

## nag\_robust\_corr\_estim (g02hkc)

### 1. Purpose

**nag\_robust\_corr\_estim (g02hkc)** computes a robust estimate of the covariance matrix for an expected fraction of gross errors.

### 2. Specification

```
#include <nag.h>
#include <nagg02.h>

void nag_robust_corr_estim(Integer n, Integer m, double x[], Integer tdx,
                           double eps, double cov[], double theta[], Integer max_iter,
                           Integer print_iter, char *outfile, double tol, Integer *iter,
                           NagError *fail)
```

### 3. Description

For a set  $n$  observations on  $m$  variables in a matrix  $X$ , a robust estimate of the covariance matrix,  $C$ , and a robust estimate of location,  $\theta$ , are given by:

$$C = \tau^2 (A^T A)^{-1}$$

where  $\tau^2$  is a correction factor and  $A$  is a lower triangular matrix found as the solution to the following equations.

$$z_i = A(x_i - \theta)$$

$$\frac{1}{n} \sum_{i=1}^n w(\|z_i\|_2) z_i = 0$$

and

$$\frac{1}{n} \sum_{i=1}^n u(\|z_i\|_2) z_i z_i^T - I = 0,$$

where  $x_i$  is a vector of length  $m$  containing the elements of the  $i$ th row of  $X$ ,

$z_i$  is a vector of length  $m$ ,

$I$  is the identity matrix and  $0$  is the zero matrix,

and  $w$  and  $u$  are suitable functions.

nag\_robust\_corr\_estim uses weight functions:

$$w(t) = \frac{a_u}{t^2}, \quad \text{if } t < a_u^2$$

$$w(t) = 1, \quad \text{if } a_u^2 \leq t \leq b_u^2$$

$$w(t) = \frac{b_u}{t^2}, \quad \text{if } t > b_u^2$$

and

$$w(t) = 1, \quad \text{if } t \leq c_w$$

$$w(t) = \frac{c_w}{t}, \quad \text{if } t > c_w$$

for constants  $a_u$ ,  $b_u$  and  $c_w$ .

These functions solve a minimax problem considered by Huber (1981). The values of  $a_u$ ,  $b_u$  and  $c_w$  are calculated from the expected fraction of gross errors,  $\epsilon$  (see Huber (1981) and Marazzi (1987)). The expected fraction of gross errors is the estimated proportion of outliers in the sample.

In order to make the estimate asymptotically unbiased under a Normal model a correction factor,  $\tau^2$ , is calculated, (see Huber (1981) and Marazzi (1987)).

Initial estimates of  $\theta_j$ , for  $j = 1, 2, \dots, m$ , are given by the median of the  $j$ th column of  $X$  and the initial value of  $A$  is based on the median absolute deviation (see Marazzi (1987)). nag\_robust\_corr\_estim is based on routines in ROBETH, (see Marazzi (1987)).

#### 4. Parameters

**n**

Input: the number of observations,  $n$ .

Constraint:  $\mathbf{n} > 1$ .

**m**

Input: the number of columns of the matrix  $X$ , i.e., number of independent variables,  $m$ .

Constraint:  $1 \leq \mathbf{m} \leq \mathbf{n}$ .

**x[n][tdx]**

Input:  $\mathbf{x}[i-1][j-1]$  must contain the  $i$ th observation for the  $j$ th variable, for  $i = 1, 2, \dots, n$ ;  $j = 1, 2, \dots, m$ .

**tdx**

Input: the second dimension of the array  $\mathbf{x}$  as declared in the function from which nag\_robust\_corr\_estim is called.

Constraint:  $\mathbf{tdx} \geq \mathbf{m}$ .

**eps**

Input: the expected fraction of gross errors expected in the sample,  $\epsilon$ .

Constraint:  $0.0 \leq \mathbf{eps} < 1.0$ .

**cov[m\*(m+1)/2]**

Output: the  $\mathbf{m} \times (\mathbf{m} + 1)/2$  elements of **cov** contain the upper triangular part of the covariance matrix. They are stored packed by column, i.e.,  $C_{ij}$ ,  $j \geq i$ , is stored in  $\mathbf{cov}[j(j+1)/2 + i]$ , for  $i = 0, 1, \dots, \mathbf{m} - 1$  and  $j = i, i + 1, \dots, \mathbf{m} - 1$ .

