NAG Fortran Library Routine Document F08BFF (DGEOP3)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F08BFF (DGEQP3) computes the QR factorization, with column pivoting, of a real m by n matrix.

2 Specification

SUBROUTINE FO8BFF (M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)

INTEGER
M, N, LDA, JPVT(*), LWORK, INFO

double precision
A(LDA,*), TAU(*), WORK(*)

The routine may be called by its LAPACK name dgeap3.

3 Description

F08BFF (DGEQP3) forms the QR factorization, with column pivoting, of an arbitrary rectangular real m by n matrix.

If $m \ge n$, the factorization is given by:

$$AP = Q\binom{R}{0},$$

where R is an n by n upper triangular matrix, Q is an m by m orthogonal matrix and P is an n by n permutation matrix. It is sometimes more convenient to write the factorization as

$$AP = (Q_1 \quad Q_2) \binom{R}{0},$$

which reduces to

$$AP = Q_1R$$
,

where Q_1 consists of the first n columns of Q_1 , and Q_2 the remaining m-n columns.

If m < n, R is trapezoidal, and the factorization can be written

$$AP = Q(R_1 R_2),$$

where R_1 is upper triangular and R_2 is rectangular.

The matrix Q is not formed explicitly but is represented as a product of min(m, n) elementary reflectors (see the F08 Chapter Introduction for details). Routines are provided to work with Q in this representation (see Section 8).

Note also that for any k < n, the information returned in the first k columns of the array A represents a QR factorization of the first k columns of the permuted matrix AP.

The routine allows specified columns of A to be moved to the leading columns of AP at the start of the factorization and fixed there. The remaining columns are free to be interchanged so that at the ith stage the pivot column is chosen to be the column which maximizes the 2-norm of elements i to m over columns i to n.

5 Parameters

1: M – INTEGER Input

On entry: m, the number of rows of the matrix A.

Constraint: M > 0.

2: N – INTEGER Input

On entry: n, the number of columns of the matrix A.

Constraint: $N \ge 0$.

3: A(LDA,*) – *double precision* array

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the m by n matrix A.

On exit: if $m \ge n$, the elements below the diagonal are overwritten by details of the orthogonal matrix Q and the upper triangle is overwritten by the corresponding elements of the n by n upper triangular matrix R.

If m < n, the strictly lower triangular part is overwritten by details of the orthogonal matrix Q and the remaining elements are overwritten by the corresponding elements of the m by n upper trapezoidal matrix R.

4: LDA – INTEGER

Input

On entry: the first dimension of the array A as declared in the (sub)program from which F08BFF (DGEQP3) is called.

Constraint: LDA $\geq \max(1, M)$.

5: JPVT(*) – INTEGER array

Input/Output

Note: the dimension of the array JPVT must be at least max(1, N).

On entry: if $JPVT(j) \neq 0$, then the jth column of A is moved to the beginning of AP before the decomposition is computed and is fixed in place during the computation. Otherwise, the jth column of A is a free column (i.e., one which may be interchanged during the computation with any other free column).

On exit: details of the permutation matrix P. More precisely, if JPVT(j) = k, then the kth column of A is moved to become the jth column of AP; in other words, the columns of AP are the columns of A in the order $JPVT(1), JPVT(2), \ldots, JPVT(n)$.

6: TAU(*) – *double precision* array

Output

Note: the dimension of the array TAU must be at least max(1, min(M, N)).

On exit: the scalar factors of the elementary reflectors.

7: WORK(*) – *double precision* array

Workspace

Note: the dimension of the array WORK must be at least max(1, LWORK).

On exit: if INFO = 0, WORK(1) contains the minimum value of LWORK required for optimal performance.

8: LWORK – INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which F08BFF (DGEQP3) is called.

If LWORK = -1, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Suggested value: for optimal performance, LWORK $\geq 2 \times N + (N+1) \times nb$, where nb is the optimal **block size**.

Constraint: LWORK $\geq 3 \times N + 1$ or LWORK = -1.

9: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = -i, the *i*th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix (A + E), where

$$||E||_2 = O(\epsilon)||A||_2$$

and ϵ is the *machine precision*.

8 Further Comments

The total number of floating-point operations is approximately $\frac{2}{3}n^2(3m-n)$ if $m \ge n$ or $\frac{2}{3}m^2(3n-m)$ if m < n.

To form the orthogonal matrix Q F08BFF (DGEQP3) may be followed by a call to F08AFF (DORGQR):

```
CALL DORGQR (M,M,MIN(M,N),A,LDA,TAU,WORK,LWORK,INFO)
```

but note that the second dimension of the array A must be at least M, which may be larger than was required by F08BFF (DGEQP3).

When $m \ge n$, it is often only the first n columns of Q that are required, and they may be formed by the call:

```
CALL DORGQR (M,N,N,A,LDA,TAU,WORK,LWORK,INFO)
```

To apply Q to an arbitrary real rectangular matrix C, F08BFF (DGEQP3) may be followed by a call to F08AGF (DORMQR). For example,

forms $C = Q^{T}C$, where C is m by p.

To compute a QR factorization without column pivoting, use F08AEF (DGEQRF).

The complex analogue of this routine is F08BTF (ZGEQP3).

9 Example

This example solves the linear least-squares problems

$$\min_{x} ||b_j - Ax_j||_2, \quad j = 1, 2$$

for the basic solutions x_1 and x_2 , where

$$A = \begin{pmatrix} -0.09 & 0.14 & -0.46 & 0.68 & 1.29 \\ -1.56 & 0.20 & 0.29 & 1.09 & 0.51 \\ -1.48 & -0.43 & 0.89 & -0.71 & -0.96 \\ -1.09 & 0.84 & 0.77 & 2.11 & -1.27 \\ 0.08 & 0.55 & -1.13 & 0.14 & 1.74 \\ -1.59 & -0.72 & 1.06 & 1.24 & 0.34 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 7.4 & 2.7 \\ 4.2 & -3.0 \\ -8.3 & -9.6 \\ 1.8 & 1.1 \\ 8.6 & 4.0 \\ 2.1 & -5.7 \end{pmatrix}$$

and b_j is the *j*th column of the matrix *B*. The solution is obtained by first obtaining a *QR* factorization with column pivoting of the matrix *A*. A tolerance of 0.01 is used to estimate the rank of *A* from the upper triangular factor, *R*.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.
