

NAG Fortran Library Routine Document

E04FCF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

E04FCF is a comprehensive algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables ($m \geq n$). No derivatives are required.

The routine is intended for functions which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2 Specification

```

SUBROUTINE E04FCF(M, N, LSQFUN, LSQMON, IPRINT, MAXCAL, ETA, XTOL,
1          STEPMX, X, FSUMSQ, FVEC, FJAC, LJ, S, V, LV, NITER,
2          NF, IW, LIW, W, LW, IFAIL)
    INTEGER      M, N, IPRINT, MAXCAL, LJ, LV, NITER, NF, IW(LIW), LIW,
1          LW, IFAIL
    real        ETA, XTOL, STEPMX, X(N), FSUMSQ, FVEC(M), FJAC(LJ,N),
1          S(N), V(LV,N), W(LW)
    EXTERNAL    LSQFUN, LSQMON

```

3 Description

This routine is essentially identical to the subroutine LSQNDN in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

$$\text{Minimize } F(x) = \sum_{i=1}^m [f_i(x)]^2$$

where $x = (x_1, x_2, \dots, x_n)^T$ and $m \geq n$. (The functions $f_i(x)$ are often referred to as 'residuals'.)

The user must supply a subroutine LSQFUN to calculate the values of the $f_i(x)$ at any point x .

From a starting point $x^{(1)}$ supplied by the user, the routine generates a sequence of points $x^{(2)}, x^{(3)}, \dots$, which is intended to converge to a local minimum of $F(x)$. The sequence of points is given by

$$x^{(k+1)} = x^{(k)} + \alpha^{(k)} p^{(k)}$$

where the vector $p^{(k)}$ is a direction of search, and $\alpha^{(k)}$ is chosen such that $F(x^{(k)} + \alpha^{(k)} p^{(k)})$ is approximately a minimum with respect to $\alpha^{(k)}$.

The vector $p^{(k)}$ used depends upon the reduction in the sum of squares obtained during the last iteration. If the sum of squares was sufficiently reduced, then $p^{(k)}$ is an approximation to the Gauss–Newton direction; otherwise additional function evaluations are made so as to enable $p^{(k)}$ to be a more accurate approximation to the Newton direction.

The method is designed to ensure that steady progress is made whatever the starting point, and to have the rapid ultimate convergence of Newton's method.

Gill P E and Murray W (1978) Algorithms for the solution of the nonlinear least-squares problem *SIAM J. Numer. Anal.* **15** 977–992

5 Parameters

- 1: M – INTEGER *Input*
 2: N – INTEGER *Input*

On entry: the number m of residuals, $f_i(x)$, and the number n of variables, x_j .

Constraint: $1 \leq N \leq M$.

- 3: LSQFUN – SUBROUTINE, supplied by the user. *External Procedure*

LSQFUN must calculate the vector of values $f_i(x)$ at any point x . (However, if the user does not wish to calculate the residuals at a particular x , there is the option of setting a parameter to cause E04FCF to terminate immediately.)

Its specification is:

<pre style="margin: 0;">SUBROUTINE LSQFUN(IFLAG, M, N, XC, FVECC, IW, LIW, W, LW) INTEGER IFLAG, M, N, IW(LIW), LIW, LW real XC(N), FVECC(M), W(LW)</pre>	
<p>1: IFLAG – INTEGER <i>Input/Output</i></p> <p><i>On entry:</i> IFLAG has a non-negative value.</p> <p><i>On exit:</i> if LSQFUN resets IFLAG to some negative number, E04FCF will terminate immediately, with IFAIL set to the user's setting of IFLAG.</p>	
<p>2: M – INTEGER <i>Input</i></p> <p>3: N – INTEGER <i>Input</i></p> <p><i>On entry:</i> the numbers m and n of residuals and variables, respectively.</p>	
<p>4: XC(N) – real array <i>Input</i></p> <p><i>On entry:</i> the point x at which the values of the f_i are required.</p>	
<p>5: FVECC(M) – real array <i>Output</i></p> <p><i>On exit:</i> unless IFLAG is reset to a negative number, on exit FVECC(i) must contain the value of f_i at the point x, for $i = 1, 2, \dots, m$.</p>	
<p>6: IW(LIW) – INTEGER array <i>Workspace</i></p> <p>7: LIW – INTEGER <i>Input</i></p> <p>8: W(LW) – real array <i>Workspace</i></p> <p>9: LW – INTEGER <i>Input</i></p>	
<p>LSQFUN is called with these parameters as in the call to E04FCF, so users can pass quantities to LSQFUN from the (sub)program which calls E04FCF by using partitions of IW and W beyond those used as workspace by E04FCF. However, because of the danger of mistakes in partitioning, it is recommended that this facility be used very selectively, e.g., for stable applications packages which need to pass their own variable dimension workspace to LSQFUN. It is recommended that the normal method for passing information from the user's (sub)program to LSQFUN should be via COMMON. In any case, users must not change LIW, LW or the elements of IW and W used as workspace by E04FCF.</p>	

