## **Limited Warranty**

The GPIB-VXI/C is warranted against defects in materials and workmanship for a period of one year from the date of shipment, as evidenced by receipts or other documentation. National Instruments will, at its option, repair or replace equipment that proves to be defective during the warranty period. This warranty includes parts and labor.

A Return Material Authorization (RMA) number must be obtained from the factory and clearly marked on the outside of the package before any equipment will be accepted for warranty work. National Instruments will pay the shipping costs of returning to the owner parts which are covered by warranty.

National Instruments believes that the information in this manual is accurate. The document has been carefully reviewed for technical accuracy. In the event that technical or typographical errors exist, National Instruments reserves the right to make changes to subsequent editions of this document without prior notice to holders of this edition. The reader should consult National Instruments if errors are suspected. In no event shall National Instruments be liable for any damages arising out of or related to this document or the information contained in it.

EXCEPT AS SPECIFIED HEREIN, NATIONAL INSTRUMENTS MAKES NO WARRANTIES, EXPRESS OR IMPLIED, AND SPECIFICALLY DISCLAIMS ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. CUSTOMER'S RIGHT TO RECOVER DAMAGES CAUSED BY FAULT OR NEGLIGENCE ON THE PART OF NATIONAL INSTRUMENTS SHALL BE LIMITED TO THE AMOUNT THERETOFORE PAID BY THE CUSTOMER. NATIONAL INSTRUMENTS WILL NOT BE LIABLE FOR DAMAGES RESULTING FROM LOSS OF DATA, PROFITS, USE OF PRODUCTS, OR INCIDENTAL OR CONSEQUENTIAL DAMAGES, EVEN IF ADVISED OF THE POSSIBILITY THEREOF. This limitation of the liability of National Instruments will apply regardless of the form of action, whether in contract or tort, including negligence. Any action against National Instruments must be brought within one year after the cause of action accrues. National Instruments shall not be liable for any delay in performance due to causes beyond its reasonable control. The warranty provided herein does not cover damages, defects, malfunctions, or service failures caused by owner's failure to follow the National Instruments installation, operation, or maintenance instructions; owner's modification of the product; owner's abuse, misuse, or negligent acts; and power failure or surges, fire, flood, accident, actions of third parties, or other events outside reasonable control.

## **Copyright**

Under the copyright laws, this publication may not be reproduced or transmitted in any form, electronic or mechanical, including photocopying, recording, storing in an information retrieval system, or translating, in whole or in part, without the prior written consent of National Instruments Corporation.

## **Trademarks**

NAT4882<sup>®</sup>, Turbo488<sup>®</sup>, MIGA<sup>™</sup>, and TIC<sup>™</sup> are trademarks of National Instruments Corporation.

Product names and company names listed are trademarks or trade names of their respective companies.

## **Warning Regarding Medical and Clinical Use of National Instruments Products**

National Instruments products are not designed with components and testing intended to ensure a level of reliability suitable for use in treatment and diagnosis of humans. Applications of National Instruments products involving medical or clinical treatment can create a potential for accidental injury caused by product failure, or by errors on the part of the user or application designer. Any use or application of National Instruments products for or involving medical or clinical treatment must be performed by properly trained and qualified medical personnel, and all traditional medical safeguards, equipment, and procedures that are appropriate in the particular situation to prevent serious injury or death should always continue to be used when National Instruments products are being used. National Instruments products are NOT intended to be a substitute for any form of established process, procedure, or equipment used to monitor or safeguard human health and safety in medical or clinical treatment.

## FCC/DOC Radio Frequency Interference Compliance

This equipment generates and uses radio frequency energy and, if not installed and used in strict accordance with the instructions in this manual, may cause interference to radio and television reception. This equipment has been tested and found to comply with the following two regulatory agencies:

### Federal Communications Commission

This device complies with Part 15 of the Federal Communications Commission (FCC) Rules for a Class A digital device. Operation is subject to the following two conditions:

1. This device may not cause harmful interference in commercial environments.
2. This device must accept any interference received, including interference that may cause undesired operation.

### Canadian Department of Communications

This device complies with the limits for radio noise emissions from digital apparatus set out in the Radio Interference Regulations of the Canadian Department of Communications (DOC).

Le présent appareil numérique n'émet pas de bruits radioélectriques dépassant les limites applicables aux appareils numériques de classe A prescrites dans le règlement sur le brouillage radioélectrique édicté par le ministère des communications du Canada.

### Instructions to Users

These regulations are designed to provide reasonable protection against harmful interference from the equipment to radio reception in commercial areas. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user will be required to correct the interference at his own expense.

There is no guarantee that interference will not occur in a particular installation. However, the chances of interference are much less if the equipment is installed and used according to this instruction manual.

If the equipment does cause interference to radio or television reception, which can be determined by turning the equipment on and off, one or more of the following suggestions may reduce or eliminate the problem.

- Operate the equipment and the receiver on different branches of your AC electrical system.
- Move the equipment away from the receiver with which it is interfering.
- Reorient or relocate the receiver's antenna.
- Be sure that the equipment is plugged into a grounded outlet and that the grounding has not been defeated with a cheater plug.

**Notice to user:** Changes or modifications not expressly approved by National Instruments could void the user's authority to operate the equipment under the FCC Rules.

If necessary, consult National Instruments or an experienced radio/television technician for additional suggestions. The following booklet prepared by the FCC may also be helpful: *How to Identify and Resolve Radio-TV Interference Problems*. This booklet is available from the U.S. Government Printing Office, Washington, DC 20402, Stock Number 004-000-00345-4.

# About This Manual

---

This manual contains information you will need to use the GPIB-VXI/C in your VXIbus system. It describes the function and behavior of GPIB-VXI/C units configured with the standard user firmware option.

## Organization of This Manual

The *GPIB-VXI/C User Manual* is organized as follows.

- Chapter 1, *General Description*, contains a brief overview of the GPIB-VXI/C and its VXIbus and GPIB capabilities. This chapter also contains an overview of the local command set, an introduction to Code Instruments (CIs), and a description of the front panel.
- Chapter 2, *Configuration and Startup Procedures*, contains information about the system configuration, GPIB-VXI/C configuration, and startup operation.
- Chapter 3, *Local Command Set*, contains descriptions of the GPIB-VXI/C local command set. The descriptions of the commands and queries include syntax, format and error handling information, as well as examples of the use of the commands and queries.
- Chapter 4, *Nonvolatile Configuration*, describes the method for editing and reviewing the contents of the nonvolatile memory, which is used for storing configuration information on the GPIB-VXI/C.
- Chapter 5, *Diagnostic Tests*, contains information for executing the GPIB-VXI/C diagnostic self-tests. The diagnostics test each GPIB-VXI/C subcircuit and are useful in detecting and isolating problems.
- Appendix A, *Code Instrument Overview*, contains an overview of the functions, applications, and implementations of software modules known as Code Instruments (CIs) and presents comparisons and illustrations of GPIB-VXI/C operation with and without CIs.
- Appendix B, *Using the DMAmove and CDS-852 Adapter Code Instruments*, contains instructions for installing and using the National Instruments-supplied Code Instruments (CI).
- Appendix C, *Specifications*, lists the specifications of the GPIB-VXI/C, such as physical dimensions and power requirements.
- Appendix D, *Connectors*, describes the connectors found on the GPIB-VXI/C.
- Appendix E, *Error Codes*, lists the local command set error codes and describes the error associated with each error code.
- Appendix F, *GPIB-VXI/C Trigger Support*, contains an overview of the VXI triggering capabilities of the GPIB-VXI/C.

- Appendix G, *Customer Communication*, contains forms you can use to request help from National Instruments or to comment on our products and manuals.
- The *Glossary* contains an alphabetical list of terms used in this manual, including abbreviations, acronyms, metric prefixes, mnemonics, and symbols.
- The *Index* contains an alphabetical list of key terms and topics used in this manual, including the page where you can find each one.

## Conventions Used in This Manual

Throughout this manual, the following conventions are used to distinguish elements of text:

*italic*                      Italic text denotes emphasis, a cross reference, or an introduction to a key concept. In this manual, italics are also used to denote Word Serial commands and queries.

monospace                 Text in this font denotes text or characters that are to be literally input from the keyboard, sections of code, command or query syntax, console responses, and syntax examples. This font is also used for the names of all commands and queries used in the GPIB-VXI/C local command set.

<CR>                        Angle brackets enclosing a term in Times font denote a key on the keyboard, or the equivalent ASCII character.

<hex value>              Angle brackets enclosing a term in monospace denote a parameter.

Numbers in this manual are base 10 unless noted as follows:

- Binary numbers are indicated by a -b suffix (for example, 11010101b)
- Octal numbers are indicated by an -o suffix (for example, 325o)
- Hexadecimal numbers are indicated by an -h suffix (for example, D5h)
- ASCII character and string values are indicated by double quotation marks (for example, "This is a string").

In this manual, the symbol <CR> is used to indicate the ASCII carriage return character. The symbol <LF> is used to indicate the ASCII linefeed character. The symbol <CRLF> is used to indicate a carriage return followed by a linefeed.

Terminology that is specific to a chapter or section is defined at its first occurrence.

## Related Documentation

The following documents contain information that you may find helpful as you read this manual:

- *16/32-Bit Highly Integrated Microprocessor SCC68070 User Manual*, Philips
- *GPIB-VXI/CP Software Reference Manual*, part number 320405-01
- *IEEE Standard Codes, Formats, Protocols, and Common Commands*, ANSI/IEEE Standard 488.2-1987

## Customer Communication

National Instruments wants to receive your comments on our products and manuals. We are interested in the applications you develop with our products, and we want to help if you have problems with them. To make it easy for you to contact us, this manual contains comment and configuration forms for you to complete. These forms are in Appendix G, *Customer Communication*, at the end of this manual.

# Chapter 1

## General Description

---

This chapter contains a brief overview of the GPIB-VXI/C and its VXIbus and GPIB capabilities. This chapter also contains an overview of the local command set, an introduction to Code Instruments (CIs), and a description of the front panel.

### Overview

The GPIB-VXI/C is a C-sized VXIbus module that links the industry standard IEEE-488 (GPIB) bus and the VXIbus. The GPIB-VXI/C performs transparent conversion of the GPIB signals and protocols to VXIbus signals and protocols, so that a GPIB Controller can control VXIbus instruments in the same way that it controls GPIB instruments. Figure 1-1 shows the GPIB-VXI/C interface module.

Figure 1-1. The GPIB-VXI/C Interface Module

The GPIB-VXI/C is factory configured to function as the system Resource Manager (RM). It performs the VXIbus startup configuration, self-test, and initialization functions, as well as VXIbus Slot 0-related services.

The RM and Slot 0 functions can be defeated individually so that the GPIB-VXI/C can coexist with another RM and/or be located in any slot.

## What Your Kit Should Contain

Your GPIB-VXI/C kit contains a GPIB-VXI/C module and documentation. The GPIB-VXI/C part number and serial number are printed on the label affixed to its shield casing.

**Note:** The full part number of the GPIB-VXI/C is determined by configuration options corresponding to the extension *-XYZM* in the part number. The *X*, *Y*, and *Z* options are described below. The *M* corresponds to the manufacturer.

<i>X</i>	68881 coprocessor option
	0 without coprocessor
	1 with coprocessor
<i>Y</i>	ROM option
	1 user firmware
	2 development firmware
	3 user firmware and EPROM expansion
	4 development firmware and EPROM expansion
<i>Z</i>	RAM option
	1 512 KB
	2 1 MB
	3 2 MB
	4 4 MB

## Optional Equipment

You can contact National Instruments to order any of the following cables.

- Type S5 serial port cable, 25-pin (2 m)
- Type S6 serial port cable, 9-pin (2 m)
- Type X2 double-shielded GPIB cables (1 m, 2 m, 4 m, or 8 m)

## Unpacking

Follow these steps when unpacking your GPIB-VXI/C:

1. Verify that the pieces contained in the package you received match the kit parts list. Do not remove the module from its plastic bag at this point.
2. Your GPIB-VXI/C module is shipped packaged in an antistatic plastic bag to prevent electrostatic damage to the module. Several components on the module can be damaged by electrostatic discharge. To avoid such damage while handling the module, touch the plastic bag to a metal part of your VXIbus mainframe chassis before removing the module from the bag.
3. Remove the module from the bag and inspect the module for loose components or any other sign of damage. Notify National Instruments if the module appears damaged in any way. *Do not* install a damaged module into your VXIbus mainframe.

## VXIbus Characteristics

The GPIB-VXI/C has the following VXIbus capabilities:

- Fully compatible with VXIbus System Specification
- VXIbus Resource Manager (RM) (defeatable)
- VXIbus Slot 0 support (defeatable)
- VXIbus Message-Based Commander and Message-Based Servant
- VXIbus master (A16, A24, D16, D08(EO))
- VXIbus slave (A16, A24, A32, D16, D08(EO))
- Up to 4 Megabytes of dual-ported (shared) memory
- Three programmable VXIbus interrupt handlers
- IEEE 488.1 and IEEE 488.2-compatible multiple primary or multiple secondary 488-VXIbus translator

## **GPIB Characteristics**

The GPIB-VXI/C has the following GPIB characteristics:

- Communication with VXIbus Message-Based devices
  - VXI logical addresses are mapped to GPIB addresses
  - Automatically configured at startup
  - Programmable
- Interface
  - NAT4882 and Turbo488 ASICs coupled with DMA
  - Full, transparent support of individual status bytes for each GPIB address
  - Buffered operation decouples GPIB and VXIbus operation
  - Controller can address one VXIbus device to talk and one or more other VXIbus devices to listen
- IEEE 488.1 capabilities
  - SH1 (Source Handshake)
  - AH1 (Acceptor Handshake)
  - T5, TE5 (Talker, Extended Talker): multiple primary or multiple secondary addressing
  - L3, LE3 (Listener, Extended Listener): multiple primary or multiple secondary addressing
  - SR1 (Service Request)
  - DC1 (Device Clear)
  - DT1 (Device Trigger)
  - RL0 (Remote Local)
  - PP0 (Parallel Poll)
- IEEE 488.2-compatible 488-VXIbus translation

The IEEE 488.1 capabilities are supported for all VXIbus devices associated with GPIB addresses. The IEEE 488.2 compatibility applies to 488.2-compatible VXIbus devices associated with GPIB addresses through the GPIB-VXI/C.

## Local Command Set Overview

The GPIB-VXI/C local command set supports the following types of operations:

- System configuration and control
  - Help
  - General configuration
  - RM information extraction
  - VXI-defined common ASCII system commands
  - Dynamic system configuration and reconfiguration
  - GPIB address configuration
  - VXIbus interrupt handler configuration
  - IEEE 488.2 common commands
- Instrument development and test
  - VXIbus access
  - Word Serial communication
- CI use and development
  - CI configuration

You can access the command set from the GPIB port, the serial port, and through Word Serial Protocol communication. You can also use separate programmable local command response modes for interactive and control program operation.

## Code Instruments

The GPIB-VXI/C can run software modules called *Code Instruments* or *CIs* that perform special functions in the VXIbus environment. Typical applications of CIs include:

- Translating and interpreting command language
- Creating virtual (hierarchical) instrument
- Implementing Message-Based interface for Register-Based devices and non-VXI devices

CIs can be implemented in three forms:

- As part of the National Instruments-supplied firmware (*Resident CIs*, or *RCIs*)
- As user-developed downloadable object code (*Downloaded CIs*, or *DCIs*)
- As user-add-on firmware (*EPROMed CIs*, or *ECIs*)

For more information about CI capabilities and applications, see Appendix A, *Code Instrument Overview*.

## Front Panel Features

The GPIB-VXI/C has the following front panel features:

- Five front panel LEDs
  - *SYSFAIL* LED reflects the status of the backplane *SYSFAIL\** signal and indicates that a VXIbus device in the system has failed.
  - *FAILED*, *TEST*, and *ON LINE* LEDs indicate the current status of the GPIB-VXI/C.
  - *ACCESS* LED indicates when the GPIB-VXI/C is accessed from GPIB or VXIbus or when its *MODID* is asserted.
- Five front panel connectors
  - GPIB interface
  - Serial port
  - Trigger input
  - Trigger output
  - External CLK10 I/O
- Configurable reset pushbutton
  - Pushbutton resets backplane
  - Pushbutton resets GPIB-VXI/C
  - Pushbutton resets both backplane and GPIB-VXI/C

# Chapter 2

## Configuration and Startup Procedures

---

This chapter contains information about the system configuration, GPIB-VXI/C configuration, and startup operation.

### System Configuration

The typical system includes the following components:

- A VXIbus system mainframe containing the GPIB-VXI/C and instrument modules
- A host computer with a GPIB interface module and associated driver software (available for many computers from National Instruments) connected to the GPIB-VXI/C GPIB port
- A dumb terminal or host running a terminal emulator connected to the GPIB-VXI/C serial port (optional)

The serial port settings are 9600 baud, 8-bit data, no parity, and one stop bit. Refer to Appendix D, *Connectors*, for descriptions of the RS-232 serial connector and the GPIB interface connector.

Cables for connecting the GPIB-VXI/C serial port to an RS-232 terminal or COM1 port on an IBM PC-compatible computer are available from National Instruments (see *Optional Equipment* in Chapter 1).

## GPIB-VXI/C Configuration

The GPIB-VXI/C factory configuration is shown in Table 2-1. The RAM, firmware and coprocessor are configured according to the GPIB-VXI/C purchase options.

Table 2-1. GPIB-VXI/C Factory Configuration

Function	Factory Configuration
Startup Mode	488-VXI Runtime System Mode
VXIbus Characteristics Resource Manager (RM) Logical Address Servant Area Size Shared Memory Address Modifiers	Enabled 0 0 0% of Installed Memory Supervisor A16, Supervisor A24 data
VXIbus Slot 0 Services CLK10 Driver CLK10 Source SYSCLK Driver Priority Arbiter Bus Timeout	Enabled Onboard Clock Enabled Enabled Enabled (BTO $\geq 250 \mu\text{sec}$ )
Bus Requester	Level 3
VXI Interrupt Handlers	Unassigned
GPIB Addressing Mode	Multiple Secondary Addressing
GPIB-VXI/C GPIB Primary Address	1
Serial Port System Startup Messages Console Local Command Port Discrete Fault Indicator (DFI)	Disabled Enabled Normally Open
Front Panel BNC Termination External Clock Input External Trigger Input	Unterminated Unterminated

You do not have to change the GPIB-VXI/C factory configuration to use it as a Slot 0 Resource Manager. The following pages describe the factory configuration settings and present alternate configurations.

Figure 2-1 shows the location of the GPIB-VXI/C configurable components and their physical location relative to some of the major circuit components. The jumpers and switches are represented in their factory default positions.

**Note:** The GPIB-VXI/C is housed in a metal enclosure that has cut-outs for access to all switches and jumpers associated with Slot 0/Non-Slot 0 settings, start-up mode, and Shared RAM settings. Under normal circumstances, you should not find it necessary to open the enclosure.

Figure 2-1. GPIB-VXI/C Parts Locator Diagram

## Setting the Logical Address, GPIB Primary Address, and Servant Area Size

You can change the logical address, GPIB primary address, and Servant area size by running the nonvolatile memory configuration utility as described in the *Change Configuration Information* section of Chapter 4, *Nonvolatile Configuration*.

## Verifying the Installed RAM Size

Up to 4 megabytes of local RAM can be factory-installed on the GPIB-VXI/C. The minimum amount of memory is 512 kilobytes. Table 2-2 lists the RAM configurations and their associated switch settings. You can use this information to verify the board configuration.

Table 2-2. Installed RAM Configuration

Installed Memory Size	Switch S7 Setting	Switch S5 Setting	Jumper W6 Setting
512 kilobytes	OFF	OFF	OFF
1 megabyte	OFF	ON	OFF
2 megabytes	ON	OFF	ON
4 megabytes	ON	ON	ON

Table 2-3 shows the relationship between the amount of installed memory, the local address range occupied by the memory, and the range of VXI A24 addresses accessible by the GPIB-VXI/C as a bus master.

Table 2-3. GPIB-VXI/C CPU Local and A24 Memory Ranges

Installed Memory Size	Installed Memory Local Address Range		Accessible VXI A24 Address Range	
	Start	End	Start	End
512 kilobytes	000000h	07FFFFh	080000h	E7FFFFh
1 megabyte	000000h	0FFFFFFh	100000h	E7FFFFh
2 megabytes	000000h	1FFFFFFh	200000h	E7FFFFh
4 megabytes	000000h	3FFFFFFh	400000h	E7FFFFh

## Setting the Shared Memory Size

You can set the amount of installed memory that is shared with the VXIbus by altering the settings of switches S8 and S6. Table 2-4 gives the S8 and S6 switch settings for sharing various portions of RAM with the VXIbus for each possible installed memory configuration.

Table 2-4. Shared Memory Switch Settings

Installed Memory Size	Amount of Installed Memory Shared with VXIbus			
	S6 ON S8 ON	S6 ON S8 OFF	S6 OFF S8 ON	S6 OFF S8 OFF
<b>512 kilobytes</b>	512 kilobytes	256 kilobytes	128 kilobytes	none
<b>1 megabyte</b>	1 megabyte	512 kilobytes	256 kilobytes	none
<b>2 megabytes</b>	2 megabytes	1 megabyte	512 kilobytes	none
<b>4 megabytes</b>	4 megabytes	2 megabytes	1 megabyte	none

**Note:** The RAM shared with the VXIbus will be the upper portion of the installed memory.

The GPIB-VXI/C Offset Register holds the shared memory VXI A24 base address, as described in the VXIbus specification. The RM automatically configures the Offset Register at startup.

## Setting the Reset Operation

The GPIB-VXI/C has three configurable reset parameters. They can be enabled or disabled and are as follows:

- Pushbutton resets backplane (asserts SYSRESET\* signal).
- Pushbutton resets GPIB-VXI/C (asserts local reset signal).
- Backplane SYSRESET\* signal resets GPIB-VXI/C (SYSRESET\* on backplane asserts local reset).

The reset parameters can be altered by the nonvolatile memory configuration as described in the *Change Configuration Information* section of Chapter 4.

## Setting the VXIbus Requester Level

You can change the VXIbus requester level of the GPIB-VXI/C by moving the jumpers on jumper blocks W1, W2, W3, W4, and W5 as shown in Figure 2-2. The GPIB-VXI/C is configured at the factory to be a Level 3 requester.

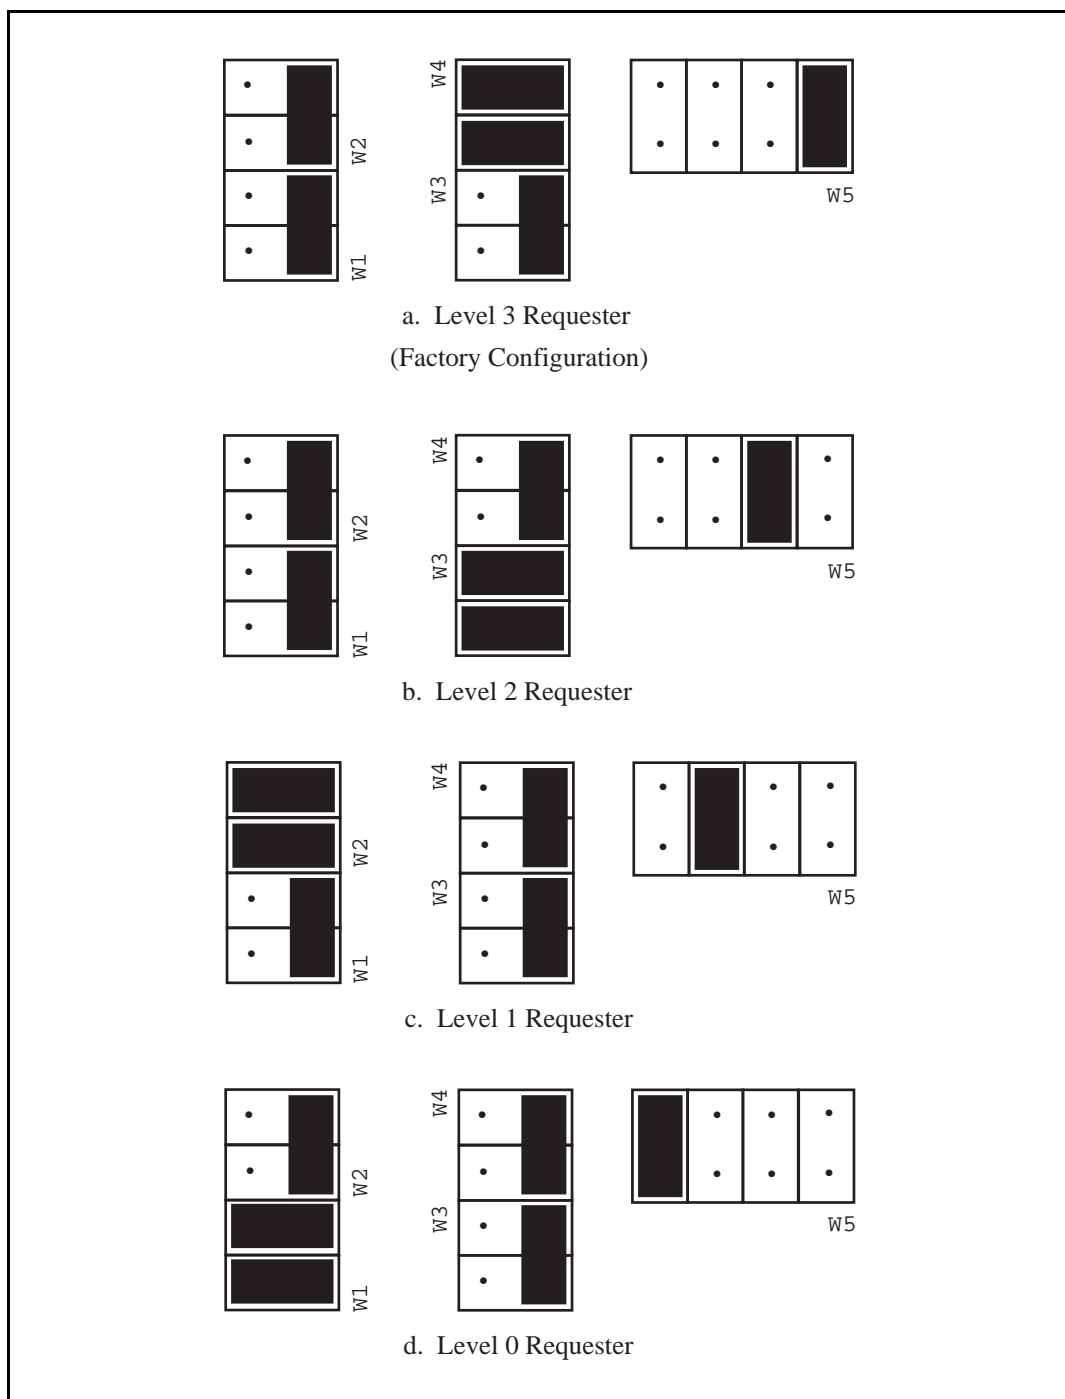

Figure 2-2. VXIbus Requester Jumper Settings

## Setting the VXI Interrupt Handler Levels

As part of the hardware capabilities on the GPIB-VXI/C, there are three VXI programmable interrupt handlers. They can be assigned dynamically by the RM or statically according to the contents of the nonvolatile memory as described in Chapter 4.

### External Input Termination

Switches S15 and S16 enable a 50-ohm termination to ground for the external trigger and external clock inputs, respectively. The GPIB-VXI/C is factory-configured with the termination disabled for both the external trigger and the external clock inputs. Figure 2-3 shows the settings required to enable or disable the termination on the external trigger. Figure 2-4 shows the settings required to enable or disable the termination on the external clock.

