| IN_NET       | NUMBER       | Total incoming network wait time (in hundredths of a second)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| OUT_NET      | NUMBER       | Total outgoing network wait time (in hundredths of a second)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| REQUESTS     | NUMBER       | Total number of requests taken from the common queue in this server's lifetime                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| BOUND_TIME   | NUMBER       | Time that a circuit and shared server have been bound (in centiseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| BOUND_REASON | VARCHAR2(32) | Provides a reason (a short explanation) for why a shared server and circuit could not be unbound.<br><br>This column is empty when a circuit is not bound to a server. When the server starts serving a circuit, BOUND_REASON is empty and remains empty unless the server tries unsuccessfully to unbind the circuit (after it finishes serving the current request). When this column is not empty, it will be cleared once the server and circuit are unbound (that is, once the resources preventing the session migration to another shared server are released). |
| CON_ID       | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul>                                                                                                                        |

## 10.42 V\$SHARED\_SERVER\_MONITOR

V\$SHARED\_SERVER\_MONITOR displays information for tuning the shared server.

| Column              | Datatype | Description                                                                                                                                                                                                                                                                                |
|---------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXIMUM_CONNECTIONS | NUMBER   | Highest number of virtual circuits in use at one time since the instance started. If this value reaches the value set for the CIRCUITS initialization parameter, then consider raising the value of CIRCUITS.<br><br><b>See Also:</b> "CIRCUITS"                                           |
| MAXIMUM_SESSIONS    | NUMBER   | Highest number of shared server sessions in use at one time since the instance started. If this reaches the value set for the SHARED_SERVER_SESSIONS initialization parameter, then consider raising the value of SHARED_SERVER_SESSIONS.<br><br><b>See Also:</b> "SHARED_SERVER_SESSIONS" |
| SERVERS_STARTED     | NUMBER   | Total number of shared servers started since the instance started (but not including those started during startup)                                                                                                                                                                         |

| Column             | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SERVERS_TERMINATED | NUMBER   | Total number of shared servers stopped by Oracle since the instance started                                                                                                                                                                                                                                                                                                                                                                     |
| SERVERS_HIGHWATER  | NUMBER   | Highest number of servers running at one time since the instance started. If this value reaches the value set for the <code>MAX_SHARED_SERVERS</code> initialization parameter, then consider raising the value of <code>SHARED_SERVERS</code> .<br><b>See Also:</b> " <a href="#">SHARED_SERVERS</a> "                                                                                                                                         |
| DISPATCHERS_CPU    | NUMBER   | Total CPU time of all dispatchers since the instance started (in millionths of a second)                                                                                                                                                                                                                                                                                                                                                        |
| CON_ID             | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.43 V\$SORT\_SEGMENT

V\$SORT\_SEGMENT displays information about every sort segment in a given instance. The view is only updated when the tablespace is of the `TEMPORARY` type.

| Column          | Datatype     | Description                                            |
|-----------------|--------------|--------------------------------------------------------|
| TABLESPACE_NAME | VARCHAR2(30) | Name of the tablespace                                 |
| SEGMENT_FILE    | NUMBER       | File number of the first extent                        |
| SEGMENT_BLOCK   | NUMBER       | Block number of the first extent                       |
| EXTENT_SIZE     | NUMBER       | Extent size                                            |
| CURRENT_USERS   | NUMBER       | Number of active users of the segment                  |
| TOTAL_EXTENTS   | NUMBER       | Total number of extents in the segment                 |
| TOTAL_BLOCKS    | NUMBER       | Total number of blocks in the segment                  |
| USED_EXTENTS    | NUMBER       | Extents allocated to active sorts                      |
| USED_BLOCKS     | NUMBER       | Blocks allocated to active sorts                       |
| FREE_EXTENTS    | NUMBER       | Extents not allocated to any sort                      |
| FREE_BLOCKS     | NUMBER       | Blocks not allocated to any sort                       |
| ADDED_EXTENTS   | NUMBER       | Number of extent allocations                           |
| EXTENT_HITS     | NUMBER       | Number of times an unused extent was found in the pool |
| FREED_EXTENTS   | NUMBER       | Number of deallocated extents                          |
| FREE_REQUESTS   | NUMBER       | Number of requests to deallocate                       |
| MAX_SIZE        | NUMBER       | Maximum number of extents ever used                    |
| MAX_BLOCKS      | NUMBER       | Maximum number of blocks ever used                     |
| MAX_USED_SIZE   | NUMBER       | Maximum number of extents used by all sorts            |
| MAX_USED_BLOCKS | NUMBER       | Maximum number of blocks used by all sorts             |

| Column          | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAX_SORT_SIZE   | NUMBER   | Maximum number of extents used by an individual sort                                                                                                                                                                                                                                                                                                                                                                                            |
| MAX_SORT_BLOCKS | NUMBER   | Maximum number of blocks used by an individual sort                                                                                                                                                                                                                                                                                                                                                                                             |
| RELATIVE_FNO    | NUMBER   | Relative file number of the sort segment header                                                                                                                                                                                                                                                                                                                                                                                                 |
| TS#             | NUMBER   | Tablespace number                                                                                                                                                                                                                                                                                                                                                                                                                               |
| CON_ID          | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| IS_LOCAL_TEMP   | NUMBER   | Indicates whether the sort segment is allocated from a local temporary tablespace (1) or not (0).                                                                                                                                                                                                                                                                                                                                               |

## 10.44 V\$SPPARAMETER

V\$SPPARAMETER displays information about the contents of the server parameter file. If a server parameter file was not used to start the instance, then each row of the view will contain FALSE in the ISSPECIFIED column.

| Column         | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FAMILY         | VARCHAR2(80)  | For internal use only                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SID            | VARCHAR2(80)  | SID for which the parameter is defined.                                                                                                                                                                                                                                                                                                                                                                                                         |
| NAME           | VARCHAR2(80)  | Name of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                           |
| TYPE           | VARCHAR2(11)  | Parameter type                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| VALUE          | VARCHAR2(255) | Parameter value (null if a server parameter file was not used to start the instance)                                                                                                                                                                                                                                                                                                                                                            |
| DISPLAY_VALUE  | VARCHAR2(255) | Parameter value in a user-friendly format. For example, if the VALUE column shows the value 262144 for a big integer parameter, then the DISPLAY_VALUE column will show the value 256K.                                                                                                                                                                                                                                                         |
| ISSPECIFIED    | VARCHAR2(6)   | Indicates whether the parameter was specified in the server parameter file (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                |
| ORDINAL        | NUMBER        | Position (ordinal number) of the parameter value (0 if a server parameter file was not used to start the instance). Useful only for parameters whose values are lists of strings.                                                                                                                                                                                                                                                               |
| UPDATE_COMMENT | VARCHAR2(255) | Comments associated with the most recent update (null if a server parameter file was not used to start the instance)                                                                                                                                                                                                                                                                                                                            |
| CON_ID         | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.45 V\$SQL

V\$SQL lists statistics on shared SQL areas without the `GROUP BY` clause and contains one row for each child of the original SQL text entered. Statistics displayed in V\$SQL are normally updated at the end of query execution. However, for long running queries, they are updated every 5 seconds. This makes it easy to see the impact of long running SQL statements while they are still in progress.

| Column                | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_TEXT              | VARCHAR2(1000) | First thousand characters of the SQL text for the current cursor                                                                                                                                                                                                                                                                                                                                                                                                                    |
| SQL_FULLTEXT          | CLOB           | Full text for the SQL statement exposed as a CLOB column. The full text of a SQL statement can be retrieved using this column instead of joining with the V\$SQLTEXT dynamic performance view.                                                                                                                                                                                                                                                                                      |
| SQL_ID                | VARCHAR2(13)   | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                                                                                                                                                            |
| SHARABLE_MEM          | NUMBER         | Amount of shared memory used by the child cursor (in bytes)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PERSISTENT_MEM        | NUMBER         | Fixed amount of memory used for the lifetime of the child cursor (in bytes)                                                                                                                                                                                                                                                                                                                                                                                                         |
| RUNTIME_MEM           | NUMBER         | Fixed amount of memory required during the execution of the child cursor                                                                                                                                                                                                                                                                                                                                                                                                            |
| SORTS                 | NUMBER         | Number of sorts that were done for the child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| LOADED_VERSIONS       | NUMBER         | Indicates whether the context heap is loaded (1) or not (0)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| OPEN_VERSIONS         | NUMBER         | Indicates whether the child cursor is locked (1) or not (0)                                                                                                                                                                                                                                                                                                                                                                                                                         |
| USERS_OPENING         | NUMBER         | Number of users that have any of the child cursors open                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FETCHES               | NUMBER         | Number of fetches associated with the SQL statement                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| EXECUTIONS            | NUMBER         | Number of executions that took place on this object since it was brought into the library cache                                                                                                                                                                                                                                                                                                                                                                                     |
| PX_SERVERS_EXECUTIONS | NUMBER         | Total number of executions performed by parallel execution servers (0 when the statement has never been executed in parallel)                                                                                                                                                                                                                                                                                                                                                       |
| END_OF_FETCH_COUNT    | NUMBER         | Number of times this cursor was fully executed since the cursor was brought into the library cache. The value of this statistic is not incremented when the cursor is partially executed, either because it failed during the execution or because only the first few rows produced by this cursor are fetched before the cursor is closed or re-executed. By definition, the value of the END_OF_FETCH_COUNT column should be less or equal to the value of the EXECUTIONS column. |
| USERS_EXECUTING       | NUMBER         | Number of users executing the statement                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| LOADS                 | NUMBER         | Number of times the object was either loaded or reloaded                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FIRST_LOAD_TIME       | VARCHAR2(76)   | Timestamp of the parent creation time                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| INVALIDATIONS         | NUMBER         | Number of times this child cursor has been invalidated                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PARSE_CALLS           | NUMBER         | Number of parse calls for this child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DISK_READS            | NUMBER         | Number of disk reads for this child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DIRECT_WRITES         | NUMBER         | Number of direct writes for this child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DIRECT_READS          | NUMBER         | Number of direct reads for this child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| BUFFER_GETS           | NUMBER         | Number of buffer gets for this child cursor                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                                                                                                |
|--------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APPLICATION_WAIT_TIME    | NUMBER        | Application wait time (in microseconds)                                                                                                                                                                                                                                                                                                    |
| CONCURRENCY_WAIT_TIME    | NUMBER        | Concurrency wait time (in microseconds)                                                                                                                                                                                                                                                                                                    |
| CLUSTER_WAIT_TIME        | NUMBER        | Cluster wait time (in microseconds)                                                                                                                                                                                                                                                                                                        |
| USER_IO_WAIT_TIME        | NUMBER        | User I/O Wait Time (in microseconds)                                                                                                                                                                                                                                                                                                       |
| PLSQL_EXEC_TIME          | NUMBER        | PL/SQL execution time (in microseconds)                                                                                                                                                                                                                                                                                                    |

