

NAG Fortran Library Routine Document

F08BSF (CGEQPF/ZGEQPF)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F08BSF (CGEQPF/ZGEQPF) computes the QR factorization, with column pivoting, of a complex m by n matrix.

2 Specification

```
SUBROUTINE F08BSF(M, N, A, LDA, JPVT, TAU, WORK, RWORK, INFO)
ENTRY      cgeqpf (M, N, A, LDA, JPVT, TAU, WORK, RWORK, INFO)
INTEGER    M, N, LDA, JPVT(*), INFO
real      RWORK(*)
complex   A(LDA,*), TAU(*), WORK(*)
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3 Description

This routine forms the QR factorization with column pivoting of an arbitrary rectangular complex m by n matrix.

If $m \geq n$, the factorization is given by:

$$AP = Q \begin{pmatrix} R \\ 0 \end{pmatrix}$$

where R is an n by n upper triangular matrix (with real diagonal elements), Q is an m by m unitary matrix and P is an n by n permutation matrix. It is sometimes more convenient to write the factorization as

$$AP = (Q_1 \quad Q_2) \begin{pmatrix} R \\ 0 \end{pmatrix}$$

which reduces to

$$AP = Q_1 R,$$

where Q_1 consists of the first n columns of Q , and Q_2 the remaining $m - n$ columns.

If $m < n$, R is trapezoidal, and the factorization can be written

$$AP = Q(R_1 \quad R_2),$$

where R_1 is upper triangular and R_2 is rectangular.

The matrix Q is not formed explicitly but is represented as a product of $\min(m, n)$ elementary reflectors (see the F08 Chapter Introduction for details). Routines are provided to work with Q in this representation (see Section 8).

Note also that for any $k < n$, the information returned in the first k columns of the array A represents a QR factorization of the first k columns of the permuted matrix AP .

The routine allows specified columns of A to be moved to the leading columns of AP at the start of the factorization and fixed there. The remaining columns are free to be interchanged so that at the i th stage the pivot column is chosen to be the column which maximizes the 2-norm of elements i to m over columns i to n .

5 Parameters

- 1: M – INTEGER *Input*
On entry: m , the number of rows of the matrix A .
Constraint: $M \geq 0$.
- 2: N – INTEGER *Input*
On entry: n , the number of columns of the matrix A .
Constraint: $N \geq 0$.
- 3: A(LDA,*) – **complex** array *Input/Output*
Note: the second dimension of the array A must be at least $\max(1, N)$.
On entry: the m by n matrix A .
On exit: if $m \geq n$, the elements below the diagonal are overwritten by details of the unitary matrix Q and the upper triangle is overwritten by the corresponding elements of the n by n upper triangular matrix R .
 If $m < n$, the strictly lower triangular part is overwritten by details of the unitary matrix Q and the remaining elements are overwritten by the corresponding elements of the m by n upper trapezoidal matrix R .
 The diagonal elements of R are real.
- 4: LDA – INTEGER *Input*
On entry: the first dimension of the array A as declared in the (sub)program from which F08BSF (CGEQPF/ZGEQPF) is called.
Constraint: $LDA \geq \max(1, M)$.
- 5: JPVT(*) – INTEGER array *Input/Output*
Note: the dimension of the array JPVT must be at least $\max(1, N)$.
On entry: if $JPVT(i) \neq 0$, then the i th column of A is moved to the beginning of AP before the decomposition is computed and is fixed in place during the computation. Otherwise, the i th column of A is a free column (i.e., one which may be interchanged during the computation with any other free column).
On exit: details of the permutation matrix P . More precisely, if $JPVT(i) = k$, then the k th column of A is moved to become the i th column of AP ; in other words, the columns of AP are the columns of A in the order $JPVT(1), JPVT(2), \dots, JPVT(n)$.
- 6: TAU(*) – **complex** array *Output*
Note: the dimension of the array TAU must be at least $\max(1, \min(M, N))$.
On exit: further details of the unitary matrix Q .
- 7: WORK(*) – **complex** array *Workspace*
Note: the dimension of the array WORK must be at least $\max(1, 3 * N)$.
- 8: RWORK(*) – **real** array *Workspace*
Note: the dimension of the array RWORK must be at least $\max(1, 2 * N)$.

9: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = $-i$, the i th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix $A + E$, where

$$\|E\|_2 = O(\epsilon)\|A\|_2,$$

and ϵ is the *machine precision*.

8 Further Comments

The total number of real floating-point operations is approximately $\frac{8}{3}n^2(3m - n)$ if $m \geq n$ or $\frac{8}{3}m^2(3n - m)$ if $m < n$.

To form the unitary matrix Q this routine may be followed by a call to F08ATF (CUNGQR/ZUNGQR):

```
CALL CUNGQR (M,M,MIN(M,N),A,LDA,TAU,WORK,LWORK,INFO)
```

but note that the second dimension of the array A must be at least M, which may be larger than was required by F08BSF (CGEQPF/ZGEQPF).

When $m \geq n$, it is often only the first n columns of Q that are required, and they may be formed by the call:

```
CALL CUNGQR (M,N,N,A,LDA,TAU,WORK,LWORK,INFO)
```

To apply Q to an arbitrary complex rectangular matrix C , this routine may be followed by a call to F08AUF (CUNMQR/ZUNMQR). For example,

```
CALL CUNMQR ('Left','Conjugate Transpose',M,P,MIN(M,N),A,LDA,TAU,
+ C,LDC,WORK,LWORK,INFO)
```

forms $C = Q^H C$, where C is m by p .

To compute a QR factorization without column pivoting, use F08ASF (CGEQRF/ZGEQRF).

The real analogue of this routine is F08BEF (SGEQPF/DGEQPF).

9 Example

To solve the linear least-squares problem

$$\text{minimize } \|Ax_i - b_i\|_2 \text{ for } i = 1, 2$$

where b_1 and b_2 are the columns of the matrix B ,

$$A = \begin{pmatrix} 0.47 - 0.34i & -0.40 + 0.54i & 0.60 + 0.01i & 0.80 - 1.02i \\ -0.32 - 0.23i & -0.05 + 0.20i & -0.26 - 0.44i & -0.43 + 0.17i \\ 0.35 - 0.60i & -0.52 - 0.34i & 0.87 - 0.11i & -0.34 - 0.09i \\ 0.89 + 0.71i & -0.45 - 0.45i & -0.02 - 0.57i & 1.14 - 0.78i \\ -0.19 + 0.06i & 0.11 - 0.85i & 1.44 + 0.80i & 0.07 + 1.14ik \end{pmatrix}$$

and

$$B = \begin{pmatrix} -0.85 - 1.63i & 2.49 + 4.01i \\ -2.16 + 3.52i & -0.14 + 7.98i \\ 4.57 - 5.71i & 8.36 - 0.28i \\ 6.38 - 7.40i & -3.55 + 1.29i \\ 8.41 + 9.39i & -6.72 + 5.03ik \end{pmatrix}.$$

Here A is approximately rank-deficient, and hence it is preferable to use F08BSF (CGEQPF/ZGEQPF) rather than F08ASF (CGEQR/ ZGEQR).

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