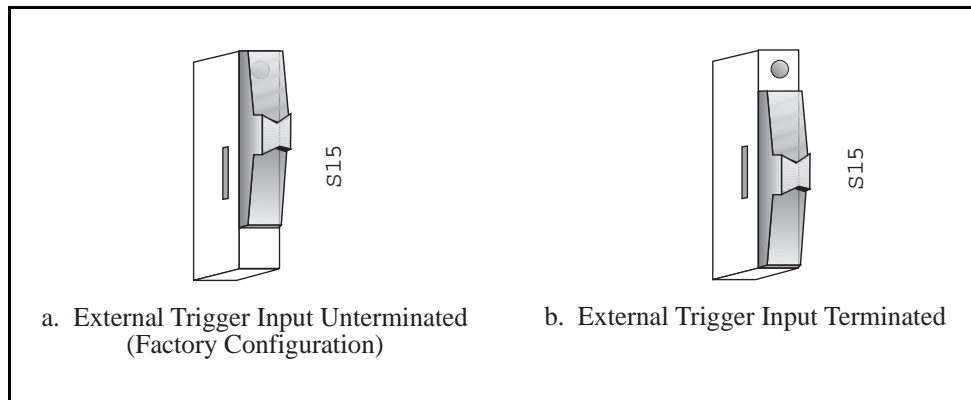

Figure 2-3. External Trigger Input Termination

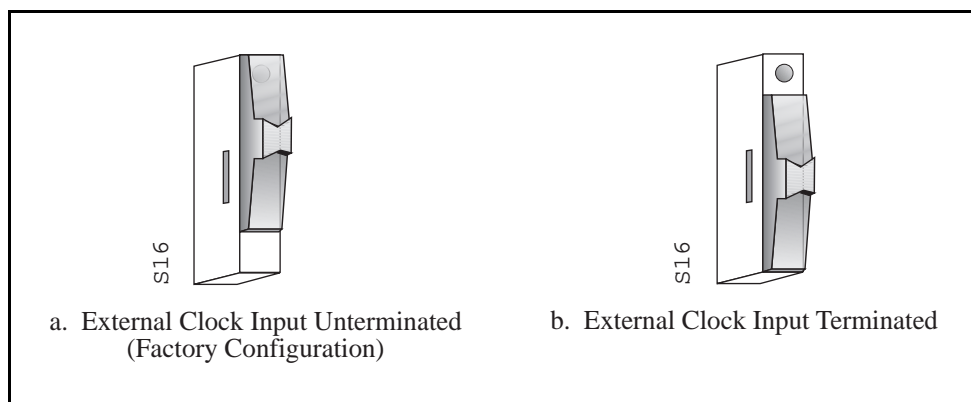

Figure 2-4. External Clock Input Termination

## EPROM Configuration

The amount of read-only memory (ROM) in the GPIB-VXI/C can vary from 512 kilobytes to 1 megabyte. The standard configuration consists of 512 kilobytes of EPROM, which is used for the operating firmware. In addition, you can order an EPROM expansion option that will give you an additional 512 kilobytes of EPROM space. The EPROM expansion option contains four sockets and four switches that you can use to install your own user-developed code.

The EPROM expansion sockets accommodate combinations of 2764, 27128, 27256, 27512, and 27010 EPROMs. Table 2-5 lists the possible EPROM memory configurations. Bank 2 has a base address of E80000h and Bank 3 starts at EC0000h. The maximum EPROM expansion memory size is 512 kilobytes.

Table 2-5. Expansion EPROM Configurations

EPROM Size	BANK 2 (U84, U85)	BANK 3 (U94, U95)	S21	S23	S20	S22	End Address
16K	2764	None	OFF	OFF	OFF	OFF	E83FFFh
32K	27128	None	OFF	OFF	OFF	OFF	E87FFFh
64K	27256	None	OFF	ON	OFF	OFF	E8FFFFh
128K	27512	None	ON	ON	OFF	OFF	E9FFFFh
256K	27010	None	ON	ON	OFF	OFF	EBFFFFh
272K	27010	2764	ON	ON	OFF	OFF	EC3FFFh
288K	27010	27128	ON	ON	OFF	OFF	EC7FFFh
320K	27010	27256	ON	ON	OFF	ON	ECFFFFh
384K	27010	27512	ON	ON	ON	ON	EDFFFFh
512K	27010	27010	ON	ON	ON	ON	EFFFFFFh

When you insert EPROMs into the expansion EPROM slots, orient them according to the silkscreen printed on the board as shown in Figure 2-1. The 2764, 27128, 27256 and 27512 EPROMs have fewer pins than the expansion sockets. In these cases, align the *bottom* pins of the EPROM with the *bottom* pins of the socket, leaving the top pins open, as illustrated in Figure 2-5.

**Warning:** Improper EPROM installation can result in damage to the EPROM, the GPIB-VXI/C, or both.

Figure 2-5. EPROM Insertion Position

## Discrete Fault Indicator Configuration

The GPIB-VXI/C comes with a MATE-compatible Discrete Fault Indicator (DFI). The GPIB-VXI/C monitors the status of the VXIbus SYSFAIL\* signal and relays the status to pins 1 and 6 of the RS-232 serial port (see Appendix D, *Connectors*, in the back of this manual).

As shown in Figure 2-6 and Table 2-6, switch S18 determines the relationship between the SYSFAIL\* signal and the serial port pins. If S18 is in the OFF position, the GPIB-VXI/C DFI is set to the normally open mode. Therefore, if SYSFAIL\* is not asserted while the backplane is powered up, pins 1 and 6 will present an electrical open-circuit. In contrast, if the backplane is unpowered or SYSFAIL\* is asserted, pins 1 and 6 will present an electrical short-circuit.

If S18 is in the ON position, the GPIB-VXI/C DFI is set to the normally closed mode. Therefore, if SYSFAIL\* is not asserted while the backplane is powered-up, pins 1 and 6 will present an electrical short-circuit. In contrast, if the backplane is unpowered or SYSFAIL\* is asserted, pins 1 and 6 will present an electrical open-circuit.

Figure 2-6. Discrete Fault Indicator Configuration

Table 2-6. Discrete Fault Indicator Options

Switch S18	Power	SYSFAIL	Pins 1 & 6
OFF Figure 2-6(a)	OFF ON ON	N/A Asserted Unasserted	Short-Circuit Short-Circuit Open-Circuit
ON Figure 2-6(b)	OFF ON ON	N/A Asserted Unasserted	Open-Circuit Open-Circuit Short-Circuit

## Address Modifier Configuration

By setting onboard switches you can have the GPIB-VXI/C specify the state of the VXIbus Address Modifiers during a VXI master access. During A16 accesses the lines AM5, AM4, and AM3 are needed high, low, and high, respectively, and AM1 is needed low. During A24 accesses the lines AM5, AM4, and AM3 are all needed high. The GPIB-VXI/C drives the upper three address modifier lines appropriately for every access. You should configure the GPIB-VXI/C to drive the lower three address modifier lines as needed.

Switches S1, S4, and S9 control the AM2, AM1, and AM0 signals. Figure 2-7 shows the valid settings of S1, S4, and S9.

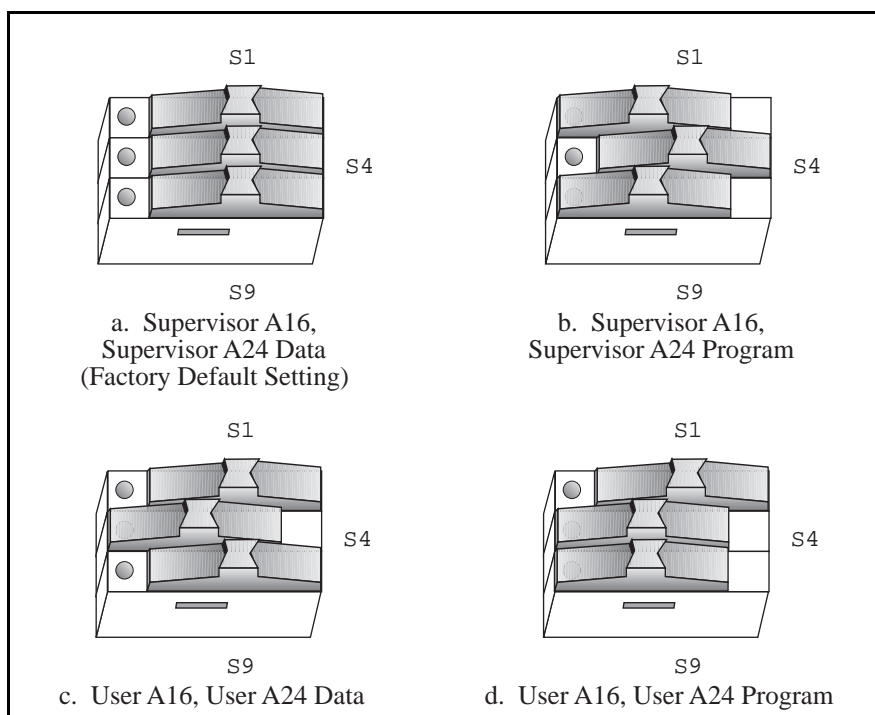

Figure 2-7. Address Modifier Signals Switch Settings

## GPIB-VXI/C Startup Mode Configuration

Startup mode switches S13 and S12 control the GPIB-VXI/C operation mode at system startup. They select one of four modes, as shown in Figure 2-8. The four possible modes of startup are 488-VXI runtime system mode, nonvolatile configuration mode, diagnostics mode, and VXI pROBE mode.

- *488-VXI runtime system mode* is the startup mode for normal operation in a VXI system. The GPIB-VXI/C is configured at the factory to start up in this mode. The remainder of this chapter contains a description of operation in this mode.
- In *nonvolatile configuration mode*, you can edit the contents of the nonvolatile configuration parameter memory. See Chapter 4 for more information on the nonvolatile configuration mode of the GPIB-VXI/C.
- In *diagnostics mode*, you can perform extensive offline diagnostic tests on the GPIB-VXI/C. See Chapter 5, *Diagnostic Tests*, for a description of the GPIB-VXI/C self-tests.
- In *VXI pROBE mode*, you can use the enhanced pROBE debugger. This mode is available only with the GPIB-VXI/C development firmware option. If you select this mode on a GPIB-VXI/C with the user firmware option, it will enter the 488-VXI runtime system mode. Refer to the *GPIB-VXI/CP Software Reference Manual*, part number 320405-01, for a description of how to use the VXI pROBE debugger.

Figure 2-8. Startup Mode Switch Settings

## 488-VXI Runtime System Operation

The GPIB-VXI/C is factory configured as a Slot 0 Resource Manager. The Slot 0 and Resource Manager (RM) functions can be independently defeated, resulting in four modes of operation:

- Slot 0 Resource Manager (factory configuration)
- Non-Slot 0 Resource Manager
- Non-Slot 0 Message-Based device (non-Resource Manager)
- Slot 0 Message-Based device (non-Resource Manager)

This section describes the GPIB-VXI/C configuration procedures and startup behavior for each mode of operation.

**Warning:** Never install a GPIB-VXI/C configured for Non-Slot 0 operation in Slot 0 or a GPIB-VXI/C configured for Slot 0 operation in any slot other than Slot 0. Doing so can damage the GPIB-VXI/C, the mainframe, or other modules.

### System Startup Message Printing

The serial port startup printout enable switch S11 controls whether or not VXI system startup messages are printed to the serial port, as shown in Figure 2-9. The factory default configuration disables this function.

Figure 2-9. VXI System Startup Message Switch Settings

## Slot 0 Resource Manager Configuration

You can configure the GPIB-VXI/C for Slot 0 Resource Manager operation by enabling the VXIbus Slot 0 functions and setting the logical address to 0, as shown in Table 2-7.

Table 2-7. Slot 0 Resource Manager Operation Switch and Jumper Settings

Jumper/Switch	Position	Function
CLK10 jumpers	See Figure 2-10.	CLK10 sourcing for backplane is enabled.
Switches S14 and S17	See Table 2-8.	CLK10 routing options.
Switch S3	ON	VXI BTO enabled.
Switch S19	ON	MODID pulled up.
Switch S2	ON	Bus arbiter and SYSCLK enabled.
Logical Address	See Chapter 4.	Logical address is 0. Set in nonvolatile configuration.
Slot 0 Model Code	See Chapter 4.	Model code is set to the Slot 0 value. Set in nonvolatile configuration.

Table 2-8. CLK10 Routing Options

Switch S14	Switch S17	Function
OFF	OFF	CLK10 sourced from onboard clock.
OFF	ON	CLK10 and EXT CLK connector sourced from onboard clock.
ON	OFF	CLK10 sourced from an external clock via the EXT CLK connector.
ON	ON	Invalid. Do not use this setting.

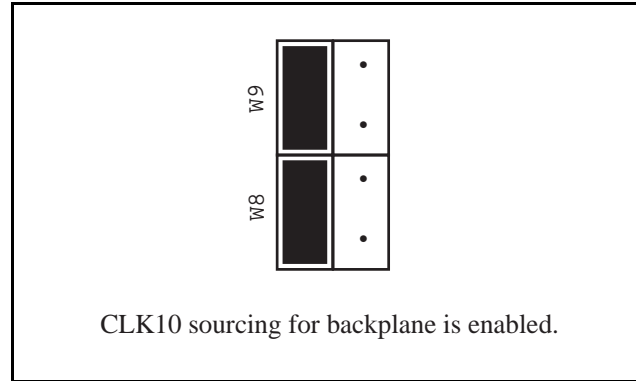

Figure 2-10. CLK10 Jumper Settings for Slot 0 Resource Manager Operation

### Slot 0 Resource Manager Operation

At startup, a GPIB-VXI/C configured as a Slot 0 Resource Manager performs its self-tests, executes the RM functions, and then enters its normal mode of operation.

### Front Panel LED Indications for RM Operation

The five front panel LEDs are *SYSFAIL*, *FAILED*, *TEST*, *ON LINE*, and *ACCESS*. The GPIB-VXI/C uses the *FAILED*, *TEST*, and *ON LINE* LEDs to indicate the progress of its self-initialization, self-test, and RM functions. The LED indications are shown in Table 2-9. A successful system startup will sequence through the first five states. The point of failure is indicated for states in which the *FAILED* LED is lit for an extended period of time. The LED indications are identical for Slot 0 Resource Manager and Non-Slot 0 Resource Manager operation.

Table 2-9. Front Panel LED Indications for RM Operation

Sequence	FAILED	TEST	ON LINE	State	Point of Failure
1	OFF	OFF	OFF	No power	
2	ON	OFF	OFF	In self-initialization	Failed before self-test
3	ON	ON	OFF	In self-test	Failed in self-test
4	OFF	ON	ON	Performing RM	
5	OFF	OFF	ON	Online	
	ON	ON	ON	Failed	Failed while in RM
	ON	OFF	ON	Failed	Failed while online
	OFF	ON	OFF	In VXI pROBE, nonvolatile configuration, or diagnostics mode	

The *SYSFAIL* LED is lit whenever any device in the system is asserting the VXIbus *SYSFAIL*\* signal.

The *ACCESS* LED flashes whenever the GPIB-VXI/C is accessed from the GPIB or from the VXIbus. It also indicates when its *MODID* is asserted.

### Self-Test Operation

The self-test sequence tests the basic functionality of many GPIB-VXI/C components, including EPROM, RAM, I<sup>2</sup>C bus, RS-232 port, DMA channels, GPIB port, interrupt logic, timer, and VXIbus registers (MIGA). You can execute full tests of the GPIB-VXI/C in diagnostics mode, as described in Chapter 5.

## RM Operation

The RM waits until all devices have stopped driving the VXIbus SYSFAIL\* signal, or until five seconds have elapsed after the VXIbus SYSRESET\* signal is negated. During this period, all of the VXIbus devices in the system should have completed their self-tests.

**Note:** You can configure the GPIB-VXI/C to wait for any number of seconds before RM operations begin.

The RM then scans Logical Addresses 1 through 254 for *static configuration devices (SC devices)*. For each SC device found, it reads the device class and manufacturer's ID code from the ID Register and the model code from the Device Type Register. If the device is an extended device, the RM reads its Subclass Register. The RM then performs slot associations for each static configuration device by reading its Status Register while asserting each MODID line.

The RM then looks for *dynamic configuration devices (DC devices)* at Logical Address 255 by asserting each MODID line and reading the device's ID Register. DC devices initially have a logical address of 255. The RM subsequently assigns each DC device a different logical address. For each DC device found, it not only reads the device's configuration registers as with SC devices, but also assigns each device the next unused logical address by writing the appropriate value to the device's Logical Address Register. Using the nonvolatile configuration mode, you can set the starting logical address for the RM to begin assigning DC devices. Refer to Chapter 4 for more information on nonvolatile configuration.

If any device has not passed its self-test, the RM forces that device offline by setting the Sysfail Inhibit and Reset bits in that device's Control Register.

The RM then determines the address space of each device by reading its ID Register. If the device's address space is A16/A24 or A16/A32, the RM allocates a section of A24 or A32 memory space to the device according to the memory requirements indicated by the contents of its Device Type Register and writes an appropriate value to the device's Offset Register.

The RM configures the initial Commander/Servant hierarchy according to each Commander's Servant area size, using the algorithm described in the VXIbus specification. The RM issues the appropriate *Read Servant Area* and *Device Grant* commands to each SC Commander. The RM retains all devices not assigned to other Commanders as its immediate Servants. Regardless of where DC device logical addresses are assigned, they are never granted to an SC Commander. The DC Commander/Servant hierarchy can be created in one of two ways:

1. All DC devices can be automatically assigned as Servants of Logical Address 0 (the Resource Manager).
2. A custom hierarchy can be created through the use of the local command set functions, as described in the *DC Commands and Queries* section of Chapter 3, *Local Command Set*.

The RM then sends the *Read Protocols* query to all Message-Based devices. The response to the query is saved internally for later use in interrupt handler and GPIB configuration.

The RM configures the VXI interrupter and interrupt handlers using a seven-entry table contained in nonvolatile configurations. During the VXI interrupt configuration, the RM assigns interrupt levels to all Programmable Handlers (PH) and Programmable Interrupters (PI). Each entry in the table represents the logical address of the handler that handles the corresponding level (1 through 7). If the handler is static, PI Servants are assigned to the level. If the device is a PH device, the RM assigns both it and any PI Servants to the corresponding level. Notice that

if the table entry is FFh, the level is free to be assigned to any PH device. If only PH and PI devices are in a system, all entries may contain FFh. See Chapter 4 for more complete details.

The remainder of the RM procedure depends upon whether the RM found any DC devices in the system.

### Static Configuration Operation

When all of the previous operations are complete and successful, the RM sends the Word Serial command *Identify Commander* to all immediate Message-Based Servants with bus master capability. At this point, the RM is ready to bring the system into the Normal Operation sub-state. This is accomplished by sending the Word Serial query *Begin Normal Operation* to all top-level Commanders and immediate Message-Based Servants.

### Dynamic Configuration Operation

If the system is a DC system (at least one DC device was found), and the nonvolatile configuration specifies that the RM should create a hierarchy with DC devices assigned to Logical Address 0, the RM follows the same steps as previously described in the *Static Configuration Operation* section. DC devices are treated as SC devices from this point on.

However, if you want to customize your own DC hierarchy and the nonvolatile configuration specifies that the RM not finish configuring the hierarchy, the GPIB-VXI/C RM does not send *Identify Commander* or *Begin Normal Operation* to any devices, either static or dynamic. The outside controller (or EPROMed CI) can then create the DC Commander/Servant hierarchy without having to dynamically reconfigure the system. Use the GPIB-VXI/C local command *DCGrantDev* to create the DC hierarchy. When the system is configured and ready to make a transition to the Normal Operation sub-state, send the GPIB-VXI/C local command *DCBNOSend*. *DCBNOSend* sends the *Identify Commander* and *Begin Normal Operation* commands to Message-Based devices as previously described in the *Static Configuration Operation* section. See the *DC Commands and Queries* section of Chapter 3 for further information about dynamic configuration operation.

The GPIB-VXI/C then performs general configuration operations. The GPIB-VXI/C creates GPIB address links for its immediate Message-Based SC Servants. After this, the GPIB-VXI/C RM and general configuration operations are complete.

### GPIB Address Assignment

The GPIB-VXI/C automatically assigns GPIB addresses (primary or secondary) to itself and to each of its immediate Message-Based SC Servants. If the Message-Based device does not support minimal Word Serial[I] or VXIbus 488.2[I4] capabilities, no GPIB address link is created. The GPIB-VXI/C assigns a GPIB address to each device according to the top five bits of its logical address. For example, the GPIB address of a device with Logical Address 96 (01100000b) would be 12 (01100b).

If two or more devices have logical addresses with the same top five bits, the GPIB-VXI/C assigns GPIB addresses to devices in order of the least significant three bits. Conflicting devices are given the next available GPIB address. For example, if the GPIB-VXI/C and its Message-

Based Servants have Logical Addresses 0, 24, 27, and 33, the GPIB-VXI/C assigns GPIB addresses as shown in Table 2-10.

Table 2-10. Example GPIB Address Assignment

Logical Address		3 LSB (Order of Assignment)	5 MSB	GPIB Address
Decimal	Binary	Binary	Binary	Decimal
0	00000000b	000b	00000b	0
24	00011000b	000b	00011b	3
33	00100001b	001b	00100b	4
27	00011011b	011b	00011b	5

In the example shown in Table 2-10, the device at Logical Address 27 was assigned GPIB Address 5 because addresses 3 and 4 were previously assigned. By spacing the GPIB-VXI/C Message-Based Servants at intervals of eight logical address locations you can avoid situations in which removing or adding one device changes the GPIB address of another device.

The default configuration for the GPIB-VXI/C is to use multiple GPIB secondary addresses (not multiple primary addresses). You can change the configuration to use multiple primary addresses through nonvolatile memory configuration as described in the *Change Configuration Information* section of Chapter 4.

You can change the self-assigned default GPIB address of the GPIB-VXI/C through the nonvolatile memory configuration as described in the *Change Configuration Information* section of Chapter 4. The default GPIB address of the GPIB-VXI/C when configured for multiple secondary addresses is Secondary Address 0 (Primary Address 1). The default GPIB address of the GPIB-VXI/C when configured for multiple primary addresses is Primary Address 1 (no secondary address).

At times, especially when using multiple primary addressing, you may find it necessary to avoid particular GPIB addresses to avoid conflicts with GPIB instruments outside of the VXI mainframe. You can specify what GPIB addresses to avoid through the nonvolatile memory configuration as described in the *Change Configuration Information* section of Chapter 4.

### System Configuration Table

During the execution of the RM and general configuration operations, the GPIB-VXI/C builds up a table of system configuration information. Each device has an entry in the table containing the device's logical address, its Commander's logical address, its GPIB address, slot number, device class, manufacturer ID number, model code, memory space requirement, memory base address, and memory size. The GPIB-VXI/C retains this table after the RM and general configuration operations are complete. The information in the table is accessible through the GPIB-VXI/C local command set. The GPIB address entry is meaningful only for immediate Message-Based Servants of the GPIB-VXI/C.

### Non-Slot 0 Resource Manager Configuration

Follow these steps to configure the GPIB-VXI/C for Non-Slot 0 Resource Manager operation. See Table 2-11.

1. Disable the VXIbus Slot 0 hardware functions.
2. Set the model code of the GPIB-VXI/C to be configured for Non-Slot 0 operation using the nonvolatile configuration mode.
3. Set the logical address to 0 in nonvolatile configuration mode.

Table 2-11. Non-Slot 0 Resource Manager Operation Switch and Jumper Settings

Jumper/Switch	Position	Function
CLK10 jumpers	See Figure 2-11.	CLK10 receiving from backplane is enabled.
Switch S17		If S17 is ON, the GPIB-VXI/C also routes CLK10 to the EXT CLK connector on the front panel.
Switch S3	OFF	VXI BTO disabled.
Switch S19	OFF	MODID pulled down.
Switch S2	OFF	Bus arbiter and SYSCLK disabled.
Logical Address	See Chapter 4.	Logical address is 0. Set in nonvolatile configuration.
Non-Slot 0 Model Code	See Chapter 4.	Model code is set to the Non-Slot 0 value. Set in nonvolatile configuration.

Figure 2-11. CLK10 Jumper Settings for Non-Slot 0 Resource Manager Operation

## Non-Slot 0 Resource Manager Operation

The startup sequence for a GPIB-VXI/C configured for Non-Slot 0 Resource Manager operation is nearly identical to the Slot 0 Resource Manager operation. In Non-Slot 0 RM operation, however, the GPIB-VXI/C controls the Slot 0 resources remotely.

A VXIbus Slot 0 device must be in the system. It must be either a Register-Based device that implements the MODID Register, or a Message-Based device that supports the Word Serial commands *Read MODID*, *Set Lower MODID*, and *Set Upper MODID*. VXIbus Specification Revision 1.2 Message-Based Slot 0 devices are *not* supported.

## Non-Slot 0 Message-Based Device Configuration (Non-Resource Manager)

Follow these steps to configure the GPIB-VXI/C for Non-Slot 0 Message-Based operation. See Table 2-12.

1. Disable the VXIbus Slot 0 functions.
2. Set the model code of the GPIB-VXI/C to be configured for Non-Slot 0 operation using the nonvolatile configuration mode.
3. Set the logical address to a non-zero value with an appropriate Servant area size using the nonvolatile configuration mode.

If the logical address is set to FFh, the GPIB-VXI/C will participate in dynamic configuration. Otherwise, the GPIB-VXI/C is a static configuration device.

Table 2-12. Non-Slot 0 Message-Based Device Operation Switch and Jumper Settings

Jumper/Switch	Position	Function
CLK10 jumpers	See Figure 2-12.	CLK10 receiving from backplane is enabled.
Switch S17		If S17 is ON, the GPIB-VXI/C sources CLK10 at the front panel EXT CLK connector.
Switch S3	OFF	VXI BTO disabled.
Switch S19	OFF	MODID pulled down.
Switch S2	OFF	Bus arbiter and SYSCLK disabled.
Logical Address	See Chapter 4.	Logical address is not equal to 0. Set in nonvolatile configuration.
Non-Slot 0 Model Code	See Chapter 4.	Model code is set to the Non-Slot 0 value. Set in nonvolatile configuration.
Servant Area Size	See Chapter 4.	Set appropriate Servant area size. Set in nonvolatile configuration.

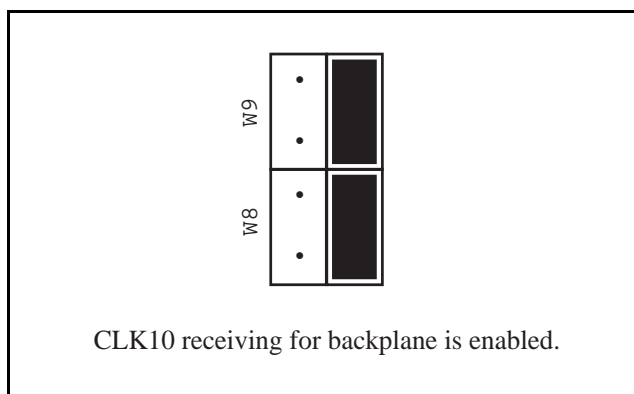

Figure 2-12. CLK10 Jumper Settings for Non-Slot 0 Message-Based Device Operation

### Non-Slot 0 Message-Based Device Operation

At startup, a GPIB-VXI/C configured as a Non-Slot 0 Message-Based device performs its self-tests. It then waits until it receives its *Device Grant* and *Begin Normal Operation* Word Serial commands. The RM grants any logical addresses to the GPIB-VXI/C that reside within its Servant area. When it responds to the *Begin Normal Operation* command, the GPIB-VXI/C enters its normal mode of operation.

### Front Panel LED Indications for Message-Based Device Operation

The GPIB-VXI/C indicates the progress of its self-test with the *FAILED*, *TEST*, and *ON LINE* LEDs. The LED indications are shown in Table 2-13. A successful system startup sequences through the first five states. The point of failure is indicated for states in which the *FAILED* LED is lit for an extended period of time. The LED indications are identical for Non-Slot 0 Message-Based device and Slot 0 Message-Based device operation.

Table 2-13. Front Panel LED Indications for Message-Based Device Operation

Sequence	FAILED	TEST	ON LINE	State	Point of Failure
1	OFF	OFF	OFF	No power	
2	ON	OFF	OFF	In self-initialization	Failed before self-test
3	ON	ON	OFF	In self-test	Failed in self-test
4	OFF	ON	ON	Waiting for BNO	
5	OFF	OFF	ON	Online	
	ON	OFF	ON	Failed	Failed while online
	OFF	ON	OFF	In VXI pROBE, nonvolatile configuration, or diagnostics mode	

## Slot 0 Message-Based Device Configuration

Follow these steps to configure the GPIB-VXI/C for Slot 0 Message-Based operation. See Table 2-14.

1. Enable the VXIbus Slot 0 functions.
2. Set the model code of the GPIB-VXI/C to be configured for Slot 0 operation using the nonvolatile configuration mode.
3. Set the logical address to a non-zero value with an appropriate Servant area size.

If the logical address is set to FFh, the GPIB-VXI/C will participate in dynamic configuration. Otherwise, the GPIB-VXI/C is a static configuration device.

Table 2-14. Slot 0 Message-Based Device Operation Switch and Jumper Settings

Jumper/Switch	Position	Function
CLK10 jumpers	See Figure 2-13.	CLK10 sourcing for backplane is enabled.
Switches S14 and S17	See Table 2-15.	CLK10 routing options.
Switch S3	ON	VXI BTO enabled.
Switch S19	ON	MODID pulled up.
Switch S2	ON	Bus arbiter and SYSCLK enabled.
Logical Address	See Chapter 4.	Logical address is not equal to 0. Set in nonvolatile configuration.
Slot 0 Model Code	See Chapter 4.	Model code is set to the Slot 0 value. Set in nonvolatile configuration.
Servant Area Size	See Chapter 4.	Set appropriate Servant area size. Set in nonvolatile configuration.

Table 2-15. CLK10 Routing Options

Switch S14	Switch S17	Function
OFF	OFF	CLK10 sourced from onboard clock.
OFF	ON	CLK10 and EXT CLK connector sourced from onboard clock.
ON	OFF	CLK10 sourced from an external clock via the EXT CLK connector.
ON	ON	Invalid. Do not use this setting.