| ROWS_PROCESSED           | NUMBER        | Total number of rows the parsed SQL statement returns                                                                                                                                                                                                                                                                                      |
| COMMAND_TYPE             | NUMBER        | Oracle command type definition                                                                                                                                                                                                                                                                                                             |
| OPTIMIZER_MODE           | VARCHAR2(10)  | Mode under which the SQL statement was executed                                                                                                                                                                                                                                                                                            |
| OPTIMIZER_COST           | NUMBER        | Cost of this query given by the optimizer                                                                                                                                                                                                                                                                                                  |
| OPTIMIZER_ENV            | RAW(2000)     | Optimizer environment                                                                                                                                                                                                                                                                                                                      |
| OPTIMIZER_ENV_HASH_VALUE | NUMBER        | Hash value for the optimizer environment                                                                                                                                                                                                                                                                                                   |
| PARSING_USER_ID          | NUMBER        | User ID of the user who originally built this child cursor                                                                                                                                                                                                                                                                                 |
| PARSING_SCHEMA_ID        | NUMBER        | Schema ID that was used to originally build this child cursor                                                                                                                                                                                                                                                                              |
| PARSING_SCHEMA_NAME      | VARCHAR2(128) | Schema name that was used to originally build this child cursor                                                                                                                                                                                                                                                                            |
| KEPT_VERSIONS            | NUMBER        | Indicates whether this child cursor has been marked to be kept pinned in the cache using the DBMS_SHARED_POOL package                                                                                                                                                                                                                      |
| ADDRESS                  | RAW(4   8)    | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                        |
| TYPE_CHK_HEAP            | RAW(4   8)    | Descriptor of the type check heap for this child cursor                                                                                                                                                                                                                                                                                    |
| HASH_VALUE               | NUMBER        | Hash value of the parent statement in the library cache                                                                                                                                                                                                                                                                                    |
| OLD_HASH_VALUE           | NUMBER        | Old SQL hash value                                                                                                                                                                                                                                                                                                                         |
| PLAN_HASH_VALUE          | NUMBER        | Numeric representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line).                                                                                                                       |
| FULL_PLAN_HASH_VALUE     | NUMBER        | Numeric representation of the complete SQL plan for this cursor. Comparing one FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible. |
| CHILD_NUMBER             | NUMBER        | Number of this child cursor                                                                                                                                                                                                                                                                                                                |
| SERVICE                  | VARCHAR2(64)  | Service name                                                                                                                                                                                                                                                                                                                               |
| SERVICE_HASH             | NUMBER        | Hash value for the name listed in the SERVICE column                                                                                                                                                                                                                                                                                       |
| MODULE                   | VARCHAR2(64)  | Contains the name of the module that was executing when the SQL statement was first parsed, which is set by calling DBMS_APPLICATION_INFO.SET_MODULE                                                                                                                                                                                       |
| MODULE_HASH              | NUMBER        | Hash value of the module listed in the MODULE column                                                                                                                                                                                                                                                                                       |
| ACTION                   | VARCHAR2(64)  | Contains the name of the action that was executing when the SQL statement was first parsed, which is set by calling DBMS_APPLICATION_INFO.SET_ACTION                                                                                                                                                                                       |
| ACTION_HASH              | NUMBER        | Hash value of the action listed in the ACTION column                                                                                                                                                                                                                                                                                       |

| Column              | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SERIALIZABLE_ABORTS | NUMBER        | Number of times the transaction failed to serialize, producing ORA-08177 errors, per cursor                                                                                                                                                                                                                                                                                                                                   |
| OUTLINE_CATEGORY    | VARCHAR2(64)  | If an outline was applied during construction of the cursor, then this column displays the category of that outline. Otherwise the column is left blank.                                                                                                                                                                                                                                                                      |
| CPU_TIME            | NUMBER        | CPU time (in microseconds) used by this cursor for parsing, executing, and fetching                                                                                                                                                                                                                                                                                                                                           |
| ELAPSED_TIME        | NUMBER        | Elapsed time (in microseconds) used by this cursor for parsing, executing, and fetching. If the cursor uses parallel execution, then ELAPSED_TIME is the cumulative time for the query coordinator, plus all parallel query slave processes.                                                                                                                                                                                  |
| OUTLINE_SID         | NUMBER        | Outline session identifier                                                                                                                                                                                                                                                                                                                                                                                                    |
| CHILD_ADDRESS       | RAW(4   8)    | Address of the child cursor                                                                                                                                                                                                                                                                                                                                                                                                   |
| SQLTYPE             | NUMBER        | Denotes the version of the SQL language used for this statement                                                                                                                                                                                                                                                                                                                                                               |
| REMOTE              | VARCHAR2(1)   | Indicates whether the cursor is remote mapped (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                  |
| OBJECT_STATUS       | VARCHAR2(19)  | Status of the cursor: <ul style="list-style-type: none"> <li>VALID - Valid, authorized without errors</li> <li>VALID_AUTH_ERROR - Valid, authorized with authorization errors</li> <li>VALID_COMPILE_ERROR - Valid, authorized with compilation errors</li> <li>VALID_UNAUTH - Valid, unauthorized</li> <li>INVALID_UNAUTH - Invalid, unauthorized</li> <li>INVALID - Invalid, unauthorized but keep the timestamp</li> </ul> |
| LITERAL_HASH_VALUE  | NUMBER        | Hash value of the literals which are replaced with system-generated bind variables and are to be matched, when CURSOR_SHARING is used. This is not the hash value for the SQL statement. If CURSOR_SHARING is not used, then the value is 0.                                                                                                                                                                                  |
| LAST_LOAD_TIME      | VARCHAR2(76)  | Time at which the query plan was loaded into the library cache                                                                                                                                                                                                                                                                                                                                                                |
| IS_OBSOLETE         | VARCHAR2(1)   | Indicates whether the cursor has become obsolete (Y) or not (N). This can happen if the number of child cursors is too large.                                                                                                                                                                                                                                                                                                 |
| IS_BIND_SENSITIVE   | VARCHAR2(1)   | Indicates whether the cursor is bind sensitive (Y) or not (N). A query is considered bind-sensitive if the optimizer peeked at one of its bind variable values when computing predicate selectivities and where a change in a bind variable value may cause the optimizer to generate a different plan.                                                                                                                       |
| IS_BIND_AWARE       | VARCHAR2(1)   | Indicates whether the cursor is bind aware (Y) or not (N). A query is considered bind-aware if it has been marked to use extended cursor sharing. The query would already have been marked as bind-sensitive.                                                                                                                                                                                                                 |
| IS_SHAREABLE        | VARCHAR2(1)   | Indicates whether the cursor can be shared (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                     |
| CHILD_LATCH         | NUMBER        | Child latch number that is protecting the cursor. This column is obsolete and maintained for backward compatibility.                                                                                                                                                                                                                                                                                                          |
| SQL_PROFILE         | VARCHAR2(64)  | SQL profile used for this statement, if any                                                                                                                                                                                                                                                                                                                                                                                   |
| SQL_PATCH           | VARCHAR2(128) | SQL patch used for this statement, if any                                                                                                                                                                                                                                                                                                                                                                                     |
| SQL_PLAN_BASELINE   | VARCHAR2(128) | SQL plan baseline used for this statement, if any                                                                                                                                                                                                                                                                                                                                                                             |
| PROGRAM_ID          | NUMBER        | Program identifier                                                                                                                                                                                                                                                                                                                                                                                                            |

| PHYSICAL_WRITE_BYTES           | NUMBER      | Number of bytes written to disks by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                                                        |
| OPTIMIZED_PHY_READ_REQUESTS    | NUMBER      | Number of physical read I/O requests from Database Smart Flash Cache issued by the monitored SQL                                                                                                                                                                                                                                                                                                                                                             |
| LOCKED_TOTAL                   | NUMBER      | Total number of times the child cursor has been locked                                                                                                                                                                                                                                                                                                                                                                                                       |
| PINNED_TOTAL                   | NUMBER      | Total number of times the child cursor has been pinned                                                                                                                                                                                                                                                                                                                                                                                                       |
| IO_CELL_UNCOMPRESSED_BYTES     | NUMBER      | Number of uncompressed bytes (that is, size after decompression) that are offloaded to the Exadata cells<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                                       |
| IO_CELL_OFFLOAD_RETURNED_BYTES | NUMBER      | Number of filtered bytes returned by Exadata cells (that is, the number of bytes returned after processing has been offloaded on the Exadata cells)<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                            |
| CON_ID                         | NUMBER      | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul>              |
| IS_REOPTIMIZABLE               | VARCHAR2(1) | This column shows whether the next execution matching this child cursor will trigger a reoptimization. The values are: <ul style="list-style-type: none"> <li>Y: If the next execution will trigger a reoptimization</li> <li>R: If the child cursor contains reoptimization information, but will not trigger reoptimization because the cursor was compiled in reporting mode</li> <li>N: If the child cursor has no reoptimization information</li> </ul> |

