

NAG Fortran Library Routine Document

F07CUF (ZGTCON)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of ***bold italicised*** terms and other implementation-dependent details.

1 Purpose

F07CUF (ZGTCON) estimates the reciprocal condition number of a complex n by n tridiagonal matrix A , using the LU factorization returned by F07CRF (ZGTTRF).

2 Specification

```
SUBROUTINE F07CUF (NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK,
1 INFO)
INTEGER N, IPIV(*), INFO
double precision ANORM, RCOND
complex*16 DL(*), D(*), DU(*), DU2(*), WORK(*)
CHARACTER*1 NORM
```

The routine may be called by its LAPACK name ***zgtcon***.

3 Description

F07CUF (ZGTCON) should be preceded by a call to F07CRF (ZGTTRF), which uses Gaussian elimination with partial pivoting and row interchanges to factorize the matrix A as

$$A = PLU,$$

where P is a permutation matrix, L is unit lower triangular with at most one non-zero subdiagonal element in each column, and U is an upper triangular band matrix, with two superdiagonals. F07CUF (ZGTCON) then utilizes the factorization to estimate either $\|A^{-1}\|_1$ or $\|A^{-1}\|_\infty$, from which the estimate of the reciprocal of the condition number of A , $1/\kappa(A)$ is computed as either

$$1/\kappa_1(A) = 1/\left(\|A\|_1 \|A^{-1}\|_1\right)$$

or

$$1/\kappa_\infty(A) = 1/\left(\|A\|_\infty \|A^{-1}\|_\infty\right).$$

$1/\kappa(A)$ is returned, rather than $\kappa(A)$, since when A is singular $\kappa(A)$ is infinite.

Note that $\kappa_\infty(A) = \kappa_1(A^T)$.

5 Parameters

1: NORM – CHARACTER*1	<i>Input</i>
<i>On entry:</i> specifies the norm to be used to estimate $\kappa(A)$.	
NORM = '1' or 'O'	
Estimate $\kappa_1(A)$.	

NORM = 'I'

Estimate $\kappa_\infty(A)$.

Constraint: NORM = '1', 'O' or 'I'.

2: N – INTEGER

Input

On entry: n, the order of the matrix A.

Constraint: N ≥ 0 .

3: DL(*) – **complex*16** array

Input

Note: the dimension of the array DL must be at least max(1, N – 1).

On entry: must contain the (n – 1) multipliers that define the matrix L of the LU factorization of A.

4: D(*) – **complex*16** array

Input

Note: the dimension of the array D must be at least max(1, N).

On entry: must contain the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

5: DU(*) – **complex*16** array

Input

Note: the dimension of the array DU must be at least max(1, N – 1).

On entry: must contain the (n – 1) elements of the first superdiagonal of U.

6: DU2(*) – **complex*16** array

Input

Note: the dimension of the array DU2 must be at least max(1, N – 2).

On entry: must contain the (n – 2) elements of the second superdiagonal of U.

7: IPIV(*) – INTEGER array

Input

Note: the dimension of the array IPIV must be at least max(1, N).

On entry: must contain the n pivot indices that define the permutation matrix P. At the ith step, row i of the matrix was interchanged with row IPIV(i), and IPIV(i) must always be either i or (i + 1), IPIV(i) = i indicating that a row interchange was not performed.

8: ANORM – **double precision**

Input

On entry: if NORM = '1' or 'O', ANORM must contain $\|A\|_1$.

If NORM = 'I', ANORM must contain $\|A\|_\infty$.

ANORM may be computed by calling F06UNF with the same value for NORM.

ANORM must be computed either before calling F07CRF (ZGTTRF), or else from a copy of the original matrix A.

9: RCOND – **double precision**

Output

On exit: contains an estimate of the reciprocal condition number.

10: WORK(*) – **complex*16** array

Workspace

Note: the dimension of the array WORK must be at least max(1, 2 × N).

11: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = $-i$, the i th argument had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

In practice the condition number estimator is very reliable, but it can underestimate the true condition number; see Section 15.3 of Higham (2002) for further details.

8 Further Comments

The condition number estimation typically requires between four and five solves and never more than eleven solves, following the factorization. The total number of floating-point operations required to perform a solve is proportional to n .

The real analogue of this routine is F07CGF (DGTCOM).

9 Example

To estimate the condition number in the 1-norm of the tridiagonal matrix A given by

$$A = \begin{pmatrix} -1.3 + 1.3i & 2.0 - 1.0i & 0 & 0 & 0 \\ 1.0 - 2.0i & -1.3 + 1.3i & 2.0 + 1.0i & 0 & 0 \\ 0 & 1.0 + 1.0i & -1.3 + 3.3i & -1.0 + 1.0i & 0 \\ 0 & 0 & 2.0 - 3.0i & -0.3 + 4.3i & 1.0 - 1.0i \\ 0 & 0 & 0 & 1.0 + 1.0i & -3.3 + 1.3i \end{pmatrix}.$$