Figure 2-13. CLK10 Jumper Settings for Slot 0 Message-Based Device Operation

### Slot 0 Message-Based Device Operation

At startup, a GPIB-VXI/C configured as a Slot 0 Message-Based device performs its self-tests. It then waits until it receives its *Device Grant* (if any) and *Begin Normal Operation* Word Serial commands. The RM grants any logical addresses to the GPIB-VXI/C that reside within its Servant area. When the GPIB-VXI/C responds to the *Begin Normal Operation* command, it enters the normal mode of operation.

After the GPIB-VXI/C Passed bit is set, the RM can manipulate or read the MODID lines by sending the Word Serial queries *Read MODID*, *Set Lower MODID*, or *Set Upper MODID* to the GPIB-VXI/C.

# Chapter 3

## Local Command Set

---

This chapter contains descriptions of the GPIB-VXI/C local command set. The descriptions of the commands and queries include syntax, format and error handling information, as well as examples of the use of the commands and queries. The local command set supports the following types of operations:

- System configuration and control
  - Help
  - General configuration
  - Resource Manager (RM) information extraction
  - Dynamic system configuration and reconfiguration
  - VXI-defined Common ASCII System Commands
  - GPIB address configuration
  - VXIbus interrupt handler configuration
  - IEEE-488.2 common commands
- Instrument development and test
  - VXIbus access
  - VXI TTL/ECL trigger access
  - Word Serial communication
- Code Instrument (CI) use and development
  - CI configuration

The GPIB-VXI/C command set consists of commands and queries. *Commands* cause the GPIB-VXI/C to take some action. A *query* may also cause the GPIB-VXI/C to take some action, but it also returns a response containing data or other information.

### Command Set Access

You can execute the local commands from the following ports:

- RS-232
- GPIB
- VXI Word Serial Communication
- Individual Code Instruments

All ports are active when the GPIB-VXI/C is in the Normal Operation substate and operate independently of one another. The GPIB-VXI/C returns query responses only to the port originating the query. The GPIB-VXI/C also maintains a separate status state for each port. You can use local commands to disable and re-enable each port's access to the local command set. The RS-232 port prompts you to enter a local command with the `GPIB-VXI>` prompt.

## Command Syntax

The local command set parser is syntactically compatible with the IEEE-488.2 standard. It will accept numeric parameters in the 488.2 binary, octal, decimal, or hexadecimal formats. 488.2 binary parameters are prefixed with `#b`. Octal parameters are prefixed with `#q`, and hexadecimal parameters are prefixed with `#h`. Table 3-1 lists the most common numeric parameter types. The ranges given in Table 3-1 apply unless otherwise specified.

Table 3-1. Valid Ranges for Common Numeric Command Parameters

Parameter	488.2 Decimal	488.2 Hexadecimal
<logical address>	0 to 254	#h0 to #hFE
<GPIB address>	0 to 30	#h0 to #h1E
<handler>	1 to 3	#h1 to #h3
<level>	0 to 7	#h0 to #h7
<A16 address>	0 to 65535	#h0 to #hFFFF
<A24 address>	2097152 to 14680062	#h200000 to #hE7FFFE
<word value>	0 to 65535	#h0 to #hFFFF
<byte value>	0 to 255	#h0 to #hFF
<Boolean>	0 or 1	#h0 or #h1

The logical value of a <Boolean> parameter is FALSE for the numeric value 0, and TRUE for the numeric value 1.

The first parameter is delimited from the command name by a space ( ). Additional parameters are delimited from one another by a comma ( , ). The command names are not case-sensitive.

In the command descriptions, parameters are enclosed in angle brackets (< >), and optional parameters are also enclosed in square brackets ([ ]). Do not enter the brackets as part of the command.

Multiple commands may be concatenated in a single command line if they are separated with semicolons (for example, `OBRAM? ; DPRAM?<CR>`).

## Command Line Termination

The serial port command line termination is a carriage return, shown in the subsequent function descriptions as <CR> (ASCII 0Dh). If the command contains a trailing linefeed, shown in the subsequent function descriptions as <LF> (ASCII 0Ah), it is ignored. The GPIB termination is EOI. Commands issued to the GPIB-VXI/C via VXI Word Serial Protocol are terminated by setting the END bit in the last *Byte Available* command. Responses are terminated by setting the END bit in response to the last *Byte Request* query.

## Command and Query Responses

The local commands and queries have two response formats: *program* mode and *console* mode. Program mode responses have a terse data-only format that is intended for a control program to read and parse. Console responses are returned in the form of readable sentences, which are better suited for interactive command entry.

You can enable or disable each mode independently, except that one response mode must be enabled at all times. If both modes are simultaneously enabled, the program response is returned first, followed by the console response. The local commands used to control the response modes are ProgMode and ConsMode.

The response mode configuration is independent for each command source. Table 3-2 lists the default (startup/reset) response mode configurations.

Table 3-2. Default Response Mode Configurations

Port	Response Mode
RS-232	Console mode enabled, program mode disabled
GPIB	Program mode enabled, console mode disabled
VXI Word Serial	Program mode enabled, console mode disabled
Individual Code Instruments	Program mode enabled, console mode disabled

## Command Response Format

Commands do not have program mode responses. They do not return a response to a port configured for console mode response only, unless the GPIB-VXI/C detects an error condition.

Console mode command responses are self-explanatory, and are not described in this manual.

## Query Response Format

Queries have both program and console mode responses. Program mode query responses are fixed-field formatted, with commas delimiting the fields. For example, the list of logical addresses returned by the `LADDRS?` query is returned as groups of three characters (to allow the field to accommodate the valid range of 0 to 254) separated by commas. The values are right-justified and padded with the ASCII space character ( ) (20h). For example, Logical Address 45 would be returned as ( )45. Unless otherwise noted, all returned values are decimal.

Console mode query responses are self-explanatory, and are not described in this manual.

The query response line termination sequence, shown in the query descriptions as `<CRLF>`, indicates an ASCII 0Dh followed by 0Ah.

## Error Reporting

Command syntax and execution errors are reported to the port where the command originated. If the program response mode is enabled, the GPIB-VXI/C returns an error message in the following format:

```
$ <error code><CRLF>
```

The distinguishing characteristic of a program mode error message is the leading dollar sign character (\$). A list of error code descriptions is given in Appendix E, *Error Codes*.

If the console response mode is enabled, the GPIB-VXI/C returns an error message in the following format:

```
<error description><CRLF>
```

If both response modes are enabled, the program mode error message is returned first, followed by the console mode message.

## The Help Query

The Help? query is a quick online reference to the syntax and functionality of the GPIB-VXI/C local command set.

### Help?

**Purpose:** List syntax and descriptions of local command set.

### Query

**Syntax:** Help? [ <type>[ ,<type> , . . . . ] ]

or

Help [ <type>[ ,<type> , . . . . ] ]

<type> is the category of command information requested, as follows:

he	Help	ci	Code Instruments
al	All	sa	GPIB address configuration
gc	General configuration	ih	Interrupt handler configuration
dc	Dynamic configuration	ba	VXIbus access
rc	Dynamic reconfiguration	ws	Word Serial communication
rm	Resource Manager	tr	TTL trigger access
cc	Common commands		

The default type is All.

**Response:** The local command set is displayed in the following format:

GPIB-VXI Local Command Set<CRLF>	
Command/Query Format	Description<CRLF>
<Command Syntax>	<Command description><CRLF>
<Command Syntax>	<Command description><CRLF>
<Command Syntax>	<Command description><CRLF>
•	•
•	•
•	•

**Example:** List syntax and descriptions of general configuration and GPIB address commands.

```
Help? gc,sa
```

## General Configuration Commands and Queries

The general configuration commands and queries are described on the following pages.

- CONF
- ConsoleEna
- ConsMode
- DIAG
- DPRAM?
- NVconf?
- OBRAM?
- ProgMode
- WordSerEna

The ConsMode and ProgMode commands enable and disable the console and program response modes for the port originating the command.

The ConsoleEna and WordSerEna commands control access to the local command set from the RS-232 and VXI Word Serial ports.

The NVconf? query returns the contents of the onboard nonvolatile memory. CONF reboots the GPIB-VXI/C and enters the nonvolatile configuration editor.

DIAG reboots the GPIB-VXI/C and enters diagnostic mode.

The OBRAM? query can be used to determine the amount of GPIB-VXI/C installed RAM, and the DPRAM? query returns the amount of the installed RAM that is shared with VXI A24 space.

## CONF

**Purpose:** Reboot into nonvolatile configuration mode.

**Command Syntax:** CONF

**Example:** Reboot into nonvolatile configuration mode.

```
CONF
```

---

## ConsoleEna

**Purpose:** Enable or disable the RS-232 port as the console. When the RS-232 port is disabled as the console, a CI can take control of the serial port.

**Command Syntax:** ConsoleEna <Boolean>

**Action:** If <Boolean> is TRUE, ConsoleEna sets the RS-232 port to be a local command set input.

If <Boolean> is FALSE, ConsoleEna disables the RS-232 port connection to the local command set. Notice that once the console has been disabled, it must be re-enabled from a command source other than the RS-232 port (such as the GPIB port).

**Examples:** Disable console.

```
ConsoleEna 0
```

Enable console.

```
ConsoleEna 1
```

---

## ConsMode

**Purpose:** Enable or disable the console data mode.

**Command**

**Syntax:** ConsMode <Boolean>

**Action:** If <Boolean> is TRUE, ConsMode enables console format responses for the command source issuing the command.

If <Boolean> is FALSE, ConsMode disables console format responses for the command source issuing the command.

The console response mode applies only to the response path connected to the ConsMode command source. For example, disabling the console response mode from the GPIB port does not affect the response mode on the serial port.

**Example:** Disable console format responses.

```
ConsMode 0
```

Enable console format responses.

```
ConsMode 1
```

---

## DIAG

**Purpose:** Reboot into diagnostics mode.

**Command**

**Syntax:** DIAG

**Example:** Reboot into diagnostics mode.

```
DIAG
```

---

**DPrAm?**

**Purpose:** Get the A24/A32 starting address and the size of the GPIB-VXI/C VXI shared RAM.

**Query**

**Syntax:** DPrAm?

**Response:** Program response:

<A24/A32 starting address>, <shared RAM size><CRLF>

Console response:

This GPIB-VXI has <shared RAM size>K bytes shared with [A24, A32] Address <A24/A32 hex starting address><CRLF>

where <A24/A32 starting address> is the shared RAM base address in decimal integer format.

<shared RAM size> is in kilobytes.

<A24/A32 hex starting address> is in C language hexadecimal format.

---

**NVconf?**

**Purpose:** Display the contents of the nonvolatile (NV) configuration parameter memory.

**Query**

**Syntax:** NVconf?

**Response:** The contents of the onboard EEPROM are displayed in the following format:

```

===== Nonvolatile Configuration Information =====

Logical Address: 0x00          Device Type      : Message Based
Manufacturer Id: 0xFF6        Model Code       : 0xFF (Slot 0)

#28: 0         #29: 0         #30: 0         #31: 0

```

---

## OBram?

**Purpose:** Get the amount of RAM installed onboard the GPIB-VXI/C.

**Query**

**Syntax:** OBram?

**Response:** Program response:

<memsize><CRLF>

where <memsize> is the amount of installed RAM, in kilobytes.

Console response:

This GPIB-VXI has <expression> of RAM installed onboard.<CRLF>

where <expression> is the amount of installed RAM.

---

## ProgMode

**Purpose:** Enable or disable the program data mode.

**Command**

**Syntax:** ProgMode <Boolean>

**Action:** If <Boolean> is TRUE, ProgMode enables program format responses for the command source issuing the command.

If <Boolean> is FALSE, ProgMode disables program format responses for the command source issuing the command.

The program response mode applies only to the response path connected to the ProgMode command source. For example, disabling the program response mode from the GPIB port does not affect the response mode on the serial port.

**Examples:** Disable program format responses.

ProgMode 0

Enable program format responses.

ProgMode 1

---

## WordSerEna

**Purpose:** Assign control of the GPIB-VXI/C physical Word Serial registers to an onboard logical address (GPIB-VXI/C command interpreter or code instrument).

### Command

**Syntax:** WordSerEna <logical address>

**Action:** Control of the physical Word Serial registers is passed to <logical address>. <logical address> must be the logical address of the GPIB-VXI/C or an onboard code instrument.

The default control of the physical registers is given to the GPIB-VXI/C local command set parser.

**Examples:** Pass control of the physical registers to code instrument at Logical Address 5.

```
WordSerEna 5
```

Pass control of the physical registers back to GPIB-VXI/C local command parser at Logical Address 0.

```
WordSerEna 0
```

---

## RM Information Queries

The RM information queries are described on the following pages.

- A24MemMap?
- A32MemMap?
- Cmdr?
- CmdrTable?
- Laddrs?
- NumLaddrs?
- RmEntry?
- Srvnts?
- StatusState?

**Note:** The system information commands (NumLaddrs?, Laddrs?, CmdrTable?, A24MemMap?, and A32MemMap?) return information about the known system. If the GPIB-VXI/C is the system RM, it can access information about the entire system. If it is not the RM, it has information only about itself and its immediate Servants.

The Numladdrs? query is used to find out how many devices there are in the system. The number of devices could then be used by a control program to determine the allocation size for an array that is to hold the logical addresses of each device.

The Laddrs? query returns a list of logical addresses for devices in the system.

The RmEntry?, Srvnts?, Cmdr?, and StatusState? queries return RM information for a particular device.

The CmdrTable? query returns the system hierarchy table.

The A24MemMap? and A32MemMap? queries return the A24 and A32 memory configuration lists.

## A24MemMap?

**Purpose:** Get the A24 address space allocation for the system.

**Query**

**Syntax:** A24MemMap?

**Response:** Program response:

```
<la1>, <A24 memory base>, <A24 memory size> <CRLF>
<la2>, <A24 memory base>, <A24 memory size> <CRLF>
.
.
<laN>, <A24 memory base>, <A24 memory size> <CRLF>
```

where <la1> through <laN> are logical addresses containing A24 address space.

Console response:

```
A24 Memory Map is as follows: <CRLF>
```

```
Logical Address <la1> has <A24 memory size>K
(<A24 memory size> bytes) at A24 Address <A24 memory base> <CRLF>
```

```
.
.
Logical Address <laN> has <A24 memory size>K
(<A24 memory size> bytes) at A24 Address <A24 memory base> <CRLF>
```

**Example:** Get A24 address map for the system.

```
A24MemMap?
```

---

## A32MemMap?

**Purpose:** Get the A32 address space allocation for the system.

**Query**

**Syntax:** A32MemMap?

**Response:** Program response:

```
<la1>, <A32 memory base>, <A32 memory size> <CRLF>
<la2>, <A32 memory base>, <A32 memory size> <CRLF>
.
.
<laN>, <A32 memory base>, <A32 memory size> <CRLF>
```

where <la1> through <laN> are logical addresses containing A32 address space.

Console response:

```
A32 Memory Map is as follows: <CRLF>
```

```
Logical Address <la1> has <A32 memory size>K
(<A32 memory size> bytes) at A32 Address <A32 memory base> <CRLF>
```

```
.
.
Logical Address <laN> has <A32 memory size>K
(<A32 memory size> bytes) at A32 Address <A32 memory base> <CRLF>
```

**Example:** Get A32 address map for the system.

```
A32MemMap?
```

---

**Cmdr?**

**Purpose:** Get the logical address of a device's Commander.

**Query**

**Syntax:** Cmdr? <logical address>

where <logical address> is the logical address of the device.

**Response:** Program response:

<Commander's logical address><CRLF>

Console response:

The Commander of Logical Address <logical address> is Logical Address <Commander's logical address><CRLF>

**Example:** Get the Commander's logical address for Logical Address 15.

Cmdr? 15

---

## CmdrTable?

**Purpose:** Get the known system hierarchy table.

**Query**

**Syntax:** CmdrTable?

**Response:** Program response:

```
<cla0>,<cla1>,<cla2>,<cla3>,<cla4>, . . . ,<cla254><CRLF>
```

where  $\langle claN \rangle$  is either the Commander's logical address for Logical Address  $N$ , or 0 for top-level Commanders and unused logical addresses. Notice that no value is returned for Logical Address 255.

Console response:

```
Known Hierarchy is as follows:<CRLF>
Logical address <la1> has Servants: <sa1,1>,...,<sa1,M> <comment><CRLF>
Logical address <la2> has Servants: <sa2,1> ,...,<sa2,M> <comment><CRLF>
.
.
Logical address <laN> has Servants: <saN,1> ,...,<saN,M> <comment><CRLF>
```

where  $\langle laX \rangle$  is a valid logical address with Servant addresses  $\langle saX,1 \rangle$  through  $\langle saX,M \rangle$ .

The `<comment>` field indicates any relevant information about the status and/or capabilities of the device at Logical Address  $\langle laX \rangle$ .

## Laddrs?

**Purpose:** Get a list of the known logical addresses.

**Query**

**Syntax:** Laddrs?

**Response:** Program response:

```
<la1>,<la2>,..., <laN><CRLF>
```

where  $\langle la1 \rangle$  through  $\langle laN \rangle$  are the known logical addresses.

Console response:

```
Known logical addresses are <la1>,<la2>,..., <laN><CRLF>
```

CI logical addresses are terminated with an asterisk (\*) in the console mode response.

## NumLADDRS?

**Purpose:** Get the number of known logical addresses.

**Query**

**Syntax:** NumLADDRS?

**Response:** Program response:

```
<num las><CRLF>
```

where <num las> is the number of known logical addresses.

Console response:

```
There are <num las> known Logical Addresses<CRLF>
```

## RmEntry?

**Purpose:** Return RM information about a device or all devices. RmEntry? does not return the Servant list.

**Query**

**Syntax:** RmEntry? [<logical address>]

(If <logical address> is omitted, RmEntry? returns the RM information for all devices.)

**Response:** Program response:

```
<la>,<cla>,<sa>,<slot>,<devclass>,<subclass>,<manID>,<modelcode>,<memspace>,<membase>,<memsize>,<state>,<line status><CRLF>
```

Console response:

```
Resource manager entry for Logical Address <logical address>:
```

```
<CRLF>
```

```
<CRLF>
```

Commander's Logical Address	:<cla><CRLF>
GPiB Address	:<addr><CRLF>
Slot	:<slot><CRLF>
Device class	:<devclass> (class)<CRLF>
Extended Sub Class	:<subclass><CRLF>
Manufacturer's ID	:<manID> (manufacturer's name)<CRLF>
Model code	:<modelcode><CRLF>
Memory space	:<memspace> (memory space)<CRLF>
Memory Base	:<membase><CRLF>
Memory Size	:<memsize>K (<memsize> bytes)<CRLF>
Status State	:<state> (state)<CRLF>
Forced Offline?	:<line status> (yes/no)<CRLF>

The mnemonics have the following meanings:

la	Device's logical address
cla	Commander's logical address
addr	Device's GPIB address (255 if not assigned GPIB address)
slot	Slot number (255 if unknown, such as if the device does not have MODID capability)
devclass	Device class; the following values may be used:  0 = Memory Class 1 = Extended Class 2 = Message-Based 3 = Register-Based
subclass	Extended class device's subclass
manID	Manufacturer's ID number
modelcode	Device's manufacturer-assigned model code
memspace	Memory space requirement:  0 = A16 only 1 = A16/A24 2 = A16/A32
membase	Memory base address
memsize	Memory size in bytes
state	Status state:  0 = Failed and not Ready 1 = Passed and not Ready 2 = Failed and Ready 3 = Passed and Ready
line status	Online/offline status:  0 = online 1 = forced offline

The program mode response format is the same for all devices. However, the console mode response returns only the lines that are relevant. For example, memory base address and memory size lines are not returned for A16-only memory space devices.

**Example:** Get RM information for a device at Logical Address 78.

```
RmEntry? 78
```

---

## Srvnts?

**Purpose:** Get a list of a device's Servants.

### Query

**Syntax:** Srvnts? <logical address>

<logical address> is the device's logical address.

**Response:** Program response:

```
<sla1>, <sla2>, . . . , <slaN><CRLF>
```

where <sla1> through <slaN> are the Servant device logical addresses.

Console response:

```
Logical Address <logical address> has Servants:
<sla1>, <sla2>, . . . , <slaN> <comment><CRLF>
```

if the device has Servants, or

```
Logical Address <logical address> has Servants:
none <comment><CRLF>
```

if the device has no Servants.

The <comment> field indicates any relevant information about the status and/or capabilities of the device.

**Example:** Get a list of Servants for device at Logical Address 15.

```
Srvnts? 15
```

---

## StatusState?

**Purpose:** Get a device's current self-test status.

**Query**

**Syntax:** StatusState? <logical address>

<logical address> is the logical address for the device.

**Response:** Program response:

<val><CRLF>

The value of <val> is equivalent to the value of the field in the device's status register containing the Ready and Passed bits. <val> can be interpreted as follows:

- 0 The device is Failed and not Ready.
- 1 The device is Passed and not Ready.
- 2 The device is Failed and Ready.
- 3 The device is Passed and Ready.

Console response:

Device at Logical Address <logical address> is FAILED and not Ready<CRLF>

or

Device at Logical Address <logical address> is PASSED and not Ready<CRLF>

or

Device at Logical Address <logical address> is FAILED and Ready<CRLF>

or

Device at Logical Address <logical address> is PASSED and Ready<CRLF>

**Example:** Get self-test status for device at Logical Address 48.

```
StatusState? 48
```

---

## Dynamic Configuration Commands and Queries

The dynamic configuration (DC) commands and queries are described on the following pages.

- DCBNOSend
- DCGrantDev
- DCSystem?

The DC commands are used to configure the VXI system when all of these conditions are present:

- The GPIB-VXI/C is the RM.
- At least one DC device is present in the system.
- The nonvolatile configuration setup specifies *not* to send *Begin Normal Operation* (user-specified hierarchy).
- The system is still in the startup Configure substate (DCBNOSend has not been sent).

The DCSystem? query response indicates whether the system contains a DC device. If the system is found to be a DC system, the DCGrantDev command is used to configure the Commander/Servant hierarchy. The DCBNOSend command is used to end the DC phase and to cause the system to enter normal operation.

### DCBNOSend

**Purpose:** Cause a DC system to exit the Configure substate and enter the Normal Operation substate.

**Command**

**Syntax:** DCBNOSend

**Action:** Send the *Begin Normal Operation* command to all top-level Commanders.

---

## DCGrantDev

**Purpose:** Grant a device to a Message-Based Commander in a DC system. DCGrantDev can be used only to configure the initial Commander/Servant hierarchy of a DC system, and before DCBNOSEND is used to cause the system to enter the Normal Operation substate.

### Command

**Syntax:** DCGrantDev <Commander's logical address>,  
<Servant's logical address>

**Action:** DCGrantDev sends the *Device Grant* command to the Commander at <Commander's logical address>, granting it the device at <Servant's logical address>.

**Example:** Grant Servant at Logical Address 7 to Commander at Logical Address 5.

```
DCGrantDev 5,7
```

---

## DCSystem?

**Purpose:** Determine if the system is a DC system. A system is DC if it has at least one DC device.

### Query

**Syntax:** DCSystem?

**Response:** Program response:

```
1 <CRLF>
```

if it is a DC system, or

```
0 <CRLF>
```

if it is not a DC system, or if it is no longer dynamically configurable because the *Begin Normal Operation* command has already been sent to the top-level Commanders through the DCBNOSEND local command.

Console response:

```
This IS a Dynamic Configured system.<CRLF>
```

if it is a DC system, or

```
This is NOT a Dynamic Configured system.<CRLF>
```

if it is not a DC system.

---

## Dynamic Reconfiguration Queries

The dynamic reconfiguration queries are described on the following pages.

- Broadcast?
- GrantDev?
- RelSrvnt?

The dynamic reconfiguration commands are used to reconfigure the GPIB-VXI/C's Servant subtree after the system has entered the Normal Operation substate. If the GPIB-VXI/C is RM, these commands can be used to reconfigure the entire system.

The Broadcast? query can be used to make the system or subtree enter the Configure substate by broadcasting the *End Normal Operation* Word Serial query, or the *Clear* Word Serial command followed by the *Abort Normal Operation* Word Serial query.

The RelSrvnt? and GrantDev? queries can then be used to restructure the Commander/Servant hierarchy. You could perform dynamic reconfiguration directly by using the WSCmd and WSCmd? local commands, but the GPIB-VXI/C's RM table would not be updated. By using the RelSrvnt? and GrantDev? queries to reconfigure the system, you ensure that the GPIB-VXI/C's system hierarchy and GPIB address link records do not become corrupted.

You can return the system or subtree to the Normal Operation substate by using the Broadcast? query to broadcast the *Identify Commander* and *Begin Normal Operation* Word Serial commands.

## Broadcast?

**Purpose:** Broadcast dynamic reconfiguration initialization or termination Word Serial commands to the GPIB-VXI/C's Message-Based Servants or to all top-level Commanders in the system.

### Query

**Syntax:** Broadcast? <Boolean>, <ws cmd>

If <Boolean> is 1, the GPIB-VXI/C broadcasts <ws cmd> to all top-level Commanders. If <Boolean> is 0, it broadcasts <ws cmd> to its Message-Based Servants. Notice that the GPIB-VXI/C should only broadcast to top-level Commanders when it is RM.

The Broadcast? query can fail due to inability to complete a Word Serial operation, or because an invalid code was returned from a device in response to ANO or ENO.

<ws cmd> is a mnemonic as follows:

<ws cmd>	Word Serial Command Name	Type
ANO	<i>Abort Normal Operation</i>	Query
BNO	<i>Begin Normal Operation</i>	Query
CLR	<i>Clear</i>	Command
ENO	<i>End Normal Operation</i>	Query
IDN	<i>Identify Commander</i>	Command

**Response:** Program response:

<CRLF>

if the command was successful, or

<la>, <cmd val>, <ws response>, <ws error code>

if the command failed.

Console response:

Done broadcasting Word Serial command: <Word Serial command name>.

if the command was successful, or

Logical address <la> returned <ws response> from ENO (Unable to halt)

or

Logical address <la> returned <ws response> from ANO (Invalid response)

or

Error sending Logical Address <la> Word Serial command <hex cmd val><CRLF><space><space><ws error><CRLF>

if the command failed.

<la> is the logical address of the device to which the broadcast failed.

<cmd val> is the value of the Word Serial command, in decimal. <hex cmd val> is the value in hexadecimal.

For Word Serial queries, <ws response> is the Word Serial response of the device at Logical Address <la>. For Word Serial commands <ws response> is 0.

<Word Serial command name> is the name of the command name as shown in the previous table.

<ws error code> is a decimal value that can be interpreted by converting it to a binary bit pattern. A value of 1 in the bit positions shown in the following table indicates that an error occurred during the attempt to broadcast the Word Serial command:

Bit	Word Serial Error
0	Word Serial command completed successfully (no Word Serial error)
1	Timeout waiting to send Word Serial command to device at <la>
2	Timeout waiting for Word Serial response from device at <la>
3	Device at <la> did not recognize the command
6	Multiple query error
10	Read Protocol error not supported
13	Read Ready (RR) violation
14	Write Ready (WR) violation

None of the other bits has significance in this context.

<ws error> is a string explaining the Word Serial error as shown in the previous table.

**Example:** Broadcast the *Identify Commander* Word Serial command to all top-level Commanders.

```
broadcast? 1, IDN
```

---

## GrantDev?

**Purpose:** Grant a Servant to a Commander.

### Query

**Syntax:** GrantDev? <Commander's logical address>, <Servant's logical address>

**Action:** Grants the device at <Servant's logical address> to device at <Commander's logical address>.

The GPIB-VXI/C must own the device at <Servant's logical address>. The GPIB-VXI/C can get ownership of any device with the RelSrvnt? command.

Notice that before the GrantDev? query is used, the Word Serial *End Normal Operation* query, or a *Clear* command followed by the *Abort Normal Operation* query should have been broadcast with the Broadcast? query.

**Response:** Program response:

```
0<CRLF>
```

indicates that the command was successful.

Console response:

```
Logical Address <Commander's logical address> granted device at
Logical Address <Servant's logical address>.
```

**Example:** Grant Device 16 to Commander at Logical Address 8.

```
Grantdev? 8,16
```

---

## RelSrvnt?

**Purpose:** Recover a Servant from a Commander.

### Query

**Syntax:** RelSrvnt? <Commander's logical address>, <Servant's logical address>

**Action:** Commands device at <Commander's logical address> to release ownership of the device at <Servant's logical address>. The GPIB-VXI/C assumes ownership of the device.

**Response:** Program response:

254 <CRLF>

if the Commander released the Servant. Any other response indicates that an error occurred.

Console response:

Logical Address <Commander's logical address> released device at  
Logical Address <Servant's logical address>.

**Example:** Recover Servant at Logical Address 16 from Commander at Logical Address 8.

```
Relsrvnt? 8,16
```

---

## VXI-Defined Common ASCII System Commands

The VXI-defined Common ASCII System Commands and Queries are described on the following pages.

- DCON?
- DINF?
- DLAD?
- DNUM?
- DRES?
- RREG?
- WREG

You can use these commands and queries to retrieve device information/configuration, perform a soft reset, and peek/poke a device's registers.

The DNUM? query is used to find out how many devices are in the system. The DLAD? query returns a list of logical addresses for devices in the system.