| Column                       | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IS_RESOLVED_ADAPTIVE_PLAN    | VARCHAR2(1)   | This column shows whether all of the adaptive parts of a plan have been resolved to the final plan. Once the plan is resolved, the plan hash value and the plan displayed by DBMS_XPLAN will not change through the end of execution. The values for this column are: <ul style="list-style-type: none"> <li>• NULL: If the plan is not adaptive</li> <li>• Y: If the plan is fully resolved</li> <li>• N: If the plan is not yet fully resolved</li> </ul> <b>See Also:</b> <i>Oracle Database PL/SQL Packages and Types Reference</i> for more information about the DBMS_XPLAN package |
| IM_SCANS                     | NUMBER        | Number of In-Memory Column Store (IM column store) segment scans                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| IM_SCAN_BYTES_UNCOMPRESSED   | NUMBER        | Uncompressed size of data scanned from the IM column store                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| IM_SCAN_BYTES_INMEMORY       | NUMBER        | In-memory size of data scanned from the IM column store                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DDL_NO_INVALIDATE            | VARCHAR2(1)   | Indicates if a DDL statement updated a dependent object and did not invalidate this cursor. The values are: <ul style="list-style-type: none"> <li>• N: There has not been a DDL statement that updated a dependent object without invalidating this cursor.</li> <li>• Y: A DDL statement updated a dependent object and did not invalidate this cursor, but the cursor has not executed since this happened.</li> <li>• X: A DDL statement updated a dependent object and did not invalidate this cursor, and the cursor has executed since this happened.</li> </ul>                   |
| IS_ROLLING_INVALID           | VARCHAR2(1)   | Indicates if this cursor is rolling validated. The values are: <ul style="list-style-type: none"> <li>• N: This cursor is not rolling invalidated.</li> <li>• Y: This cursor is rolling invalidated, but the cursor has not executed in this state.</li> <li>• X: This cursor is rolling invalidated, and the cursor has executed in this state.</li> </ul>                                                                                                                                                                                                                               |
| IS_ROLLING_REFRESH_INVALID   | VARCHAR2(1)   | Indicates if this cursor is rolling validated and requires execution time refresh. The values are: <ul style="list-style-type: none"> <li>• N: This cursor is not a cursor that is rolling invalidated and requires execution time refresh.</li> <li>• Y: This cursor is rolling invalidated and requires execution time refresh, but the cursor has not executed in this state.</li> <li>• X: This cursor is rolling invalidated and requires execution time refresh, and the cursor has executed in this state.</li> </ul>                                                              |
| RESULT_CACHE                 | VARCHAR2(1)   | Indicates whether the SQL statement used the result cache (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SQL_QUARANTINE               | VARCHAR2(128) | If the execution plan for this cursor is quarantined, then this column contains the name of the SQL quarantine configuration (corresponds to the NAME column in the DBA_SQL_QUARANTINE view). Otherwise, this column is null.                                                                                                                                                                                                                                                                                                                                                             |
| AVOIDED_EXECUTIONS           | NUMBER        | Number of times this cursor was prevented from being used due to the plan being quarantined                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| HEAP0_LOAD_TIME <sup>1</sup> | DATE          | Time at which heap0 of the library cache object was loaded                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Column                       | Datatype | Description                                                                                                                                                                                                                                                                                                                  |
|------------------------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HEAP6_LOAD_TIME <sup>1</sup> | DATE     | Time at which heap6 of the library cache object was loaded<br>A time difference of more than one minute between HEAP0_LOAD_TIME and HEAP6_LOAD_TIME indicates that heap6 has been partially reloaded. For example, the database might have aged out heap6 due to shared pool space pressure and reloaded it at a later time. |

<sup>1</sup> This column is available starting with Oracle Database 21c.

## 10.46 V\$SQL\_BIND\_CAPTURE

V\$SQL\_BIND\_CAPTURE displays information on bind variables used by SQL cursors. Each row in the view contains information for one bind variable defined in a cursor. This includes:

- Reference to the cursor defining the bind variable  
(`hash_value`, `address`) for the parent cursor and (`hash_value`, `child_address`) for the child cursor.
- Bind metadata  
Name, position, data type, character set ID, precision, scale, and maximum length of the bind variable.
- Bind data  
One of the bind values used for the bind variable during a past execution of its associated SQL statement. Bind values are not always captured for this view. Bind values are displayed by this view only when the type of the bind variable is simple (this excludes LONG, LOB, and ADT data types) and when the bind variable is used in the WHERE or HAVING clauses of the SQL statement.

Bind capture is disabled when the `STATISTICS_LEVEL` initialization parameter is set to BASIC. This view can be joined with `V$SQLAREA` on (`HASH_VALUE`, `ADDRESS`) and with `V$SQL` on (`HASH_VALUE`, `CHILD_ADDRESS`).

| Column          | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS         | RAW(4   8)     | Address of the parent cursor                                                                                                                                                                                                                                                                                                                                                                                                                    |
| HASH_VALUE      | NUMBER         | Hash value of the parent cursor in the library cache. The hash value is a fixed index for the view and should always be used to speed up access to the view.                                                                                                                                                                                                                                                                                    |
| SQL_ID          | VARCHAR2(13)   | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                                                                                                                        |
| CHILD_ADDRESS   | RAW(4   8)     | Address of the child cursor                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CHILD_NUMBER    | NUMBER         | Child cursor number                                                                                                                                                                                                                                                                                                                                                                                                                             |
| NAME            | VARCHAR2(128)  | Name of the bind variable                                                                                                                                                                                                                                                                                                                                                                                                                       |
| POSITION        | NUMBER         | Position of the bind variable in the SQL statement                                                                                                                                                                                                                                                                                                                                                                                              |
| DUP_POSITION    | NUMBER         | If the binding is performed by name and the bind variable is duplicated, then this column gives the position of the primary bind variable.                                                                                                                                                                                                                                                                                                      |
| DATATYPE        | NUMBER         | Internal identifier for the bind data type. Beginning in Oracle Database 12c, a number representing a PL/SQL data type can appear in this column.                                                                                                                                                                                                                                                                                               |
| DATATYPE_STRING | VARCHAR2(15)   | Textual representation of the bind data type. Beginning in Oracle Database 12c, a text representation of a PL/SQL-only data type can appear in this column. If the actual data type is a PL/SQL sub type, the name of the data type, not the sub type will be displayed.                                                                                                                                                                        |
| CHARACTER_SID   | NUMBER         | National character set identifier                                                                                                                                                                                                                                                                                                                                                                                                               |
| PRECISION       | NUMBER         | Precision (for numeric binds)                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SCALE           | NUMBER         | Scale (for numeric binds)                                                                                                                                                                                                                                                                                                                                                                                                                       |
| MAX_LENGTH      | NUMBER         | Maximum bind length                                                                                                                                                                                                                                                                                                                                                                                                                             |
| WAS_CAPTURED    | VARCHAR2(3)    | Indicates whether the bind value was captured (YES) or not (NO)                                                                                                                                                                                                                                                                                                                                                                                 |
| LAST_CAPTURED   | DATE           | Date when the bind value was captured. Bind values are captured when SQL statements are executed. To limit the overhead, binds are captured at most every 15 minutes for a given cursor.                                                                                                                                                                                                                                                        |
| VALUE_STRING    | VARCHAR2(4000) | Value of the bind represented as a string                                                                                                                                                                                                                                                                                                                                                                                                       |
| VALUE_ANYDATA   | ANYDATA        | Value of the bind represented using the ANYDATA data type. This representation is useful to programmatically decode the value of the bind variable. This column is NULL if a PL/SQL-only data type appears in the DATATYPE column.                                                                                                                                                                                                              |
| CON_ID          | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.47 V\$SQL\_BIND\_DATA

V\$SQL\_BIND\_DATA describes information related to bind variables.

V\$SQL\_BIND\_DATA describes, for each distinct bind variable in each cursor owned by the session querying this view:

- Actual bind data, if the bind variable is user defined
- The underlying literal, if the `CURSOR_SHARING` parameter is set to `FORCE` and the bind variable is system generated. (System-generated binds have a value of 256 in the `SHARED_FLAG2` column.)

| Column          | Datatype       | Description                                                                                                                                       |
|-----------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| CURSOR_NUM      | NUMBER         | Cursor number for this bind                                                                                                                       |
| POSITION        | NUMBER         | Bind position                                                                                                                                     |
| DATATYPE        | NUMBER         | Internal identifier for the bind data type. Beginning in Oracle Database 12c, a number representing a PL/SQL data type can appear in this column. |
| SHARED_MAX_LEN  | NUMBER         | Shared maximum length for this bind from the shared cursor object associated with this bind                                                       |
| PRIVATE_MAX_LEN | NUMBER         | Private maximum length for this bind sent from the client                                                                                         |
| ARRAY_SIZE      | NUMBER         | Maximum number of array elements (for array binds only)                                                                                           |
| PRECISION       | NUMBER         | Precision (for numeric binds)                                                                                                                     |
| SCALE           | NUMBER         | Scale (for numeric binds)                                                                                                                         |
| SHARED_FLAG     | NUMBER         | Shared bind data flags                                                                                                                            |
| SHARED_FLAG2    | NUMBER         | Shared bind data flags (continued)                                                                                                                |
| BUF_ADDRESS     | RAW(4   8)     | Bind buffer memory address                                                                                                                        |
| BUF_LENGTH      | NUMBER         | Bind buffer length                                                                                                                                |
| VAL_LENGTH      | NUMBER         | Actual bind value length                                                                                                                          |
| BUF_FLAG        | NUMBER         | Bind buffer flags                                                                                                                                 |
| INDICATOR       | NUMBER         | Bind indicator                                                                                                                                    |
| VALUE           | VARCHAR2(4000) | Contents of the bind buffer                                                                                                                       |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.48 V\$SQL\_BIND\_METADATA

V\$SQL\_BIND\_METADATA describes metadata related to bind variables.