LSQFUN must be declared as EXTERNAL in the (sub)program from which E04FCF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

Note: LSQFUN should be tested separately before being used in conjunction with E04FCF.

4: LSQMON – SUBROUTINE, supplied by the user.

External Procedure

If IPRINT ≥ 0 , the user must supply a subroutine LSQMON which is suitable for monitoring the minimization process. LSQMON must not change the values of any of its parameters.

If IPRINT < 0 , the dummy routine E04FDZ can be used as LSQMON. (In some implementations the name of this routine is FDZE04; refer to the Users' Note for your implementation.)

Its specification is:

```

SUBROUTINE LSQMON(M, N, XC, FVECC, FJACC, LJC, S, IGRADE, NITER, NF,
1                IW, LIW, W, LW)
  INTEGER          M, N, LJC, IGRADE, NITER, NF, IW(LIW), LIW, LW
  real           XC(N), FVECC(M), FJACC(LJC,N), S(N), W(LW)

```

Important: the dimension declaration for FJACC must contain the variable LJC, not an integer constant.

1: M – INTEGER *Input*
 2: N – INTEGER *Input*

On entry: the numbers m and n of residuals and variables, respectively.

3: XC(N) – **real** array *Input*

On entry: the co-ordinates of the current point x .

4: FVECC(M) – **real** array *Input*

On entry: the values of the residuals f_i at the current point x .

5: FJACC(LJC,N) – **real** array *Input*

On entry: FJACC(i, j) contains the value of $\frac{\partial f_i}{\partial x_j}$, at the current point x , for $i = 1, 2, \dots, m$; $j = 1, 2, \dots, n$.

6: LJC – INTEGER *Input*

On entry: the first dimension of the array FJACC.

7: S(N) – **real** array *Input*

On entry: the singular values of the current approximation to the Jacobian matrix. Thus S may be useful as information about the structure of the user's problem.

8: IGRADE – INTEGER *Input*

On entry: E04FCF estimates the dimension of the subspace for which the Jacobian matrix can be used as a valid approximation to the curvature (see Gill and Murray (1978)). This estimate is called the grade of the Jacobian matrix, and IGRADE gives its current value.

9: NITER – INTEGER *Input*

On entry: the number of iterations which have been performed in E04FCF.

10: NF – INTEGER *Input*

On entry: the number of times that LSQFUN has been called so far. (However, for intermediate calls of LSQMON, NF is calculated on the assumption that the latest linear search has been successful. If this is not the case, then the n evaluations allowed for approximating the Jacobian at the new point will not in fact have been made. NF will be accurate at the final call of LSQMON.)

11:	IW(LIW) – INTEGER array	Workspace
12:	LIW – INTEGER	Input
13:	W(LW) – <i>real</i> array	Workspace
14:	LW – INTEGER	Input

These parameters correspond to the parameters IW, LIW, W, LW of E04FCF. They are included in LSQMON's parameter list primarily for when E04FCF is called by other Library routines.

LSQMON must be declared as EXTERNAL in the (sub)program from which E04FCF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

Note: the user should normally print the sum of squares of residuals, so as to be able to examine the sequence of values of $F(x)$ mentioned in Section 7. It is usually helpful to print XC, the estimated gradient of the sum of squares, NITER and NF.

