# nag\_ode\_ivp\_rk\_range (d02pcc)

### 1. Purpose

nag\_ode\_ivp\_rk\_range (d02pcc) is a function for solving the initial value problem for a first order system of ordinary differential equations using Runge-Kutta methods.

## 2. Specification

### 3. Description

This function and its associated functions (nag\_ode\_ivp\_rk\_setup (d02pvc), nag\_ode\_ivp\_rk\_errass (d02pzc)) solve the initial value problem for a first order system of ordinary differential equations. The functions, based on Runge-Kutta methods and derived from RKSUITE (Brankin *et al*, 1991) integrate

```
y' = f(t, y) given y(t_0) = y_0
```

where y is the vector of **neq** solution components and t is the independent variable.

This function is designed for the usual task, namely to compute an approximate solution at a sequence of points. You must first call nag\_ode\_ivp\_rk\_setup (d02pvc) to specify the problem and how it is to be solved. Thereafter you call nag\_ode\_ivp\_rk\_range repeatedly with successive values of twant, the points at which you require the solution, in the range from tstart to tend (as specified in nag\_ode\_ivp\_rk\_setup (d02pvc)). In this manner nag\_ode\_ivp\_rk\_range returns the point at which it has computed a solution tgot (usually twant), the solution there ygot and its derivative ypgot. If nag\_ode\_ivp\_rk\_range encounters some difficulty in taking a step toward twant, then it returns the point of difficulty tgot and the solution and derivative computed there ygot and ypgot.

In the call to nag\_ode\_ivp\_rk\_setup (d02pvc) you can specify the first step size for nag\_ode\_ivp\_rk\_range to attempt or that it compute automatically an appropriate value. Thereafter nag\_ode\_ivp\_rk\_range estimates an appropriate step size for its next step. This value and other details of the integration can be obtained after any call to nag\_ode\_ivp\_rk\_range by examining the contents of the structure opt, see Section 4. The local error is controlled at every step as specified in nag\_ode\_ivp\_rk\_setup (d02pvc). If you wish to assess the true error, you must set errass = Nag\_ErrorAssess\_on in the call to nag\_ode\_ivp\_rk\_setup (d02pvc). This assessment can be obtained after any call to nag\_ode\_ivp\_rk\_range by a call to the function nag\_ode\_ivp\_rk\_errass (d02pzc).

For more complicated tasks, you are referrred to functions nag\_ode\_ivp\_rk\_onestep (d02pdc), nag\_ode\_ivp\_rk\_interp (d02pxc) and nag\_ode\_ivp\_rk\_reset\_tend (d02pwc).

# 4. Parameters

```
neq
```

Input: the number of ordinary differential equations in the system to be solved. Constraint:  $\mathbf{neq} \geq 1$ .

f

This function must evaluate the first derivatives  $y'_i$  (that is the functions  $f_i$ ) for given values of the arguments  $t, y_i$ .

```
neq Input: the number of differential equations. 

t Input: the current value of the independent variable, t.

y[neq] Input: the current values of the dependent variables, y_i for i=1,2,\ldots,neq.

yp[neq] Output: the values of f_i for i=1,2,\ldots,neq.

comm Input/Output: pointer to a structure of type Nag_User with the following member:

p - Pointer Input/Output: The pointer comm->p should be cast to the required type, e.g. struct user *s = (struct user *) comm->p, to obtain the original object's address with appropriate type. (See the argument comm below.)
```

#### twant

Input: the next value of the independent variable, t, where a solution is desired.

Constraints: **twant** must be closer to **tend** than the previous of **tgot** (or **tstart** on the first call to nag\_ode\_ivp\_rk\_range); see nag\_ode\_ivp\_rk\_setup (d02pvc) for a description of **tstart** and **tend**. **twant** must not lie beyond **tend** in the direction of integration.

#### tgot

Output: the value of the independent variable t at which a solution has been computed. On successful exit with fail.code = **NE\_NOERROR**, **tgot** will equal **twant**. For non-trivial values of fail.code (i.e., those not related to an invalid call of nag\_ode\_ivp\_rk\_range) a solution has still been computed at the value of **tgot** but in general **tgot** will not equal **twant**.

#### ygot[neq]

Input: on the first call to nag\_ode\_ivp\_rk\_range, **ygot** need not be set. On all subsequent calls **ygot** must remain unchanged.

Output: an approximation to the true solution at the value of **tgot**. At each step of the integration to **tgot**, the local error has been controlled as specified in nag\_ode\_ivp\_rk\_setup (d02pvc). The local error has still been controlled even when **tgot**  $\neq$  **twant**, that is after a return with a non-trivial error.

