number of rows read from `InnoDB` tables.

- `Innodb_rows_updated`

  The number of rows updated in `InnoDB` tables.

- `Key_blocks_not_flushed`

  The number of key blocks in the key cache that have changed but have not yet been flushed to disk.

- `Key_blocks_unused`

  The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.1.3, “Server System Variables”.

- `Key_blocks_used`

  The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests`

  The number of requests to read a key block from the cache.

- `Key_reads`

  The number of physical reads of a key block from disk. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads`/`Key_read_requests`.

- `Key_write_requests`

  The number of requests to write a key block to the cache.

- `Key_writes`

  The number of physical writes of a key block to disk.

- `Last_query_cost`

  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

  The `Last_query_cost` value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or `UNION`. For the latter, the value is set to 0.

- `Max_used_connections`

  The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

  The number of rows waiting to be written in `INSERT DELAY` queues.

- `Open_files`

  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

  The number of cached `.frm` files.

- `Open_tables`

  The number of tables that are open.

- `Opened_files`

  The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

  The number of `.frm` files that have been cached. This variable was added in MySQL 6.0.4.

- `Opened_tables`

  The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Prepared_stmt_count`

  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

  The number of free memory blocks in the query cache.

- `Qcache_free_memory`

  The amount of free memory for the query cache.

- `Qcache_hits`

  The number of query cache hits.

- `Qcache_inserts`

  The number of queries added to the query cache.

- `Qcache_lowmem_prunes`

  The number of queries that were deleted from the query cache because of low memory.

- `Qcache_not_cached`

  The number of non-cached queries (not cacheable, or not cached due to the `query_cache_type` setting).

- `Qcache_queries_in_cache`

  The number of queries registered in the query cache.

- `Qcache_total_blocks`

  The total number of blocks in the query cache.

- `Queries`

  The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. This variable was added in MySQL 6.0.10.

- `Questions`

  The number of statements executed by the server. As of MySQL 6.0.6, this includes only statements sent to the server by clients and no longer includes statements executed within stored programs, unlike the `Queries` variable.

- `Rpl_semi_sync_master_clients`

  The number of semisynchronous slaves.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

  The number of commits that were not acknowledged successfully by a slave.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

  Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

  For internal use.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

  The number of commits that were acknowledged successfully by a slave.

  This variable is was added in MySQL 6.0.8. It is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

  Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

  This variable is was added in MySQL 6.0.8. It is available only if the slave-side semisynchronous replication plugin is installed.

- `Rpl_status`

  The status of fail-safe replication (not yet implemented).

- `Select_full_join`

  The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

  The number of joins that used a range search on a reference table.

- `Select_range`

  The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

  The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

  The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period`

  Shows the replication heartbeat interval (in seconds) on a replication slave.

  This variable was added in MySQL 6.0.4.

- `Slave_open_temp_tables`

  The number of temporary tables that the slave SQL thread currently has open.

- `Slave_received_heartbeats`

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

This variable was added in MySQL 6.0.4.

- `Slave_retried_transactions`

  The total number of times since startup that the replication slave SQL thread has retried transactions.

- `Slave_running`

  In MySQL 6.0.10 and earlier, this is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

  In MySQL 6.0.11 and later, this status variable takes on of 3 values:

  - `ON`, if this server is a slave that is connected to a replication master, and both the I/O SQL and threads are running
  - `OFF`, if the slave I/O thread is not running
  - `CONNECTING`, if the slave I/O thread is running, but this server is not connected to a replication master

  Also in MySQL 6.0.11 and later, the value of `Slave_running` corresponds with the value shown for `Slave_IO_running` in the output of `SHOW SLAVE STATUS`, which was not always the case previously. (Bug#30703)

- `Slow_launch_threads`

  The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

  The number of queries that have taken more than `long_query_time` seconds. See Section 5.2.5, “The Slow Query Log”.

- `Sort_merge_passes`

  The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

  The number of sorts that were done using ranges.

- `Sort_rows`

  The number of sorted rows.

- `Sort_scan`

  The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

  The number of negotiates needed to establish the connection.

- `Ssl_accepts`

  The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

  The number of callback cache hits.

- `Ssl_cipher`

  The current SSL cipher (empty for non-SSL connections).

- `Ssl_cipher_list`

  The list of possible SSL ciphers.

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

  The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

  The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

  The SSL context verification mode.

- `Ssl_default_timeout`

  The default SSL timeout.

- `Ssl_finished_accepts`

  The number of successful SSL connections to the server.

- `Ssl_finished_connects`

  The number of successful slave connections to an SSL-enabled master.

- `Ssl_session_cache_hits`

  The number of SSL session cache hits.

- `Ssl_session_cache_misses`

  The number of SSL session cache misses.

- `Ssl_session_cache_mode`

  The SSL session cache mode.

- `Ssl_session_cache_overflows`

  The number of SSL session cache overflows.

- `Ssl_session_cache_size`

  The SSL session cache size.

- `Ssl_session_cache_timeouts`

  The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

  How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

  How many SSL session cache entries were used.

- `Ssl_verify_depth`

  The verification depth for replication SSL connections.

- `Ssl_verify_mode`

  The verification mode for replication SSL connections.

- `Ssl_version`

  The SSL version number.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

  The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Tc_log_max_pages_used`

  For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. Currently, this variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines capable of two-phase commit is greater than one. (`InnoDB` is the only applicable engine.)

- `Tc_log_page_size`

  The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. Currently, this variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- `Tc_log_page_waits`

  For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- `Threads_cached`

  The number of threads in the thread cache.

- `Threads_connected`

  The number of currently open connections.

- `Threads_created`

  The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created`/`Connections`.

- `Threads_running`

  The number of threads that are not sleeping.

- `Uptime`

  The number of seconds that the server has been up.

- `Uptime_since_flush_status`

  The number of seconds since the most recent `FLUSH STATUS` statement. This variable was added in 6.0.5.

5.1.7. Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

For answers to some questions that are often asked about server SQL modes in MySQL, see Section A.3, “MySQL 6.0 FAQ — Server SQL Mode”.

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="`*`modes`*`"` option, or by using `sql-mode="`*`modes`*`"` in `my.cnf` (Unix operating systems) or `my.ini` (Windows). *`modes`* is a list of different modes separated by comma (“`,`”) characters. The default value is empty (no modes set). The *`modes`* value also can be empty (`--sql-mode=""` on the command line, or `sql-mode=""` in `my.cnf` on Unix systems or in `my.ini` on Windows) if you want to clear it expli-

citly.

You can change the SQL mode at runtime by using a `SET [GLOBAL|SESSION] sql_mode='modes'` statement to set the `sql_mode` system value. Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Any client can change its own session `sql_mode` value at any time.

> **Important**
>
> **SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.
>
> See Section 17.5, “Restrictions and Limitations on Partitioning”, for more information.

You can retrieve the current global or session `sql_mode` value with the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

The most important `sql_mode` values are probably these:

- `ANSI`

  This mode changes syntax and behavior to conform more closely to standard SQL.

- `STRICT_TRANS_TABLES`

  If a value could not be inserted as given into a transactional table, abort the statement. For a non-transactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More detail is given later in this section.

- `TRADITIONAL`

  Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column.

  > **Note**
  >
  > The `INSERT`/`UPDATE` aborts as soon as the error is noticed. This may not be what you want if you are using a non-transactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode where at least one of `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` is enabled.

The following list describes all supported modes:

- `ALLOW_INVALID_DATES`

  Don't do full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

  The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To allow such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

  Treat “`"`” as an identifier quote character (like the “`` ` ``” quote character) and not as a string quote character. You can still use “`` ` ``” to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotes to quote literal strings, because it is interpreted as an identifier.

- `ERROR_FOR_DIVISION_BY_ZERO`

  Produce an error in strict mode (otherwise a warning) when a division by zero (or `MOD(X,0)`) occurs during an `INSERT` or

UPDATE. If this mode is not enabled, MySQL instead returns NULL for divisions by zero. For INSERT IGNORE or UPDATE IGNORE, MySQL generates a warning for divisions by zero, but the result of the operation is NULL.

- HIGH_NOT_PRECEDENCE

  The precedence of the NOT operator is such that expressions such as NOT a BETWEEN b AND c are parsed as NOT (a BETWEEN b AND c). In some older versions of MySQL, the expression was parsed as (NOT a) BETWEEN b AND c. The old higher-precedence behavior can be obtained by enabling the HIGH_NOT_PRECEDENCE SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
       -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
       -> 1
```

- IGNORE_SPACE

  Allow spaces between a function name and the "(" character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 8.2, "Schema Object Names". For example, because there is a COUNT() function, the use of count as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

  The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

  The IGNORE_SPACE SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always allowable to have spaces after a UDF or stored function name, regardless of whether IGNORE_SPACE is enabled.

  For further discussion of IGNORE_SPACE, see Section 8.2.4, "Function Name Parsing and Resolution".

- NO_AUTO_CREATE_USER

  Prevent the GRANT statement from automatically creating new users if it would otherwise do so, unless a non-empty password also is specified.

- NO_AUTO_VALUE_ON_ZERO

  NO_AUTO_VALUE_ON_ZERO affects handling of AUTO_INCREMENT columns. Normally, you generate the next sequence number for the column by inserting either NULL or 0 into it. NO_AUTO_VALUE_ON_ZERO suppresses this behavior for 0 so that only NULL generates the next sequence number.

  This mode can be useful if 0 has been stored in a table's AUTO_INCREMENT column. (Storing 0 is not a recommended practice, by the way.) For example, if you dump the table with mysqldump and then reload it, MySQL normally generates new sequence numbers when it encounters the 0 values, resulting in a table with contents different from the one that was dumped. Enabling NO_AUTO_VALUE_ON_ZERO before reloading the dump file solves this problem. mysqldump now automatically includes in its output a statement that enables NO_AUTO_VALUE_ON_ZERO, to avoid this problem.

- NO_BACKSLASH_ESCAPES

  Disable the use of the backslash character ("\") as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- NO_DIR_IN_CREATE

  When creating a table, ignore all INDEX DIRECTORY and DATA DIRECTORY directives. This option is useful on slave replication servers.

- NO_ENGINE_SUBSTITUTION

  Control automatic substitution of the default storage engine when a statement such as CREATE TABLE or ALTER TABLE specifies a storage engine that is disabled or not compiled in.

  Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

  With NO_ENGINE_SUBSTITUTION disabled, for CREATE TABLE the default engine is used and a warning occurs if the desired engine is unavailable. For ALTER TABLE, a warning occurs and the table is not altered.

With NO_ENGINE_SUBSTITUTION enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- NO_FIELD_OPTIONS

  Do not print MySQL-specific column options in the output of SHOW CREATE TABLE. This mode is used by mysqldump in portability mode.

- NO_KEY_OPTIONS

  Do not print MySQL-specific index options in the output of SHOW CREATE TABLE. This mode is used by mysqldump in portability mode.

- NO_TABLE_OPTIONS

  Do not print MySQL-specific table options (such as ENGINE) in the output of SHOW CREATE TABLE. This mode is used by mysqldump in portability mode.

- NO_UNSIGNED_SUBTRACTION

  In integer subtraction operations, do not mark the result as UNSIGNED if one of the operands is unsigned. In other words, *the result of a subtraction is always signed whenever this mode is in effect, even if one of the operands is unsigned*. For example, compare the type of column c2 in table t1 with that of column c2 in table t2:

```
mysql> SET SQL_MODE='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
+-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned |      |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+

mysql> SET SQL_MODE='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| c2    | bigint(21) |      |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

  Note that this means that BIGINT UNSIGNED is not 100% usable in all contexts. See Section 11.9, “Cast Functions and Operators”.

```
mysql> SET SQL_MODE = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+--------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+--------------------------+
|    18446744073709551615 |
+--------------------------+

mysql> SET SQL_MODE = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+--------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+--------------------------+
|                       -1 |
+--------------------------+
```

- NO_ZERO_DATE

  In strict mode, don't allow '0000-00-00' as a valid date. You can still insert zero dates with the IGNORE option. When not in strict mode, the date is accepted but a warning is generated.

- NO_ZERO_IN_DATE

  In strict mode, do not accept dates where the year part is nonzero but the month or day part is 0 (for example, '0000-00-00' is legal but '2010-00-01' and '2010-01-00' are not). If used with the IGNORE option, MySQL inserts a '0000-00-00' date for any such date. When not in strict mode, the date is accepted but a warning is generated.

- ONLY_FULL_GROUP_BY

  Do not allow queries for which the SELECT list refers to non-aggregated columns that are not named in the GROUP BY clause. The following query is invalid with this mode enabled because address is not named in the GROUP BY clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

This mode also restricts references to non-aggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause.

- `PAD_CHAR_TO_FULL_LENGTH`

  By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------+----------------+
| c1   | CHAR_LENGTH(c1) |
+------+----------------+
| xy   |              2 |
+------+----------------+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------+----------------+
| c1         | CHAR_LENGTH(c1) |
+------------+----------------+
| xy         |             10 |
+------------+----------------+
1 row in set (0.00 sec)
```

- `PIPES_AS_CONCAT`

  Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- `REAL_AS_FLOAT`

  Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- `STRICT_ALL_TABLES`

  Enable strict mode for all storage engines. Invalid data values are rejected. Additional detail follows.

- `STRICT_TRANS_TABLES`

  Enable strict mode for transactional storage engines, and when possible for non-transactional storage engines. Additional details follow.

Strict mode controls how MySQL handles input values that are invalid or missing. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.)

For transactional tables, an error occurs for invalid or missing values in a statement when either of the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` modes are enabled. The statement is aborted and rolled back.

For non-transactional tables, the behavior is the same for either mode, if the bad value occurs in the first row to be inserted or updated. The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict option is enabled:

- For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, in this case, the earlier rows still have been inserted or updated. This means that you might get a partial update, which might not be what you want. To avoid this, it is best to use single-row statements because these can be aborted without changing the table.
- For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and insert the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL

generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 10.1.4, “Data Type Default Values”.

Strict mode disallows invalid date values such as `'2004-04-31'`. It does not disallow dates with zero month or day parts such as `'2004-04-00'` or “zero” dates. To disallow these as well, enable the `NO_ZERO_IN_DATE` and `NO_ZERO_DATE` SQL modes in addition to strict mode.

If you are not using strict mode (that is, neither `STRICT_TRANS_TABLES` nor `STRICT_ALL_TABLES` is enabled), MySQL inserts adjusted values for invalid or missing values and produces warnings. In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`. See Section 12.5.6.40, “`SHOW WARNINGS` Syntax”.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See Section 5.1.4, “Session System Variables”.)

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

- `ANSI`

  Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`.

  `ANSI` mode causes the server to return an error for queries where a set function *`S`* with an outer reference *`S(outer_ref)`* cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

  ```
  SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
  ```

  Here, `MAX(t1.b)` cannot aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` mode is not enabled, the server treats *`S(outer_ref)`* in such queries the same way that it would interpret *`S(const)`*.

  See Section 1.7.3, “Running MySQL in ANSI Mode”.

- `DB2`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MAXDB`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `MSSQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MYSQL323`

  Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- `MYSQL40`

  Equivalent to `NO_FIELD_OPTIONS`, `HIGH_NOT_PRECEDENCE`.

- `ORACLE`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `POSTGRESQL`

  Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `TRADITIONAL`

Equivalent to STRICT_TRANS_TABLES, STRICT_ALL_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER.

5.1.8. Server-Side Help

MySQL Server supports a HELP statement that returns online information from the MySQL Reference manual (see Section 12.3.3, "HELP Syntax"). The proper operation of this statement requires that the help tables in the mysql database be initialized with help topic information, which is done by processing the contents of the fill_help_tables.sql script.

For a MySQL binary distribution on Unix, help table setup occurs when you run mysql_install_db. For an RPM distribution on Linux or binary distribution on Windows, help table setup occurs as part of the MySQL installation process.

For a MySQL source distribution, you can find the fill_help_tables.sql file in the scripts directory. To load the file manually, make sure that you have initialized the mysql database by running mysql_install_db, and then process the file with the mysql client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

If you are working with Bazaar and a MySQL development source tree, the tree doesn't contain fill_help_tables.sql. You can download the proper file for your version of MySQL from http://dev.mysql.com/doc/. After downloading and uncompressing the file, process it with mysql as just described.

5.1.9. Server Response to Signals

On Unix, signals can be sent to processes. mysqld responds to signals sent to it as follows:

- SIGTERM causes the server to shut down.
- SIGHUP causes the server to reload the grant tables and flush the logs (like FLUSH PRIVILEGES and FLUSH LOGS). It also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:       8388600
Block_size:           1024
Division_limit:        100
Age_limit:             300
blocks used:             0
not flushed:             0
w_requests:              0
writes:                  0
r_requests:              0
reads:                   0

handler status:
read_key:            0
read_next:           0
read_rnd             0
read_first:          1
write:               0
delete               0
update:              0

Table status:
Opened tables:          5
Open tables:            0
Open files:             7
Open streams:           0

Alarm status:
Active alarms:   1
Max used alarms: 2
Next alarm time: 67
```

On some Mac OS X 10.3 versions, mysqld ignores SIGHUP and SIGQUIT.

5.1.10. The Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   Server shutdown can be initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   ```
   Error: Can't create thread to kill server
   ```

3. The server stops accepting new connections.

   To prevent new activity from being initiated during shutdown, the server stops accepting new client connections. It does this by closing the network connections to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

   For each thread that is associated with a client connection, the connection to the client is broken and the thread is marked as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 12.5.7.4, “`KILL` Syntax”, in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

   For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a non-transactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated, because the operation can terminate before completion.

   If the server is a master replication server, threads associated with currently connected slaves are treated like other client threads. That is, each one is marked as killed and exits when it next checks its state.

   If the server is a slave replication server, the I/O and SQL threads, if active, are stopped before client threads are marked as killed. The SQL thread is allowed to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread was in the middle of a transaction at this point, the transaction is rolled back.

5. Storage engines are shut down or closed.

   At this stage, the table cache is flushed and all open tables are closed.

   Each storage engine performs any actions necessary for tables that it manages. For example, `MyISAM` flushes any pending index writes for a table. `InnoDB` flushes its buffer pool to disk, unless `innodb_fast_shutdown` is 2, writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

5.2. MySQL Server Logs

MySQL has several different logs that can help you find out what is going on inside `mysqld`.

Log Type	Information Written to Log
The error log	Problems encountered starting, running, or stopping `mysqld`
The general query log	Established client connections and statements received from clients
The binary log	All statements that change data (also used for replication)
The slow query log	All queries that took more than `long_query_time` seconds to execute or didn't use indexes

By default, all log files are created in the `mysqld` data directory. You can force `mysqld` to close and reopen the log files (or in

some cases switch to a new log) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute `mysqladmin flush-logs` or `mysqladmin refresh`. See Section 12.5.7.3, "`FLUSH` Syntax", and Section 4.5.2, "`mysqladmin` — Client for Administering a MySQL Server".

If you are using MySQL replication capabilities, slave replication servers maintain additional log files called relay logs. Chapter 16, *Replication*, discusses relay log contents and configuration.

The server can write general query and slow query entries to log tables, log files, or both. For details, see Section 5.2.1, "Selecting General Query and Slow Query Log Output Destinations".

You can also control during runtime the general query and slow query logs. You can enable or disable logging, or change the name of the log file. See Section 5.2.3, "The General Query Log", and Section 5.2.5, "The Slow Query Log".

See Section 5.5.6.1, "Administrator Guidelines for Password Security", for information about keeping logs secure.

> **MySQL Enterprise**
> The MySQL Enterprise Monitor provides a number of advisors specifically related to the various log files. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

5.2.1. Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination for log output. Log entries can be written to log files or to the `general_log` and `slow_log` tables in the `mysql` database. If logging is enabled, either or both destinations can be selected.

> **Note**
>
> The log tables are created during the installation procedure along with the other system tables. If you upgrade MySQL from a release older than 5.1.6 to MySQL 5.1.6 or higher, you must upgrade the system tables after upgrading to make sure that the log tables exist. See Section 4.4.8, "`mysql_upgrade` — Check Tables for MySQL Upgrade".

Currently, logging to tables incurs significantly more server overhead than logging to files. If you enable the general log or slow query log and require highest performance, you should log to files and not to tables.

Log control at server startup. The `--log-output` option specifies the destination for log output, if logging is enabled, but the option does not in itself enable the logs. The syntax for this option is `--log-output[=value,...]`:

- If `--log-output` is given with a value, the value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` is omitted or given without a value, the default is `FILE`.

The `--general_log` option, if given, enables logging to the general query log for the selected log destinations. `--general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, use `--general_log_file=file_name`. Similarly, the `--slow_query_log` option, if given, enables logging to the slow query log for the selected destinations and `--slow_query_log_file=file_name` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, logging of queries to the file does not occur unless the `FILE` log destination is selected. Prior to MySQL 6.0.8, the `--log` and `--log-slow-queries` options enable the general query log and slow query log. Either option may be given with a file name argument to specify a log file name to override the default.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE` to select both log destinations and the `--general_log` option to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE` to select tables as the log destination and the `--general_log` and `--slow_query_log` options to enable both logs.
- To write slow query log entries only to the log file, use `--log-output=FILE` to select files as the log destination and the `--slow_query_log` option to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output` option.)

Log control at runtime. Several system variables are associated with log tables and files and enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. As of MySQL 6.0.8, you can set these variables at server startup or at runtime to change the names of the log files. (Before MySQL 6.0.8, you can set these variables only at runtime, but the `--log` and `--log-slow-queries` options can be given with a file name argument at startup to change the log file names from their default values.)
- The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible via SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

  The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.
- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
CREATE TABLE IF NOT EXISTS general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are allowed only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the global `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.

- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.
- It is not allowed to partition log tables.

5.2.2. The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See MySQL Internals: Porting.

You can specify where `mysqld` writes the error log with the `--log-error[=file_name]` option. If no *`file_name`* value is given, `mysqld` uses the name *`host_name`*`.err` by default and writes the file in the data directory. If you execute `FLUSH LOGS`, the error log is renamed with the suffix `-old` and `mysqld` creates a new empty log file. (No renaming occurs if the `--log-error` option was not given to `mysqld`.)

If you do not specify `--log-error`, or (on Windows) if you use the `--console` option, errors are written to `stderr`, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the `.err` file if `--console` is not given.

The `--log-warnings` option or `log_warnings` system variable can be used to control warning logging to the error log. The default value is enabled (1). Warning logging can be disabled using a value of 0. If the value is greater than 1, aborted connections are written to the error log. See Section B.1.2.11, “Communication Errors and Aborted Connections”.

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or to `syslog` `mysqld_safe` has three error-logging options, `--syslog`, `--skip-syslog`, and `--log-error`. The default with no logging options or with `--skip-syslog` is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option.

If you specify `--log-error` in an option file in a section that `mysqld` reads, `mysqld_safe` also will find and use the option.

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

If `mysqld_safe` is used to start `mysqld` and `mysqld` dies unexpectedly, `mysqld_safe` notices that it needs to restart `mysqld` and writes a `restarted mysqld` message to the error log.

5.2.3. The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order contrasts to the binary log, for which statements are written after they are executed but before any locks are released. (Also, the query log contains all statements, whereas the binary log does not contain statements that only select data.)

To enable the general query log, start `mysqld` with the `--log[=file_name]` or `-l [file_name]` option, and optionally use `--log-output` to specify the log destination (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). As of MySQL 6.0.8, `--log` and `-l` are deprecated: Use `--general_log` to enable the general query log, and optionally `--general_log_file=file_name` to specify a log file name. `--general_log` takes an optional argument of 1 or 0 to enable or disable the log.

If you specify no file name for the general query log, the default name is *`host_name`*`.log` in the data directory. If you specify a file name that is not an absolute path name, the server writes the file in the data directory.

When `--log` or `-l` is specified, `--general_log` also may be given to specify the initial general query log state. With no argument or an argument of 0, the option disables the log. If omitted or given with an argument of 1, the option enables the log.

For runtime control of the general query log, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, output is written to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, no queries are written even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). On Unix, you can rename the file and create a new one by using the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> cp host_name-old.log backup-directory
shell> rm host_name-old.log
```

On Windows, you can rename the general query log or slow query log while the server has it open. You cannot rename the error log file while the server has it open. You must stop the server and rename the file, and then restart the server to create a new log file. However, a stop and restart can be avoided by using `FLUSH LOGS`, which causes the server to rename the error log with an `-old` suffix and open a new error log.

You can disable the general query log at runtime:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The general query log should be protected because logged statements might contain passwords. See Section 5.5.6.1, “Administrator Guidelines for Password Security”.

5.2.4. The Binary Log

The binary log contains all statements that update data. It also contains statements that potentially could have updated it (for example, a `DELETE` which matched no rows), unless row-based logging is used. Statements are stored in the form of “events” that describe the modifications. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 16.4, “Replication Implementation”.
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 6.2.2, “Using Backups for Recovery”.

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. If you want to log all statements (for example, to identify a problem query), use the general query log. See Section 5.2.3, “The General Query Log”.

The binary log should be protected because logged statements might contain passwords. See Section 5.5.6.1, “Administrator Guidelines for Password Security”.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For more information on logging formats, see Section 5.2.4.1, “Binary Logging Formats”.

> **MySQL Enterprise**
> The binary log can also be used to track significant DDL events. Analyzing the binary log in this way is an integral part of the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Running the server with the binary log enabled makes performance about 1% slower. However, the benefits of the binary log for restore operations and in allowing you to set up replication generally outweigh this minor performance decrement.

When started with the `--log-bin[=base_name]` option, `mysqld` writes a log file containing all SQL statements that update

data (both DDL and DML statements). If no *base_name* value is given, the default name is the value of the pid-file option (which by default is the name of host machine) followed by -bin. If the basename is given, but not as an absolute path name, the server writes the file in the data directory. It is recommended that you specify a basename; see Additional Known Issues, for the reason.

> **Note**
>
> From MySQL 6.0.0 through 6.0.3, "mysql" was used when no *base_name* was specified. Also in these versions, a path given as part of the --log-bin options was treated as absolute rather than relative. The previous behaviors were restored in MySQL 6.0.4. (See Bug#28603 and Bug#28597.)

If you supply an extension in the log name (for example, --log-bin=*base_name.extension*), the extension is silently removed and ignored.

mysqld appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically when the current log's size reaches max_binlog_size. A binary log file may become larger than max_binlog_size if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, mysqld also creates a binary log index file that contains the names of all used binary log files. By default, this has the same basename as the binary log file, with the extension '.index'. You can change the name of the binary log index file with the --log-bin-index[=*file_name*] option. You should not manually edit this file while mysqld is running; doing so would confuse mysqld.

You can delete all binary log files with the RESET MASTER statement, or a subset of them with PURGE BINARY LOGS. See Section 12.5.7.6, "RESET Syntax", and Section 12.6.1.1, "PURGE BINARY LOGS Syntax".

Writes to the binary log file and binary log index file are handled in the same way as writes to MyISAM tables. See Section B.1.4.3, "How MySQL Handles a Full Disk".

The binary log format has some known limitations that can affect recovery from backups. See Section 16.3.1, "Replication Features and Issues".

Binary logging for stored routines and triggers is done as described in Section 18.6, "Binary Logging of Stored Programs".

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the --log-slave-updates option (see also Section 16.1.3.3, "Replication Slave Options and Variables").

Evaluation of update selection options. The server evaluates the options for logging or ignoring updates to the binary log according to the following rules:

1. Are there --binlog-do-db or --binlog-ignore-db rules?
   - No: Write the statement to the binary log and exit.
   - Yes: Go to the next step.
2. There are some rules (--binlog-do-db, --binlog-ignore-db, or both). Is there a default database (has any database been selected by USE?)?
   - No: Do *not* write the statement, and exit.
   - Yes: Go to the next step.
3. There is a default database. Are there some --binlog-do-db rules?
   - Yes: Does the default database match any of the --binlog-do-db rules?
     - Yes: Write the statement and exit.
     - No: Do *not* write the statement, and exit.
   - No: Go to the next step.
4. There are some --binlog-ignore-db rules. Does the default database match any of the --binlog-ignore-db rules?
   - Yes: Do not write the statement, and exit.
   - No: Write the query and exit.

> **Important**
>
> An exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements (see Section 16.1.3.4, "Binary Log Options and Variables"). In those cases, the database being *created, altered, or dropped* replaces the default database when determining whether to log or ignore updates.

For example, a slave running with only `--binlog-do-db=sales` does not write to the binary log any statement for which the default database is different from `sales` (in other words, `--binlog-do-db` can sometimes mean "ignore other databases").

If you are using replication, you should not delete old binary log files until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See Section 12.6.1.1, "`PURGE BINARY LOGS` Syntax".

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See Section 5.1.4, "Session System Variables".

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

See Section 4.6.8, "`mysqlbinlog` — Utility for Processing Binary Log Files", for more information on the `mysqlbinlog` utility and how to use it. `mysqlbinlog` also can be used with relay log files because they are written using the same format as binary log files.

Binary logging is done immediately after a statement completes but before any locks are released or any commit is done. This ensures that the log is logged in execution order.

Updates to non-transactional tables are stored in the binary log immediately after execution. In MySQL 6.0.3 and earlier versions of MySQL 6.0, an `UPDATE` statement using a stored function that modified a non-transactional table was not logged if it failed, and an `INSERT ... ON DUPLICATE KEY UPDATE` statement that encountered a duplicate key constraint — but which did not actually change any data — was not logged. Beginning with MySQL 6.0.4, both of these statements are written to the binary log. (Bug#23333)

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `BDB` or `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed. When the thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

Modifications to non-transactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to non-transactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statement. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement based logging then the original statement is written to the log.

Note that the binary log format is different in MySQL 6.0 from previous versions of MySQL, due to enhancements in replication. See Section 16.3.2, "Replication Compatibility Between MySQL Versions".

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every *N* writes to the binary log, with the `sync_binlog` system variable. See Section 5.1.3, "Server System Variables". 1 is the safest value for `sync_binlog`, but also the slowest. Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into `InnoDB`. If the server crashes between those two operations, the transaction is rolled back by `InnoDB` at restart but still exists in the binary log. To resolve this, you should set `--innodb_support_xa` to 1. Although this op-

tion is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the `InnoDB` logs to disk at every transaction. The `InnoDB` logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back `InnoDB` transactions from the binary log. This ensures that the binary log reflects the exact data of `InnoDB` tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed `InnoDB` transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some don't), so the server prints an error message `The binary log <name> is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

5.2.4.1. Binary Logging Formats

A number of different logging formats are used to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

  Mixed logging is the default logging mode in MySQL 6.0.

  The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when logging, and more specifically replicating, certain statements between a master and slave which are using different storage engines.

5.2.4.2. Setting The Binary Log Format

The default binary logging format is mixed-based in MySQL 6.0.

You can force the replication format by starting the MySQL server with `--binlog-format=`*`type`*. When set, all replication slaves connecting to the server will read the events according to this setting. The supported values for *`type`* are:

- `ROW` causes replication to be row-based.
- `STATEMENT` causes replication to be statement-based.
- `MIXED` causes replication to use mixed format.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable. (To change the global value, you must have need the `SUPER` privilege. This is also true for the `SESSION` value as of MySQL 6.0.8.)

To switch to statement-based format, use either of these statements:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 1;
```

To switch to row-based format, use either of these statements:

```
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 2;
```

To switch to mixed format, use either of these statements:

```
mysql> SET GLOBAL binlog_format = 'MIXED';
mysql> SET GLOBAL binlog_format = 3;
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`. For example:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

In addition to switching the logging format manually, a slave server may switch the format *automatically*. This happens when the server is running in either `STATEMENT` or `MIXED` format and encounters a row in the binary log that is written in `ROW` logging format. In that case, the slave switches to row-based replication temporarily for that event, and switches back to the previous format afterwards.

There are two reasons why you might want to set replication logging on a per-connection basis:

- A thread that makes many small changes to the database might want to use row-based logging. A thread that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in any of these cases results in an error.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binlog format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 1024.

> **Warning**
>
> When using *statement-based logging* in a replication scenario, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *non-deterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Additional Known Issues.

5.2.4.3. Mixed Binary Logging Format

When running in `MIXED` mode, automatic switching from statement-based to row-based replication takes place under the following conditions:

- When a function contains `UUID()`
- When 2 or more tables with `AUTO_INCREMENT` columns are updated
- When any `INSERT DELAYED` is executed
- When the body of a view requires row-based replication, the statement creating the view also uses it — for example, this occurs when the statement creating a view uses the `UUID()` function
- When a call to a UDF is involved
- If a statement is logged by row and the client that executed the statement has any temporary tables, then logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that client are dropped

  This is true whether or not any temporary tables are actually logged

  Temporary tables cannot be logged using the row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe, and we approximate this condition by treating all statements made by that client as unsafe until the client no longer holds any temporary tables
- Beginning with MySQL 6.0.4:
  - When `FOUND_ROWS()` or `ROW_COUNT()` is used (Bug#12092, Bug#30244)
  - When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used (Bug#28086)
  - Beginning with MySQL 6.0.5, when a statement refers to one or more system variables. (Bug#31168)

> **Note**
>
> A warning is generated if you try to log execute a statement in statement-logging mode that should be logged in row-logging mode. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time a statement is executed. However, only the first statement that generated the warning for each client session is logged to the `mysqld` error log to prevent flooding the error log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The following table lists the logging formats supported by each storage engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
`ARCHIVE`	Yes	Yes
`BLACKHOLE`	No	Yes
`CSV`	Yes	Yes
`EXAMPLE`	Yes	No
`Falcon`	Yes	No
`FEDERATED`	Yes	Yes
`HEAP`	Yes	Yes
`InnoDB`	Yes	Yes
`MyISAM`	Yes	Yes
`MERGE`	Yes	Yes

A given storage engine can support either or both logging formats; the logging capabilities of an individual engine can be further defined as follows:

- If an engine supports row-based logging, then the engine is said to be *row-logging capable*.

- If an engine supports statement-based logging, then the engine is said to be *statement-logging capable*.

When determining the logging mode to be used, the capabilities of all the tables affected by the event are combined. The set of affected tables is then marked according to these rules:

- A set of tables is defined as *row logging restricted* if the tables are row logging capable but not statement logging capable.
- A set of tables is defined as *statement logging restricted* if the tables are statement logging capable but not row logging capable.

Once the determination of the possible logging formats required by the statement is complete it is compared to the current `binlog_format` setting. The following table is used to decide how the information is recorded in the binary log or, if appropriate, whether an error is raised. In the table, a safe operation is defined as one that is deterministic. A number of rules decide whether the statement is deterministic or not, as shown in the following table (where **RLC** stands for "row-logging capable" and **SLC** stands for "statement-logging capable").

Condition				**Action**	
Safe/unsafe	**`binlog_format`**	**RLC**	**SLC**	**Error/Warning**	**Logged as**
Safe	STATEMENT	N	N	Error: not loggable	
Safe	STATEMENT	N	Y		STATEMENT
Safe	STATEMENT	Y	N	Error: not loggable	
Safe	STATEMENT	Y	Y		STATEMENT
Safe	MIXED	N	N	Error: not loggable	
Safe	MIXED	N	Y		STATEMENT
Safe	MIXED	Y	N		ROW
Safe	MIXED	Y	Y		STATEMENT
Safe	ROW	N	N	Error: not loggable	
Safe	ROW	N	Y	Error: not loggable	
Safe	ROW	Y	N		ROW
Safe	ROW	Y	Y		ROW
Unsafe	STATEMENT	N	N	Error: not loggable	
Unsafe	STATEMENT	N	Y	Warning: unsafe	STATEMENT
Unsafe	STATEMENT	Y	N	Error: not loggable	
Unsafe	STATEMENT	Y	Y	Warning: unsafe	STATEMENT
Unsafe	MIXED	N	N	Error: not loggable	
Unsafe	MIXED	N	Y	Error: not loggable	
Unsafe	MIXED	Y	N		ROW
Unsafe	MIXED	Y	Y		ROW
Unsafe	ROW	N	N	Error: not loggable	
Unsafe	ROW	N	Y	Error: not loggable	
Unsafe	ROW	Y	N		ROW
Unsafe	ROW	Y	Y		ROW

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged. The log message will include the SQL statement that was attempted.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

5.2.4.4. Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log us-

ing the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

5.2.5. The Slow Query Log

The slow query log consists of all SQL statements that took more than `long_query_time` seconds to execute and (as of MySQL 6.0.4) required at least `min_examined_row_limit` rows to be examined. The time to acquire the initial table locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might be different from execution order. The default value of `long_query_time` is 10. Prior to MySQL 6.0.4, the minimum value is 1, and the value for this variable must be an integer. Beginning with MySQL 6.0.4, the minimum is 0, and a resolution of microseconds is supported when logging to a file. However, the microseconds part is ignored and only integer values are written when logging to tables.

To enable the slow query log, start `mysqld` with the `--log-slow-queries[=file_name]` option, and optionally use `--log-output` to specify the log destination (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). As of MySQL 6.0.8, `--log-slow-queries` is deprecated: Use `--slow_query_log` to enable the slow query log, and optionally `--slow_query_log_file=file_name` to specify a log file name. `--slow_query_log` takes an optional argument of 1 or 0 to enable or disable the log.

If you specify no file name for the slow query log, the default name is `host_name-slow.log` in the data directory. If you specify a file name that is not an absolute path name, the server writes the file in the data directory.

When `--log-slow-queries` is specified, `--slow_query_log` also may be given to specify the initial slow query log state. With no argument or an argument of 0, the option disables the log. If omitted or given with an argument of 1, the option enables the log.

For runtime control of the general query log, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, output is written to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, no queries are written even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

When the slow query log is enabled, output is written to any destinations specified by the `--log-output` option or `log_output` system variable. If the destination is `NONE`, no output is written even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process the slow query log using the `mysqldumpslow` command to summarize the queries that appear in the log. Use `mysqldumpslow --help` to see the options that this command supports.

