NAG Fortran Library Routine Document F08CVF (ZGEROF)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F08CVF (ZGERQF) computes an RQ factorization of a complex m by n matrix A.

2 Specification

SUBROUTINE FO8CVF (M, N, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER
M, N, LDA, LWORK, INFO

complex*16
A(LDA,*), TAU(*), WORK(*)

The routine may be called by its LAPACK name zgerqf.

3 Description

F08CVF (ZGERQF) forms the RQ factorization of an arbitrary rectangular real m by n matrix. If $m \le n$, the factorization is given by

$$A = (0 R)Q$$

where R is an m by m lower triangular matrix and Q is an n by n unitary matrix. If m > n the factorization is given by

$$A = RQ$$

where R is an m by n upper trapezoidal matrix and Q is again an n by n unitary matrix. In the case where m < n the factorization can be expressed as

$$A = (0 \quad R) \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = RQ_2,$$

where Q_1 consists of the first (n-m) rows of Q and Q_2 the remaining m rows.

The matrix Q is not formed explicitly, but is represented as a product of $\min(m, n)$ elementary reflectors (see the F08 Chapter Introduction for details). Routines are provided to work with Q in this representation (see Section 8).

5 Parameters

: M – INTEGER Input

On entry: m, the number of rows of the matrix A.

Constraint: $M \ge 0$.

2: N – INTEGER Input

On entry: n, the number of columns of the matrix A.

Constraint: $N \ge 0$.

3: A(LDA,*) - complex*16 array

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the m by n matrix A.

On exit: if $m \le n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the m by m upper triangular matrix R.

If $m \ge n$, the elements on and above the (m-n)th subdiagonal contain the m by n upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of $\min(m, n)$ elementary reflectors (see Section 3.3.6 in the F08 Chapter Introduction).

4: LDA – INTEGER Input

On entry: the first dimension of the array A as declared in the (sub)program from which F08CVF (ZGERQF) is called.

Constraint: LDA $\geq \max(1, M)$.

5: TAU(*) - complex*16 array

Output

Note: the dimension of the array TAU must be at least max(1, min(M, N)).

On exit: the scalar factors of the elementary reflectors.

6: WORK(*) - complex*16 array

Workspace

Note: the dimension of the array WORK must be at least max(1, LWORK).

On exit: if INFO = 0, the real part of WORK(1) contains the minimum value of LWORK required for optimal performance.

7: LWORK – INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which F08CVF (ZGERQF) is called.

If LWORK =-1, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Suggested value: for optimal performance, LWORK \geq M \times nb, where nb is the optimal **block size**. Constraint: LWORK \geq max(1, M) or LWORK = -1.

8: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = -i, the *i*th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

F08CVF (ZGERQF).2 [NP3657/21]

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix A + E, where

$$||E||_2 = O\epsilon ||A||_2$$

and ϵ is the *machine precision*.

8 Further Comments

The total number of floating point operations is approximately $\frac{2}{3}m^2(3n-m)$ if $m \le n$, or $\frac{2}{3}n^2(3m-n)$ if m > n.

To form the unitary matrix Q F08CVF (ZGERQF) may be followed by a call to F08CWF (ZUNGRQ):

```
CALL ZUNGRO (N,N,MIN(M,N),A,LDA,TAU,WORK,LWORK,INFO)
```

but note that the first dimension of the array A must be at least N, which may be larger than was required by F08CVF (ZGERQF). When $m \le n$, it is often only the first m rows of Q that are required and they may be formed by the call:

```
CALL ZUNGRQ (M,N,M,A,LDA,TAU,WORK,LWORK,INFO)
```

To apply Q to an arbitrary real rectangular matrix C, F08CVF (ZGERQF) may be followed by a call to F08CXF (ZUNMRQ). For example:

forms $C = Q^{H}C$, where C is n by p.

The real analogue of this routine is F08CHF (DGERQF).

9 Example

This example finds the minimum norm solution to the underdetermined equations

$$Ax = b$$

where

$$A = \begin{pmatrix} 0.28 - 0.36i & 0.50 - 0.86i & -0.77 - 0.48i & 1.58 + 0.66i \\ -0.50 - 1.10i & -1.21 + 0.76i & -0.32 - 0.24i & -0.27 - 1.15i \\ 0.36 - 0.51i & -0.07 + 1.33i & -0.75 + 0.47i & -0.08 + 1.01i \end{pmatrix}$$
 and

$$b = \begin{pmatrix} -1.35 + 0.19i \\ 9.41 - 3.56i \\ -7.57 + 6.93i \end{pmatrix}.$$

The solution is obtained by first obtaining an RQ factorization of the matrix A.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.