5: IPRINT – INTEGER *Input*

On entry: the frequency with which LSQMON is to be called.

If IPRINT > 0, LSQMON is called once every IPRINT iterations and just before exit from E04FCF.

If IPRINT = 0, LSQMON is just called at the final point.

If IPRINT < 0, LSQMON is not called at all.

IPRINT should normally be set to a small positive number.

Suggested value: IPRINT = 1.

6: MAXCAL – INTEGER *Input*

On entry: the limit set by the user on the number of times that LSQFUN may be called by E04FCF. There will be an error exit (see Section 6) after MAXCAL calls of LSQFUN.

Suggested value: MAXCAL = 400 × n .

Constraint: MAXCAL ≥ 1.

7: ETA – *real* *Input*

Every iteration of E04FCF involves a linear minimization i.e., minimization of $F(x^{(k)} + \alpha^{(k)}p^{(k)})$ with respect to $\alpha^{(k)}$.

On entry: specifies how accurately the linear minimizations are to be performed. The minimum with respect to $\alpha^{(k)}$ will be located more accurately for small values of ETA (say 0.01) than for large values (say 0.9). Although accurate linear minimizations will generally reduce the number of iterations performed by E04FCF, they will increase the number of calls of LSQFUN made each iteration. On balance it is usually more efficient to perform a low accuracy minimization.

Suggested value: ETA = 0.5 (ETA = 0.0 if N = 1).

Constraint: 0.0 ≤ ETA < 1.0.

8: XTOL – *real* *Input*

On entry: the accuracy in x to which the solution is required.

If x_{true} is the true value of x at the minimum, then x_{sol} , the estimated position prior to a normal exit, is such that

$$\|x_{sol} - x_{true}\| < XTOL \times (1.0 + \|x_{true}\|),$$

where $\|y\| = \sqrt{\sum_{j=1}^n y_j^2}$. For example, if the elements of x_{sol} are not much larger than 1.0 in modulus and if XTOL = 1.0E-5, then x_{sol} is usually accurate to about 5 decimal places. (For further details see Section 7.)

If $F(x)$ and the variables are scaled roughly as described in Section 8 and ϵ is the **machine precision**, then a setting of order $\text{XTOL} = \sqrt{\epsilon}$ will usually be appropriate. If XTOL is set to 0.0 or some positive value less than 10ϵ , E04FCF will use 10ϵ instead of XTOL, since 10ϵ is probably the smallest reasonable setting.

Constraint: $\text{XTOL} \geq 0.0$.

9: STEPMX – *real**Input*

On entry: an estimate of the Euclidean distance between the solution and the starting point supplied by the user. (For maximum efficiency, a slight overestimate is preferable.) E04FCF will ensure that, for each iteration,

$$\sum_{j=1}^n (x_j^{(k)} - x_j^{(k-1)})^2 \leq (\text{STPMX})^2$$

where k is the iteration number. Thus, if the problem has more than one solution, E04FCF is most likely to find the one nearest to the starting point. On difficult problems, a realistic choice can prevent the sequence $x^{(k)}$ entering a region where the problem is ill-behaved and can help avoid overflow in the evaluation of $F(x)$. However, an underestimate of STEPMX can lead to inefficiency.

Suggested value: $\text{STPMX} = 100000.0$.

Constraint: $\text{STPMX} \geq \text{XTOL}$.

10: X(N) – *real* array*Input/Output*

On entry: $X(j)$ must be set to a guess at the j th component of the position of the minimum, for $j = 1, 2, \dots, n$.

On exit: the final point $x^{(k)}$. Thus, if $\text{IFAIL} = 0$ on exit, $X(j)$ is the j th component of the estimated position of the minimum.

11: FSUMSQ – *real**Output*

On exit: the value of $F(x)$, the sum of squares of the residuals $f_i(x)$, at the final point given in X.

12: FVEC(M) – *real* array*Output*

On exit: the value of the residual $f_i(x)$ at the final point given in X, for $i = 1, 2, \dots, m$.