The DINF? query returns static information about a device. The DCON? query returns configuration information about a device.

The DRES? query is used to perform a soft-reset sequence on a device.

The RREG? query and WREG command are used to peek (read from) and poke (write to) registers on a VXI device.

**DCON?**

**Purpose:** Return system configuration information about a device or all devices.

**Query**

**Syntax:** DCON? [<logical address>]

(If <logical address> is omitted, DCON? returns the configuration information for all devices.)

**Response:** Program response:

```
<la1>, <cla>, <IHANS>, <INTS>, <status>, <sstate>, <com> <CRLF>
```

Console response:

```
Device configuration at Logical Address <la>: <CRLF>
<CRLF>
Commander's Logical Address      : <cla> <CRLF>
Interrupt Handlers                : <IHANS> <CRLF>
Interrupters                     : <INTS> <CRLF>
Passed/Failed/Ready              : <status> <CRLF>
Device Substate                  : <sstate> <CRLF>
Manufacturer Specific Comment    : <com> <CRLF>
```

The mnemonics have the following meanings:

la	Device's logical address
cla	Commander's logical address
IHANS	Interrupt handler levels used by this device where IHANS is a 7-digit binary representing the seven VXI interrupt levels and a one in each position, meaning Interrupt Handler present
INTS	Interrupter levels used by this device where INTS is a 7-digit binary representing the seven VXI interrupt levels and a one in each position, meaning Interrupter present
status	Status state of the device: <ul style="list-style-type: none"> <li>PASS</li> <li>FAIL</li> <li>IFAIL</li> <li>READY</li> </ul>
sstate	Substate of the device <ul style="list-style-type: none"> <li>NOP</li> <li>CONF</li> <li>NONE</li> </ul>
com	Not used; always returns " "

**Example:** Get device configuration information for Logical Address 6.

```
DCON? 6
```

---

## DINF?

**Purpose:** Return static system information about a device.

### Query

**Syntax:** DINF? [<logical address>]

(If <logical address> is omitted, DINF? returns static information for all devices.)

**Response:** Program response:

```
<la1>, <manID>, <modelcode>, <devclass>, <memspace>, <membase>,
<memsize>, <slot>, <slot0>, <ext>, <attr>, <com> <CRLF>
```

Console response:

```
Device configuration at Logical Address <la>: <CRLF>
<CRLF>
Manufacturer ID Number      :<manid> (manufacturer name) <CRLF>
Model Code                  :<modelcode> <CRLF>
Device Class                :<devclass> <CRLF>
A16/A24/A32 Memory Space   :<memspace> <CRLF>
A16/A24/A32 Memory Base    :<membase> <CRLF>
A16/A24/A32 Memory Size    :<memsize> <CRLF>
Slot                        :<slot> <CRLF>
Slot 0 Logical Address      :<slot0> <CRLF>
Extended Subclass          :<ext> <CRLF>
Attribute                   :<attr> <CRLF>
Manufacturer Specific Comment :<com> <CRLF>
```

The mnemonics have the following meanings:

la	Device's logical address
manid	Manufacturer's ID number
devclass	Device class; the following values may be used:

```
REG = Register-Based device
MSG = Message-Based device
EXT = Extended-Class device
MEM = Memory-Based device
```

memspace	Memory space requirement A16 A16/A24 A16/A32
membase	Memory-based address for A16, A24, A32 "HHHH, HHHHHH, HHHHHHHH"
memsize	Memory sizes for A16, A24, A32 "HHHH, HHHHHH, HHHHHHHH"
slot	Slot number (-1 if unknown)
slot0	Slot 0 Logical Address (-1 if unknown)
ext	Extended device's subclass
attr	Memory device's attributes
com	Not used, always " "

## DLAD?

**Purpose:** Get a list of the known logical addresses.

### Query

**Syntax:** DLAD?

**Response:** Program response:

<la1>,<la2>,..., <laN><CRLF>

where <la1> through <laN> are the known logical addresses.

Console response:

Known logical addresses are <la1>,<la2>,..., <laN><CRLF>

CI logical addresses are terminated with an asterisk (\*) in the console mode response.

**Example:** Get a list of the known logical addresses.

DLAD?

**DNUM?**

**Purpose:** Get the number of the known logical addresses.

**Query**

**Syntax:** DNUM?

**Response:** Program response:

<num las><CRLF>

where <num las> is the number of known logical addresses.

Console response:

There are <num las> known Logical Addresses.<CRLF>

**Example:** Get the number of the known logical addresses.

DNUM?

---

**DRES?**

**Purpose:** Perform a soft-reset sequence on a device.

**Query**

**Syntax:** DRES? <logical address> [, <sysfail flag>]

**Note:** If the device stays failed for five seconds after the soft-reset sequence, <sysfail flag> determines whether or not the device is kept sysfail-inhibited.

**Response:** Program response:

<status><CRLF>

Console response:

Logical Address <logical address> is <status>. SYSFAIL Inhibit is <state>.<CRLF>

where <status> is one of the following:

PASS  
FAIL  
IFAIL  
READY

and <state> is one of the following:

ON  
OFF

**Example:** Soft-reset device at Logical Address 3.

DRES? 3

---

**RREG?**

**Purpose:** Read a 16-bit VXI register from a device.

**Query**

**Syntax:** RREG? <logical address>, <reg offset>

where <logical address> is the device to read from and <reg offset> is the number of bytes to offset from the base of the VXI registers for that device.

**Response:** Program response:

<hex word value><CRLF>

Console response:

Value 0x<hex word value> (<word value>) read from Logical Address <logical address>, Register offset 0x<reg offset><CRLF>

**Example:** Read Device Type register from Logical Address 12.

```
RREG? 12,2
```

---

**WREG**

**Purpose:** Write a 16-bit VXI register on a particular device.

**Query**

**Syntax:** WREG <logical address>, <reg offset>, <value>

where <logical address> is the device to write, <reg offset> is the register offset to write to, and <value> is the 16-bit value to write.

**Action:** Write <value> to <logical address>, register offset <reg offset>.

**Example:** Write the Data Low register for Logical Address 4 with the value 65535.

```
WREG 4,14,65535
```

---

## GPIB Address Configuration Commands and Queries

The GPIB address configuration commands are described on the following pages.

- LaSaddr
- LaSaddr?
- Primary?
- SaddrLa?
- Saddr?
- SaDisCon

These commands and queries configure and report the relationships between VXI logical addresses and GPIB addresses.

You can determine the GPIB-VXI/C's primary address when used for multiple GPIB secondary addressing by using the `Primary?` query from the serial port. You can determine the relationships between GPIB addresses and VXI logical addresses by using the `Saddr?` query followed by `SaddrLa?` queries, or by using the RM information query `Laddr?` followed by `LaSaddr?` queries.

You can assign GPIB address links to Message-Based Servants of the GPIB-VXI/C with the `LaSaddr` command. The `SaDisCon` command deletes all GPIB address links except the link to the GPIB-VXI/C local commands.

**Note:** The letters *SA* or *SADDR* in this chapter originally stood for *GPIB Secondary Address*. The GPIB-VXI/C can be configured to handle multiple primary addresses as well. The terminology has been left the same to maintain backwards compatibility.

## LaSaddr

**Purpose:** Attach or detach a GPIB address to a logical address.

**Command**

**Syntax:** LaSaddr <logical address>, <GPIB address>

**Action:** If <GPIB address> is not equal to 255, attach <GPIB address> to <logical address>.

If <GPIB address> is equal to 255, release <GPIB address> currently attached to <logical address>.

Attaching a GPIB address to a logical address that already has a GPIB address will cause the first GPIB address to be replaced by the new GPIB address.

Attempting to release or change a GPIB address will result in a Delete I/O Link error if any of the following conditions is true:

- The GPIB address does not exist.
- The GPIB address is addressed to talk or listen; unable to delete.
- There is still data in the GPIB address input or output queue.

**Examples:** Attach GPIB Address 6 to Logical Address 4.

```
LaSaddr 4,6
```

Release GPIB address currently attached to Logical Address 8.

```
LaSaddr 8,255
```

---

**LaSaddr?**

**Purpose:** Get the GPIB address attached to a logical address.

**Query**

**Syntax:** LaSaddr? <logical address>

**Response:** Program response:

<GPIB address><CRLF>

where <GPIB address> is the GPIB address attached to the logical address. A value of 255 indicates that no GPIB address is attached to the logical address.

Console response:

Logical Address <logical address> is attached to GPIB Address <GPIB address><CRLF>

for logical addresses with attached GPIB addresses, or

Logical Address <logical address> is NOT attached to a GPIB <type> Address<CRLF>

for logical addresses without attached GPIB addresses.

**Example:** Get the GPIB address attached to Logical Address 9.

LaSaddr? 9

**Primary?**

**Purpose:** Get a GPIB primary address.

**Query**

**Syntax:** Primary?

**Response:** Program response:

<primary address><CRLF>

where <primary address> is the GPIB primary address of GPIB-VXI/C.

Console response:

The GPIB primary address of the GPIB-VXI is <primary address><CRLF>

## SaddrLa?

**Purpose:** Get the logical address that a GPIB address is attached to.

**Query**

**Syntax:** SaddrLa? <GPIB address>

**Response:** Program response:

<logical address><CRLF>

where <logical address> is the logical address that the GPIB address is attached to. A value of 255 indicates that the GPIB address is not attached to a logical address.

Console response:

GPIB <type> Address <GPIB address> is attached to  
Logical Address <logical address><CRLF>

for a GPIB address that is attached to a logical address, or

GPIB <type> Address <GPIB address> is NOT attached to a  
Logical Address<CRLF>

for a GPIB address that is not attached to any logical address.

**Example:** Get the logical address attached to GPIB Address 9.

SaddrLa? 9

---

## Saddr?

**Purpose:** Get a list of used GPIB addresses.

**Query**

**Syntax:** Saddr?

**Response:** Program response:

```
<sa1>,<sa2>,. . .,<saN><CRLF>
```

where <sa1> through <saN> are the GPIB addresses currently attached to logical addresses.

Console response:

```
Current GPIB Addresses used:  
Address <sa1>:  connected to Logical Address <la1>.  
Address <sa2>:  connected to Logical Address <la2>.  
.  
.  
<type> Address <saN>:  connected to Logical Address <laN><CRLF>
```

---

## SaDisCon

**Purpose:** Detach *all* GPIB address links except the GPIB address link to the GPIB-VXI/C command set.

**Command**

**Syntax:** SaDisCon

**Action:** Detaches all GPIB address links from Servants of the GPIB-VXI/C.

---

## VXIbus Interrupt Handler Configuration Commands and Queries

The interrupt handler configuration commands and queries are described on the following pages.

- AllHandlers?
- AssgnHndlr
- HandlerLine?
- RdHandlers?

The interrupt handler commands and queries configure and report the relationships between the GPIB-VXI/C interrupt handlers and VXIbus interrupt levels.

The GPIB-VXI/C has three programmable interrupter handlers. An application program can confirm this with the RdHandlers? query. The AllHandlers? and HandlerLine? queries return the current VXI interrupt level assignments for the handlers. The AssgnHndlr command can be used to change the level assignments.

## AllHandlers?

**Purpose:** Get the VXIbus interrupt level assigned to all GPIB-VXI/C interrupt handlers.

**Query**

**Syntax:** AllHandlers?

**Response:** Program response:

```
<level1>, <level2>, <level3><CRLF>
```

where <level1> is the interrupt level assigned to Handler 1, <level2> is the interrupt level assigned to Handler 2, and <level3> is the interrupt level assigned to Handler 3.

If <levelN> equals 0, Interrupt Handler <handlerN> is not assigned to an interrupt level.

Console response:

```
VXI Interrupt Handler 1 assigned to interrupt level <level1><CRLF>  
VXI Interrupt Handler 2 assigned to interrupt level <level2><CRLF>  
VXI Interrupt Handler 3 assigned to interrupt level <level3><CRLF>
```

if all handlers are assigned to levels, or

```
VXI Interrupt Handler <handler> NOT assigned to any interrupt  
level.<CRLF>
```

if <handlerN> is not assigned to a level.

**Example:** Get the interrupt level assigned to all interrupt handlers.

```
AllHandlers?
```

---

## AssgnHndlr

**Purpose:** Assign a VXIbus interrupt level to a GPIB-VXI/C interrupt handler.

**Command**

**Syntax:** AssgnHndlr <handler>, <level>

where <handler> is a numeric integer quantity in the range 1 to 3, and <level> is a numeric integer quantity in the range 0 to 7.

**Action:** If <level> is in the range 1 to 7, VXIbus Interrupt Line <level> is assigned to Interrupt Handler <handler>.

If <level> is 0, the current VXIbus interrupt line held by Interrupt Handler <handler> is released.

**Examples:** Assign the Interrupt Level 6 to the GPIB-VXI/C Interrupt Handler 2.

```
AssgnHndlr 2,6
```

Release the interrupt level currently held by the GPIB-VXI/C Interrupt Handler 1.

```
AssgnHndlr 1,0
```

---

## HandlerLine?

**Purpose:** Get the level assigned to a GPIB-VXI/C interrupt handler.

**Query**

**Syntax:** HandlerLine? <handler>

**Response:** Program response:

<level><CRLF>

Console response:

VXI Interrupt Handler <handler> assigned to interrupt level  
<level><CRLF>

<level> is the interrupt level assigned to handler <handler>. If <level> equals 0, Interrupt Handler <handler> is not assigned an interrupt level.

**Example:** Get the interrupt level assigned to Interrupt Handler 3.

HandlerLine? 3

---

## RdHandlers?

**Purpose:** Get the number of assignable GPIB-VXI/C interrupt handlers.

**Query**

**Syntax:** RdHandlers?

**Response:** Program response:

3 <CRLF>

Console response:

This GPIB-VXI has 3 configurable VXI interrupt handlers. <CRLF>

**Example:** Get the number of assignable GPIB-VXI/C interrupt handlers.

RdHandlers?

---

## IEEE-488.2 Common Commands and Queries

The IEEE-488.2 commands and queries are as follows:

- \*CLS
- \*ESE
- \*ESE?
- \*ESR?
- \*IDN?
- \*OPC
- \*OPC?
- \*RST
- \*SRE
- \*SRE?
- \*STB?
- \*TRG
- \*TST?
- \*WAI

These commands conform to the minimal 488.2 requirements. Many of these 488.2 commands have limited meaning in the VXI environment, but are included for compatibility. The GPIB-VXI/C has no reason to interrupt as a 488.2 instrument. It is only a parser. All other functions of the GPIB-VXI/C are considered to be interface functions for other 488.2 VXI devices. It is the responsibility of each VXI device connected via the GPIB to the GPIB-VXI/C to implement 488.2 protocols if individual device 488.2 compatibility is required.

**\*CLS****488.2**

**Intent:** Clear the device status data structures, and force it to the Operation Complete Query Idle state.

**Command**

**Syntax:** \*CLS

**Action:** None.

---

**\*ESE****488.2**

**Intent:** Set the GPIB-VXI/C's Standard Event Status Enable (ESE) register bits.

**Command**

**Syntax:** \*ESE <byte value>

where <byte value> is the new value of the ESE register.

**Action:** Sets ESE to <byte value>.

**Example:** Set the ESE register to 45.

```
*ESE 45
```

---

**\*ESE?****488.2**

**Intent:** Get the contents of the ESE register.

**Query**

**Syntax:** \*ESE?

**Response:** <ESE val><CRLF>

where <ESE val> is the current value of the ESE register. The default value is FFh.

---

**\*ESR?****488.2**

**Intent:** Read and clear the Standard Event Status register (ESR).

**Query**

**Syntax:** \*ESR?

**Response:** <ESR val><CRLF>

<ESR val> is the current value of the ESR.

---

**\*IDN?****488.2**

**Intent:** Get the GPIB-VXI/C's manufacturer, model, serial number, and firmware level.

**Query**

**Syntax:** \*IDN?

**Response:** "National Instruments", "GPIB-VXI", <serial number>, <firmware version><CRLF>

---

**\*OPC****488.2**

**Intent:** Cause the GPIB-VXI/C to generate the operation complete message in the ESR when all pending selected device operations have been finished.

**Command**

**Syntax:** \*OPC

**Action:** None.

Notice that because the GPIB-VXI/C only parses and routes commands, there are never any pending commands on the GPIB-VXI/C.

---

**\*OPC?****488.2**

**Intent:** Cause the GPIB-VXI/C to place an ASCII 1 in its output queue when all pending operations have completed.

**Query**

**Syntax:** \*OPC?

**Response:** 1 <CRLF>

---

**\*RST****488.2**

**Intent:** Return a device to a known initial state.

**Command**

**Syntax:** \*RST

**Action:** None.

Other than the response mode configuration, the GPIB-VXI/C does not depart from its initial state.

---

**\*SRE****488.2**

**Intent:** Set the device's Service Request Enable (SRE) register bits.

**Command**

**Syntax:** \*SRE <byte value>

where <byte value> is the new value of the SRE register.

**Action:** Sets the SRE to <byte value>.

**Example:** Set the SRE register to 120.

\*SRE 120

---

**\*SRE?****488.2**

**Intent:** Get the contents of the SRE register.

**Query**

**Syntax:** \*SRE?

**Response:** <SRE val><CRLF>

<SRE val> is the current value of the SRE register. The default value is FFh.

---

**\*STB?****488.2**

**Intent:** Get the contents of a device's Status Byte.

**Query**

**Syntax:** \*STB?

**Response:** <STB value><CRLF>

where <STB value> is the current status of the path to the GPIB-VXI/C local command parser.

---

**\*TRG****488.2**

**Intent:** Cause a device to execute a stored trigger sequence.

**Command**

**Syntax:** \*TRG

**Action:** None.

---

**\*TST?****488.2**

**Intent:** Perform self-test and return passed or failed status.

**Query**

**Syntax:** \*TST?

**Response:** 0 <CRLF>

Failure to complete the self-test is indicated by a failure to respond to this query. If the response is received, the self-test was successful.

---

**\*WAI****488.2**

**Intent:** Prevent device from executing any further commands until the No-Operation Pending flag is TRUE.

**Command**

**Syntax:** \*WAI

**Action:** None.

---

## VXIbus Access Commands and Queries

The VXIbus access commands and queries are described on the following pages.

- A16
- A16?
- A24
- A24?
- SYSRESET

The A16 and A24 commands can be used to *poke*, or write, locations in VXI A16 and A24 memory space. The A16? and A24? queries can be used to *peek*, or read, locations in VXI A16 and A24 memory space.

**Note:** If your application requires block moving or higher speed accesses to or from the VXIbus address spaces, refer to Appendix B, *Using the DMAmove and CDS-852 Adapter Code Instruments*.

The SYSRESET command can be used to remotely reset the system.

### A16

**Purpose:** Write a 16-bit value into VXI A16 space.

**Command**

**Syntax:** A16 <A16 address>, <word value>

**Action:** Write <word value> to <A16 address>.

**Example:** Write A502h to VXI A16 address 4305h.

```
A16 #h4305, #hA502
```

---

## A16?

**Purpose:** Read word value from VXI A16 address space.

**Query**

**Syntax:** A16? <A16 address>

**Response:** Program response:

<word value><CRLF>

Console response:

Value <hex word value> (<word value>) read from A16 address <A16 hex address> (<A16 address>)<CRLF>

where <word value> is in decimal integer format, <hex word value> is in C language hexadecimal format, <A16 hex address> is in C language hexadecimal format, and <A16 address> is in decimal integer format.

**Example:** Read the ID register of Logical Address 16.

A16? #hc400

---

## A24

**Purpose:** Write a 16-bit value into VXI A24 space.

**Command**

**Syntax:** A24 <A24 address>, <word value>

Notice that <A24 address> has a valid range of 2097152 to 14680062 (#h200000 to #hE7FFFE).

**Action:** Write <word value> to <A24 address>.

**Example:** Write the value A502h to VXI A24 address 504305h.

A24 #h504305, #hA502

---

## A24?

**Purpose:** Read a word value from VXI A24 address space.

**Query**

**Syntax:** A24? <A24 address>

**Response:** Program response:

<word value><CRLF>

Console response:

Value <hex word value> (<word value>) read from A24 address <A42 hex address (<A24 address>)<CRLF>

where <word value> is in decimal integer format, <hex word value> is in C language hexadecimal format, <A24 hex address> is in C language hexadecimal format, and <A24 address> is in decimal integer format.

**Example:** Read the word at A24 address 205634h.

A24? #h205634

---

## SYSRESET

**Purpose:** Remotely reset system.

**Command**

**Syntax:** SYSRESET

**Action:** Asserts the VXI backplane signal SYSRESET\*.

---

## TTL/ECL Trigger Access Commands

The TTL/ECL Trigger Access commands are described on the following pages.

- AckTrig
- DisTrigSense
- EnaTrigSense
- GetTrigHndlr
- MapTrigTrig
- SetTrigHndlr
- SrcTrig
- TrigAsstConf
- TrigCntrConf
- TrigExtConf
- TrigTickConf
- TrigToREQT
- UMapTrigTrig
- WaitForTrig

These commands can be used to directly manipulate the VXI TTL/ECL trigger lines and the front panel trigger connectors of the GPIB-VXI/C. The trigger functions are grouped into the following four categories.

- *Source trigger commands* act as a standard interface for asserting (sourcing) TTL and ECL triggers, as well as for detecting acknowledgements from accepting devices. These commands can source any of the VXI-defined trigger protocols from the GPIB-VXI/C. The source trigger commands are SrcTrig, SetTrigHndlr, and GetTrigHndlr.
- *Acceptor trigger commands* act as a standard interface for sensing (accepting) TTL and ECL triggers, as well as for sending acknowledgements back to the sourcing device. These functions can sense any of the VXI-defined trigger protocols on the GPIB-VXI/C. The acceptor trigger commands are EnaTrigSense, DisTrigSense, SetTrigHndlr, and GetTrigHndlr.
- *Map trigger commands* are configuration commands for routing and signal conditioning. You can use the MapTrigTrig and UMapTrigTrig commands to configure the GPIB-VXI/C hardware to route specified source trigger locations to destination trigger locations. You can use these commands as a cross-point switch/signal conditioning configurator.
- *Trigger configuration commands* are configuration tools for configuring not only the general settings of the trigger inputs and outputs, but also the National Instruments Trigger Interface Chip (TIC) counter and tick timers. The trigger configuration commands are TrigAsstConf, TrigExtConf, TrigCntrConf, TrigTickConf, and TrigToREQT. TrigToREQT is a special function for the GPIB-VXI/C to map trigger interrupt sources to SRQ on the GPIB so that VXI trigger protocols can be completely controlled from an external GPIB controller.

**AckTrig**

**Purpose:** Acknowledge the specified TTL/ECL or external (GPIO) trigger.

**Query**

**Syntax:** AckTrig <line>

where the value of <line> corresponds to the trigger line to acknowledge:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
40 to 49	External source/destination (GPIO 0 to 9)

**Response:** Program response: 0

Console response:

Trigger acknowledged (line = <line text>).<CRLF>

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
40 to 49	GPIO (<line> - 40)

**Example:** Acknowledge a trigger interrupt for TTL line 4.

AckTrig 4

---

## DisTrigSense

**Purpose:** Disable the sensing of the specified TTL/ECL trigger line, counter, or tick timer that was enabled by `EnaTrigSense`.

**Query**

**Syntax:** `DisTrigSense <line>`

where the value of `<line>` corresponds to the trigger line on which to disable sensing:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
50	TIC counter
60	TIC TICK timers

**Response:** Program response: 0

Console response:

```
Trigger sense disabling (line = <line text>) complete.<CRLF>
```

where the meaning of `<line text>` corresponds to the value of `<line>` as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
50	TCNTR
60	TICK 1

**Example:** Disable sensing of TTL line 4.

```
DisTrigSense 4
```

## EnaTrigSense

**Purpose:** Enable the sensing of the specified TTL/ECL trigger line or starts up the counter or tick timer for the specified protocol.

**Query**

**Syntax:** EnaTrigSense <line>, <protocol>

where the value of <line> corresponds to the trigger line on which to disable sensing:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
50	TIC counter
60	TIC TICK timers

and the value of <protocol> specifies the protocol to use:

<u>Value</u>	<u>Protocol</u>
2	START
3	STOP
4	SYNC
5	SEMI-SYNC
6	ASYN

**Response:** Program response: 0

Console response:

Trigger sense enabling (line = <line text>, protocol = <protocol text>) complete.<CRLF>

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
50	TCNTR
60	TICK 1

and the meaning of <protocol text> corresponds to the value of <protocol> as follows:

<u>Value of &lt;protocol&gt;</u>	<u>Value of &lt;protocol text&gt;</u>
2	START
3	STOP
4	SYNC
5	SEMI-SYNC
6	ASYN

**Example:** Enable sensing of TTL line 4 for SEMI-SYNC protocol.

```
EnaTrigSense 4, 5
```

---

## GetTrigHndlr

**Purpose:** Get the address of the current TTL/ECL trigger, counter, or tick timer interrupt handler for a specified trigger source.

**Query**

**Syntax:** GetTrigHndlr <line>

where the value of <line> corresponds to the trigger line or counter/tick source:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
50	TIC counter
60	TIC TICK1 tick timer

**Response:** Program response: 0

Console response:

```
Trigger handler (line = <line text>): DefaultTrigHandler().<CRLF>
```

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
50	TCNTR
60	TICK 1

**Example:** Get the address of the trigger interrupt handler for TTL trigger line 4.

```
GetTrigHndlr 4
```

---

## MapTrigTrig

**Purpose:** Map a specified TTL, ECL, Star X, Star Y, external connection (GPIO), or miscellaneous signal line to another.

### Query

**Syntax:** MapTrigTrig <srcTrig>, <destTrig>, <mode>

where <srcTrig> is the source line to map to a destination, the value of <destTrig> corresponds to the destination line to map from the source:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
40 to 49	External source/destination (GPIO 0 to 9)
40	Front panel In (connector 1)
41	Front panel Out (connector 2)
42	Front panel In (unbuffered)
43	Connection to EXTCLK input pin
44 to 49	Hardware-dependent GPIOs 4 to 9
50	TIC counter pulse output (TCNTR)
51	TIC counter finished output (GCNTR)
60	TIC TICK1 tick timer output
61	TIC TICK2 tick timer output

and the value of <mode> specifies the signal conditioning mode (where 0 = no conditioning). The conditioning effects for bits 0 to 3 are as follows:

<u>Bit</u>	<u>Conditioning Effect</u>
0	Synchronize with next CLK edge
1	Invert signal polarity
2	Pulse stretch to one CLK minimum
3	Use EXTCLK (not CLK10) for conditioning

**Response:** Program response: 0

Console response:

```
Mapping complete (line = <line text source> mapped to line = <line
text destination>, mode = <mode>).<CRLF>
```

where the meaning of <line text source> and <line text destination> correspond to the value of <srcTrig> and <destTrig> as follows:

<u>Value of &lt;srcTrig&gt; or &lt;destTrig&gt;</u>	<u>Value of &lt;line text source&gt; or &lt;line text destination&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
40 to 49	GPIO (<line> - 40)
50	TCNTR
51	GCNTR
60	TICK1
61	TICK2

**Example:** Map TTL line 4 to go out of the front panel with no signal conditioning.

```
MapTrigTrig 4, 41, 0
```

## SetTrigHndlr

**Purpose:** Replace the current TTL/ECL trigger, counter, or tick timer interrupt handler with a specified trigger source with a specified function.

### Query

**Syntax:** SetTrigHndlr <lines>, <function>

where <lines> is a bit vector of trigger lines (1 = set; 0 = do not set), where the value corresponds to the trigger line(s) to set:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
14	TIC counter
15	TIC TICK timers

and <function> is a pointer to the new trigger interrupt handler, where the value is defined as follows:

<u>Value</u>	<u>Interrupt Handler</u>
0	Specify DefaultTrigHandler
1	Specify DefaultTrigHandler2
other	User-installed trigger interrupt handler

**Response:** Program response: 0

Console response:

```
Trigger handler(s) installed (lines = <lines text>):
DefaultTrigHandler().<CRLF>
```

where the meaning of <lines text> = x, y, z..., where x, y, and z are bits that are set in <lines>.

**Example:** Set a trigger interrupt handler for TTL trigger line 4.

```
SetTrigHndlr 16
```

**Note:** DefaultTrigHandler automatically acknowledges acceptor protocols that require acknowledgement, while DefaultTrigHandler2 does not. If DefaultTrigHandler2 is used, send AckTrig to acknowledge the trigger.

