nag_multid_quad_adapt (d01fcc)

1. Purpose

nag_multid_quad_adapt (d01fcc) attempts to evaluate a multi-dimensional integral (up to 15 dimensions), with constant and finite limits,

$$\int_{a_1}^{b_1}\int_{a_2}^{b_2}\ldots\int_{a_n}^{b_n} f(x_1,x_2,\ldots,x_n)dx_n\ldots dx_2dx_1$$

to a specified relative accuracy, using an adaptive subdivision strategy.

2. Specification

```
#include <nag.h>
#include <nagd01.h>

void nag_multid_quad_adapt(Integer ndim, double (*f)(Integer ndim, double x[]),
                double a[], double b[], Integer *minpts, Integer maxpts,
                double eps, double *finval, double *acc, NagError *fail)
```

3. Description

The routine evaluates an estimate of a multi-dimensional integral over a hyper-rectangle (i.e., with constant limits), and also an estimate of the relative error. The user sets the relative accuracy required, supplies the integrand as a function **f**, and also sets the minimum and maximum acceptable number of calls to **f** (in **minpts** and **maxpts**).

The routine operates by repeated subdivision of the hyper-rectangular region into smaller hyper-rectangles. In each subregion, the integral is estimated using a seventh-degree rule, and an error estimate is obtained by comparison with a fifth-degree rule which uses a subset of the same points. The fourth differences of the integrand along each co-ordinate axis are evaluated, and the subregion is marked for possible future subdivision in half along that co-ordinate axis which has the largest absolute fourth difference.

If the estimated errors, totalled over the subregions, exceed the requested relative error (or if fewer than **minpts** calls to **f** have been made), further subdivision is necessary, and is performed on the subregion with the largest estimated error, that subregion being halved along the appropriate co-ordinate axis.

The routine will fail if the requested relative error level has not been attained by the time **maxpts** calls to **f** have been made.

nag_multid_quad_adapt is based on the HALF subroutine developed by van Dooren and de Ridder (1976). It uses a different basic rule, described by Genz and Malik (1980).

4. Parameters

ndim

Input: the number of dimensions of the integral, n.
Constraint: $2 \leq$ **ndim** ≤ 15.

f

The function **f**, supplied by the user, must return the value of the integrand f at a given point.
The specification of **f** is:

```
double f(Integer ndim, double x[])
```

ndim
Input: the number of dimensions of the integral.

x[**ndim**]
Input: the co-ordinates of the point at which the integrand must be evaluated.

a[ndim]
Input: the lower limits of integration, a_i, for $i = 1, 2, \ldots, n$.

b[ndim]
Input: the upper limits of integration, b_i, for $i = 1, 2, \ldots, n$.

minpts
Input: **minpts** must be set to the minimum number of integrand evaluations to be allowed.
Output: **minpts** contains the actual number of integrand evaluations used by the function nag_multid_quad_adapt.

maxpts
Input: the maximum number of integrand evaluations to be allowed.
Constraints: **maxpts** $\geq$ **minpts**.
maxpts $\geq 2^{\mathbf{ndim}} + 2 \times \mathbf{ndim}^2 + 2 \times \mathbf{ndim} + 1$.

eps
Input: the relative error acceptable to the user. When the solution is zero or very small relative accuracy may not be achievable but the user may still set **eps** to a reasonable value and check **fail.code** for **NE_QUAD_MAX_INTEGRAND_EVAL**.
Constraint: **eps** > 0.0.

finval
Output: the best estimate obtained for the integral.

acc
Output: the estimated relative error in **finval**.

fail
The NAG error parameter, see the Essential Introduction to the NAG C Library.
Users are recommended to declare and initialize **fail** and set **fail.print** = TRUE for this function.

5. Error Indications and Warnings

NE_INVALID_INT_RANGE_2
Value ⟨*value*⟩ given to **ndim** not valid. Correct range is $2 \leq$ **ndim** ≤ 15.

NE_2_INT_ARG_LT
On entry, **maxpts** = ⟨*value*⟩ while **minpts** = ⟨*value*⟩.
These parameters must satisfy **maxpts** $\geq$ **minpts**.

NE_QUAD_MAX_INTEGRAND_CONS
maxpts < ⟨*value*⟩. Constraint: **maxpts** $\geq 2^{\mathbf{ndim}} + 2 \times \mathbf{ndim}^2 + 2 \times \mathbf{ndim} + 1$.

NE_REAL_ARG_LE
On entry, **eps** must not be less than or equal to 0.0: **eps** = ⟨*value*⟩.

NE_ALLOC_FAIL
Memory allocation failed.

NE_QUAD_MAX_INTEGRAND_EVAL
maxpts was too small to obtain the required accuracy.
On return, **finval** and **acc** contain estimates of the integral and the relative error, but **acc** will be greater than **eps**.

6. Further Comments

Execution time will usually be dominated by the time taken to evaluate the integrand **f**, and hence the maximum time that could be taken will be proportional to **maxpts**.

6.1. Accuracy

A relative error estimate is output through the parameter **acc**.

8. Example

This example program estimates the integral

$$\int_0^1 \int_0^1 \int_0^1 \int_0^1 \frac{4z_1 z_3^2 \exp(2z_1 z_3)}{(1+z_2+z_4)^2} dz_4 dz_3 dz_2 dz_1 = 0.575364.$$

The accuracy requested is one part in 10,000.