In MySQL 6.0, queries that do not use indexes are logged in the slow query log if the `--log-queries-not-using-indexes` option is specified. See Section 5.1.2, “Server Command Options”.

> **MySQL Enterprise**
> Excessive table scans are indicative of missing or poorly optimized indexes. Using an advisor specifically designed for the task, the MySQL Enterprise Monitor can identify such problems and offer advice on resolution. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

In MySQL 6.0, the `--log-slow-admin-statements` server option enables you to request logging of slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

Queries handled by the query cache are not added to the slow query log, nor are queries that would not benefit from the presence of an index because the table has zero rows or one row.

Prior to MySQL 6.0.11, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. (Bug#23300)

The slow query log should be protected because logged statements might contain passwords. See Section 5.5.6.1, “Administrator Guidelines for Password Security”.

5.2.6. Server Log Maintenance

MySQL Server can create a number of different log files that make it easy to see what is going on. See Section 5.2, “MySQL Server Logs”. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 6.1, “Database Backups”.

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. You should be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see Section 5.1.3, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

You can force MySQL to start using new log files by issuing a `FLUSH LOGS` statement or executing `mysqladmin flush-logs` or `mysqladmin refresh`. See Section 12.5.7.3, “FLUSH Syntax”, and Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”.

A log flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was given an error log file name with the `--log-error` option, it renames the error log with the suffix `-old` and creates a new empty error log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current logs before flushing them. At flush time, the server will open new logs with the original names. For example, if the general and slow query logs are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

At this point, you can make a backup of `mysql.old` and `mysql-slow.log` and then remove them from disk.

On Windows, you can rename the general query log or slow query log while the server has it open. You cannot rename the error log file while the server has it open. You must stop the server and rename the file, and then restart the server to create a new log file. However, a stop and restart can be avoided by using `FLUSH LOGS`, which causes the server to rename the error log with an `-old` suffix and open a new error log.

You can disable the general query log or slow query log at runtime:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

5.3. General Security Issues

This section describes some general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 5.4, “The MySQL Access Privilege System”.

For answers to some questions that are often asked about MySQL Server security issues, see Section A.9, “MySQL 6.0 FAQ — Security”.

5.3.1. General Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, we emphasize the necessity of fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines whenever possible:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn the MySQL access privilege system. The `GRANT` and `REVOKE` statements are used for controlling access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

  Checklist:

  - Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See Section 2.10.3, “Securing the Initial MySQL Accounts”.
  - Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store any plain-text passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `MD5()`, `SHA1()`, or some other one-way hashing function and store the hash value.
- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Mary had a little lamb” results in a password of “Mhall”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

  Checklist:

  - Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. Another simple way to check whether or not your MySQL port is open is to try the following command from some remote machine, where *`server_host`* is the host name or IP number of the host on which your MySQL server runs:

    ```
    shell> telnet server_host 3306
    ```

    If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open. If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be.
- Do not trust any data entered by users of your applications. They can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “`; DROP DATABASE mysql;`”. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotes around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing non-numeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is allowable to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Try to enter single and double quote marks ("`'`" and "`"`") in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` ("`"`"), `%23` ("#"), and `%27` ("`'`") to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

- Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:
  - MySQL C API: Use the `mysql_real_escape_string()` API call.
  - MySQL++: Use the `escape` and `quote` modifiers for query streams.
  - PHP: Use the `mysql_real_escape_string()` function (available as of PHP 4.3.0, prior to that PHP version use `mysql_escape_string()`, and prior to PHP 4.0.3, use `addslashes()`). Note that only `mysql_real_escape_string()` is character set-aware; the other functions can be "bypassed" when using (invalid) multi-byte character sets. In PHP 5, you can use the `mysqli` extension, which supports the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders.
  - Perl DBI: Use placeholders or the `quote()` method.
  - Ruby DBI: Use placeholders or the `quote()` method.
  - Java JDBC: Use a `PreparedStatement` object and placeholders.

  Other programming interfaces might have similar capabilities.
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections as of version 4.0. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

> **Warning**
>
> If you do not see plaintext data, this does not always mean that the information actually is encrypted. If you need high security, you should consult with a security expert.

5.3.2. Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 5.5.6.3, “Password Hashing in MySQL”, for a discussion of the different password handling methods.)

> **MySQL Enterprise**
> The MySQL Enterprise Monitor enforces best practices for maximizing the security of your servers. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Section 5.5.7, “Using SSL for Secure Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at http://www.openssh.org/, and a commercial SSH client at http://www.ssh.com/.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 5.5.5, “Assigning Account Passwords”.

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

  `mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

  ```
  [mysqld]
  user=mysql
  ```

  This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section 5.3.5, “How to Run MySQL as a Normal User”.

  Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not allow the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 7.6.1.2, “Using Symbolic Links for Tables on Unix”.

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.

- Do not grant the `PROCESS` or `SUPER` privilege to non-administrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is allowed to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

  `mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

  The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not grant the `FILE` privilege to non-administrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. To make this a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

  The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs

as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

- If you do not trust your DNS, you should use IP numbers rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections allowed to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use allowed to an account. See Section 12.5.1.3, "`GRANT` Syntax".

5.3.3. Security-Related `mysqld` Options

The following `mysqld` options affect security:

Table 5.4. `mysqld` Security Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
allow-suspicious-udfs	Yes	Yes				
automatic_sp_privileges			Yes		Global	Yes
chroot	Yes	Yes				
des-key-file	Yes	Yes				
local_infile			Yes		Global	Yes
local-infile	Yes	Yes				
- *Variable*: local_infile						
old-passwords	Yes	Yes			Both	Yes
- *Variable*: old_passwords			Yes		Both	Yes
safe-show-database	Yes	Yes	Yes		Global	Yes
safe-user-create	Yes	Yes				
secure-auth	Yes	Yes			Global	Yes
- *Variable*: secure_auth			Yes		Global	Yes
secure-backup-file-priv	Yes	Yes			Global	No
- *Variable*: secure_backup_file_priv			Yes		Global	No
secure-file-priv	Yes	Yes			Global	No
- *Variable*: secure_file_priv			Yes		Global	No
skip-grant-tables	Yes	Yes				
skip-name-resolve	Yes	Yes				
skip-networking	Yes	Yes			Global	No
- *Variable*: skip_networking			Yes		Global	No
skip-show-database	Yes	Yes			Global	No
- *Variable*: skip_show_database			Yes		Global	No

- `--allow-suspicious-udfs`

  This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See Section 21.3.2.6, "User-Defined Function Security Precautions".

- `--local-infile[={0|1}]`

  If you start the server with `--local-infile=0`, clients cannot use `LOCAL` in `LOAD DATA` statements. See Section 5.3.4, "Security Issues with `LOAD DATA LOCAL`".

- `--old-passwords`

Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.5.6.3, “Password Hashing in MySQL”.

> **MySQL Enterprise**
> The MySQL Enterprise Monitor offers advice on the security implications of using this option. For subscription information, see http://www.mysql.com/products/enterprise/advisors.html.

- `--safe-show-database` (*OBSOLETE*)

  In previous versions of MySQL, this option caused the `SHOW DATABASES` statement to display the names of only those databases for which the user had some kind of privilege. In MySQL 6.0, this option is no longer available as this is now the default behavior, and there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See Section 12.5.1.3, “`GRANT` Syntax”.

- `--safe-user-create`

  If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

  ```
  GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
  ```

  This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

  Disallow authentication for accounts that have old (pre-4.1) passwords.

  The `mysql` client also has a `--secure-auth` option, which prevents connections to a server if the server requires a password in old format for the client account.

- `--secure-backup-file-priv=path`

Command Line Format	`--secure-backup-file-priv`	
Config File Format	`secure-backup-file-priv`	
Option Sets Variable	Yes, `secure_backup_file_priv`	
Variable Name	`secure_backup_file_priv`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

  This option limits the effect of the `BACKUP DATABASE` and `RESTORE` statements to work only with files in the specified directory. This option was added in MySQL 6.0.11; in older releases, use `--secure-file-priv` instead.

- `--secure-file-priv=path`

Command Line Format	`--secure-file-priv`	
Config File Format	`secure-file-priv`	
Option Sets Variable	Yes, `secure_file_priv`	
Variable Name	`secure_file_priv`	
Variable Scope	Global	
Dynamic Variable	No	
Value Set	**Type**	`string`

  This option limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory. Before MySQL 6.0.11, it also applies to the `BACKUP DATABASE` and `RESTORE` statements; as of 6.0.11, `--secure-backup-file-priv` applies to those statements.

- `--skip-grant-tables`

This option causes the server not to use the privilege system at all. This gives anyone with access to the server *unrestricted access* to *all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement. This option also suppresses loading of plugins and user-defined functions (UDFs).

- `--skip-name-resolve`

  Host names are not resolved. All `Host` column values in the grant tables must be IP numbers or `localhost`.

- `--skip-networking`

  Do not allow TCP/IP connections over the network. All connections to `mysqld` must be made via Unix socket files.

- `--skip-show-database`

  With this option, the `SHOW DATABASES` statement is allowed only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. Without this option, `SHOW DATABASES` is allowed to all users, but displays each database name only if the user has the `SHOW DATABASES` privilege or some privilege for the database. Note that any global privilege is a privilege for the database.

- `--ssl*`

  Options that begin with `--ssl` specify whether to allow clients to connect via SSL and indicate where to find SSL keys and certificates. See Section 5.5.7.3, “SSL Command Options”.

5.3.4. Security Issues with `LOAD DATA LOCAL`

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `--enable-local-infile` option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke `configure` with the `--enable-local-infile` option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See Section 20.10.3.49, “mysql_options()”.
- You can disable all `LOAD DATA LOCAL` commands from the server side by starting `mysqld` with the `--local-infile=0` option.
- For the `mysql` command-line client, enable `LOAD DATA LOCAL` by specifying the `--local-infile[=1]` option, or disable it with the `--local-infile=0` option. For `mysqlimport`, local data file loading is off by default; enable it with the `--local` or `-L` option. In any case, successful use of a local load operation requires that the server is enabled to allow it.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives

the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

MySQL Enterprise
Security advisors notify subscribers to the MySQL Enterprise Monitor whenever a server is started with the `--local-infile` option enabled. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

5.3.5. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user *`user_name`*, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that *`user_name`* has privileges to read and write files in them (you might need to do this as the Unix `root` user):

   ```
   shell> chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server will not be able to access databases or tables when it runs as *`user_name`*.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.
3. Start the server as user *`user_name`*. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=`*`user_name`* option. `mysqld` starts up, then switches to run as the Unix user *`user_name`* before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

   ```
   [mysqld]
   user=user_name
   ```

If your Unix machine itself isn't secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10, “Post-Installation Setup and Testing”.

5.4. The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See Section 12.5.1, “Account Management Statements”.

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations allowed to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by allowing you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

Stage 1: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see Section 5.4.4, “Access Control, Stage 1: Connection Verification”, and Section 5.4.5, “Access Control, Stage 2: Request Verification”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 5.4.6, “When Privilege Changes Take Effect”.

For general security-related advice, see Section 5.3, “General Security Issues”. For help in diagnosing privilege-related problems, see Section 5.4.7, “Causes of Access-Denied Errors”.

5.4.1. Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the `user`, `db`, `host`, `tables_priv`, `columns_priv`, and `procs_priv` tables in the `mysql` database (see Section 5.4.2, “Privilege System Grant Tables”). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in Section 5.4.6, “When Privilege Changes Take Effect”. Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new access privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

The following table shows the privilege names used at the SQL level in the `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

Privilege	Column	Context
`CREATE`	`Create_priv`	databases, tables, or indexes
`DROP`	`Drop_priv`	databases or tables

GRANT OPTION	Grant_priv	databases, tables, or stored routines
REFERENCES	References_priv	databases or tables
EVENT	Event_priv	databases
ALTER	Alter_priv	tables
DELETE	Delete_priv	tables
INDEX	Index_priv	tables
INSERT	Insert_priv	tables
SELECT	Select_priv	tables
UPDATE	Update_priv	tables
CREATE TEMPORARY TABLES	Create_tmp_table_priv	tables
LOCK TABLES	Lock_tables_priv	tables
TRIGGER	Trigger_priv	tables
CREATE VIEW	Create_view_priv	views
SHOW VIEW	Show_view_priv	views
ALTER ROUTINE	Alter_routine_priv	stored routines
CREATE ROUTINE	Create_routine_priv	stored routines
EXECUTE	Execute_priv	stored routines
FILE	File_priv	file access on server host
CREATE TABLESPACE	Create_tablespace_priv	server administration
CREATE USER	Create_user_priv	server administration
PROCESS	Process_priv	server administration
RELOAD	Reload_priv	server administration
REPLICATION CLIENT	Repl_client_priv	server administration
REPLICATION SLAVE	Repl_slave_priv	server administration
SHOW DATABASES	Show_db_priv	server administration
SHUTDOWN	Shutdown_priv	server administration
SUPER	Super_priv	server administration
ALL [PRIVILEGES]		server administration
USAGE		server administration

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The ALL or ALL PRIVILEGES privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except GRANT OPTION). For example, granting ALL at the global or table level grants all global privileges or all table-level privileges.
- The ALTER privilege enables use of ALTER TABLE to change the structure of or rename tables. (ALTER TABLE also requires the INSERT and CREATE privileges.)

  MySQL Enterprise
  In some circumstances, the ALTER privilege is entirely unnecessary — on slaves where there are no non-replicated tables, for instance. The MySQL Enterprise Monitor notifies subscribers when accounts have inappropriate privileges. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- The ALTER ROUTINE privilege is needed to alter or drop stored routines (procedures and functions).
- The CREATE privilege enables creation of new databases and tables.
- The CREATE ROUTINE privilege is needed to create stored routines (procedures and functions).
- The CREATE TABLESPACE privilege is needed to create, alter, or drop tablespaces and log file groups. This privilege was added in MySQL 6.0.7.
- The CREATE TEMPORARY TABLES privilege enables the use of the keyword TEMPORARY in CREATE TABLE statements.

- The `CREATE USER` privilege enables use of `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`.
- The `CREATE VIEW` privilege enables use of `CREATE VIEW`.
- The `DELETE` privilege enables rows to be deleted from tables in a database.
- The `DROP` privilege enables you to drop (remove) existing databases, tables, and views. The `DROP` privilege is required in order to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`. *If you grant the `DROP` privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored.*
- The `EVENT` privilege is required to create, alter, or drop events for the Event Scheduler.
- The `EXECUTE` privilege is required to execute stored routines (procedures and functions).
- The `FILE` privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` privilege also enables the user to create new files in any directory where the MySQL server has write access. As a security measure, the server will not overwrite existing files.
- The `GRANT OPTION` privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The `INDEX` privilege enables you to create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.
- The `INSERT` privilege enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.
- The `LOCK TABLES` privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.
- The `PROCESS` privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads.
- The `REFERENCES` privilege currently is unused.
- The `RELOAD` privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

  The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.
- The `REPLICATION CLIENT` privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.
- The `REPLICATION SLAVE` privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.
- The `SELECT` privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

- The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that *any* global privilege is a privilege for the database.

> **MySQL Enterprise**
> The `SHOW DATABASES` privilege should be granted only to users who need to see all the databases on a MySQL server. Subscribers to the MySQL Enterprise Monitor are alerted when servers are started without

> the `--skip-show-database` option. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- The `SHOW VIEW` privilege enables use of `SHOW CREATE VIEW`.
- The `SHUTDOWN` privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.
- The `SUPER` privilege enables use of `CHANGE MASTER TO`, `KILL` or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), `PURGE BINARY LOGS`, and `SET GLOBAL` statements, the `mysqladmin debug` command, and allows you to connect (once) even if the connection limit controlled by the `max_connections` system variable is reached.

  To create or alter stored functions if binary logging is enabled, you may also need the `SUPER` privilege, as described in Section 18.6, “Binary Logging of Stored Programs”.
- The `TRIGGER` privilege enables you to create and drop triggers. You must have this privilege for a table to create or drop triggers for that table.
- The `UPDATE` privilege enables rows to be updated in tables in a database.
- The `USAGE` privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- The `FILE` privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- The `GRANT OPTION` privilege enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.
- The `ALTER` privilege may be used to subvert the privilege system by renaming tables.
- The `SHUTDOWN` privilege can be abused to deny service to other users entirely by terminating the server.
- The `PROCESS` privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The `SUPER` privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `user` table `Password` column can change an account's password, and then connect to the MySQL server using that account.

> **MySQL Enterprise**
> Accounts with unnecessary global privileges constitute a security risk. Subscribers to the MySQL Enterprise Monitor are automatically alerted to the existence of such accounts. For detailed information, see http://www.mysql.com/products/enterprise/advisors.html.

5.4.2. Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables indirectly by using statements such as `GRANT` and `REVOKE` to set up accounts and control the privileges available to each one. See Section 12.5.1, “Account Management Statements”. The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'thomas.loc.gov'` and `'bob'` would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'thomas.loc.gov'`, `'bob'` and `'reports'` would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv`

scope columns indicate the stored routine to which each row applies.

- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 5.4.5, “Access Control, Stage 2: Request Verification”, describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or allow incoming connections. For allowed connections, any privileges granted in the `user` table indicate the user's global (superuser) privileges. Any privilege granted in this table applies to *all* databases on the server.

  > **Note**
  >
  > Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are allowed. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

- The `host` table is used in conjunction with the `db` table when you want a given `db` table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the `Host` value empty in the user's `db` table row, then populate the `host` table with a row for each of those hosts. This mechanism is described more detail in Section 5.4.5, “Access Control, Stage 2: Request Verification”.

  > **Note**
  >
  > The `host` table must be modified directly with statements such as `INSERT`, `UPDATE`, and `DELETE`. It is not affected by statements such as `GRANT` and `REVOKE` that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The `procs_priv` table applies to stored routines. A privilege granted at the routine level applies only to a single routine.

The server uses the `user`, `db`, and `host` tables in the `mysql` database at both the first and second stages of access control (see Section 5.4, “The MySQL Access Privilege System”). The columns in the `user` and `db` tables are shown here. The `host` table is similar to the `db` table but has a specialized use as described in Section 5.4.5, “Access Control, Stage 2: Request Verification”.

Table Name	user	db
Scope columns	`Host`	`Host`
	`User`	`Db`
	`Password`	`User`
Privilege columns	`Select_priv`	`Select_priv`
	`Insert_priv`	`Insert_priv`
	`Update_priv`	`Update_priv`
	`Delete_priv`	`Delete_priv`
	`Index_priv`	`Index_priv`
	`Alter_priv`	`Alter_priv`
	`Create_priv`	`Create_priv`
	`Drop_priv`	`Drop_priv`
	`Grant_priv`	`Grant_priv`
	`Create_view_priv`	`Create_view_priv`
	`Show_view_priv`	`Show_view_priv`
	`Create_routine_priv`	`Create_routine_priv`
	`Alter_routine_priv`	`Alter_routine_priv`
	`Execute_priv`	`Execute_priv`

	Trigger_priv	Trigger_priv
	Event_priv	Event_priv
	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv
	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
	Create_tablespace_priv	
Security columns	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
Resource control columns	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

The Create_tablespace_priv column was added in MySQL 6.0.7.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the user, db, and host grant tables, the server may also consult the tables_priv and columns_priv tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table Name	tables_priv	columns_priv
Scope columns	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
Privilege columns	Table_priv	Column_priv
	Column_priv	
Other columns	Timestamp	Timestamp
	Grantor	

The Timestamp and Grantor columns currently are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the procs_priv table, which has the columns shown in the following table.

Table Name	procs_priv
Scope columns	Host
	Db
	User
	Routine_name

	`Routine_type`
Privilege columns	`Proc_priv`
Other columns	`Timestamp`
	`Grantor`

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

Column Name	Type
`Host`	`CHAR(60)`
`User`	`CHAR(16)`
`Password`	`CHAR(41)`
`Db`	`CHAR(64)`
`Table_name`	`CHAR(64)`
`Column_name`	`CHAR(64)`
`Routine_name`	`CHAR(64)`

For access-checking purposes, comparisons of `User`, `Password`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host`, `Column_name`, and `Routine_name` values are not case sensitive.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N','Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table Name	Column Name	Possible Set Elements
`tables_priv`	`Table_priv`	`'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'`
`tables_priv`	`Column_priv`	`'Select', 'Insert', 'Update', 'References'`
`columns_priv`	`Column_priv`	`'Select', 'Insert', 'Update', 'References'`
`procs_priv`	`Proc_priv`	`'Execute', 'Alter Routine', 'Grant'`

Administrative privileges (such as `RELOAD` or `SHUTDOWN`) are specified only in the `user` table. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, to determine whether you can perform an administrative operation, the server need consult only the `user` table.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The `mysqld` server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in Section 5.4.6, “When Privilege Changes Take Effect”.

When you modify an account's privileges, it is a good idea to verify that the changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement (see Section 12.5.6.22, “SHOW GRANTS Syntax”). For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

5.4.3. Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

Within SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names are written using the following rules:

- Syntax for account names is *`'user_name'@'host_name'`*.
- An account name consisting only of a user name is equivalent to *`'user_name'@'%'`*. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a *`user_name`* string containing special characters (such as "`-`"), or a *`host_name`* string containing special characters or wildcard characters (such as "`%`"); for example, `'test-user'@'%.com'`.
- Quote user names and host names as identifiers or as strings, using either backticks ("`` ` ``"), single quotes ("`'`"), or double quotes ("`"`").
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`; the latter is interpreted as `'me@localhost'@'%'`.

Account names are stored in grant tables using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. Another column, `Password`, stores the account password. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.

For additional detail about grant table structure, see Section 5.4.2, "Privilege System Grant Tables".

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a non-blank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `''@'localhost'`.

The host part of an account name can take many forms, and wildcards are allowed:

- A host value can be a host name or an IP number. `'localhost'` indicates the local host. `'127.0.0.1'` indicates the loopback interface.
- You can use the wildcard characters "`%`" and "`_`" in host values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of `'%'` matches any host name, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain. `'192.168.1.%'` matches any host in the 192.168.1 class C network.

  Because you can use IP wildcard values in host values (for example, `'192.168.1.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP numbers, not host names.

  > **MySQL Enterprise**
  > An overly broad host specifier such as "`%`" constitutes a security risk. The MySQL Enterprise Monitor provides safeguards against this kind of vulnerability. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- For host values specified as IP numbers, you can specify a netmask indicating how many address bits to use for the network number. The syntax is *`host_ip/netmask`*. For example:

  ```
  CREATE USER 'david'@'192.58.197.0/255.255.255.0';
  ```

  This enables `david` to connect from any client host having an IP number *`client_ip`* for which the following condition is

true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP numbers that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to `192.58.197.255`.

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- `192.0.0.0/255.0.0.0`: anything on the 192 class A network
- `192.168.0.0/255.255.0.0`: anything on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: anything on the 192.168.1 class C network
- `192.168.1.1`: only this specific IP

The following netmask (28 bits) will not work:

```
192.168.0.1/255.255.255.240
```

5.4.4. Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for allowable `Host` and `User` values are given in Section 5.4.3, “Specifying Account Names”.

If the `User` column value is non-blank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password.

Non-blank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. (This is done without the encrypted password ever traveling over the connection.) See Section 5.5.1, “User Names and Passwords”.

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give non-administrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

`Host` Value	`User` Value	Allowable Connections
`'thomas.loc.gov'`	`'fred'`	`fred`, connecting from `thomas.loc.gov`
`'thomas.loc.gov'`	`''`	Any user, connecting from `thomas.loc.gov`
`'%'`	`'fred'`	`fred`, connecting from any host

'%'	''	Any user, connecting from any host
'%.loc.gov'	'fred'	fred, connecting from any host in the loc.gov domain
'x.y.%'	'fred'	fred, connecting from x.y.net, x.y.com, x.y.edu, and so on; this is probably not useful
'144.155.166.177'	'fred'	fred, connecting from the host with IP address 144.155.166.177
'144.155.166.%'	'fred'	fred, connecting from any host in the 144.155.166 class C subnet
'144.155.166.0/255.255.255.0'	'fred'	Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the user table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from thomas.loc.gov by fred.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the user table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

To see how this works, suppose that the user table looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| %         | root     | ...
| %         | jeffrey  | ...
| localhost | root     | ...
| localhost |          | ...
+-----------+----------+-
```

When the server reads the table into memory, it orders the rows with the most-specific Host values first. Literal host names and IP numbers are the most specific. (The specificity if a literal IP number is not affected by whether it has a netmask, so 192.168.1.13 and 192.168.1.0/255.255.255.0 are considered equally specific.) The pattern '%' means “any host” and is least specific. Rows with the same Host value are ordered with the most-specific User values first (a blank User value means “any user” and is least specific). For the user table just shown, the result after sorting looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| localhost | root     | ...
| localhost |          | ...
| %         | jeffrey  | ...
| %         | root     | ...
+-----------+----------+-
```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from localhost by jeffrey, two of the rows from the table match: the one with Host and User values of 'localhost' and '', and the one with values of '%' and 'jeffrey'. The 'localhost' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the user table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| %              | jeffrey  | ...
| thomas.loc.gov |          | ...
+----------------+----------+-
```

The sorted table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| thomas.loc.gov |          | ...
| %              | jeffrey  | ...
+----------------+----------+-
```

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

> **Note**
>
> It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Section 11.11.3, "Information Functions".) It returns a value in *`user_name@host_name`* format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
+----------------+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

5.4.5. Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue via that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to Section 5.4.2, "Privilege System Grant Tables", which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! In other words, `user` table privileges are superuser privileges. It is wise to grant privileges in the `user` table only to superusers such as database administrators. For other users, you should leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- A blank `User` value in the `db` table matches the anonymous user. A non-blank value matches literally; there are no wildcards in user names.
- The wildcard characters "`%`" and "`_`" can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character ("`_`") as part of a database name, specify it as "`\_`" in the `GRANT` statement.
- A `'%'` `Host` value in the `db` table means "any host." A blank `Host` value in the `db` table means "consult the `host` table for further information" (a process that is described later in this section).
- A `'%'` or blank `Host` value in the `host` table means "any host."
- A `'%'` or blank `Db` value in either table means "any database."

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters “%” and “_” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A `'%'` or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row allows the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row doesn't grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global (superuser) privileges by looking in the `user` table row. If the row allows the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.
2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the user's database-specific privileges.
3. If the matching `db` table row's `Host` column is blank, it signifies that the `host` table enumerates which hosts should be allowed access to the database. In this case, a further lookup is done in the `host` table to find a match on the `Host` and `Db` columns. If no `host` table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the `db` and `host` table entries; that is, the privileges that are `'Y'` in both entries. (This way you can grant general privileges in the `db` table row and then selectively restrict them on a host-by-host basis using the `host` table entries.)

After determining the database-specific privileges granted by the `db` and `host` table entries, the server adds them to the global privileges granted by the `user` table. If the result allows the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and allows or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The `host` table is not affected by the `GRANT` or `REVOKE` statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers on the local network that are granted all privileges.

You can also use the `host` table to indicate hosts that are *not* secure. Suppose that you have a machine `public.your.domain` that is located in a public area that you do not consider secure. You can enable access to all hosts on your network except that machine by using `host` table entries like this:

```
+--------------------+----+-
| Host               | Db | ...
+--------------------+----+-
| public.your.domain | %  | ... (all privileges set to 'N')
| %.your.domain      | %  | ... (all privileges set to 'Y')
+--------------------+----+-
```

5.4.6. When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, or `SET PASSWORD`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes do not seem to make any difference!

To tell the sever to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

When the server reloads the grant tables, privileges for each existing client connection are affected as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

  Note

  Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.
- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Anyone can connect and do anything. To cause a server thus started to read the tables and enable access checking, flush the privileges.

5.4.7. Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database con-

taining the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see Section 2.10.2, "Unix Post-Installation Procedures".

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see Section 2.10.3, "Securing the Initial MySQL Accounts".

> **MySQL Enterprise**
> The MySQL Enterprise Monitor enforces security-related best practices. For example, subscribers are alerted whenever there is any account without a password. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 4.4.8, "`mysql_upgrade` — Check Tables for MySQL Upgrade".

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 5.5.6.3, "Password Hashing in MySQL", and Section B.1.2.4, "`Client does not support authentication protocol`".

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Section 4.2.3.2, "Using Option Files". Environment variables are listed in Section 2.13, "Environment Variables".

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see Section 5.5.5, "Assigning Account Passwords".

If you have lost or forgotten the `root` password, see Section B.1.4.1, "How to Reset the Root Password".

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See Section 5.5.5, “Assigning Account Passwords”, and Section 12.5.1.1, “`CREATE USER` Syntax”.

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

  To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.

- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

  ```
  SELECT * FROM user;
  ```

  The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

  ```
  Host ... is not allowed to connect to this MySQL server
  ```

  You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

  If you do not know the IP number or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it allows connections from any host for the given user name.

  On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP number, it means that the MySQL server got an error when trying to resolve the IP number of the client host to a name:

  ```
  shell> mysqladmin -u root -pxxxx -h some_hostname ver
  Access denied for user 'root'@'' (using password: YES)
  ```

  If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

  ```
  Access denied for user ''@'unknown'
  ```

  These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host name cache. See Section 7.5.11, “How MySQL Uses DNS”.

  Some permanent solutions are:

  - Determine what is wrong with your DNS server and fix it.
  - Specify IP numbers rather than host names in the MySQL grant tables.
  - Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.

  - Start `mysqld` with the `--skip-name-resolve` option.
  - Start `mysqld` with the `--skip-host-cache` option.
  - On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
  - On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.

- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where *`your_hostname`* is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host `'pluto'` in the `user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the entry does not work. Try adding an entry to the `user` table that contains the IP number of your host as the `Host` column value. (Alternatively, you could add an entry to the `user` table with a `Host` value that contains a wildcard; for example, `'pluto.%'`. However, use of `Host` values ending with "`%`" is *insecure* and is *not* recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named *`other_db`*.

- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

- If you cannot figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain `'%'` or `'_'` characters). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this allows you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also Section 5.4.4, "Access Control, Stage 1: Connection Verification".

- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your account does not have the `FILE` privilege.

- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` command, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 5.4.6, "When Privilege Changes Take Effect".

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)

- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

- If you get the following error, you may have a problem with the `db` or `host` table:

```
Access to database denied
```

  If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to. This problem occurs infrequently because the `host` table is rarely used.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See MySQL Internals: Porting.
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.6, "How to Report Bugs or Problems". In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

5.5. MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also Section 12.5.1, "Account Management Statements", which describes the syntax and use for all user-management SQL statements.

5.5.1. User Names and Passwords

A MySQL account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account also has a password. There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs allow any user name to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

  > **Warning**
  >
  > The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.
  >
  > You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in Section 4.4.8, "`mysql_upgrade` — Check Tables for MySQL Upgrade". Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior.

- MySQL passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.
- MySQL encrypts passwords using its own algorithm. This encryption is the same as that implemented by the `PASSWORD()` SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the `ENCRYPT()` SQL function. See the descriptions of the `PASSWORD()` and `ENCRYPT()` functions in Section 11.11.2, "Encryption and Compression Functions".

  From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.) Section 5.5.6.3, "Password Hashing in MySQL", discusses password encryp-

tion further.

When you install MySQL, the grant tables are populated with an initial set of accounts. These accounts have names and access privileges that are described in Section 2.10.3, “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `GRANT` and `REVOKE`. See Section 12.5.1, “Account Management Statements”.

When you connect to a MySQL server with a command-line client, you should specify the user name and password for the account that you want to use:

```
shell> mysql --user=monty --password=guess db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -pguess db_name
```

There must be *no space* between the `-p` option and the following password value. For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.2, “Connecting to the MySQL Server”.

5.5.2. Adding User Accounts

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as `CREATE USER` or `GRANT`. These statements cause the server to make appropriate modifications to the grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use account-creation statements because they are more concise and less error-prone than manipulating the grant tables directly. `CREATE USER` and `GRANT` are described in Section 12.5.1, “Account Management Statements”.

Another option for creating accounts is to use one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in Section 2.10.3, “Securing the Initial MySQL Accounts”. This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` privilege for the `mysql` database and the `RELOAD` administrative privilege.

As noted in the examples where appropriate, some of the statements will fail if the server's SQL mode has been set to enable certain restrictions. In particular, strict mode (`STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`) and `NO_AUTO_CREATE_USER` will prevent the server from accepting some of the statements. Workarounds are indicated for these cases. For more information about SQL modes and their effect on grant table manipulation, see Section 5.1.7, “Server SQL Modes”, and Section 12.5.1.3, “`GRANT` Syntax”.

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you'll also need to supply a `--password` or `-p` option, both for this `mysql` command and for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> CREATE USER 'monty'@'localhost' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
    ->     WITH GRANT OPTION;
mysql> CREATE USER 'monty'@'%' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
    ->     WITH GRANT OPTION;
mysql> CREATE USER 'admin'@'localhost';
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> CREATE USER 'dummy'@'localhost';
```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. The `'monty'@'localhost'` account can be used only when connecting from the local host. The `'monty'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

  It is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in Section 5.4.4, "Access Control, Stage 1: Connection Verification".)

- The `'admin'@'localhost'` account has no password. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges allow the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist` . No privileges are granted for accessing any databases. You could add such privileges later by issuing additional `GRANT` statements.

- The `'dummy'@'localhost'` account has no password. This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account later.

The statements that create accounts with no password will fail if the `NO_AUTO_CREATE_USER` SQL mode is enabled. To deal with this, use an `IDENTIFIED BY` clause that specifies a non-empty password.

To check the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----------------------------------------------------+
| Grants for admin@localhost                          |
+-----------------------------------------------------+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

As an alternative to `CREATE USER` and `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables using `FLUSH PRIVILEGES`:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
    ->     VALUES('localhost','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
    ->     VALUES('%','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
    ->     '','','','',0,0,0,0);
mysql> INSERT INTO user SET Host='localhost',User='admin',
    ->     Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

When you create accounts with `INSERT`, it is necessary to use `FLUSH PRIVILEGES` to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `CREATE USER`, `FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD()` function with `INSERT` is to encrypt the password. The `CREATE USER` statement encrypts the password for you, so `PASSWORD()` is unnecessary.

The `'Y'` values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of `'Y'` values in the first two `INSERT` statements. The `INSERT` statement for the `admin` account employs the more readable extended `INSERT` syntax using `SET`.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of `'N'`. This is equivalent to what `CREATE USER` does.

If strict SQL mode is enabled, all columns that have no default value must have a value specified. In this case, `INSERT` statements must explicitly specify values for the `ssl_cipher`, `x509_issuer`, and `x509_subject` columns.

To set up a superuser account, it is necessary only to create a `user` table entry with the privilege columns set to `'Y'`. The `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of `custom` and password of `obscure`.

To create the accounts with `CREATE USER` and `GRANT`, use the following statements:

```
shell> mysql --user=root mysql
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON bankaccount.*
    ->     TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON expenses.*
    ->     TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'server.domain' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON customer.*
    ->     TO 'custom'@'server.domain';
```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.
- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('localhost','bankaccount','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('host47.example.com','expenses','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('server.domain','customer','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three `INSERT` statements add `user` table entries that allow the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of `'N'`). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, `mydomain.com`), you can use the "`%`" wildcard character in the host part of the account name:

```
mysql> CREATE USER 'myname'@'%.mydomain.com' IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
    ->     VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

5.5.3. Removing User Accounts

To remove an account, use the `DROP USER` statement, which is described in Section 12.5.1.2, "`DROP USER` Syntax".

5.5.4. Limiting Account Resources

One means of limiting use of MySQL server resources is to set the `max_user_connections` system variable to a nonzero value. However, this limits only the number of simultaneous connections made using a single account, and not what a client can do once connected. In addition, this method is strictly global, and does not allow for management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 6.0, you can limit the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server an account can have

Any statement that a client can issue counts against the query limit. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a single row in the `user` table. That is, connections are assessed against the `User` and `Host` values in the `user` table row that applies to the connection. Suppose that there is a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to allow `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

The server limits account resources based on the resource-related columns of the `user` table in the `mysql` database: `max_questions`, `max_updates`, `max_connections`, and `max_user_connections`. If your `user` table does not have these columns, it must be upgraded; see Section 4.4.8, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

To set resource limits, use the `GRANT` statement and provide a `WITH` clause that names each resource to be limited. For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank';
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
    ->     WITH MAX_QUERIES_PER_HOUR 20
    ->          MAX_UPDATES_PER_HOUR 10
    ->          MAX_CONNECTIONS_PER_HOUR 5
    ->          MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. If the `GRANT` statement has no `WITH` clause, the limits are each set to the default value of zero (that is, no limit). For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections the account can make at any one time. If the limit is set to the default value of zero, the `max_user_connections` system variable determines the number of simultaneous connections for the account.

To modify limits for an existing account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->     WITH MAX_QUERIES_PER_HOUR 100;
```

This statement leaves the account's existing privileges unchanged and modifies only the limit values specified.

To remove an existing limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->     WITH MAX_CONNECTIONS_PER_HOUR 0;
```

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

Queries for which results are served from the query cache do not count against the MAX_QUERIES_PER_HOUR limit.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a FLUSH USER_RESOURCES statement. The counts also can be reset by reloading the grant tables (for example, with a FLUSH PRIVILEGES statement or a mysqladmin reload command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use GRANT USAGE as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the MAX_USER_CONNECTIONS limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

For the MAX_USER_CONNECTIONS limit, an edge case can occur if the account currently has open the maximum number of connections allowed to it: A disconnect followed quickly by a connect can result in an error (ER_TOO_MANY_USER_CONNECTIONS or ER_USER_LIMIT_REACHED) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be allowed.

5.5.5. Assigning Account Passwords

To assign a password when you create a new account with CREATE USER, include an IDENTIFIED BY clause:

```
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'biscuit';
```

To assign or change a password for an existing account, one way is to issue a SET PASSWORD statement:

```
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('biscuit');
```

Only users such as root that have update access to the mysql database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the FOR clause:

```
mysql> SET PASSWORD = PASSWORD('biscuit');
```

You can also use a GRANT USAGE statement at the global level (ON *.*) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost' IDENTIFIED BY 'biscuit';
```

Passwords can be assigned from the command line by using the mysqladmin command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command resets the password is the one with a user table row that matches *user_name* in the User column and the client host *from which you connect* in the Host column.