13: FJAC(LJ,N) – *real* array*Output*

On exit: the estimate of the first derivative $\frac{\partial f_i}{\partial x_j}$ at the final point given in X, for $i = 1, 2, \dots, m$; $j = 1, 2, \dots, n$.

14: LJ – INTEGER

Input

On entry: the first dimension of the array FJAC as declared in the (sub)program from which E04FCF is called.

Constraint: $\text{LJ} \geq \text{M}$.

15: S(N) – *real* array*Output*

On exit: the singular values of the estimated Jacobian matrix at the final point. Thus S may be useful as information about the structure of the user's problem.

- 16: $V(LV,N)$ – *real* array *Output*
On exit: the matrix V associated with the singular value decomposition
- $$J = U S V^T$$
- of the estimated Jacobian matrix at the final point, stored by columns. This matrix may be useful for statistical purposes, since it is the matrix of orthonormalised eigenvectors of $J^T J$.
- 17: LV – INTEGER *Input*
On entry: the first dimension of the array V as declared in the (sub)program from which E04FCF is called.
Constraint: $LV \geq N$.
- 18: $NITER$ – INTEGER *Output*
On exit: the number of iterations which have been performed in E04FCF.
- 19: NF – INTEGER *Output*
On exit: the number of times that the residuals have been evaluated (i.e., number of calls of LSQFUN).
- 20: $IW(LIW)$ – INTEGER array *Workspace*
 21: LIW – INTEGER *Input*
On entry: the dimension of the array IW as declared in the (sub)program from which E04FCF is called.
Constraint: $LIW \geq 1$.
- 22: $W(LW)$ – *real* array *Workspace*
 23: LW – INTEGER *Input*
On entry: the dimension of the array W as declared in the (sub)program from which E04FCF is called.
Constraints:
- $$LW \geq 6 \times N + M \times N + 2 \times M + N \times (N - 1)/2, \text{ if } N > 1$$
- $$LW \geq 7 + 3 \times M, \text{ if } N = 1.$$
- 24: $IFAIL$ – INTEGER *Input/Output*
On entry: $IFAIL$ must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.
On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).
 For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, because for this routine the values of the output parameters may be useful even if $IFAIL \neq 0$ on exit, the recommended value is -1 . **When the value -1 or 1 is used it is essential to test the value of $IFAIL$ on exit.**

6 Error Indicators and Warnings

If on entry $IFAIL = 0$ or -1 , explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL < 0

A negative value of IFAIL indicates an exit from E04FCF because the user has set IFLAG negative in LSQFUN. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry, $N < 1$,
 or $M < N$,
 or $MAXCAL < 1$,
 or $ETA < 0.0$,
 or $ETA \geq 1.0$,
 or $XTOL < 0.0$,
 or $STEPMX < XTOL$,
 or $LJ < M$,
 or $LV < N$,
 or $LIW < 1$,
 or $LW < 6 \times N + M \times N + 2 \times M + N \times (N - 1)/2$, when $N > 1$,
 or $LW < 7 + 3 \times M$, when $N = 1$.

When this exit occurs, no values will have been assigned to FSUMSQ, or to the elements of FVEC, FJAC, S or V.

IFAIL = 2

There have been MAXCAL calls of LSQFUN. If steady reductions in the sum of squares, $F(x)$, were monitored up to the point where this exit occurred, then the exit probably occurred simply because MAXCAL was set too small, so the calculations should be restarted from the final point held in X. This exit may also indicate that $F(x)$ has no minimum.

IFAIL = 3

The conditions for a minimum have not all been satisfied, but a lower point could not be found. This could be because XTOL has been set so small that rounding errors in the evaluation of the residuals make attainment of the convergence conditions impossible.

IFAIL = 4

The method for computing the singular value decomposition of the estimated Jacobian matrix has failed to converge in a reasonable number of sub-iterations. It may be worth applying E04FCF again starting with an initial approximation which is not too close to the point at which the failure occurred.

The values IFAIL = 2, 3 and 4 may also be caused by mistakes in LSQFUN, by the formulation of the problem or by an awkward function. If there are no such mistakes it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure.