V\$SQL\_BIND\_METADATA describes, for each distinct bind variable in each cursor owned by the session querying this view:

- Bind metadata provided by the client, if the bind variable is user defined
- Metadata based on the underlying literal, if the CURSOR\_SHARING parameter is set to FORCE and the bind variable is system-generated.

| Column     | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS    | RAW(4   8)    | Memory address of the child cursor that owns this bind variable                                                                                                                                                                                                                                                                                                                                                                                 |
| POSITION   | NUMBER        | Bind position                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DATATYPE   | NUMBER        | Internal identifier for the bind data type. Beginning in Oracle Database 12c, a number representing a PL/SQL data type can appear in this column.                                                                                                                                                                                                                                                                                               |
| MAX_LENGTH | NUMBER        | Maximum length of the bind value                                                                                                                                                                                                                                                                                                                                                                                                                |
| ARRAY_LEN  | NUMBER        | Maximum number of array elements (for array binds only)                                                                                                                                                                                                                                                                                                                                                                                         |
| BIND_NAME  | VARCHAR2(128) | User-defined or system-generated bind variable name (if used)                                                                                                                                                                                                                                                                                                                                                                                   |
| CON_ID     | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.49 V\$SQL\_CS\_HISTOGRAM

V\$SQL\_CS\_HISTOGRAM summarizes the monitoring information stored by adaptive cursor sharing. This information is used to decide whether to enable extended cursor sharing for a query. It is stored in a histogram, whose bucket's contents are exposed by this view.

| Column       | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS      | RAW(4   8)   | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                                                                                                                             |
| HASH_VALUE   | NUMBER       | Hash value of the parent statement in the library cache                                                                                                                                                                                                                                                                                                                                                                                         |
| SQL_ID       | VARCHAR2(13) | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                                                                                                                        |
| CHILD_NUMBER | NUMBER       | Number of the child cursor being monitored                                                                                                                                                                                                                                                                                                                                                                                                      |
| BUCKET_ID    | NUMBER       | Bucket number of the monitoring histogram                                                                                                                                                                                                                                                                                                                                                                                                       |
| COUNT        | NUMBER       | Value in this bucket of the histogram                                                                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID       | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.50 V\$SQL\_CS\_SELECTIVITY

V\$SQL\_CS\_SELECTIVITY exposes the valid selectivity ranges for a child cursor in extended cursor sharing mode. A valid range consists of a low and high value for each predicate containing binds. Each predicate's selectivity (with the current bind value) must fall between the corresponding low and high values in order for the child cursor to be shared.

| Column       | Datatype     | Description                                                                               |
|--------------|--------------|-------------------------------------------------------------------------------------------|
| ADDRESS      | RAW(4   8)   | Address of the handle to the parent for this cursor                                       |
| HASH_VALUE   | NUMBER       | Hash value of the parent statement in the library cache                                   |
| SQL_ID       | VARCHAR2(13) | SQL identifier of the parent cursor in the library cache                                  |
| CHILD_NUMBER | NUMBER       | Number of the child cursor                                                                |
| PREDICATE    | VARCHAR2(40) | Predicate whose selectivity must fall between low and high values                         |
| RANGE_ID     | NUMBER       | Identifier for the range used to match up the low and high values for multiple predicates |
| LOW          | VARCHAR2(10) | Lower bound for allowable selectivity                                                     |
| HIGH         | VARCHAR2(10) | Upper bound for allowable selectivity                                                     |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.51 V\$SQL\_CS\_STATISTICS

V\$SQL\_CS\_STATISTICS contains the raw execution statistics used by the monitoring component of adaptive cursor sharing. A sample of the executions is monitored. This view exposes which executions were sampled, and what the statistics were for those executions. The statistics are cumulative for each distinct set of bind values.

| Column              | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS             | RAW(4   8)   | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                                                                                                                             |
| HASH_VALUE          | NUMBER       | Hash value of the parent statement in the library cache                                                                                                                                                                                                                                                                                                                                                                                         |
| SQL_ID              | VARCHAR2(13) | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                                                                                                                        |
| CHILD_NUMBER        | NUMBER       | Number of the child cursor being monitored                                                                                                                                                                                                                                                                                                                                                                                                      |
| BIND_SET_HASH_VALUE | NUMBER       | Hash of the values of the binds                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PEEKED              | VARCHAR2(1)  | Indicates if this is the bind set used to build the cursor (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                       |
| EXECUTIONS          | NUMBER       | Number of times this bind set has been executed and monitored                                                                                                                                                                                                                                                                                                                                                                                   |
| ROWS_PROCESSED      | NUMBER       | Cumulative number of rows processed by all row sources in the plan over all monitored executions with this bind set                                                                                                                                                                                                                                                                                                                             |
| BUFFER_GETS         | NUMBER       | Cumulative number of buffer gets over all monitored executions with this bind set                                                                                                                                                                                                                                                                                                                                                               |
| CPU_TIME            | NUMBER       | Cumulative CPU time (in microseconds) used by this cursor for monitored executions with this bind set                                                                                                                                                                                                                                                                                                                                           |
| CON_ID              | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.52 V\$SQL\_CURSOR

V\$SQL\_CURSOR displays debugging information for each cursor associated with the session querying this view.

| Column        | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CURNO         | NUMBER       | Cursor number                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| FLAG          | NUMBER       | Flags set in the cursor                                                                                                                                                                                                                                                                                                                                                                                                                         |
| STATUS        | VARCHAR2(9)  | Status of the cursor; that is, what state the cursor is in                                                                                                                                                                                                                                                                                                                                                                                      |
| PARENT_HANDLE | RAW(4   8)   | Pointer to the parent cursor handle                                                                                                                                                                                                                                                                                                                                                                                                             |
| PARENT_LOCK   | RAW(4   8)   | Pointer to the parent cursor lock                                                                                                                                                                                                                                                                                                                                                                                                               |
| CHILD_LOCK    | RAW(4   8)   | Pointer to the child cursor lock                                                                                                                                                                                                                                                                                                                                                                                                                |
| CHILD_PIN     | RAW(4   8)   | Pointer to the child cursor pin                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PERS_HEAP_MEM | NUMBER       | Total amount of memory allocated from persistent heap for this cursor                                                                                                                                                                                                                                                                                                                                                                           |
| WORK_HEAP_MEM | NUMBER       | Total amount of memory allocated from the work heap for this cursor                                                                                                                                                                                                                                                                                                                                                                             |
| BIND_VARS     | NUMBER       | Total number of bind positions in the query currently parsed into this cursor                                                                                                                                                                                                                                                                                                                                                                   |
| DEFINE_VARS   | NUMBER       | Total number of define variables in the query currently parsed into this cursor                                                                                                                                                                                                                                                                                                                                                                 |
| BIND_MEM_LOC  | VARCHAR2(64) | Which memory heap the bind variables are stored in: either the UGA or the CGA                                                                                                                                                                                                                                                                                                                                                                   |

| INST_FLAG2    | VARCHAR2(64) | Instantiation object flags (continued)                                                                                                                                                                                                                                                                                                                                                                                                          |
| CHILD_HANDLE  | RAW(4   8)   | Pointer to the child cursor handle                                                                                                                                                                                                                                                                                                                                                                                                              |
| CON_ID        | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.53 V\$SQL\_JOIN\_FILTER

V\$SQL\_JOIN\_FILTER displays performance information about the characteristics of join filters when they are used for a parallel cursor. (A join filter is a bitmap filter applied to table rows before a join operation in order to avoid parallel communication.)

| Column              | Datatype | Description                                                                                                      |
|---------------------|----------|------------------------------------------------------------------------------------------------------------------|
| QC_SESSION_ID       | NUMBER   | QC (Query Coordinator) session ID of the given cursor for the given parallel query                               |
| QC_INSTANCE_ID      | NUMBER   | QC (Query Coordinator) instance ID of the given cursor for the given parallel query                              |
| SQL_PLAN_HASH_VALUE | NUMBER   | SQL plan hash value of the given cursor for the given parallel query                                             |
| FILTER_ID           | NUMBER   | An ID that identifies the join filter in the given cursor and corresponds to the filter ID in the execution plan |
| LENGTH              | NUMBER   | Total size of the join filter field                                                                              |

| Column   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BITS_SET | NUMBER   | Number of bits set in this filter                                                                                                                                                                                                                                                                                                                                                                                                               |
| FILTERED | NUMBER   | Number of rows seen by the join filter                                                                                                                                                                                                                                                                                                                                                                                                          |
| PROBED   | NUMBER   | Number of rows of the right table that have been tested against the bitmap filter. This is the sum of the filtered rows plus the non-filtered rows.                                                                                                                                                                                                                                                                                             |
| ACTIVE   | NUMBER   | Whether the filter is active (Yes) or not (No)                                                                                                                                                                                                                                                                                                                                                                                                  |
| CON_ID   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.54 V\$SQL\_MONITOR

V\$SQL\_MONITOR displays SQL statements whose execution have been (or are being) monitored by Oracle.

This view contains global, high-level information about simple and composite database operations.

Oracle Database monitors simple database operations, which are top SQL statements and PL/SQL subprograms, when any of the following conditions is true:

- The operations run in parallel.
- The operations have consumed at least 5 seconds of CPU or I/O time in a single execution.
- Tracking for the operations is forced by the `/*+ MONITOR */` hint.

For simple database operations, monitoring statistics are not cumulative over several executions. In this case, one entry in V\$SQL\_MONITOR is dedicated to a single execution of a SQL statement. If the database monitors two executions of the same SQL statement, then each execution has a separate entry in V\$SQL\_MONITOR.

For simple database operations, V\$SQL\_MONITOR has one entry for the parallel execution coordinator process and one entry for each parallel execution server process. Each entry has corresponding entries in V\$SQL\_PLAN\_MONITOR. Because the processes allocated for the parallel execution of a SQL statement are cooperating for the same execution, these entries share the same execution key (the combination of SQL\_ID, SQL\_EXEC\_START, and SQL\_EXEC\_ID).

