

NAG Fortran Library Routine Document

G05YBF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

To generate multi-dimensional quasi-random sequences with a Gaussian or log-normal probability distribution.

2 Specification

```

SUBROUTINE G05YBF(FCALL, SEQ, LNORM, MEAN, STD, ISKIP, IDIM, QUASI,
1                IREF, IFAIL)
  INTEGER          ISKIP, IDIM, IREF(2000), IFAIL
  real           MEAN(IDIM), STD(IDIM), QUASI(IDIM)
  LOGICAL         FCALL, LNORM
  CHARACTER*1     SEQ

```

3 Description

Low discrepancy (quasi-random) sequences are used in numerical integration, simulation and optimisation. Like pseudo-random numbers they are uniformly distributed but they are not statistically independent, rather they are designed to give more even distribution in multidimensional space (uniformity). Therefore they are often more efficient than pseudo-random numbers in multidimensional Monte Carlo methods.

G05YBF generates multi-dimensional quasi-random sequences with a Gaussian or log-normal probability distribution. The sequences are generated in pairs using the Box-Muller method. This means that an even number of dimensions are required by G05YBF. If an odd number of dimensions are required then the extra dimension must be computed, but can then be ignored.

G05YBF uses the sequences as described in G05YAF.

5 Parameters

1: FCALL – LOGICAL *Input*

On entry: if FCALL = .TRUE., the first call for initialisation and there is no output via array QUASI. If FCALL = .FALSE., the sequence has already been initialised by a prior call to G05YBF with FCALL = .TRUE.. Random numbers are output via array QUASI.

2: SEQ – CHARACTER*1 *Input*

On entry: the type of sequence to generate.

If SEQ = 'S', a Sobol sequence.

If SEQ = 'N', a Niederreiter sequence.

If SEQ = 'F', a Faure sequence.

Constraint: SEQ = 'S', 'N' or 'F'.

- 3: LNORM – LOGICAL *Input*
On entry: indicates whether to create Gaussian or log-normal variates. If LNORM = .TRUE. then the variates are log-normal, otherwise they are Gaussian.
- 4: MEAN(IDIM) – *real* array *Input*
On entry: MEAN(k) is the mean of distribution for the k th dimension.
- 5: STD(IDIM) – *real* array *Input*
On entry: STD(k) is the standard deviation of the distribution for the k th dimension.
Constraint: STD(i) > 0.0, for $i = 1, \dots, \text{IDIM}$.
- 6: ISKIP – INTEGER *Input*
On entry: the number of terms in the sequence to skip on initialisation. ISKIP is not referenced when SEQ = 'F'.
Constraint: ISKIP \geq 0, if SEQ = 'N' or SEQ = 'S' and FCALL = .TRUE..
- 7: IDIM – INTEGER *Input*
On entry: the number of dimensions required.
Constraint: $2 \leq \text{IDIM} \leq 40$ and IDIM must be even.
- 8: QUASI(IDIM) – *real* array *Output*
On exit: the random numbers, generated in pairs. That is, on the first call with FCALL = .FALSE., QUASI(k) contains the first quasi-random number for the k th dimension. On the next call QUASI(k) contains the second quasi-random number for the k th dimension, etc..
- 9: IREF(2000) – INTEGER array *Workspace*
On entry/on exit: workspace used to contain information between calls to the routine. The contents of this array should not be changed.
- 10: IFAIL – INTEGER *Input/Output*
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).
 For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, because for this routine the values of the output parameters may be useful even if IFAIL \neq 0 on exit, the recommended value is -1. **When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.**

6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL = 1

On entry, ISKIP < 0 if SEQ = 'N' or SEQ = 'S' and FCALL = .TRUE.,

or IDIM < 2,
 or IDIM > 40,
 or SEQ ≠ 'F' or SEQ ≠ 'N' or SEQ ≠ 'S',
 or $\text{STD}(i) \leq 0.0$, for some $i = 1, \dots, \text{IDIM}$.

IFAIL = 2

On entry, the array IREF has not been correctly initialised.

IFAIL = 3

The value of ISKIP is too large.

IFAIL = 4

There have been too many calls in the sequence.

IFAIL = 5

An internal error has occurred within the routines. Please contact NAG.

7 Accuracy

Not applicable.

8 Further Comments

The maximum length of the generated sequences is $2^{29} - 1$, this should be adequate for practical purposes. For more information see G05YAF.

9 Example

This example program calculates the sum of the expected values of the kurtosis of 20 independent Gaussian samples. A quasi-random Faure sequence generator is used.

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
