## **g05 – Random Number Generators**

### **Contents**

- 1 Scope of the Chapter**
- 2 Background**
- 3 References**
- 4 Available Functions**
  - 4.1 Continuous Distributions
  - 4.2 Discrete Distributions
  - 4.3 Other Random Structures
  - 4.4 Time Series Simulation
  - 4.5 Utility Functions

## 1 Scope of the Chapter

This chapter covers the generation of sequences of independent pseudo-random numbers from various distributions and processes.

## 2 Background

A sequence of *pseudo-random numbers* is a sequence of numbers generated in some systematic way such that its statistical properties are as close as possible to those of true random numbers: for example negligible correlation between consecutive numbers. The most common method used is a *multiplicative congruential* algorithm defined as:

$$n_i = (an_{i-1}) \bmod m. \quad (1)$$

The integers  $n_i$  are then divided by  $m$  to give uniformly distributed random numbers in the range (0,1).

The NAG generator uses the values  $a = 13^{13}$  and  $m = 2^{59}$ ; for further details see `nag_random_continuous_uniform` (g05cac). This generator gives a *cycle length* (i.e., the number of random numbers before the sequence starts repeating itself) of  $2^{57}$ . A good rule of thumb is never to use more numbers than the square root of the cycle length in any one experiment as the statistical properties are impaired. For closely related reasons breaking numbers down into their bit patterns and using individual bits may cause trouble.

The sequence given in (1) needs an initial value  $n_0$ , known as the *seed*. The use of the same seed will lead to the same sequence of numbers. One method of obtaining the seed is to use the real-time clock, this will give a non-repeatable sequence. It is important to note that the statistical properties of the random numbers are only guaranteed within sequences and not between sequences. Repeated initialization will thus render the numbers obtained less rather than more independent.

It may also be useful to store the state of the generator at a particular point and restart from that point later; facilities for this are provided.

Random numbers from other distributions may be obtained from the uniform random numbers by the use of transformations, rejection techniques and for discrete distributions table based methods.

Transformations can be based on the fact that if a continuous random variable  $x$  has cumulative distribution function (CDF)  $F(x)$  then a random observation can be generated by  $F^{-1}(u)$ , where  $u$  is a uniform (0,1) variate. For example, the CDF of the *logistic* distribution is:  $1 - [1 + \exp((x - a)/k)]^{-1}$ , so variates can be generated using  $a + k \log(u/(1 - u))$ . Another example is the *Weibull* distribution which can be generated by  $b(-\log u)^{1/a}$ . Alternatively the relationship between distributions can be used, for example an  $F$  variate can easily be obtained from a beta variate and a Student's  $t$  distribution with  $n$  degrees of freedom can be generated as  $v\sqrt{(n/w)}$  where  $v$  has a Normal distribution and  $w$  has a gamma distribution. In some cases the distribution is just a special case of another distribution, for example the  $\chi^2$  distribution is a special case of the gamma distribution.

Rejection techniques are based on the ability to easily generate random numbers from a distribution (called the envelope) similar to the distribution required. The value from the envelope distribution is then accepted as a random number from the required distribution with a certain probability; otherwise it is rejected and a new number generated from the envelope distribution.

For discrete distributions the cumulative probabilities,  $P_i = \text{Prob}(x \leq i)$  can be stored in a table then, given a uniform (0,1) random variate,  $u$ , the table is searched for  $i$  such that  $P_{i-1} < u \leq P_i$ . The returned value  $i$  will have the required distribution. The table searching can be made more efficient by using an index, see Ripley (1987). The table and its index are stored in a reference vector, the effort to construct the reference may be considerable but the methods are very efficient when many values can be generated from a single reference vector.

This chapter also contains functions for generating realisations of ARMA and GARCH time series models. These models are described in the g13 Chapter Introduction.

Whilst more efficient methods are provided for low-dimensional quadrature in Chapter d01, it should be observed that the uniform generator provides the basic tool for Monte Carlo integration.

### 4 Available Functions

#### 4.1 Continuous Distributions

g05dbc Pseudo-random real number, (negative) exponential distribution

g05ddc Pseudo-random real number, Normal distribution

g05cac Pseudo-random real number, uniform distribution over (0,1)

g05dac Pseudo-random real number, uniform distribution over  $(a, b)$

g05fec Pseudo-random real numbers from the beta distribution

g05ffc Pseudo-random real numbers from the gamma distribution

g05eac Set up reference vector for multivariate Normal distribution

g05ezc Pseudo-random multivariate Normal vector from reference vector

#### 4.2 Discrete Distributions

g05dyc Pseudo-random integer from uniform distribution

g05eyc Pseudo-random integer from reference vector

The following functions set up a reference vector for use by `nag_return_discrete` (g05eyc):

g05ecc Set up reference vector for generating pseudo-random integers, Poisson distribution

g05edc Set up reference vector for generating pseudo-random integers, binomial distribution

g05exc Set up reference vector from supplied cumulative distribution function or probability distribution function

#### 4.3 Other Random Structures

g05ehc Pseudo-random permutation of a vector of integers

g05ejc Pseudo-random sample without replacement from an integer vector

#### 4.4 Time Series Simulation

g05hac ARMA time series of  $n$  terms

g05hkc Univariate time series, generate  $n$  terms of either a symmetric GARCH process or a GARCH process with asymmetry of the form  $(\epsilon_{t-1} + \gamma)^2$

g05hlc Univariate time series, generate  $n$  terms of a GARCH process with asymmetry of the form  $(|\epsilon_{t-1}| + \gamma\epsilon_{t-1})^2$

g05hmc Univariate time series, generate  $n$  terms of an asymmetric Glosten, Jagannathan and Runkle (GJR) GARCH process

#### 4.5 Utility Functions

- g05cbc Initialise random number generating functions to give repeatable sequence
  - g05ccc Initialise random number generating functions to give non-repeatable sequence
  - g05cgc Restore state of random number generating functions
  - g05cfc Save state of random number generating functions
-