Oracle Database monitors composite database operations when either of the following conditions is true:

- A database operation was started with `DBMS_SQL_MONITOR.BEGIN_OPERATION` and the operation has consumed at least 5 seconds of CPU or I/O time.
- Tracking for the operation is forced by setting `FORCE_TRACKING` to `Y` in `DBMS_SQL_MONITOR.BEGIN_OPERATION`.

For composite database operations, each row contains an operation whose statistics are accumulated over the SQL statements and PL/SQL subprograms that run in the same session as part of the operation.

The `V$SQL_MONITOR` view contains a subset of the statistics available in `V$SQL`. However, unlike `V$SQL`, monitoring statistics are not cumulative over several executions. Instead, one entry in `V$SQL_MONITOR` is dedicated to a single execution of a SQL statement. If the database monitors two executions of the same SQL statement, then each execution has a separate entry in `V$SQL_MONITOR`.

The primary key is the combination of the columns `SQL_ID`, `SQL_EXEC_START`, and `SQL_EXEC_ID`.

`V$SQL_MONITOR` has one entry for the parallel execution coordinator process, and one entry for each parallel execution server process. Each entry has corresponding entries in `V$SQL_PLAN_MONITOR`. Because the processes allocated for the parallel execution of a SQL statement are cooperating for the same execution, these entries share the same execution key (the composite `SQL_ID`, `SQL_EXEC_START`, and `SQL_EXEC_ID`). You can aggregate the execution key to determine the overall statistics for a parallel execution.

When the SQL statement being monitored is executing, statistics in `V$SQL_MONITOR` are generally refreshed in near real time, once every second. Once the execution ends, monitoring information is not deleted immediately. Instead, it is kept in `V$SQL_MONITOR` for at least one minute. The entry will eventually be deleted to reclaim its space as new statements are monitored.

| Column            | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KEY               | NUMBER        | Artificial join key to efficiently join <code>V\$SQL_MONITOR</code> with its corresponding plan level monitoring statistics stored in <code>V\$SQL_PLAN_MONITOR</code>                                                                                                                                                                                                                                                                                            |
| REPORT_ID         | NUMBER        | Unique ID of the XML report stored in Automatic Workload Repository (AWR) for this monitored entity                                                                                                                                                                                                                                                                                                                                                               |
| STATUS            | VARCHAR2(19)  | SQL execution status: <ul style="list-style-type: none"> <li>QUEUED - SQL statement is queued</li> <li>EXECUTING - SQL statement is still executing</li> <li>DONE (ERROR) - Execution terminated with an error</li> <li>DONE (FIRST N ROWS) - Execution terminated by the application before all rows were fetched</li> <li>DONE (ALL ROWS) - Execution terminated and all rows were fetched</li> <li>DONE - Execution terminated (parallel execution)</li> </ul> |
| USER#             | NUMBER        | User ID of the database user who issued the SQL being monitored                                                                                                                                                                                                                                                                                                                                                                                                   |
| USERNAME          | VARCHAR2(128) | User name of the database user who issued the SQL being monitored                                                                                                                                                                                                                                                                                                                                                                                                 |
| MODULE            | VARCHAR2(64)  | Name of the executing module when sampled, as set by the <code>DBMS_APPLICATION_INFO.SET_MODULE</code> procedure                                                                                                                                                                                                                                                                                                                                                  |
| ACTION            | VARCHAR2(64)  | Name of the executing action when sampled, as set by the <code>DBMS_APPLICATION_INFO.SET_ACTION</code> procedure                                                                                                                                                                                                                                                                                                                                                  |
| SERVICE_NAME      | VARCHAR2(64)  | Service name of the user session                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CLIENT_IDENTIFIER | VARCHAR2(64)  | Client identifier from the user session                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Column                    | Datatype       | Description                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLIENT_INFO               | VARCHAR2(64)   | Client information for the user session                                                                                                                                                                                                                                                                                                            |
| PROGRAM                   | VARCHAR2(84)   | Name of the operating system program that issued the monitored SQL                                                                                                                                                                                                                                                                                 |
| PLSQL_ENTRY_OBJECT_ID     | NUMBER         | Object ID of the top-most PL/SQL subprogram on the stack; NULL if there is no PL/SQL subprogram on the stack                                                                                                                                                                                                                                       |
| PLSQL_ENTRY_SUBPROGRAM_ID | NUMBER         | Subprogram ID of the top-most PL/SQL subprogram on the stack; NULL if there is no PL/SQL subprogram on the stack                                                                                                                                                                                                                                   |
| PLSQL_OBJECT_ID           | NUMBER         | Object ID of the currently executing PL/SQL subprogram; NULL if executing SQL                                                                                                                                                                                                                                                                      |
| PLSQL_SUBPROGRAM_ID       | NUMBER         | Subprogram ID of the currently executing PL/SQL object; NULL if executing SQL                                                                                                                                                                                                                                                                      |
| FIRST_REFRESH_TIME        | DATE           | Time when monitoring of the SQL statement started, generally a few seconds after execution start time                                                                                                                                                                                                                                              |
| LAST_REFRESH_TIME         | DATE           | Time when statistics in V\$SQL_MONITOR were last updated for the SQL statement. Statistics are generally refreshed every second when the statement executes.                                                                                                                                                                                       |
| REFRESH_COUNT             | NUMBER         | Number of times V\$SQL_MONITOR statistics have been refreshed (generally once every second when the SQL statement executes)                                                                                                                                                                                                                        |
| DBOP_EXEC_ID              | NUMBER         | Database operation execution identifier for the current execution. If the type is SQL, the DBOP_EXEC_ID will be NULL.                                                                                                                                                                                                                              |
| DBOP_NAME                 | VARCHAR2(30)   | Database operation name. If the type is SQL, the DBOP_NAME will be NULL.                                                                                                                                                                                                                                                                           |
| SID                       | NUMBER         | Session identifier executing (or having executed) the SQL statement being monitored                                                                                                                                                                                                                                                                |
| PROCESS_NAME              | VARCHAR2(5)    | Process name identifier executing (or having executed) the statement; ora if the process is foreground, else the background process name (for example, p001 for PX server p001)                                                                                                                                                                    |
| SQL_ID                    | VARCHAR2(13)   | SQL identifier of the statement being monitored                                                                                                                                                                                                                                                                                                    |
| SQL_TEXT                  | VARCHAR2(2000) | Up to the first 2000 characters of the text of the SQL being monitored                                                                                                                                                                                                                                                                             |
| IS_FULL_SQLTEXT           | VARCHAR2(1)    | Indicates whether the SQL_TEXT column has the entire SQL text (Y) or not (N)                                                                                                                                                                                                                                                                       |
| SQL_EXEC_START            | DATE           | Time when the execution started                                                                                                                                                                                                                                                                                                                    |
| SQL_EXEC_ID               | NUMBER         | Execution identifier. Together, the three columns SQL_ID, SQL_EXEC_START, and SQL_EXEC_ID represent the execution key. The execution key is used to uniquely identify one execution of the SQL statement.                                                                                                                                          |
| SQL_PLAN_HASH_VALUE       | NUMBER         | SQL plan hash value                                                                                                                                                                                                                                                                                                                                |
| SQL_FULL_PLAN_HASH_VALUE  | NUMBER         | Numeric representation of the complete SQL plan for this cursor. Comparing one SQL_FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the SQL_FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible. |
| EXACT_MATCHING_SIGNATURE  | NUMBER         | Signature calculated on the normalized SQL text. The normalization includes the removal of white space and the uppercasing of all non-literal strings.                                                                                                                                                                                             |

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                                                |
|--------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORCE_MATCHING_SIGNATURE | NUMBER        | Same as EXACT_MATCHING_SIGNATURE but literals in the SQL text are replaced by binds                                                                                                                                                                                                        |
| SQL_CHILD_ADDRESS        | RAW(4   8)    | Address of the child cursor (can be used with SQL_ID to join with V\$SQL)                                                                                                                                                                                                                  |
| SESSION_SERIAL#          | NUMBER        | Session serial number executing the statement being monitored                                                                                                                                                                                                                              |
| PX_IS_CROSS_INSTANCE     | VARCHAR2(1)   | Indicates whether the SQL statement ran parallel across multiple instances (Y) or not (N)                                                                                                                                                                                                  |
| PX_MAXDOP                | NUMBER        | Maximum degree of parallelism for any plan operation executed on behalf of the monitored SQL                                                                                                                                                                                               |
| PX_MAXDOP_INSTANCES      | NUMBER        | Number of database instances touched at the maximum degree of parallelism                                                                                                                                                                                                                  |
| PX_SERVERS_REQUESTED     | NUMBER        | Total number of parallel execution servers requested to execute the monitored SQL                                                                                                                                                                                                          |
| PX_SERVERS_ALLOCATED     | NUMBER        | Actual number of parallel execution servers allocated to execute the query                                                                                                                                                                                                                 |
| PX_SERVER#               | NUMBER        | Logical parallel execution server process number executing (or having executed) the statement being monitored; NULL if this monitoring entry is not associated with an execution server. This is a logical number within the parallel server set (see SERVER# in V\$PX_SESSION).           |
| PX_SERVER_GROUP          | NUMBER        | Logical parallel execution server group number to which PX_SERVER# belongs (see SERVER_GROUP in V\$PX_SESSION); NULL if this monitoring entry is not associated with a parallel execution server. This value is generally 1 unless the SQL statement has one or more parallel sub-queries. |
| PX_SERVER_SET            | NUMBER        | Number (1 or 2) of the logical set of parallel execution servers to which PX_SERVER# belongs (see SERVER_SET in V\$PX_SESSION); NULL if this monitoring entry is not associated with a parallel execution server                                                                           |
| PX_QCINST_ID             | NUMBER        | Instance identifier where the parallel execution coordinator runs; NULL if PX_SERVER# is NULL                                                                                                                                                                                              |
| PX_QCSID                 | NUMBER        | Session identifier for the parallel execution coordinator; NULL if PX_SERVER# is NULL                                                                                                                                                                                                      |
| ERROR_NUMBER             | VARCHAR2(40)  | Error number encountered in case a SQL fails to execute successfully (for example, 932 in case of ORA-00932)                                                                                                                                                                               |
| ERROR_FACILITY           | VARCHAR2(4)   | Error facility in case a SQL fails to execute successfully (for example, ORA in case of ORA-00932)                                                                                                                                                                                         |
| ERROR_MESSAGE            | VARCHAR2(256) | Detailed error message displayed corresponding to the error number and error facility when a SQL fails to execute successfully                                                                                                                                                             |
| BINDS_XML                | CLOB          | Information about bind variables used with the SQL, such as name, position, value, data type, and so on (stored in XML format)                                                                                                                                                             |
| OTHER_XML                | CLOB          | Additional information about SQL execution stored in XML format                                                                                                                                                                                                                            |
| ELAPSED_TIME             | NUMBER        | Elapsed time (in microseconds); updated as the statement executes                                                                                                                                                                                                                          |
| QUEUING_TIME             | NUMBER        | Duration of time (in microseconds) spent by SQL in the statement queue                                                                                                                                                                                                                     |
| CPU_TIME                 | NUMBER        | CPU time (in microseconds); updated as the statement executes                                                                                                                                                                                                                              |

