NAG Fortran Library Routine Document

D04AAF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

D04AAF calculates a set of derivatives (up to order 14) of a function of one real variable at a point, together with a corresponding set of error estimates, using an extension of the Neville algorithm.

2 Specification

SUBROUTINE D04[AAF \(XVAL, NDER, HBASE, DER, ER](#page-1-0)[EST, FUN, IFAIL\)](#page-2-0) INTEGER NDER, IFAIL $double\ precision$ XVAL, HBASE, DER(14), EREST(14) EXTERNAL FUN

3 Description

D04AAF provides a set of approximations:

$$
DER(j), \quad j = 1, 2, \ldots, n
$$

to the derivatives:

$$
f^{(j)}(x_0), \quad j = 1, 2, \dots, n
$$

of a real valued function $f(x)$ at a real abscissa x_0 , together with a set of error estimates:

$$
EREST(j), \quad j=1,2,\ldots,n
$$

which hopefully satisfy:

$$
\left|\text{DER}(j) - f^{(j)}(x_0)\right| < \text{EREST}(j), \quad j = 1, 2, \dots, n.
$$

You must provide the value of x_0 , a value of n (which is reduced to 14 should it exceed 14) a function (sub)program which evaluates $f(x)$ for all real x, and a step length h. The results DER (i) and EREST (i) are based on 21 function values:

$$
f(x_0), f(x_0 \pm (2i-1)h), \quad i = 1, 2, ..., 10.
$$

Internally the routine calculates the odd order derivatives and the even order derivatives separately. There is a user option for restricting the calculation to only odd (or even) order derivatives. For each derivative the routine employs an extension of the Neville Algorithm (see Lyness and Moler (1969)) to obtain a selection of approximations.

For example, for odd derivatives, based on 20 function values, the routine calculates a set of numbers:

$$
T_{k,p,s}
$$
, $p = s, s + 1, ..., 6$, $k = 0, 1, ..., 9-p$

each of which is an approximation to $f^{(2s+1)}(x_0)/(2s+1)!$. A specific approximation $T_{k,p,s}$ is of polynomial degree $2p + 2$ and is based on polynomial interpolation using function values $f(x_0 \pm (2i-1)h)$, for $i = k, k+1, \ldots, k+p$. In the absence of round-off error, the better approximations would be associated with the larger values of p and of k . However, round-off error in function values has an increasingly contaminating effect for successively larger values of p . This routine proceeds to make a judicious choice between all the approximations in the following way.

For a specified value of s, let:

$$
R_p = U_p - L_p, \quad p = s, s+1, \ldots, 6
$$

where $U_p = \max_k (T_{k,p,s})$, for $k = 0, 1, ..., 9 - p$; $L_p = \min_k (T_{k,p,s})$, for $k = 0, 1, ..., 9 - p$, and let \bar{p} be such that $R_{\bar{p}} = \min_{p}(R_p)$, for $p = s, s + 1, \ldots, 6$.

The routine returns:

DER
$$
(2s + 1)
$$
 = $\frac{1}{8 - \bar{p}} \times \left\{ \sum_{k=0}^{9 - \bar{p}} T_{k, \bar{p}, s} - U_{\bar{p}} - L_{\bar{p}} \right\} \times (2s + 1)!$

and

$$
EREST(2s + 1) = R_{\bar{p}} \times (2s + 1)! \times K_{2s} + 1
$$

where K_j is a safety factor which has been assigned the values:

$$
K_j = 1, \quad j \le 9K_j = 1.5, \quad j = 10, 11K_j = 2 \quad j \ge 12,
$$

on the basis of performance statistics.

The even order derivatives are calculated in a precisely analogous manner.

5 Parameters

1: XVAL – **double precision** Input

On entry: the point at which the derivatives are required, x_0 .

2: NDER – INTEGER *Input*

On entry: must be set so that its absolute value is the highest order derivative required.

 $NDER > 0$

All derivatives up to order $min(NDER, 14)$ are calculated.

 $NDER < 0$ and $NDER$ is even

Only even order derivatives up to order $min(-NDER, 14)$ are calculated.

NDER < 0 and NDER is odd

Only odd order derivatives up to order $min(-NDER, 13)$ are calculated.

3: HBASE – *double precision* Input

On entry: the initial step length which may be positive or negative.

(If set to zero the routine does not proceed with any calculation, but sets the er[ror flag IFAIL and](#page-2-0) returns to the (sub)program from which D04AAF is called.) For advice on the choice of HBASE see Sectio[n 8.](#page-3-0)

4: $DER(14) - double precision array$ Output

On exit: an approximation to the *j*th derivative of $f(x)$ at $x =$ XVAL, so long as the *j*th derivative is one of those requested by you when specifying NDER. For other values of j, $DER(j)$ is unused.

refer to Chapter P01 for details.