7 Accuracy

A successful exit (IFAIL = 0) is made from E04FCF when (B1, B2 and B3) or B4 or B5 hold, where

$$\begin{aligned} B1 &\equiv \alpha^{(k)} \times \|p^{(k)}\| < (XTOL + \epsilon) \times (1.0 + \|x^{(k)}\|) \\ B2 &\equiv |F^{(k)} - F^{(k-1)}| < (XTOL + \epsilon)^2 \times (1.0 + F^{(k)}) \\ B3 &\equiv \|g^{(k)}\| < (\epsilon^{1/3} + XTOL) \times (1.0 + F^{(k)}) \\ B4 &\equiv F^{(k)} < \epsilon^2 \\ B5 &\equiv \|g^{(k)}\| < (\epsilon \times \sqrt{F^{(k)}})^{1/2} \end{aligned}$$

and where $\|\cdot\|$ and ϵ are as defined in Section 5, and $F^{(k)}$ and $g^{(k)}$ are the values of $F(x)$ and its vector of estimated first derivatives at $x^{(k)}$. If IFAIL = 0 then the vector in X on exit, x_{sol} , is almost certainly an estimate of x_{true} , the position of the minimum to the accuracy specified by XTOL.

If $\text{IFAIL} = 3$, then x_{sol} may still be a good estimate of x_{true} , but to verify this the user should make the following checks. If

- (a) the sequence $\{F(x^{(k)})\}$ converges to $F(x_{sol})$ at a superlinear or a fast linear rate, and
- (b) $g(x_{sol})^T g(x_{sol}) < 10\epsilon$,

where T denotes transpose, then it is almost certain that x_{sol} is a close approximation to the minimum. When (b) is true, then usually $F(x_{sol})$ is a close approximation to $F(x_{true})$. The values of $F(x^{(k)})$ can be calculated in LSQMON, and the vector $g(x_{sol})$ can be calculated from the contents of FVEC and FJAC on exit from E04FCF.

Further suggestions about confirmation of a computed solution are given in the E04 Chapter Introduction.

8 Further Comments

The number of iterations required depends on the number of variables, the number of residuals, the behaviour of $F(x)$, the accuracy demanded and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04FCF varies, but for $m \gg n$ is approximately $n \times m^2 + O(n^3)$. In addition, each iteration makes at least $n + 1$ calls of LSQFUN. So, unless the residuals can be evaluated very quickly, the run time will be dominated by the time spent in LSQFUN.

Ideally, the problem should be scaled so that, at the solution, $F(x)$ and the corresponding values of the x_j are each in the range $(-1, +1)$, and so that at points one unit away from the solution, $F(x)$ differs from its value at the solution by approximately one unit. This will usually imply that the Hessian matrix of $F(x)$ at the solution is well-conditioned. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04FCF will take less computer time.

When the sum of squares represents the goodness-of-fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in the arrays S and V. See E04YCF for further details.

9 Example

To find least-squares estimates of x_1, x_2 and x_3 in the model

$$y = x_1 + \frac{t_1}{x_2 t_2 + x_3 t_3}$$

using the 15 sets of data given in the following table.

y	t_1	t_2	t_3
0.14	1.0	15.0	1.0
0.18	2.0	14.0	2.0
0.22	3.0	13.0	3.0
0.25	4.0	12.0	4.0
0.29	5.0	11.0	5.0
0.32	6.0	10.0	6.0
0.35	7.0	9.0	7.0
0.39	8.0	8.0	8.0
0.37	9.0	7.0	7.0
0.58	10.0	6.0	6.0
0.73	11.0	5.0	5.0
0.96	12.0	4.0	4.0
1.34	13.0	3.0	3.0
2.10	14.0	2.0	2.0
4.39	15.0	1.0	1.0

The program uses (0.5, 1.0, 1.5) as the initial guess at the position of the minimum.

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.

9.3 Program Results

E04FCF Example Program Results

```

On exit, the sum of squares is      0.0082
at the point      0.0824      1.1330      2.3437
The estimated gradient is  -6.039E-12  3.636E-11  9.685E-11
                    (machine dependent)

```

and the residuals are

```

-5.9E-03
-2.7E-04
 2.7E-04
 6.5E-03
-8.2E-04
-1.3E-03