| Column                  | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FETCHES                 | NUMBER        | Number of fetches associated with the SQL statement; updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                            |
| BUFFER_GETS             | NUMBER        | Number of buffer get operations; updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DISK_READS              | NUMBER        | Number of disk reads; updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DIRECT_WRITES           | NUMBER        | Number of direct writes; updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| IO_INTERCONNECT_BYTES   | NUMBER        | Number of I/O bytes exchanged between Oracle Database and the storage system                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PHYSICAL_READ_REQUESTS  | NUMBER        | Number of physical read I/O requests issued by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PHYSICAL_READ_BYTES     | NUMBER        | Number of bytes read from disks by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PHYSICAL_WRITE_REQUESTS | NUMBER        | Number of physical write I/O requests issued by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PHYSICAL_WRITE_BYTES    | NUMBER        | Number of bytes written to disks by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| APPLICATION_WAIT_TIME   | NUMBER        | Application wait time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                        |
| CONCURRENCY_WAIT_TIME   | NUMBER        | Concurrency wait time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                        |
| CLUSTER_WAIT_TIME       | NUMBER        | Cluster wait time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                            |
| USER_IO_WAIT_TIME       | NUMBER        | User I/O Wait Time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                           |
| PLSQL_EXEC_TIME         | NUMBER        | PL/SQL execution time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                        |
| JAVA_EXEC_TIME          | NUMBER        | Java execution time (in microseconds); updated as the statement executes                                                                                                                                                                                                                                                                                                                                                                                                                          |
| RM_LAST_ACTION          | VARCHAR2(48)  | <p>The most recent action that was taken on this SQL operation by Resource Manager. Its value is one of the following:</p> <ul style="list-style-type: none"> <li>• CANCEL_SQL</li> <li>• KILL_SESSION</li> <li>• LOG_ONLY</li> <li>• SWITCH TO &lt;CG NAME&gt;</li> </ul> <p>For the last value, &lt;CG NAME&gt; is the name of the consumer group that the SQL operation was switched to. If the Resource Plan has since been changed then &lt;CG NAME&gt; is the ID of the consumer group.</p> |
| RM_LAST_ACTION_REASON   | VARCHAR2(128) | <p>The reason for the most recent action that was taken on this SQL operation by Resource Manager. Its value is one of the following:</p> <ul style="list-style-type: none"> <li>• SWITCH_CPU_TIME</li> <li>• SWITCH_IO_REQS</li> <li>• SWITCH_IO_MBS</li> <li>• SWITCH_ELAPSED_TIME</li> <li>• SWITCH_IO_LOGICAL</li> </ul>                                                                                                                                                                      |
| RM_LAST_ACTION_TIME     | DATE          | The time of the most recent action that was taken on this SQL operation by Resource Manager                                                                                                                                                                                                                                                                                                                                                                                                       |
| RM_CONSUMER_GROUP       | VARCHAR2(128) | The current consumer group for this SQL operation                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Column                         | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID                         | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| CON_NAME                       | VARCHAR2(128) | Container name of the object. The value of this column is NULL in non-CDBs.                                                                                                                                                                                                                                                                                                                                                                     |
| ECID                           | VARCHAR2(64)  | Execution context identifier (sent by Application Server)                                                                                                                                                                                                                                                                                                                                                                                       |
| IS_ADAPTIVE_PLAN               | VARCHAR2(1)   | Indicates whether the statistics are from an adaptive plan (Y) or not (N).                                                                                                                                                                                                                                                                                                                                                                      |
| IS_FINAL_PLAN                  | VARCHAR2(1)   | Indicates whether the statistics are from the final plan (Y) or not (N).                                                                                                                                                                                                                                                                                                                                                                        |
| IN_DBOP_NAME                   | VARCHAR2(30)  | If the SQL that is monitored was executed by a session that was also monitored by a database operation (DBOP), then this column specifies the name of that DBOP                                                                                                                                                                                                                                                                                 |
| IN_DBOP_EXEC_ID                | NUMBER        | If the SQL that is monitored was executed by a session that was also monitored by a database operation (DBOP), then this column specifies the execution ID of that DBO                                                                                                                                                                                                                                                                          |
| IO_CELL_UNCOMPRESSED_BYTES     | NUMBER        | Number of uncompressed bytes (that is, size after decompression) that are offloaded to the Exadata cells<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                          |
| IO_CELL_OFFLOAD_ELIGIBLE_BYTES | NUMBER        | Number of I/O bytes which can be filtered by the Exadata storage system<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                                                           |
| IO_CELL_OFFLOAD_RETURNED_BYTES | NUMBER        | Number of filtered bytes returned by Exadata cells (that is, the number of bytes returned after processing has been offloaded on the Exadata cells)<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                               |
| CURRENT_USER#                  | NUMBER        | Unique number identifying the current user                                                                                                                                                                                                                                                                                                                                                                                                      |
| CURRENT_USERNAME               | VARCHAR2(128) | Username for the current user                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 10.55 V\$SQL\_MONITOR\_SESSTAT

V\$SQL\_MONITOR\_SESSTAT displays information about statistics that are exposed in V\$SESSTAT.

| Column     | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID     | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| KEY        | NUMBER   | Artificial join key to efficiently join with other database operation views                                                                                                                                                                                                                                                                                                                                                                           |
| STATISTIC# | NUMBER   | Statistic number                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| VALUE      | NUMBER   | Value associated with the statistic                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 10.56 V\$SQL\_MONITOR\_STATNAME

V\$SQL\_MONITOR\_STATNAME provides information about the plan line statistics exposed in V\$SQL\_PLAN\_MONITOR. A plan line statistic is identified by its group ID (column GROUP\_ID) and its ID (column ID).

| Column      | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID      | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| ID          | NUMBER        | Plan line statistic ID                                                                                                                                                                                                                                                                                                                                                                                                                          |
| GROUP_ID    | NUMBER        | Plan line statistic group ID                                                                                                                                                                                                                                                                                                                                                                                                                    |
| NAME        | VARCHAR2(40)  | Short name for the statistic                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DESCRIPTION | VARCHAR2(200) | Short description for the statistic                                                                                                                                                                                                                                                                                                                                                                                                             |

## 10.57 V\$SQL\_OPTIMIZER\_ENV

V\$SQL\_OPTIMIZER\_ENV displays the contents of the optimizer environment used to build the execution plan of a SQL cursor. This view can be joined with V\$SQLAREA on (HASH\_VALUE, ADDRESS) and with V\$SQL on (HASH\_VALUE, CHILD\_ADDRESS).

| Column        | Datatype     | Description                                                                                                                                                                                            |
|---------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS       | RAW(4   8)   | Address of the parent cursor                                                                                                                                                                           |
| HASH_VALUE    | NUMBER       | Hash value of the parent cursor in the library cache. The hash value is the fixed index for the view and should be used when querying V\$SQL_OPTIMIZER_ENV to avoid scanning the entire library cache. |
| SQL_ID        | VARCHAR2(13) | SQL identifier                                                                                                                                                                                         |
| CHILD_ADDRESS | RAW(4   8)   | Address of the child cursor                                                                                                                                                                            |
| CHILD_NUMBER  | NUMBER       | Child cursor number                                                                                                                                                                                    |
| ID            | NUMBER       | Unique identifier of the parameter in the optimizer environment                                                                                                                                        |
| NAME          | VARCHAR2(40) | Name of the parameter                                                                                                                                                                                  |
| ISDEFAULT     | VARCHAR2(3)  | Indicates whether the parameter is set to the default value (YES) or not (NO)                                                                                                                          |
| VALUE         | VARCHAR2(25) | Value of the parameter                                                                                                                                                                                 |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.58 V\$SQL\_PLAN

V\$SQL\_PLAN contains the execution plan information for each child cursor loaded in the library cache.