IFAIL on exit.

6 Error Indicators and Warnings

If on entry IFAIL $= 0$ or -1 , explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

 $IFAIL = 1$

On entry, NDER $= 0$, or $HBASE = 0.$

If IFAIL has a value zero on exit then D04AAF has terminated successfully, but before any use is made of a derivative $DER(j)$ the value of $EREST(j)$ must be checked.

7 Accuracy

The accuracy of the results is problem dependent. An estimate of the accuracy of each result $DER(j)$ is returned in $EREST(i)$ (see Sectio[ns 3,](#page-0-0) [5 a](#page-1-0)[nd 8\).](#page-3-0)

[NP3657/21] D04AAF.3

6: $FUN - *double precision* FUNCTION, supplied by the user *External Procedure*$ FUN must evaluate the function $f(x)$ at a specified point.

Its specification is:

double precision FUNCTION FUN (X) double precision X

For other values of *j*, $EREST(j)$ is unused.

1: $X - \text{double precision}$ Input

On entry: the value of the argument x .

If you have equally spaced tabular data, the following information may be useful:

On exit: an estimate of the absolute error in the corresponding result $DER(i)$ so long as the *i*th derivative is one of those requested by you when sp[ecifying NDER. The](#page-1-0) sign of $EREST(j)$ is positive unless the result $DER(j)$ is questionable. It is set negative when $|DER(j)| < |EREST(j)|$ or when for some other reason there is doubt about the validity of the result $DER(j)$ (see Section 6).

- (i) in any call of D04AAF the only values of X that will be required are $X = XVAL$ and $X = XVAL \pm (2j - 1)HBASE$, for $j = 1, 2, ..., 10$; and
- (iii) FUN $(XVAL)$ is always called, but it is disregarded when only odd order derivatives are required.

FUN must be declared as EXTERNAL in the (sub)program from which D04AAF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

7: IFAIL – INTEGER Input/Output

On entry: IFAIL must be set to $0, -1$ or 1. If you are unfamiliar with this parameter you should

On exit: IFAIL $= 0$ unless the routine detects an error (see Section 6).

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, if you are not familiar with this parameter the recommended value is 0. When the value -1 or 1 is used it is essential to test the value of

5: $EREST(14) - double precision array$ Output

A basic feature of any floating-point routine for numerical differentiation based on real function values on the real axis is that successively higher order derivative approximations are successively less accurate. It is expected that in most cases DER (14) will be unusable. As an aid to this process, the sign of EREST (i) is set negative when the estimated absolute error is greater than the approximate derivative itself, i.e., when the approximate derivative may be so inaccurate that it may even have the wrong sign. It is also set negative in some other cases when information available to the routine indicates that the corresponding value of $DER(j)$ is questionable.

The actual [values in EREST depend](#page-2-0) on the accuracy of the function values, the properties of the machine arithmetic, the analytic properties of the function being differentiated and the user-supplied step length [HBASE \(see Sec](#page-1-0)tion 8). The only hard and fast rule is that for a given $FUN(X)$ [and HBASE, the valu](#page-1-0)es of $EREST(j)$ increase with increasing j. The limit of 14 is dictated by experience. Only very rarely can one obtain meaningful approximations for higher order derivatives on conventional machines.

8 Further Comments

The time taken by D04AAF depends on the time spent for function evaluations. Otherwise the time is roughly equivalent to that required to evaluate the function 21 times and calculate a finite difference table having about 200 entries in total.

The results depend very critically on the choice of the user-supplied st[ep length HBASE. The ov](#page-1-0)erall accuracy is dim[inished as HBASE becomes](#page-1-0) small (because of the effect of round-off err[or\) and as HBASE](#page-1-0) becomes large (because the discretization error also becomes large). If the routine is used four or five times with different [values of HBASE one can fi](#page-1-0)nd a reasonably good value. A process in which the value [of HBASE is succes](#page-1-0)sively halved (or doubled) is usually quite effective. Experience has shown that in cases in which the Taylor series for $FUN(X)$ [about XVAL has a fi](#page-1-0)nite radius of convergence R, the choices of HBASE > $R/21$ are not likely to lead to good results. In this case some function values lie outside the circle of convergence.

9 Example

This example evaluates the odd-order derivatives of the function:

$$
f(x) = \frac{1}{2}e^{2x-1}
$$

up to order 7 at the point $x = \frac{1}{2}$. Several different [values of HBASE are used](#page-1-0), to illustrate that:

- (i) extreme c[hoices of HBASE, either to](#page-1-0)o large or too small, yield poor results;
- (ii) the quality of these results is adequately indicated by the [values of EREST.](#page-2-0)
