nag_real_cholesky_skyline_solve (f04mcc)

1. Purpose

nag_real_cholesky_skyline_solve (f04mcc) computes the approximate solution of a system of real linear equations with multiple right-hand sides, $AX = B$, where A is a symmetric positive-definite variable-bandwidth matrix, which has previously been factorized by nag_real_cholesky_skyline (f01mcc). Related systems may also be solved.

2. Specification

```
#include <nag.h>
#include <nagf04.h>

void nag_real_cholesky_skyline_solve(Nag_SolveSystem selct, Integer n,
     Integer nrhs, double al[], Integer lal, double d[], Integer row[],
     double b[], Integer tdb, double x[], Integer tdx, NagError *fail)
```

3. Description

The normal use of this function is the solution of the systems $AX = B$, following a call of nag_real_cholesky_skyline (f01mcc) to determine the Cholesky factorization $A = LDL^T$ of the symmetric positive-definite variable-bandwidth matrix A.

However, the function may be used to solve any one of the following systems of linear algebraic equations:

$$LDL^TX = B \text{ (usual system)} \quad (1)$$
$$LDX = B \text{ (lower triangular system)} \quad (2)$$
$$DL^TX = B \text{ (upper triangular system)} \quad (3)$$
$$LL^TX = B \quad (4)$$
$$LX = B \text{ (unit lower triangular system)} \quad (5)$$
$$L^TX = B \text{ (unit upper triangular system).} \quad (6)$$

L denotes a unit lower triangular variable-bandwidth matrix of order n, D a diagonal matrix of order n, and B a set of right-hand sides.

The matrix L is represented by the elements lying within its **envelope**, i.e., between the first non-zero of each row and the diagonal (see Section 8 for an example). The width **row**$[i]$ of the ith row is the number of elements between the first non-zero element and the element on the diagonal inclusive.

4. Parameters

selct

Input: **selct** must specify the type of system to be solved, as follows:
selct = **Nag_LDLTX**: solve $LDL^TX = B$
selct = **Nag_LDX**: solve $LDX = B$
selct = **Nag_DLTX**: solve $DL^TX = B$
selct = **Nag_LLTX**: solve $LL^TX = B$
selct = **Nag_LX**: solve $LX = B$
selct = **Nag_LTX**: solve $L^TX = B$.
Constraint: **selct** must be one of **Nag_LDLTX**, **Nag_LDX**, **Nag_DLTX**, **Nag_LLTX**, **Nag_LX**, **Nag_LTX**.

n

Input: n, the order of the matrix L.
Constraint: $\mathbf{n} \geq \mathbf{1}$.

nrhs

Input: r, the number of right-hand sides.
Constraint: $\mathbf{nrhs} \geq \mathbf{1}$.

al[lal]

Input: the elements within the envelope of the lower triangular matrix L, taken in row by row order, as returned by nag_real_cholesky_skyline (f01mcc). The unit diagonal elements of L must be stored explicitly.

lal

Input: the dimension of the array **al** as declared in the function from which nag_real_cholesky_skyline_solve is called.
Constraint: $\mathbf{lal} \geq \mathbf{row}[0] + \mathbf{row}[1] + \ldots + \mathbf{row}[n-1]$.

d[n]

Input: the diagonal elements of the diagonal matrix D. **d** is not referenced if **selct** = **Nag_LLTX**, **Nag_LX** or **Nag_LTX**

row[n]

Input: $\mathbf{row}[i]$ must contain the width of row i of L, i.e., the number of elements between the first (left-most) non-zero element and the element on the diagonal, inclusive.
Constraint: $1 \leq \mathbf{row}[i] \leq i+1$ for $i = 0, 1, \ldots, n-1$.

b[n][tdb]

Input: the n by r right-hand side matrix B. See also Section 6.

tdb

Input: the second dimension of the array **b** as declared in the function from which nag_real_cholesky_skyline_solve is called.
Constraint: $\mathbf{tdb} \geq \mathbf{nrhs}$.

x[n][tdx]

Output: the n by r solution matrix X. See also Section 6.

tdx

Input: the second dimension of the array **x** as declared in the function from which nag_real_cholesky_skyline_solve is called.
Constraint: $\mathbf{tdx} \geq \mathbf{nrhs}$.

fail

The NAG error parameter, see the Essential Introduction to the NAG C Library.

5. Error Indications and Warnings

NE_INT_ARG_LT

On entry, **n** must not be less than 1: $\mathbf{n} = \langle value \rangle$.
On entry, $\mathbf{row}[\langle value \rangle]$ must not be less than 1: $\mathbf{row}[\langle value \rangle] = \langle value \rangle$.
On entry, **nrhs** must not be less than 1: $\mathbf{nrhs} = \langle value \rangle$.

NE_2_INT_ARG_GT

On entry, $\mathbf{row}[i] = \langle value \rangle$ while $i = \langle value \rangle$. These parameters must satisfy $\mathbf{row}[i] \leq i+1$.

NE_2_INT_ARG_LT

On entry, $\mathbf{lal} = \langle value \rangle$ while $\mathbf{row}[0] + \ldots + \mathbf{row}[n-1] = \langle value \rangle$. These parameters must satisfy $\mathbf{lal} \geq \mathbf{row}[0] + \ldots + \mathbf{row}[n-1]$.
On entry, $\mathbf{tdb} = \langle value \rangle$ while $\mathbf{nrhs} = \langle value \rangle$. These parameters must satisfy $\mathbf{tdb} \geq \mathbf{nrhs}$.
On entry, $\mathbf{tdx} = \langle value \rangle$ while $\mathbf{nrhs} = \langle value \rangle$. These parameters must satisfy $\mathbf{tdx} \geq \mathbf{nrhs}$.

NE_BAD_PARAM

On entry, parameter **selct** had an illegal value.

NE_ZERO_DIAG

The diagonal matrix D is singular as it has at least one zero element. The first zero element has been located in the array $\mathbf{d}[\langle value \rangle]$

NE_NOT_UNIT_DIAG

The lower triangular matrix L has at least one diagonal element which is not equal to unity. The first non-unit element has been located in the array $\mathbf{al}[\langle value \rangle]$

6. Further Comments

The time taken by the function is approximately proportional to pr, where $p = \textbf{row}[0] + \textbf{row}[1] + \ldots + \textbf{row}[n-1]$.

The function may be called with the same actual array supplied for the parameters **b** and **x**, in which case the solution matrix will overwrite the right-hand side matrix.

6.1. Accuracy

The usual backward error analysis of the solution of triangular system applies: each computed solution vector is exact for slightly perturbed matrices L and D, as appropriate (see Wilkinson and Reinsch (1971) pp 25-27 and 54-55).

8. Example

To solve the system of equations $AX = B$, where

$$A = \begin{pmatrix} 1 & 2 & 0 & 0 & 5 & 0 \\ 2 & 5 & 3 & 0 & 14 & 0 \\ 0 & 3 & 13 & 0 & 18 & 0 \\ 0 & 0 & 0 & 16 & 8 & 24 \\ 5 & 14 & 18 & 8 & 55 & 17 \\ 0 & 0 & 0 & 24 & 17 & 77 \end{pmatrix}$$

and

$$B = \begin{pmatrix} 6 & -10 \\ 15 & -21 \\ 11 & -3 \\ 0 & 24 \\ 51 & -39 \\ 46 & 67 \end{pmatrix}.$$

Here A is symmetric and positive-definite and must first be factorized by nag_real_cholesky_skyline (f01mcc).