| Column               | Datatype      | Description                                                                                                                                                                                                                                                                                                                                |
|----------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS              | RAW(4   8)    | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                        |
| HASH_VALUE           | NUMBER        | Hash value of the parent statement in the library cache. The two columns ADDRESS and HASH_VALUE can be used to join with V\$SQLAREA to add the cursor-specific information.                                                                                                                                                                |
| SQL_ID               | VARCHAR2(13)  | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                   |
| PLAN_HASH_VALUE      | NUMBER        | Numerical representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line).                                                                                                                     |
| FULL_PLAN_HASH_VALUE | NUMBER        | Numeric representation of the complete SQL plan for this cursor. Comparing one FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible. |
| CHILD_ADDRESS        | RAW(4   8)    | Address of the child cursor                                                                                                                                                                                                                                                                                                                |
| CHILD_NUMBER         | NUMBER        | Number of the child cursor that uses this execution plan. The columns ADDRESS, HASH_VALUE, and CHILD_NUMBER can be used to join with V\$SQL to add the child cursor-specific information.                                                                                                                                                  |
| TIMESTAMP            | DATE          | Date and time when the execution plan was generated                                                                                                                                                                                                                                                                                        |
| OPERATION            | VARCHAR2(120) | Name of the internal operation performed in this step (for example, TABLE ACCESS)                                                                                                                                                                                                                                                          |
| OPTIONS              | VARCHAR2(120) | A variation on the operation described in the OPERATION column (for example, FULL)                                                                                                                                                                                                                                                         |
| OBJECT_NODE          | VARCHAR2(160) | Name of the database link used to reference the object (a table name or view name). For local queries that use parallel execution, this column describes the order in which output from operations is consumed.                                                                                                                            |
| OBJECT#              | NUMBER        | Object number of the table or the index                                                                                                                                                                                                                                                                                                    |
| OBJECT_OWNER         | VARCHAR2(128) | Name of the user who owns the schema containing the table or index                                                                                                                                                                                                                                                                         |
| OBJECT_NAME          | VARCHAR2(128) | Name of the table or index                                                                                                                                                                                                                                                                                                                 |

| Column            | Datatype       | Description                                                                                                                                                                                                                                       |
|-------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OBJECT_ALIAS      | VARCHAR2(261)  | Alias for the object                                                                                                                                                                                                                              |
| OBJECT_TYPE       | VARCHAR2(80)   | Type of the object                                                                                                                                                                                                                                |
| OPTIMIZER         | VARCHAR2(80)   | Current mode of the optimizer for the first row in the plan (statement line), for example, ALL_ROWS. When the operation is a database access (for example, TABLE ACCESS), this column indicates whether or not the object is analyzed.            |
| ID                | NUMBER         | A number assigned to each step in the execution plan                                                                                                                                                                                              |
| PARENT_ID         | NUMBER         | ID of the next execution step that operates on the output of the current step                                                                                                                                                                     |
| DEPTH             | NUMBER         | Depth (or level) of the operation in the tree. It is not necessary to issue a CONNECT BY statement to get the level information, which is generally used to indent the rows from the PLAN_TABLE table. The root operation (statement) is level 0. |
| POSITION          | NUMBER         | Order of processing for all operations that have the same PARENT_ID                                                                                                                                                                               |
| SEARCH_COLUMNS    | NUMBER         | Number of index columns with start and stop keys (that is, the number of columns with matching predicates)                                                                                                                                        |
| COST              | NUMBER         | Cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                  |
| CARDINALITY       | NUMBER         | Estimate, by the cost-based optimizer, of the number of rows produced by the operation                                                                                                                                                            |
| BYTES             | NUMBER         | Estimate, by the cost-based optimizer, of the number of bytes produced by the operation                                                                                                                                                           |
| OTHER_TAG         | VARCHAR2(140)  | Describes the contents of the OTHER column. See EXPLAIN PLAN for values.                                                                                                                                                                          |
| PARTITION_START   | VARCHAR2(256)  | Start partition of a range of accessed partitions                                                                                                                                                                                                 |
| PARTITION_STOP    | VARCHAR2(256)  | Stop partition of a range of accessed partitions                                                                                                                                                                                                  |
| PARTITION_ID      | NUMBER         | Step that computes the pair of values of the PARTITION_START and PARTITION_STOP columns                                                                                                                                                           |
| OTHER             | VARCHAR2(4000) | Other information specific to the execution step that users may find useful. See EXPLAIN PLAN for values.                                                                                                                                         |
| DISTRIBUTION      | VARCHAR2(80)   | Stores the method used to distribute rows from producer query servers to consumer query servers                                                                                                                                                   |
| CPU_COST          | NUMBER         | CPU cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                              |
| IO_COST           | NUMBER         | I/O cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                              |
| TEMP_SPACE        | NUMBER         | Temporary space usage of the operation (sort or hash-join) as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                             |
| ACCESS_PREDICATES | VARCHAR2(4000) | Predicates used to locate rows in an access structure. For example, start or stop predicates for an index range scan.                                                                                                                             |
| FILTER_PREDICATES | VARCHAR2(4000) | Predicates used to filter rows before producing them                                                                                                                                                                                              |
| PROJECTION        | VARCHAR2(4000) | Expressions produced by the operation                                                                                                                                                                                                             |

| Column      | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIME        | NUMBER         | Elapsed time (in seconds) of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| QBLOCK_NAME | VARCHAR2(128)  | Name of the query block                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| REMARKS     | VARCHAR2(4000) | Remarks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| OTHER_XML   | CLOB           | Provides extra information specific to an execution step of the execution plan. The content of this column is structured using XML since multiple pieces of information can be stored there. This includes: <ul style="list-style-type: none"> <li>Name of the schema against which the query was parsed</li> <li>Release number of the Oracle Database that produced the explain plan</li> <li>Hash value associated with the execution plan</li> <li>Name (if any) of the outline or the SQL profile used to build the execution plan</li> <li>Indication of whether or not dynamic statistics were used to produce the plan</li> <li>The outline data, a set of optimizer hints that can be used to regenerate the same plan</li> <li>Additional data that describes the relationship between rows in the plan table and subplans of adaptive plans. Note that in Oracle Database 12c, there will be extra rows in the plan table and V\$SQL_PLAN.</li> </ul> |
| CON_ID      | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 10.59 V\$SQL\_PLAN\_MONITOR

V\$SQL\_PLAN\_MONITOR displays plan level monitoring statistics for each SQL statement found in V\$SQL\_MONITOR. Each row in V\$SQL\_PLAN\_MONITOR corresponds to an operation of the execution plan being monitored. As with V\$SQL\_MONITOR, statistics exposed in V\$SQL\_PLAN\_MONITOR are generally updated every second when the statement executes. These statistics are recycled on the same basis as V\$SQL\_MONITOR.

To eliminate the overhead of SQL plan monitoring, statistics collected for each operation of the plan do not record timing information such as elapsed time, CPU time, or I/O time. Instead, this timing information can be estimated quite accurately by joining V\$SQL\_PLAN\_MONITOR with V\$ACTIVE\_SESSION\_HISTORY on SQL\_ID, SQL\_EXEC\_START, SQL\_EXEC\_ID, and SQL\_PLAN\_LINE\_ID (simply named PLAN\_LINE\_ID in V\$SQL\_PLAN\_MONITOR). The result of that join is a sample of the activity performed by each operation in the plan, from which an estimate of CPU time and wait time can be derived. This can be achieved by breaking statement level monitoring time statistics found in V\$SQL\_MONITOR in proportion to the number of samples found in V\$ACTIVE\_SESSION\_HISTORY for the corresponding activity type.

| Column              | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID              | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| KEY                 | NUMBER        | Foreign key to efficiently join V\$SQL_PLAN_MONITOR with V\$SQL_MONITOR (see V\$SQL_MONITOR)                                                                                                                                                                                                                                                                                                                                                    |
| STATUS              | VARCHAR2(19)  | SQL execution status: <ul style="list-style-type: none"> <li>EXECUTING - SQL statement is still executing</li> <li>DONE (ERROR) - Execution terminated with an error</li> <li>DONE (FIRST N ROWS) - Execution terminated by the application before all rows were fetched</li> <li>DONE (ALL ROWS) - Execution terminated and all rows were fetched</li> <li>DONE - Execution terminated (parallel execution)</li> </ul>                         |
| FIRST_REFRESH_TIME  | DATE          | Time when monitoring of the SQL statement started                                                                                                                                                                                                                                                                                                                                                                                               |
| LAST_REFRESH_TIME   | DATE          | Time when statistics were last updated for the SQL statement                                                                                                                                                                                                                                                                                                                                                                                    |
| FIRST_CHANGE_TIME   | DATE          | First time a row was produced by this operation                                                                                                                                                                                                                                                                                                                                                                                                 |
| LAST_CHANGE_TIME    | DATE          | Last time a row was produced by this operation                                                                                                                                                                                                                                                                                                                                                                                                  |
| REFRESH_COUNT       | NUMBER        | Number of times statistics have been refreshed                                                                                                                                                                                                                                                                                                                                                                                                  |
| SID                 | NUMBER        | Session identifier executing (or having executed) the SQL statement being monitored                                                                                                                                                                                                                                                                                                                                                             |
| PROCESS_NAME        | VARCHAR2(5)   | Process name identifier                                                                                                                                                                                                                                                                                                                                                                                                                         |
| SQL_ID              | VARCHAR2(13)  | SQL identifier                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SQL_EXEC_START      | DATE          | Time when the execution started                                                                                                                                                                                                                                                                                                                                                                                                                 |
| SQL_EXEC_ID         | NUMBER        | Execution identifier                                                                                                                                                                                                                                                                                                                                                                                                                            |
| SQL_PLAN_HASH_VALUE | NUMBER        | SQL plan hash value                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SQL_CHILD_ADDRESS   | RAW(4   8)    | Address of the child cursor                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PLAN_PARENT_ID      | NUMBER        | ID of the next execution step that operates on the output of the current step                                                                                                                                                                                                                                                                                                                                                                   |
| PLAN_LINE_ID        | NUMBER        | Plan line number for the entry                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PLAN_OPERATION      | VARCHAR2(30)  | Plan operation name (from V\$SQL_PLAN)                                                                                                                                                                                                                                                                                                                                                                                                          |
| PLAN_OPTIONS        | VARCHAR2(30)  | Plan option name (from V\$SQL_PLAN)                                                                                                                                                                                                                                                                                                                                                                                                             |
| PLAN_OBJECT_OWNER   | VARCHAR2(128) | Name of the user who owns the schema containing the table or index                                                                                                                                                                                                                                                                                                                                                                              |
| PLAN_OBJECT_NAME    | VARCHAR2(128) | Name of the table or index                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PLAN_OBJECT_TYPE    | VARCHAR2(80)  | Type of the object                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PLAN_DEPTH          | NUMBER        | Depth (or level) of the operation in the tree. It is not necessary to issue a CONNECT BY statement to get the level information, which is generally used to indent the rows from the PLAN_TABLE table. The root operation (statement) is level 0.                                                                                                                                                                                               |