**theta[m]**

Output: the robust estimate of the location parameters  $\theta_j$ , for  $j = 1, 2, \dots, m$ .

**max\_iter**

Input: the maximum number of iterations that will be used during the calculation of the covariance matrix.

Suggested value: **max\_iter** = 150.

Constraint: **max\_iter** > 0.

**print\_iter**

Input: indicates if the printing of information on the iterations is required and the rate at which printing is produced. The following values are available.

If **print\_iter** ≤ 0, then no iteration monitoring is printed.

If **print\_iter** > 0, then the value of  $A$ ,  $\theta$  and  $\delta$  (see Section 6.1) will be printed at the first and every **print\_iter** iterations.

**outfile**

Input: a null terminated character string giving the name of the file to which results should be printed. If **outfile** = **NULL** or an empty string then the **stdout** stream is used. Note that the file will be opened in the append mode.

**tol**

Input: the relative precision for the final estimates of the covariance matrix.

Constraint: **tol** > 0.0.

**iter**

Output: the number of iterations performed.

**fail**

The NAG error parameter, see the Essential Introduction to the NAG C Library.

For this function the values of output parameters may be useful even if **fail.code** ≠ **NE\_NOERROR** on exit. Users are therefore advised to supply the **fail** parameter and set **fail.print** = TRUE.

## 5. Error Indications and Warnings

### NE\_INT\_ARG\_LT

On entry,  $n$  must not be less than 2:  $n = \langle value \rangle$ .

On entry,  $m$  must not be less than 1:  $m = \langle value \rangle$ .

### NE\_2\_INT\_ARG\_GT

On entry,  $m = \langle value \rangle$  while  $n = \langle value \rangle$ . These parameters must satisfy  $m \leq n$ .

### NE\_2\_INT\_ARG\_LT

On entry,  $tdx = \langle value \rangle$  while  $m = \langle value \rangle$ . These parameters must satisfy  $tdx \geq m$ .

### NE\_INT\_ARG\_LE

On entry,  $\text{max\_iter}$  must not be less than or equal to 0:  $\text{max\_iter} = \langle value \rangle$ .

### NE\_REAL\_ARG\_LT

On entry,  $\text{eps} = \langle value \rangle$  must not be less than 0.0:  $\text{eps} = \langle value \rangle$ .

### NE\_REAL\_ARG\_GE

On entry,  $\text{eps} = \langle value \rangle$  must be not be greater than or equal to 1.0:  $\text{eps} = \langle value \rangle$ .

### NE\_REAL\_ARG\_LE

On entry,  $\text{tol} = \langle value \rangle$  must not be less than or equal to 0.0:  $\text{tol} = \langle value \rangle$ .

### NE\_CONST\_COL

On entry, column  $\langle value \rangle$  of array  $x$  has constant value.

### NE\_TOO\_MANY

Too many iterations( $\langle value \rangle$ ).

The iterative procedure to find the co-variance matrix  $C$ , has failed to converge in  $\text{max\_iter}$  iterations.

### NE\_C\_ITER\_UNSTABLE

The iterative procedure to find  $C$  has become unstable. This may happen if the value of  $\text{eps}$  is too large.

### NE\_NOT\_APPEND\_FILE

Cannot open file  $\langle string \rangle$  for appending.

### NE\_NOT\_CLOSE\_FILE

Cannot close file  $\langle string \rangle$ .

### NE\_ALLOC\_FAIL

Memory allocation failed.

## 6. Further Comments

The existence of  $A$ , and hence  $c$ , will depend upon the function  $u$ , (see Marazzi (1987)), also if  $X$  is not of full rank a value of  $A$  will not be found. If the columns of  $X$  are almost linearly related, then convergence will be slow.

### 6.1. Accuracy

On successful exit the accuracy of the results is related to the value of  $\text{tol}$ , see Section 4. At an iteration let

(i)  $d1 =$  the maximum value of the absolute relative change in  $A$

(ii)  $d2 =$  the maximum absolute change in  $u(\|z_i\|_2)$

(iii)  $d3 =$  the maximum absolute relative change in  $\theta_j$

and let  $\delta = \max(d1, d2, d3)$ . Then the iterative procedure is assumed to have converged when  $\delta < \text{tol}$ .

## 8. Example

A sample of 10 observations on three variables is read in and the robust estimate of the covariance matrix is computed assuming 10% gross errors are to be expected. The robust covariance is then printed.