Although it is generally preferable to assign passwords using one of the preceding methods, you can also do so by modifying the user table directly:

- To establish a password when creating a new account, provide a value for the Password column:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
    -> VALUES('localhost','jeffrey',PASSWORD('biscuit'));
mysql> FLUSH PRIVILEGES;
```

- To change the password for an existing account, use UPDATE to set the Password column value:

```
shell> mysql -u root mysql
mysql> UPDATE user SET Password = PASSWORD('bagel')
    -> WHERE Host = 'localhost' AND User = 'francis';
mysql> FLUSH PRIVILEGES;
```

When you assign passwords using CREATE USER or GRANT with an IDENTIFIED BY clause or with the mysqladmin

`password` command, they take care of encrypting the password for you.

When you assign an account a non-empty password using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must use the `PASSWORD()` function to encrypt the password. `PASSWORD()` is necessary because the `user` table stores passwords in encrypted form, not as plaintext. If you forget that fact, you are likely to set passwords like this:

```
shell> mysql -u root mysql
mysql> INSERT INTO user (Host,User,Password)
    -> VALUES('localhost','jeffrey','biscuit');
mysql> FLUSH PRIVILEGES;
```

The result is that the literal value `'biscuit'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'biscuit'`, so the comparison fails and the server rejects the connection:

```
shell> mysql -u jeffrey -pbiscuit test
Access denied
```

> **Note**
>
> `PASSWORD()` encryption differs from Unix password encryption. See Section 5.5.1, “User Names and Passwords”.

5.5.6. Password Security in MySQL

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable administrators and end users to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally.

5.5.6.1. Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any non-administrative accounts.

Passwords can appear as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`. If these statements are logged by the MySQL server, the passwords become available to anyone with access to the logs. This applies to the general query log, the slow query log, and the binary log (see Section 5.2, “MySQL Server Logs”). To guard against unwarranted exposure to log files, they should be located in a directory that restricts access to only the server and the database administrator. If you log to tables in the `mysql` database, access to the tables should never be granted to any non-administrative accounts.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

5.5.6.2. End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use a `-p`*`your_pass`* or `--password=`*`your_pass`* option on the command line. For example:

  ```
  shell> mysql -u francis -pfrank db_name
  ```

  This is convenient *but insecure*, because your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

  If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

  ```
  shell> mysql -u francis -p db_name
  Enter password: ********
  ```

The "*" characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs non-interactively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

Section 4.2.3.2, "Using Option Files", discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See Section 2.13, "Environment Variables".

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. If you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see Section 4.5.1, "`mysql` — The MySQL Command-Line Tool"). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can appear as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

5.5.6.3. Password Hashing in MySQL

MySQL user accounts are listed in the `user` table of the `mysql` database. Each MySQL account is assigned a password, although what is stored in the `Password` column of the `user` table is not the plaintext version of the password, but a hash value computed from it. Password hash values are computed by the `PASSWORD()` function.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account that the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hashes for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using the `GRANT` or `SET PASSWORD` statements.

In other words, the server *uses* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a `GRANT` or `SET PASSWORD` statement to set or change a password.

The password hashing mechanism was updated in MySQL 4.1 to provide better security and to reduce the risk of passwords being intercepted. However, this new mechanism is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the old and new password hashing mechanisms. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 3.23 `mysql` client that attempts to connect to a 6.0 server may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

Another common example of this phenomenon occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See Section 20.11.5, "Common Problems with MySQL and PHP".)

The following discussion describes the differences between the old and new password mechanisms, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. Additional information can be found in Section B.1.2.4, “`Client does not support authentication protocol`”. This information is of particular importance to PHP programmers migrating MySQL databases from version 4.0 or lower to version 4.1 or higher.

> **Note**
>
> This discussion contrasts 4.1 behavior with pre-4.1 behavior, but the 4.1 behavior described here actually begins with 4.1.1. MySQL 4.1.0 is an “odd” release because it has a slightly different mechanism than that implemented in 4.1.1 and up. Differences between 4.1.0 and more recent versions are described further in MySQL 5.1 Reference Manual.

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` function are 16 bytes long. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+--------------------+
| PASSWORD('mypass') |
+--------------------+
| 6f8c114b58f2ce9e   |
+--------------------+
```

The `Password` column of the `user` table (in which these hashes are stored) also is 16 bytes long before MySQL 4.1.

As of MySQL 4.1, the `PASSWORD()` function has been modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                        |
+-------------------------------------------+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-------------------------------------------+
```

Accordingly, the `Password` column in the `user` table also must be 41 bytes long to store these values:

- If you perform a new installation of MySQL 6.0, the `Password` column is made 41 bytes long automatically.
- Upgrading from MySQL 4.1 (4.1.1 or later in the 4.1 series) to MySQL 6.0 should not give rise to any issues in this regard because both versions use the same password hashing mechanism. If you wish to upgrade an older release of MySQL to version 6.0, you should upgrade to version 4.1 first, then upgrade the 4.1 installation to 6.0.

A widened `Password` column can store password hashes in both the old and new formats. The format of any given password hash value can be determined two ways:

- The obvious difference is the length (16 bytes versus 41 bytes).
- A second difference is that password hashes in the new format always begin with a “`*`” character, whereas passwords in the old format never do.

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, although because they know only about the old hashing mechanism, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `--old-passwords` option. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and the `--old-passwords` option must not be given. These conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using `PASSWORD()`, `GRANT`, or `SET PASSWORD`. This is the behavior that occurs if you have upgraded to 4.1 but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, `PASSWORD()`, `GRANT`, and `SET PASSWORD` generate long hashes unless the server was started with the `--old-passwords` option. That option forces the server to generate short password hashes instead.

The purpose of the `--old-passwords` option is to enable you to maintain backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option doesn't affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that to occur, the account no longer could be used by pre-4.1 clients. Without the `--old-passwords` option, the following undesirable scenario is possible:

- An old client connects to an account that has a short password hash.
- The client changes its own password. Without `--old-passwords`, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the new hashing mechanism during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it, because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is dangerous to run a 4.1 or newer server without using the `--old-passwords` option. By running the server with `--old-passwords`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of the `--old-passwords` option is that any passwords you create or change use short hashes, even for 4.1 clients. Thus, you lose the additional security provided by long password hashes. If you want to create an account that has a long hash (for example, for use by 4.1 clients), you must do so while running the server without `--old-passwords`.

> **MySQL Enterprise**
> Subscribers to the MySQL Enterprise Monitor are automatically alerted whenever a server is running with the `--old-passwords` option. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

The following scenarios are possible for running a 4.1 or later server:

Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The `--old-passwords` option can be used but is superfluous because with a short `Password` column, the server generates only short password hashes anyway.

Scenario 2: Long `Password` column; server not started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made via `GRANT`, `PASSWORD()`, or `SET PASSWORD` results in the account being given a long password hash. From that point on, no pre-4.1 client can authenticate to that account until the client upgrades to 4.1.

To deal with this problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

Scenario 3: Long `Password` column; 4.1 or newer server started with `--old-passwords` option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes (but note that it is possible to create long hashes only when the server is started without `--old-passwords`).
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()`, `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, you cannot create accounts that have long password hashes, because the `--old-passwords` option prevents generation of long hashes. Also, if you create an account with a long hash before using the `--old-passwords` option, changing the account's password while `--old-passwords` is in effect results in the account being given a short password, causing it to lose the security benefits of a longer hash.

The disadvantages for these scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

In scenario 3, `--old-passwords` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes, and you cannot change them back to long hashes while `--old-passwords` is in effect.

5.5.6.4. Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA1()` or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided for generate short hashes in the old format. However, you should note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running under circumstances where it generates short hashes, `OLD_PASSWORD()` is available but is equivalent to `PASSWORD()`.

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see Section 20.11, “MySQL PHP API”.

5.5.7. Using SSL for Secure Connections

MySQL supports secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. For information on how to require users to use SSL connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in Section 12.5.1.3, “`GRANT` Syntax”.

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. Doing so would make the client/server protocol much slower. Encrypting data is a CPU-intensive operation that requires the computer to do additional work and can delay other MySQL tasks. For applications that require the security provided by encrypted connections, the extra computation is warranted.

MySQL allows encryption to be enabled on a per-connection basis. You can choose a normal unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

Secure connections are based on the OpenSSL API and are available through the MySQL C API. Replication uses the C API, so secure connections can be used between master and slave servers.

Another way to connect securely is from within an SSH connection to the MySQL server host. For an example, see Section 5.5.8, “Connecting to MySQL Remotely from Windows with SSH”.

5.5.7.1. Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. In fact, today's practice requires many additional security elements from encryption algorithms. They should resist many kind of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some company called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

If you need more information about SSL, X509, or encryption, use your favorite Internet search engine to search for the keywords in which you are interested.

5.5.7.2. Using SSL Connections

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or yaSSL and your version of MySQL must be built with SSL support.

To make it easier to use secure connections, MySQL is bundled with yaSSL. (MySQL and yaSSL employ the same licensing model, whereas OpenSSL uses an Apache-style license.) yaSSL support initially was available only for a few platforms, but now it is available on all MySQL platforms supported by Sun Microsystems, Inc.

To get secure connections to work with MySQL and SSL, you must do the following:

1. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, and you are going to use OpenSSL rather than the bundled yaSSL library, install OpenSSL if it has not already been installed. We have tested MySQL with OpenSSL 0.9.6. To obtain OpenSSL, visit http://www.openssl.org.

2. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, configure a MySQL

source distribution to use SSL. When you configure MySQL, invoke the `configure` script like this:

```
shell> ./configure --with-ssl
```

That configures the distribution to use the bundled yaSSL library. To use OpenSSL instead, specify the `--with-ssl` option with the path to the directory where the OpenSSL header files and libraries are located:

```
shell> ./configure --with-ssl=path
```

Note that yaSSL support on Unix platforms requires that either `/dev/urandom` or `/dev/random` be available to retrieve true random numbers. For additional information (especially regarding yaSSL on Solaris versions prior to 2.8 and HP-UX), see Bug#13164.

3. Make sure that the `user` in the `mysql` database includes the SSL-related columns (beginning with `ssl_` and `x509_`). If your `user` table does not have these columns, it must be upgraded; see Section 4.4.8, "`mysql_upgrade` — Check Tables for MySQL Upgrade".

4. To check whether a server binary is compiled with SSL support, invoke it with the `--ssl` option. An error will occur if the server does not support SSL:

   ```
   shell> mysqld --ssl --help
   060525 14:18:52 [ERROR] mysqld: unknown option '--ssl'
   ```

   To check whether a running `mysqld` server supports SSL, examine the value of the `have_ssl` system variable:

   ```
   mysql> SHOW VARIABLES LIKE 'have_ssl';
   +---------------+-------+
   | Variable_name | Value |
   +---------------+-------+
   | have_ssl      | YES   |
   +---------------+-------+
   ```

   If the value is `YES`, the server supports SSL connections. If the value is `DISABLED`, the server supports SSL connections but was not started with the appropriate `--ssl-xxx` options (described later in this section).

To enable SSL connections, the proper SSL-related options must be used (see Section 5.5.7.3, "SSL Command Options").

To start the MySQL server so that it allows clients to connect via SSL, use the options that identify the key and certificate files the server needs when establishing a secure connection:

```
shell> mysqld --ssl-ca=cacert.pem \
       --ssl-cert=server-cert.pem \
       --ssl-key=server-key.pem
```

- `--ssl-ca` identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` identifies the server private key.

To establish a secure connection to a MySQL server with SSL support, the options that a client must specify depend on the SSL requirements of the user account that the client uses. (See the discussion of the `REQUIRE` clause in Section 12.5.1.3, "`GRANT` Syntax".)

If the account has no special SSL requirements or was created using a `GRANT` statement that includes the `REQUIRE SSL` option, a client can connect securely by using just the `--ssl-ca` option:

```
shell> mysql --ssl-ca=cacert.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=cacert.pem \
       --ssl-cert=client-cert.pem \
       --ssl-key=client-key.pem
```

In other words, the options are similar to those used for the server. Note that the Certificate Authority certificate has to be the same.

A client can determine whether the current connection with the server uses SSL by checking the value of the `Ssl_cipher` status variable. The value of `Ssl_cipher` is non-empty if SSL is used, and empty otherwise. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+---------------+--------------------+
| Variable_name | Value              |
+---------------+--------------------+
| Ssl_cipher    | DHE-RSA-AES256-SHA |
+---------------+--------------------+
```

For the `mysql` client, you can use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL:                    Not in use
...
```

Or:

```
mysql> \s
...
SSL:                    Cipher in use is DHE-RSA-AES256-SHA
...
```

To establish a secure connection from within an application program, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See Section 20.10.3.67, “`mysql_ssl_set()`”. After the connection is established, you can use `mysql_get_ssl_cipher()` to determine whether SSL is in use. A non-`NULL` return value indicates a secure connection and names the SSL cipher used for encryption. A `NULL` return value indicates that SSL is not being used. See Section 20.10.3.33, “`mysql_get_ssl_cipher()`”.

5.5.7.3. SSL Command Options

The following list describes options that are used for specifying the use of SSL, certificate files, and key files. They can be given on the command line or in an option file. These options are not available unless MySQL has been built with SSL support. See Section 5.5.7.2, “Using SSL Connections”.

Table 5.5. `mysqld` SSL Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
have_openssl			Yes		Global	No
have_ssl			Yes		Global	No
skip-ssl	Yes	Yes				
ssl	Yes	Yes				
ssl-ca	Yes	Yes			Global	No
- *Variable*: ssl_ca			Yes		Global	No
ssl-capath	Yes	Yes			Global	No
- *Variable*: ssl_capath			Yes		Global	No
ssl-cert	Yes	Yes			Global	No
- *Variable*: ssl_cert			Yes		Global	No
ssl-cipher	Yes	Yes			Global	No
- *Variable*: ssl_cipher			Yes		Global	No
ssl-key	Yes	Yes			Global	No
- *Variable*: ssl_key			Yes		Global	No
ssl-verify-server-cert	Yes	Yes				

- `--ssl`

  For the server, this option specifies that the server allows SSL connections. For a client program, it allows the client to connect to the server using SSL. This option is not sufficient in itself to cause an SSL connection to be used. You must also specify the `--ssl-ca` option, and possibly the `--ssl-cert` and `--ssl-key` options.

This option is more often used in its opposite form to override any other SSL options and indicate that SSL should *not* be used. To do this, specify the option as `--skip-ssl` or `--ssl=0`.

Note that use of `--ssl` does not *require* an SSL connection. For example, if the server or client is compiled without SSL support, a normal unencrypted connection is used.

The secure way to require use of an SSL connection is to create an account on the server that includes a `REQUIRE SSL` clause in the `GRANT` statement. Then use that account to connect to the server, where both the server and the client have SSL support enabled.

The `REQUIRE` clause allows other SSL-related restrictions as well. The description of `REQUIRE` in Section 12.5.1.3, "`GRANT` Syntax", provides additional detail about which SSL command options may or must be specified by clients that connect using accounts that are created using the various `REQUIRE` options.

- `--ssl-ca=file_name`

  The path to a file that contains a list of trusted SSL CAs.

- `--ssl-capath=directory_name`

  The path to a directory that contains trusted SSL CA certificates in PEM format.

- `--ssl-cert=file_name`

  The name of the SSL certificate file to use for establishing a secure connection.

- `--ssl-cipher=cipher_list`

  A list of allowable ciphers to use for SSL encryption. For greatest portability, *`cipher_list`* should be a list of one or more cipher names, separated by colons. Examples:

  ```
  --ssl-cipher=AES128-SHA
  --ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
  ```

  This format is understood both by OpenSSL and yaSSL. OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at http://www.openssl.org/docs/apps/ciphers.html. However, this extended syntax will fail if used with a MySQL installation compiled against yaSSL.

  If no cipher in the list is supported, SSL connections will not work.

- `--ssl-key=file_name`

  The name of the SSL key file to use for establishing a secure connection.

- `--ssl-verify-server-cert`

  This option is available for client programs only, not the server. It causes the server's Common Name value in the certificate that the server sends to the client to be verified against the host name that the client uses for connecting to the server, and the connection is rejected if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

If you use SSL when establishing a client connection, you can tell the client not to authenticate the server certificate by specifying neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established via `GRANT` statements for the client, and it still uses any `--ssl-ca`/`--ssl-capath` values that were passed to server at startup time.

5.5.7.4. Setting Up SSL Certificates for MySQL

This section demonstrates how to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Following the third example, instructions are given for using the files to test SSL connections. You can also use the files as described in Section 5.5.7.2, "Using SSL Connections".

Example 1: Creating SSL files from the command line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to re-

spond to several prompts by the `openssl` commands. For testing, you can press Enter to all prompts. For production use, you should provide non-empty responses.

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

# Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 1000 \
         -key ca-key.pem > ca-cert.pem

# Create server certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
         -nodes -keyout server-key.pem > server-req.pem
shell> openssl x509 -req -in server-req.pem -days 1000 \
         -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > server-cert.pem

# Create client certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
         -nodes -keyout client-key.pem > client-req.pem
shell> openssl x509 -req -in client-req.pem -days 1000 \
         -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > client-cert.pem
```

Example 2: Creating SSL files using a script on Unix

Here is an example script that shows how to set up SSL certificates for MySQL:

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/cacert.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ................++++++
# .........++++++
# writing new private key to '/home/monty/openssl/private/cakey.pem'
# Enter PEM pass phrase:

Example 3: Creating SSL files on Windows

Download OpenSSL for Windows. An overview of available packages can be seen here: http://www.slproweb.com/products/Win32OpenSSL.html

Choose of the following packages, depending on your architecture (32-bit or 64-bit):

- Win32 OpenSSL v0.9.8j Light, available at: http://www.slproweb.com/download/Win32OpenSSL_Light-0_9_8j.exe
- Win64 OpenSSL v0.9.8j Light, available at: http://www.slproweb.com/download/Win64OpenSSL_Light-0_9_8j.exe

if a message occurs during setup indicating `'...critical component is missing: Microsoft Visual C++ 2008 Redistributables'`, cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at: http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF“isplaylang=en
- Visual C++ 2008 Redistributables (x64), available at: http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6“isplaylang=en

After installing the additional package, restart the OpenSSL setup.

During installation, leave the default `C:\OpenSSL` as the install path, and also leave the default option `'Copy OpenSSL DLL files to the Windows system directory'` selected.

When the installation has finished, add `C:\OpenSSL\bin` to the Windows System Path variable of your server:

- On the Windows desktop, right-click on the My Computer icon, and select Properties.
- Next select the Advanced tab from the SYSTEM PROPERTIES menu that appears, and click the ENVIRONMENT VARIABLES button.
- Under **SYSTEM VARIABLES**, select Path, and then click the EDIT button. The EDIT SYSTEM VARIABLE dialogue should appear.
- Add `';C:\OpenSSL\bin'` to the end (notice the semicolon).
- Press OK 3 times.
- Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \
```

```
C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding instructions might be slightly different.

After OpenSSL has been installed, use the instructions from Example 1 (shown earlier in this section), with the following changes:

- Change the follow Unix commands:

  ```
  # Create clean environment
  shell> rm -rf newcerts
  shell> mkdir newcerts && cd newcerts
  ```

  On Windows, use these commands instead:

  ```
  # Create clean environment
  shell> md c:\newcerts
  shell> cd c:\newcerts
  ```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.
- For references to `my.cnf` option files, substitute `my.ini` instead.

Testing SSL connections

To test SSL connections, start the server as follows, where `$DIR` is the path name to the directory where the sample `my.cnf` option file is located:

```
shell> mysqld --defaults-file=$DIR/my.cnf &
```

Then invoke a client program using the same option file:

```
shell> mysql --defaults-file=$DIR/my.cnf
```

If you have a MySQL source distribution, you can also test your setup by modifying the preceding `my.cnf` file to refer to the demonstration certificate and key files in the `mysql-test/std_data` directory of the distribution.

5.5.8. Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson `<dcarlson@mplcomm.com>`.

1. Install an SSH client on your Windows machine. As a user, the best non-free one I have found is from `SecureCRT` from http://www.vandyke.com/. Another option is `f-secure` from http://www.f-secure.com/. You can also find some free ones on `Google` at http://directory.google.com/Top/Computers/Internet/Protocols/SSH/Clients/Windows/.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

5.5.9. Auditing MySQL Account Activity

Applications can use the following guidelines to perform auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `''@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. If this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| user1@localhost | @localhost     |
+----------------+----------------+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-------------------------+---------------------+
| USER()                  | CURRENT_USER()      |
+-------------------------+---------------------+
| user2@remote.example.com | user2@%.example.com |
+-------------------------+---------------------+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not allow `User` to be empty (which creates an anonymous-user account), and do not allow pattern characters or netmask notation in `Host` values. All accounts must have a non-empty `User` value and literal `Host` value.

With respect to the previous examples, the `''@'localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+--------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+--------------------------------------+
| user1                                |
+--------------------------------------+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+---------------------------------------+
| localhost                             |
+---------------------------------------+
```

5.6. Running Multiple MySQL Servers on the Same Machine

In some cases, you might want to run multiple `mysqld` servers on the same machine. You might want to test a new MySQL release while leaving your existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

To run multiple servers on a single machine, each server must have unique values for several operating parameters. These can be set on the command line or in option files. See Section 4.2.3, “Specifying Program Options”.

At least the following options must be different for each server:

- `--port=port_num`

  `--port` controls the port number for TCP/IP connections. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)

- `--socket=path`

  `--socket` controls the Unix socket file path on Unix and the name of the named pipe on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers that support named-pipe connections.

- `--shared-memory-base-name=name`

  This option currently is used only on Windows. It designates the shared-memory name used by a Windows server to allow clients to connect via shared memory. It is necessary to specify distinct shared-memory names only for those servers that support shared-memory connections.

- `--pid-file=file_name`

  This option is used only on Unix. It indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, they must be different for each server:

- `--general_log` or `--log[=file_name]`
- `--log-bin[=file_name]`
- `--slow_query_log` or `--log-slow-queries[=file_name]`
- `--log-error[=file_name]`

Section 5.2.6, “Server Log Maintenance”, discusses the log file options further.

For better performance, you can specify the following options differently for each server, to spread the load between several physical disks:

- `--tmpdir=path`

Having different temporary directories is also recommended to make it easier to determine which MySQL server created any given temporary file.

With very limited exceptions, each server should use a different data directory, which is specified using the `--datadir=path` option.

> **Warning**
>
> Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files. Please note that this kind of setup only works with `MyISAM` and `MERGE` tables, and not with any of the other storage engines.

The warning against sharing a data directory among servers also applies in an NFS environment. Allowing multiple MySQL servers to access a common data directory over NFS is a *very bad idea*.

- The primary problem is that NFS is the speed bottleneck. It is not meant for such use.
- Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Make it easy for yourself: Forget about sharing a data directory among servers over NFS. A better solution is to have one computer that contains several CPUs and use an operating system that handles threads efficiently.

If you have multiple MySQL installations in different locations, you can specify the base installation directory for each server with the `--basedir=path` option to cause each server to use a different data directory, log files, and PID file. (The defaults for all these values are determined relative to the base directory). In that case, the only other options you need to specify are the `--socket` and `--port` options. For example, suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by setting environment variables or by specifying appropriate command-line options. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

5.6.1. Running Multiple Servers on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters. On Windows NT-based systems, you also have the option of installing several servers as Windows services and running them that way. General instructions for running MySQL servers from the command line or as services are given in Section 2.3, “Installing MySQL on Windows”. This section describes how to make sure that you start each server with different values for those startup options that must be unique per server, such as the data directory. These options are described in Section 5.6, “Running Multiple MySQL Servers on the Same Machine”.

5.6.1.1. Starting Multiple Windows Servers at the Command Line

To start multiple servers manually from the command line, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-debug` on port 3308 with a data directory of `C:\mydata2`. (To do this, make sure that before you start the servers, each data directory exists and has its own copy of the `mysql` database that contains the grant tables.) Then create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

Then start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-debug --defaults-file=C:\my-opts2.cnf
```

On NT, each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, you must connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described allow clients to connect over TCP/IP. If your version of Windows supports named pipes specify the options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Then start the server this way:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
```

Modify `C:\my-opts2.cnf` similarly for use by the second server.

A similar procedure applies for servers that you want to support shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

5.6.1.2. Starting Multiple Windows Servers as Services

On NT-based systems, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.11, “Starting MySQL as a Windows Service”.

You can also install multiple MySQL servers as services. In this case, you must make sure that each server uses a different service name in addition to all the other parameters that must be unique for each server.

For the following instructions, assume that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.0.19` and `C:\mysql-6.0.12`, respectively. (This might be the case if you're running 5.0.19 as your production server, but also want to conduct tests using 6.0.12.)

The following principles apply when installing a MySQL service with the `--install` or `--install-manual` option:

- If you specify no service name, the server uses the default service name of `MySQL` and the server reads options from the `[mysqld]` group in the standard option files.
- If you specify a service name after the `--install` option, the server ignores the `[mysqld]` option group and instead reads options from the group that has the same name as the service. The server reads options from the standard option files.
- If you specify a `--defaults-file` option after the service name, the server ignores the standard option files and reads options only from the `[mysqld]` group of the named file.

> **Note**
>
> Before MySQL 4.0.17, only a server installed using the default service name (`MySQL`) or one installed explicitly with a service name of `mysqld` will read the `[mysqld]` group in the standard option files. As of 4.0.17, all servers read the `[mysqld]` group if they read the standard option files, even if they are installed using another service name. This allows you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group named after each service for use by the server installed with that service name.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, be sure that you shut down and remove any existing MySQL services first.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.0.19 `mysqld` using the service name of `mysqld1` and the 6.0.12 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.0.19 and the `[mysqld2]` group for 6.0.12. For example, you can set up `C:\my.cnf` like this:

  ```
  # options for mysqld1 service
  ```

```
[mysqld1]
basedir = C:/mysql-5.0.19
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-6.0.12
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.0.19\bin\mysqld --install mysqld1
C:\> C:\mysql-6.0.12\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

  With this approach, to specify options for the 5.0.19 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

  ```
  [mysqld]
  basedir = C:/mysql-5.0.19
  port = 3307
  enable-named-pipe
  socket = mypipe1
  ```

  For the 6.0.12 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

  ```
  [mysqld]
  basedir = C:/mysql-6.0.12
  port = 3308
  enable-named-pipe
  socket = mypipe2
  ```

  Install the services as follows (enter each command on a single line):

  ```
  C:\> C:\mysql-5.0.19\bin\mysqld --install mysqld1
            --defaults-file=C:\my-opts1.cnf
  C:\> C:\mysql-6.0.12\bin\mysqld --install mysqld2
            --defaults-file=C:\my-opts2.cnf
  ```

  To use a `--defaults-file` option when you install a MySQL server as a service, you must precede the option with the service name.

  After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it.

5.6.2. Running Multiple Servers on Unix

The easiest way is to run multiple servers on Unix is to compile them with different TCP/IP ports and Unix socket files so that each one is listening on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.0.19 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 6.0.12 server to have different operating parameters, use a `configure` command something like this:

```
shell> ./configure --with-tcp-port=port_number \
            --with-unix-socket-path=file_name \
            --prefix=/usr/local/mysql-6.0.12
```

Here, *`port_number`* and *`file_name`* must be different from the default TCP/IP port number and Unix socket file path name, and the `--prefix` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

Note that if you specify `localhost` as a host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. From MySQL 4.1 onward, you can explicitly specify the connection protocol to use by using the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You don't have to compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=`*`path`* option to `mysqld_safe` so that the server uses a different data directory.

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Section 2.13, “Environment Variables”, includes a list of other environment variables you can use to affect `mysqld`.

For automatic server execution, the startup script that is executed at boot time should execute the following command once for each server with an appropriate option file path for each command:

```
shell> mysqld_safe --defaults-file=file_name
```

Each option file should contain option values specific to a given server.

On Unix, the `mysqld_multi` script is another way to start multiple servers. See Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

5.6.3. Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=`*`host_name`* `--port=`*`port_number`* to connect via TCP/IP to a remote server, with `--host=127.0.0.1 --port=`*`port_number`* to connect via TCP/IP to a local server, or with `--host=localhost --socket=`*`file_name`* to connect to a local server via a Unix socket file or a Windows named pipe.
- As of MySQL 4.1, start the client with `--protocol=TCP` to connect via TCP/IP, `--protocol=SOCKET` to connect via a Unix socket file, `--protocol=PIPE` to connect via a named pipe, or `--protocol=MEMORY` to connect via shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and

TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 2.13, "Environment Variables".

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.3.2, "Using Option Files".
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 20.10.3, "C API Function Descriptions".
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
     . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 20.12, "MySQL Perl API".

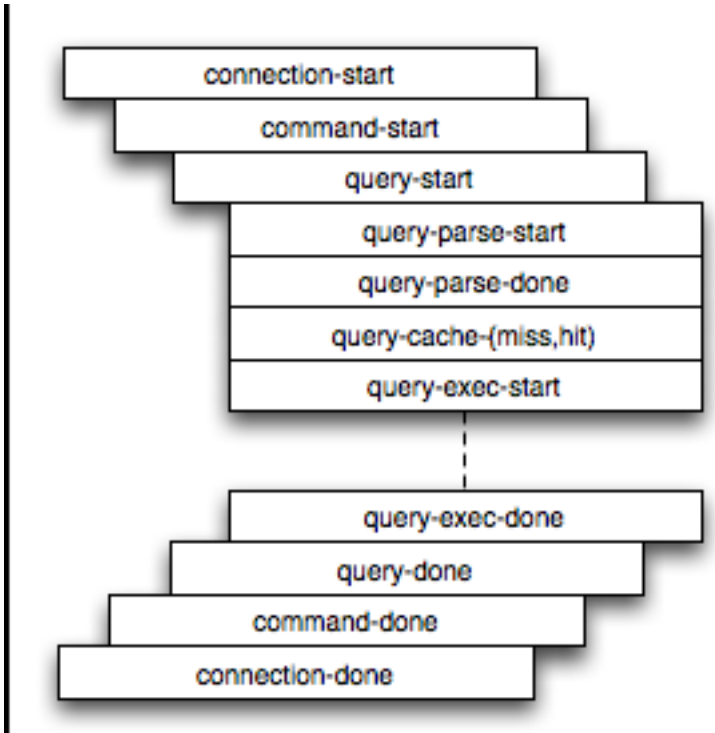
Other programming interfaces may provide similar capabilities for reading option files.

5.7. Tracing `mysqld` Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

Figure 5.1. The MySQL architecture using pluggable storage engines



Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (`connection-start`, `command-start`,

`query-start`, and `query-exec-start`). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

Support for DTrace probes was added in MySQL 6.0.4, with the recommended list of probes supported in MySQL 6.0.8 and higher. DTrace probes in MySQL are supported on Solaris 10 Update 5 (Solaris 5/08), and OpenSolaris 2008.05 and higher on SPARC, x86 and x86_64 platforms. Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `--enable-dtrace` or `--disable-dtrace` option to `configure`.

5.7.1. `mysqld` DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality, starting with MySQL 6.0.8.

Table 5.6. MySQL DTrace Probes

Group	Probes	Introduced
Connection	`connection-start`, `connection-done`	6.0.8
Command	`command-start`, `command-done`	6.0.8
Query	`query-start`, `query-done`	6.0.8
Query Parsing	`query-parse-start`, `query-parse-done`	6.0.8
Query Cache	`query-cache-hit`, `query-cache-miss`	6.0.8
Query Execution	`query-exec-start`, `query-exec-done`	6.0.8
Row Level	`insert-row-start`, `insert-row-done`	6.0.8
	`update-row-start`, `update-row-done`	6.0.8
	`delete-row-start`, `delete-row-done`	6.0.8
Lock	`handler-rdlock-start`, `handler-rdlock-done`	6.0.8
	`handler-wrlock-start`, `handler-wrlock-done`	6.0.8
	`handler-unlock-start`, `handler-unlock-done`	6.0.8
Filesort	`filesort-start`, `filesort-done`	6.0.8
Statement	`select-start`, `select-done`	6.0.8
	`insert-start`, `insert-done`	6.0.8
	`insert-select-start`, `insert-select-done`	6.0.8
	`update-start` , `update-done`	6.0.8
	`multi-update-start`, `multi-update-done`	6.0.8
	`delete-start`, `delete-done`	6.0.8
	`multi-delete-start`, `multi-delete-done`	6.0.8
Network	`net-read-start`, `net-read-done`, `net-write-start`, `net-write-done`	6.0.8

> **Note**
>
> When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are provided with a descriptive name, but you must access the information using the corresponding `argN` parameter.

5.7.1.1. Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
query-done(status, connectionid)
```

- `connection-start` — is triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:

  - `connectionid` — is an `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.
  - `user` — is the username used when authenticating. The value will be blank for the anonymous user.
  - `host` — is the host of the client connection. For a connection made using UNIX sockets, the value will be blank.
- `connection-done` — is triggered just as the connection to the client has been closed. The arguments are:
  - `status` — the status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
  - `connectionid` — the connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
  self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
  @ = quantize(((timestamp - self->start)/1000000));
  self->start = 0;
}

tick-60s
{
  printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
  1  57413                      :tick-60s

           value  ------------- Distribution ------------- count
              -1 |                                         0
               0 |@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
               1 |                                         59
               2 |                                         5
               4 |                                         20
               8 |                                         29
              16 |                                         18
              32 |                                         27
              64 |                                         30
             128 |                                         11
             256 |                                         10
             512 |                                         1
            1024 |                                         6
            2048 |                                         8
            4096 |                                         9
            8192 |                                         8
           16384 |                                         2
           32768 |                                         1
           65536 |                                         1
          131072 |                                         0
          262144 |                                         1
          524288 |                                         0
```

5.7.1.2. Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start` — triggered when a command is submitted to the server.
  - `connectionid` — the connection ID of the client executing the command.

- `command` — an integer representing the command that was executed. Possible values are shown in the following table.

Value	Name	Description
00	COM_SLEEP	Internal thread state
01	COM_QUIT	Close connection
02	COM_INIT_DB	Select database (`USE ...`)
03	COM_QUERY	Execute a query
04	COM_FIELD_LIST	Get a list of fields
05	COM_CREATE_DB	Create a database (deprecated)
06	COM_DROP_DB	Drop a database (deprecated)
07	COM_REFRESH	Refresh connection
08	COM_SHUTDOWN	Shutdown server
09	COM_STATISTICS	Get statistics
10	COM_PROCESS_INFO	Get processes (`SHOW PROCESSLIST`)
11	COM_CONNECT	Initialize connection
12	COM_PROCESS_KILL	Kill process
13	COM_DEBUG	Get debug information
14	COM_PING	Ping
15	COM_TIME	Internal thread state
16	COM_DELAYED_INSERT	Internal thread state
17	COM_CHANGE_USER	Change user
18	COM_BINLOG_DUMP	Used by a replication slave or `mysqlbinlog` to initiate a binary log read
19	COM_TABLE_DUMP	Used by a replication slave to get the master table information
20	COM_CONNECT_OUT	Used by a replication slave to log a connection to the server
21	COM_REGISTER_SLAVE	Used by a replication slave during registration
22	COM_STMT_PREPARE	Prepare a statement
23	COM_STMT_EXECUTE	Execute a statement
24	COM_STMT_SEND_LONG_DATA	Used by a client when requesting extended data
25	COM_STMT_CLOSE	Close a prepared statement
26	COM_STMT_RESET	Reset a prepared statement
27	COM_SET_OPTION	Set a server option
28	COM_STMT_FETCH	Fetch a prepared statement

  - `user` — the user executing the command.
  - `host` — the client host.
- `command-done` — triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The `command-start` and `command-done` probes are best used when combined with the statement probes to get an idea of overall execution time.

