d01 – Quadrature d01alc

NAG C Library Function Document

nag_1d_quad_brkpts (d01alc)

1 Purpose

nag_1d_quad_brkpts (d01alc) is a general purpose integrator which calculates an approximation to the integral of a function f(x) over a finite interval [a,b]:

$$I = \int_a^b f(x) \ dx.$$

where the integrand may have local singular behaviour at a finite number of points within the integration interval.

2 Specification

3 Description

This function is based upon the QUADPACK routine QAGP (Piessens *et al.* (1983)). It is very similar to nag_1d_quad_gen (d01ajc), but allows the user to supply 'break-points', points at which the function is known to be difficult. It is an adaptive routine, using the Gauss 10-point and Kronrod 21-point rules. The algorithm described by De Doncker (1978), incorporates a global acceptance criterion (as defined by Malcolm and Simpson (1976)) together with the ϵ -algorithm (Wynn (1956)) to perform extrapolation. The user-supplied 'break-points' always occur as the end-points of some sub-interval during the adaptive process. The local error estimation is described by Piessens *et al.* (1983).

4 Parameters

1: \mathbf{f} – function supplied by user

Function

The function f, supplied by the user, must return the value of the integrand f at a given point. The specification of f is:

2: \mathbf{a} - double

On entry: the lower limit of integration, a.

3: \mathbf{b} - double Input

On entry: the upper limit of integration, b. It is not necessary that a < b.

[NP3491/6] d01alc.1

4: **nbrkpts** – Integer

Input

On entry: the number of user-supplied break-points within the integration interval.

Constraint: $\mathbf{nbrkpts} \geq 0$.

5: **brkpts[nbrkpts]** – double

Input

On entry: the user-specified break-points.

Constraint: the break-points must all lie within the interval of integration (but may be supplied in any order).

6: **epsabs** – double

Input

On entry: the absolute accuracy required. If **epsabs** is negative, the absolute value is used. See Section 6.1.

7: **epsrel** – double

Input

On entry: the relative accuracy required. If **epsrel** is negative, the absolute value is used. See Section 6.1.

8: max num subint – Integer

Input

On entry: the upper bound on the number of sub-intervals into which the interval of integration may be divided by the function. The more difficult the integrand, the larger **max_num_subint** should be.

Suggested values: a value in the range 200 to 500 is adequate for most problems.

Constraint: $max_num_subint \ge 1$.

9: **result** – double *

Output

On exit: the approximation to the integral I.

10: **abserr** – double *

Output

On exit: an estimate of the modulus of the absolute error, which should be an upper bound for |I-result|.

11: **qp** – Nag QuadProgress *

Pointer to structure of type Nag_QuadProgress with the following members:

```
num subint – Integer
```

Output

On exit: the actual number of sub-intervals used.

fun count - Integer

Output

On exit: the number of function evaluations performed by nag 1d quad brkpts.

```
sub_int_beg_ptsOutputsub_int_end_ptsOutputsub_int_resultOutputsub_int_errorOutputoutputOutput
```

On exit: these pointers are allocated memory internally with max_num_subint elements. If an error exit other than NE_INT_ARG_LT, NE_2_INT_ARG_LE or NE_ALLOC_FAIL occurs, these arrays will contain information which may be useful. For details, see Section 6.

Before a subsequent call to nag_1d_quad_brkpts is made, or when the information contained in these arrays is no longer useful, the user should free the storage allocated by these pointers using the NAG macro **NAG FREE**.

d01alc.2 [NP3491/6]

d01 – Quadrature d01alc

12: **fail** – NagError *

Input/Output

The NAG error parameter (see the Essential Introduction).

Users are recommended to declare and initialise fail and set fail.print = TRUE for this function.

5 Error Indicators and Warnings

NE_INT_ARG_LT

On entry, **max_num_subint** must not be less than 1: **max_num_subint** = <*value*>. On entry, **nbrkpts** must not be less than 0: **nbrkpts** = <*value*>.

NE 2 INT ARG LE

On entry, max_num_subint = <value> while nbrkpts = <value>. These parameters must satisfy max num subint > nbrkpts.

NE ALLOC FAIL

Memory allocation failed.

NE QUAD MAX SUBDIV

The maximum number of subdivisions has been reached: **max num subint** = $\langle value \rangle$.

The maximum number of subdivisions has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g., a singularity of the integrand or its derivative, a peak, a discontinuity, etc.) you will probably gain from splitting up the interval at this point and calling the integrator on the sub-intervals. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**, or increasing the value of **max_num_subint**.

NE QUAD ROUNDOFF TOL

Round-off error prevents the requested tolerance from being achieved: **epsabs** = <*value*>, **epsrel** = <*value*>.

The error may be underestimated. Consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**.

NE_QUAD_BAD_SUBDIV

Extremely bad integrand behaviour occurs around the sub-interval (<*value*>, <*value*>). The same advice applies as in the case of **NE QUAD MAX SUBDIV**.

NE_QUAD_ROUNDOFF_EXTRAPL

Round-off error is detected during extrapolation.

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best that can be obtained.

The same advice applies as in the case of NE QUAD MAX SUBDIV.

NE_QUAD_NO_CONV

The integral is probably divergent, or slowly convergent.

Please note that divergence can occur with any error exit other than NE_INT_ARG_LT, NE_2_INT_ARG_LE and NE_ALLOC_FAIL.

NE_QUAD_BRKPTS_INVAL

On entry, break points outside (a, b): $a = \langle value \rangle$, $b = \langle value \rangle$.

[NP3491/6] d01alc.3

6 Further Comments

The time taken by nag 1d quad brkpts depends on the integrand and the accuracy required.

If the function fails with an error exit other than NE_INT_ARG_LT, NE_2_INT_ARG_LE or NE_ALLOC_FAIL, then the user may wish to examine the contents of the structure qp. These contain the end-points of the sub-intervals used by nag_1d_quad_brkpts along with the integral contributions and error estimates over the sub-intervals.

Specifically, for i = 1, 2, ..., n, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of [a, b] and e_i be the corresponding absolute error estimate.

Then, $\int_{a_i}^{b_i} f(x) dx \simeq r_i$ and **result** = $\sum_{i=1}^n r_i$ unless the function terminates while testing for divergence of the integral (see Section 3.4.3 of Piessens *et al.* (1983)). In this case, **result** (and **abserr**) are taken to be the values returned from the extrapolation process. The value of n is returned in **num_subint**, and the values a_i , b_i , r_i and e_i are stored in the structure **qp** as

$$a_i = \mathbf{sub_int_beg_pts}[i-1],$$

 $b_i = \mathbf{sub_int_end_pts}[i-1],$
 $r_i = \mathbf{sub_int_result}[i-1]$ and
 $e_i = \mathbf{sub_int_error}[i-1].$

6.1 Accuracy

The function cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \mathbf{result}| \le tol$$

where

$$tol = \max\{|\mathbf{epsabs}|, |\mathbf{epsrel}| \times |I|\}$$

and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. Moreover it returns the quantity **abserr** which, in normal circumstances, satisfies

$$|I - \mathbf{result}| \le \mathbf{abserr} \le tol.$$
