NAG Fortran Library Routine Document

G02EAF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of ***bold italicised*** terms and other implementation-dependent details.

1 Purpose

G02EAF calculates the residual sums of squares for all possible linear regressions for a given set of independent variables.

2 Specification

```
 SUBROUTINE G02EAF(MEAN, WEIGHT, N, M, X, LDX, NAME, ISX, Y, WT, NMOD,
1                  MODEL, LDM, RSS, NTERMS, MRANK, WK, IFAIL)
 INTEGER           N, M, LDX, ISX(M), NMOD, LDM, NTERMS(LDM), MRANK(LDM),
1                  IFAIL
 real              X(LDX,M), Y(N), WT(*), RSS(LDM), WK(N*(M+1))
 CHARACTER*1       MEAN, WEIGHT
 CHARACTER*(*)     NAME(M), MODEL(LDM,M)
```

3 Description

For a set of k possible independent variables there are 2^k linear regression models with from zero to k independent variables in each model. For example if $k = 3$ and the variables are A, B and C then the possible models are:

(i) null model
(ii) A
(iii) B
(iv) C
(v) A and B
(vi) A and C
(vii) B and C
(viii)
A, B and C.

G02EAF calculates the residual sums of squares from each of the 2^k possible models. The method used involves a QR decomposition of the matrix of possible independent variables. Independent variables are then moved into and out of the model by a series of Givens rotations and the residual sums of squares computed for each model; see Clark (1981) and Smith and Bremner (1989).

The computed residual sums of squares are then ordered first by increasing number of terms in the model, then by decreasing size of residual sums of squares. So the first model will always have the largest residual sum of squares and the 2^kth will always have the smallest. This aids the user in selecting the best possible model from the given set of independent variables.

G02EAF allows the user to specify some independent variables that must be in the model, the forced variables. The other independent variables from which the possible models are to be formed are the free variables.

5 Parameters

1: MEAN – CHARACTER*1 *Input*

On entry: indicates if a mean term is to be included.

If MEAN = 'M' (Mean), a mean term, intercept, will be included in the models.

If MEAN = 'Z' (Zero), the models will pass through the origin, zero-point.

Constraint: MEAN = 'M' or 'Z'.

2: WEIGHT – CHARACTER*1 *Input*

On entry: indicates if weights are to be used.

If WEIGHT = 'U' (Unweighted), least-squares estimation is used.

If WEIGHT = 'W' (Weighted), weighted least-squares is used and weights must be supplied in array WT.

Constraint: WEIGHT = 'U' or 'W'.

3: N – INTEGER *Input*

On entry: the number of observations.

Constraint: N ≥ 2.

4: M – INTEGER *Input*

On entry: the maximum number of variables contained in X.

Constraint: M ≥ 2.

5: X(LDX,M) – ***real*** array *Input*

On entry: X(i,j) must contain the ith observation for the jth independent variable, for $i = 1,2,\ldots,\mathrm{N}$; $j = 1,2,\ldots,\mathrm{M}$.

6: LDX – INTEGER *Input*

On entry: the first dimension of the array X as declared in the (sub)program from which G02EAF is called.

Constraint: LDX $\geq$ N.

7: NAME(M) – CHARACTER*(*) array *Input*

On entry: NAME(j) must contain the name of the variable in column j of X, for $j = 1,2,\ldots,\mathrm{M}$.

8: ISX(M) – INTEGER array *Input*

On entry: indicates which independent variables are to be considered in the model.

If ISX$(j) \geq 2$, then the variable contained in the jth column of X is included in all regression models, i.e., is a forced variable.

If ISX$(j) = 1$, then the variable contained in the jth column of X is included in the set from which the regression models are chosen, i.e., is a free variable.

If ISX$(j) = 0$, then the variable contained in the jth column of X is not included in the models.

Constraint: ISX$(j) \geq 0$, for $j = 1,2,\ldots,\mathrm{M}$ and at least one value of ISX $= 1$.