5.7.1.3. Query Probes

The `query-start` and `query-done` probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
```

```
query-done(status)
```

- `query-start` — is triggered after the query string has been received from the client. The arguments are:
  - `query` — the full text of the submitted query.
  - `connectionid` — the connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database` — the database name on which the query is being executed.
  - `user` — the username used to connect to the server.
  - `host` — the hostname of the client.
- `query-done` — is triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
   printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->connid = arg1;
   self->db    = copyinstr(arg2);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->querystart = timestamp;
}

mysql*:::query-done
{
   printf("%-20s %-20s %-40s %-9d\n",self->who,self->db,self->query,
          (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```
shell> ./query.d
Who                  Database             Query                                    Time(ms)
root@localhost       test                 select * from t1 order by i limit 10     0
root@localhost       test                 set global query_cache_size=0            0
root@localhost       test                 select * from t1 order by i limit 10     776
root@localhost       test                 select * from t1 order by i limit 10     773
root@localhost       test                 select * from t1 order by i desc limit 10 795
```

5.7.1.4. Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```
query-parse-start(query)
query-parse-done(status)
```

- `query-parse-start` — is triggered just before the statement is parsed by the MySQL query parser. The single argument, `query`, is a string containing the full text of the original query.
- `query-parse-done` — is triggered when the parsing of the original statement has been completed. The `status` is an integer describing the status of the operation. A `0` indicates that the query was successfully parsed. A `1` indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
```

```
mysql*:::query-parse-start
{
   self->parsestart = timestamp;
   self->parsequery = copyinstr(arg0);
}

mysql*:::query-parse-done
/arg0 == 0/
{
   printf("Parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
}

mysql*:::query-parse-done
/arg0 != 0/
{
   printf("Error parsing %s: %d microseconds\n", self->parsequery,((timestamp - self->parsestart)/1000));
}
```

In the above script a predicate is used on `query-parse-done` so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

5.7.1.5. Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- `query-cache-hit` — triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.
- `query-cache-misss` — triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
   printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->connid = arg1;
   self->db    = copyinstr(arg2);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->querystart = timestamp;
   self->qc = 0;
}

mysql*:::query-cache-hit
{
   self->qc = 1;
}

mysql*:::query-cache-miss
{
   self->qc = 0;
}

mysql*:::query-done
{
   printf("%-20s %-20s %-40s %-2s %-9d\n",self->who,self->db,self->query,(self->qc ? "Y" : "N"),
```

```
          (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost       test                select * from t1 order by i limit 10     N  1072
root@localhost                           set global query_cache_size=262144       N  0
root@localhost       test                select * from t1 order by i limit 10     N  781
root@localhost       test                select * from t1 order by i limit 10     Y  0
```

5.7.1.6. Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

> **Note**
>
> The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- `query-exec-start` — is triggered when the execution of a individual query is started. The arguments are:
  - `query` — the full text of the submitted query.
  - `connectionid` — the connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database` — the database name on which the query is being executed.
  - `user` — the username used to connect to the server.
  - `host` — the hostname of the client.
  - `exec_type` — the type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

Value	Description
0	Executed query from sql_parse, top-level query.
1	Executed prepared statement
2	Executed cursor statement
3	Executed query in stored procedure

- `query-exec-done` — is triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

5.7.1.7. Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```
insert-row-start(database, table)
insert-row-done(status)

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
delete-row-done(status)
```

- `insert-row-start` — is triggered before a row is inserted into a table.
- `insert-row-done` — is triggered after a row is inserted into a table.
- `update-row-start` — is triggered before a row is updated in a table.
- `update-row-done` — is triggered before a row is updated in a table.
- `delete-row-start` — is triggered before a row is deleted from a table.
- `delete-row-done` — is triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database` — the database name.
- `table` — the table name.
- `status` — the status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
   printf("%-2s %-10s %-10s %9s %9s %-s \n",
          "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->db    = copyinstr(arg2);
   self->connid = arg1;
   self->querystart = timestamp;
   self->rowdur = 0;
}

mysql*:::query-done
{
   this->elapsed = (timestamp - self->querystart) /1000000;
   printf("%2d %-10s %-10s %9d %9d %s\n",
          arg0, self->who, self->db,
          self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
   printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

mysql*:::insert-row-start
{
   self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
   self->rowstart = timestamp;
}

mysql*:::update-row-start
{
   self->rowstart = timestamp;
}

mysql*:::insert-row-done
{
   self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
```

```
{
   self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
   self->rowdur += (timestamp-self->rowstart);
}
```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

```
St Who        DB            ConnID    Dur ms Query
 0 @localhost test              13     20767 insert into t1(select * from t2)
                                        4827 -> Row ops
```

5.7.1.8. Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the correspnding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- `handler-rdlock-start` — triggered when a read lock is requested on the specified `database` and `table`.
- `handler-wrlock-start` — triggered when a write lock is requested on the specified `database` and `table`.
- `handler-unlock-start` — triggered when an unlock request is made on the specified `database` and `table`.
- `handler-rdlock-done` — triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-wrlock-done` — triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-unlock-done` — triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or `>0` on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
   self->rdlockstart = timestamp;
   this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
   self->lockmap[this->lockref] = self->rdlockstart;
   printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
   self->wrlockstart = timestamp;
   this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
   self->lockmap[this->lockref] = self->rdlockstart;
   printf("Start: Lock->Write  %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-unlock-start
{
   self->unlockstart = timestamp;
   this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
   printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",
          copyinstr(arg0),copyinstr(arg1),
          (timestamp - self->lockmap[this->lockref])/1000000);
}
```

```
mysql*:::handler-rdlock-done
{
   printf("End:   Lock->Read   %d ms\n",
          (timestamp - self->rdlockstart)/1000000);
}

mysql*:::handler-wrlock-done
{
   printf("End:   Lock->Write  %d ms\n",
          (timestamp - self->wrlockstart)/1000000);
}

mysql*:::handler-unlock-done
{
   printf("End:   Lock->Unlock %d ms\n",
          (timestamp - self->unlockstart)/1000000);
}
```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
```

5.7.1.9. Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see Section 7.2.17, “`ORDER BY` Optimization”.

```
filesort-start(database, table)
filesort-done(status, rows)
```

- `filesort-start` — is triggered when the filesort operation starts on a table. The two arguments to the probe, `database` and `table`, will identify the table being sorted.
- `filesort-done` — is triggered when the filesort operation completes. Two arguments are supplied, the `status` (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
   printf("%-2s %-10s %-10s %9s %18s %-s \n",
          "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->db    = copyinstr(arg2);
   self->connid = arg1;
   self->querystart = timestamp;
   self->filesort = 0;
   self->fsdb = "";
   self->fstable = "";
}

mysql*:::filesort-start
{
  self->filesort = timestamp;
  self->fsdb = copyinstr(arg0);
  self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
```

```
{
   this->elapsed = (timestamp - self->filesort) /1000;
   printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
          arg0, self->who, self->fsdb,
          self->connid, this->elapsed, self->fstable);
}

mysql*:::query-done
{
   this->elapsed = (timestamp - self->querystart) /1000;
   printf("%2d %-10s %-10s %9d %18d %s\n",
          arg0, self->who, self->db,
          self->connid, this->elapsed, self->query);
}
```

Executing a query on a large table with an `ORDER BY` clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

```
St Who        DB            ConnID       Dur microsec Query
 0 @localhost test              14          11335469 Filesort on t1
 0 @localhost test              14          11335787 select * from t1 order by i limit 100
 0 @localhost test              14         466734378 create index t1a on t1 (i)
 0 @localhost test              14             26472 select * from t1 order by i limit 100
```

5.7.1.10. Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as a the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (`0` for success, `>0` for failure) is provided. For `SELECT`, `INSERT`, `INSERT ... (SELECT FROM ...)`, `DELETE`, and `DELETE FROM t1,t2` operations the number of rows affected is returned.

For `UPDATE` and `UPDATE t1,t2 ...` statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding `WHERE` clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```
select-start(query)
select-done(status,rows)

insert-start(query)
insert-done(status,rows)

insert-select-start(query)
insert-select-done(status,rows)

update-start(query)
update-done(status,rowsmatched,rowschanged)

multi-update-start(query)
multi-update-done(status,rowsmatched,rowschanged)

delete-start(query)
delete-done(status,rows)

multi-delete-start(query)
multi-delete-done(status,rows)
```

- `select-start` — triggered before a `SELECT` statement.
- `select-done` — triggered at the end of a `SELECT` statement.
- `insert-start` — triggered before a `INSERT` statement.
- `insert-done` — triggered at the end of an `INSERT` statement.
- `insert-select-start` — triggered before an `INSERT ... SELECT` statement.
- `insert-select-done` — triggered at the end of an `INSERT ... SELECT` statement.
- `update-start` — triggered before an `UPDATE` statement.
- `update-done` — triggered at the end of an `UPDATE` statement.
- `multi-update-start` — triggered before an `UPDATE` statement involving multiple tables.
- `multi-update-done` — triggered at the end of an `UPDATE` statement involving multiple tables.
- `delete-start` — triggered before a `DELETE` statement.

- `delete-done` — triggered at the end of a `DELETE` statement.
- `multi-delete-start` — triggered before a `DELETE` statement involving multiple tables.
- `multi-delete-done` — triggered at the end of a `DELETE` statement involving multiple tables.

The arguments for the statement probes are:

- `query` — the query string.
- `status` — the status of the query. `0` for success, and `>0` for failure.
- `rows` — the number of rows affected by the statement. This returns the number rows found for `SELECT`, the number of rows deleted for `DELETE`, and the number of rows successfully inserted for `INSERT`.
- `rowsmatched` — the number of rows matched by the `WHERE` clause of an `UPDATE` operation.
- `rowschanged` — the number of rows actually changed during an `UPDATE` operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
   printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
           self->query,
           0,
           arg1,
           this->elapsed);
    self->querystart = 0;
}

mysql*:::update-done, mysql*:::multi-update-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
           self->query,
           arg1,
           arg2,
           this->elapsed);
    self->querystart = 0;
}
```

When executed you can see the basic execution times and rows matches:

```
Query                                                        RowsU    RowsM    Dur (ms)
select * from t2                                             0        275      0
insert into t2 (select * from t2)                            0        275      9
update t2 set i=5 where i > 75                               110      110      8
update t2 set i=5 where i < 25                               254      134      12
delete from t2 where i < 5                                   0        0        0
```

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
```

```
mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{
        @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::insert-done, mysql*:::insert-select-done
{
        @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
        @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::delete-done, mysql*:::multi-delete-done
{
        @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

tick-30s
{
        printa(@statements);
}
```

The above scipt aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

```
 delete                                                  0
  update                                                 0
  insert                                                23
  select                                              2484

  delete                                                 0
  update                                                 0
  insert                                                39
  select                                             10744

  delete                                                 0
  update                                                26
  insert                                                56
  select                                             10944

  delete                                                 0
  update                                                26
  insert                                              2287
  select                                             15985
```

5.7.1.11. Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```
net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)
```

- `net-read-start` — triggered when a network read operation is started.
- `net-read-done` — triggered when the network read operation completes. The `status` is an `integer` representing the return status for the operation, `0` for success and `1` for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- `net-start-bytes` — triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.
- `net-write-done` — triggered when the network write operation has completed. The single argument, `status`, is an integer representing the return status for the operation, `0` for success and `1` for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumlative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the `dynvarsize` option) to cope with the rapid firing of the individual probes for the network reads/writes.

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN
{
   printf("%-2s %-30s %-10s %9s %18s %-s \n",
          "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
   self->query = copyinstr(arg0);
   self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
   self->db    = copyinstr(arg2);
   self->connid = arg1;
   self->querystart = timestamp;
   self->netwrite = 0;
   self->netwritecum = 0;
   self->netwritebase = 0;
   self->netread = 0;
   self->netreadcum = 0;
   self->netreadbase = 0;
}

mysql*:::net-write-start
{
   self->netwrite += arg0;
   self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
   self->netwritecum += (timestamp - self->netwritebase);
   self->netwritebase = 0;
}

mysql*:::net-read-start
{
   self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
   self->netread += arg1;
   self->netreadcum += (timestamp - self->netreadbase);
   self->netreadbase = 0;
}

mysql*:::query-done
{
   this->elapsed = (timestamp - self->querystart) /1000000;
   printf("%2d %-30s %-10s %9d %18d %s\n",
          arg0, self->who, self->db,
          self->connid, this->elapsed, self->query);
   printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n",
               self->netread, (self->netreadcum/1000000),
               self->netwrite, (self->netwritecum/1000000));
}
```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

```
St Who                            DB            ConnID       Dur microsec Query
 0 root@::ffff:192.168.0.108      test             31               3495 select * from t1 limit 1000000
Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms)
```

Chapter 6. Backup and Recovery

It is important to back up your databases in case problems occur so that you can recover your data and be up and running again. MySQL offers a variety of backup strategies from which you can choose to select whatever methods best suit the requirements for your installation.

Briefly summarized, backup concepts with which you should be familiar include the following:

- Logical versus physical backups
- Online versus offline backups
- Local versus remote backups
- Snapshot backups
- Full versus incremental backups
- Point-in-time recovery
- Backup scheduling, compression, and encryption
- Table maintenance

More generally, the following discussion amplifies on the properties of different backup methods.

- **Logical versus physical (raw) backups.** Logical backups save information represented as logical database structure (`CREATE DATABASE`, `CREATE TABLE` statements) and content (`INSERT` statements or delimited-text files). Physical backups consist of raw copies of the directories and files that store database contents.

  Logical backup methods have these characteristics:

  - The backup is done by going through the MySQL server to obtain database structure and content information.
  - Backup is slower than physical methods because the server must access database information, convert it to logical format, and send it to the backup program.
  - Output is larger than for physical backup, particularly when saved in text format.
  - Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
  - The backup does not include log or configuration files, or other database-related files that are not part of databases.
  - Backups stored in logical format are machine independent and highly portable.
  - Logical backups are performed with the MySQL server running (the server is not taken offline).
  - Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.

    For restore, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

  Physical backup methods have these characteristics:

  - The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory. Data from `MEMORY` tables cannot be backed up this way because their contents are not stored on disk.
  - Physical backup methods are faster than logical because they involve only file copying without conversion.
  - Output is more compact than for logical backup.
  - Backup and restore granularity extends from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. (Each `MyISAM` table corresponds uniquely to a set of files, but an `InnoDB` table shares file storage with other `InnoDB` tables.)
  - In addition to databases, the backup can include any related files such as log or configuration files.

  - Backups are portable only to other machines that have identical or similar hardware characteristics.
  - Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup.
  - Physical backup tools include file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), `mysqlhotcopy` for `MyISAM` tables, `ibbackup` for `InnoDB` tables, or `START BACKUP` for `NDB` tables.

    For restore, files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands; `ibback` restores `InnoDB` tables, and `ndb_restore` restores `NDB` tables.

- **Online versus offline backups.** Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. (This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.)

  Online backup methods have these characteristics:

  - Less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
  - Care must be taken to impose appropriate locking so that data modifications do not take place that compromise backup integrity.

  Offline backup methods have these characteristics:

  - Affects clients adversely because the server is unavailable during backup.
  - Simpler backup procedure because there is no possibility of interference from client activity.

- **Local versus remote backups.** A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is initiated from a different host.

  - `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
  - `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
  - `SELECT ... INTO OUTFILE` can be initiated from a remote client host, but the output file is created on the server host.
  - Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for file copies might be remote.

- **Snapshot backups.** Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without having to physically copy the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas or LVM.

- **Full versus incremental backups.** A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data since the full backup. MySQL has different ways to perform full backups, such as those described in previous items. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

- **Point-in-time recovery.** One use for the binary log is to achieve point-in-time recovery. This is done by recovering first from the backup files to restore the server to its state when the backup was made, and then by re-executing changes in subsequently written binary log files to redo data modifications up to the desired point in time.

- **Backup scheduling, compression, and encryption.** Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. `ibbackup` can compress `InnoDB` backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

- **Table maintenance.** Data integrity can be compromised if tables become corrupt. MySQL provides programs for checking tables and repairing them should problems be found. These programs apply primarily to `MyISAM` tables. See Section 6.5, “Table Maintenance and Crash Recovery”.

Additional resources

Resources related to backup or to maintaining data availability include the following:

- A forum dedicated to backup issues is available at http://forums.mysql.com/list.php?93.
- The syntax of the SQL statements described here is given in Chapter 12, *SQL Statement Syntax*.
- Details for `mysqldump`, `mysqlhotcopy`, and other MySQL backup programs can be found in Chapter 4, *MySQL Programs*.
- For additional information about `InnoDB` backup procedures, see Section 13.7.6, "Backing Up and Recovering an `InnoDB` Database".
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as allowing client load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups using a slave server without affecting the master. See Chapter 16, *Replication*.
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See MySQL Cluster NDB 6.X/7.X, which provides information about MySQL Cluster NDB 6.2 and 6.3 (based on MySQL 5.1 but containing the latest improvements and fixes for the `NDBCLUSTER` storage engine).

  Note

  The `NDBCLUSTER` storage engine is currently not supported in MySQL 6.0.
- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See Chapter 14, *High Availability and Scalability*

6.1. Database Backups

This section summarizes some general methods for making backups.

Making Backups by Copying Files

`MyISAM` tables are stored as files, so it is easy to do a backup by copying files. To get a consistent backup, do a `LOCK TABLES` on the relevant tables, followed by `FLUSH TABLES` for the tables. See Section 12.4.5, "`LOCK TABLES` and `UNLOCK TABLES` Syntax", and Section 12.5.7.3, "`FLUSH` Syntax". You need only a read lock; this allows other clients to continue to query the tables while you are making a copy of the files in the database directory. The `FLUSH TABLES` statement is needed to ensure that the all active index pages are written to disk before you start the backup.

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because allowing files to be overwritten would constitute a security risk. See Section 12.2.9, "`SELECT` Syntax". This method works for any kind of data file, but saves only table data, not the table structure.

To reload the output file, use `LOAD DATA INFILE` or `mysqlimport`.

Making Backups with `mysqldump` or `mysqlhotcopy`

Another technique for backing up a database is to use the `mysqldump` program or the `mysqlhotcopy` script. `mysqldump` is more general because it can back up all kinds of tables. `mysqlhotcopy` works only with some storage engines. (See Section 4.5.4, "`mysqldump` — A Database Backup Program", and Section 4.6.10, "`mysqlhotcopy` — A Database Backup Program".)

Create a full backup of your database:

```
shell> mysqldump --tab=/path/to/some/dir --opt db_name
```

Or:

```
shell> mysqlhotcopy db_name /path/to/some/dir
```

You can also create a binary backup simply by copying all table files (`*.frm`, `*.MYD`, and `*.MYI` files), as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that these methods do not work if your database contains `InnoDB` tables. `InnoDB` does not necessarily store table contents in database directories, and `mysqlhotcopy` works only

for MyISAM and ISAM tables.)

For InnoDB tables, it is possible to perform an online backup that takes no locks on tables; see Section 4.5.4, “mysqldump — A Database Backup Program”.

Using the Binary Log to Enable Incremental Backups

MySQL supports incremental backups: You must start the server with the --log-bin option to enable binary logging; see Section 5.2.4, “The Binary Log”. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using FLUSH LOGS. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 6.4, “Point-in-Time Recovery”. The next time you do a full backup, you should also rotate the binary log using FLUSH LOGS, mysqldump --flush-logs, or mysqlhotcopy --flushlog. See Section 4.5.4, “mysqldump — A Database Backup Program”, and Section 4.6.10, “mysqlhotcopy — A Database Backup Program”.

Backing Up Replication Slaves

If your MySQL server is a slave replication server, then regardless of the backup method you choose, you should also back up the master.info and relay-log.info files when you back up your slave's data. These files are always needed to resume replication after you restore the slave's data. If your slave is subject to replicating LOAD DATA INFILE commands, you should also back up any SQL_LOAD-* files that may exist in the directory specified by the --slave-load-tmpdir option. (This location defaults to the value of the tmpdir system variable if not specified.) The slave needs these files to resume replication of any interrupted LOAD DATA INFILE operations.

> **MySQL Enterprise**
> The MySQL Enterprise Monitor provides numerous advisors that issue immediate warnings should replication issues arise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Chapter 16, *Replication*.

Recovering Corrupt Tables

If you have to restore MyISAM tables that have become corrupt, try to recover them using REPAIR TABLE or myisamchk -r first. That should work in 99.9% of all cases. If myisamchk fails, try the following procedure. It is assumed that you have enabled binary logging by starting MySQL with the --log-bin option.

1. Restore the original mysqldump backup, or binary backup.
2. Execute the following command to re-run the updates in the binary logs:

   ```
   shell> mysqlbinlog binlog.[0-9]* | mysql
   ```

   In some cases, you may want to re-run only certain binary logs, from certain positions (usually you want to re-run all binary logs from the date of the restored backup, excepting possibly some incorrect statements). See Section 6.4, “Point-in-Time Recovery”.

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute FLUSH TABLES WITH READ LOCK.
2. From another shell, execute mount vxfs snapshot.
3. From the first client, execute UNLOCK TABLES.
4. Copy files from the snapshot.
5. Unmount the snapshot.

6.2. Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that allows you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` programs. You should include such options as necessary so that the MySQL server allows you to connect to it.

We assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. We also assume that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and non-committed transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that we must already have made backups. To make sure that is the case, we should design a backup policy.

6.2.1. Backup Policy

We all know that backups must be scheduled periodically. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, `InnoDB Hot Backup` provides online non-blocking physical backup of the `InnoDB` data files, and `mysqldump` provides online logical backup. This discussion uses `mysqldump`.

> **MySQL Enterprise**
> For expert advice on backups and replication, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Assume that we make a backup on Sunday at 1 p.m., when load is low. The following command makes a full backup of all our `InnoDB` tables in all databases:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

We assumed earlier that our tables are `InnoDB` tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to `InnoDB` tables are not seen by the `mysqldump` process.) If we do also have other types of tables, we must assume that they are not changed during the backup. For example, for the `MyISAM` tables in the `mysql` database, we must assume that no administrative changes are being made to MySQL accounts during the backup.

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

Full backups are necessary, but they are not always convenient. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. After we have made the initial full backup, it is more efficient to make incremental backups. They are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. The MySQL server should always be started with the `--log-bin` option so that it stores these changes in a file while it updates data. This option enables binary logging, so that the server writes each SQL statement that updates data into a file called a MySQL binary log. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem  guilhem   1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem  guilhem         4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem  guilhem        79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem  guilhem       508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem  guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem  guilhem    998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem  guilhem       361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory. This file is used for replication.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, then any binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
         --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`. The resulting `.sql` file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The `.sql` file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the `.sql`, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
         --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

> **Note**
>
> Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 12.6.1.1, “`PURGE BINARY LOGS` Syntax”.

6.2.2. Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file at hand, and we could apply it using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash.

6.2.3. Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=`*`log_name`*, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in Section 6.2.1, “Backup Policy”, that makes an online, non-blocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

6.3. Using MySQL Backup

MySQL Backup is available as of MySQL 6.0.5. This feature comprises the `BACKUP DATABASE` and `RESTORE` statements. They provide a way to make a copy of a database or set of databases at a given point in time, and a way to restore each database to its state as of that time.

A backup operation can include tables for different storage engines and the backup image will still be consistent. That is, you need not care which storage engines you're using. `BACKUP DATABASE` saves the data in a consistent backup image with respect to its “validity point.”

The validity point ties the backup to the binary log. Restoring a backup can be combined with use of the binary log to accomplish point-in-time recovery: If the restore operation is done because data loss has occurred after the backup was made (that is, after the validity point), restored databases can be brought up to the time of data loss by executing the data changes in the binary log between the times when the backup was made and when the data loss occurred.

A goal of the `BACKUP DATABASE` and `RESTORE` statements is to enable other database operations to proceed concurrently, to make it unnecessary to take databases offline or prevent clients from accessing them. `BACKUP DATABASE` must block some operations from occurring (such as dropping tables from a database while it is being backed up), but the attempt is made to keep blocking to a minimum. Generally, blocked operations are those involving Data Definition Language (DDL) statements. `RESTORE` must do more blocking because it writes database contents rather than just reading them.

The following discussion covers these aspects of `BACKUP DATABASE` and `RESTORE`:

- Quick guide to making backups and restoring them
- How `BACKUP DATABASE` and `RESTORE` work
- Status reporting and monitoring for backup and restore operations

For additional information about the BACKUP DATABASE and RESTORE statements, see these sections of the manual:

- Section 12.5.3.1, “BACKUP DATABASE Syntax”, and Section 12.5.3.3, “RESTORE Syntax”, describes the syntax for these statements.
- Limitations on the use of these statements are discussed in Section D.8, “Restrictions on BACKUP DATABASE and RESTORE”.

6.3.1. Quick Guide to MySQL Backup

Use the BACKUP DATABASE and RESTORE statements like this:

- BACKUP DATABASE backs up one or more databases to a named file:

```
BACKUP DATABASE world TO '/tmp/mybackupfile';
```

  To back up more than one database, separate the names by commas:

```
BACKUP DATABASE world, sakila TO '/tmp/mybackupfile';
```

  To select all databases for backup, use the * selector as a shortcut:

```
BACKUP DATABASE * TO '/tmp/mybackupfile';
```

- RESTORE restores databases using the contents of the backup file:

```
RESTORE FROM '/tmp/mybackupfile';
```

BACKUP DATABASE backs up database and table definitions, table data, stored routines, triggers, events, and views. TEMPORARY tables are not included. Tablespace backup support is limited to the Falcon storage engine.

Prior to MySQL 6.0.7, BACKUP DATABASE did not save any privileges in the backup image file and RESTORE did not restore privileges. As of MySQL 6.0.7, privileges are saved and restored according to these rules:

- BACKUP DATABASE saves privileges for the backed-up databases in the backup image file. The privileges are stored in the form of GRANT statements.
- Only privileges are the database level or below (table, column, routine) are saved. Global privileges are not saved because they are not specific to the databases included in the backup.
- Privileges that specify the database name using a pattern (containing the '%' or '_' wildcard character) are not saved because they might apply to databases not included in the backup.
- For restore operations, only those privileges are restore that pertain to accounts that exist on the MySQL server performing the restore. Other privileges are ignored with a warning. (These warnings can be displayed with SHOW WARNINGS.) Suppose that a backup contains this GRANT statement:

```
GRANT SELECT, INSERT ON db1.* to 'someuser'@'localhost'
```

  The privileges specified by this statement will be restored if the 'someuser'@'localhost' account exists, and ignored with a warning otherwise.

  Restoration of privileges for accounts that do not exist is not done because that would implicitly create accounts that have no password, which is a security risk.

Storage of GRANT statement in backup image files has a security implication: Backup images should be stored in a secure location so that unauthorized users cannot modify the GRANT statements contained therein to change the privileges granted by restore operations.

For anything else not explicitly listed, assume that it is not backed up. This includes but is not limited to items such as UDF definitions and files, logs, and option files.

BACKUP DATABASE currently does not back up the contents of the mysql database. This database contains the grant tables that

define user accounts and their privileges, as well as other system information. To make a full server instance backup that includes account information in addition to data, use the BACKUP DATABASE statement together with the mysqldump program. In the following instructions, *path* represents the full path name to the directory where you store your backup files.

1. Use mysqldump to back up the mysql database. This is a blocking operation that prevents changes to the database during the dump, but the mysql database normally is relatively small and can be dumped quickly:

   ```
   shell> mysqldump --databases mysql > path/mysql-db.sql
   ```

2. Use BACKUP DATABASE to back up the data from other databases. This is a non-blocking operation:

   ```
   mysql> BACKUP DATABASE * TO 'path/other-dbs.bak';
   ```

Restore the server instance later like this:

1. To restore the user accounts, reload the mysql database dump file using the mysql client:

   ```
   shell> mysql -u root -p < path/mysql-db.sql
   ```

2. To restore the data for other databases, use RESTORE with the image file produced by BACKUP DATABASE:

   ```
   mysql> RESTORE FROM 'path/other-dbs.bak';
   ```

For more information about the operation of the BACKUP DATABASE and RESTORE statements, see Section 12.5.3.1, “BACKUP DATABASE Syntax”, and Section 12.5.3.3, “RESTORE Syntax”.

6.3.2. How MySQL Backup Works

A backup operation creates a backup of one or more databases at a given point in time and saves it as a backup image, a file that contains the backup data (table contents) and metadata (definitions for databases, tables, and other objects, and server information).

The backup is intended to provide a consistent snapshot of the backed-up data as of the point at which the operation began, and it is intended to provide online operation as much as possible that allows other server activity to proceed without blocking.

A backup operation begins at time *t1* and ends at time *t2*, producing a backup image that contains the backup state (database state) at time *t*, where *t1* < *t* < *t2*. The time *t* is called the validity point of the backup image. It represents the time when all storage engines are synchronized for the backup. Restoring this image restores the state to be the same as it was at time *t*.

Consistency of the backup means that these constraints must be true:

- Data from transactional tables is included only for committed transactions.
- Data from non-transactional tables is included only for completed statements.
- Referential integrity is maintained between all backed-up tables within a given backup image.

The referential-integrity constraint does not necessarily hold if two tables are related but only one of them is included in a backup. Restoring the backup then would restore only the backed-up table, which can produce tables for which referential integrity no longer holds.

For a backup to proceed properly, certain types of server activity must be blocked, so the backup system incorporates a commit blocker and a Backup Metadata Lock.

The commit blocker has these properties:

- Changes for non-transactional tables must be blocked.
- Changes for transactional tables are not blocked, but only changes that have been committed when the backup occurs appear in the backup. Changes that occur during the backup operation are not included in the backup image.

When a backup or restore operation is in progress, it is not allowable to modify the structure of database objects. Consequently, during the operation, the Backup Metadata Lock blocks statements that change database metadata from executing. A backup image

stores metadata for the following types of objects:

- Databases
- Tablespaces
- Privileges
- Tables
- Views
- Stored programs (functions, procedures, events, triggers)

This requires that the following metadata changes be frozen during backup operation:

- Databases being backed up should not disappear or be changed.
- `BACKUP DATABASE * ...`, new databases should not appear.
- The list of objects inside each database should not change.
- Metadata for objects in the databases should not change.
- The set of privileges for each database should not change.
- Users for which privileges are stored should not disappear or change.
- Tablespaces used by tables being backed up should not disappear or change.

To achieve these requirements, the Backup Metadata Lock blocks the following statements:

```
DROP   DATABASE/TABLE/VIEW/FUNCTION/PROCEDURE/EVENT/TRIGGER/INDEX/
       USER/TABLESPACE
CREATE DATABASE/TABLE/VIEW/FUNCTION/PROCEDURE/EVENT/TRIGGER/INDEX
ALTER  DATABASE/TABLE/VIEW/FUNCTION/PROCEDURE/EVENT/TABLESPACE
RENAME TABLE/USER
GRANT/REVOKE
TRUNCATE/OPTIMIZE/REPAIR TABLE
```

Currently, all instances of statements that change metadata are blocked, even for database or table objects that are not included in the backup. Eventually, the goal is to block only metadata-changing statements for objects in the backup.

Blocking works in both directions. A backup or restore blocks DDL statements, but if a backup or restore operation is initiated while DDL statements are in progress, the operation waits until the statements have finished.

Implementation of `BACKUP DATABASE` and `RESTORE` uses an architecture with the following design:

- The MySQL server communicates with the backup kernel.
- The backup kernel is responsible for communicating with backup engines and for handling metadata (definitions for databases, tables, and other objects, as well as server information).
- Each backup engine provides backup and restore drivers for the backup kernel to use.
- An engine's backup and restore drivers perform actual transfer of data (table contents).

The backup system chooses from among the backup engines available to it:

- There is a default backup engine to be used if a better one is not found. This engine provides default backup and restore drivers that use a blocking algorithm. For example, the backup driver locks all tables at the start of the backup and unlocks them after the last one is processed (which may occur before the operation is complete).
- A consistent-snapshot engine implements the same kind of backup as that made by `mysqldump --single-transaction`.

The backup driver for the snapshot engine works with only those storage engines that support consistent read via the handler interface, which currently includes only `InnoDB` and `Falcon`. The backup driver creates a logical backup because it reads rows one at a time and returns them to the backup kernel to be stored in the backup image.

A backup image must have contents that are consistent with the binary log coordinates taken from the time of the backup. Otherwise, point-in-time recovery using the backup image plus the binary log contents will not work correctly. `BACKUP DATABASE` synchronizes with binary logging to make sure that the backup image and binary log are consistent with each other. This way, if data loss occurs later, use of the backup image combined with the binary log makes point-in-time recovery possible:

1. Restore the backup image
2. Re-execute binary log contents beginning from the coordinates of the backup's validity point up to the desired point of recovery

6.3.3. MySQL Backup Status Reporting and Monitoring

MySQL provides information about the status or progress of `BACKUP DATABASE` or `RESTORE` operations in the following ways:

- `SHOW PROCESSLIST` displays information while a thread performing a backup or restore is executing.
- Upon successful completion, the `BACKUP DATABASE` and `RESTORE` statements return a result set with the backup number. (This number is the ID for the corresponding row or rows in the metadata tables described later.) Warnings produced during the operation can be displayed with `SHOW WARNINGS`.

  If errors occur during a backup or restore operation, they are written to the error log, recorded in the progress tables, and are available via the `SHOW ERRORS` and `SHOW WARNINGS` statements.

  If a fatal error occurs, the `BACKUP DATABASE` or `RESTORE` statement reports it to the user.
- The server maintains `backup_history` and `backup_progress` tables in the `mysql` database that contain metadata indicating backup status and progress. It is also possible to write log information to files. For information about selecting log destinations, see Section 6.3.3.1, “MySQL Backup Log Control”. For a description of what is logged, see Section 6.3.3.2, “MySQL Backup Log Contents”.

  If you upgrade to MySQL 6.0.5 or later from an older version, be sure to run `mysql_upgrade` to ensure that the backup log tables exist. From MySQL 6.0.5 through 6.0.7, these tables were named `online_backup` and `online_backup_progress`.

  Currently, there are no `INFORMATION_SCHEMA` tables corresponding to the `backup_history` and `backup_progress` tables.

6.3.3.1. MySQL Backup Log Control

MySQL Backup provides status and progress logging. This capability can be enabled or disabled. If logging is enabled, tables in the `mysql` database or log files can be used as the destinations for log output. These features are similar to those provided for the general query log and slow query log (see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”), although the options and variables are different.

This section describes how to control MySQL Backup logging. For a description of what is logged, see Section 6.3.3.2, “MySQL Backup Log Contents”.

> **Note**
>
> The features described here are available as of MySQL 6.0.8. Before 6.0.8, MySQL Backup logs to the `online_backup` and `online_backup_progress` tables in the `mysql` database. Logging to files is not supported and logging cannot be disabled.

Log control at server startup. The `--log-backup-output` option specifies the destination for log output, if logging is enabled, but the option does not in itself enable the logs. The syntax for this option is `--log-backup-output[=value,...]`:

- If `--log-backup-output` is given with a value, the value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.

- If `--log-backup-output` is omitted or given without a value, the default is `TABLE`.

The `--backup_history_log` and `--backup_progress_log` options, if given, enable logging to the history and progress logs for the selected log destinations. (By default, both logs are enabled.) These options take an optional argument of 1 or 0 to enable or disable the log. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, logging to the file does not occur unless the `FILE` log destination is selected.

Examples:

- With no logging arguments, MySQL Backup logs to the log tables by default.
- To write log entries to the log tables and log files, use `--log-backup-output=TABLE,FILE` to select both log destinations.

Log control at runtime. Several system variables are associated with log tables and files and enable runtime control over logging:

- The global `log_backup_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The global `backup_history_log` and `backup_progress_log` variables indicate whether the history and progress logs are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `backup_history_log_file` and `backup_progress_log_file` variables indicate the names of the history and progress log files. You can set these variables at server startup or at runtime to change the names of the log files.

6.3.3.2. MySQL Backup Log Contents

If you enable backup logging to tables, MySQL Backup uses the `backup_history` and `backup_progress` tables in the `mysql` database. For logging to files, MySQL Backup uses the `backup_history.log` and `backup_progress.log` files in the MySQL data directory by default. The log file names can be changed by setting the global `backup_history_log_file` and `backup_progress_log_file` system variables. For information about selecting log destinations, see Section 6.3.3.1, “MySQL Backup Log Control”.

The contents of the log tables are discussed following. For logging to files, the server writes lines with a field for each column in the corresponding log table. The server also writes an initial line to the file at startup to indicate the names of the fields. Backup log contents can be culled with the `PURGE BACKUP LOGS` statement. See Section 12.5.3.2, “`PURGE BACKUP LOGS` Syntax”.

If the table destination is selected for backup logging, the server uses these tables:

- The `backup_history` table contains a row for each backup and restore operation. A row is created when an operation completes. The rows in this table serve as a history of all backup and restore operations performed on the server. The table can be queried to obtained detailed information about the operations or as a means to create a summary of the operations. The rows are not removed from the table by the server. Any table maintenance, such as removing old rows, is intended to be performed by the database administrator.
- The `backup_progress` table contains progress data describing the steps in the most recent backup or restore operation. There may be multiple rows for the operation. Rows are added to this table over the course of the operation and are not updated. This enables the table to be used to track the current progress of the operation. Each row in the table represents a step in the operation and may contain informational statements, errors, and other pertinent information. The data in this table has a limited lifetime. At the start of each operation, the table is truncated and new data is added. The database administrator should not need to perform maintenance for this data.

The `backup_history` table has this structure:

```
CREATE TABLE backup_history (
    backup_id           BIGINT UNSIGNED PRIMARY KEY AUTO_INCREMENT,
    process_id          INT UNSIGNED NOT NULL,
    binlog_pos          INT UNSIGNED DEFAULT 0,
    binlog_file         CHAR(64),
    backup_state        ENUM('complete', 'starting', 'validity point',
                             'running', 'error', 'cancel') NOT NULL,
    operation           ENUM('backup', 'restore') NOT NULL,
    error_num           INT NOT NULL DEFAULT 0,
    num_objects         INT UNSIGNED NOT NULL DEFAULT 0,
    total_bytes         BIGINT UNSIGNED,
    validity_point_time DATETIME,
    start_time          DATETIME,
    stop_time           DATETIME,
```

```
    host_or_server_name CHAR (30),
    username            CHAR (30),
    backup_file         CHAR (100),
    backup_file_path    VARCHAR (512),
    user_comment        VARCHAR (200),
    command             VARCHAR (512),
    engines             VARCHAR (100),
) ENGINE=CSV CHARSET=utf8;
```

The `backup_history` columns are used as follows:

- `backup_id`

  The ID for the table row. `BACKUP DATABASE` and `RESTORE` return a result set containing a backup ID, which is the value that tells you which row in the `backup_history` table corresponds to the backup or restore operation.

- `process_id`

  The process ID that the operation ran as.

- `binlog_pos`, `binlog_file`

  For a backup, the binary log position and file name at the time the validity point is generated (the time when all storage engines are synchronized). Before that time, the values are 0 and `NULL`.

- `backup_state`

  The status of the operation.

- `operation`

  The type of operation.

- `error_num`

  The error from this operation (0 = no error).

- `num_objects`

  The number of objects in the backup.

- `total_bytes`

  The size of the backup image file in bytes.

- `validity_point_time`

  For a backup, this is the time that the validity point was generated. Before that time, the value is `NULL`. For a restore, the value currently is always `NULL`.

- `start_time`, `stop_time`

  The date and time when the operation started and stopped.

- `host_or_server_name`

  The server name where the operation ran.

- `username`

  The name of the user who ran the operation.

- `backup_file`

  The name of the backup image file. As of MySQL 6.0.8, this column contains the file basename.

- `backup_file_path`

  The directory containing the image file. This column was added in MySQL 6.0.8.

- `user_comment`

The comment from the user entered at the command line.

- `command`

  The statement used to perform the operation.

- `drivers`

  The names of the drivers used in the operation. Before MySQL 6.0.7, this column was named `engines`.

The `backup_progress` table has this structure:

```
CREATE TABLE backup_progress (
    backup_id   BIGINT UNSIGNED NOT NULL
    object      CHAR (30) NOT NULL
    start_time  DATATIME
    stop_time   DATATIME
    total_bytes BIGINT
    progress    BIGINT UNSIGNED
    error_num   INT NOT NULL DEFAULT 0
    notes       CHAR(100)
) ENGINE=CSV CHARSET=utf8;
```

The `backup_progress` columns are used as follows:

- `backup_id`

  The `backup_id` value of the `backup_history` table row with which the rows in the `backup_progress` table are associated.

- `object`

  The object being operated on.

- `start_time`, `stop_time`

  The date and time when the operation started and stopped.

- `total_bytes`

  The size of the object in bytes.

- `progress`

  The number of bytes processed.

- `error_num`

  The error from this operation (0 = no error).

- `notes`

  Commentary from the backup engine.

6.4. Point-in-Time Recovery

If a MySQL server was started with the `--log-bin` option to enable binary logging, you can use the `mysqlbinlog` utility to recover data from the binary log files, starting from a specified point in time (for example, since your last backup) until the present or another specified point in time. For information on enabling the binary log and using `mysqlbinlog`, see Section 5.2.4, “The Binary Log”, and Section 4.6.8, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

> **MySQL Enterprise**
> For maximum data recovery, the MySQL Enterprise Monitor advises subscribers to synchronize to disk at each write. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

To restore data from a binary log, you must know the location and name of the current binary log file. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. Typically the option is given in an option file (that is, `my.cnf` or `my.ini`, depending on your system). It can also be given on the command line when the server is started. To determine the name of the current binary log file, issue the following

statement:

```
mysql> SHOW MASTER STATUS
```

If you prefer, you can execute the following command from the command line instead:

```
shell> mysql -u root -p -E -e "SHOW MASTER STATUS"
```

Enter the `root` password for your server when `mysql` prompts you for it.

To view the contents of a binary log, use `mysqlbinlog`. See Section 4.6.8, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

6.4.1. Specifying Times for Recovery

To indicate the start and end times for recovery, specify the `--start-datetime` and `--stop-datetime` options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
        /var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
        /var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on. You should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the file with a text editor to examine it.

6.4.2. Specifying Positions for Recovery

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
        --stop-datetime="2005-04-20 10:05:00" \
        /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you don't want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position="368312" /var/log/mysql/bin.123456 \
        | mysql -u root -p

shell> mysqlbinlog --start-position="368315" /var/log/mysql/bin.123456 \
        | mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

6.5. Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see Section 4.6.3, "`myisamchk` — MyISAM Table-Maintenance Utility".

You can use `myisamchk` to get information about your database tables or to check, repair, or optimize them. The following sections describe how to perform these operations and how to set up a table maintenance schedule.

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause `FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.3.1, "`myisamchk` General Options".

In many cases, you may find it simpler to do `MyISAM` table maintenance using the SQL statements that perform operations that `myisamchk` can do:

- To check or repair `MyISAM` tables, use `CHECK TABLE` or `REPAIR TABLE`.
- To optimize `MyISAM` tables, use `OPTIMIZE TABLE`.
- To analyze `MyISAM` tables, use `ANALYZE TABLE`.

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server. See Section 12.5.2.1, "`ANALYZE TABLE` Syntax", Section 12.5.2.2, "`CHECK TABLE` Syntax", Section 12.5.2.4, "`OPTIMIZE TABLE` Syntax", and Section 12.5.2.5, "`REPAIR TABLE` Syntax".

6.5.1. Using `myisamchk` for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.1.4.2, "What to Do If MySQL Keeps Crashing".

For an explanation of how `MyISAM` tables can become corrupted, see Section 13.5.4, "`MyISAM` Table Problems".

If you run `mysqld` with external locking disabled (which is the default as of MySQL 4.0), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each `MyISAM` table *`tbl_name`* in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
`tbl_name``.frm`	Definition (format) file
`tbl_name``.MYD`	Data file
`tbl_name``.MYI`	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but

instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

6.5.2. How to Check `MyISAM` Tables for Errors

To check a `MyISAM` table, use the following commands:

- `myisamchk *tbl_name*`

  This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m *tbl_name*`

  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e *tbl_name*`

  This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i *tbl_name*`

  This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

6.5.3. How to Repair Tables

The discussion in this section describes how to use `myisamchk` on `MyISAM` tables (extensions `.MYI` and `.MYD`).

You can also (and should, if possible) use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See Section 12.5.2.2, “`CHECK TABLE` Syntax”, and Section 12.5.2.5, “`REPAIR TABLE` Syntax”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- *`tbl_name`*`.frm` is locked against change
- Can't find file *`tbl_name`*`.MYI` (Errcode: *`nnn`*)
- Unexpected end of file
- Record file is crashed
- Got error *`nnn`* from table handler

To get more information about the error, run `perror` *`nnn`*, where *`nnn`* is the error number. The following example shows how to use `perror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 6.5.2, "How to Check `MyISAM` Tables for Errors"), or you want to use the extended features that `myisamchk` provides.

The options that you can use for table maintenance with `myisamchk` are described in Section 4.6.3, "`myisamchk` — MyISAM Table-Maintenance Utility".

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still alive for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as "checked."

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means "quick recovery mode"). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means "recovery mode"). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

> **Note**
>
> If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

> **Important**
>
> If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See Section 12.5.2.5, "`REPAIR TABLE` Syntax".

Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

6.5.4. Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 12.5.2.4, "`OPTIMIZE TABLE` Syntax".

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze`, `-a`
- `--sort-index`, `-S`
- `--sort-records=index_num`, `-R index_num`

For a full description of all available options, see Section 4.6.3, "`myisamchk` — MyISAM Table-Maintenance Utility".

6.5.5. Getting Information About a Table

To obtain a description of a table or statistics about it, use the commands shown here. We explain some of the information in more detail later.

- `myisamchk -d tbl_name`

  Runs `myisamchk` in "describe mode" to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -d -v tbl_name`

  Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about what it is doing.

- `myisamchk -eis tbl_name`

  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

  This is like `-eis`, but tells you what is being done.

The *`tbl_name`* argument can be either the name of a `MyISAM` table or the name of its index file, as described in Section 4.6.3, "`myisamchk` — MyISAM Table-Maintenance Utility". Multiple *`tbl_name`* arguments can be given.

Sample output for some of these commands follows. They are based on a table with these data and index file sizes:

```
-rw-rw-r--   1 monty    tcx     317235748 Jan 12 17:30 company.MYD
-rw-rw-r--   1 davida   tcx      96482304 Jan 12 18:35 company.MYI
```

Example of `myisamchk -d` output:

```
MyISAM file:     company.MYI
Record format:   Fixed length
Data records:    1403698  Deleted blocks:         0
Recordlength:    226

table description:
Key Start Len Index   Type
1   2     8   unique  double
2   15    10  multip. text packed stripped
3   219   8   multip. double
4   63    10  multip. text packed stripped
5   167   2   multip. unsigned short
6   177   4   multip. unsigned long
7   155   4   multip. text
8   138   4   multip. unsigned long
9   177   4   multip. unsigned long
    193   1           text
```

Example of `myisamchk -d -v` output:

```
MyISAM file:         company
Record format:       Fixed length
File-version:        1
Creation time:       1999-10-30 12:12:51
Recover time:        1999-10-31 19:13:01
Status:              checked
Data records:            1403698  Deleted blocks:              0
Datafile parts:          1403698  Deleted data:                0
Datafile pointer (bytes):      3  Keyfile pointer (bytes):     3
Max datafile length:  3791650815  Max keyfile length: 4294967294
Recordlength:               226

table description:
Key Start Len Index   Type                 Rec/key     Root Blocksize
1   2     8   unique  double                     1 15845376      1024
2   15    10  multip. text packed stripped       2 25062400      1024
3   219   8   multip. double                    73 40907776      1024
4   63    10  multip. text packed stripped       5 48097280      1024

```

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous.

- `MyISAM file`

  Name of the `MyISAM` (index) file.

- `File-version`

  Version of `MyISAM` format. Currently always 2.

- `Creation time`

  When the data file was created.

- `Recover time`

  When the index/data file was last reconstructed.

- `Data records`

  How many rows are in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 6.5.4, “Table Optimization”.

- `Datafile parts`

  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 6.5.4, "Table Optimization".

- `Datafile pointer`

  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

  How long the table data file can become, in bytes.

- `Max keyfile length`

  How long the table index file can become, in bytes.

- `Recordlength`

  How much space each row takes, in bytes.

- `Record format`

  The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`.

- `table description`

  A list of all keys in the table. For each key, `myisamchk` displays some low-level information:

  - `Key`

    This key's number.

  - `Start`

    Where in the row this portion of the index starts.

  - `Len`

    How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column.

  - `Index`

    Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

  - `Type`

    What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

  - `Root`

    Address of the root index block.

  - `Blocksize`

    The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

  - `Rec/key`

    This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

  For the table shown in the examples, there are two `table description` lines for the ninth index. This indicates that it is a multiple-part index with two parts.

- `Keyblocks used`

  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, as for the table in the examples, the values are very high (very near theoretical maximum).

- `Packed`

  MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the third of the preceding examples, the fourth key is 10 characters long and a 60% reduction in space is achieved.

- `Max levels`

  How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

  How many rows are in the table.

- `M.recordlength`

  The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

  MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

  What percentage of the data file is used.

- `Empty space`

  What percentage of the data file is unused.

- `Blocks/Record`

  Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 6.5.4, “Table Optimization”.

- `Recordblocks`

  How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

  How many blocks (links) are deleted.

- `Recorddata`

  How many bytes in the data file are used.

- `Deleted data`

  How many bytes in the data file are deleted (unused).

- `Lost space`

  If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

If a table has been compressed with `myisampack`, `myisamchk -d` prints additional information about each table column. See Section 4.6.5, "`myisampack` — Generate Compressed, Read-Only MyISAM Tables", for an example of this information and a description of what it means.

6.5.6. Setting Up a Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair `MyISAM` tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See Section 12.5.2.2, "`CHECK TABLE` Syntax", and Section 12.5.2.5, "`REPAIR TABLE` Syntax".

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic `MyISAM` table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are "expected crashed tables.") To check `MyISAM` tables automatically, start the server with the `--myisam-recover` option. See Section 5.1.2, "Server Command Options".

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

We recommend that to start with, you execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to `MyISAM` tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --sort_buffer_size=16M */*.MYI
```

Chapter 7. Optimization

Optimization is a complex task because ultimately it requires understanding of the entire system to be optimized. Although it may be possible to perform some local optimizations with little knowledge of your system or application, the more optimal you want your system to become, the more you must know about it.

This chapter tries to explain and give some examples of different ways to optimize MySQL. Remember, however, that there are always additional ways to make the system even faster, although they may require increasing effort to achieve.

7.1. Optimization Overview

The most important factor in making a system fast is its basic design. You must also know what kinds of processing your system is doing, and what its bottlenecks are. In most cases, system bottlenecks arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When we have the data in main memory, we need to process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

7.1.1. MySQL Design Limitations and Tradeoffs

When using the `MyISAM` storage engine, MySQL uses extremely fast table locking that allows multiple readers or a single writer. The biggest problem with this storage engine occurs when you have a steady stream of mixed updates and slow selects on a single table. If this is a problem for certain tables, you can use another storage engine for them. See Chapter 13, *Storage Engines*.

MySQL can work with both transactional and non-transactional tables. To make it easier to work smoothly with non-transactional tables (which cannot roll back if something goes wrong), MySQL has the following rules. Note that these rules apply *only* when not running in strict SQL mode or if you use the `IGNORE` specifier for `INSERT` or `UPDATE`.

- All columns have default values.
- If you insert an inappropriate or out-of-range value into a column, MySQL sets the column to the “best possible value” instead of reporting an error. For numerical values, this is 0, the smallest possible value or the largest possible value. For strings, this is either the empty string or as much of the string as can be stored in the column.
- All calculated expressions return a value that can be used instead of signaling an error condition. For example, 1/0 returns `NULL`.

To change the preceding behaviors, you can enable stricter data handling by setting the server SQL mode appropriately. For more information about data handling, see Section 1.7.6, “How MySQL Deals with Constraints”, Section 5.1.7, “Server SQL Modes”, and Section 12.2.5, “`INSERT` Syntax”.

7.1.2. Designing Applications for Portability

Because all SQL servers implement different parts of standard SQL, it takes work to write portable database applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even more difficult.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

To make a complex application portable, you need to determine which SQL servers it must work with, and then determine what features those servers support. You can use the MySQL `crash-me` program to find functions, types, and limits that you can use

with a selection of database servers. `crash-me` does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests. An example of the type of information `crash-me` can provide is that you should not use column names that are longer than 18 characters if you want to be able to use Informix or DB2.

The `crash-me` program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you must do to make your own applications database independent. The programs can be found in the `sql-bench` directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods. See Section 7.1.4, "The MySQL Benchmark Suite".

If you strive for database independence, you need to get a good feeling for each SQL server's bottlenecks. For example, MySQL is very fast in retrieving and updating rows for `MyISAM` tables, but has a problem in mixing slow readers and writers on the same table. Transactional database systems in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application *really* database independent, you should define an easily extendable interface through which you manipulate your data. For example, C++ is available on most systems, so it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the `REPLACE` statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative might be slower, it enables the other servers to perform the same tasks.

With MySQL, you can use the `/*! */` syntax to add MySQL-specific keywords to a statement. The code inside `/* */` is treated as a comment (and ignored) by most other SQL servers. For information about writing comments, see Section 8.5, "Comment Syntax".

If high performance is more important than exactness, as for some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results expire after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache size and set the expiration timeout higher until things get back to normal.

In this case, the table creation information should contain information about the initial cache size and how often the table should normally be refreshed.

An attractive alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See Section 7.5.5, "The MySQL Query Cache".

7.1.3. What We Have Used MySQL For

This section describes an early application for MySQL.

During MySQL initial development, the features of MySQL were made to fit our largest customer, which handled data warehousing for a couple of the largest retailers in Sweden.

From all stores, we got weekly summaries of all bonus card transactions, and were expected to provide useful information for the store owners to help them find how their advertising campaigns were affecting their own customers.

The volume of data was quite huge (about seven million summary transactions per month), and we had data for 4–10 years that we needed to present to the users. We got weekly requests from our customers, who wanted instant access to new reports from this data.

We solved this problem by storing all information per month in compressed "transaction tables." We had a set of simple macros that generated summary tables grouped by different criteria (product group, customer id, store, and so on) from the tables in which the transactions were stored. The reports were Web pages that were dynamically generated by a small Perl script. This script parsed a Web page, executed the SQL statements in it, and inserted the results. We would have used PHP or `mod_perl` instead, but they were not available at the time.

For graphical data, we wrote a simple tool in C that could process SQL query results and produce GIF images based on those results. This tool also was dynamically executed from the Perl script that parses the Web pages.

In most cases, a new report could be created simply by copying an existing script and modifying the SQL query that it used. In some cases, we needed to add more columns to an existing summary table or generate a new one. This also was quite simple because we kept all transaction-storage tables on disk. (This amounted to about 50GB of transaction tables and 200GB of other customer data.)

We also let our customers access the summary tables directly with ODBC so that the advanced users could experiment with the data themselves.

This system worked well and we had no problems handling the data with quite modest Sun Ultra SPARCstation hardware (2×200MHz). Eventually the system was migrated to Linux.

7.1.4. The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from http://dev.mysql.com/downloads/, or use the current development source tree. (See Section 2.9.3, “Installing from the Development Source Tree”.)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See Section 2.14, “Perl Installation Notes”.

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit http://www.mysql.com/why-mysql/benchmarks/.

7.1.5. Using Your Own Benchmarks

You should definitely benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See Section 7.1.4, “The MySQL Benchmark Suite”. You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at http://osdb.sourceforge.net/.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, you should put some effort into benchmarking your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.7, "`mysqlslap` — Load Emulation Client".
- You can also try Super Smack, available at http://jeremy.zawodny.com/mysql/super-smack/.

As suggested by the names of these programs, they can bring a system to its knees, so make sure to use them only on your development systems.

7.2. Optimizing `SELECT` and Other Statements

First, one factor affects all statements: The more complex your permissions setup, the more overhead you have. Using simpler permissions when you issue `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, it may be worth the time to use a simplified grant structure to reduce permission-checking overhead.

If your problem is with a specific MySQL expression or function, you can perform a timing test by invoking the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count,expression)`. The return value is always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+------------------------+
| BENCHMARK(1000000,1+1) |
+------------------------+
|                      0 |
+------------------------+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

All MySQL functions should be highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

7.2.1. Optimizing Queries with `EXPLAIN`

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`:

  ```
  EXPLAIN tbl_name
  ```

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the `SELECT`, including information about how tables are joined and in which order:

  ```
  EXPLAIN [EXTENDED | PARTITIONS] SELECT select_options
  ```

- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables. For details, see Section 17.3.4, "Obtaining Information About Partitions".

This section describes the second use of `EXPLAIN` for obtaining query execution plan information. See also Section 12.3.2, "`EXPLAIN` Syntax". For a description of the `DESCRIBE` and `SHOW COLUMNS` statements, see Section 12.3.1, "`DESCRIBE` Syntax", and Section 12.5.6.6, "`SHOW COLUMNS` Syntax".

With the help of `EXPLAIN`, you can see where you should add indexes to tables to get a faster `SELECT` that uses indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optim-

izer to use a join order corresponding to the order in which the tables are named in the SELECT statement, begin the statement with SELECT STRAIGHT_JOIN rather than just SELECT. (See Section 12.2.9, "SELECT Syntax".)

If you have a problem with indexes not being used when you believe that they should be, you should run ANALYZE TABLE to update table statistics such as cardinality of keys, that can affect the choices the optimizer makes. See Section 12.5.2.1, "ANALYZE TABLE Syntax".

EXPLAIN returns a row of information for each table used in the SELECT statement. The tables are listed in the output in the order that MySQL would read them while processing the query. MySQL resolves all joins using a *single-sweep multi-join* method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

When the EXTENDED keyword is used, EXPLAIN produces extra information that can be viewed by issuing a SHOW WARNINGS statement following the EXPLAIN statement. This information displays how the optimizer qualifies table and column names in the SELECT statement, what the SELECT looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process. EXPLAIN EXTENDED also displays the filtered column.

> **Note**
>
> You cannot use the EXTENDED and PARTITIONS keywords together in the same EXPLAIN statement.

Each output row from EXPLAIN provides information about one table, and each row contains the following columns:

- id

  The SELECT identifier. This is the sequential number of the SELECT within the query.

- select_type

  The type of SELECT, which can be any of those shown in the following table.

SIMPLE	Simple SELECT (not using UNION or subqueries)
PRIMARY	Outermost SELECT
UNION	Second or later SELECT statement in a UNION
DEPENDENT UNION	Second or later SELECT statement in a UNION, dependent on outer query
UNION RESULT	Result of a UNION.
SUBQUERY	First SELECT in subquery
DEPENDENT SUBQUERY	First SELECT in subquery, dependent on outer query
DERIVED	Derived table SELECT (subquery in FROM clause)
UNCACHEABLE SUBQUERY	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query
UNCACHEABLE UNION	The second or later select in a UNION that belongs to an uncacheable subquery (see UNCACHEABLE SUBQUERY)

  DEPENDENT typically signifies the use of a correlated subquery. See Section 12.2.10.7, "Correlated Subqueries".

  "DEPENDENT SUBQUERY" evaluation differs from UNCACHEABLE SUBQUERY evaluation. For "DEPENDENT SUBQUERY", the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context. Cacheability of subqueries is subject to the restrictions detailed in Section 7.5.5.1, "How the Query Cache Operates". For example, referring to user variables makes a subquery uncacheable.

- table

  The table to which the row of output refers.

- type

  The join type. The different join types are listed here, ordered from the best type to the worst:

  - system

    The table has only one row (= system table). This is a special case of the const join type.

- `const`

  The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

  `const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, *`tbl_name`* can be used as a `const` table:

  ```
  SELECT * FROM tbl_name WHERE primary_key=1;

  SELECT * FROM tbl_name
    WHERE primary_key_part1=1 AND primary_key_part2=2;
  ```

- `eq_ref`

  One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE` index.

  `eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process *`ref_table`*:

  ```
  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column=other_table.column;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
  ```

- `ref`

  All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

  `ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process *`ref_table`*:

  ```
  SELECT * FROM ref_table WHERE key_column=expr;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column=other_table.column;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
  ```

- `fulltext`

  The join is performed using a `FULLTEXT` index.

- `ref_or_null`

  This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process *`ref_table`*:

  ```
  SELECT * FROM ref_table
    WHERE key_column=expr OR key_column IS NULL;
  ```

  See Section 7.2.9, “`IS NULL` Optimization”.

- `index_merge`

  This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see Section 7.2.6, “Index Merge Optimization”.

- `unique_subquery`

This type replaces `ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

  This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for non-unique indexes in subqueries of the following form:

  ```
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- `range`

  Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

  `range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, or `IN()` operators:

  ```
  SELECT * FROM tbl_name
    WHERE key_column = 10;

  SELECT * FROM tbl_name
    WHERE key_column BETWEEN 10 and 20;

  SELECT * FROM tbl_name
    WHERE key_column IN (10,20,30);

  SELECT * FROM tbl_name
    WHERE key_part1= 10 AND key_part2 IN (10,20,30);
  ```

- `index`

  This join type is the same as `ALL`, except that only the index tree is scanned. This usually is faster than `ALL` because the index file usually is smaller than the data file.

  MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

  A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually *very* bad in all other cases. Normally, you can avoid `ALL` by adding indexes that allow row retrieval from the table based on constant values or column values from earlier tables.

- `possible_keys`

  The `possible_keys` column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

  If this column is `NULL`, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See Section 12.1.6, “`ALTER TABLE` Syntax”.

  To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key`

  The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

  It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

  For `InnoDB`, a secondary index might cover the selected columns even if the query also selects the primary key because `InnoDB` stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing

the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 12.2.9.2, “Index Hint Syntax”.

For `MyISAM` tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For `MyISAM` tables, `myisamchk --analyze` does the same. See Section 12.5.2.1, “`ANALYZE TABLE` Syntax”, and Section 6.5, “Table Maintenance and Crash Recovery”.

- `key_len`

  The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses.

- `ref`

  The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- `rows`

  The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

  For `InnoDB` tables, this number is an estimate, and may not always be exact.

- `filtered`

  The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. That is, `rows` shows the estimated number of rows examined and `rows` × `filtered` / `100` shows the number of rows that will be joined with previous tables. This column is displayed if you use `EXPLAIN EXTENDED`.

- `Extra`

  This column contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, you should look out for `Extra` values of `Using filesort` and `Using temporary`.

  - `Distinct`

    MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

  - `FirstMatch(`*`tbl_name`*`)`

    The semi-join FirstMatch join shortcutting strategy is used for *`tbl_name`*.

  - `Full scan on NULL key`

    This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

  - `Impossible WHERE noticed after reading const tables`

    MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

  - `LooseScan(`*`m`*`..`*`n`*`)`

    The semi-join LooseScan strategy is used. *`m`* and *`n`* are key part numbers.

  - `No tables`

    The query has no `FROM` clause, or has a `FROM DUAL` clause.

  - `Not exists`

    MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

    ```
    SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
      WHERE t2.id IS NULL;
    ```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- `Range checked for each record (index map: N)`

  MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in Section 7.2.5, “Range Optimization”, and Section 7.2.6, “Index Merge Optimization”, with the exception that all column values for the preceding table are known and considered to be constants.

  Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value *`N`* is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- `Scanned N databases`

  This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in Section 7.2.24, “`INFORMATION_SCHEMA` Optimization”. The value of *`N`* can be 0, 1, or `all`.

- `Select tables optimized away`

  The query contained only aggregate functions (`MIN()`, `MAX()`) that were all resolved using an index, or `COUNT(*)` for `MyISAM`, and no `GROUP BY` clause. The optimizer determined that only one row should be returned.

- `Skip_open_table`, `Open_frm_only`, `Open_trigger_only`, `Open_full_table`

  These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables, as described in Section 7.2.24, “`INFORMATION_SCHEMA` Optimization”.

  - `Skip_open_table`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
  - `Open_frm_only`: Only the table's `.frm` file need be opened.
  - `Open_trigger_only`: Only the table's `.TRG` file need be opened.
  - `Open_full_table`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

- `Start materialize`, `End materialize`, `Scan`

  This indicates temporary table use for materialization.

- `Start temporary`, `End temporary`

  This indicates temporary table use for the semi-join Duplicate Weedout strategy.

- `Using filesort`

  MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 7.2.17, “`ORDER BY` Optimization”.

- `Using index`

  The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

  For `InnoDB` tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` and `key` is `PRIMARY`.

- `Using index condition`

  Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See Section 7.2.8, “Index Condition Pushdown Optimization”.

- `Using index for group-by`

  Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 7.2.18, "`GROUP BY` Optimization".

- `Using join buffer`

  Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table.

- `Using MRR`

  Tables are read using the Multi-Range Read optimization strategy. See Section 7.2.14, "Multi-Range Read Optimization".

- `Using sort_union(...)`, `Using union(...)`, `Using intersect(...)`

  These indicate how index scans are merged for the `index_merge` join type. See Section 7.2.6, "Index Merge Optimization".

- `Using temporary`

  To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where`

  A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See Section 7.5.3, "Tuning Server Parameters".

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
               tt.ProjectReference, tt.EstimatedShipDate,
               tt.ActualShipDate, tt.ClientID,
               tt.ServiceCodes, tt.RepetitiveID,
               tt.CurrentProcess, tt.CurrentDPPerson,
               tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
               et_1.COUNTRY, do.CUSTNAME
        FROM tt, et, et AS et_1, do
        WHERE tt.SubmitTime IS NULL
          AND tt.ActualPC = et.EMPLOYID
          AND tt.AssignedPC = et_1.EMPLOYID
          AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
`tt`	`ActualPC`	`CHAR(10)`
`tt`	`AssignedPC`	`CHAR(10)`
`tt`	`ClientID`	`CHAR(10)`
`et`	`EMPLOYID`	`CHAR(15)`
`do`	`CUSTNMBR`	`CHAR(15)`

- The tables have the following indexes.

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The tt.ActualPC values are not evenly distributed.

Initially, before any optimizations have been performed, the EXPLAIN statement produces the following information:

```
table type possible_keys key  key_len ref  rows  Extra
et    ALL  PRIMARY       NULL NULL    NULL 74
do    ALL  PRIMARY       NULL NULL    NULL 2135
et_1  ALL  PRIMARY       NULL NULL    NULL 74
tt    ALL  AssignedPC,   NULL NULL    NULL 3872
           ClientID,
           ActualPC
      Range checked for each record (index map: 0x23)
```

Because type is ALL for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is 74 × 2135 × 74 × 3872 = 45,268,558,720 rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, VARCHAR and CHAR are considered the same if they are declared as the same size. tt.ActualPC is declared as CHAR(10) and et.EMPLOYID is CHAR(15), so there is a length mismatch.

To fix this disparity between column lengths, use ALTER TABLE to lengthen ActualPC from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now tt.ActualPC and et.EMPLOYID are both VARCHAR(15). Executing the EXPLAIN statement again produces this result:

```
table type   possible_keys key     key_len ref         rows    Extra
tt    ALL    AssignedPC,   NULL    NULL    NULL        3872    Using
             ClientID,                                         where
             ActualPC
do    ALL    PRIMARY       NULL    NULL    NULL        2135
      Range checked for each record (index map: 0x1)
et_1  ALL    PRIMARY       NULL    NULL    NULL        74
      Range checked for each record (index map: 0x1)
et    eq_ref PRIMARY       PRIMARY 15      tt.ActualPC 1
```

This is not perfect, but is much better: The product of the rows values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the tt.AssignedPC = et_1.EMPLOYID and tt.ClientID = do.CUSTNMBR comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
    ->                MODIFY ClientID   VARCHAR(15);
```

After that modification, EXPLAIN produces the output shown here:

```
table type   possible_keys key      key_len ref           rows Extra
et    ALL    PRIMARY       NULL     NULL    NULL          74
tt    ref    AssignedPC,   ActualPC 15      et.EMPLOYID   52   Using
             ClientID,                                         where
             ActualPC
et_1  eq_ref PRIMARY       PRIMARY  15      tt.AssignedPC 1
do    eq_ref PRIMARY       PRIMARY  15      tt.ClientID   1
```

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the tt.ActualPC column are evenly distributed, and that is not the case for the tt table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

```
table type   possible_keys key     key_len ref           rows Extra
tt    ALL    AssignedPC    NULL    NULL    NULL          3872 Using

do    eq_ref PRIMARY       PRIMARY 15      tt.ClientID   1
```

Note that the `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see Section 12.2.10.8, “Subqueries in the FROM clause”.

7.2.2. Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: `log(`*`row_count`*`) / log(`*`index_block_length`*` / 3 × 2 / (`*`index_length`*` + `*`data_pointer_length`*`)) + 1`.

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates `log(500,000)/log(1024/3×2/(3+4)) + 1` = 4 seeks.

This index would require storage of about 500,000 × 7 × 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

Note that the preceding discussion does not mean that your application performance slowly degenerates by log *`N`*. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by log *`N`*). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See Section 7.5.3, “Tuning Server Parameters”.

> The MySQL Enterprise Monitor provides a number of advisors specifically designed to improve query performance. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

7.2.3. Speed of `SELECT` Queries

In general, when you want to make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. All references between different tables should usually be done with indexes. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See Section 7.2.1, “Optimizing Queries with EXPLAIN”, and Section 7.4.4, “How MySQL Uses Indexes”.

Some general tips for speeding up queries on `MyISAM` tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a non-constant expression. You can check the result from the table analysis by using `SHOW INDEX FROM` *`tbl_name`* and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

7.2.4. WHERE Clause Optimization

This section discusses optimizations that can be made for processing WHERE clauses. The examples use SELECT statements, but the same optimizations apply for WHERE clauses in DELETE and UPDATE statements.

Work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL performs a great many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
   ((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
   (a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
   (B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- COUNT(*) on a single table without a WHERE is retrieved directly from the table information for MyISAM and MEMORY tables. This is also done for any NOT NULL expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some SELECT statements are impossible and returns no rows.
- HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT(), MIN(), and so on).
- For each table in a join, a simpler WHERE is constructed to get a fast WHERE evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a WHERE clause on a PRIMARY KEY or a UNIQUE index, where all index parts are compared to constant expressions and are defined as NOT NULL.

  All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in ORDER BY and GROUP BY clauses come from the same table, that table is preferred first when joining.
- If there is an ORDER BY clause and a different GROUP BY clause, or if the ORDER BY or GROUP BY contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the SQL_SMALL_RESULT option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the HAVING clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

7.2.5. Range Optimization

The `range` access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the `WHERE` clause.

7.2.5.1. The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the `WHERE` clause, so we speak of *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both `BTREE` and `HASH` indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=>`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.
- For `BTREE` indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character.
- For all types of indexes, multiple range conditions combined with `OR` or `AND` form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a `const` or `system` table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```
SELECT * FROM t1
  WHERE key_col > 1
  AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
  OR key_col IN (15,18,20);
```

```
SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
  OR key_col BETWEEN 'bar' AND 'foo';
```

Note that some non-constant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

   ```
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
   (key1 < 'bar' AND nonkey = 4) OR
   (key1 < 'uux' AND key1 > 'z')
   ```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

   ```
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
   (key1 < 'bar' AND TRUE) OR
   (key1 < 'uux' AND key1 > 'z')
   ```

3. Collapse conditions that are always true or false:

   - `(key1 LIKE 'abcde%' OR TRUE)` is always true
   - `(key1 < 'uux' AND key1 > 'z')` is always false

   Replacing these conditions with constants, we get:

   ```
   (key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
   ```

   Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

   ```
   (key1 < 'abc') OR (key1 < 'bar')
   ```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

   ```
   (key1 < 'bar')
   ```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND`/`OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

Currently, MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

7.2.5.2. The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following

set of key tuples listed in key order:

```
key_part1  key_part2  key_part3
  NULL       1          'abc'
  NULL       1          'xyz'
  NULL       2          'foo'
   1         1          'abc'
   1         1          'xyz'
   1         2          'abc'
   2         1          'aaa'
```

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For `HASH` indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

  ```
      key_part1 cmp const1
  AND key_part2 cmp const2
  AND ...
  AND key_partN cmp constN;
  ```

  Here, `const1`, `const2`, … are constants, `cmp` is one of the `=`, `<=>`, or `IS NULL` comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part `HASH` index:

  ```
  key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
  ```

  For the definition of what is considered to be a constant, see Section 7.2.5.1, “The Range Access Method for Single-Part Indexes”.

- For a `BTREE` index, an interval might be usable for conditions combined with `AND`, where each condition compares a key part with a constant value using `=`, `<=>`, `IS NULL`, `>`, `<`, `>=`, `<=`, `!=`, `<>`, `BETWEEN`, or `LIKE 'pattern'` (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if `<>` or `!=` is used). For example, for this condition:

  ```
  key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
  ```

  The single interval is:

  ```
  ('foo',10,10) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
  ```

  It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with `OR`, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with `AND`, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

  ```
  (key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
  ```

  The intervals are:

  ```
  (1,-inf) < (key_part1,key_part2) < (1,2)
  (5,-inf) < (key_part1,key_part2)
  ```

  In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the `EXPLAIN` output indicates the maximum length of the key prefix used.

  In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be `NULL`. Then the `key_len` column displays two key part lengths for the following con-

dition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

Section 7.2.5.1, “The Range Access Method for Single-Part Indexes”, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

7.2.6. Index Merge Optimization

The *Index Merge* method is used to retrieve rows with several `range` scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans. This access method merges index scans from a single table; it does not merge scans across multiple tables.

In `EXPLAIN` output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key=30;

SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
  AND t2.key1=t1.some_col;

SELECT * FROM t1, t2
  WHERE t1.key1=1
  AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the `Extra` field of `EXPLAIN` output):

- `Using intersect(...)`
- `Using union(...)`
- `Using sort_union(...)`

The following sections describe these methods in greater detail.

> **Note**
>
> The Index Merge optimization algorithm has the following known deficiencies:

- If a range scan is possible on some key, the optimizer will not consider using Index Merge Union or Index Merge Sort-Union algorithms. For example, consider this query:

  ```
  SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
  ```

  For this query, two plans are possible:

  - An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
  - A range scan using the `badkey < 30` condition.

  However, the optimizer considers only the second plan.

- If your query has a complex `WHERE` clause with deep `AND`/`OR` nesting and MySQL doesn't choose the optimal plan, try distributing terms using the following identity laws:

  ```
  (x AND y) OR z = (x OR z) AND (y OR z)
  (x OR y) AND z = (x AND z) OR (y AND z)
  ```

- Index Merge is not applicable to fulltext indexes. We plan to extend it to cover these in a future MySQL release.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

7.2.6.1. The Index Merge Intersection Access Algorithm

This access algorithm can be employed when a `WHERE` clause was converted to several range conditions on different keys combined with `AND`, and each condition is one of the following:

- In this form, where the index has exactly *`N`* parts (that is, all index parts are covered):

  ```
  key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
  ```

- Any range condition over a primary key of an `InnoDB` table.

Examples:

```
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_col1=20;

SELECT * FROM tbl_name
  WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved (`EXPLAIN` output contains `Using index` in `Extra` field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;
```

If the used indexes don't cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an `InnoDB` table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

7.2.6.2. The Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's `WHERE` clause was converted to several range conditions on different keys combined with `OR`, and each condition is one of the following:

- In this form, where the index has exactly *`N`* parts (that is, all index parts are covered):

  ```
  key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
  ```

- Any range condition over a primary key of an `InnoDB` table.
- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;

SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR
  (key3='foo' AND key4='bar') AND key5=5;
```

7.2.6.3. The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the `WHERE` clause was converted to several range conditions combined by `OR`, but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_col1 < 10 OR key_col2 < 20;

SELECT * FROM tbl_name
  WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

7.2.7. Condition Pushdown Optimization

This optimization improves the efficiency of a direct comparison between a non-indexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. In MySQL 6.0, this optimization can be used only by the `MyISAM` storage engine; it may be implemented for additional storage engines in future versions of MySQL.

Suppose that a table is defined as follows:

```
CREATE TABLE t1 (
    a INT,
    b INT,
    KEY(a)
) ENGINE=MyISAM;
```

> **Note**
>
> It is not necessary to use an explicit `ENGINE` option to create a `MyISAM` table if this is the default MySQL storage engine type at the time the table is created; condition pushdown can still be employed with such a `MyISAM` table.