**SrcTrig**

**Purpose:** Source a specified protocol on a specified TTL, ECL, or external trigger line.

**Query**

**Syntax:** SrcTrig <line>, <protocol>, <timeout>

where the value of <line> corresponds to the trigger line to source:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
40 to 49	External source/destination (GPIO 0 to 9) (supports ON, OFF, START, STOP, and SYNC protocols only)
50	TIC counter (supports SYNC and SEMI-SYNC protocols only)
60	TIC TICK timers (supports SYNC and SEMI-SYNC protocols only)

the value of <protocol> specifies the protocol to use:

<u>Value</u>	<u>Protocol</u>
0	ON
1	OFF
2	START
3	STOP
4	SYNC
5	SEMI-SYNC
6	ASYN
7	SEMI-SYNC and wait for Acknowledge
8	ASYN and wait for Acknowledge
ffffh	Abort previous Acknowledge pending (5 and 6)

and <timeout> is the timeout value in milliseconds

**Response:** Program response: 0

Console response:

```
Trigger sourcing (line = <line text>, protocol = <protocol text>)
complete.<CRLF>
```

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
40 to 49	GPIO (<line> - 40)
50	TCNTR
60	TICK1

and the meaning of <protocol text> corresponds to the value of <protocol> as follows:

<u>Value of &lt;protocol&gt;</u>	<u>Value of &lt;protocol text&gt;</u>
0	ON
1	OFF
2	START
3	STOP
4	SYNC
5	SEMI-SYNC
6	ASYNC
7	SEMI-SYNC wait ACK
8	ASYNC wait ACK
ffffh	wait ACK ABORT

**Example:** Source TTL line 4 for SEMI-SYNC protocol.

```
SrcTrig 4, 5, 0L
```

---

## TrigAsstConf

**Purpose:** Configure a specified TTL/ECL trigger line assertion method.

### Query

**Syntax:** TrigAsstConf <line>, <mode>

where the value of <line> corresponds to the trigger line to configure:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
ffffh	General assertion configuration (all lines)

and <mode> specifies the configuration mode, where

<u>Bit</u>	<u>Specific Line Configuration Modes</u>
0	1 = Synchronize falling edge of CLK10 0 = Synchronize rising edge of CLK10
<u>Bit</u>	<u>General Configuration Modes</u>
1	1 = Pass trigger through asynchronously 0 = Synchronize with next CLK10 edge
2	1 = Participate in SEMI-SYNC with external trigger acknowledge protocol 0 = Do not participate

All other values are reserved for future expansion.

**Response:** Program response: 0

Console response:

```
Trigger assertion configuration (line = <line text>, mode =
<mode>) complete.<CRLF>
```

where the meaning of <line text> corresponds to the value of <line>:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
ffffh	GENERAL CONFIG

**Example 1:** Configure all TTL/ECL trigger lines generally to synchronize to the falling edge of CLK10 (as opposed to the rising edge).

```
TrigAsstConf -1, 1
```

**Example 2:** Configure TTL trigger line 4 to synchronize to CLK10 for any assertion method and do not participate in SEMI-SYNC.

```
TrigAsstConf 4, 0
```

## TrigCntrConf

**Purpose:** Configure the TIC chip internal 16-bit counter.

### Query

**Syntax:** TrigCntrConf <mode>, <source>, <count>

where <mode> specifies the configuration mode:

<u>Value</u>	<u>Mode</u>
0	Initialize the counter
2	Reload the counter leaving enabled
3	Disable/abort any count in progress

<source> specifies the trigger line to configure as input to counter:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
70	CLK10
71	EXTCLK

and <count> specifies the number of input pulses to count before terminating.

**Response:** Program response: 0

Console response:

```
CNTR configured (mode = <mode text>, source = <source text>,
count = <count>).<CRLF>
```

where the meaning of <mode text> corresponds to the value of <mode>:

<u>Value of &lt;mode&gt;</u>	<u>Value of &lt;mode text&gt;</u>
0	INIT
2	RELOAD
3	DISABLE

and the meaning of <source text> corresponds to the value of <source>:

<u>Value of &lt;source&gt;</u>	<u>Value of &lt;source text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
70	CLK10
71	EXTCLK

**Example :** Configure the counter count 25 assertions on TTL trigger line 5 (the <protocol> parameter when calling EnaTrigSense will determine whether the counter accepts SYNC or SEMI-SYNC assertions).

```
TrigCntrConf 0, 5, 25
```

## TrigExtConf

**Purpose:** Configure the external trigger (GPIO) lines.

**Query**

**Syntax:** TrigExtConf <extline>, <mode>

where the value of <extline> is the trigger line to configure:

<u>Value</u>	<u>Trigger Line</u>
40 to 49	External source/destination (GPIO 0 to 9)
40	Front panel In (connector 1)
41	Front panel Out (connector 2)
42	ECL bypass from front panel
43	EXTCLK
44 to 49	Hardware-dependent GPIOs 4 to 9

and <mode> specifies the configuration mode, where

<u>Bit</u>	<u>Configuration Modes</u>
0	1 = Feed back any line mapped as input into the cross-point switch 0 = Drive input to external (GPIO) pin
1	1 = Assert input (regardless of feedback) 0 = Leave input unconfigured
2	1 = If assertion selected, assert low 0 = If assertion selected, assert high
3	1 = Invert external input (not feedback) 0 = Pass external input unchanged

All other values are reserved for future expansion.

**Response:** Program response: 0

Console response:

```
External connection (GPIO) configuration complete (extline =
<extline text>, mode = <mode>).<CRLF>
```

where the meaning of <extline text> corresponds to the value of <extline> as follows:

<u>Value of &lt;extline&gt;</u>	<u>Value of &lt;extline text&gt;</u>
40 to 49	GPIO (<extline> - 40)

**Example 1 :** Configure external line 41 (front panel Out) to not be used as feedback and left tristated for use as a mapped output via MapTrigTrig.

```
TrigExtConf 41, 0
```

**Example 2 :** Configure external line 40 (front panel In) to not be used as feedback and left tristated for use as a mapped input via MapTrigTrig.

```
TrigExtConf 40, 8
```

**Example 3 :** Configure external line 48 (GPIO 8) to be used as feedback for use as a cross-point switch input and output via MapTrigTrig.

```
TrigExtConf 48, 1
```

---

## TrigTickConf

**Purpose:** Configure the TIC chip internal dual 5-bit tick timers.

**Query**

**Syntax:** TrigTickConf <mode>, <source>, <tcount1>, <tcount2>

where <mode> specifies the configuration mode:

<u>Value</u>	<u>Mode</u>
0	Initialize the tick timers (rollover mode)
1	Initialize the tick timers (non-rollover mode)
2	Reload the tick timers leaving enabled
3	Disable/abort any count in progress

and the value of <source> is the trigger line to configure as input to counter:

<u>Value</u>	<u>Trigger Line</u>
40 to 49	External source/destination (GPIO 0 to 9)
70	CLK10
71	EXTCLK

and the values of <tcount1> and <tcount2> are the number of input pulses (as a power of two) to count before asserting TICK1 output or TICK2 output, respectively (and terminating the tick timer if configured for non-rollover mode).

**Response:** Program response: 0

Console response:

```
TICKs configured (mode = <mode text>, source = <source text>,
t1 = tcount1, t2 = tcount2).<CRLF>
```

where the meaning of <mode text> corresponds to the value of <mode>:

<u>Value of &lt;mode&gt;</u>	<u>Value of &lt;mode text&gt;</u>
0	INIT w/ROLL
1	INIT w/NOROLL
2	RELOAD
3	DISABLE

and the meaning of <source text> corresponds to the value of <source>:

<u>Value of &lt;source&gt;</u>	<u>Value of &lt;source text&gt;</u>
40 to 49	GPIO (<source> - 40)
70	CLK10
71	EXTCLK

**Example 1 :** Configure the tick timers to interrupt every 6.55 milliseconds by dividing down CLK10 as an input. Call `EnaTrigSense` to start the tick timers and enable interrupts.

```
TrigTickConf 0, 70, 16, 0
```

**Example 2 :** Configure the tick timers to output a continuous 9.765-kHz square wave on TICK1 output and a 1.25-MHz clock on TICK2 output by dividing down CLK10 as an input. Call `SrcTrig` to start the tick timers.

```
TrigTickConf 0, 70, 10, 3
```

---

## TrigToREQT

**Purpose:** Map trigger interrupt to GPIB SRQ condition (REQT generation for a particular GPIB address).

### Command

**Syntax:** TrigToREQT <la>, <line>

where <la> identifies the device for which to assert SRQ, and <line> is the trigger line for which to map the interrupt, where the value of <line> corresponds to the trigger line or counter/tick:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
50	TIC counter
60	TIC TICK1 tick timer

**Action:** The GPIB-VXI/C is set up to assert SRQ for a device attached to a GPIB address for a given trigger line's interrupt, as configured using either the SrcTrig or EnableSense function.

**Response:** Program response: 0

Console response:

```
Line: <line text>, configured to generate an REQT for Logical
Address <la>.<CRLF>
```

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
50	TCNTR
60	TICK1

**Example:** Set up Logical Address 4 to assert SRQ when a trigger interrupt occurs on TTL trigger line 2.

```
TrigToREQT 4, 2
```

## UMapTrigTrig

**Purpose:** Unmap a specified TTL, ECL, Star X, Star Y, external connection (GPIO), or miscellaneous signal line that was mapped to another line using the MapTrigTrig function.

### Query

**Syntax:** UMapTrigTrig <srcTrig>, <destTrig>

where <srcTrig> is the source line to unmap from a destination, and the value of <destTrig> corresponds to the destination line mapped from the source:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
40 to 49	External source/destination (GPIO 0 to 9)
40	Front panel In (connector 1)
41	Front panel Out (connector 2)
42	Front panel In (unbuffered)
43	Connection to EXTCLK input pin
44 to 49	Hardware-dependent GPIOs 4 to 9
50	TIC counter pulse output (TCNTR)
51	TIC counter finished output (GCNTR)
60	TIC TICK1 tick timer output
61	TIC TICK2 tick timer output

**Response:** Program response: 0

Console response:

```
Unmapping complete (line <line text source> unmapped from line
<line text destination>).<CRLF>
```

where the meaning of <line text source> and <line text destination> correspond to the value of <srcTrig> and <destTrig>:

<u>Value of &lt;srcTrig&gt; or &lt;destTrig&gt;</u>	<u>Value of &lt;line text source&gt; or &lt;line text destination&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
40 to 49	GPIO (<line> - 40)
50	TCNTR
51	GCNTR
60	TICK1
61	TICK2

**Example:** Unmap route of TTL line 4 to go out of the front panel as mapped by MapTrigTrig.

```
UMapTrigTrig 4, 49
```

## WaitForTrig

**Purpose:** Wait for the specified trigger line to be sensed for the specified time. EnaTrigSense must be called to sensitize the hardware to the particular trigger protocol to be sensed.

### Query

**Syntax:** WaitForTrig <line>, <timeout>

where the value of <line> corresponds to the trigger line to wait for:

<u>Value</u>	<u>Trigger Line</u>
0 to 7	TTL trigger lines 0 to 7
8 to 9	ECL trigger lines 0 to 1
50	TIC counter
60	TIC TICK1 tick timer

**Response:** Program response: 0

Console response:

Trigger received (line = <line text>), wait complete. <CRLF>

where the meaning of <line text> corresponds to the value of <line> as follows:

<u>Value of &lt;line&gt;</u>	<u>Value of &lt;line text&gt;</u>
0 to 7	TTL <line>
8 to 9	ECL (<line> - 8)
50	TCNTR
60	TICK1

**Example:** Wait for TTL line 4 to be encountered.

```
WaitForTrig 4, 10000L
```

## Word Serial Communication Commands and Queries

The Word Serial communication commands and queries are described on the following pages.

- ProtErr?
- RespReg?
- WScmd
- WScmd?
- WSresp?
- WSstr
- WSstr?

You can use these commands to directly generate Word Serial communication operations with any Message-Based device, including the GPIB-VXI/C itself, regardless of whether or not it is the GPIB-VXI/C's Servant.

**Note:** The Word Serial communication commands and queries are intended for debugging purposes. National Instruments does not guarantee that these commands will work when other Word Serial paths are open, such as the GPIB address link.

Some of the Word Serial commands as defined in the VXIbus specification require a response from the Message-Based device, while other commands do not. To distinguish between the two types of Word Serial commands, and to avoid confusion between Word Serial commands and GPIB-VXI/C local commands and queries, the following terminology will be used in this section:

*Word Serial command*—A VXI-defined Word Serial command that does not require a response from the Message-Based device.

*Word Serial query*—A VXI-defined Word Serial command that requires a response from the Message-Based device.

*Command*—A GPIB-VXI/C command, as defined in this chapter.

*Query*—A GPIB-VXI/C query, as defined in this chapter.

You can use the WScmd command to send a Word Serial command to a Message-Based device. The WScmd? query is used to send a Word Serial query to the Message-Based device, and to automatically read and return the device's response.

You can also use WScmd to send a Word Serial query to a Message-Based device. Because WScmd does not read the query response, the intermediate state of the device can be examined using the RespReg? query, after which the response can be read using the WSresp? query.

You can use the WSstr command to send device-dependent commands and queries to a device. If the string sent to the device was a device-dependent query, you can use the WSstr? query to read the device's response.

The `ProtErr?` query sends a *Read Protocol Error Word Serial* query to a device and reports the error response. The `RespReg?` query returns the value of a device's response register.

---

## ProtErr?

**Purpose:** Send a *Read Protocol Error Word Serial* query to a Message-Based device.

### Query

**Syntax:** `ProtErr? <log addr>`

**Action:** *Read Protocol Error* query is sent to a Message-Based device. Response is read and reported.

**Response:** Program response:

```
<hex value><CRLF>
```

where `<hex value>` is the hexadecimal value of the Data Low register response.

Console response:

```
Read Protocol Error for Logical Address <log addr> returned 0x<hex value>:  
  <description>
```

where `<description>` is text explaining the error response.

**Example:** `ProtErr? 3`

---

## RespReg?

**Purpose:** Get the Response register contents of a Message-Based device.

### Query

**Syntax:** RespReg? <log addr>

**Action:** Returns the contents of the device's Response register at Logical Address <log addr>.

**Response:** Program response:

<hex value><CRLF>

where <hex value> is the hexadecimal value of the Response register contents.

Console response:

```
Logical Address <log addr>'s Response register:<CRLF>
[0x<hex value>]: <dor> <dir> <err> <rr> <wr> <fhs> <locked><CRLF>
```

where <dor>, <dir>, <err>, <rr>, <wr>, <fhs>, and <locked> are text flags that interpret the state of the Response register bit flags. Capitalized text in a text flag indicates that the corresponding bit flag is in the logic TRUE state. Lowercase text indicates that the corresponding bit flag is in the logic FALSE state.

## WScmd

**Purpose:** Send a 16-bit Word Serial command or query to a Message-Based device.

### Command

**Syntax:** WScmd <log addr>, <WS cmd>

**Action:** Sends the Word Serial command <WS cmd> to the device at <log addr>.

**Example:** Write the *Begin Normal Operation* Word Serial query (FCFFh) to a device at Logical Address 3.

```
WScmd 3, #hFCFF
```

## WScmd?

**Purpose:** Send a 16-bit Word Serial query to a Message-Based device.

### Query

**Syntax:** WScmd? <log addr>, <WS cmd>

**Action:** Sends the Word Serial query <WS cmd> to the device at <log addr>. Reads and returns the device's response.

**Response:** Program response:

<hex value><CRLF>

where <hex value> is the hexadecimal value of the Data Low register response.

Console response:

Logical Address <log addr> Word Serial Query 0xceff returned  
0x<hex value>.<CRLF>

**Example:** Write the *Read Servant Area* Word Serial query (CEFFh) to a device at Logical Address 4.

```
WScmd? 4, #hCEFF
```

---

**WSresp?**

**Purpose:** Read a 16-bit Word Serial response to a previously sent query.

**Query**

**Syntax:** WSresp? <log addr>

**Action:** Reads and returns the response of the device at <log addr>.

**Response:** Program response:

<hex value><CRLF>

where <hex value> is the hexadecimal value of the Data Low register response.

Console response:

Logical Address <log addr> returned response 0x<hex value><CRLF>

**Example:** Read the 16-bit response to a previously sent Word Serial query from Logical Address 3.

```
WSresp? 3
```

---

## WSstr

**Purpose:** Send a device-dependent command string to a Message-Based device.

**Command**

**Syntax:** WSstr <log addr>, <string>

where <string> is an ASCII character sequence enclosed by double quotation marks (").

The following sequences of characters within the <string> parameter are special cases and will be interpreted as follows:

\n	linefeed (LF)
\r	carriage return (CR)
\\	backslash (\)
\xHH	any binary 8-bit value where HH is the ASCII hexadecimal representation of that value

**Action:** Writes the string <string> to the device at <log addr> as a series of *Byte Available* commands.

**Example:** Write the string "start" to a device at Logical Address 8.

```
WSstr 8, "start"
```

---

**WSstr?**

**Purpose:** Read a device-dependent response string from a Message-Based device.

**Query**

**Syntax:** WSstr? <log addr>, <max cnt>

**Action:** Reads and returns a string, up to a maximum character count of <max cnt>, using a series of *Byte Request* commands.

**Response:** Program response:

<resp string>

where <resp string> is the response string returned by the device.

Console response:

```
Logical Address <log addr> read <# bytes> (<hex # bytes>) through  
Word Serial: <CRLF><CRLF> <resp string>
```

where <# bytes> and <hex # bytes> are the number of bytes in <resp string>, in decimal and hexadecimal, respectively.

**Example:** Read a device-dependent response up to 20 characters long from a device at Logical Address 10.

```
WSstr? 10, 20
```

---

## CI Configuration Commands and Queries

The CI configuration commands and queries are described on the following pages.

- `CIAddr?`
- `CIArea`
- `CIArea?`
- `CIBlocks?`
- `CIDelete?`
- `CIList?`
- `DCIDownLdPI`
- `DCIDownload`
- `DCISetup?`
- `DCISetupPI?`
- `ECIboot?`

These commands and queries manipulate CIs and their related resources, and extract information about the CI configuration.

The query `CIList?` returns the list of code instrument logical addresses. The RM information queries that access information for physical devices (`Cmdr?`, `RmEntry?`, `Srvnts?`, `StatusState?`) can be used to retrieve the equivalent information for a CI. The `CIDelete` query deletes a CI.

The amount of RAM reserved for all CIs set by the GPIB-VXI/C depends upon its nonvolatile configuration, the amount of RAM installed, and the use of the command `CIArea`. The CI RAM area is partitioned into blocks of 4 kilobytes in size. The `CIArea?` query can determine the current location and size of the CI RAM area. The `CIBlocks?` query returns the allocation state of each block in the CI RAM area. The `CIAddr?` query can determine the base address of a particular CI's RAM area.

Static Downloaded CIs (DCIs) are downloaded to the GPIB-VXI/C and initialized with the local commands `DCISetUp?` and `DCIDownload`.

Position Independent DCIs are downloaded to the GPIB-VXI/C and initialized with the local commands `DCISetupPI?` and `DCIDownLdPI`.

`ECIboot?` may be used for debug or runtime purposes to start up an EPROMed Code Instrument that is already installed on the GPIB-VXI/C. This is an alternative to nonvolatile configuration.

**CIAddr?**

**Purpose:** Get the local base RAM address of a CI.

**Query**

**Syntax:** CIAddr? <logical address>

**Response:** Program response:

<base address><CRLF>

where <base address> is the CI's base address in decimal.

Console response:

CI at Logical Address <logical address> base Local Address is <hex base address><CRLF>

where <hex base address> is the CI's base address in C language hexadecimal notation.

**Example:** Get the local address of the CI at Logical Address 9.

CIAddr? 9

---

## CIArea

**Purpose:** Change the location and size of the CI RAM area.

### Command

**Syntax:** `CIArea <Base Address>, <Number of blocks>`

**Action:** Sets the CI global RAM to start at <Base Address>, and span <Number of blocks> blocks of 4096 bytes each.

The default base address and size of the CI RAM area are set by the nonvolatile configuration parameters `CI Block Base` and `CI Num Blocks`.

<Base Address> is the new base address of the CI RAM area. It must be a multiple of 4096 decimal (1000h), and must be in the region above the top of pSOS Region 1 and below the top of memory. pSOS Region 1 starts at 10000h, and its size is determined by the nonvolatile configuration parameter `Region 1 Size`. For example, if `Region 1 Size` = 60000h, the lowest allowed value for <Base Address> is as follows:

$$10000h + 60000h = 70000h$$

<Number of blocks> is the number of 4096 (1000h) byte blocks in the CI RAM area. The size of the CI RAM area is limited by the amount of physical RAM on the GPIB-VXI/C, so the maximum allowed value for <Number of blocks> is as follows:

$$(\text{<RAM size>} - \text{<Base Address>}) / 1000h$$

For example, if the GPIB-VXI/C is configured with 512 kilobytes (80000h) of RAM, and <New Base Address> is 70000h, the maximum allowed value for <Number of blocks> is given by the following formula:

$$(80000h - 70000h) / 1000h = 10h = 16$$

If <Number of blocks> is set to 0, CI's are disabled.

**Example:** Set the base of CI RAM area to 80000h, and the size to 128 blocks of 4 kilobytes.

```
CIArea #h80000, 128
```

**CIArea?**

**Purpose:** Return the base address and size of CI global memory area.

**Query**

**Syntax:** CIArea?

**Response:** Program response:

```
<base address>, <number of blocks><CRLF>
```

where <base address> and <number of blocks> are the current base address and size of the CI RAM area in blocks of 4 kilobytes, respectively.

Console response:

```
CI Global Base is local Address <hex base address> with <number of
blocks> 4K blocks<CRLF>
```

<hex base address> is the base address of the CI RAM area in C language hexadecimal notation. <number of blocks> is the size of the CI RAM area (in blocks of 4 kilobytes) in decimal.

**CIBlocks?**

**Purpose:** Return a listing of used and unused CI memory area blocks.

**Query**

**Syntax:** CIBlocks?

**Response:** Program response:

```
<b0>, <b1>, . . . , <bL-1><CRLF>
```

where <bJ> is a Boolean value that indicates whether the Jth block is unused (0) or used (1). L is the number of blocks of 4 kilobytes in the CI global memory area.

Console response:

```
Blocks Used of the <L> Blocks of CI Global Memory: <CRLF>
<r0start> - <r0stop>, <r1start> - <r1stop>, . . . ,<rN-1start> -
<rN-1stop><CRLF>
```

where <rMstart> and <rMstop> are the start and stop block numbers for the Mth occupied memory region.

**CIDelete?**

**Purpose:** Delete a CI.

**Query**

**Syntax:** CIDelete? <code instrument logical address>

<code instrument logical address> is the logical address of the CI to be deleted.

**Response:** Program response:

<error code><CRLF>

where <error code> is a decimal value that indicates the result of the attempt to delete the CI. If <error code> is equal to 0, the attempt was successful.

Console response:

Code Instrument at Logical Address <code instrument logical address> successfully deleted<CRLF>

if the attempt was successful, or

Error Deleting Code Instrument (Error code = <hex error code>)

if the attempt was unsuccessful.

<hex error code> is a value in C language hexadecimal format that indicates the result of the attempt to delete the CI.

<error code> and <hex error code> can be interpreted by converting them to a binary bit pattern. A value of 1 in any bit position indicates that the error shown in the following table occurred during the attempt to delete the CI.

Bit	Error condition
0	The GPIB-VXI/C was unable to delete the CI's GPIB address link.
1	The GPIB-VXI/C was unable to delete the CI's message exchange.
2	The GPIB-VXI/C was unable to delete the CI's Async process.
3	The GPIB-VXI/C was unable to delete the CI's Worker process.
4	The GPIB-VXI/C was unable to delete the CI's Word Serial I/O structures.
5	The GPIB-VXI/C was unable to free the PI CI's dynamic memory.

Any error encountered is unrecoverable in the sense that the CI is not restored. Any further attempts to communicate with it will have undetermined results, and can adversely affect the behavior of the GPIB-VXI/C.

## CIList?

**Purpose:** Get a list of logical addresses for CIs running on the GPIB-VXI/C.

### Query

**Syntax:** CIList?

**Response:** Program response:

```
<ci la1>,<ci la2>, . . . ,<ci laN><CRLF>
```

where <ci la<sub>J</sub>> is the logical address of the Jth local CI. *N* is the total number of local CIs.

Console response:

```
Local CI Logical Addresses are: <ci la1>,<ci la2>, . . . ,
<ci laN><CRLF>
```

## DCIDownLdPI

**Purpose:** Download a Position Independent (PI) CI to RAM and start running it.

**Command**

**Syntax:** DCIDownLdPI [ <Boolean> ]

**Action:** Bytes of code and data (up to the number requested in the DCISetupPI? command) are downloaded from the command source. When the download is complete, the pSOS processes associated with the PI DCI are initiated.

DCIs can only be downloaded from the GPIB port or via Word Serial Protocol, because the download is terminated on GPIB EOI or the Word Serial END command. Because there is no analogy for EOI or END for the serial port (that is, a carriage return is a valid binary number), it cannot be used to download PI DCIs.

If <Boolean> is 1, debug statements are printed to the serial port during the various stages of PI DCI initialization. If <Boolean> is 0 or if it is omitted, the debug statements are not output. The debug printing mode is only available with the development firmware option.

The DCIDownLdPI command should always be immediately preceded by a DCISetupPI? command that configures the download parameters. Executing intermediate GPIB-VXI/C commands between DCISetupPI? and DCIDownLdPI may invalidate the download setup.

**Example:** Download and initialize a PI DCI, generating debug statements.

```
DCIDownLdPI 1
```

---

## DCIDownload

**Purpose:** Download a CI to RAM and start running it.

**Command**

**Syntax:** DCIDownload [ <Boolean> ]

**Action:** Blocks of code and data (up to the number requested in the DCISetup? command) are downloaded from the command source. When the download is complete, the pSOS processes associated with the DCI are initiated.

DCIs can only be downloaded from the GPIB port or via Word Serial protocol, because the download is terminated on GPIB EOI or the Word Serial END command. Because there is no analogy for EOI or END for the serial port, it cannot be used to download DCIs.

If <Boolean> is 1, debug statements are printed to the serial port during the various stages of DCI initialization. If <Boolean> is 0 or if it is omitted, the debug statements are not output. The debug printing mode is only available with the development firmware option.

The DCIDownload command should always be immediately preceded by a DCISetup? command that configures the download parameters. Executing intermediate GPIB-VXI/C commands between DCISetup? and DCIDownload may invalidate the download setup.

**Example:** Download and initialize a DCI, generating debug statements.

```
DCIDownload 1
```

---

## DCISetup?

**Purpose:** Set up parameters for a DCI download.

### Query

**Syntax:** DCISetup? <logical address>, <Commander's logical address>, <start block>, <number of blocks>, <stack size>, [, <Servant1>, [<Servant2>, ..., <ServantN>]]

The DCISetup? query provides the GPIB-VXI/C with the information it needs to prepare for executing a DCIDownload command. This command is performed separately from the DCIDownload command so that the download parameters can be validated before the object code download is initiated.

The GPIB-VXI/C interprets the DCISetup? query parameters as follows:

- The DCI is to be assigned Logical Address <logical address>, and granted to the Commander at <Commander's logical address> as a Servant.
- Up to <number of blocks> of DCI code and data are to be loaded into CI RAM area starting at <start block>.
- A stack of size <stack size> words is to be allocated for the CI worker process. If <stack size> is less than 1024, a stack size of 1024 words (2 kilobytes) is to be allocated for the CI.
- <Servant1> through <ServantN> are to be granted to the CI as Servants.

Any GPIB address links to <Servant1>, <Servant2> through <ServantN> must be disconnected before the DCI is downloaded. You can delete the links by using the SaDisCon or LaSaddr commands.

**Response:** Program response:

0 <CRLF>

0 is returned to report the successful completion of the DCISetup? command. Any errors are reported in the form of an error code.

Console response:

DCI parameters OK, Ready to download.<CRLF>

**Example:** Set up to download a DCI at Logical Address C0h, to be a Servant of the device at Logical Address 2 and Commander of device at Logical Address 50. Set up to download to the first 20 blocks of DCI memory area, and allocate a 2048-word stack.

```
DCISetup? #hC0,2,0,20,#h800,50
```

## DCISetupPI?

**Purpose:** Set up parameters for a PI DCI download.

### Query

**Syntax:** DCISetupPI? <logical address>, <Commander's logical address>, <dynamic RAM size>, <stack size>, [, <Servant1>, [<Servant2>, ..., <ServantN>]]

The DCISetupPI? query provides the GPIB-VXI/C with the information it needs to prepare for executing a DCIDownLdPI command. This command is performed separately from the DCIDownLdPI command so that the download parameters can be validated before the object code download is initiated.

The GPIB-VXI/C interprets the DCISetupPI? query parameters as follows:

- The PI DCI is to be assigned Logical Address <logical address>, and granted to the Commander at <Commander's logical address> as a Servant.
- Up to <dynamic RAM size> bytes of PI DCI code and data are to be loaded into a pSOS dynamic RAM segment allocated when the DCIDownloadPI command is sent.
- A stack of size <stack size> words is to be allocated for the CI worker process. If <stack size> is less than 1024, a stack size of 1024 words (2K) is to be allocated for the CI.
- <Servant1> through <ServantN> are to be granted to the CI as Servants.

Any GPIB address links to <Servant1>, <Servant2> through <ServantN> must be disconnected before the PI DCI is downloaded. You can delete the links by using the SaDisCon or LaSaddr commands.

**Response:** Program response:

0 <CRLF>

0 is returned to report the successful completion of the DCISetupPI? command. Any errors are reported in the form of an error code.