9: Y(N) – ***real*** array *Input*

On entry: Y(i) must contain the ith observation on the dependent variable, y_i, for $i = 1, 2, \ldots, n$.

10: WT(∗) – ***real*** array *Input*

On entry: if WEIGHT = 'W', then WT must contain the weights to be used in the weighted regression.

If WT(i) = 0.0, then the ith observation is not included in the model, in which case the effective number of observations is the number of observations with non-zero weights.

If WEIGHT = 'U', then WT is not referenced and the effective number of observations is N.

Constraint: if WEIGHT = 'W', WT(i) $\geq$ 0.0, for $i = 1, 2, \ldots, n$.

11: NMOD – INTEGER *Output*

On exit: the total number of models for which residual sums of squares have been calculated.

12: MODEL(LDM,M) – CHARACTER*(*) array *Output*

On exit: the first NTERMS(i) elements of the ith row of MODEL contain the names of the independent variables, as given in NAME, that are included in the ith model.

Constraint: the length of MODEL should be greater or equal to the length of NAME.

13: LDM – INTEGER *Input*

On entry: the first dimension of the array MODEL as declared in the (sub)program from which G02EAF is called.

Constraint: at a minimum LDM $\geq$ M, but LDM also needs to be greater or equal to the number of models to be generated. If there are k free independent variables then LDM $\geq 2^k$.

14: RSS(LDM) – ***real*** array *Output*

On exit: RSS(i) contains the residual sum of squares for the ith model, for $i = 1, 2, \ldots,$ NMOD.

15: NTERMS(LDM) – INTEGER array *Output*

On exit: NTERMS(i) contains the number of independent variables in the ith model, not including the mean if one is fitted, for $i = 1, 2, \ldots,$ NMOD.

16: MRANK(LDM) – INTEGER array *Output*

On exit: MRANK(i) contains the rank of the residual sum of squares for the ith model, i.e., model with smallest sum of squares has rank 1.

17: WK(N∗(M+1)) – ***real*** array *Workspace*

18: IFAIL – INTEGER *Input/Output*

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, for users not familiar with this parameter the recommended value is 0. **When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.**

6 Error Indicators and Warnings

If on entry IFAIL $= 0$ or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL $= 1$

On entry, N < 2,
or M < 2,
or LDX $<$ N,
or LDM $<$ M,
or MEAN $\neq$ 'M' or 'Z',
or WEIGHT $\neq$ 'U' or 'W'.

IFAIL $= 2$

On entry, WEIGHT $=$ 'W' and a value of WT < 0.0.

IFAIL $= 3$

On entry, a value of ISX < 0.0,
or there are no free variables, i.e., no element of ISX $= 1$.

IFAIL $= 4$

On entry, LDM $<$ the number of possible models $= 2^k$, where k is the number of free independent variables from ISX.

IFAIL $= 5$

On entry, the number of independent variables to be considered (forced plus free plus mean if included) is greater or equal to the effective number of observations.

IFAIL $= 6$

The full model is not of full rank i.e., some of the independent variables may be linear combinations of other independent variables. Variables must be excluded from the model in order to give full rank.

7 Accuracy

For a discussion of the improved accuracy obtained by using a method based on the QR decomposition see Smith and Bremner (1989).

8 Further Comments

G02ECF may be used to compute R^2 and C_p-values from the results of G02EAF.

If a mean has been included in the model and no variables are forced in then RSS(1) contains the total sum of squares and in many situations a reasonable estimate of the variance of the errors is given by RSS(NMOD)/(N $-$ 1 $-$ NTERMS(NMOD)).

9 Example

The data for this example is given in Weisberg (1985). The independent variables and the dependent variable are read, as are the names of the variables. These names are as given in Weisberg (1985). The residual sums of squares computed and printed with the names of the variables in the model.

9.1 Program Text

Note: the listing of the example program presented below uses ***bold italicised*** terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
