

# NAG Fortran Library Routine Document

## **F07FFF (DPOEQU)**

**Note:** before using this routine, please read the Users' Note for your implementation to check the interpretation of ***bold italicised*** terms and other implementation-dependent details.

### 1 Purpose

F07FFF (DPOEQU) computes a diagonal scaling matrix  $S$  intended to equilibrate a real  $n$  by  $n$  symmetric positive-definite matrix  $A$  and reduce its condition number.

### 2 Specification

```
SUBROUTINE F07FFF (N, A, LDA, S, SCOND, AMAX, INFO)
INTEGER N, LDA, INFO
double precision A(LDA,*), S(*), SCOND, AMAX
```

The routine may be called by its LAPACK name ***dpoequ***.

### 3 Description

F07FFF (DPOEQU) computes a diagonal scaling matrix  $S$  chosen so that

$$s_j = 1/\sqrt{a_{jj}}.$$

This means that the matrix  $B$  given by

$$B = SAS,$$

has diagonal elements equal to unity. This in turn means that the condition number of  $B$ ,  $\kappa_2(B)$ , is within a factor  $n$  of the matrix of smallest possible condition number over all possible choices of diagonal scalings (see Corollary 7.6 of Higham (2002)).

### 4 References

### 5 Parameters

- |   |              |
|---|--------------|
| 1: N – INTEGER  | <i>Input</i> |
| <p><i>On entry:</i> <math>n</math>, the order of the matrix <math>A</math>.</p> <p><i>Constraint:</i> <math>N \geq 0</math>.</p>  |              |
| 2: A(LDA,*) – <b>double precision</b> array   | <i>Input</i> |
| <p><b>Note:</b> the second dimension of the array A must be at least <math>\max(1, N)</math>.</p> <p><i>On entry:</i> the matrix <math>A</math> whose scaling factors are to be computed. Only the diagonal elements of the array A are referenced.</p> |              |
| 3: LDA – INTEGER  | <i>Input</i> |
| <p><i>On entry:</i> the first dimension of the array A as declared in the (sub)program from which F07FFF (DPOEQU) is called.</p> <p><i>Constraint:</i> <math>LDA \geq \max(1, N)</math>.</p>  |              |

|  |  |               |
|--|--|---------------|
| 4:   | $S(*)$ – <i>double precision</i> array   | <i>Output</i> |
| <b>Note:</b> the dimension of the array $S$ must be at least $\max(1, N)$ .  |  |               |
| <i>On exit:</i> if $\text{INFO} = 0$ on exit, $S$ contains the diagonal elements of the scaling matrix $S$ .   |  |               |
| 5:   | $\text{SCOND}$ – <i>double precision</i> | <i>Output</i> |
| <i>On exit:</i> if $\text{INFO} = 0$ on exit, $\text{SCOND}$ contains the ratio of the smallest value of $S(i)$ to the largest value of $S(i)$ . If $\text{SCOND} \geq 0.1$ and $\text{AMAX}$ is neither too large nor too small, it is not worth scaling by $S$ . |  |               |
| 6:   | $\text{AMAX}$ – <i>double precision</i>  | <i>Output</i> |
| <i>On exit:</i> $\max  a_{ij} $ . If $\text{AMAX}$ is very close to overflow or underflow, the matrix $A$ should be scaled.  |  |               |
| 7:   | $\text{INFO}$ – INTEGER                  | <i>Output</i> |
| <i>On exit:</i> $\text{INFO} = 0$ unless the routine detects an error (see Section 6).   |  |               |

## 6 Error Indicators and Warnings

Errors or warnings detected by the routine:

$\text{INFO} < 0$

If  $\text{INFO} = -i$ , the  $i$ th argument had an illegal value. An explanatory message is output, and execution of the program is terminated.

$\text{INFO} > 0$

If  $\text{INFO} = i$ , the  $i$ th diagonal element of  $A$  is not positive (and hence  $A$  cannot be positive-definite).

## 7 Accuracy

The computed scale factors will be close to the exact scale factors.

## 8 Further Comments

The complex analogue of this routine is F07FTF (ZPOEQU).

## 9 Example

To equilibrate the symmetric positive-definite matrix  $A$  given by

$$A = \begin{pmatrix} 4.16 & -3.12 \times 10^5 & 0.56 & -0.10 \\ -3.12 \times 10^5 & 5.03 \times 10^{10} & -0.83 \times 10^5 & 1.18 \times 10^5 \\ 0.56 & -0.83 \times 10^5 & 0.76 & 0.34 \\ -0.10 & 1.18 \times 10^5 & 0.34 & 1.18 \end{pmatrix}.$$

Details of the scaling factors and the scaled matrix are output.