### ypgot[neq]

Output: an approximation to the first derivative of the true solution at tgot.

### ymax[neq]

Input: on the first call to nag\_ode\_ivp\_rk\_range, **ymax** need not be set. On all subsequent calls **ymax** must remain unchanged.

Output:  $\mathbf{ymax}[i-1]$  contains the largest value of  $\mid y_i \mid$  computed at any step in the integration so far.

# $\mathbf{opt}$

Input: pointer to a structure of type Nag\_ODE\_RK as initialised by the setup function nag\_ode\_ivp\_rk\_setup (d02pvc).

Output: the following structure members hold information as follows:

### totfcn - Integer

The total number of evaluations of f used in the primary integration so far; this does not include evaluations of f for the secondary integration specified by a prior call to nag\_ode\_ivp\_rk\_setup (d02pvc) with errass = Nag\_ErrorAssess\_on.

#### stpcst - Integer

The cost in terms of number of evaluations of f of a typical step with the method being

3.d02pcc. 2 [NP3275/5/pdf]

used for the integration. The method is specified by the parameter **method** in a prior call to nag\_ode\_ivp\_rk\_setup (d02pvc).

#### waste - double

The number of attempted steps that failed to meet the local error requirement divided by the total number of steps attempted so far in the integration. A "large" fraction indicates that the integrator is having trouble with the problem being solved. This can happen when the problem is "stiff" and also when the solution has discontinuities in a low order derivative.

### stpsok - Integer

The number of accepted steps.

#### hnext - double

The step size the integrator plans to use for the next step.

#### comm

Input/Output: pointer to a structure of type Nag\_User with the following member:

### **p** - Pointer

Input/Output: The pointer p, of type Pointer, allows the user to communicate information to and from the user-defined function f(). An object of the required type should be declared by the user, e.g. a structure, and its address assigned to the pointer p by means of a cast to Pointer in the calling program, e.g. comm.p = (Pointer)&s. The type pointer will be void \* with a C compiler that defines <math>void \* and char \* otherwise.

#### fail

The NAG error parameter, see the Essential Introduction to the NAG C Library.

### 5. Error Indications and Warnings

### NE\_PREV\_CALL

The previous call to a function had resulted in a severe error. You must call nag\_ode\_ivp\_rk\_setup (d02pvc) to start another problem.

### NE\_NO\_SETUP

The setup function nag\_ode\_ivp\_rk\_setup (d02pvc) has not been called.

### NE\_RK\_INVALID\_CALL

The function to be called as specified in the setup routine nag\_ode\_ivp\_rk\_setup (d02pvc) was nag\_ode\_ivp\_rk\_onestep (d02pdc). However the actual call was made to nag\_ode\_ivp\_rk\_range. This is not permitted.

# NE\_PREV\_CALL\_INI

The previous call to the function nag\_ode\_ivp\_rk\_range had resulted in a severe error. You must call nag\_ode\_ivp\_rk\_setup (d02pvc) to start another problem.

### NE\_NEQ

The value of **neq** supplied is not the same as that given to the setup function nag\_ode\_ivp\_rk\_setup (d02pvc).

 $\mathbf{neq} = \langle value \rangle$  but the value given to nag\_ode\_ivp\_rk\_setup (d02pvc) was  $\langle value \rangle$ .

### NE\_RK\_TGOT\_EQ\_TEND

The call to nag\_ode\_ivp\_rk\_range has been made after reaching tend. The previous call to nag\_ode\_ivp\_rk\_range resulted in tgot (tstart on the first call) = tend. You must call nag\_ode\_ivp\_rk\_setup (d02pvc) to start another problem.

### NE\_RK\_TGOT\_RANGE\_TEND

The call to nag\_ode\_ivp\_rk\_range has been made with a **twant** that does not lie between the previous value of **tgot** (**tstart** on the first call) and **tend**. This is not permitted.

### NE\_RK\_TGOT\_RANGE\_TEND\_CLOSE

The call to nag\_ode\_ivp\_rk\_range has been made with a **twant** that does not lie between the previous value of **tgot** (**tstart** on the first call) and **tend**. This is not permitted. However twant is very close to **tend**, so you may have meant it to be **tend** exactly. Check your program.

#### NE\_RK\_TWANT\_CLOSE\_TGOT

The call to nag\_ode\_ivp\_rk\_range has been made with a **twant** that is not sufficiently different from the last value of **tgot** (**tstart** on the first call). When using **method** = **Nag\_RK\_7\_8**, it must differ by at least  $\langle value \rangle$ .