Condition pushdown can be used with a query against this table such as the query shown here:

```
SELECT a,b FROM t1 WHERE b = 10;
```

This can be seen in the output of `EXPLAIN SELECT`:

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using where with pushed condition
```

However, condition pushdown *cannot* be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```

With regard to the first of these two queries, condition pushdown is not applicable because an index exists on column `a`. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) In the case of the second query, condition pushdown cannot be employed because the comparison involving the non-indexed column `b` is indirect. (However, condition pushdown could be applied if you were to reduce `b + 1 = 10` to `b = 9` in the `WHERE` clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a `>` or `<` operator:

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE a<2\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t1
         type: range
possible_keys: a
          key: a
      key_len: 5
          ref: NULL
         rows: 2
        Extra: Using where with pushed condition
```

Other comparisons which are supported for condition pushdown include the following:

- *`column`* `[NOT] LIKE` *`pattern`*

pattern must be a string literal containing the pattern to be matched; for syntax, see Section 11.4.1, “String Comparison Functions”.

- *column* `IS [NOT] NULL`
- *column* `IN (`*value_list*`)`

  Each item in the *value_list* must be a constant, literal value.

- *column* `BETWEEN` *constant1* `AND` *constant2*

  constant1 and *constant2* must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Condition pushdown capability is not used by default. To enable it, you can start `mysqld` with the `--engine-condition-pushdown` option, or you can execute either of the following statements at runtime:

```
SET engine_condition_pushdown=ON;
```

```
SET engine_condition_pushdown=1;
```

Limitations. Condition pushdown is subject to the following limitations:

- In MySQL 6.0, condition pushdown is supported by the `MyISAM` storage engine only.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
- Columns used in comparisons cannot be of any of the `BLOB` or `TEXT` types.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use `EXPLAIN EXTENDED` to determine which conditions are actually pushed down.

> **Note**
>
> The `NDBCLUSTER` storage engine used by MySQL Cluster also supports condition pushdown; however, this storage engine is currently not available in MySQL 6.0. If you are interested in using MySQL Cluster, see MySQL Cluster NDB 6.X/7.X, which provides information about MySQL Cluster NDB 6.2 and 6.3, which are based on MySQL 5.1 but contain the latest improvements and fixes for `NDBCLUSTER`.

7.2.8. Index Condition Pushdown Optimization

Index Condition Pushdown optimization is used for the `range`, `ref`, `eq_ref`, and `ref_or_null` access methods when there is a need to access full table rows. The optimization is that the server tries to use index information to defer (“push down”) reading of full table rows unless it is known to be necessary. This is done by performing early tests on index tuples first. This strategy can be used for `MyISAM` tables.

To see how this optimization works, consider first how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.
2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the scan proceeds like this instead:

1. Get the next rows's index tuple (but not the full table row).
2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the next row.
3. Use the index tuple to locate and read the full table row.

4. Test the part of the WHERE condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the Extra column in EXPLAIN output shows Using index condition. It will not show Index only because that does not apply when full table rows must be read.

Suppose that we have a table containing information about people and their addresses and that the table has an index defined as INDEX (zipcode, lastname, firstname). If we know a person's zipcode value but are not sure about the last name, we can search like this:

```
SELECT * FROM people
  WHERE zipcode='95054'
  AND lastname LIKE '%etrunia%'
  AND address LIKE '%Main Street%'
```

MySQL can use the index to scan through people with zipcode='95054'. The second part (lastname LIKE '%etrunia%') cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all the people who have zipcode='95054'.

With Index Condition Pushdown, MySQL will check the lastname LIKE '%etrunia%' part before reading the full table row. This avoids reading full rows corresponding to all index tuples that do not match the lastname condition. The full-row test is "pushed down" to take place later than the index-only test.

Index Condition Pushdown is enabled by default; it can be controlled with the engine_condition_pushdown system variable. This variable also controls table Condition Pushdown as used for NDB; see Section 7.2.7, "Condition Pushdown Optimization".

7.2.9. IS NULL Optimization

MySQL can perform the same optimization on *col_name* IS NULL that it can use for *col_name* = *constant_value*. For example, MySQL can use indexes and ranges to search for NULL with IS NULL.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
  WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a WHERE clause includes a *col_name* IS NULL condition for a column that is declared as NOT NULL, that expression is optimized away. This optimization does not occur in cases when the column might produce NULL anyway; for example, if it comes from a table on the right side of a LEFT JOIN.

MySQL can also optimize the combination *col_name* = *expr* OR *col_name* IS NULL, a form that is common in resolved subqueries. EXPLAIN shows ref_or_null when this optimization is used.

This optimization can handle one IS NULL for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns a and b of table t2:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
  OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

ref_or_null works by first doing a read on the reference key, and then a separate search for rows with a NULL key value.

Note that the optimization can handle only one IS NULL level. In the following query, MySQL uses key lookups only on the expression (t1.a=t2.a AND t2.a IS NULL) and is not able to use the key part on b:

```
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL)
  OR (t1.b=t2.b AND t2.b IS NULL);
```

7.2.10. LEFT JOIN and RIGHT JOIN Optimization

MySQL implements an *A* `LEFT JOIN` *B* `join_condition` as follows:

- Table *B* is set to depend on table *A* and all tables on which *A* depends.
- Table *A* is set to depend on all tables (except *B*) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table *B*. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard `WHERE` optimizations are performed.
- If there is a row in *A* that matches the `WHERE` clause, but there is no row in *B* that matches the `ON` condition, an extra *B* row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: *`col_name`* `IS NULL` in the `WHERE` part, where *`col_name`* is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The implementation of `RIGHT JOIN` is analogous to that of `LEFT JOIN` with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by `LEFT JOIN` or `STRAIGHT_JOIN` helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on `b` because the `LEFT JOIN` forces it to be read before `d`:

```
SELECT *
  FROM a JOIN b LEFT JOIN c ON (c.key=a.key)
  LEFT JOIN d ON (d.key=a.key)
  WHERE b.key=d.key;
```

The fix in this case is reverse the order in which `a` and `b` are listed in the `FROM` clause:

```
SELECT *
  FROM b JOIN a LEFT JOIN c ON (c.key=a.key)
  LEFT JOIN d ON (d.key=a.key)
  WHERE b.key=d.key;
```

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to a normal join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use `STRAIGHT_JOIN`. (See Section 12.2.9, “`SELECT` Syntax”.)

7.2.11. Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

```
Table   Join Type
t1      range
t2      ref
t3      ALL
```

If a simple NLJ algorithm is used, the join would be processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions,
      send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, tables processed in the inner loops typically are read many times.

Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) Join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. The reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The `join_buffer_size` system variable determines the size of each join buffer.
- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`. As of MySQL 6.0.9, use of buffering is extended to be applicable to outer joins and semi-joins, as described in Section 7.2.15, “Block Nested-Loop and Batched Key Access Joins”.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first non-const table, even if it would be of type `ALL` or `index`.
- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join would be done as follow using join buffering:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions,
          send to client
        }
      }
      empty buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions,
      send to client
    }
  }
}
```

If *`S`* is the size of each stored `t1`, `t2` combination is the join buffer and *`C`* is the number of combinations in the buffer, the number of times table `t3` is scanned is:

```
(S * C)/join_buffer_size + 1
```

One implication is that the number of `t3` scans decreases as the value of `join_buffer_size` increases, up to the point when `join_buffer_size` is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

7.2.12. Nested Join Optimization

The syntax for expressing joins allows nested joins. The following discussion refers to the join syntax described in Section 12.2.9.1, “JOIN Syntax”.

The syntax of *table_factor* is extended in comparison with the SQL Standard. The latter accepts only *table_reference*, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of *table_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
   ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
    ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows `(1)`, `(2)`
- Table `t2` contains row `(1,101)`
- Table `t3` contains row `(101)`

In this case, the first expression returns a result set including the rows `(1,1,101,101)`, `(2,NULL,NULL,NULL)`, whereas the second expression returns the rows `(1,1,101,101)`, `(2,NULL,NULL,101)`:

```
mysql> SELECT *
    -> FROM t1
    ->      LEFT JOIN
    ->      (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
    ->      ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL | NULL |
+------+------+------+------+

mysql> SELECT *
    -> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
    ->      LEFT JOIN t3
    ->      ON t2.b=t3.b OR t2.b IS NULL;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL |  101 |
+------+------+------+------+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
    -> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL | NULL |
+------+------+------+------+

mysql> SELECT *
    -> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | NULL | NULL |  101 |
+------+------+------+------+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

is equivalent to this expression:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

for any tables `t1,t2,t3` and any condition `P` over attributes `t2.b` and `t3.b`.

Whenever the order of execution of the join operations in a join expression (*`join_table`*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
  WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
  WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression `(t2,t3)`.)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables `T1,T2,T3` of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
                 INNER JOIN T3 ON P2(T2,T3)
  WHERE P(T1,T2,T3).
```

Here, `P1(T1,T2)` and `P2(T3,T3)` are some join conditions (on expressions), whereas `P(t1,t2,t3)` is a condition over columns of tables `T1,T2,T3`.

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
         t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

The notation `t1||t2||t3` means “a row constructed by concatenating the columns of rows `t1`, `t2`, and `t3`.” In some of the following examples, `NULL` where a row name appears means that `NULL` is used for each column of that row. For example, `t1||t2||NULL` means “a row constructed by concatenating the columns of rows `t1` and `t2`, and `NULL` for each column of `t3`.”

Now let's consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
             (T2 LEFT JOIN T3 ON P2(T2,T3))
             ON P1(T1,T2)
  WHERE P(T1,T2,T3).
```

For this query, we modify the nested-loop pattern to get:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
      f1=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

Note that for the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
         t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
  WHERE P(T1,T2,T3)
```

The nestings are these:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t1,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

and:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t3 in T3 such that P2(t1,t3) {
    FOR each row t2 in T2 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

In both nestings, `T1` must be processed in the outer loop because it is used in an outer join. `T2` and `T3` are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, `T2` and `T3` can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our `WHERE` condition `P(T1,T2,T3)` can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```
FOR each row t1 in T1 such that C1(t1) {
  FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2)  {
    FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
      IF P(t1,t2,t3) {
         t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

You see that each of the conjuncts `C1(T1)`, `C2(T2)`, `C3(T3)` are pushed out of the most inner loop to the most outer loop where it can be evaluated. If `C1(T1)` is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table `T1` passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the `WHERE` condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

the nested-loop schema using guarded pushed-down conditions looks like this:

```
FOR each row t1 in T1 such that C1(t1) {
```

```
  BOOL f1:=FALSE;
  FOR each row t2 in T2
      such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3
        such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
      IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
      f1=TRUE;
    }
    IF (!f2) {
      IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1 && P(t1,NULL,NULL)) {
      t:=t1||NULL||NULL; OUTPUT t;
  }
}
```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Note that access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL 6.0.)

7.2.13. Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

```
(T1, ...) RIGHT JOIN (T2,...) ON P(T1,...,T2,...) =
(T2, ...) LEFT JOIN (T1,...) ON P(T1,...,T2,...)
```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2`, `P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

```
SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
  WHERE P(T1,T2) AND R(T2)
```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the `WHERE` condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```
T1 LEFT JOIN T2 ON T1.A=T2.A
```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 LEFT JOIN T3 ON T3.B=T1.B
  WHERE T3.C > 0
```

the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 INNER JOIN T3 ON T3.B=T1.B
  WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order `T1,T2,T3`. For the replacing query, it additionally considers the access sequence `T3,T1,T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 LEFT JOIN T3 ON T3.B=T2.B
  WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                 INNER JOIN T3 ON T3.B=T2.B
  WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
  WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition `T3.B=T2.B` is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
  WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
  WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
              (T2 INNER JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A
  WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
              (T2,T3)
              ON (T2.A=T1.A AND T3.B=T2.B)
  WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the `WHERE` condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
              (T2 LEFT JOIN T3 ON T3.B=T2.B)
              ON T2.A=T1.A AND T3.C=T1.C
  WHERE T3.D > 0 OR T1.D > 0
```

the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
              (T2, T3)
              ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
  WHERE T3.D > 0 OR T1.D > 0
```

7.2.14. Multi-Range Read Optimization

The Multi-Range Read (MRR) optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.
- MRR enables batch processing of requests for key access for operations that require access to data rows via index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for `MyISAM` tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for `NDB` tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the `Extra` column in `EXPLAIN` output shows `Using MRR`.

`MyISAM` does not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples; MRR provides no benefit.

Example query for which MRR can be used, assuming that there is an index on `(key_part1, key_part2)`:

```
SELECT * FROM t
  WHERE key_part1 >= 1000 AND key_part1 < 2000
  AND key_part2 = 10000;
```

The index consists of tuples of `(key_part1, key_part2)` values, ordered first by `key_part1` and then by `key_part2`.

Without MRR, an index scan covers all index tuples for the `key_part1` range from 1000 up to 2000, regardless of the `key_part2` value in these tuples. The scan does extra work to the extent that tuples in the range contain `key_part2` values other than 10000.

With MRR, the scan is broken up into multiple ranges, each for a single value of `key_part1` (1000, 1001, ... , 1999). Each of these scans need look only for tuples with `key_part2` = 10000. If the index contains many tuples for which `key_part2` is not 10000, MRR results in many fewer index tuples being read.

To express this using interval notation, the non-MRR scan must examine the index range `[{1000, 10000}, {2000, MIN_INT})`, which may include many tuples other than those for which `key_part2` = 10000. The MRR scan examines multiple single-point intervals `[{1000, 10000}]`, ..., `[{1999, 10000}]`, which includes only tuples with `key_part2` = 10000.

The `optimizer_use_mrr` system variable provides an interface to the use of MRR optimization. It has supported values of `force` and `disable`. The default value is `force`. That is, MRR is used whenever it is applicable.

For MRR, a storage engine uses the value of the `read_rnd_buffer_size` system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to `read_rnd_buffer_size` bytes and determines the number of ranges to process in a single pass.

7.2.15. Block Nested-Loop and Batched Key Access Joins

Starting from MySQL 6.0.9, a new algorithm that uses both index access to the joined table and a join buffer has been implemented. It is called the Batched Key Access (BKA) Join algorithm. The algorithm supports inner join, outer join and semi-join operations, including nested outer joins and nested semi-joins. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins has been extended and can be employed for outer join and semi-join operations, including nested outer joins and nested semi-joins.

For BKA, benefits include improved join performance for `NDBCLUSTER` due to a reduced number of round trips, and for disk-based storage engines such as `MyISAM`, `InnoDB`, `Falcon`, and `Maria` due to more efficient table scanning.

The following sections discuss the new join buffer management that underlies the reimplementation of the original BNL algorithm, the extended BNL algorithm, the BKA algorithm, and describe how these algorithms operate.

7.2.15.1. Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

Starting from version 6.0.9, MySQL Server can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semi-joins that appear after subquery flattening. Moreover, a join buffer now can be effectively used when there is an index access to the inner table.

The new join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the `VARCHAR` type.

The new code supports two types of buffers, regular and incremental. Suppose that join buffer `B1` is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer `B2`:

- A regular join buffer contains columns from each join operand. If `B2` is a regular join buffer, each row `r` put into `B2` is composed of the columns of a row `r1` from `B1` and the interesting columns of a matching row `r2` from table `t2`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If `B2` is an incremental join buffer, the interesting columns of the row `r2` are stored with a link to the row `r1` from `B1`.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer `B1` used to join tables `t1` and `t2` must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row `r` whose columns are stored in the previous join buffers insofar as all these rows match row `r`.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced

by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `join_cache_level` system variable controls for which join operations of which types join buffers are supposed to be used. The allowable `join_cache_level` values are shown in the following table.

Option	Description
`0`	No join buffer is used for any join operation. This setting can be useful to for assessing baseline join performance in comparison to performance with nonzero values that enable use of join buffering.
`1`	This is the default value. Join buffers are employed exactly in the same cases as in versions of MySQL prior to 6.0.9: They are used only for inner joins that are executed by the original Block Nested-Loop (BNL) join algorithm. When this algorithm is applied, rows of the inner table are accessed through a table scan, a plain index scan, or a range index scan.
`2`	The server employs an incremental join buffer for a join operation if its first operand is produced by a join operation that uses a join buffer itself.
`3`	The BNL algorithm is used for an outer join and semi-join operation with one inner table, and for inner joins.
`4`	The BNL algorithm uses incremental buffers for inner tables. In this case, the BNL algorithm can be used for nested outer joins and semi-joins (outer joins and semi-joins with several inner tables). Such an operation can be executed only if incremental join buffers are used to join all inner tables but the first one.
`5`	The BKA algorithm uses regular buffers for any join operation with index access to the joined table.
`6`	The BKA algorithm uses incremental buffers for any join operation with index access to the joined table.
`7`	The BKA algorithm uses regular join buffers with a hash table.
`8`	The BKA algorithm uses incremental join buffers with a hash table.

7.2.15.2. Block Nested-Loop Algorithm for Outer Joins and Semi-Joins

As of MySQL 6.0.9, the original implementation of the BNL algorithm has been extended to support outer join and semi-join operations.

When any of these operations is executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by `NULL` complements (`NULL` values for each column in the second operand) and sent for further extensions by the remaining join operations.

If a join buffer is used for a semi-join operation, only the first extension by a row from the inner table is sent for further extensions by the remaining join operations.

If the value of `join_cache_level` is 3, the BNL algorithm is used for an outer join and semi-join operation with one inner table.

If the value of `join_cache_level` is 4, the BNL algorithm uses incremental buffers for inner tables. In this case, the BNL algorithm can be used for nested outer joins and semi-joins (outer joins and semi-joins with several inner tables). Such an operation can be executed only if incremental join buffers are used to join all inner tables but the first one.

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer` and the `type` value is `ALL`, `index`, or `range`.

7.2.15.3. Batched Key Access Joins

MySQL 6.0.9 introduces a new algorithm to join tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. Each key in the batch is supplemented with a reference to the row in the join buffer from which the key originates. This reference is called the key/range association. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see Section 7.2.14, “Multi-Range Read Optimization”). After submission of the keys, the MMR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows.

For BKA to be used, `join_cache_level` must have a value from 5 to 8 (as described shortly) and the value of the `optimizer_use_mrr` system variable must not be `'disabled'`.

Each matching row is coupled with a reference to a row in the join buffer. This is exactly the reference passed with the key by which the matching row has been fetched. so this is the reference to the matched row in the join buffer. The BKA join algorithm effectively uses this reference to build the joined rows from the matched and the matching rows.

There are two scenarios by which MRR functions execute:

- The first scenario is used for remote storage engines such as `NDBCLUSTER`. A package of keys for a portion of rows from the join buffer, together with their associations, is sent by MySQL Server to NDB nodes. In return, the Server receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new portion of keys are sent to NDB nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to NDB nodes and the MySQL server receives and joins all rows matching these keys. This improves performance because the fewer packages with keys the MySQL Server sends to the Cluster, the fewer round trips between the server and the Cluster nodes are required to perform the join operation.
- The second scenario is used for conventional disk-based storage engine such as `MyISAM`, `InnoDB`, `Falcon`, and `Maria`. For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The row are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.

With the second scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MMR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

If the value of `join_cache_level` is 5 or 6, the BKA algorithm is used for any join operation with index access to the joined table. Level 5 uses regular join buffers. Level 6 uses incremental join buffers.

The BKA algorithm supports outer join as well as semi-join operations. For outer joins and semi-joins with one inner table, both regular and incremental join buffers can be used. For nested outer joins and semi-joins, only incremental join buffers can be used.

Currently, the `Falcon` storage engine cannot use associations passed to it together with keys. `Falcon` builds a bitmap of rows for keys and uses this bitmap to access matching rows, so it returns a matching row without a reference to the matched row. To quickly find all matched rows in the join buffer, a hash table of the keys passed to the MRR interface is built at the very end of the join buffer.

Any row in the join buffer with key *k* is linked to a list of rows with the same key. The list is attached to the key that is stored in the hash table.

If the average frequency of keys in the join buffer is 2 or greater, it makes sense to use a join buffer with a hash table with the `MyISAM` or `InnoDB` storage engine as well. In this case, fewer keys are passed for lookups.

To use a join buffer with hash table, set the value of `join_cache_level` to 7 or 8. Level 7 is used for regular join buffers with all interesting columns. Level 8 is used for incremental join buffers.

In `EXPLAIN` output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer` and the `type` value is `ref` or `eq_ref`.

7.2.16. Semi-Join Strategies

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named `class` and `roster` that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```
SELECT class.class_num, class.class_name
FROM class INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that `class_num` is a primary key in the `class` table, duplicate suppression could be achieved by using `SELECT DISTINCT`, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```
SELECT class_num, class_name
FROM class
WHERE class_num IN (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the `IN` clause requires the subquery to return only one instance of each class number from the `roster` table. In this case, the query can be executed as a *semi-join*—that is, an operation that returns only one instance of each row in `class` that is matched by rows in `roster`.

In MySQL, a subquery must satisfy these criteria to be handled as a semi-join:

- It must be an `IN` (or `=ANY`) subquery that appears at the top level of the `WHERE` or `ON` clause, possibly as a term in an `AND` expression. For example:

  ```
  SELECT ...
  FROM ot1, ...
  WHERE (oe1, ...) IN (SELECT ie1, ... FROM it1, ... WHERE ...);
  ```

  Here, `ot_i` and `it_i` represent tables in the outer and inner parts of the query, and `oe_i` and `ie_i` represent expressions that refer to columns in the outer and inner tables.

- It must be a single `SELECT` without `UNION` constructs.
- It must not contain a `GROUP BY` or `HAVING` clause or aggregate functions.
- It must not have `ORDER BY` with `LIMIT`.
- The number of outer and inner tables together must be less than the maximum number of tables allowed in a join.

The subquery may be correlated or uncorrelated. `DISTINCT` is allowed, as is `LIMIT` unless `ORDER BY` is also used.

If a subquery meets the preceding criteria, MySQL converts it to a semi-join and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.
- Duplicate Weedout: Run the semi-join as if it was a join and remove duplicate records using a temporary table.
- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into a temporary table with an index and use it to perform a join. The temporary table index is used to remove duplicates and when joining with the outer tables.

Each of these strategies except Duplicate Weedout can be enabled or disabled using the `optimizer_switch` system variable. See Section 7.2.22, “Using optimizer_switch to Control the Optimizer”.

The use of semi-join strategies is indicated in `EXPLAIN` output as follows:

- Semi-joined tables show up in the outer select. `EXPLAIN EXTENDED` plus `SHOW WARNINGS` shows the rewritten query, which displays the semi-join structure. From this you can get an idea about which tables were pulled out of the semi-join. If a subquery was converted to a semi-join, you will see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.
- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` will have their `rowid` in the temporary table.
- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.
- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. *`m`* and *`n`* are key part numbers.

- Temporary table use for materialization is indicated by `Start materialize`, `End materialize`, and `Scan` in the `Extra` column.

7.2.17. `ORDER BY` Optimization

In some cases, MySQL can use an index to satisfy an `ORDER BY` clause without doing any extra sorting.

The index can also be used even if the `ORDER BY` does not match the index exactly, as long as all of the unused portions of the index and all the extra `ORDER BY` columns are constants in the `WHERE` clause. The following queries use the index to resolve the `ORDER BY` part:

```
SELECT * FROM t1
  ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
  WHERE key_part1=constant
  ORDER BY key_part2;

SELECT * FROM t1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1=1
  ORDER BY key_part1 DESC, key_part2 DESC;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- You use `ORDER BY` on different keys:

  ```
  SELECT * FROM t1 ORDER BY key1, key2;
  ```

- You use `ORDER BY` on non-consecutive parts of a key:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
  ```

- You mix `ASC` and `DESC`:

  ```
  SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
  ```

- The key used to fetch the rows is not the same as the one used in the `ORDER BY`:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
  ```

- You use `ORDER BY` with an expression that includes terms other than the key column name:

  ```
  SELECT * FROM t1 ORDER BY ABS(key);
  SELECT * FROM t1 ORDER BY -key;
  ```

- You are joining many tables, and the columns in the `ORDER BY` are not all from the first non-constant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- You have different `ORDER BY` and `GROUP BY` expressions.
- You index only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if you have a `CHAR(20)` column, but index only the first 10 bytes, the index cannot distinguish values past the 10th byte and a `filesort` will be needed.
- The type of table index used does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, so for the reference to `a` in the `ORDER BY`, the index can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, so for the reference to `a` in the `ORDER BY`, the index cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` uses that, and the index can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an `ORDER BY` clause explicitly that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs. If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See Section 7.2.1, “Optimizing Queries with EXPLAIN”.

MySQL has two `filesort` algorithms for sorting and retrieving results. The original method uses only the `ORDER BY` columns. The modified method uses not just the `ORDER BY` columns, but all the columns used in the query.

The optimizer selects which `filesort` algorithm to use. It normally uses the modified algorithm except when `BLOB` or `TEXT` columns are involved, in which case it uses the original algorithm.

The original `filesort` algorithm works as follows:

1. Read all rows according to key or by table scanning. Rows that do not match the `WHERE` clause are skipped.
2. For each row, store a pair of values in a buffer (the sort key and the row pointer). The size of the buffer is the value of the `sort_buffer_size` system variable.
3. When the buffer gets full, run a qsort (quicksort) on it and store the result in a temporary file. Save a pointer to the sorted block. (If all pairs fit into the sort buffer, no temporary file is created.)
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to `MERGEBUFF` (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.
6. Repeat the following until there are fewer than `MERGEBUFF2` (15) blocks left.
7. On the last multi-merge, only the pointer to the row (the last part of the sort key) is written to a result file.
8. Read the rows in sorted order by using the row pointers in the result file. To optimize this, we read in a big block of row pointers, sort them, and use them to read the rows in sorted order into a row buffer. The size of the buffer is the value of the `read_rnd_buffer_size` system variable. The code for this step is in the `sql/records.cc` source file.

One problem with this approach is that it reads rows twice: One time when evaluating the `WHERE` clause, and again after sorting the pair values. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified `filesort` algorithm incorporates an optimization such that it records not only the sort key value and row position, but also the columns required for the query. This avoids reading the rows twice. The modified `filesort` algorithm works like this:

1. Read the rows that match the `WHERE` clause.
2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.
3. Sort the tuples by sort key value
4. Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

Using the modified `filesort` algorithm, the tuples are longer than the pairs used in the original method, and fewer of them fit in the sort buffer (the size of which is given by `sort_buffer_size`). As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is that you should see high disk activity and low CPU activity.)

For slow queries for which `filesort` is not used, you might try lowering `max_length_for_sort_data` to a value that is appropriate to trigger a `filesort`.

If you want to increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the size of the `sort_buffer_size` variable.
- Increase the size of the `read_rnd_buffer_size` variable.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change `tmpdir` to point to a dedicated file system with large amounts of free space. Also, this option accepts several paths that are used in round-robin fashion, so you can use this feature to spread the load across several directories. Paths should be separated by colon characters (“`:`”) on Unix and semicolon characters (“`;`”) on Windows, NetWare, and OS/2. The paths should be for directories in file systems that are located on different *physical* disks, not different partitions on the same disk.

7.2.18. `GROUP BY` Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a `BTREE` index and not a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

In MySQL, `GROUP BY` is used for sorting, so the server may also apply `ORDER BY` optimizations to grouping. See Section 7.2.17, “`ORDER BY` Optimization”.

There are two ways to execute a `GROUP BY` query via index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

7.2.18.1. Loose index scan

The most efficient way to process `GROUP BY` is when the index is used to directly retrieve the group columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *loose index scan*. When there is no `WHERE` clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range` join type in Section 7.2.1, “Optimizing Queries with `EXPLAIN`”), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` includes the first consecutive parts of the index. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to the beginning of the index.)
- The only aggregate functions used (if any) are `MIN()` and `MAX()`, and all of them refer to the same column.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.

The `EXPLAIN` output for such queries shows `Using index for group-by` in the `Extra` column.

The following queries fall into this category, assuming that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`, for example:

  ```
  SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
  ```

- The columns in the `GROUP BY` clause do not refer to the beginning of the index, as shown here:

  ```
  SELECT c1,c2 FROM t1 GROUP BY c2, c3;
  ```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant, an example being:

  ```
  SELECT c1,c3 FROM t1 GROUP BY c1, c2;
  ```

7.2.18.2. Tight index scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it is still possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. Notice that with a tight index scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any "gaps" in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method (assuming that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`).

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

  ```
  SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
  ```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

  ```
  SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
  ```

7.2.19. `DISTINCT` Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, you should be aware of how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See Section 11.12.3, "`GROUP BY` and `HAVING` with Hidden Columns".

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see Section 7.2.18, “`GROUP BY` Optimization”.

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

7.2.20. Optimizing `IN`/`=ANY` Subqueries

Certain optimizations are applicable to comparisons that use the `IN` operator to test subquery results (or that use `=ANY`, which is equivalent). This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. Suggestions on what you can do to help the optimizer are given at the end of the discussion.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery's `WHERE` clause. That is, the comparison is converted to this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows that it must examine when evaluating the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
  (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
                         AND oe_1 = ie_1
                         AND ...
                         AND oe_N = ie_N)
```

The following discussion assumes a single pair of outer and inner expression values for simplicity.

The conversion just described has its limitations. It is valid only if we ignore possible `NULL` values. That is, the “pushdown” strategy works as long as both of these two conditions are true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You do not need to distinguish `NULL` from `FALSE` subquery results. (If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you don't care.)

When either or both of those conditions do not hold, optimization is more complex.

Suppose that `outer_expr` is known to be a non-`NULL` value but the subquery does not produce a row such that `outer_expr` = `inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- `NULL`, if the `SELECT` produces any row where `inner_expr` is `NULL`
- `FALSE`, if the `SELECT` produces only non-`NULL` values or produces nothing

In this situation, the approach of looking for rows with *outer_expr = inner_expr* is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where *inner_expr* is NULL. Roughly speaking, the subquery can be converted to:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
        (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra IS NULL condition is why MySQL has the ref_or_null access method:

```
mysql> EXPLAIN
    -> SELECT outer_expr IN (SELECT t2.maybe_null_key
    ->                       FROM t2, t3 WHERE ...)
    -> FROM t1;
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        table: t1
...
*************************** 2. row ***************************
           id: 2
  select_type: DEPENDENT SUBQUERY
        table: t2
         type: ref_or_null
possible_keys: maybe_null_key
          key: maybe_null_key
      key_len: 5
          ref: func
         rows: 2
        Extra: Using where; Using index
...
```

The unique_subquery and index_subquery subqery-specific access methods also have or-null variants. However, they are not visible in EXPLAIN output, so you must use EXPLAIN EXTENDED followed by SHOW WARNINGS (note the checking NULL in the warning message):

```
mysql> EXPLAIN EXTENDED
    -> SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        table: t1
...
*************************** 2. row ***************************
           id: 2
  select_type: DEPENDENT SUBQUERY
        table: t2
         type: index_subquery
possible_keys: maybe_null_key
          key: maybe_null_key
      key_len: 5
          ref: func
         rows: 2
        Extra: Using index

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Note
   Code: 1003
Message: select (`test`.`t1`.`outer_expr`,
         (((`test`.`t1`.`outer_expr`) in t2 on
         maybe_null_key checking NULL))) AS `outer_expr IN (SELECT
         maybe_null_key FROM t2)` from `test`.`t1`
```

The additional OR ... IS NULL condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when *outer_expr* can be NULL. According to the SQL interpretation of NULL as “unknown value,” NULL IN (SELECT *inner_expr* ...) should evaluate to:

- NULL, if the SELECT produces any rows
- FALSE, if the SELECT produces no rows

For proper evaluation, it is necessary to be able to check whether the SELECT has produced any rows at all, so *outer_expr = inner_expr* cannot be pushed down into the subquery. This is a problem, because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of *outer_expr*.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that *outer_expr* might be NULL.

If *outer_expr* is NULL, to evaluate the following expression, it is necessary to run the SELECT to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to run the original SELECT here, without any pushed-down equalities of the kind mentioned earlier.

On the other hand, when *outer_expr* is not NULL, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow. To solve the dilemma of whether to push down or not push down conditions into the subquery, the conditions are wrapped in “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
                          AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

and converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
                          AND trigcond(oe_1=ie_1)
                          AND ...
                          AND trigcond(oe_N=ie_N)
       )
```

Each trigcond(*X*) is a special function that evaluates to the following values:

- *X* when the “linked” outer expression *oe_i* is not NULL
- TRUE when the “linked” outer expression *oe_i* is NULL

Note that trigger functions are *not* triggers of the kind that you create with CREATE TRIGGER.

Equalities that are wrapped into trigcond() functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any trigcond(*X*) to be an unknown function and ignore it. At the moment, triggered equalities can be used by those optimizations:

- Reference optimizations: trigcond(*X*=*Y* [OR *Y* IS NULL]) can be used to construct ref, eq_ref, or ref_or_null table accesses.
- Index lookup-based subquery execution engines: trigcond(*X*=*Y*) can be used to construct unique_subquery or index_subquery accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition will be checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In EXPLAIN output, the fallback shows up as Full scan on NULL key in the Extra column:

```
mysql> EXPLAIN SELECT t1.col1,
    -> t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
*************************** 1. row ***************************
           id: 1
```

```
  select_type: PRIMARY
        table: t1
        ...
*************************** 2. row ***************************
           id: 2
  select_type: DEPENDENT SUBQUERY
        table: t2
         type: index_subquery
possible_keys: key1
          key: key1
      key_len: 5
          ref: func
         rows: 2
        Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN EXTENDED` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
*************************** 1. row ***************************
  Level: Note
   Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
         <in_optimizer>(`test`.`t1`.`col1`,
         <exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
         on key1 checking NULL
         where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
         trigcond(<is_not_null_test>(`test`.`t2`.`key1`))))) AS
         `t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
         from `test`.`t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy was to improve compliance and not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` will be particularly slow because the join optimizer doesn't optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these tips:

- A column must be declared as `NOT NULL` if it really is. (This also helps other aspects of the optimizer.)
- If you don't need to distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

  ```
  outer_expr IN (SELECT inner_expr FROM ...)
  ```

  with this expression:

  ```
  (outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
  ```

  Then `NULL IN (SELECT ...)` will never be evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

7.2.21. `LIMIT` Optimization

In some cases, MySQL handles a query differently when you are using `LIMIT row_count` and not using `HAVING`:

- If you are selecting only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you use `LIMIT row_count` with `ORDER BY`, MySQL ends the sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause must be selected, and most or all of them must be sorted, before it can be ascertained that the first `row_count` rows have been found. In either case, after the initial rows have been found, there is no need to sort any remainder of the result set, and MySQL does not do so.
- When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the key in order (or doing a sort on the key) and then calculating summaries until the key value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using

SQL_CALC_FOUND_ROWS.

- LIMIT 0 quickly returns an empty set. This can be useful for checking the validity of a query. When using one of the MySQL APIs, it can also be employed for obtaining the types of the result columns. (This trick does not work in the MySQL Monitor (the mysql program), which merely displays Empty set in such cases; you should instead use SHOW COLUMNS or DESCRIBE for this purpose.)
- When the server uses temporary tables to resolve the query, it uses the LIMIT *row_count* clause to calculate how much space is required.

7.2.22. Using optimizer_switch to Control the Optimizer

The optimizer_switch system variable enables control over optimizer behavior.

As of MySQL 6.0.11, the value of the optimizer_switch system variable is a set of flags, each of which has a value of on or off to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: firstmatch=on,index_merge=on,
                    index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    loosescan=on,materialization=on,
                    semijoin=on
```

To change the value of optimizer_switch, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each *command* value should have one of the forms shown in the following table.

Command Syntax	Meaning
default	Reset every optimization to its default value
opt_name=default	Set the named optimization to its default value
opt_name=off	Disable the named optimization
opt_name=on	Enable the named optimization

The order of the commands in the value does not matter, although default is executed first if present. Specifying any given *opt_name* more than once in the value is not allowed and causes an error. Any errors in the value cause the entire statement to fail with an error and the current value of optimizer_switch remains unchanged.

The following table lists the allowable *opt_name* flag names.

Flag Name	Meaning
index_merge	Controls all Index Merge optimizations
index_merge_union	Controls the Index Merge Union Access optimization
index_merge_sort_union	Controls the Index Merge Sort-Union Access optimization
index_merge_intersection	Controls the Index Merge Intersection Access optimization
semijoin	Controls use of semi-join strategies
materialization	Controls materialization (including semi-join materialization)
loosescan	Controls the semi-join LooseScan strategy (not to be confused with LooseScan for GROUP BY)
firstmatch	Controls the semi-join FirstMatch strategy

For information about Index Merge and semi-joins, see Section 7.2.6, “Index Merge Optimization”, and Section 7.2.16, “Semi-Join Strategies”.

When you assign a value to optimizer_switch, flags that are not mentioned keep their current values. This makes it possible

to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: firstmatch=on,index_merge=on,
                    index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    loosescan=on,materialization=on,
                    semijoin=on
1 row in set (0.00 sec)
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: firstmatch=on,index_merge=on,
                    index_merge_union=off,
                    index_merge_sort_union=off,
                    index_merge_intersection=on,
                    loosescan=on,materialization=on,
                    semijoin=on
1 row in set (0.00 sec)
```

7.2.23. How to Avoid Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 7.2.4, “`WHERE` Clause Optimization”.
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

> **MySQL Enterprise**
> For expert advice on avoiding excessive table scans subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE` *`tbl_name`* to update the key distributions for the scanned table. See Section 12.5.2.1, “`ANALYZE TABLE` Syntax”.
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
    WHERE t1.col_name=t2.col_name;
  ```

  See Section 12.2.9.2, “Index Hint Syntax”.
- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.3, “Server System Variables”.

7.2.24. `INFORMATION_SCHEMA` Optimization

As of MySQL 6.0.4, the implementation of `INFORMATION_SCHEMA` is such that certain types of queries for `INFORMATION_SCHEMA` tables can be optimized to execute more quickly. This section provides guidelines on writing queries that take advantage of these optimizations. In general, the strategies outlined here minimize the need for the server to access the file system to

obtain the information that makes up the contents of INFORMATION_SCHEMA tables. By writing queries that enable the server to avoid directory scans or opening table files, you will obtain better performance.