Console response:

PI DCI parameters OK, Ready to download.<CRLF>

**Example:** Set up to download a PI DCI at Logical Address C0h, to be a Servant of the device at Logical Address 2 and Commander of device at Logical Address 50. Set up to download up to 10000 bytes of code and data to a pSOS dynamic memory segment, and allocate a 2048-word stack.

```
DCISetupPI? #hC0,0,10000,#h800,50
```

---

## ECIboot?

**Purpose:** Start up an EPROMed Code Instrument (static or position independent) that already resides in memory of the GPIB-VXI/C.

### Query

**Syntax:** ECIboot? <address>, <debug>

**Response:** Program response:

none

Console response:

```
EPROMed Code Instrument at address <address> booting  
complete.<CRLF>
```

where <address> is the local GPIB-VXI/C memory-mapped address of the EPROMed Code Instrument.

**Example:** Boot EPROMed Code Instrument at address f7C000h with debug off.

```
ECIboot? #hf7C000, 0
```

---

# Chapter 4

## Nonvolatile Configuration

---

This chapter describes the method for editing and reviewing the contents of the nonvolatile memory, which is used for storing configuration information on the GPIB-VXI/C.

The GPIB-VXI/C nonvolatile (NV) memory is a 256-byte EEPROM that is accessible as 64 longword locations. The first half of the NV memory (32 longwords) is reserved for use by National Instruments. The second half of NV memory is allocated for storing Code Instrument (CI) configuration variables.

The configuration parameters include the following:

- Local register configuration
- pSOS configuration
- VXI interrupt line assignment
- Resource Manager (RM) A24 and A32 address assignment base
- Servant area size
- DC starting logical address and hierarchy configuration
- Device failure mode
- GPIB configuration
- Default CI configuration
- CI RAM area configuration
- Resident CI locations
- CI user configuration variables

You can enter NV configuration mode through any of the following methods.

- Set the startup mode switches to the nonvolatile configuration mode as described in the *GPIB-VXI/C Startup Mode Configuration* section of Chapter 2. For this mode, set switch S12 to the *ON* position and set switch S13 to the *OFF* position. Restart the system
- In 488-VXI runtime system mode, you can enter NV configuration mode through the `CONF` command.
- In VXI pPROBE mode (on development modules only) you can enter NV configuration mode through the `CONF` command.

The nonvolatile configuration commands must be executed from the RS-232 port.

The EEPROM is connected to the microprocessor via an I<sup>2</sup>C serial bus. Because it takes five to ten seconds to write the contents of the memory, the GPIB-VXI/C creates a copy of the contents of the EEPROM in RAM, which can be quickly edited. When the editing is complete, the entire contents of the RAM copy can be written back to the EEPROM.

Notice that some of the changes (such as the pSOS parameters) do not take effect until the system is restarted. This can be accomplished by the pROBE commands IN or BO, by resetting the system, or by cycling the system power.

## The GPIB-VXI/C Nonvolatile Configuration Main Menu

When you enter the NV configuration mode, the GPIB-VXI/C displays the menu shown in Figure 4-1.

```
GPIB-VXI Nonvolatile Configuration Main Menu
(C) 1991 National Instruments
=====
1). Read In Nonvolatile Configuration
2). Print Configuration Information
3). Change Configuration Information
4). Set Configuration to Factory Settings
5). Write Back (Save) Changes
6). Quit Configuration

Choice (1-6):
```

Figure 4-1. The GPIB-VXI/C Nonvolatile Configuration Main Menu

From the main menu, you can select the NV memory editing function you want to perform. To select an item in the menu, enter its number at the prompt. The effect of selecting each item is described below.

### Read in Nonvolatile Configuration

The item Read In Nonvolatile Configuration reads the contents of the EEPROM into RAM.

### Print Configuration Information

The item Print Configuration Information displays the Nonvolatile Configuration Information from the RAM copy. Figure 4-2 shows an example of this display.

```

===== Nonvolatile Configuration Information =====

Logical Address: 0x00          Device Type      : Message Based

```

Figure 4-2. The Nonvolatile Configuration Information Display

The first four sections display the National Instruments-reserved variables. The last section displays hexadecimal values representing the contents of the user-defined variables. In this example, no user-defined variables have been initialized.

The following paragraphs contains descriptions of the fields in the Nonvolatile Configuration Information Display.

### Logical Address

This field contains the VXI logical address of the GPIB-VXI/C. It specifies the location of the GPIB-VXI/C registers in VXI A16 space. The formula is as follows:

$$C000h + (40h * \text{Logical Address})$$

If the Logical Address is set to 0, the GPIB-VXI/C will attempt to be the VXI Resource Manager. If the Logical Address is set in the range of 01 to FEh (1 through 254), the GPIB-VXI/C is set up to be a Static Configuration (SC) Message-Based (or possibly Register-Based) device. If the Logical Address is set to FFh (255), the GPIB-VXI/C is set up to be a Dynamic Configuration (DC) Message-Based (or possibly Register-Based) device. The factory setting is Logical Address 0.

### Device Type

You can set up the GPIB-VXI/C to be either a Message-Based or a Register-Based VXI device. Normally, the GPIB-VXI/C should be a Message-Based device. In Register-Based mode, however, the GPIB-VXI/C can reside virtually transparently in the VXI system for use as a debugging tool. It can still access the VXIbus directly as a bus master, perform Word Serial operations and GPIB transactions, and use Code Instruments. None of the functionality is removed; however, the Resource Manager does not grant any Servants to a Register-Based GPIB-VXI/C.

### Manufacturer Id

The Manufacturer Id is set at the factory and cannot be changed. Manufacturer Ids are assigned by the VXI Consortium. The Manufacturer Id for National Instruments is FF6h.

### Model Code, Slot 0/Non-Slot 0

You can configure the GPIB-VXI/C for either Slot 0 or Non-Slot 0 operation. According to the VXIbus specification, a device configured to be in Slot 0 must have a Model Code between 000h and 0FFh. A device configured to be in a slot other than Slot 0 must have a Model Code greater than 0FFh. The GPIB-VXI/C Model Codes are assigned by National Instruments. This field is used only to configure which one of the two GPIB-VXI/C Model Codes to use. The factory setting is for Slot 0.

### Slave Address Space

The GPIB-VXI/C can be configured to share 0%, 25%, 50%, or 100% of its onboard RAM with the VXIbus in either A24 or A32 address spaces. The percentage shared with the VXIbus is set via switches S6 and S8. Consult Table 2-4 in the *Setting the Shared Memory Size* section of Chapter 2 for further information. The VXI address space to be shared with the local RAM is set with this field in nonvolatile configuration mode. The factory setting is 0% dual-ported RAM.

## Protocol Register

You can configure the GPIB-VXI/C to have a user-defined Protocol register. Only the FHS\* and INT bits are not permitted to be active.

## RESET Configuration

The GPIB-VXI/C has three configurable reset parameters. They can be enabled or disabled and are as follows:

- Pushbutton resets backplane (asserts SYSRESET\* signal).
- Pushbutton resets GPIB-VXI/C (asserts local reset signal).
- Backplane SYSRESET\* signal resets GPIB-VXI/C (SYSRESET\* on backplane asserts local reset).

## Serial Number

The serial number is a 32-bit quantity used to identify a particular GPIB-VXI/C. This value is set at the factory and cannot be altered.

## User pROBE Parser

For developmental GPIB-VXI/Cs, you can install a parser to implement any commands you may need for a custom test/debug environment within the pROBE environment. If the specified address is not 0 (no parser), use the following code to call the specified address:

```
long UserParser (inputline)
char *inputline;
```

where `inputline` is a pointer to the typed line on the pROBE command line. The return value should be 1 if the command on the `inputline` was valid, and 0 if it was not valid.

## pSOS Region 1 Size

pSOS Region 1 is the Dynamic Memory pool used for the majority of memory requirements of the GPIB-VXI/C. All process control blocks (PCBs), process stacks, queues, messages, GPIB buffers, and so on, are allocated from this region. The first 64 kilobytes (0 to FFFFh) of any size onboard RAM configuration are reserved for use by National Instruments. You can allocate the rest for Region 1, Code Instruments, or a device-dependent use. Region 1 always starts at local address 10000h. The minimum size is 60000h. The maximum size is the amount of RAM minus 10000h.

## Number of pSOS Processes

You can use this parameter to configure the maximum allowable number of pSOS processes. The GPIB-VXI/C requires a minimum of 16 processes. The factory setting is 32.

### Number of pSOS Message Exchanges

You can use this parameter to configure the maximum allowable number of pSOS message exchanges. The GPIB-VXI/C requires a minimum of 16 message exchanges. The factory setting is 32.

### Number of pSOS Message Buffers

You can use this parameter to configure the maximum allowable number of pSOS message buffers. The GPIB-VXI/C requires a minimum of 100h message buffers. The factory setting is 180h.

### Console

You can use this parameter to set the GPIB-VXI/C RS-232 local command console to default to enabled or disabled. You can use the local command `ConsoleEna` to change the setting at runtime.

### VXI Interrupt Level to Handler Logical Address

This is a table of logical addresses the Resource Manager can use during resource management of the VXI interrupt lines. If an interrupter is hard-configured (not a VXI programmable interrupter), place the logical address of the interrupt handler device in the corresponding level. If an interrupt handler is hard-configured (not a VXI programmable handler), place its logical address in the corresponding level to avoid conflicts with other programmable handlers and also to permit the Resource Manager to assign programmable interrupters to the correct levels. If all interrupters and interrupt handlers are programmable, you can keep the value of FFh for all entries in the table.

As part of the hardware capabilities on the GPIB-VXI/C, there are three VXI programmable interrupt handlers. They can be assigned dynamically by the RM or statically according to the contents of the nonvolatile memory.

### A24 Assign Base

This entry determines the A24 address where the Resource Manager will begin allocating A24 address space for VXI devices. You can use this field to avoid conflicts with VME devices that use A24 address space. In addition, you can guarantee that a bus master can access the range of address space that a particular device is configured to occupy. The VXIbus specification requires A24 bus masters to *see* addresses from 200000h to DFFFFFFh.

### A32 Assign Base

This entry determines the A32 address where the Resource Manager will begin allocating A32 address space for VXI devices. You can use this field to avoid conflicts with VME devices that use A32 address space. In addition, you can guarantee that a bus master can access the range of address space that a particular device is configured to occupy. The VXIbus specification requires A32 bus masters to *see* addresses from 20000000h to DFFFFFFFh.

## DC Starting Logical Address

This parameter specifies the first logical address the Resource Manager should use to begin assigning Dynamic Configuration (DC) devices. DC devices will be assigned the next higher unassigned logical address.

## BNO

This parameter specifies whether the Resource Manager should send *Identify Commander* and *Begin Normal Operation* in a DC system. DC systems cannot specify an intended hierarchy and must be configured externally (normally through the local commands `DCGrantDev` and `DCBNOsend`). The most common configuration, however, is to assign all DC devices to Logical Address 0 (the RM). If BNO is specified to be sent, all DC devices are assigned to Logical Address 0 and the *Identify Commander* and *Begin Normal Operation* commands are sent. If BNO is specified *not* to be sent, no devices (either SC or DC) will be sent the *Begin Normal Operation* command. `DCBNOsend` must be sent to the local command set to initiate normal operation after the hierarchy is established.

## For FAILED Device

The VXIbus specification requires Commanders to Sysfail-Inhibit a Servant device that has failed (asserted the `SYSFAIL*` line and the Passed bit in its Status register). The specification permits Commanders to also set the reset bit of a failed device. This parameter specifies which method to use.

## Servant Area

This parameter specifies what Servant area value to return to the Resource Manager during a Word Serial *Read Servant Area* query. This parameter applies only when the GPIB-VXI/C is *not* Resource Manager.

## GPIB Primary

This parameter specifies the GPIB primary address of the GPIB-VXI/C to be used when in multiple secondary addressing mode.

## GPIB Address Assignment Method

This parameter specifies what method to use to configure the GPIB address of the GPIB-VXI/C. The choices are as follows:

- Default:
  - 0 for multiple secondary addressing
  - 1 for multiple primary addressing
- Always a particular GPIB address
- No GPIB address

**GPIB Flags**

MultPrimary: Multiple primary addressing mode is set.

MultSecond: Multiple secondary addressing mode is set.

Others: These flags are for information purposes only; do not modify.

**GPIB Addresses to Avoid**

This is a 32-bit bit mask of GPIB addresses to avoid during address assignment for either multiple primary or multiple secondary addressing modes.

**Code Instrument Block Base**

This parameter specifies the local GPIB-VXI/C address base for Static Code Instruments.

**Code Instrument Number of RAM Blocks**

This parameter specifies the number of 4-kilobyte RAM blocks allocated from the block base for use by Static Code Instruments.

**Resident Code Instrument Locations**

These parameters specify the base addresses of EPROMed Code Instruments. These Code Instruments are automatically started up after the Resource Manager operations complete.

**Code Instrument Nonvolatile User Configuration Variables**

These parameters are completely user-defined and can be used for any purpose.

## Change Configuration Information

The item `Change Configuration Information` displays the GPIB-VXI/C Nonvolatile Configuration Changer as shown in Figure 4-3.

```
          GPIB-VXI Nonvolatile Configuration Changer
                (C) 1991  National Instruments
=====
0). Edit Local Register Configuration
1). Edit pSOS Configuration
2). Edit VXI Interrupt Handler Logical Address
3). Edit Resource Manager A24/A32 Assign Bases
4). Edit Servant Area and DC Configuration
5). Edit FAILED Device Handling Mode
6). Edit GPIB Configuration
7). Edit Default CI Configuration
8). Edit Resident CI Base Locations
9). Edit CI User Configuration Variables
Q). Quit Editor

          Choice (0-9,Q):
```

Figure 4-3. The GPIB-VXI/C Nonvolatile Configuration Changer

You can edit the National Instruments-reserved configuration parameters and CI user configuration variables by selecting the corresponding menu item. In each case, you are prompted to enter constants for the new values, with default values supplied where appropriate. For the pSOS configuration parameters, the GPIB-VXI/C prints a formula for calculating an appropriate value for each parameter if you type in 0 in response to the prompt requesting the value.

The Default CI Configuration and Resident CI Base Locations options are only important when installing a Resident CI. Refer to Appendix B, *Using the DMAmove and CDS-852 Adapter Code Instruments*, for instructions on installing the Resident CIs.

**Note:** The `Change Configuration Information` editor modifies only the RAM copy of the NV memory contents. You must update the NV memory with the `Write Back (Save) Changes` command in the main menu to retain the changes after the GPIB-VXI/C has been reset or powered-down.

Select `Quit Editor` to return the display to the main menu.

## Set Configuration to Factory Settings

The item `Set Configuration to Factory Settings` sets the contents of the RAM copy of the NV memory to the default (original) factory settings. Notice that only the RAM copy is affected. You must use the `Write Back (Save) Changes` command in the main menu to write back the NV memory and retain the changes after the GPIB-VXI/C has been reset or powered-down.

## Write Back (Save) Changes

The item `Write Back (Save) Changes` writes the modified copy of the NV memory back to the EEPROM. The write-back procedure takes five to ten seconds.

## Quit Configuration

The item `Quit Configuration` prompts you to select a different startup configuration, or re-enters `pROBE`, depending upon how the nonvolatile configuration mode was entered.

# Chapter 5

## Diagnostic Tests

---

This chapter contains information for executing the GPIB-VXI/C diagnostic self-tests. The diagnostics test each GPIB-VXI/C subcircuit and are useful in detecting and isolating problems.

You can enter diagnostics mode through any of the following methods.

- Set the startup mode switches to the diagnostics mode as described in the *GPIB-VXI/C Startup Mode Configuration* section of Chapter 2. For this mode, set switch S12 to the *OFF* position and set switch S13 to the *ON* position. Restart the system.
- In VXI pROBE mode (on development modules only) you can enter the diagnostic mode through the pROBE *DIAG* command.
- In 488-VXI runtime system mode, you can enter the diagnostic mode through the *DIAG* command.

The diagnostic commands must be executed from the RS-232 port.

### Configuration for Diagnostic Testing

The diagnostic tests require the GPIB-VXI/C to be disconnected from all other GPIB devices to prevent interference with the GPIB tests.

### Diagnostic Test Structure

A total of 263 diagnostic routines, or *tests*, are organized in *groups* as shown in Table 5-1. Each test is composed of one or more subroutines called *commands*.

Each test is designed to functionally test a specific part of the GPIB-VXI/C circuitry. You can execute the diagnostics by test groups or by individual tests.

Table 5-1. Diagnostic Tests

		Test Numbers	
Test Name	Group Number	From	To
RAM	1	1	4
68070 CPU	2	5	21
MIGA	3	22	44
GPIB	4	45	132
TIC	5	133	236
DMA	6	237	247
68881 Coprocessor	7	248	248
RAM (exhaustive)	8	249	250
Interrupts	9	251	253
Miscellaneous Tests	10	254	263

## Diagnostics Mode Selection

Two hierarchical levels of menus control execution of the diagnostic tests. The highest-level menu is the Diagnostics Mode menu, which you can use to select whether to execute a test group or tests, and the mode in which to run them. The Diagnostics Mode menu is shown in Figure 5-1 and described in Table 5-2.

```

GPIB-VXI/C DIAGNOSTICS:  < XXX DRAM Reported >

    Default Diags(all)    ===> d
    Tests                 ===> t
    Test Groups          ===> g
    Over Night Loop      ===> o
    Quit                 ===> q

PRINT TOGGLE             ===> p
SINGLE STEP TOGGLE       ===> s
LOOPING TOGGLE          ===> l
ERROR REPORT TOGGLE     ===> e
REPORT ERROR LOG        ===> r
CLEAR ERROR LOG         ===> c
(Current settings: PRINT(OFF), ERROR(ON), SINGLE(OFF), LOOP(OFF))

Enter Selection      :

```

Figure 5-1. The Diagnostics Mode Menu

Table 5-2. Diagnostics Mode Menu Option Descriptions

Selection	Description
Default Diags (all)	Runs all the tests.
Tests	Presents a menu of tests to be selected.
Test Groups	Presents a menu of test groups to be selected.
Over Night Loop	Runs selected tests continuously. Only stops when an error occurs or when system is reset.
Print Toggle	Turn printing of test groups/tests on or off.
Single Step Toggle	Turns single-stepping of test groups/tests on or off.
Looping Toggle	Turns looping of selected test groups/tests on or off.
Error Report Toggle	Turns printing of error statements on or off.
Report Error Log	Prints the first 11 errors that occurred.
Clear Error Log	Erases the buffer of errors.

By default, single-stepping, looping, and test message printing are turned off while error reporting is turned on. The selected diagnostics run uninterrupted until they complete or until an error occurs. If an error has occurred, an error message is printed to the screen. The message displays the test number, group number, the value expected, and the value received. Please contact National Instruments for further interpretation of diagnostic error messages.

You can suppress the error reporting with the `e` command. With error reporting turned off, you can select and run tests to completion without being interrupted by error messages. The GPIB-VXI/C informs you if any errors have occurred after all the tests you selected have completed. To view the errors, select `r` to display the error log. Select `c` to clear the error log.

Single Step Toggle is another useful feature you can use to pinpoint problems. Select `s` to toggle this command on or off. With this feature, each access to memory or to a register is reported on the screen. In addition, the GPIB-VXI/C waits for you to press a key before actually performing the displayed step.

## Diagnostic Test Selection

If you select the Default Diags (all) option or the Over Night Loop option, the appropriate tests begin immediately. The default option performs all of the tests, while the Over Night Loop option performs all except the interactive tests and tests that drive signals on the VXIbus. When you select either the Tests or the Test Groups option, a new menu appears from which you can select any or all tests or test groups. Figure 5-2 shows the Test Selection menu. The Test Group Selection menu is very similar.

GROUP NAME	GROUP NUM	TEST NOs FROM - TO
RAM	1	1 - 4
68070 - I2C	2	5 - 7
68070 - UART	2	8 - 20
68070 - TIMER	2	19 - 21
MIGA	3	22 - 44
GPiB - NAT4882	4	45 - 99
GPiB - TURBO 488	4	100 - 132
TIC	5	133 - 236
DMA	6	237 - 247
MC68881	7	248 - 248
RAM(exhaustive)	8	249 - 250
INTERRUPTS	9	251 - 253
MISC TESTS	10	254 - 263

ENTER TEST NUMBERS

e.g : 15,30,31,40-80,99,\*(all)

Hit 'q' to quit

Enter:

Figure 5-2. The Test Selection Menu

When you have completed all the diagnostic tests, select `q` to quit and exit diagnostics mode. If you had entered diagnostics mode from `pROBE`, quitting returns you to `pROBE`. Otherwise, the `GPiB-VXI/C` prompts you to reboot the system in a different startup mode.

## Diagnostic Test Groups

### Group 1–RAM

This group tests the RAM to ensure that the CPU can correctly read and write from RAM addresses. Table 5-3 gives the test numbers and names of the RAM tests.

Table 5-3. RAM Tests

Test Number	Test Description
1	Data path test
2	Self-test cell test (not exhaustive)
3	Cell test
4	Read and Modify Write test

### Group 2–68070 CPU

This group tests the 68070 I<sup>2</sup>C interface, UART interface, and timers. Tests 5 through 7 test the 68070 I<sup>2</sup>C interface; tests 8 through 18 test the UART interface; and tests 19 through 21 test the timers. Table 5-4 gives the test numbers and names of the 68070 CPU tests.

Table 5-4. 68070 CPU Tests

Test Number	Test Description
5	I <sup>2</sup> C interface test – maximum clock frequency
6	I <sup>2</sup> C interface test – minimum clock frequency
7	I <sup>2</sup> C interface test – interrupt trigger
8	Test baud rate 75
9	Test baud rate 150
10	Test baud rate 300
11	Test baud rate 1200
12	Test baud rate 2400
13	Test baud rate 4800
14	Test baud rate 9600
15	Test baud rate 19200
16	Baud = 9600; test odd parity with two stop bits
17	Baud = 9600; test even parity with two stop bits
18	Baud = 9600; test interrupts
19	Test Timer 0 interrupt capability
20	Test Timer 1 matched mode
21	Test Timer 2 matched mode

### Group 3–MIGA

This group tests the MIGA registers. The MIGA, a gate array designed by National Instruments, contains the VXI registers as defined for Message-Based devices. Table 5-5 gives the test numbers and names of the MIGA tests.

Table 5-5. MIGA Tests

Test Number	Test Description
22	Logical address test
23	ID test
24	Device type test
25	Offset test
26	Protocol test
27	A24 Pointer High test
28	A24 Pointer Low test
29	A32 Pointer High test
30	A32 Pointer Low test
31	Data Extended test
32	Data High (device) test
33	Data Low (device) test
34	Data High (local) test
35	Data Low (local) test
36	Status test
37	Control test
38	Response test
39	ICR & ISR test
40	I/O test
41	Signal test
42	Interrupts test
43	Word Serial Protocol test
44	SYSFAIL circuitry test

## Group 4—GPIB

This group tests the NAT4882 and Turbo488 GPIB interface ICs. Tests 45 through 99 test the NAT4882 and tests 100 through 132 test the Turbo488. Table 5-6 gives the test numbers and names of the GPIB tests.

Table 5-6. GPIB Tests

Test Number	Test Description
45	INIT
46	Presence test using ADSR
47	Check SPMR and SPSR
48	Check address register bits
49	Check can be listener
50	Check can be talker
51	Check can listen to all 32 listen addresses
52	Check can be unaddressed as listener
53	Check can talk to all 32 talk addresses
54	Check can be unaddressed as talker
55	Check can listen to all 960 external addresses
56	Check can be unaddressed as external listener
57	Check can talk to all 960 external addresses
58	Check can be unaddressed as external talker
59	Check can recognize DI and HLDA bits
60	Check can recognize ERR
61	Check can recognize DCL command
62	Check can recognize SDC
63	Check can set END bit on EOI
64	Check can set EOI bit on EOI
65	Check can set END on 8-bit EOS
66	Check can set END on 7-bit EOS
67	Check can recognize GET command
68	Check set APT on unrecognized command
69	Check can recognize undefined command
70	Check can set REM, REMC, LOK, LOKC bits
71	Check can clear REM and LOK bits
72	Check can set SRQI
73	Check can do serial poll
74	Check can do parallel poll
75	Check DHADT
76	Check DHADC
77	Check DHATA
78	Check DHALA
79	Check DHUNTL

(continues)

Table 5-6. GPIB Tests (continued)

Test Number	Test Description
80	Check NTNL
81	Check NTNL with ATN asserted
82	Check RPP
83	Check CHES
84	Check PP2
85	Check SDB
86	Check NL
87	Check EOS
88	Check 9914 and 7210 mode switch
89	Check able to untalk
90	Check able to unlisten
91	Check NBAF and NTNL
92	Check REQTC
93	Check REQFC
94	Check holdoff now command
95	Check DHALL
96	Check effect of REQT during serial poll
97	Check for spurious interrupts
98	Check INT on SYNC
99	Check global interrupt
100	Set and clear SC
101	Set and clear DUALADD
102	Trigger INTSCR1 and INTSRC2
103	Set STOP DONE HALT and DAV in read mode
104	Verify set of STS1, ISR3 bits with 8-bit read
105	Verify write mode and TLCINT set by error
106	Read/write CNTL, CNTH registers
107	Verify bits in IMR3 register
108	Reset ISR3
109	Reset ISR3 and STS1
110	Reset STS2
111	Reset TIMER
112	Check flags on 16-bit independent FIFO
113	Fill and empty 16-bit independent FIFO
114	Fill and empty 16-bit FIFO
115	Reset non-full FIFO
116	Reset full FIFO
117	16-bit FIFO read
118	Fill and empty 16-bit FIFO
119	STOP and HALT in 16-bit A-1st mode

(continues)

Table 5-6. GPIB Tests (continued)

Test Number	Test Description
120	Holdoff when FIFO and DIR are full
121	HALT and EOI when last byte in FIFO
122	Enable carry cycle
123	Disable carry cycle
124	16-bit FIFO write
125	Fill and empty 16-bit FIFO
126	Carry cycle with EOI

### Group 5–TIC

This group tests the TIC ASIC. The TIC, an ASIC designed by National Instruments, handles the TTL/ECL trigger interface and CLK10 conversion. Table 5-7 gives the test numbers and names of the TIC tests.

Table 5-7. TIC Tests

Test Number	Test Description
133	Initialization
134	Register initialization

## Group 6–DMA

This group tests the DMA Channel 2 and memory-to-memory DMA transfers. Table 5-8 gives the test numbers and names of the DMA tests.

Table 5-8. DMA Tests

Test Number	Test Description
237	Poll test (burst, bytes, mem-to-dev, from even addresses)
238	Poll test (cycle steal, bytes, mem-to-dev, even addresses)
239	Poll test (burst, words, mem-to-dev, from even addresses)
240	Poll test (cycle steal, words, mem-to-dev, even addresses)
241	Poll test (burst, bytes, mem-to-dev, from odd addresses)
242	Poll test (cycle steal, bytes, mem-to-dev, odd addresses)
243	Poll test (burst, bytes, dev-to-mem, from even addresses)
244	Poll test (burst, words, dev-to-mem, from even addresses)
245	DMA interrupt test
246	Minimum functionality test
247	Maximum transfer test

## Group 7–68881 Coprocessor

This is a test of the numeric coprocessor operation. If the 68881 is not installed, the GPIB-VXI/C skips this test. Table 5-9 gives the test number and name of the 68881 Coprocessor test.

Table 5-9. 68881 Coprocessor Test

Test Number	Test Description
248	Test floating point coprocessor

## Group 8–RAM (Exhaustive)

This exhaustive RAM test checks the entire onboard RAM and the address and data paths. Table 5-10 gives the test numbers and names of the exhaustive RAM tests.

Table 5-10. RAM (Exhaustive) Tests

Test Number	Test Description
249	Data path test (exhaustive)
250	Address path and cell test (exhaustive)

## Group 9–Interrupts

This group tests the GPIB and MIGA local interrupts. Table 5-11 gives the test numbers and names of the Interrupt tests.

Table 5-11. Interrupt Tests

Test Number	Test Description
251	Verify interrupt on INT2N using SYSFAIL
252	Verify SYSFAIL disable interrupt
253	Verify interrupt on INT1N using done int

## Group 10–Miscellaneous Tests

This group tests the EPROM, EEPROM, Sanity Timer, LEDs, MODID register, Local Bus timeouts, and VXI bus timeout. Table 5-12 gives the test numbers and names of the Miscellaneous tests.

Table 5-12. Miscellaneous Tests

Test Number	Test Description
254	LED test: SYSFAIL and FAILED LED
255	LED test: ACCESS LED
256	LED test: TEST LED
257	LED test: ONLINE LED
258	Switch test: Startup switches (S10, S11, S12)
259	Local BTO test: Test local bus timeout unit
260	VXI BTO test: Test VXI bus timeout unit
261	Sanity timer test: Test enabled/disabled
262	EPROM checksum test
263	EEPROM stamp and checksum test

# Appendix A

## Code Instrument Overview

---

This appendix contains an overview of the functions, applications, and implementations of software modules known as Code Instruments (CIs), and presents comparisons and illustrations of GPIB-VXI/C operation with and without CIs.