### NE\_RK\_PDC\_STEP

In order to satisfy the error requirements nag\_ode\_ivp\_rk\_range would have to use a step size of  $\langle value \rangle$  at current  $\mathbf{t} = \langle value \rangle$ . This is too small for the machine precision.

### NE\_RK\_PDC\_GLOBAL\_ERROR\_T

The global error assessment may not be reliable for t past tgot.  $tgot = \langle value \rangle$ .

### NE\_RK\_PDC\_GLOBAL\_ERROR\_S

The global error assessment algorithm failed at the start of the integration.

### NE\_STIFF\_PROBLEM

The problem appears to be stiff.

### NW\_RK\_TOO\_MANY

Approximately  $\langle value \rangle$  function evaluations have been used to compute the solution since the integration started or since this message was last printed.

#### NE\_RK\_PCC\_METHOD

The efficiency of the integration has been degraded. Consider calling the set up function nag\_ode\_ivp\_rk\_setup (d02pvc) to re-initialize the integration at the current point with the method changed to **NE\_RK\_4\_5**. Alternatively nag\_ode\_ivp\_rk\_range (d02pcc) can be called again to resume at the current point.

#### NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

### NE\_MEMORY\_FREED

Internally allocated memory has been freed by a call to nag\_ode\_ivp\_rk\_free (d02ppc) without a subsequent call to the set up function nag\_ode\_ivp\_rk\_setup (d02pvc).

### 6. Further Comments

If nag\_ode\_ivp\_rk\_range returns with fail.code = NE\_RK\_PDC\_STEP and the accuracy specified by tol and thres is really required then you should consider whether there is a more fundamental difficulty. For example, the solution may contain a singularity. In such a region the solution components will usually be of a large magnitude. Successive output values of ygot and ymax should be monitored (or the routine nag\_ode\_ivp\_rk\_onestep (d02pdc) should be used since this takes one integration step at a time) with the aim of trapping the solution before the singularity. In any case numerical solution cannot be continued through a singularity, and analytical treatment may be necessary.

Performance statistics are available after any return from nag\_ode\_ivp\_rk\_range by examining the structure **opt** see Section 4. If **errass** was set to **Nag\_ErrorAssess\_on** in the call to nag\_ode\_ivp\_rk\_setup (d02pvc), global error assessment is available after any return from nag\_ode\_ivp\_rk\_range (except when the error is due to incorrect input arguments or incorrect setup) by a call to the routine nag\_ode\_ivp\_rk\_errass (d02pzc). The approximate extra number of evaluations of f used is given by  $2 \times \text{stpsok} \times \text{stpcst}$  for method **NAG\_RK\_4\_5** or **NAG\_RK\_7\_8** and  $3 \times \text{stpsok} \times \text{stpcst}$  for method = **NAG\_RK\_2\_3**.

After a failure with fail.code = NE\_RK\_PDC\_STEP, NE\_RK\_PDC\_GLOBAL\_ERROR\_T or NE\_RK\_PDC\_GLOBAL\_ERROR\_S the diagnostic routine nag\_ode\_ivp\_rk\_errass (d02pzc) may be called only once.

If nag\_ode\_ivp\_rk\_range returns with fail.code = NE\_STIFF\_PROBLEM then it is advisable to change to another code more suited to the solution of stiff problems. nag\_ode\_ivp\_rk\_range will not return with fail.code = NE\_STIFF\_PROBLEM if the problem is actually stiff but it is estimated that integration can be completed using less function evaluations than already computed.

3.d02pcc.4 [NP3275/5/pdf]

### 6.1. Accuracy

The accuracy of integration is determined by the parameters **tol** and **thres** in a prior call to nag\_ode\_ivp\_rk\_setup (d02pvc). Note that only the local error at each step is controlled by these parameters. The error estimates obtained are not strict bounds but are usually reliable over one step. Over a number of steps the overall error may accumulate in various ways, depending on the properties of the differential system.

### 8. Example

We solve the equation

$$y'' = -y,$$
  $y(0) = 0, y'(0) = 1$ 

reposed as

$$y_1' = y_2 \qquad y_2' = -y_1$$

over the range  $[0,2\pi]$  with initial conditions  $y_1=0.0$  and  $y_2=1.0$ . We use relative error control with threshold values of 1.0e-8 for each solution component and compute the solution at intervals of length  $\pi/4$  across the range. We use a low order Runge-Kutta method (**method = Nag\_RK\_2\_3**) with tolerances  $\mathbf{tol} = 1.0e-3$  and  $\mathbf{tol} = 1.0e-4$  in turn so that we may compare the solutions. The value of  $\pi$  is obtained by using X01AAC.

See also the example program for nag\_ode\_ivp\_rk\_errass (d02pzc).