1) Try to use constant lookup values for database and table names in the WHERE clause

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.
- Avoid queries that use a non-constant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.
- Within a database, avoid queries that use a non-constant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the INFORMATION_SCHEMA tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For example, if you are selecting from TABLES, using a constant lookup value for TABLE_SCHEMA in the WHERE clause enables a data directory scan to be avoided.

Table	Column to specify to avoid data directory scan	Column to specify to avoid database directory scan
COLUMNS	TABLE_SCHEMA	TABLE_NAME
KEY_COLUMN_USAGE	TABLE_SCHEMA	TABLE_NAME
PARTITIONS	TABLE_SCHEMA	TABLE_NAME
REFERENTIAL_CONSTRAINTS	CONSTRAINT_SCHEMA	TABLE_NAME
STATISTICS	TABLE_SCHEMA	TABLE_NAME
TABLES	TABLE_SCHEMA	TABLE_NAME
TABLE_CONSTRAINTS	TABLE_SCHEMA	TABLE_NAME
TRIGGERS	EVENT_OBJECT_SCHEMA	EVENT_OBJECT_TABLE
VIEWS	TABLE_SCHEMA	TABLE_NAME

The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name test enables the server to check only the test database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern 'test%':

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name t1 enables the server to check only the files for the t1 table, regardless of how many tables there might be in the test database. By contrast, the following query requires a scan of the test database directory to determine which table names match the pattern 't%':

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern 'test%', and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern 't%':

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test%' AND TABLE_NAME LIKE 't%';
```

2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain INFORMATION_SCHEMA table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus, TABLE_NAME requires no files to be opened. The ENGINE (storage engine) value can be determined by opening the table's .frm file, without touching other table files such as the .MYD or .MYI file.

Some values, such as INDEX_LENGTH for MyISAM tables, require opening the .MYD or .MYI file as well.

The file-opening optimization types are denoted thus:

- SKIP_OPEN_TABLE: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- OPEN_FRM_ONLY: Only the table's .frm file need be opened.
- OPEN_TRIGGER_ONLY: Only the table's .TRG file need be opened.
- OPEN_FULL_TABLE: The unoptimized information lookup. The .frm, .MYD, and .MYI files must be opened.

The following list indicates how the preceding optimization types apply to INFORMATION_SCHEMA table columns. For tables and columns not named, none of the optimizations apply.

- COLUMNS: OPEN_FRM_ONLY applies to all columns
- KEY_COLUMN_USAGE: OPEN_FULL_TABLE applies to all columns
- PARTITIONS: OPEN_FULL_TABLE applies to all columns
- REFERENTIAL_CONSTRAINTS: OPEN_FULL_TABLE applies to all columns
- STATISTICS:

Column	Optimization type
TABLE_CATALOG	OPEN_FRM_ONLY
TABLE_SCHEMA	OPEN_FRM_ONLY
TABLE_NAME	OPEN_FRM_ONLY
NON_UNIQUE	OPEN_FRM_ONLY
INDEX_SCHEMA	OPEN_FRM_ONLY
INDEX_NAME	OPEN_FRM_ONLY
SEQ_IN_INDEX	OPEN_FRM_ONLY
COLUMN_NAME	OPEN_FRM_ONLY
COLLATION	OPEN_FRM_ONLY
CARDINALITY	OPEN_FULL_TABLE
SUB_PART	OPEN_FRM_ONLY
PACKED	OPEN_FRM_ONLY
NULLABLE	OPEN_FRM_ONLY
INDEX_TYPE	OPEN_FULL_TABLE
COMMENT	OPEN_FRM_ONLY

- TABLES:

Column	Optimization type

TABLE_CATALOG	SKIP_OPEN_TABLE
TABLE_SCHEMA	SKIP_OPEN_TABLE
TABLE_NAME	SKIP_OPEN_TABLE
TABLE_TYPE	OPEN_FRM_ONLY
ENGINE	OPEN_FRM_ONLY
VERSION	OPEN_FRM_ONLY
ROW_FORMAT	OPEN_FULL_TABLE
TABLE_ROWS	OPEN_FULL_TABLE
AVG_ROW_LENGTH	OPEN_FULL_TABLE

CREATE_OPTIONS	OPEN_FRM_ONLY
TABLE_COMMENT	OPEN_FRM_ONLY

- TABLE_CONSTRAINTS: OPEN_FULL_TABLE applies to all columns
- TRIGGERS: OPEN_TRIGGER_ONLY applies to all columns
- VIEWS:

Column	Optimization type
TABLE_CATALOG	OPEN_FRM_ONLY
TABLE_SCHEMA	OPEN_FRM_ONLY
TABLE_NAME	OPEN_FRM_ONLY
VIEW_DEFINITION	OPEN_FRM_ONLY
CHECK_OPTION	OPEN_FRM_ONLY
IS_UPDATABLE	OPEN_FULL_TABLE
DEFINER	OPEN_FRM_ONLY
SECURITY_TYPE	OPEN_FRM_ONLY
CHARACTER_SET_CLIENT	OPEN_FRM_ONLY
COLLATION_CONNECTION	OPEN_FRM_ONLY

3) Use EXPLAIN to determine whether the server can use INFORMATION_SCHEMA optimizations for a query

The Extra value in EXPLAIN output indicates which, if any, of the optimizations described earlier the server can use to evaluate INFORMATION_SCHEMA queries. The following examples demonstrate the kinds of information you can expect to see in the Extra value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE
    -> TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v1'\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: VIEWS
         type: ALL
possible_keys: NULL
          key: TABLE_SCHEMA,TABLE_NAME
```

```
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: Using where; Open_frm_only; Scanned 0 databases
```

Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

```
mysql> EXPLAIN SELECT TABLE_NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.TABLES\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: TABLES
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: Open_full_table; Scanned all databases
```

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

```
mysql> EXPLAIN SELECT TABLE_NAME, TABLE_TYPE FROM INFORMATION_SCHEMA.TABLES
    -> WHERE TABLE_SCHEMA = 'test'\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: TABLES
         type: ALL
possible_keys: NULL
          key: TABLE_SCHEMA
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: Using where; Open_frm_only; Scanned 1 database
```

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.

```
mysql> EXPLAIN SELECT B.TABLE_NAME
    -> FROM INFORMATION_SCHEMA.TABLES AS A, INFORMATION_SCHEMA.COLUMNS AS B
    -> WHERE A.TABLE_SCHEMA = 'test'
    -> AND A.TABLE_NAME = 't1'
    -> AND B.TABLE_NAME = A.TABLE_NAME\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: A
         type: ALL
possible_keys: NULL
          key: TABLE_SCHEMA,TABLE_NAME
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: Using where; Skip_open_table; Scanned 0 databases
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        table: B
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra: Using where; Open_frm_only; Scanned all databases;
               Using join buffer
```

For the first `EXPLAIN` output row: Constant database and table lookup values enable the server to avoid directory scans for `TABLES` values. References to `TABLES.TABLE_NAME` require no further table files.

For the second `EXPLAIN` output row: All `COLUMNS` table values are `OPEN_FRM_ONLY` lookups, so `COLUMNS.TABLE_NAME` requires the `.frm` file to be opened.

```
mysql> EXPLAIN SELECT * FROM INFORMATION_SCHEMA.COLLATIONS\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: COLLATIONS
```

```
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: NULL
        Extra:
```

In this case, no optimizations apply because `COLLATIONS` is not one of the `INFORMATION_SCHEMA` tables for which optimizations are available.

7.2.25. Speed of `INSERT` Statements

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by log *`N`*, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a non-empty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See Section 5.1.3, “Server System Variables”.
- If multiple clients are inserting a lot of rows, you can get higher speed by using the `INSERT DELAYED` statement. See Section 12.2.5.2, “`INSERT DELAYED` Syntax”.
- For a `MyISAM` table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running, if there are no deleted rows in middle of the data file. See Section 7.3.3, “Concurrent Inserts”.
- When loading a table from a text file, use `LOAD DATA INFILE`. This is usually 20 times faster than using `INSERT` statements. See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.
- With some extra work, it is possible to make `LOAD DATA INFILE` run even faster for a `MyISAM` table when the table has many indexes. Use the following procedure:

  1. Optionally create the table with `CREATE TABLE`.
  2. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.
  3. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name`. This removes all use of indexes for the table.
  4. Insert data into the table with `LOAD DATA INFILE`. This does not update any indexes and therefore is very fast.
  5. If you intend only to read from the table in the future, use `myisampack` to compress it. See Section 13.5.3.3, “Compressed Table Characteristics”.
  6. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster that updating the index during `LOAD DATA INFILE` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  7. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

  `LOAD DATA INFILE` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk`

allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA INFILE` statement.

You can also disable or enable the non-unique indexes for a `MyISAM` table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLE` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for non-transactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

To obtain faster insertions for transactional tables, you should use `START TRANSACTION` and `COMMIT` instead of `LOCK TABLES`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to allow other threads access to the table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA INFILE`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA INFILE` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See Section 7.5.3, “Tuning Server Parameters”.

7.2.26. Speed of `UPDATE` Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a `MyISAM` table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use `OPTIMIZE TABLE` occasionally. See Section 12.5.2.4, “`OPTIMIZE TABLE` Syntax”.

7.2.27. Speed of `DELETE` Statements

The time required to delete individual rows is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 7.5.3, “Tuning Server Parameters”.

To delete all rows from a table, `TRUNCATE TABLE tbl_name` is faster than than `DELETE FROM tbl_name`. Truncate oper-

ations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 12.2.11, “TRUNCATE Syntax”.

7.2.28. Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- Use persistent connections to the database to avoid connection overhead. If you cannot use persistent connections and you are initiating many new connections to the database, you may want to change the value of the `thread_cache_size` variable. See Section 7.5.3, “Tuning Server Parameters”.
- Always check whether all your queries really use the indexes that you have created in the tables. In MySQL, you can do this with the `EXPLAIN` statement. See Section 7.2.1, “Optimizing Queries with EXPLAIN”.
- Try to avoid complex `SELECT` queries on `MyISAM` tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, you should consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore allow concurrent inserts), even in tables that have deleted rows. See Section 7.3.3, “Concurrent Inserts”.

  > **MySQL Enterprise**
  > For optimization tips geared to your specific circumstances subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- To fix any compression issues that may have occurred with `ARCHIVE` tables, you can use `OPTIMIZE TABLE`. See Section 13.13, “The ARCHIVE Storage Engine”.
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.
- In some cases, it may make sense to introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it may be much faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
  WHERE hash_col=MD5(CONCAT(col1,col2))
  AND col1='constant' AND col2='constant';
```

- For `MyISAM` tables that change frequently, you should try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 13, *Storage Engines*.
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a `MyISAM` table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 13, *Storage Engines*.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

  This is very important when you use MySQL storage engines such as `MyISAM` that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.
- If you need to collect statistics from large log tables, use summary tables instead of scanning the entire log table. Maintaining the summaries should be much faster than trying to calculate statistics “live.” Regenerating new summary tables from the logs when things change (depending on business decisions) is faster than changing the running application.
- If possible, you should classify reports as “live” or as “statistical,” where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

- In some cases, it is convenient to pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this may save a lot of accesses at some stage. This is practical when you have data that does not conform well to a rows-and-columns table structure.

- Normally, you should try to keep all data non-redundant (observing what is referred to in database theory as *third normal form*). However, there may be situations in which it can be advantageous to duplicate information or create summary tables to gain more speed.

- Stored routines or UDFs (user-defined functions) may be a good way to gain performance for some tasks. See Section 18.2, “Using Stored Routines (Procedures and Functions)”, and Section 21.3, “Adding New Functions to MySQL”, for more information.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. If your database system supports table locks (as do MySQL), this should help to ensure that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see Section 7.5.5, “The MySQL Query Cache”.

- Use `INSERT DELAYED` when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.

- Use `INSERT LOW_PRIORITY` when you want to give `SELECT` statements higher priority than your inserts.

  Use `SELECT HIGH_PRIORITY` to get retrievals that jump the queue. That is, the `SELECT` is executed even if there is another client waiting to do a write.

  `LOW_PRIORITY` and `HIGH_PRIORITY` have an effect only for storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`).

- Use multiple-row `INSERT` statements to store many rows with one SQL statement. Many SQL servers support this, including MySQL.

- Use `LOAD DATA INFILE` to load large amounts of data. This is faster than using `INSERT` statements.

- Use `AUTO_INCREMENT` columns so that each row in a table can be identified by a single unique value. unique values.

- Use `OPTIMIZE TABLE` once in a while to avoid fragmentation with dynamic-format `MyISAM` tables. See Section 13.5.3, “`MyISAM` Table Storage Formats”.

- Use `MEMORY` tables when possible to get more speed. See Section 13.10, “The `MEMORY` (`HEAP`) Storage Engine”. `MEMORY` tables are useful for non-critical data that is accessed often, such as information about the last displayed banner for users who don't have cookies enabled in their Web browser. User sessions are another alternative available in many Web application environments for handling volatile state data.

- With Web servers, images and other binary assets should normally be stored as files. That is, store only a reference to the file rather than the file itself in the database. Most Web servers are better at caching files than database contents, so using files is generally faster.

- Columns with identical information in different tables should be declared to have identical data types so that joins based on the corresponding columns will be faster.

- Try to keep column names simple. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, you should keep them shorter than 18 characters.

- If you need really high speed, you should take a look at the low-level interfaces for data storage that the different SQL servers support. For example, by accessing the MySQL `MyISAM` storage engine directly, you could get a speed increase of two to five times compared to using the SQL interface. To be able to do this, the data must be on the same server as the application, and usually it should only be accessed by one process (because external file locking is really slow). One could eliminate these problems by introducing low-level `MyISAM` commands in the MySQL server (this could be one easy way to get more performance if needed). By carefully designing the database interface, it should be quite easy to support this type of optimization.

- If you are using numerical data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you need not parse your text files to find line and column boundaries.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 16, *Replication*.

- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you should

ensure that the table is okay by running the server with the `--myisam-recover` option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

7.3. Locking Issues

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 7.3.1, “Internal Locking Methods”.
- External locking occurs when the server and other programs lock table files to coordinate among themselves which program can access the tables at which time. See Section 7.3.5, “External Locking”.

7.3.1. Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. External locking occurs when the server and other programs lock table files to coordinate among themselves which program can access the tables at which time. See Section 7.3.5, “External Locking”.

MySQL uses table-level locking for `MyISAM`, `MEMORY`, and `MERGE` tables, and row-level locking for `InnoDB` tables.

In many cases, you can make an educated guess about which locking type is best for an application, but generally it is difficult to say that a given lock type is better than another. Everything depends on the application and different parts of an application may require different lock types.

To decide whether you want to use a storage engine with row-level locking, you should look at what your application does and what mix of select and update statements it uses. For example, most Web applications perform many selects, relatively few deletes, updates based mainly on key values, and inserts into a few specific tables. The base MySQL `MyISAM` setup is very well tuned for this.

> **MySQL Enterprise**
> The MySQL Enterprise Monitor provides expert advice on when to use table-level locking and when to use row-level locking. To subscribe see http://www.mysql.com/products/enterprise/advisors.html.

Table locking in MySQL is deadlock-free for storage engines that use table-level locking. Deadlock avoidance is managed by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even if there is heavy `SELECT` activity for the table. However, if you have many updates for a table, `SELECT` statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 7.3.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the `Table_locks_immediate` and `Table_locks_waited` status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent INSERT and SELECT statements for a MyISAM table without locks. That is, you can insert rows into a MyISAM table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data.. This behavior is altered by the concurrent_insert system variable. See Section 7.3.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with LOCK TABLES, you can request a READ LOCAL lock rather than a READ lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many INSERT and SELECT operations on a table real_table when concurrent inserts are not possible, you can insert rows into a temporary table temp_table and update the real table with the rows from the temporary table periodically. This can be done with the following code:

```
mysql> LOCK TABLES real_table WRITE, temp_table WRITE;
mysql> INSERT INTO real_table SELECT * FROM temp_table;
mysql> DELETE FROM temp_table;
mysql> UNLOCK TABLES;
```

InnoDB uses row locks. Deadlocks are possible for InnoDB because it automatically acquires locks during the processing of SQL statements, not at the start of the transaction.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows
- Fewer changes for rollbacks
- Possible to lock a single row for a long time

Disadvantages of row-level locking:

- Requires more memory than table-level locks
- Slower than table-level locks when used on a large part of the table because you must acquire many more locks
- Slower than other locks if you often do GROUP BY operations on a large part of the data or if you must scan the entire table frequently

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

  ```
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```

- SELECT combined with concurrent INSERT statements, and very few UPDATE or DELETE statements
- Many scans or GROUP BY operations on the entire table without any writers

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 11.11.4, “Miscellaneous Functions”.

7.3.2. Table Locking Issues

To achieve a very high lock speed, MySQL uses table locking (instead of page, row, or column locking) for all storage engines except `InnoDB`.

For `InnoDB` tables, MySQL uses table locking only if you explicitly lock the table with `LOCK TABLES`. For this storage engine, we recommend that you not use `LOCK TABLES` at all, because `InnoDB` uses automatic row-level locking to ensure transaction isolation.

For large tables, table locking is often better than row locking, but there are some disadvantages:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access. During the update, all other sessions that want to access this particular table must wait until the update is done.
- Table locking causes problems in cases such as when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

Table locking is also disadvantageous under the following scenario:

- A session issues a `SELECT` that takes a long time to run.
- Another session then issues an `UPDATE` on the same table. This session waits until the `SELECT` is finished.
- Another session issues another `SELECT` statement on the same table. Because `UPDATE` has higher priority than `SELECT`, this `SELECT` waits for the `UPDATE` to finish, *after* waiting for the first `SELECT` to finish.

The following items describe some ways to avoid or reduce contention caused by table locking:

- Try to get the `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not need to wait for the first `SELECT` to finish.
- To specify that all updates issued in a specific connection should be done with low priority, use the `SET LOW_PRIORITY_UPDATES=1` statement. See Section 5.1.4, “Session System Variables”.
- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See Section 12.2.9, “`SELECT` Syntax”.
- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This allows `READ` locks after a certain number of `WRITE` locks.
- If you have problems with `INSERT` combined with `SELECT`, consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See Section 7.3.3, “Concurrent Inserts”.)
- If you mix inserts and deletes on the same table, `INSERT DELAYED` may be of great help. See Section 12.2.5.2, “`INSERT`

DELAYED Syntax".

- If you have problems with mixed SELECT and DELETE statements, the LIMIT option to DELETE may help. See Section 12.2.2, "DELETE Syntax".
- Using SQL_BUFFER_RESULT with SELECT statements can help to make the duration of table locks shorter. See Section 12.2.9, "SELECT Syntax".
- You could change the locking code in mysys/thr_lock.c to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

Here are some tips concerning table locks in MySQL:

- Concurrent users are not a problem if you do not mix updates with selects that need to examine many rows in the same table.
- You can use LOCK TABLES to increase speed, because many updates within a single lock is much faster than updating without locks. Splitting table contents into separate tables may also help.
- If you encounter speed problems with table locks in MySQL, you may be able to improve performance by converting some of your tables to InnoDB. See Section 13.7, "The InnoDB Storage Engine".

> **MySQL Enterprise**
> Lock contention can seriously degrade performance. The MySQL Enterprise Monitor provides expert advice on avoiding this problem. To subscribe, see http://www.mysql.com/products/enterprise/advisors.html.

7.3.3. Concurrent Inserts

The MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no holes in the data file (deleted rows in the middle), inserts can be performed to add rows to the end of the table at the same time that SELECT statements are reading rows from the table.

The concurrent_insert system variable can be set to modify the concurrent-insert processing. By default, the variable is set to 1 and concurrent inserts are handled as just described. If concurrent_insert is set to 0, concurrent inserts are disabled. If the variable is set to 2, concurrent inserts at the end of the table are allowed even for tables that have deleted rows. See also the description of the concurrent_insert system variable.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the DELAYED modifier for INSERT statements. See Section 12.2.5.2, "INSERT DELAYED Syntax".

If you are using the binary log, concurrent inserts are converted to normal inserts for CREATE ... SELECT or INSERT ... SELECT statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.2.4, "The Binary Log". In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With LOAD DATA INFILE, if you specify CONCURRENT with a MyISAM table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while LOAD DATA is executing. Use of the CONCURRENT option affects the performance of LOAD DATA a bit, even if no other session is using the table at the same time.

If you specify HIGH_PRIORITY, it overrides the effect of the --low-priority-updates option if the server was started with that option. It also causes concurrent inserts not to be used.

For LOCK TABLE, the difference between READ LOCAL and READ is that READ LOCAL allows non-conflicting INSERT statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

7.3.4. Metadata Locking Within Transactions

To ensure transaction serializability, the server must not allow one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted transaction in another session.

As of MySQL 6.0.11, the server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has certain implications:

- A table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the

transaction ends. For example, if a table `t1` is in use by a transaction, another session that attempts to execute `DROP TABLE t1` will block until the transaction ends.

- `FLUSH TABLES WITH READ LOCK` blocks for active transactions that hold metadata locks until those transactions end. The same is true for attempts to set the global value of the `read_only` system variable.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

Before MySQL 6.0.11, when a transaction acquired a metadata lock for a table used within a statement, it released the lock at the end of the statement. This approach had the disadvantage that if a DDL statement occurred for a table that was being used by another session in an active transaction, statements could be written to the binary log in the wrong order.

7.3.5. External Locking

External locking is the use of file system locking to manage contention for database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

  If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such a checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

  If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you don't stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See Section 7.5.2, “System Factors and Startup Parameter Tuning”.) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. From MySQL 4.0 on, external locking is disabled by default. Before MySQL 4.0, external locking is enabled by default on Linux or when MySQL is configured to use MIT-pthreads.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to `MyISAM` tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- You should not use the query cache for queries that use tables that are updated by another process.
- You should not start the server with the `--delay-key-write=ALL` option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` together with `-`

`-delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

7.4. Optimizing Database Structure

7.4.1. Make Your Data as Small as Possible

One of the most basic optimizations is to design your tables to take as little space on the disk as possible. This can result in huge improvements because disk reads are faster, and smaller tables normally require less main memory while their contents are being actively processed during query execution. Indexing also is a lesser resource burden if done on smaller columns.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application may give you a big performance gain. See Chapter 13, *Storage Engines*.

You can get better performance for a table and minimize storage space by using the techniques listed here:

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes everything faster and you save one bit per column. If you really need `NULL` in your application, you should definitely use it. Just avoid having it on all columns by default.
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but unfortunately may waste some space. See Section 13.5.3, "`MyISAM` Table Storage Formats". You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.
- `InnoDB` tables use a compact storage format. In versions of MySQL earlier than 5.0.3, `InnoDB` rows contain some redundant information, such as the number of columns and the length of each column, even for fixed-size columns. By default, tables are created in the compact format (`ROW_FORMAT=COMPACT`). If you wish to downgrade to older versions of MySQL, you can request the old format with `ROW_FORMAT=REDUNDANT`.

  The presence of the compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

  The compact `InnoDB` format also changes how `CHAR` columns containing UTF-8 data are stored. With `ROW_FORMAT=REDUNDANT`, a UTF-8 `CHAR(N)` occupies 3 × *N* bytes, given that the maximum length of a UTF-8 encoded character is three bytes. Many languages can be written primarily using single-byte UTF-8 characters, so a fixed storage length often wastes space. With `ROW_FORMAT=COMPACT` format, `InnoDB` allocates a variable amount of storage in the range from *N* to 3 × *N* bytes for these columns by stripping trailing spaces if necessary. The minimum storage length is kept as *N* bytes to facilitate in-place updates in typical cases.
- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient.
- Create only the indexes that you really need. Indexes are good for retrieval but bad when you need to store data quickly. If you access a table mostly by searching on a combination of columns, create an index on them. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, you should use the column with more duplicates first to obtain better compression of the index.
- If it is very likely that a string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see Section 12.1.11, "`CREATE INDEX` Syntax"). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See Section 7.5.3, "Tuning Server Parameters".
- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

7.4.2. Column Indexes

All MySQL data types can be indexed. Use of indexes on the relevant columns is the best way to improve the performance of `SELECT` operations.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 13, *Storage Engines*. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage en-

gines have higher limits.

With *col_name(N)* syntax in an index specification, you can create an index that uses only the first *N* characters of a string column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a BLOB or TEXT column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables). Note that prefix limits are measured in bytes, whereas the prefix length in CREATE TABLE statements is interpreted as number of characters. *Be sure to take this into account when specifying a prefix length for a column that uses a multi-byte character set.*

You can also create FULLTEXT indexes. These are used for full-text searches. Only the MyISAM storage engine supports FULLTEXT indexes and only for CHAR, VARCHAR, and TEXT columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 11.8, “Full-Text Search Functions”.

You can also create indexes on spatial data types. Currently, only MyISAM supports R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for ARCHIVE, which does not support spatial type indexing).

The MEMORY storage engine uses HASH indexes by default, but also supports BTREE indexes.

7.4.3. Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 15 columns. For certain data types, you can index a prefix of the column (see Section 7.4.2, “Column Indexes”).

A multiple-column index can be considered a sorted array containing values that are created by concatenating the values of the indexed columns.

MySQL uses multiple-column indexes in such a way that queries are fast when you specify a known quantity for the first column of the index in a WHERE clause, even if you do not specify values for the other columns.

Suppose that a table has the following specification:

```
CREATE TABLE test (
    id         INT NOT NULL,
    last_name  CHAR(30) NOT NULL,
    first_name CHAR(30) NOT NULL,
    PRIMARY KEY (id),
    INDEX name (last_name,first_name)
);
```

The name index is an index over the last_name and first_name columns. The index can be used for queries that specify values in a known range for last_name, or for both last_name and first_name. Therefore, the name index is used in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';

SELECT * FROM test
  WHERE last_name='Widenius' AND first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius'
  AND (first_name='Michael' OR first_name='Monty');

SELECT * FROM test
  WHERE last_name='Widenius'
  AND first_name >='M' AND first_name < 'N';
```

However, the name index is *not* used in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius' OR first_name='Michael';
```

The manner in which MySQL uses indexes to improve query performance is discussed further in Section 7.4.4, “How MySQL Uses Indexes”.

7.4.4. How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at

all the data. If a table has 1,000 rows, this is at least 100 times faster than reading sequentially. If you need to access most of the rows, it is faster to read sequentially, because this minimizes disk seeks.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in B-trees. Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` tables also support hash indexes.

Strings are automatically prefix- and end-space compressed. See Section 12.1.11, "`CREATE INDEX` Syntax".

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described at the end of this section.

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows.
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

  Comparison of dissimilar columns may prevent use of indexes if values cannot be compared directly without conversion. Suppose that a numeric column is compared to a string column. For a given value such as `1` in the numeric column, it might compare equal to any number of values in the string column such as `'1'`, `' 1'`, `'00001'`, or `'01.e1'`. This rules out use of any indexes for the string column.
- To find the `MIN()` or `MAX()` value for a specific indexed column *`key_col`*. This is optimized by a preprocessor that checks whether you are using `WHERE` *`key_part_N = constant`* on all key parts that occur before *`key_col`* in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
  FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable key (for example, `ORDER BY` *`key_part1, key_part2`*). If all key parts are followed by `DESC`, the key is read in reverse order. See Section 7.2.17, "`ORDER BY` Optimization", and Section 7.2.18, "`GROUP BY` Optimization".
- In some cases, a query can be optimized to retrieve values without consulting the data rows. If a query uses only columns from a table that are numeric and that form a leftmost prefix for some key, the selected values may be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
  WHERE key_part1=1
```

Suppose that you issue the following `SELECT` statement:

```
mysql> SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer will attempt to use the Index Merge optimization (see Section 7.2.6, "Index Merge Optimization"), or attempt to find the most restrictive index by deciding which index finds fewer rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to find rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use an index if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve in-

dexed columns, but `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or `BETWEEN` operators. The index also can be used for `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%_ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following `SELECT` statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the `LIKE` value begins with a wildcard character. In the second statement, the `LIKE` value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if `col_name` is indexed.

Any index that does not span all `AND` levels in the `WHERE` clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every `AND` group.

The following `WHERE` clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
    /* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
    /* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
    /* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These `WHERE` clauses do *not* use indexes:

```
    /* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

    /*  Index is not used in both parts of the WHERE clause  */
... WHERE index=1 OR A=10

    /* No index spans all rows  */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very* fast). They are not used for comparison operators such as `<` that find a range of values.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

> **MySQL Enterprise**
> Often, it is not possible to predict exactly what indexes will be required or will be most efficient — actual table usage is the best indicator. The MySQL Enterprise Monitor provides expert advice on this topic. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

7.4.5. The `MyISAM` Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the key_buffer_size system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the key_buffer_size value is too small to allocate the minimal number of block buffers (8).

> **MySQL Enterprise**
> For expert advice on identifying the optimum size for key_buffer_size, subscribe to the MySQL Enterprise Monitor. See http://www.mysql.com/products/enterprise/advisors.html.

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are non-leaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains a special queue (*LRU chain*) of all used blocks. When a block is accessed, it is placed at the end of the queue. When blocks need to be replaced, blocks at the beginning of the queue are the least recently used and become the first candidates for eviction.

7.4.5.1. Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

7.4.5.2. Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given `MyISAM` table. By default, all `MyISAM` table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement (see Section 12.5.7.2, "`CACHE INDEX` Syntax"). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

Note that you cannot destroy the default key cache. Any attempt to do this will be ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See Section 5.1.5.1, "Structured System Variables", for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, we recommend a strategy that uses three key caches:

- A "hot" key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A "cold" key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A "warm" key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to non-leaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

`CACHE INDEX` sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to

be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

> **MySQL Enterprise**
> For advice on how best to configure your `my.cnf/my.ini` option file subscribe to MySQL Enterprise Monitor. Recommendations are based on actual table usage. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

7.4.5.3. Midpoint Insertion Strategy

By default, the key cache management system uses the LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sub-chain and a warm sub-chain. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not "too short," always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sub-chain. After a certain number of hits (accesses of the block), it is promoted to the hot sub-chain. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sub-chain is placed at the end of the chain. The block then circulates within this sub-chain. If the block stays at the beginning of the sub-chain for a long enough time, it is demoted to the warm chain. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing *`N`* blocks, the block at the beginning of the hot sub-chain not accessed within the last *`N`* `× key_cache_age_threshold / 100` hits is to be moved to the beginning of the warm sub-chain. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sub-chain.

The midpoint insertion strategy allows you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sub-chain during an index scan operation as well.

7.4.5.4. Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its non-leaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading allows you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

The `IGNORE LEAVES` modifier causes only blocks for the non-leaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the non-leaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

7.4.5.5. Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of `MyISAM` tables, use the `--myisam-block-size` option at server startup.

7.4.5.6. Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

7.4.6. `MyISAM` Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how may rows must be read for each `ref` access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

  ```
  (...) JOIN tbl_name ON tbl_name.key = expr
  ```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on *`N`*/*`S`*, where *`N`* is the number of rows in the table and *`S`* is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as *`N`* `<=>` *`N`* for any other *`N`*.

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: *`expr1`* `=` *`expr2`* is not true when *`expr1`* or *`expr2`* (or both) are `NULL`. This affects `ref` accesses for comparisons of the form *`tbl_name.key`* `=` *`expr`*: MySQL will not access the table if the current value of *`expr`* is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently allow that average size to be collected or used.

For `MyISAM` tables, you have some control over collection of table statistics by means of the `myisam_stats_method` system variable. This variable has three possible values, which differ as follows:

- When `myisam_stats_method` is `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

  If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When `myisam_stats_method` is `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

  If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When `myisam_stats_method` is `nulls_ignored`, `NULL` values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `myisam_stats_method` system variable has global and session values. Setting the global value affects `MyISAM` statistics collection for all `MyISAM` tables. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=`*`method_name`*` --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but `myisam_stats_method` is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given `MyISAM` table.
- `myisam_stats_method` applies only to `MyISAM` tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

7.4.7. How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache`, `max_connections`, and `max_tmp_tables` system variables affect the maximum number of files the server keeps open. If you increase one or more of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems allow you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is

possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, you should have a table cache size of at least `200 × N`, where `N` is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable. You also have to take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. You can increase the number of file descriptors available to MySQL using the `--open-files-limit` startup option to `mysqld`. See Section B.1.2.18, “`'FILE' NOT FOUND` and Similar Errors”.

The cache of open tables is kept at a level of `table_open_cache` entries. The default value is 64; this can be changed with the `--table_open_cache` option to `mysqld`. Note that MySQL may temporarily open more tables than this to execute queries.

> **MySQL Enterprise**
> Performance may suffer if `table_open_cache` is set too low. For expert advice on the optimum value for this variable, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 12.2.4, “HANDLER Syntax”.

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables`, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, you should increase the table cache size. See Section 5.1.3, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.

7.4.8. Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries allowed in the table cache.

7.5. Optimizing the MySQL Server

7.5.1. How Compiling and Linking Affects the Speed of MySQL

Most of the following tests were performed on Linux with the MySQL benchmarks, but they should give some indication for other operating systems and workloads.

You obtain the fastest executables when you link with `-static`.

On Linux, it is best to compile the server with `pgcc` and `-O3`. You need about 200MB memory to compile `sql_yacc.cc` with these options, because `gcc` or `pgcc` needs a great deal of memory to make all functions inline. You should also set `CXX=gcc` when configuring MySQL to avoid inclusion of the `libstdc++` library, which is not needed. Note that with some versions of `pgcc`, the resulting binary runs only on true Pentium processors, even if you use the compiler option indicating that you want the resulting code to work on all x586-type processors (such as AMD).

By using a better compiler and compilation options, you can obtain a 10–30% speed increase in applications. This is particularly important if you compile the MySQL server yourself.

When we tested both the Cygnus CodeFusion and Fujitsu compilers, neither was sufficiently bug-free to allow MySQL to be compiled with optimizations enabled.

The standard MySQL binary distributions are compiled with support for all character sets. When you compile MySQL yourself, you should include support only for the character sets that you are going to use. This is controlled by the `--with-charset` option to `configure`.

Here is a list of some measurements that we have made:

- If you use `pgcc` and compile everything with `-O6`, the `mysqld` server is 1% faster than with `gcc` 2.95.2.
- If you link dynamically (without `-static`), the result is 13% slower on Linux. Note that you still can use a dynamically linked MySQL library for your client applications. It is the server that is most critical for performance.
- For a connection from a client to a server running on the same host, if you connect using TCP/IP rather than a Unix socket file, performance is 7.5% slower. (On Unix, if you connect to the host name `localhost`, MySQL uses a socket file by default.)
- For TCP/IP connections from a client to a server, connecting to a remote server on another host is 8–11% slower than connecting to a server on the same host, even for connections faster than 100Mb/s Ethernet.
- When running our benchmark tests using secure connections (all data encrypted with internal SSL support) performance was 55% slower than with unencrypted connections.
- If you compile with `--with-debug=full`, most queries are 20% slower. Some queries may take substantially longer; for example, the MySQL benchmarks run 35% slower. If you use `--with-debug` (without `=full`), the speed decrease is only 15%. For a version of `mysqld` that has been compiled with `--with-debug=full`, you can disable memory checking at runtime by starting it with the `--skip-safemalloc` option. The execution speed should then be close to that obtained when configuring with `--with-debug`.
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster than one compiled with `gcc` 3.2.
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster in 32-bit mode than in 64-bit mode.
- Compiling with `gcc` 2.95.2 for UltraSPARC with the `-mcpu=v8 -Wa,-xarch=v8plusa` options gives 4% more performance.
- On Solaris 2.5.1, MIT-pthreads is 8–12% slower than Solaris native threads on a single processor. With greater loads or more CPUs, the difference should be larger.
- Compiling on Linux-x86 using `gcc` without frame pointers (`-fomit-frame-pointer` or `-fomit-frame-pointer -ffixed-ebp`) makes `mysqld` 1–4% faster.

Binary MySQL distributions for Linux that are provided by MySQL AB used to be compiled with `pgcc`. We had to go back to regular `gcc` due to a bug in `pgcc` that would generate binaries that do not run on AMD. We will continue using `gcc` until that bug is resolved. In the meantime, if you have a non-AMD machine, you can build a faster binary by compiling with `pgcc`. The standard MySQL Linux binary is linked statically to make it faster and more portable.

7.5.2. System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In

other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing factors that apply at this level.

The operating system to use is very important. To get the best use of multiple-CPU machines, you should use Solaris (because its threads implementation works well) or Linux (because the 2.4 and later kernels have good SMP support). Note that older Linux kernels have a 2GB filesize limit by default. If you have such a kernel and a need for files larger than 2GB, you should get the Large File Support (LFS) patch for the ext2 file system. Other file systems such as ReiserFS and XFS do not have this 2GB limitation.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking. Since MySQL 4.0, the default has been for external locking to be disabled on all systems. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

  Note that disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

  The only case in which you cannot disable external locking is when you run multiple MySQL *servers* (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using MySQL Cluster.

  > **Note**
  >
  > MySQL Cluster is currently not supported in MySQL 6.0. Users wishing to upgrade a MySQL Cluster from MySQL 5.0 or 5.1 should instead migrate to MySQL Cluster NDB 6.2 or 6.3; these are based on MySQL 5.1 but contain the latest improvements and fixes for `NDBCLUSTER`.

  The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

7.5.3. Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server using this command:

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

```
abort-slave-event-count           0
allow-suspicious-udfs             FALSE
archive                           TRUE

For a `mysqld` server that is currently running, you can see the current values of its system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all system and status variables, see Section 5.1.3, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally you get better performance by giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_open_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 256MB of memory and many tables and want maximum performance with a moderate number of clients, you should use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --table_open_cache=256 \
           --sort_buffer_size=4M --read_buffer_size=1M &
```

- If you have only 128MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=16M --sort_buffer_size=1M
```

  If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
           --read_buffer_size=100K &
```

  Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \
           --table_open_cache=32 --read_buffer_size=8K \
           --net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, you should increase the value of `read_rnd_buffer_size` to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see Section 4.2.3.2.2, “Preconfigured Option Files”.

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this:

```
shell> mysqld --key_buffer_size=32M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the `--verbose` and `--help` options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the `InnoDB` storage engine, see Section 13.7.13.1, “`InnoDB` Performance Tuning Tips”.