CIs are a National Instruments GPIB-VXI/C proprietary feature. They are capable of a wide variety of application-specific translation and control functions. A CI is a set of software routines running on the GPIB-VXI/C, but the system sees a CI as a physical Message-Based device. As with physical Message-Based devices, an external controller can communicate directly with the CI via a GPIB secondary address.

CIs perform special functions in the VXI environment. Typical applications of CIs include the following:

- Parsing and interpreting command languages
- Creating virtual (hierarchical) instruments
- Creating a Message-Based interface for Register-Based or non-VXI devices

A CI is more than a CPU process that replaces another VXI device's communication path; it has all of the capabilities of a physical Message-Based Commander. These capabilities include the following:

- Having Servant(s) assigned to it
- Having Word Serial communication with its Commander and Servant(s)
- Handling VXI interrupts and signals
- Having communication with the GPIB System Controller through a secondary address
- Having bus mastership for direct access to Register-Based Servants and non-VXI devices
- Having direct access to VXIbus TTL trigger lines

CIs improve the system structure for the following reasons:

- GPIB traffic is greatly reduced.
- System performance is greatly increased.
- The System Controller can treat all devices as if they were Message-Based.
- Super instrument structures can be created.

## GPIB-VXI/C Operation without CIs

Figure A-1 illustrates typical Commander/Servant relationships for GPIB-VXI/C operation without CIs. A GPIB System Controller communicates with the local command set and the GPIB-VXI/C's Message-Based Servants through GPIB addresses. This is a complete interface solution for Message-Based devices. Although the GPIB and serial controllers are not Commanders of the command parser in the VXI sense, they are its *master* in the sense that it will respond to their commands as if they were its Commander. The GPIB-VXI/C maintains independent control paths to the local command set parser from the GPIB, the serial controller, and the GPIB-VXI/C's Commander.

The GPIB-VXI/C has four ports for communicating with other devices. Each port consists of its electrical interface and the associated system software. The GPIB-VXI/C communicates with its Commander through the Word Serial Servant port, and with its Servants through the Word Serial Commander port. The GPIB System Controller communicates with the GPIB-VXI/C and its Message-Based Servants through the GPIB port, which maps GPIB secondary addresses to VXI logical addresses. A serial controller can access the local command parser through the RS-232 port, and therefore can communicate with the GPIB-VXI/C's Message-Based Servants through the Word Serial communication commands.

The System Controller can also directly control Register-Based and non-VXI devices through the VXIbus Access local commands. This solution to the general problem of controlling Register-Based and non-VXI devices is relatively ineffective for high-performance applications, however, because of the low-level functions that the System Controller must perform and the resulting heavy GPIB traffic.

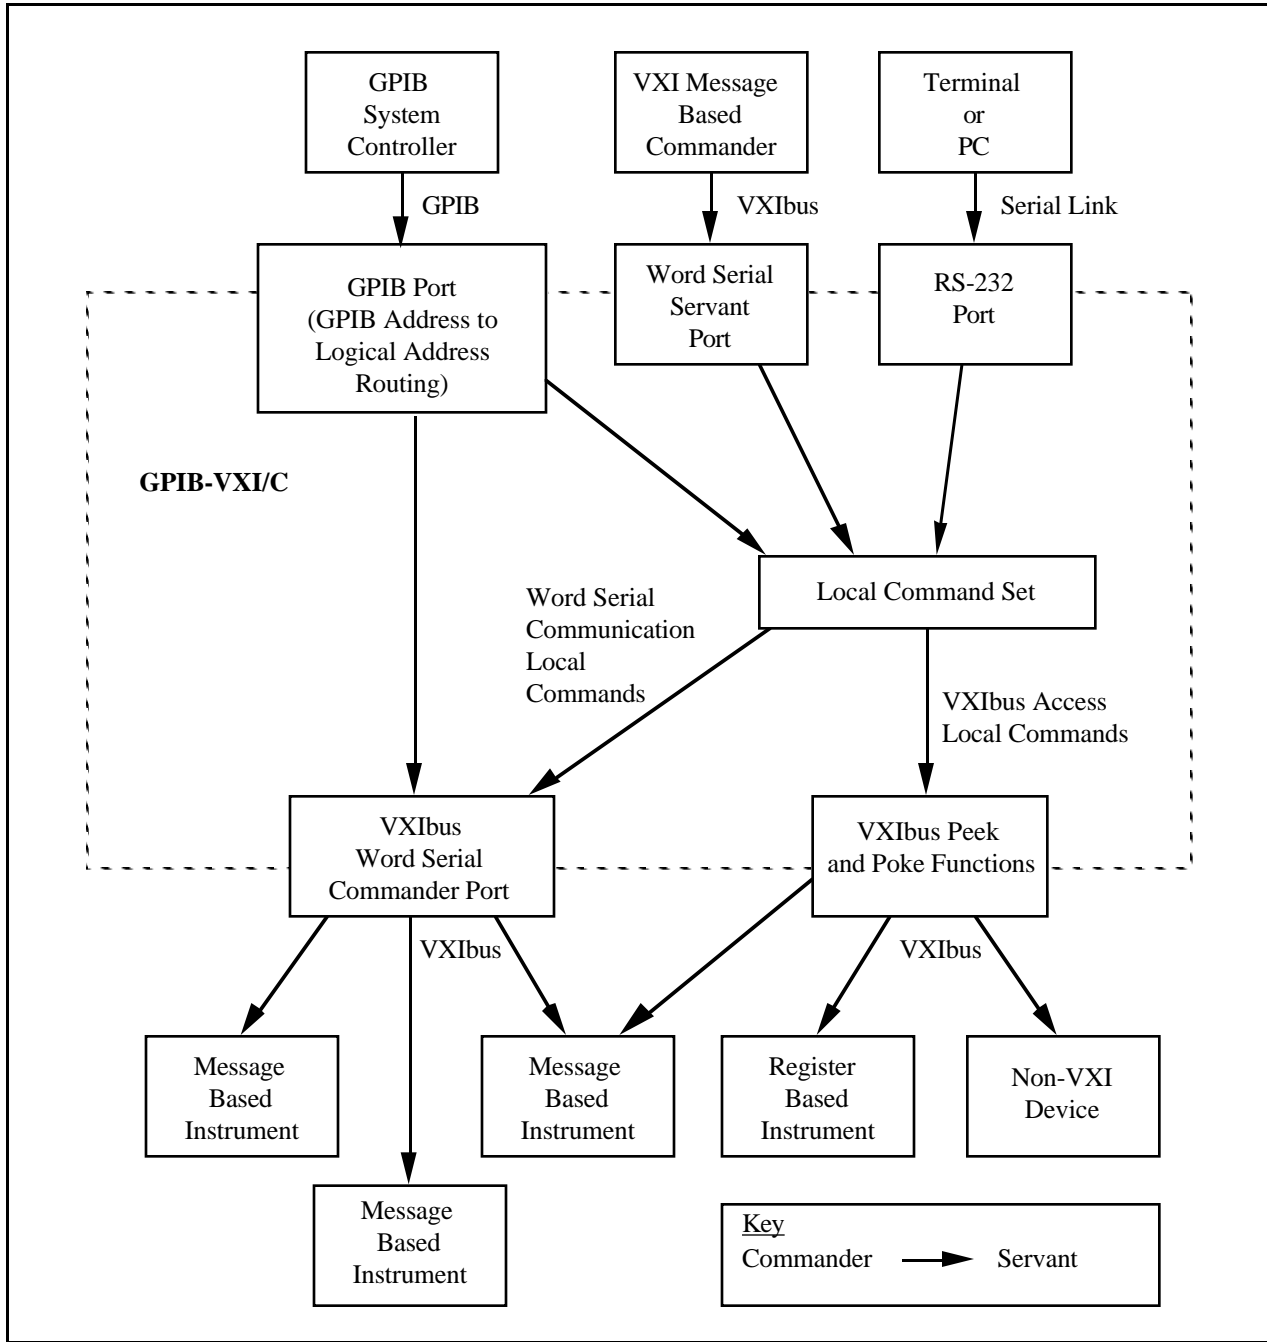

Figure A-1. GPIB-VXI/C Operation Without Code Instruments

## CI Operation

A CI is a set of software routines that can perform the functions of a physical VXI Message-Based device. These CI capabilities are illustrated in Figure A-2. CIs coexist with the IEEE-488 VXI translation and local command set functions shown in Figure A-1, with the exception that the Word Serial Servant and RS-232 ports support only one command/Servant connection (either to the local command set parser or to a CI, but not both) at one time.

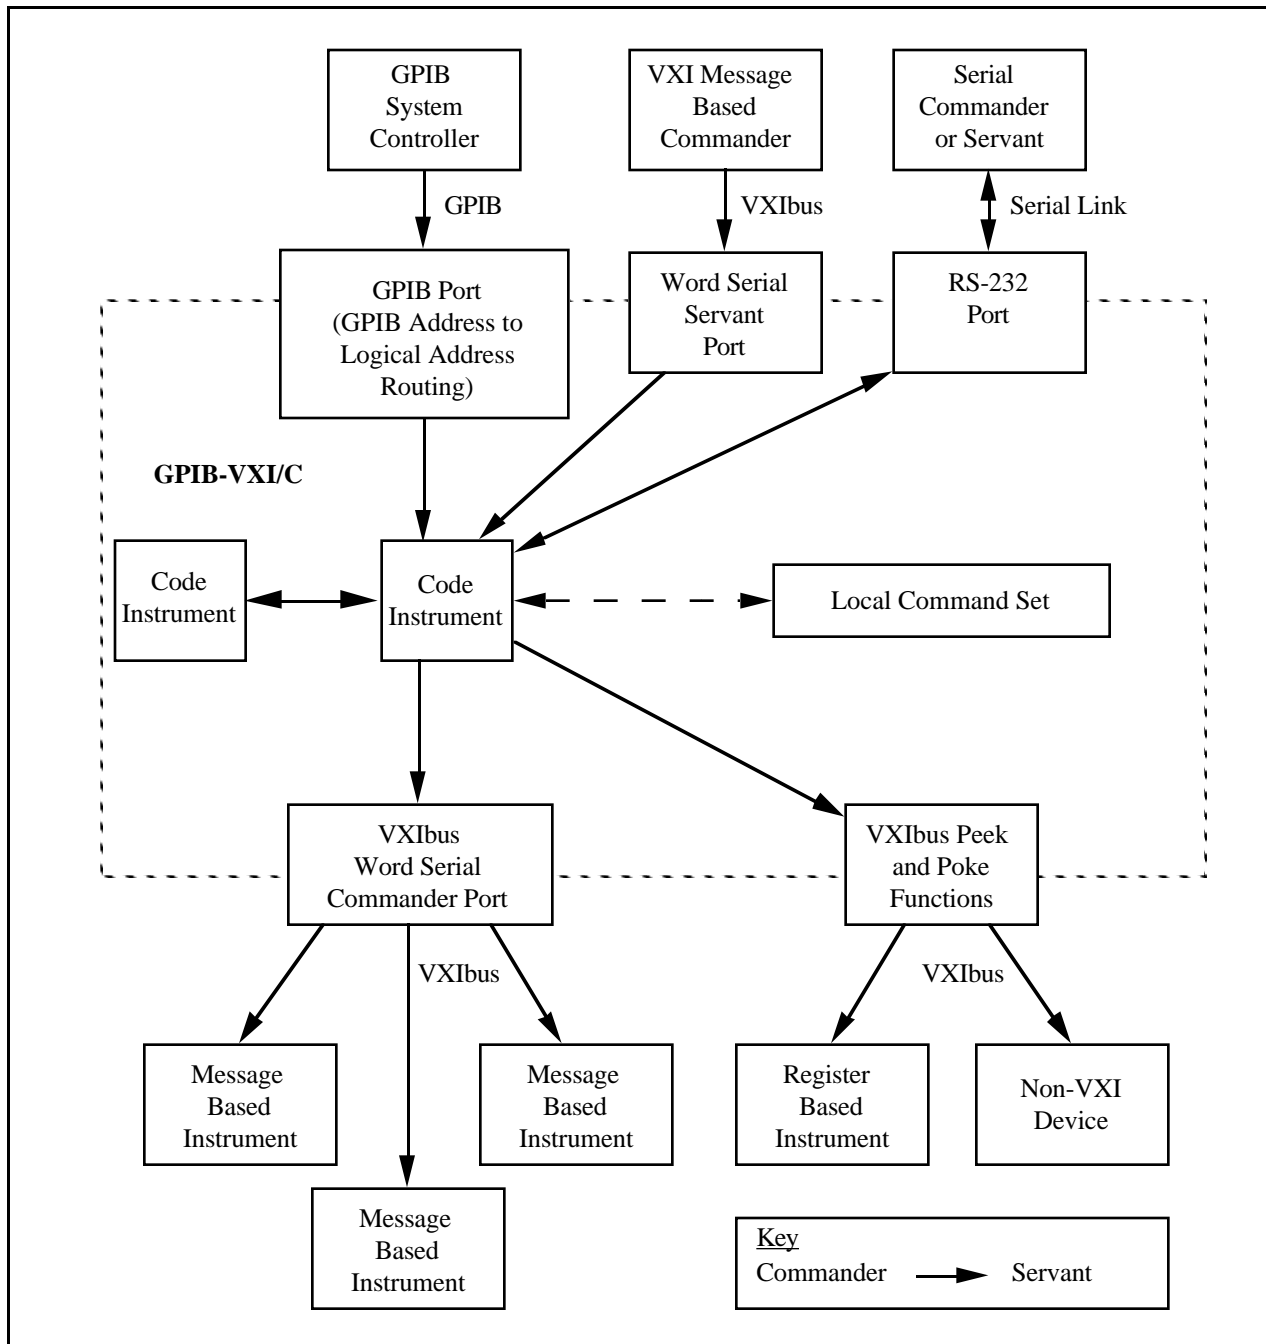

Figure A-2. Code Instrument Operation

## CI Characteristics

A CI has all of the abilities of a physical Message-Based Commander. A CI can do the following:

- Set up its own set of configuration registers
- Have Servants assigned to it
- Engage in Word Serial communication with its Commander and Servants
- Receive VXI interrupts
- Send and receive VXI signals
- Directly access the A16 or A24 registers/memory of a VXI or non-VXI device
- Communicate with the GPIB System Controller through a secondary address
- Perform memory-to-memory DMA operations using 68070 DMA channel
- Source or accept a trigger on any one TTL trigger line

As with physical devices, a CI must be an immediate Servant of the GPIB-VXI/C in order to have a GPIB address assigned to it. In addition to these VXIbus device capabilities, CIs can also communicate directly with the local command set parser and the serial port.

The GPIB-VXI/C emulates the physical capabilities of a Message-Based device for each CI. Because a CI can be a Commander or a Servant, you can construct multilevel hierarchies of CIs and physical Message-Based devices. The only restriction is that a CI cannot be mapped out of the hierarchy of devices within the GPIB-VXI/C. In other words, a CI can be any of the following:

- The Commander of any number of CIs and/or physical VXI devices
- A top-level Commander
- A Servant of another CI
- A Servant of the GPIB-VXI/C's Commander

A CI cannot, however, be the Servant of a physical VXI device that is not the GPIB-VXI/C's Commander.

A CI appears to the GPIB and to other CIs to be a physical device, because it performs all of the functions that a physical Message-Based device performs. If the CI takes control of the physical Word Serial registers on the GPIB-VXI/C, it becomes a physical VXI device. Most applications, however, do not require a CI to take control of the physical Word Serial registers, because most CIs function as Commanders to drive other Servants in the system rather than as Servants to higher level Commanders.

A non-VXI device does not have VXI configuration registers, so it does not appear in the VXI device hierarchy. A CI that provides a Message-Based interface for a non-VXI device (together with that non-VXI device) is viewed by the system as a single device. Typical examples of non-VXI devices include:

- VME cards (CPU, Register-Based, memory, and so on)
- CDS 73A-852 adapter module

## Downloaded CIs and EPROMed CIs

You can download CIs in the form of binary code into the GPIB-VXI/C's RAM. The downloaded modules are called *Downloaded CIs*, or *DCIs*. The CI Configuration local commands download and initialize CIs. You can use the DCI form to develop CIs without programming EPROMs, or to create disk-loadable CI applications.

The GPIB-VXI/C also has an interface for installing CIs in onboard EPROMs, including a mechanism for automatically initializing them at system startup. CIs stored in the EPROMs are called *EPROMed CIs*, or *ECIs*. You can use the ECI form to create stand-alone CI applications.

## Resident CIs

A *Resident CI (RCI)* that communicates with a CDS 73A-852 adapter is supplied by National Instruments as part of the GPIB-VXI/C firmware. The 852 adapter is a non-VXI device that requires a special code module somewhere in the system with a Message-Based interface. Appendix B, *Using the DMAmove and CDS-852 Adapter Code Instruments*, contains information about installing and using the 852 adapter CI.

## Summary

With these capabilities, a CI can emulate or replace any existing VXI or VME device, or extend a device's native capabilities to new levels of functionality, as a disk-loadable or stand-alone solution. To summarize, CIs improve the system structure for the following reasons:

- GPIB traffic is greatly reduced.
- Register-Based and non-VXI devices can be treated as if they were Message-Based.
  - The GPIB Controller sees one type of instrument (an IEEE-488 instrument).
  - Standard IEEE-488 communication is possible with all types of VXI/non-VXI instruments.
- GPIB control of a VXIbus system can be implemented uniformly at a high level.
- Application software is simplified due to uniformity of control.
- System performance is greatly increased.
  - Direct access results in a tight coupling with its Servants.
  - Distributed processing removes burden from outside controller.
  - Access to VXIbus bandwidth is accomplished without GPIB overhead.

# Appendix B

## Using the DMAmove and CDS-852 Adapter Code Instruments

---

This appendix contains instructions for installing and using the National Instruments-supplied Code Instruments (CIs). Two CIs come standard in the firmware of the GPIB-VXI/C. The first CI is called the *DMAmove* CI and is used for dedicating one of the GPIB-VXI/C GPIB addresses for use as a high-speed memory port. The second CI is used for controlling one or more Colorado Data Systems (CDS) 73A-852 adapter module.

The main purpose of the GPIB-VXI/C is to convert GPIB protocols to VXI protocols. However, many features within the VXI environment are not possible with GPIB. Much of this has to do with the memory-mapping architecture of VXI. The DMAmove CI gives you very fast, direct access to VXI A16 and A24 memory as well as to local GPIB-VXI/C memory. The 68070 DMA channel 2 is used within the DMAmove CI to move data around much more quickly than the VXI Word Serial protocol or individual peeks and pokes.

The 73A-852 is a non-VXI device with communication registers located in A24 space rather than in A16 space. To communicate with the 852 adapter as a Message-Based device, the 73A-852 requires special adapter software. The GPIB-VXI/C performs the Message-Based-to-852 communication translation with a CI. The GPIB-VXI/C firmware release includes one CDS-852 Position Independent CI. This CI implements the configuration and translation functions required to communicate with up to 12 CDS-852 adapter modules via the GPIB.

## Using EPROMed Code Instruments

This section discusses how to install, execute, and delete an EPROMed Code Instrument.

### Installing an EPROMed Code Instrument

You can install an EPROMed Code Instrument (the DMAmove and CDS-852 CIs are examples) either by configuring the nonvolatile configuration parameters or by using the GPIB-VXI/C local command set command `ECIboot?`. This section explains how to use the nonvolatile configuration editor to permanently install an EPROMed Code Instrument. Consult the *CI Configuration Commands and Queries* section of Chapter 3, *Local Command Set* for information about the command `ECIboot?`.

Enter the nonvolatile configuration mode as described in Chapter 4, *Nonvolatile Configuration*. The following menu is displayed:

```

          GPIB-VXI Nonvolatile Configuration Main Menu
                (C) 1991  National Instruments
=====
1). Read In Nonvolatile Configuration
2). Print Configuration Information
3). Change Configuration Information
4). Set Configuration to Factory Settings
5). Write Back (Save) Changes
6). Quit Configuration

          Choice (1-6):

```

Enter 3 to change the configuration information. The following menu then displays:

```

          GPIB-VXI Nonvolatile Configuration Changer
                (C) 1991  National Instruments
=====
0). Edit Local Register Configuration
1). Edit pSOS Configuration
2). Edit VXI Interrupt Handler Logical Address
3). Edit Resource Manager A24/A32 Assign Bases
4). Edit Servant Area and DC Configuration
5). Edit FAILED Device Handling Mode
6). Edit GPIB Configuration
7). Edit Default CI Configuration
8). Edit Resident CI Base Locations
9). Edit CI User Configuration Variables
Q). Quit Editor

          Choice (0-9,Q):

```

Enter 1 to edit pSOS configuration. The following prompt then appears:

```

-----pSOS Configuration-----

Enter Dynamic RAM Region 1 Size (default 0x70000):

Enter <CR> to keep the present value and continue to the next entry:

Enter Maximum Number of Processes (default 0x20):

```

The following formula calculates the maximum number of processes:

$$\text{Number of processes} = 10h + (\text{number of GPIB address links}) + (2 * \text{number of CIs})$$

If fewer than six CIs are installed and no other GPIB address links exist, the default value of 32 (0x20) is adequate. Increasing the number of processes affects the throughput of the GPIB-VXI/C. Enter the number of processes in hexadecimal.

The next prompt is then displayed:

Enter Maximum Number of Exchanges (default 0x20):

The following formula calculates the maximum number of exchanges:

$$\text{Number of exchanges} = 10h + (\text{number of CIs})$$

The default value of 32 (0x20) is adequate even if all 12 CIs are installed. Enter <CR> to select the default value.

The last prompt appears:

Enter Maximum Number of Message Buffers (default 0x180):

The following formula calculates the maximum number of message buffers:

$$\text{Number of message buffers} = 100h + (25 * \text{number of CIs})$$

If fewer than six CIs are installed, the default value of 384 (180h) is adequate. Increasing the number of message buffers affects the throughput of the GPIB-VXI/C. Enter the number of message buffers in hexadecimal.

When the edit menu reappears, enter 8 to edit the resident CI base locations.

For the DMAmove Code Instrument, only one CI should be created. Configure a single CI base location as shown below. For the CDS-852 adapter, configure as many CI base locations as there are 852 adapters to be controlled by the GPIB-VXI/C. For example, to control four 73A-852s, configure CI base locations 0 through 3. The addresses for the two CIs are as follows:

Code Instrument	Address (Base Location)
CDS852 CI	F7E000
DMAmove CI	F7C000

Type Y to respond yes to the Debug mode On for Resident CI 0xXX prompt. This enables debug statement printing to the terminal.

For example, to install the single DMAmove CI and two 852 adapter CIs and enable debug statement printing on the second 852 CI, enter the following sequence, which we have highlighted in boldface type for this example:

```

----- Resident CI Base Location Configuration -----
Enter Number of Base Location to EDIT (0xff = EXIT): 0
Enter Address for Base 0x01 (default = 0x000000): F7C000
Debug mode ON for Resident CI 0x01 (default NO): N
Enter Number of Base Location to EDIT (0xff = EXIT): 4
Enter Address for Base 0x00 (default = 0x000000): F7E000
Debug mode ON for Resident CI 0x00 (default NO): <CR>
Enter Number of Base Location to EDIT (0xff = EXIT): 5
Enter Address for Base 0x01 (default = 0x000000): F7E000
Debug mode ON for Resident CI 0x01 (default NO): Y
Enter Number of Base Location to EDIT (0xff = EXIT): <CR>

```

When the edit menu reappears, enter Q to exit the configuration editor. When the Nonvolatile Configuration main menu appears, enter 5 to save the configuration changes. When the Nonvolatile Configuration main menu reappears, enter 2 to confirm the configuration information. The CI configuration for the previous example would be displayed as follows:

```

----- Resident Code Instrument Locations -----
0x00: 00F7C000      0x01: 00000000      0x02: 00000000
0x03: 00000000      0x04: 00F7E000      0x05: 00F7E000
0x06: 00000000      0x07: 00000000      0x08: 00000000
0x09: 00000000      0x0A: 00000000      0x0B: 00000000

```

When the main menu reappears, enter 6 to quit the configuration mode. The following message appears:

```

Must Re-initialize PROBE or reboot for pSOS changes to take effect.
Other changes made automatically when configuration saved.

```

```

*****
*           DONE WITH CONFIGURATION           *
* Change Startup mode Dip settings to enter   *
* different mode or push RESET to reconfigure.*
*****

```

## Executing an EPROMed Code Instrument

If a CI is configured in nonvolatile configuration to be executed, the CI will be *booted* upon the next power cycle of the GPIB-VXI/C. The CI booting procedure actually occurs after the Resource Manager has run and the local command set has been initiated on all ports. This guarantees the CI access to all resources of the GPIB-VXI/C.

## Deleting a CI

To delete a CI, follow the installation procedure but set the CI's base address location to 000000. If you wish to delete the CI during runtime, after the CI has already been started up, you can use the local command set command, `CIDelete?`. Consult the *CI Configuration Commands and Queries* section of Chapter 3 for further information on the command `CIDelete?`.

## The DMAmove Code Instrument

After the nonvolatile configuration is complete and the GPIB-VXI/C is rebooted, the DMAmove Code Instrument will be up and running. You should see the following message printed on the serial port:

```
National Instruments' DMAmove Code Instrument Running
```

The following sections describe the runtime capabilities of the DMAmove Code Instrument.

## GPIB Address Assignment

The DMAmove CI is assigned Logical Address 160 by default. If a device already exists at Logical Address 160, the DMAmove CI is assigned the next highest available logical address. The GPIB address is assigned to be the upper five bits of the logical address (GPIB address 20), if available. If that GPIB address is taken, it takes the next highest available GPIB address. You can use the local command set command `LaSaddr?` to determine the GPIB address and the local command set command `LaSaddr` to change the GPIB address. You can communicate directly with the DMAmove CI through this GPIB address.

## Capabilities and Operation

The DMAmove CI is a Code Instrument built on top of the function `DMAmove()`, which is available to all Code Instruments. (This CI is provided in source code with development versions of the GPIB-VXI/C.) As such, the DMAmove CI has all of the capabilities of the DMAmove function plus a few extra device interface type features. The following is the C language prototype for the `DMAmove()` function:

```

DMAmove(source, dest, count, mode)

uint32 source      Local address to transfer from
uint32 dest        Local address to transfer to
uint32 count       Number of bytes to transfer
uint32 mode        Bit vector for mode of transfer
                   Bit 0: Transfer direction
                       0 = Source to destination
                       1 = Destination to source
                   Bit 1: Destination size
                       0 = 16 bit
                       1 = 8 bit
                   Bit 2: Operand size
                       0 = 16 bit
                       1 = 8 bit
                   Bit 3: DMA transfer mode
                       0 = Cycle steal
                       1 = Burst
                   Bit 4: Source address increment
                       0 = Increment source address by operand size
                       1 = Do not increment source address
                   Bit 5: Destination address increment
                       0 = Increment destination address by destination
                           size
                       1 = Do not increment destination address

```

The interface for the DMAmove CI is almost identical. To control the DMAmove CI, simply send 16 binary bytes of information over the GPIB with EOI on the last byte corresponding to the four 32-bit parameters in the DMAmove function prototype. The only exception to this for the DMAmove CI is that the value of zero (0) in the `source` parameter specifies to take data from the GPIB as input and the value of zero (0) in the `dest` parameter specifies for the source data to be transmitted out the GPIB. You may not specify zero in both `source` and `dest` parameters. If you are writing data with GPIB as the source, simply follow the 16-byte transfer (which has EOI on the last byte) with the continuous data transfer with EOI on the last byte. If you are reading data from the GPIB-VXI/C out to the GPIB, simply follow the 16-byte transfer (which has EOI on the last byte) with a GPIB read. If both `source` and `dest` are non-zero, the transfer will take place without further action. When either `source` or `dest` is non-zero it specifies a local GPIB-VXI/C address as shown in Figure B-1.

