## nag\_2d\_triang\_interp (e01sjc)

### 1 Purpose

nag\_2d\_triang\_interp (e01sjc) generates a two-dimensional surface interpolating a set of scattered data points, using the method of Renka and Cline.

### 2 Specification

```
#include <nag.h>
#include <nage01.h>

void nag_2d_triang_interp (Integer m, const double x[], const double y[],
    const double f[], Integer triang[], double grads[], NagError *fail)
```

### 3 Description

nag\_2d\_triang\_interp (e01sjc) constructs an interpolating surface  $F(x,y)$  through a set of  $m$  scattered data points  $(x_r, y_r, f_r)$ , for  $r = 1, 2, \dots, m$ , using a method due to Renka and Cline. In the  $(x, y)$  plane, the data points must be distinct. The constructed surface is continuous and has continuous first derivatives.

The method involves firstly creating a triangulation with all the  $(x, y)$  data points as nodes, the triangulation being as nearly equiangular as possible (see Cline and Renka (1984)). Then gradients in the  $x$ - and  $y$ -directions are estimated at node  $r$ , for  $r = 1, 2, \dots, m$ , as the partial derivatives of a quadratic function of  $x$  and  $y$  which interpolates the data value  $f_r$ , and which fits the data values at nearby nodes (those within a certain distance chosen by the algorithm) in a weighted least-squares sense. The weights are chosen such that closer nodes have more influence than more distant nodes on derivative estimates at node  $r$ . The computed partial derivatives, with the  $f_r$  values, at the three nodes of each triangle define a piecewise polynomial surface of a certain form which is the interpolant on that triangle. See Renka and Cline (1984) for more detailed information on the algorithm, a development of that by Lawson (1977). The code is derived from Renka (1984).

The interpolant  $F(x, y)$  can subsequently be evaluated at any point  $(x, y)$  inside or outside the domain of the data by a call to nag\_2d\_triang\_eval (e01skc). Points outside the domain are evaluated by extrapolation.

### 5 Arguments

- 1: **m** – Integer *Input*  
*On entry:*  $m$ , the number of data points.  
*Constraint:*  $m \geq 3$ .

- 2: **x**[**m**] – const double *Input*  
 3: **y**[**m**] – const double *Input*  
 4: **f**[**m**] – const double *Input*

*On entry:* the co-ordinates of the  $r$ th data point, for  $r = 1, 2, \dots, m$ . The data points are accepted in any order, but see Section 8.

*Constraint:* the  $(x,y)$  nodes must not all be collinear, and each node must be unique.

- 5: **triang**[ $7 \times \mathbf{m}$ ] – Integer *Output*

*On exit:* a data structure defining the computed triangulation, in a form suitable for passing to `nag_2d_triang_eval` (e01skc).

- 6: **grads**[ $2 \times \mathbf{m}$ ] – double *Output*

*On exit:* the estimated partial derivatives at the nodes, in a form suitable for passing to `nag_2d_triang_eval` (e01skc). The derivatives at node  $r$  with respect to  $x$  and  $y$  are contained in **grads**[ $2 \times (r - 1)$ ] and **grads**[ $1 + 2 \times (r - 1)$ ] respectively, for  $r = 1, 2, \dots, m$ .

- 7: **fail** – NagError \* *Input/Output*

The NAG error argument (see Section 2.6 of the Essential Introduction).

## 6 Error Indicators and Warnings

### NE\_ALL\_DATA\_COLLINEAR

All nodes are collinear. There is no unique solution.

### NE\_BAD\_PARAM

On entry, argument  $\langle value \rangle$  had an illegal value.

### NE\_DATA\_NOT\_UNIQUE

On entry,  $(\mathbf{x}[i - 1], \mathbf{y}[i - 1]) = (\mathbf{x}[j - 1], \mathbf{y}[j - 1])$ , for  $i, j = \langle value \rangle \langle value \rangle$ ,  $\mathbf{x}[i - 1], \mathbf{y}[i - 1] = \langle value \rangle \langle value \rangle$ .

### NE\_INT

On entry,  $\mathbf{m} = \langle value \rangle$ .  
 Constraint:  $\mathbf{m} \geq 3$ .

### NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please consult NAG for assistance.

## 7 Accuracy

On successful exit, the computational errors should be negligible in most situations but you should always check the computed surface for acceptability, by drawing contours for instance. The surface always interpolates the input data exactly.

## 8 Further Comments

The time taken for a call of `nag_2d_triang_interp` (e01sjc) is approximately proportional to the number of data points,  $m$ . The function is more efficient if, before entry, the values in **x**, **y** and **f** are arranged so that the **x** array is in ascending order.

## 9 Example

This example reads in a set of 30 data points and calls `nag_2d_triang_interp` (e01sjc) to construct an interpolating surface. It then calls `nag_2d_triang_eval` (e01skc) to evaluate the interpolant at a sample of points on a rectangular grid.

Note that this example is not typical of a realistic problem: the number of data points would normally be larger, and the interpolant would need to be evaluated on a finer grid to obtain an accurate plot, say.