7.5.4. Controlling Query Optimizer Performance

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7–10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization allows the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled via two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of "educated guess" rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the "future" of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

7.5.5. The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache is extremely useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

> **Note**
>
> The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

The query cache is used for prepared statements under the conditions described in Section 7.5.5.1, "How the Query Cache Operates".

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead. If you build MySQL from source, query cache capabilities can be excluded from the server entirely by invoking `configure` with the `--without-query-cache` option.

The query cache offers the potential for substantial performance improvement, but you should not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.
- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See Section 7.5.5.2, "Query Cache `SELECT` Options".)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

7.5.5.1. How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 7.5.5.3, "Query Cache Configuration", describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

- Queries that are a subquery of an outer query
- Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 7.5.5.4, "Query Cache Status and Maintenance".

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using `InnoDB` tables.

In MySQL 6.0, the result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued via the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see Section 20.10.4, "C API Prepared Statements"), are subject to limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of `?` parameter markers. The statement is compared only with other cached statements that were executed via the binary protocol. That is, for query cache purposes, prepared statements issued via the binary protocol are distinct from prepared statements issued via the text protocol (see Section 12.7, "SQL Syntax for Prepared Statements").

A query cannot be cached if it contains any of the functions shown in the following table.

`BENCHMARK()`	`CONNECTION_ID()`	`CONVERT_TZ()`
`CURDATE()`	`CURRENT_DATE()`	`CURRENT_TIME()`
`CURRENT_TIMESTAMP()`	`CURTIME()`	`DATABASE()`
`ENCRYPT()` with one parameter	`FOUND_ROWS()`	`GET_LOCK()`
`LAST_INSERT_ID()`	`LOAD_FILE()`	`MASTER_POS_WAIT()`
`NOW()`	`RAND()`	`RELEASE_LOCK()`
`SLEEP()`	`SYSDATE()`	`UNIX_TIMESTAMP()` with no parameters
`USER()`	`UUID()`	`UUID_SHORT()`

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs) or stored functions.
- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql` or `INFORMATION_SCHEMA` system database.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

  The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the MyODBC section of Chapter 20, *Connectors and APIs*.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

7.5.5.2. Query Cache `SELECT` Options

Two query cache-related options may be specified in `SELECT` statements:

- `SQL_CACHE`

  The query result is cached if it is cacheable and the value of the `query_cache_type` system variable is `ON` or `DEMAND`.

- `SQL_NO_CACHE`

  The query result is not cached.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

7.5.5.3. Query Cache Configuration

The `have_query_cache` server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

When using a standard MySQL binary, this value is always `YES`, even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.1.3, “Server System Variables”, with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache. The default size is 0, so the query cache is disabled by default.

> **MySQL Enterprise**
> For expert advice on configuring the query cache subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

> **Note**
>
> When using the Windows Configuration Wizard to install or configure MySQL, the default value for

> `query_cache_size` will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` variable. You should check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1282
Message: Query cache failed to set size 39936;
         new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| query_cache_size | 41984 |
+------------------+-------+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+--------+
| Variable_name    | Value  |
+------------------+--------+
| query_cache_size | 999424 |
+------------------+--------+
1 row in set (0.00 sec)
```

The `query_cache_size` value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of `0` or `OFF` prevents caching or retrieval of cached results.
- A value of `1` or `ON` allows caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of `2` or `DEMAND` causes caching of only those statements that begin with `SELECT SQL_CACHE`.

Setting the `GLOBAL query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the `SESSION query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set `query_cache_type` at server startup (rather than at runtime with a `SET` statement), only the numeric values are allowed.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

> **Note**
>
> You can set the maximum size that can be specified for the query cache at run time with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might

find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, you should decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).

> **MySQL Enterprise**
> If the query cache is under-utilized, performance will suffer. Advice on avoiding this problem is provided to subscribers to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

7.5.5.4. Query Cache Status and Maintenance

You can check whether the query cache is present in your MySQL server using the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |
+-------------------------+--------+
```

Descriptions of each of these variables are given in Section 5.1.6, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
  Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
  Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 7.5.5.3, "Query Cache Configuration".

7.5.6. Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement (Section 12.5.6.30, "`SHOW PROCESSLIST` Syntax")
- The `SHOW PROFILE` statement (Section 12.5.6.32, "`SHOW PROFILES` Syntax")
- The `INFORMATION_SCHEMA PROCESSLIST` table (Section 19.23, "The `INFORMATION_SCHEMA PROCESSLIST` Table")
- The `mysqladmin processlist` command (Section 4.5.2, "`mysqladmin` — Client for Administering a MySQL Server")

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS` privilege.

Each process list entry contains several pieces of information:

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none is selected.
- `Command` and `State` indicate what the thread is doing.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.
- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.
- `Info` contains the text of the statement being executed by the thread, or `NULL` if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

7.5.6.1. Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

  This is a thread on a master server for sending binary log contents to a slave server.
- `Change user`

  The thread is executing a change-user operation.
- `Close stmt`

  The thread is closing a prepared statement.
- `Connect`

  A replication slave is connected to its master.

- `Connect Out`

  A replication slave is connecting to its master.

- `Create DB`

  The thread is executing a create-database operation.

- `Daemon`

  This thread is internal to the server, not a thread that services a client connection.

- `Debug`

  The thread is generating debugging information.

- `Delayed insert`

  The thread is a delayed-insert handler.

- `Drop DB`

  The thread is executing a drop-database operation.

- `Error`

- `Execute`

  The thread is executing a prepared statement.

- `Fetch`

  The thread is fetching the results from executing a prepared statement.

- `Field List`

  The thread is retrieving information for table columns.

- `Init DB`

  The thread is selecting a default database.

- `Kill`

  The thread is killing another thread.

- `Long Data`

  The thread is retrieving long data in the result of executing a prepared statement.

- `Ping`

  The thread is handling a server-ping request.

- `Prepare`

  The thread is preparing a prepared statement.

- `Processlist`

  The thread is producing information about server threads.

- `Query`

  The thread is executing a statement.

- `Quit`

  The thread is terminating.

- `Refresh`

The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- `Register Slave`

  The thread is registering a slave server.

- `Reset stmt`

  The thread is resetting a prepared statement.

- `Set option`

  The thread is setting or resetting a client statement-execution option.

- `Shutdown`

  The thread is shutting down the server.

- `Sleep`

  The thread is waiting for the client to send a new statement to it.

- `Statistics`

  The thread is producing server-status information.

- `Table Dump`

  The thread is sending table contents to a slave server.

- `Time`

  Unused.

7.5.6.2. General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`

  Occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `Analyzing`

  The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

  The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

  The thread is performing a table check operation.

- `cleaning up`

  The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

  Means that the thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, you should verify that you do not have a full disk and that the disk is not in very heavy use.

- `converting HEAP to MyISAM`

  The thread is converting an internal temporary table from a `MEMORY` table to an on-disk `MyISAM` table.

- `copy to tmp table`

  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

- `Copying to group table`

  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

  The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

  The server is copying to a temporary table on disk. The temporary result set was larger than `tmp_table_size` and the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

  The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `deleting from main table`

  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

  The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

  This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `executing`

  The thread has begun executing a statement.

- `Execution of init_command`

  The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

  The thread has executed a command. This state is usually followed by `cleaning up`.

- `Flushing tables`

  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `init`

  This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `Killed`

  Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `Locked`

  The query is locked by another query.

- `logging slow query`

  The thread is writing a statement to the slow-query log.

- `NULL`

  This state is used for the `SHOW PROCESSLIST` state.

- `login`

  The initial state for a connection thread until the client has been authenticated successfully.

- `Opening tables`, `Opening table`

  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished.

- `preparing`

  This state occurs during query optimization.

- `Purging old relay logs`

  The thread is removing unneeded relay log files.

- `query end`

  This state occurs after processing a query but before the `freeing items` state.

- `Reading from net`

  The server is reading a packet from the network.

- `Removing duplicates`

  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

  The thread is renaming a table.

- `rename result table`

  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

  The repair code is using a sort to create indexes.

- `Repair done`

  The thread has completed a multi-threaded repair for a `MyISAM` table.

- `Repair with keycache`

  The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

  The thread is rolling back a transaction.

- `Saving state`

  For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

  The thread is processing rows for a `SELECT` statement and also is sending data to the client.

- `setup`

  The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

  The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

  The thread is doing a sort to satisfy a `ORDER BY`.

- `Sorting index`

  The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

  For a `SELECT` statement, this is similar to `Creating sort index`, but for non-temporary tables.

- `statistics`

  The server is calculating statistics to develop a query execution plan.

- `System lock`

  The thread is going to request or is waiting for an internal or external system lock for the table. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `Table lock`

  The next thread state after `System lock`. The thread has acquired an external lock and is going to request an internal table lock.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

  The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `Waiting for tables`, `Waiting for table`

  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting on cond`

  A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

  The server is writing a packet to the network.

7.5.6.3. Delayed-Insert Thread States

These thread states are associated with processing for `DELAYED` inserts (see Section 12.2.5.2, "`INSERT DELAYED` Syntax"). Some states are associated with connection threads that process `INSERT DELAYED` statements from clients. Other states are associated with delayed-insert handler threads that insert the rows. There is a delayed-insert handler thread for each table for which `INSERT DELAYED` statements are issued.

States associated with a connection thread that processes an `INSERT DELAYED` statement from the client:

- `allocating local table`

  The thread is preparing to feed rows to the delayed-insert handler thread.

- `Creating delayed handler`

  The thread is creating a handler for `DELAYED` inserts.

- `got handler lock`

  This occurs before the `allocating local table` state and after the `waiting for handler lock` state, when the connection thread gets access to the delayed-insert handler thread.

- `got old table`

  This occurs after the `waiting for handler open` state. The delayed-insert handler thread has signaled that it has ended its initialization phase, which includes opening the table for delayed inserts.

- `storing row into queue`

  The thread is adding a new row to the list of rows that the delayed-insert handler thread must insert.

- `update`

- `waiting for delay_list`

  This occurs during the initialization phase when the thread is trying to find the delayed-insert handler thread for the table, and

before attempting to gain access to the list of delayed-insert threads.

- `waiting for handler insert`

  An `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- `waiting for handler lock`

  This occurs before the `allocating local table` state when the connection thread waits for access to the delayed-insert handler thread.

- `waiting for handler open`

  This occurs after the `Creating delayed handler` state and before the `got old table` state. The delayed-insert handler thread has just been started, and the connection thread is waiting for it to initialize.

States associated with a delayed-insert handler thread that inserts the rows:

- `insert`

  The state that occurs just before inserting rows into the table.

- `reschedule`

  After inserting a number of rows, the delayed-insert thread sleeps to let other threads do work.

- `upgrading lock`

  A delayed-insert handler is trying to get a lock for the table to insert rows.

- `Waiting for INSERT`

  A delayed-insert handler is waiting for a connection thread to add rows to the queue (see `storing row into queue`).

7.5.6.4. Replication Master Thread States

The following list shows the most common states you may see in the `State` column for the master's `Binlog Dump` thread. If you see no `Binlog Dump` threads on a master server, this means that replication is not running — that is, that no slaves are currently connected.

- `Sending binlog event to slave`

  Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- `Finished reading one binlog; switching to next binlog`

  The thread has finished reading a binary log file and is opening the next one to send to the slave.

- `Has sent all binlog to slave; waiting for binlog to be updated`

  The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Waiting to finalize termination`

  A very brief state that occurs as the thread is stopping.

7.5.6.5. Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Waiting for master update`

  The initial state before `Connecting to master`.

- `Connecting to master`

  The thread is attempting to connect to the master.

- `Checking master version`

  A state that occurs very briefly, after the connection to the master is established.

- `Registering slave on master`

  A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

  A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting to reconnect after a failed binlog dump request`

  If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- `Reconnecting after a failed binlog dump request`

  The thread is trying to reconnect to the master.

- `Waiting for master to send event`

  The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Queueing master event to the relay log`

  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Waiting to reconnect after a failed master event read`

  An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

- `Reconnecting after a failed master event read`

  The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Waiting for the slave SQL thread to free enough relay log space`

  You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting for slave mutex on exit`

  A state that occurs briefly as the thread is stopping.

7.5.6.6. Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Waiting for the next event in relay log`

  The initial state before `Reading event from the relay log`.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Has read all relay log; waiting for the slave I/O thread to update it`

  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Making temp file`

  The thread is executing a `LOAD DATA INFILE` statement and is creating a temporary file containing the data from which the slave will read rows.

- `Waiting for slave mutex on exit`

  A very brief state that occurs as the thread is stopping.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

7.5.6.7. Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

  The thread is processing a `CHANGE MASTER TO` statement.

- `Killing slave`

  The thread is processing a `SLAVE STOP` statement.

- `Opening master dump table`

  This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

  This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

  This state occurs after `Reading master dump table data`.

7.5.6.8. Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

  The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

  The scheduler thread or a thread that will execute an event has been initialized.

- `Waiting for next activation`

  The scheduler has a non-empty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

  The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

  The scheduler's event queue is empty and it is sleeping.

7.5.7. How MySQL Uses Threads for Client Connections

Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

In the original thread model for handing client connections, connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

The original connection thread model uses as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

As of MySQL 6.0.4, an alternative thread model is available for dealing with the preceding issues that occur when scaling to large numbers of simultaneous connections. This model uses thread pooling:

- Connection manager threads do not dedicate a thread to each client connection. Instead, the connection is added to the set of existing connection sockets. The server collects input from these sockets and when a complete request has been received from a given client, it is queued for service.
- The server maintains a pool of service threads to process client requests. When a queued request is waiting and there is an available (not busy) service thread in the pool, the request is given to the thread to be handled. After processing the request, the service thread becomes available to process other requests.
- Service threads are created at server startup and exist until the server terminates. A given service thread is not tied to a specific client connection and the requests that it processes over time may originate from different client connections.
- The pool of service threads has a fixed size, so the amount of memory required for it does not increase as the number of client connections increases.

Thread pooling works best if the normal workload consists mostly of lightweight queries, with no more than a few simultaneous transactions or long-running statements.

Thread pooling is less suitable when you have *N* threads in the pool but it is possible that all or most of the threads will be tied up servicing transactions or long-running statements simultaneously. If this happens, the workload from other clients will be stalled. Configuring the server to use a pool larger than the maximum number of simultaneous transactions or long-running statements will help in this case.

The following examples illustrate when a too-small thread pool might cause problems. Assume a thread pool size of 1 for simplicity, but the same issues can occur for a larger pool and larger number of clients.

- One client issues a statement that takes a long time to process. This ties up the service thread. If other clients issue statements, they are queued and must wait for the statement currently executing to finish.
- One client acquires an exclusive lock on a table. If another client attempts to use the table, its statement blocks and the service thread remains occupied waiting for the block to end. Any further statements from the original client cannot execute, either, because there is no free thread available.

  In the following scenario, conflicting lock requests cause deadlock.

  Session 1:

  ```
  LOCK TABLES t1 WRITE;
  ```

  The service thread executes the statement and becomes free.

  Session 2:

  ```
  LOCK TABLES t1 WRITE;
  ```

  The service thread starts to execute the statement but blocks waiting for the exiting lock on `t1` to be released. The thread does

not become free.

Session 1:

```
INSERT INTO t1 VALUES(1,2);
```

The statement cannot execute and is queued because the service thread remains allocated to session 2. At this point, the clients are deadlocked and neither cannot continue.

A similar situation can occur in the absence of explicit locks if simultaneous transactions attempt to access tables such that one transaction blocks another. Assume that `t1` is an `InnoDB` table.

Session 1:

```
START TRANSACTION;
SELECT * FROM t1 WHERE id = 7 FOR UPDATE;
```

The service thread executes each of the statements in turn and becomes free. The `SELECT` statement acquires an exclusive lock for the selected row or rows.

Session 2:

```
START TRANSACTION;
UPDATE t1 SET a = a+1 WHERE id = 7;
```

The service thread executes the first statement and attempts to execute the second. However, the `UPDATE` blocks because it must lock the same rows already locked by session 1, so the service thread waits and does not become free.

Session 1:

```
COMMIT;
```

The statement cannot execute and is queued because the service thread remains allocated to the session 2 statement. At this point, the transactions are deadlocked. Eventually, `InnoDB` times out waiting for the lock and the session 2 `UPDATE` fails with an error. The service thread becomes free and executes the `COMMIT` for session 1.

Thread pooling is based on the `libevent` library. To build a server that includes the thread-pool capability, configure MySQL using the `--with-libevent` option. The `--without-libevent` option excludes the `libevent` code. See Section 2.9.2, “Typical `configure` Options”.

To control which thread model the server uses to manage threads that handle client connections and to monitor thread use, several system and status variables are relevant:

- At server startup, the `thread_handling` system variable controls which thread model is used. `--thread_handling=one-thread-per-connection` is the default and selects the model that allocates one thread per connected client (the original thread model). To use thread pooling, start the server with `--thread_handling=pool-of-threads`. If `libevent` is not compiled into the server, `thread_handling` is unavailable and the server defaults to one thread per client.
- When the server uses thread pooling, `thread_pool_size` controls the maximum number of requests that the server should be allowed to process simultaneously. The pool has a fixed size over the lifetime of server execution, but the size can be specified at startup. The default pool size is 20 threads. Starting the server with `--thread_pool_size=N` sets the size to *`N`* threads, up to a maximum of 16,384. If `libevent` is not compiled into the server, `thread_pool_size` is unavailable.

  With thread pooling enabled, InnoDB concurrency control becomes unnecessary, so you can disable InnoDB thread concurrency by setting `innodb_thread_concurrency` to 0.
- When the server uses one thread per client connection, it uses the thread cache, which has a size determined by the `thread_cache_size` system variable. The default value is 0 (no caching), which causes a thread to be set up for each new connection and disposed of when the connection terminates. Set `thread_cache_size` to *`N`* to allow *`N`* inactive connection threads to be cached. `thread_cache_size` can be set at server startup or changed while the server runs. A connection thread becomes inactive when the client connection with which it was associated terminates.

  To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, monitor the `Threads_cached` and `Threads_created` status variables. (See Section 5.1.6, “Server Status Variables”.)
- Regardless of thread model, you can set `max_connections` at server startup or at runtime to control the maximum number

of clients that can connect simultaneously.

- When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *N* bytes for each thread, start the server with `--thread_stack=N`.

For more information on these system and status variables, see Section 5.1.3, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.

7.5.8. How MySQL Uses Memory

The following list indicates some of the ways that the `mysqld` server uses memory. Where applicable, the name of the system variable relevant to the memory use is given:

- The key buffer is shared by all threads; its size is determined by the `key_buffer_size` variable. Other buffers used by the server are allocated as needed. See Section 7.5.3, “Tuning Server Parameters”.
- Each thread that is used to manage client connections uses some thread-specific space. The following list indicates these and which variables control their size:
  - A stack (default 192KB, variable `thread_stack`)
  - A connection buffer (variable `net_buffer_length`)
  - A result buffer (variable `net_buffer_length`)

  The connection buffer and result buffer both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.
- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all `MyISAM` tables.
- Each request that performs a sequential scan of a table allocates a *read buffer* (variable `read_buffer_size`).
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* (variable `read_rnd_buffer_size`) may be allocated in order to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.

  If an internal heap table exceeds the size of `tmp_table_size`, MySQL handles this automatically by changing the in-memory heap table to a disk-based `MyISAM` table as necessary. You can also increase the temporary table size by setting the `tmp_table_size` option to `mysqld`, or by setting the SQL option `sql_big_tables` in the client program. See Section 5.1.4, “Session System Variables”.

  > **MySQL Enterprise**
  > Subscribers to the MySQL Enterprise Monitor are alerted when temporary tables exceed `tmp_table_size`. Advisors make recommendations for the optimum value of `tmp_table_size` based on actual table usage. For more information about the MySQL Enterprise Monitor please see http://www.mysql.com/products/enterprise/advisors.html.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.1.4.4, “Where MySQL Stores Temporary Files”.
- Almost all parsing and calculating is done in a local memory store. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings. This is done with `malloc()` and `free()`.
- For each `MyISAM` table that is opened, the index file is opened once; the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size `3 × N` are allocated (where *N* is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` storage engine maintains one extra row buffer for internal use.

- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, a buffer as large as the largest `BLOB` value is allocated.
- Handler structures for all in-use tables are saved in a cache and managed as a FIFO. By default, the cache has 64 entries. If a table has been used by two running threads at the same time, the cache contains two entries for the table. See Section 7.4.7, “How MySQL Opens and Closes Tables”.
- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. You can verify this by checking available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

7.5.9. Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Currently, MySQL supports only the Linux implementation of large page support (which is called HugeTLB in Linux). Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

For some recent systems, such as Red Hat Enterprise Linux, the kernel appears to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:       0
HugePages_Free:        0
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The non-empty command output indicates that large page support is present. The zero values indicate that no pages are configured for use.

If the output is empty, your kernel needs to be reconfigured to support large pages. Consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much
# memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is allowed to access this
# memory (102 in this case). The mysql user must be a
# member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem allowed per segment
# (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory.  The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an "unlimited" value for the memlock limit. This can by done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in your server's `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `WARNING: USING CONVENTIONAL MEMORY POOL`

You can verify that large pages are being used by checking `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        2
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

7.5.10. How MySQL Uses Internal Temporary Tables

In some cases, the server creates internal temporary tables while processing queries. A temporary table can be held in memory and processed by the `MEMORY` storage engine, or stored on disk and processed by the `MyISAM` storage engine. Temporary tables can be created under conditions such as these:

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table.
- `DISTINCT` combined with `ORDER BY` may require a temporary table.

You can tell whether a query requires a temporary table by using `EXPLAIN` and checking the `Extra` column to see whether it says `Using temporary`. See Section 7.2.1, "Optimizing Queries with EXPLAIN".

Some conditions prevent the use of a `MEMORY` temporary table, in which case the server uses a `MyISAM` table instead:

- Presence of a `TEXT` or `BLOB` column in the table
- Presence of any column in a `GROUP BY` or `DISTINCT` clause larger than 512 bytes
- Presence of any column larger than 512 bytes in the `SELECT` list, if `UNION` or `UNION ALL` is used.

A temporary table that is created initially as a `MEMORY` table might be converted to a `MyISAM` table and stored on disk if it becomes too large. The `max_heap_table_size` system variable determines how large `MEMORY` tables are allowed to grow. It applies to all `MEMORY` tables, including those created with `CREATE TABLE`. However, for internal `MEMORY` tables, the actual maximum size is determined by `max_heap_table_size` in combination with `tmp_table_size`: Whichever value is smaller is

the one that applies. If the size of an internal `MEMORY` table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table.

7.5.11. How MySQL Uses DNS

When a new client connects to `mysqld`, `mysqld` spawns a new thread to handle the request. This thread first checks whether the host name is in the host name cache. If not, the thread attempts to resolve the host name:

- The thread takes the IP address and resolves it to a host name (using `gethostbyaddr()`). It then takes that host name and resolves it back to the IP address (using `gethostbyname()`) and compares to ensure it is the original IP address.
- If the operating system supports the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls, the thread uses them to perform host name resolution.
- If the operating system does not support the thread-safe calls, the thread locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve host names that are not in the host name cache until the first thread unlocks the mutex.

You can disable DNS host name lookups by starting `mysqld` with the `--skip-name-resolve` option. However, in this case, you can use only IP numbers in the MySQL grant tables.

If you have a very slow DNS and many hosts, you can get more performance by either disabling DNS lookups with `--skip-name-resolve` or by increasing the `HOST_CACHE_SIZE` define (default value: 128) and recompiling `mysqld`.

You can disable the host name cache by starting the server with the `--skip-host-cache` option. To clear the host name cache, issue a `FLUSH HOSTS` statement or execute the `mysqladmin flush-hosts` command.

To disallow TCP/IP connections entirely, start `mysqld` with the `--skip-networking` option.

7.6. Disk Issues

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links

    This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 7.6.1, “Using Symbolic Links”.
  - Striping

    Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the *`N`*-th block on the (`N MOD number_of_disks`) disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 7.1.5, “Using Your Own Benchmarks”.

    The speed difference for striping is *very* dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.
- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need 2 × *`N`* drives to hold *`N`* drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID *`N`* disk. RAID *`N`* can be a problem if you have many writes, due to the time required to update the parity bits.
- On Linux, you can get much more performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be quite good for MySQL, and probably for many other applications:

```
hdparm -m 16 -d 1
```

Note that performance and reliability when using this command depend on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, file system corruption may result, so back up everything before experimenting!

- You can also set the parameters for the file system that the database uses:

  If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

  On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you more performance without sacrificing too much reliability. (This flag is on by default on Linux.)

7.6.1. Using Symbolic Links

You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disk.

The recommended way to do this is simply to symlink databases to a different disk. Symlink tables only as a last resort.

7.6.1.1. Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a symlink to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

However, if you really need to do this, it is possible by altering the source file `mysys/my_symlink.c`, in which you should look for the following statement:

```
if (!(MyFlags & MY_RESOLVE_LINK) ||
    (!lstat(filename,&stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Change the statement to this:

```
if (1)
```

7.6.1.2. Using Symbolic Links for Tables on Unix

You should not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). You can check whether your system supports symbolic links by issuing a `SHOW VARIABLES LIKE 'have_symlink'` statement.

Symlinks are fully supported only for `MyISAM` tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links.

The handling of symbolic links for `MyISAM` tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.

- You can symlink the data file and the index file independently to different directories.
- You can instruct a running MySQL server to perform the symlinking by using the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See Section 12.1.14, "`CREATE TABLE` Syntax". Alternatively, symlinking can be accomplished manually from the command line using `ln -s` if `mysqld` is not running.

  Note

  Beginning with MySQL 6.0.5, the path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug#32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
- **Note**

  When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason why you should *not* run `mysqld` as the system `root` or allow system users to have write access to MySQL database directories.
- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, you should use the `--skip-symbolic-links` option to `mysqld` to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

Table symlink operations that are not yet supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
- The `.frm` file must *never* be a symbolic link (as indicated previously, only the data and index files can be symbolic links). Attempting to do this (for example, to make synonyms) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

  ```
  shell> cd /path/to/datadir/db1
  shell> ln -s tbl1.frm tbl2.frm
  shell> ln -s tbl1.MYD tbl2.MYD
  shell> ln -s tbl1.MYI tbl2.MYI
  ```

  Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

  - The query cache is "fooled" (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
  - `ALTER` statements on `tbl2` fail.

7.6.1.3. Using Symbolic Links for Databases on Windows

Symbolic links are enabled by default for all Windows servers. This enables you to put a database directory on a different disk by setting up a symbolic link to it. This is similar to the way that database symbolic links work on Unix, although the procedure for setting up the link is different. If you do not need symbolic links, you can disable them using the `--skip-symbolic-links` option.

On Windows, create a symbolic link to a MySQL database by creating a file in the data directory that contains the path to the destination directory. The file should be named *`db_name`*`.sym`, where *`db_name`* is the database name.

Suppose that the MySQL data directory is `C:\mysql\data` and you want to have database `foo` located at `D:\data\foo`. Set up a symlink using this procedure

1. Make sure that the `D:\data\foo` directory exists by creating it if necessary. If you already have a database directory named

`foo` in the data directory, you should move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

2. Create a text file `C:\mysql\data\foo.sym` that contains the path name `D:\data\foo\`.

   Note

   The path name to the new database and tables should be absolute. If you specify a relative path, the location will be relative to the `foo.sym` file.

After this, all tables created in the database `foo` are created in `D:\data\foo`.

The following limitations apply to the use of `.sym` files for database symbolic linking on Windows:

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The `--innodb_file_per_table` option cannot be used.
- If you run `mysqld` as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (`\\servername\path\`).

Chapter 8. Language Structure

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Reserved words
- User-defined and system variables
- Comments

8.1. Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and `NULL`. The section also covers the various nuances and "gotchas" that you may run into when dealing with these basic types in MySQL.

8.1.1. Strings

A string is a sequence of bytes or characters, enclosed within either single quote ("`'`") or double quote ("`"`") characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the `ANSI_QUOTES` SQL mode is enabled, string literals can be quoted only within single quotes because a string quoted within double quotes is interpreted as an identifier.

A *binary string* is a string of bytes that has no character set or collation. A *nonbinary string* is a string of characters that has a character set and collation. For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte. For nonbinary strings the unit is the character and some character sets allow multi-byte characters. Character value ordering is a function of the string collation.

String literals may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For more information about these forms of string syntax, see Section 9.1.3.5, "Character String Literal Character Set and Collation", and Section 9.1.3.6, "National Character Set".

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash ("`\`"), known as the *escape character*. MySQL recognizes the following escape sequences.

`\0`	An ASCII NUL (`0x00`) character.
`\'`	A single quote ("`'`") character.
`\"`	A double quote ("`"`") character.
`\b`	A backspace character.

`\n`	A newline (linefeed) character.
`\r`	A carriage return character.
`\t`	A tab character.
`\Z`	ASCII 26 (Control-Z). See note following the table.
`\\`	A backslash (“`\`”) character.
`\%`	A “`%`” character. See note following the table.
`\_`	A “`_`” character. See note following the table.

For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, “`\x`” is just “`x`”.

These sequences are case sensitive. For example, “`\b`” is interpreted as a backspace, but “`\B`” is interpreted as “`B`”.

The ASCII 26 character can be encoded as “`\Z`” to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql *db_name* < *file_name*`.

Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 9.1.3.5, “Character String Literal Character Set and Collation”.

The “`\%`” and “`\_`” sequences are used to search for literal instances of “`%`” and “`_`” in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` operator in Section 11.4.1, “String Comparison Functions”. If you use “`\%`” or “`\_`” in non-pattern-matching contexts, they evaluate to the strings “`\%`” and “`\_`”, not to “`%`” and “`_`”.

There are several ways to include quote characters within a string:

- A “`'`” inside a string quoted with “`'`” may be written as “`''`”.
- A “`"`” inside a string quoted with “`"`” may be written as “`""`”.
- Precede the quote character by an escape character (“`\`”).
- A “`'`” inside a string quoted with “`"`” needs no special treatment and need not be doubled or escaped. In the same way, “`"`” inside a string quoted with “`'`” needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '""hello""', 'hel''lo', '\'hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT "hello", "'hello'", "''hello''", "hel""lo", "\"hello";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | ''hello'' | hel"lo | "hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT 'This\nIs\nFour\nLines';
+--------------------+
| This
Is
Four
Lines |
+--------------------+

mysql> SELECT 'disappearing\ backslash';
+------------------------+
| disappearing backslash |
+------------------------+
```

If you want to insert binary data into a string column (such as a `BLOB` column), the following characters must be represented by escape sequences.

`NUL`	`NUL` byte (`0x00`). Represent this character by “`\0`” (a backslash followed by an ASCII “`0`” character).
`\`	Backslash (ASCII 92). Represent this character by “`\\`”.
`'`	Single quote (ASCII 39). Represent this character by “`\'`”.
`"`	Double quote (ASCII 34). Represent this character by “`\"`”.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See Section 20.10.3.53, “mysql_real_escape_string()”. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See Section 20.12, “MySQL Perl API”. Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

8.1.2. Numbers

Integers are represented as a sequence of digits. Floats use “`.`” as a decimal separator. Either type of number may be preceded by “`-`” or “`+`” to indicate a negative or positive value, respectively

Examples of valid integers:

```
1221
0
-32
```

Examples of valid floating-point numbers:

```
294.42
-32032.6809e+10
148.00
```

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

8.1.3. Hexadecimal Values

MySQL supports hexadecimal values, written using `X'val'`, `x'val'`, or `0xval` format, where *`val`* contains hexadecimal digits (`0..9`, `A..F`). Lettercase of the digits does not matter. For values written using `X'val'` or `x'val'` format, *`val`* must contain an even number of digits. For values written using `0xval` syntax, values that contain an odd number of digits are treated as having an extra leading `0`. For example, `0x0a` and `0xaaa` are interpreted as `0x0a` and `0x0aaa`.

In numeric contexts, hexadecimal values act like integers (64-bit precision). In string contexts, they act like binary strings, where each pair of hex digits is converted to a character:

```
mysql> SELECT X'4D7953514C';
        -> 'MySQL'
mysql> SELECT 0x0a+0;
        -> 10
mysql> SELECT 0x5061756c;
        -> 'Paul'
```

The default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use `CAST(... AS UNSIGNED)`:

```
mysql> SELECT 0x41, CAST(0x41 AS UNSIGNED);
        -> 'A', 65
```

The `X'hexstring'` syntax is based on standard SQL. The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for `BLOB` columns.

You can convert a string or a number to a string in hexadecimal format with the `HEX()` function:

```
mysql> SELECT HEX('cat');
        -> '636174'
mysql> SELECT 0x636174;
        -> 'cat'
```

8.1.4. Boolean Values

The constants `TRUE` and `FALSE` evaluate to `1` and `0`, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
```

```
        -> 1, 1, 0, 0
```

8.1.5. Bit-Field Values

Bit-field values can be written using `b'value'` or `0bvalue` notation. *`value`* is a binary value written using zeros and ones.

Bit-field notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values are returned as binary values. To display them in printable form, add 0 or use a conversion function such as `BIN()`. High-order 0 bits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b+0), OCT(b+0), HEX(b+0) FROM t;
+------+----------+----------+----------+
| b+0  | BIN(b+0) | OCT(b+0) | HEX(b+0) |
+------+----------+----------+----------+
|  255 | 11111111 | 377      | FF       |
|   10 | 1010     | 12       | A        |
|    5 | 101      | 5        | 5        |
+------+----------+----------+----------+
```

Bit values assigned to user variables are treated as binary strings. To assign a bit value as a number to a user variable, use `CAST()` or `+0`:

```
mysql> SET @v1 = 0b1000001;
mysql> SET @v2 = CAST(0b1000001 AS UNSIGNED), @v3 = 0b1000001+0;
mysql> SELECT @v1, @v2, @v3;
+------+------+------+
| @v1  | @v2  | @v3  |
+------+------+------+
| A    |   65 |   65 |
+------+------+------+
```

8.1.6. `NULL` Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase. A synonym is `\N` (case sensitive).

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See Section 12.2.6, “`LOAD DATA INFILE` Syntax”.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see Section B.1.5.3, “Problems with `NULL` Values”.

8.2. Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the allowable syntax for identifiers in MySQL. Section 8.2.2, “Identifier Case Sensitivity”, describes which types of identifiers are case sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. The set of alphanumeric characters from the current character set, “_”, and “$” are not special. Reserved words are listed at Section 8.3, “Reserved Words”. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.)

The identifier quote character is the backtick (“`”):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also allowable to quote identifiers within double quotes:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The `ANSI_QUOTES` mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotes. They cannot be enclosed within double quotes. The server SQL mode is controlled as described in Section 5.1.7, “Server SQL Modes”.

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

Aliases may be quoted either as identifiers or as strings:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
+-----+-----+
|   1 |   2 |
+-----+-----+
```

Identifiers may begin with a digit but unless quoted may not consist solely of digits.

It is recommended that you do not use names that begin with *`Me`* or *`MeN`*, where *`M`* and *`N`* are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 8.4, “User-Defined Variables”, for more information and examples of workarounds.

There are some restrictions on the characters that may appear in identifiers:

- No identifier can contain ASCII NUL (`0x00`).
- Database, table, and column names should not end with space characters.

Special characters in database and table names are encoded in the corresponding file system names as described in Section 8.2.3, “Mapping of Identifiers to File Names”. If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#`. For information about referring to such names or converting them to the newer encoding, see that section.

The following table describes the maximum length for each type of identifier.

Identifier	Maximum Length (characters)
Database	64
Table	64
Column	64
Index	64
Constraint	64
Stored Function or Procedure	64
Trigger	64
View	64
Event	64
Tablespace	64
Server	64
Log File Group	64
Alias	256

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multi-byte characters without reducing the number of characters allowed for values stored in these columns, something not true prior to MySQL 4.1. The allowable Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not allowed.

8.2.1. Identifier Qualifiers

MySQL allows names that consist of a single identifier or multiple identifiers. The components of a multiple-part name must be separated by period (“`.`”) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL, you can refer to a table column using any of the following forms.

Column Reference	Meaning
`col_name`	The column *`col_name`* from whichever table used in the statement contains a column of that name.
`tbl_name.col_name`	The column *`col_name`* from table *`tbl_name`* of the default database.
`db_name.tbl_name.col_name`	The column *`col_name`* from table *`tbl_name`* of the database *`db_name`*.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `` `my-table`.`my-column` ``, not `` `my-table.my-column` ``.

A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

You need not specify a *`tbl_name`* or *`db_name.tbl_name`* prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables `t1` and `t2` each contain a column `c`, and you retrieve `c` in a `SELECT` statement that uses both `t1` and `t2`. In this case, `c` is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as `t1.c` or `t2.c` to indicate which table you mean. Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must refer to columns in those tables as `db1.t.`*`col_name`* and `db2.t.`*`col_name`*.

The syntax *`.tbl_name`* means the table *`tbl_name`* in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a “`.`” character.

8.2.2. Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database and table names. This means database, table, and trigger names are not case sensitive in Windows, but are case sensitive in most varieties of Unix. One notable exception is Mac OS X, which is Unix-based but uses a default file system type (HFS+) that is not case sensitive. However, Mac OS X also supports UFS volumes, which are case sensitive just as on any Unix. See Section 1.7.4, “MySQL Extensions to Standard SQL”. The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.