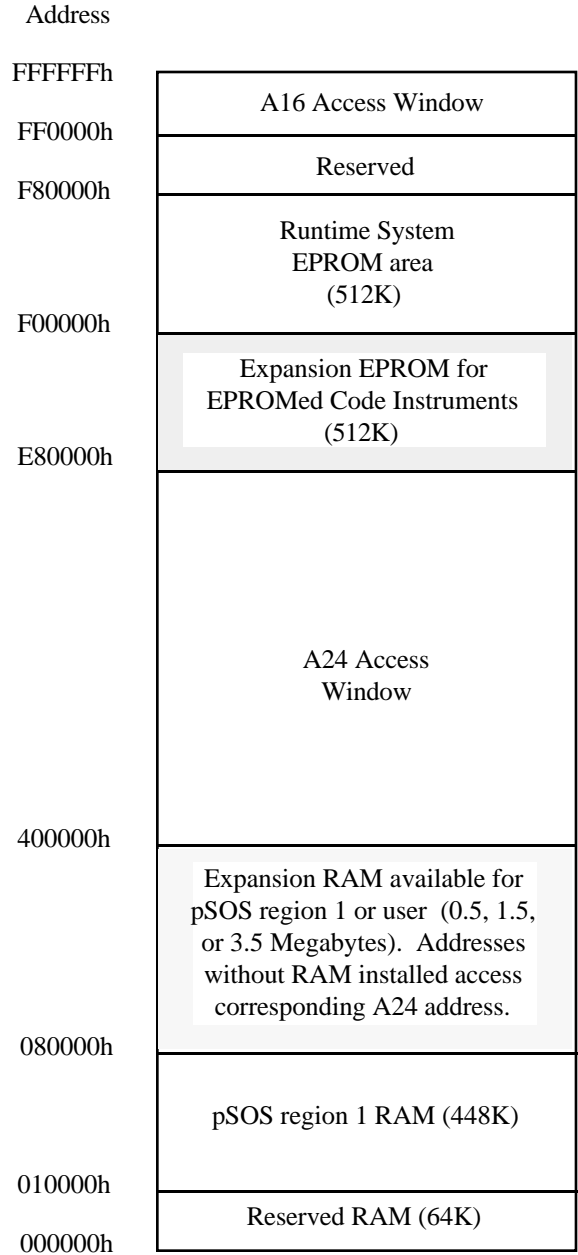

Figure B-1. GPIB-VXI/C Local Memory Map

You can use the DMAmove CI to perform any of the capabilities of the DMAmove function including moving to or from VXI A16 space, VXI A24 space, or local GPIB-VXI/C memory. It can transfer 8-bit or 16-bit quantities from either source or destination (they can be different). It can increment or not increment addresses as it counts to give fast access to FIFO registers or block memory.

The DMAmove CI reports current status and errors via its status byte and the REQ signal (GPIB SRQ line). The following is a list of the status bytes returned by the DMAmove CI and their corresponding meanings.

Status Value	Meaning
00h	Idle, no operation pending
80h	Operation underway
41h (RSV pending)	DMA timing error
42h (RSV pending)	Bus Error at source
44h (RSV pending)	Bus Error at destination
48h (RSV pending)	Unknown error

In addition, if Debug mode is specified when the DMAmove CI is booted, diagnostic messages are printed to the serial port. Every access to the DMAmove CI causes messages to be printed. All accesses to or from the GPIB and VXI are logged to the serial port.

## The CDS-852 Adapter Code Instrument

After the nonvolatile configuration is complete and the GPIB-VXI/C is rebooted, the CDS-852 Adapter Code Instrument will be up and running. You should see the following message printed on the serial port:

```
National Instruments' CDS 73A-852 Code Instrument Adapter Running
```

The following sections describe the runtime capabilities of the CDS-852 Adapter Code Instrument.

### Logical Address and A24 Address Assignment

The 852 adapter CIs are assigned logical addresses sequentially, starting with the lowest configured CI base address and Logical Address 80. For example, if the CIs at base address locations 1 and 3 are installed, the CI at location 1 is assigned Logical Address 80, and the CI at location 3 is assigned Logical Address 81.

The default offset where the CI expects to find its 73A-852 registers in VXI/VME A24 space is related to the CI's logical address as follows:

$$73A-852 \text{ A24 offset} = \text{CI logical address} * 10000h$$

For example, a CI at Logical Address 80h expects (by default) to find its 73A-852 registers at offset 800000h. The CI's A24 offset can be changed with the CI command !!L. The 73A-852 has rotary switches for changing its A24 register locations.

## 852 Adapter CI Commands

The 852 adapter CI commands are interpreted by the CI itself and do not directly affect the 852 module. If the adapter CI receives a word serial buffer that does not begin with the !! character sequence, it assumes that the buffer is for the 73A-852 and writes the buffer to the appropriate A24 register location. The CI command formats were designed to minimize the possibility of conflict with the command sets of the various plug-in instruments that are compatible with the 852 adapter. Because National Instruments has not had the opportunity to study the command sets of all CDS plug-in instruments, you need to keep in mind the possibility of conflict as you develop your applications.

The !!A and !!B commands set the CI read mode for compatibility with the CDS instrument. Some CDS command responses are in ASCII format, while others are in binary format. Refer to the appropriate CDS manual for the response format of a particular command. The !!A command sets the adapter CI mode to be compatible with the ASCII response format. If the expected response format is binary, use the !!B command to set the CI to the binary read mode.

Two termination conditions can apply to reading data from the 73A-852. Depending upon the 73A-852 configuration and the operation being performed, the 852 may terminate the transmission of data with an end-of-string (EOS) character, or it may assert the END bit (VMEbus data bit 8).

The !!E, !!T, and !!t commands configure the CI termination conditions. The EOS and END bit termination conditions are independent; that is, you can configure the CI to terminate a read from the 73A-852 on one condition, both conditions, or neither condition. In addition, you can limit the maximum size of binary mode reads with the !!S command. Notice that with binary responses, there can be no unique EOS character, so you should use the END or transfer size conditions (not EOS) to terminate binary transfers. The default read mode is ASCII. The default read termination condition is the EOS character <LF> (0Ah) with the END bit set.

The !!Q command returns information about the CI settings (always to the serial port). The !!D and !!d commands control the printing of runtime debug information to the terminal connected to the serial port.

**!!A**

**Purpose:** Set the adapter CI read mode to ASCII, for compatibility with the CDS instrument response.

**Command**

**Syntax:** !!A

or

!!a

**Action:** Sets the adapter CI read mode to ASCII. The maximum ASCII response size allowed is 512 bytes.

---

**!!B**

**Purpose:** Set the adapter CI read mode to binary.

**Command**

**Syntax:** !!B

or

!!b

**Action:** Sets the adapter CI read mode to binary. Read size is limited to 512 bytes, or as configured by the !!S command.

---

**!!D**

**Purpose:** Enable debug message printing to the serial port.

**Command**

**Syntax:** !!D

**Action:** Enables debug message printing to the serial port.

---

**!!d**

**Purpose:** Disable debug message printing to the serial port.

**Command**

**Syntax:** !!d

**Action:** Disables debug message printing to the serial port.

---

**!!E**

**Purpose:** Configure CI read termination on an EOS character.

**Command**

**Syntax:** !!E <hex number>

or

!!e <hex number>

<hex number> is the ASCII value corresponding to the desired EOS character (for example, 0Ah for <LF>).

**Action:** Enables read termination on an EOS with a value of <hex number>. If <hex number> is greater than FFh, the EOS termination condition is disabled.

**Examples:** Set the EOS character to <CR>

```
!!E 0D
```

Disable EOS read termination.

```
!!E 100
```

---

**!!L**

**Purpose:** Set the A24 base address where the adapter CI expects to find the 852 adapter.

**Command**

**Syntax:** !!L <val>

or

!!l <val>

<val> is a hex value equal to the upper 8 bits of the target adapter's A24 address.

**Action:** The adapter CI expects to find the target 852 adapter at offset <val> \* 10000h. The default (initial) value of <val> is the adapter DCI's logical address.

**Example:** Set the adapter CI to operate with a 852 adapter at A24 base address 830000h.

```
!!L 83
```

---

**!!S**

**Purpose:** Set the maximum size of a binary read.

**Command**

**Syntax:** !!S <size>

or

!!s <size>

<size> is a decimal value.

**Action:** Sets the maximum binary read size to <size> bytes. The default value of the read size is 512 bytes.

---

**!!T**

**Purpose:** Enable read termination when the END bit is set.

**Command**

**Syntax:** !!T

**Action:** Enables read termination when the END bit (bit 8) is set.

---

**!!t**

**Purpose:** Disable read termination on the END bit.

**Command**

**Syntax:** !!t

**Action:** Disables read termination on the END bit (bit 8).

---

# Appendix C

## Specifications

---

This appendix lists various module specifications of the GPIB-VXI/C, such as physical dimensions and power requirements.

### CPU

Microprocessor	16-MHz 68070
Coprocessor (optional)	16-MHz 68881
RAM	512 kilobytes, 1 Megabyte, 2 Megabytes, or 4 Megabytes

### Physical

C-size VXIbus board

Slot Requirements 1 slot

Local Bus Keying Class 1, TTL

Front Panel Indicators

- SYSFAIL (red)
- FAILED (red)
- TEST (green)
- ON LINE (green)
- ACCESS (yellow)

Front Panel Connectors

- RS-232
- GPIB
- Trigger input
- Trigger output
- External 10-MHz clock

Reset pushbutton

## Power Requirements

Source	Typical	Direct Current (max)	Dynamic Current (max)
+5.0 VDC	2.5 A	4.0 A	Not Available
+12.0 VDC	12.0 mA	15.0 mA	Not Available
-12.0 VDC	12.0 mA	15.0 mA	Not Available
-5.2 VDC	100.0 mA	200.0 mA	Not Available
-2.0 VDC	50.0 mA	100.0 mA	Not Available

## Cooling Requirements

Power Dissipation, max                      22 W

## Operating Environment

Temperature                                      0° to 55° C

Relative humidity                              0% to 95% noncondensing

## Storage Environment

Temperature                                      -40° to 125° C

Relative humidity                              0% to 100% noncondensing

## EMI

FCC    Class A verified

## Functionality

### IEEE-488

Capability Code	Description
SH1	Source Handshake
AH1	Acceptor Handshake
T5, TE5	Talker, Extended Talker
L3, LE3	Listener, Extended Listener
SR1	Service Request
DC1	Device Clear
DT1	Device Trigger
RL0	Remote Local
PP0	Parallel Poll

### VXIbus Master/Slave

- A16/A24 Addressing
- A32 Addressing (slave only)
- D08(E0)/D16 Data Paths
- Read-Modify-Write

### VXIbus

- VXIbus System Specification Compatible
- Multiframe Resource Manager (defeatable)
- Slot 0 Support (defeatable)
- Message-Based Commander and Servant
- Dynamically Configurable
- Programmable Handler (any three of seven levels)
- Trigger Source/Acceptor (SYNC, SEMI-SYNC, ASYNC, STST protocols)
- External Trigger I/O Support
- External CLK10 I/O Support

# Appendix D

## Connectors

This appendix describes the connectors found on the GPIB-VXI/C.

**Notes:** The illustrations in this appendix show the mating face of the connectors.  
An asterisk suffix (\*) on a signal name indicates that the signal is active low.

### RS-232

Connector Type: 9-pin Subminiature D HD-20

Figure D-1. RS-232 Connector

Table D-1. RS-232 Connector Signals

Pin	Signal Name	Signal Description
1	DFI1	Discrete Fault Indicator (leave unconnected)
2	RXD*	Receive Data
3	TXD*	Transmit Data
4	DTR*	Data Terminal Ready
5	GND	Ground
6	DFI2	Discrete Fault Indicator (leave unconnected)
7	RTS*	Ready to Send
8	CTS*	Clear to Send
9	n.c.	Not Connected

**Warning:** If you are building a cable for the RS-232 port, do not connect to pins 1 and 6. Connecting to these pins can result in damage to the GPIB-VXI/C. You should connect to these pins only if you are using DFI. Refer to the *Discrete Fault Indicator Configuration* section in Chapter 2, *Configuration and Startup Procedures*, for more information about DFI.

## GPIB

Connector Type: GPIB

Figure D-2. GPIB Connector

Table D-2. GPIB Connector Signals

Pin	Signal Name	Signal Description
1	DIO1*	Data Bit 1
2	DIO2*	Data Bit 2
3	DIO3*	Data Bit 3
4	DIO4*	Data Bit 4
5	EOI*	End or Identify
6	DAV*	Data Valid
7	NRFD*	Not Ready for Data
8	NDAC*	Not Data Accepted
9	IFC*	Interface Clear
10	SRQ*	Service Request
11	ATN*	Attention
12	SHIELD	Chassis ground
13	DIO5*	Data Bit 5
14	DIO6*	Data Bit 6
15	DIO7*	Data Bit 7
16	DIO8*	Data Bit 8
17	REN*	Remote Enable
18	GND	Logic Ground
19	GND	Logic Ground
20	GND	Logic Ground
21	GND	Logic Ground
22	GND	Logic Ground
23	GND	Logic Ground
24	GND	Logic Ground

## External CLK10

Connector Type: BNC

Figure D-3. EXT CLK Connector

Table D-3. EXT CLK Connector Signals

Pin	Signal Description
Center Shield	CLK10 I/O (TTL, 10 MHz) Ground

## Trigger Input

Connector Type: BNC

# Appendix E

## Error Codes

This appendix lists the local command set error codes and describes the error associated with each error code.

Table E-1. Error Codes

Error Number	Type	Description
0	Format	Command format error
1	Syntax	Command was not found
2	Syntax	Illegal identifier after <Program Data Separator>
3	Syntax	Missing <Program Data Separator>
4	Syntax	Maximum <Program Mnemonic> length is 12 characters
5	Syntax	Illegal command: Expecting upper or lower case alpha
6	Syntax	Illegal command
7	Syntax	Illegal non-numeric
8	Syntax	Illegal <Decimal Numeric Program Data>
9	Syntax	Illegal <Suffix Program Data>
10	Syntax	Maximum <Suffix Program Data> length is 12 characters
11	Syntax	Illegal <String Program Data>
12	Syntax	Illegal <Arbitrary Block Program Data>
13	Syntax	Illegal <Expression Program Data>
14	Syntax	Illegal <Character Program Data>
15	Syntax	Illegal character on input
16	Syntax	Illegal identifier after command
17	Syntax	Illegal identifier after <Program Separator>
18	Syntax	Missing <Program Separator>
19	Syntax	Too much data
30	Device	No error
31	Device	Logical address is out of range 0 through 254
32	Device	No device is at that logical address
33	Device	GPIB secondary address is out of range 0 through 30
34	Device	VXI interrupt handler number is out of range 1 through 3
35	Device	VXI interrupt level is out of range 0 through 7
36	Device	A16 address is out of range 0000h through FFFEh
37	Device	Address must be even
38	Device	Word write value is out of range 0000h through FFFFh
39	Device	A bus error occurred during the access
40	Device	A24 address is out of range 200000h through E7FFFEh
41	Device	488.2 register is out of range 0 through 255

(continues)

Table E-1. Error Codes (continued)

Error Number	Type	Description
42	Device	Console mode is disabled: must have one output mode enabled
43	Device	Logical device has no secondary address link
44	Device	Unable to delete secondary address link
45	Device	Unable to create secondary address link
46	Device	Secondary address is already attached to a logical address
47	Device	Device is not a Message-Based device
48	Device	Device is not a servant of this GPIB-VXI/C
49	Device	Device does not have commander capability
50	Device	Not Dynamically Configured
51	Device	Commander did not accept <i>Device Grant</i> command
52	Device	Servant did not accept BNO or <i>Identify Commander</i> command
53	Device	Logical address cannot be this GPIB-VXI/C
54	Device	Word Serial command is out of range 0 through FFFFh
55	Device	Logical address is not physical VXI device
56	Device	Unable to create I/O buffer
57	Device	Commander did not accept <i>Release Device</i> command
58	Device	Unable to grant CI to physical device
59	Device	Device is already a servant
60	Device	Device is not commander of servant
61	Device	Register offset out of range 0 through 3Eh
62	Device	Timeout waiting for Downloaded Data
63	Device	TTL/ECL trigger line out of range 0 through 9
100	CI	DCI functionality is inactive
101	CI	Logical address conflict
102	CI	Logical address is out of range
103	CI	Block(s) requested are used
104	CI	Block(s) requested do not exist
105	CI	Servant(s) requested do not exist
106	CI	Servant(s) requested are not servants of the GPIB-VXI/C or another DCI
107	CI	Commander requested does not exist
108	CI	Servant(s) requested do not have the same commander
109	CI	Requested zero blocks
110	CI	Logical address referenced is not a DCI
111	CI	DCI base address is out of range
112	CI	DCI area new base address is not a multiple of 4096
113	CI	DCI area request exceeds available memory
114	CI	Attempted to change DCI area while DCIs were installed
116	CI	DCI was not found
117	CI	Logical address referenced is not a DCI
120	CI	Error encountered while spawning DCI process(es)
121	CI	Error encountered while creating Asynch process exchange
122	CI	No DCI initialization information (need to do DCISetup? query)
123	CI	Download timed out

(continues)

Table E-1. Error Codes (continued)

<b>Error Number</b>	<b>Type</b>	<b>Description</b>
125	CI	Download overflowed requested blocks
126	CI	Servant(s) requested has secondary address link
127	CI	Memory requested for DCI Word Serial structures is unavailable
128	CI	Logical address referenced is not the GPIB-VXI/C or local DCI
129	CI	Logical address referenced is not GPIB-VXI/C's or CI's servant
130	CI	Stack size requested for worker process exceeds FFFFh words
301	Trigger	No Trigger hardware support for this operation
302	Trigger	Invalid Controller for trigger functions
303	Trigger	Invalid Trigger line, External line, or protocol
304	Trigger	Trigger line not supported
305	Trigger	Trigger protocol not supported
306	Trigger	Wait period exceeded, timeout occurred
307	Trigger	Line already configured, must unconfigure to configure
308	Trigger	Source line not supported
309	Trigger	Destination line not supported for this source
310	Trigger	Invalid configuration mode
311	Trigger	Line already mapped, must unmap to map
312	Trigger	Line has not been configured/mapped for this operation
313	Trigger	Invalid count (TICK = 0 through 32, CNTR = 0 through 65535)
314	Trigger	Invalid/Unsupported mapping signal conditioning mode
315	Trigger	Previous operation is still pending for this line
316	Trigger	Previous acknowledge is still pending for this line
33064	Trigger	Trigger overrun, too many triggers received
33068	Trigger	Trigger unassertion overrun, too many triggers received
33076	Trigger	Trigger pulse stretch overrun, too many triggers received

# Appendix F

## GPIB-VXI/C VXI Trigger Support

This appendix contains an overview of the VXI triggering capabilities of the GPIB-VXI/C.

The GPIB-VXI/C contains a custom ASIC designed by National Instruments called the Trigger Interface Chip (TIC). The TIC gives direct access/control to the VXI trigger lines as well as some unique hardware features such as a 16-bit counter/timer, a dual 5-bit tick timer, and a 10 by 10 crosspoint switch matrix. It also includes some minimal signal conditioning such as signal inversion, variable pulse stretching, and synchronization with a clock source. The TIC supports all VXI-defined trigger protocols on the eight VXI TTL trigger lines and the two P2 connector ECL trigger lines.

In addition, the TIC has 10 external connections referred to as General Purpose Input/Output (GPIO) connections. Figure F-1 shows the configuration of the GPIOs on the GPIB-VXI/C. You can route a GPIO to any or all of the VXI trigger lines or the 5-bit tick timer. By using the built-in 10 MHz clock or GPIO 16 kHz, 4.9152 MHz, or TRIG IN connections, you can generate a square wave on any or all of the backplane trigger lines. By using the dual 5-bit tick timers, you can divide any of these frequencies down to a lower frequency. You can also disconnect a GPIO from its external connection and use it as a crosspoint switch location. In this mode, you can use any single trigger line as the internal source for the GPIO and any or all of the remaining trigger lines as the destination.

Refer to the *TTL/ECL Trigger Access Commands* section of Chapter 3, *Local Command Set*, for information on programming the TIC.

## Customer Communication

---

For your convenience, this appendix contains forms to help you gather the information necessary to help us solve technical problems you might have as well as a form you can use to comment on the product documentation. Filling out a copy of the *Technical Support Form* before contacting National Instruments helps us help you better and faster.

National Instruments provides comprehensive technical assistance around the world. In the U.S. and Canada, applications engineers are available Monday through Friday from 8:00 a.m. to 6:00 p.m. (central time). In other countries, contact the nearest branch office. You may fax questions to us at any time.

# GPIB-VXI/C Hardware Configuration Form

---

Record the settings and revisions of your hardware on the line to the right of each item. Complete a new copy of this form each time you revise your hardware configuration, and use this form as a reference for your current configuration. Completing this form accurately before contacting National Instruments for technical support helps our applications engineers answer your questions more efficiently.

## National Instruments Products

- GPIB-VXI/C Label Information

- Complete Part Number \_\_\_\_\_
- Serial Number \_\_\_\_\_
- Revision Number \_\_\_\_\_

- GPIB-VXI/C Configuration Information (see Chapter 2)

- Factory Configuration \_\_\_\_\_ yes \_\_\_\_\_ no

If no, give the following information.

Shared Memory Size (Table 2-4)

\_\_\_\_\_ None\* \_\_\_\_\_ One-Fourth \_\_\_\_\_ One-Half \_\_\_\_\_ All

- VXIbus Requester Level (Figure 2-2)

\_\_\_\_\_ 3\* \_\_\_\_\_ 2 \_\_\_\_\_ 1 \_\_\_\_\_ 0

- External Trigger Input Termination (Figure 2-3)

\_\_\_\_\_ Unterminated\* \_\_\_\_\_ Terminated

- External Clock Input Termination (Figure 2-4)

\_\_\_\_\_ Unterminated\* \_\_\_\_\_ Terminated

- Device Configuration

\_\_\_\_\_ Slot 0 Resource Manager (Table 2-7 and Figure 2-10)\*

\_\_\_\_\_ Non-Slot 0 Resource Manager (Table 2-11 and Figure 2-11)

\_\_\_\_\_ Non-Slot 0 Message-Based (Table 2-12 and Figure 2-12)

\_\_\_\_\_ Slot 0 Message-Based (Table 2-14 and Figure 2-13)

- \* Factory Configuration

- Discrete Fault Indicator Configuration (Figure 2-6)

\_\_\_\_\_ Normally Open\*      \_\_\_\_\_ Normally Closed

- Address Modifier Configuration (Figure 2-7)

\_\_\_\_\_ Supervisor A16, Supervisor A24 Data\*  
 \_\_\_\_\_ Supervisor A16, Supervisor A24 Program  
 \_\_\_\_\_ User A16, User A24 Data  
 \_\_\_\_\_ User A16, User A24 Program

- Startup Mode Configuration (Figure 2-8)

\_\_\_\_\_ 488-VXI Runtime System Mode\*  
 \_\_\_\_\_ Nonvolatile Configuration Mode  
 \_\_\_\_\_ Diagnostic Mode  
 \_\_\_\_\_ VXI pROBE Mode

- VXI System Startup Message Printing (Figure 2-9)

\_\_\_\_\_ Disabled\*      \_\_\_\_\_ Enabled

- Nonvolatile Configuration Information (see Chapter 4)

- Logical Address \_\_\_\_\_
- Device Type \_\_\_\_\_
- Servant Area Size \_\_\_\_\_
- VXI Interrupt Handler Levels \_\_\_\_\_
- GPIB Primary Address \_\_\_\_\_
- GPIB Addressing \_\_\_\_\_
- GPIB Address Avoid \_\_\_\_\_
- Reset Operation
  - Pushbutton to Local \_\_\_\_\_ enabled      \_\_\_\_\_ disabled
  - Pushbutton to Backplane \_\_\_\_\_ enabled      \_\_\_\_\_ disabled
  - Backplane to Local \_\_\_\_\_ enabled      \_\_\_\_\_ disabled

\* Factory Configuration

# Other Products

- Monitor (Manufacturer, Model) \_\_\_\_\_
- Keyboard (Manufacturer, Model) \_\_\_\_\_
- VXIbus Mainframe Manufacturer and Model \_\_\_\_\_
- Other VXIbus Devices:

Manufacturer	Model	Function	Slot	Logical Address

Continue on a separate sheet, if necessary.

- Interrupt Level(s) of Other VXI/VME Devices (Handler/Interrupter. Indicate if VME.) \_\_\_\_\_  
 \_\_\_\_\_  
 \_\_\_\_\_  
 \_\_\_\_\_
- 488 bus Devices (Manufacturer, Model, GPIB Address) \_\_\_\_\_  
 \_\_\_\_\_  
 \_\_\_\_\_

# Documentation Comment Form

---

National Instruments encourages you to comment on the documentation supplied with our products. This information helps us provide quality products to meet your needs.

Title: **GPIB-VXI/C User Manual**

Edition Date: **June 1994**

Part Number: **320404B-01**

Please comment on the completeness, clarity, and organization of the manual.

# Glossary

---

Prefix	Meaning	Value
n-	nano-	10 <sup>-9</sup>
μ-	micro-	10 <sup>-6</sup>
m-	milli-	10 <sup>-3</sup>
k-	kilo-	10 <sup>3</sup>
M-	Mega-	10 <sup>6</sup>

°	degrees
Ω	ohms
%	percent
A	ampere
Backplane	An assembly, typically a printed circuit board, with 96 pin connectors and signal paths that bus the connector pins. VXIbus systems have either two sets of bused connectors, designated J1 and J2 backplanes, or three sets of bused connectors, designated J1, J2, and J3 backplanes.
BTO	Bus Timeout Unit
bytes/sec	bytes per second
C	Celsius
CI	See <i>Code Instrument</i> .
Code Instrument	CI; a proprietary National Instruments software structure that uses software to emulate the capabilities of a VXI Message-Based device.
Command	Causes the GPIB-VXI/C to take some action.
Commander	A Message-Based device that is also a bus master and can control one or more Servants.
Console response	Returned in the form of readable sentences, which is better suited for interactive command entry.
DC	Dynamic Configuration, or Dynamically Configured
DC device	See <i>Dynamic configuration device</i> .

DCI	See <i>Downloaded CI</i> .
Diagnostics mode	Mode in which you can perform extensive offline diagnostic tests of the GPIB-VXI/C.
Downloaded CI	DCI; a form of CI that is downloaded into the GPIB-VXI/C's RAM memory.
Dynamic configuration device	DC device; a device that initially has a logical address of 255. The RM subsequently assigns it a different, unique logical address.
ECI	See <i>EPROMed CI</i> .
EEPROM	Electrically Erasable Programmable Read Only Memory
EPROM	Erasable Programmable Read Only Memory
EPROMed CI	ECI; a form of CI that is user-installed into EPROMs.
FIFO	First-In First-Out
GPIB	General Purpose Interface Bus. The industry standard IEEE 488 bus.
GPIB-VXI/C local command set	Consists of commands and queries.
Hz	Hertz (cycles per second)
IEEE	Institute of Electrical and Electronic Engineers
in.	inches
Logical address	An 8-bit number that uniquely identifies each VXIbus device in a system. It defines a device's A16 register address and indicates Commander/Servant relationships.
LSB	Least Significant Bit
m	meter
M	Megabytes of memory
Message-Based device	An intelligent device that implements the defined VXIbus registers and communication protocols.
MODID lines	VXI backplane signals used by the Resource Manager (through the use of the Slot 0 device) in order to perform slot associations for logical addresses. There are 13 MODID lines, one for each slot in a full-size mainframe.

Module	Typically consists of a board assembly and its associated mechanical parts, front panel, optional shields, and so on. A module contains everything required to occupy a slot in a mainframe. A module can occupy one or more slots.
MSB	Most Significant Bit
Nonvolatile configuration mode	Mode in which you can edit the contents of the nonvolatile EEPROM memory.
NV	Nonvolatile memory
Peek	To read the contents.
PH	Programmable Handler
PI	Position Independent
Poke	To write a value.
pROBE	A low-level interactive debugger for use with the pSOS operating system. It is commercially available from Software Components Group, Inc. VXI pROBE is an enhanced version of pROBE supplied on developmental versions of the GPIB-VXI/C.
Program mode response	Has a terse data-only format that is intended for a control program to read and parse.
pSOS	A small, multitasking operating system kernel used on the GPIB-VXI/C. It is commercially available from Software Components Group, Inc.
Query	Similar to a command in that it also causes the GPIB-VXI/C to take some action, but it always returns a response containing data or other information.
RCI	See <i>Resident CI</i> .
Register-Based Device	A Servant-only device that supports VXIbus configuration registers. Register-Based devices are typically controlled by Message-Based devices via device-dependent register reads and writes.
Resident CI	RCI; a CI that is supplied by National Instrument and resides in the firmware.
RM	See <i>Resource Manager</i> .
Resource Manager	A Message-Based Commander located at Logical Address 0 that provides configuration management services such as address map configuration, Commander/Servant mappings, self-test and diagnostic management.

SC	Static Configuration, or Statically Configured
SC Device	See <i>Static configuration device</i> .
sec	seconds
Servant	A device that is controlled by a Commander. Any device can be a Servant.
Static configuration device	SC device; a device that has its logical address set by static means, such as by a DIP switch.
System configuration table	During the execution of the RM and general configuration operations, the GPIB-VXI/C builds up a table of system configuration information. Each device has an entry in the table containing the device's logical address, its Commander's logical address, its secondary address, slot number, device class, manufacturer ID number, model code, memory space requirement, memory base address, and memory size. This table remains after the RM and general configuration operations are complete. It is accessible through the GPIB-VXI/C local command set.
V	volts
VME	Versa Module Eurocard or IEEE 1014.
VXIbus	VMEbus Extensions for Instrumentation.
VXI pROBE mode	Mode in which you can use the enhanced pROBE debugger. This mode is available only with the GPIB-VXI/C development firmware option.
VXI system mode	The startup mode for normal operation in a VXI system.
W	watts
Word Serial communication	The simplest form of communication required by Message-Based devices. It utilizes the A16 communication registers to transfer data using a simple polling handshake method.
Word Serial Protocol	The rules and regulations involved in performing Word Serial communication.