| Column                  | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLAN_POSITION           | NUMBER        | Order of processing for all operations that have the same PARENT_ID                                                                                                                                                                                                                                                                                                                                                                                                |
| PLAN_COST               | NUMBER        | Cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is NULL.                                                                                                                                                                                                                                                                                                                   |
| PLAN_CARDINALITY        | NUMBER        | Estimate, by the cost-based optimizer, of the number of rows produced by the operation                                                                                                                                                                                                                                                                                                                                                                             |
| PLAN_BYTES              | NUMBER        | Estimate, by the cost-based optimizer, of the number of bytes produced by the operation                                                                                                                                                                                                                                                                                                                                                                            |
| PLAN_TIME               | NUMBER        | Elapsed time (in seconds) of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is NULL.                                                                                                                                                                                                                                                                                              |
| PLAN_PARTITION_START    | VARCHAR2(256) | Start partition of a range of accessed partitions                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PLAN_PARTITION_STOP     | VARCHAR2(256) | Stop partition of a range of accessed partitions                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PLAN_CPU_COST           | NUMBER        | CPU cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is NULL.                                                                                                                                                                                                                                                                                                               |
| PLAN_IO_COST            | NUMBER        | I/O cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is NULL.                                                                                                                                                                                                                                                                                                               |
| PLAN_TEMP_SPACE         | NUMBER        | Temporary space usage of the operation (sort or hash-join) as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is NULL.                                                                                                                                                                                                                                                                              |
| STARTS                  | NUMBER        | Number of times this operation was executed. For example, an operation is executed multiple times when it is on the right side of a nested-loop join (once for each row of the left input of that nested-loop join).                                                                                                                                                                                                                                               |
| OUTPUT_ROWS             | NUMBER        | Number of rows produced by this operation since the execution started. This number is cumulated for all executions of this operation. Divide by the value of the STARTS column to compute the average number of rows per execution of the operation. Note that the value in the STARTS column is equal to or higher than the value in the OUTPUT_ROWS column. The value will usually be equal, but depending on internal optimizations a higher value may be seen. |
| IO_INTERCONNECT_BYTES   | NUMBER        | Number of I/O bytes exchanged between Oracle Database and the storage system. Maintained only after Oracle starts to monitor the execution.                                                                                                                                                                                                                                                                                                                        |
| PHYSICAL_READ_REQUESTS  | NUMBER        | Number of physical read I/O requests issued by the monitored SQL. Maintained only after Oracle starts to monitor the execution.                                                                                                                                                                                                                                                                                                                                    |
| PHYSICAL_READ_BYTES     | NUMBER        | Number of bytes read from disks by the monitored SQL. Maintained only after Oracle starts to monitor the execution.                                                                                                                                                                                                                                                                                                                                                |
| PHYSICAL_WRITE_REQUESTS | NUMBER        | Number of physical write I/O requests issued by the monitored SQL. Maintained only after Oracle starts to monitor the execution.                                                                                                                                                                                                                                                                                                                                   |
| PHYSICAL_WRITE_BYTES    | NUMBER        | Number of bytes written to disks by the monitored SQL. Maintained only after Oracle starts to monitor the execution.                                                                                                                                                                                                                                                                                                                                               |
| WORKAREA_MEM            | NUMBER        | Amount of memory (in bytes) used by the operation when the query is executing; NULL if the execution is done. This applies only to operations using a work area, such as sort, hash-join, group-by, and so on.                                                                                                                                                                                                                                                     |

| Column               | Datatype | Description                                                                                                                                                                                                                                    |
|----------------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WORKAREA_MAX_MEM     | NUMBER   | Maximum value (in bytes) for WORKAREA_MEM; NULL if the operation is not using a work area. When the execution is finished, this value will hold the maximum amount of memory consumed by this operation during the execution of the statement. |
| WORKAREA_TEMPSEG     | NUMBER   | Amount of temporary space (in bytes) used by the operation when the query is executing; NULL if the operation has not spilled to disk or if the execution is finished                                                                          |
| WORKAREA_MAX_TEMPSEG | NUMBER   | Maximum value (in bytes) for WORKAREA_TEMPSEG; NULL if this operation never spilled to disk. When the execution is done, this value will hold the maximum amount of temporary space consumed by this operation during the entire execution.    |
| OTHERSTAT_GROUP_ID   | NUMBER   | Plan line statistic group identifier (see GROUP_ID column in V\$SQL_MONITOR_STATNAME)                                                                                                                                                          |
| OTHERSTAT_1_ID       | NUMBER   | Statistic identifier (see ID column in V\$SQL_MONITOR_STATNAME) for statistic number 1 of that plan line                                                                                                                                       |
| OTHERSTAT_1_TYPE     | NUMBER   | Reserved for internal use                                                                                                                                                                                                                      |
| OTHERSTAT_1_VALUE    | NUMBER   | Value of statistic number 1 of that plan line                                                                                                                                                                                                  |
| OTHERSTAT_2_ID       | NUMBER   | Statistic identifier (see ID column in V\$SQL_MONITOR_STATNAME) for statistic number 2 of that plan line                                                                                                                                       |
| OTHERSTAT_2_TYPE     | NUMBER   | Reserved for internal use                                                                                                                                                                                                                      |
| OTHERSTAT_2_VALUE    | NUMBER   | Value of statistic number 2 of that plan line                                                                                                                                                                                                  |
| OTHERSTAT_3_ID       | NUMBER   | Statistic identifier (see ID column in V\$SQL_MONITOR_STATNAME) for statistic number 3 of that plan line                                                                                                                                       |
| OTHERSTAT_3_TYPE     | NUMBER   | Reserved for internal use                                                                                                                                                                                                                      |
| OTHERSTAT_3_VALUE    | NUMBER   | Value of statistic number 3 of that plan line                                                                                                                                                                                                  |
| OTHERSTAT_4_ID       | NUMBER   | Statistic identifier (see ID column in V\$SQL_MONITOR_STATNAME) for statistic number 4 of that plan line                                                                                                                                       |
| OTHERSTAT_4_TYPE     | NUMBER   | Reserved for internal use                                                                                                                                                                                                                      |
| OTHERSTAT_4_VALUE    | NUMBER   | Value of statistic number 4 of that plan line                                                                                                                                                                                                  |
| OTHERSTAT_5_ID       | NUMBER   | Statistic identifier (see ID column in V\$SQL_MONITOR_STATNAME) for statistic number 5 of that plan line                                                                                                                                       |

| OTHERSTAT_10_VALUE      | NUMBER   | Value of statistic number 10 of that plan line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| OTHER_XML               | CLOB     | Provides extra information specific to an execution step of the execution plan. The content of this column is structured using XML because it allows multiple pieces of information to be stored, including the following: <ul style="list-style-type: none"> <li>Name of the schema against which the query was parsed</li> <li>Release number of the Oracle Database that produced the explain plan</li> <li>Hash value associated with the execution plan</li> <li>Name (if any) of the outline or the SQL profile used to build the execution plan</li> <li>Indication of whether or not dynamic statistics were used to produce the plan</li> <li>The outline data, a set of optimizer hints that can be used to regenerate the same plan</li> </ul> |
| PLAN_OPERATION_INACTIVE | NUMBER   | Indicates whether this plan operation was part of the final resolved plan                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 10.60 V\$SQL\_PLAN\_STATISTICS

V\$SQL\_PLAN\_STATISTICS provides execution statistics at the row source level for each child cursor.

| Column          | Datatype     | Description                                                                                                                                                                                                           |
|-----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS         | RAW(4   8)   | Address of the handle to the parent for this cursor                                                                                                                                                                   |
| HASH_VALUE      | NUMBER       | Hash value of the parent statement in the library cache. The two columns ADDRESS and HASH_VALUE can be used to join with V\$SQLAREA to locate the parent cursor.                                                      |
| SQL_ID          | VARCHAR2(13) | SQL identifier of the parent statement in the library cache                                                                                                                                                           |
| PLAN_HASH_VALUE | NUMBER       | Numerical representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line) |

| Column               | Datatype   | Description                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FULL_PLAN_HASH_VALUE | NUMBER     | Numeric representation of the complete SQL plan for this cursor. Comparing one FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible. |
| CHILD_ADDRESS        | RAW(4   8) | Address of the child cursor                                                                                                                                                                                                                                                                                                                |
| CHILD_NUMBER         | NUMBER     | Number of the child cursor that uses this work area. The columns ADDRESS, HASH_VALUE, and CHILD_NUMBER can be used to join with V\$SQL to locate the child cursor using this area.                                                                                                                                                         |
| OPERATION_ID         | NUMBER     | A number assigned to each step in the execution plan                                                                                                                                                                                                                                                                                       |
| EXECUTIONS           | NUMBER     | Number of times this cursor has been executed                                                                                                                                                                                                                                                                                              |
| LAST_STARTS          | NUMBER     | Number of times this operation has been started, during the last execution                                                                                                                                                                                                                                                                 |
| STARTS               | NUMBER     | Number of times this operation has been started, accumulated over the past executions                                                                                                                                                                                                                                                      |
| LAST_OUTPUT_ROWS     | NUMBER     | Number of rows produced by the row source, during the last execution                                                                                                                                                                                                                                                                       |
| OUTPUT_ROWS          | NUMBER     | Number of rows produced by the row source, accumulated over the past executions                                                                                                                                                                                                                                                            |
| LAST_CR_BUFFER_GETS  | NUMBER     | Number of buffers retrieved in consistent mode, during the last execution. Buffers are usually retrieved in consistent mode for queries.                                                                                                                                                                                                   |
| CR_BUFFER_GETS       | NUMBER     | Number of buffers retrieved in consistent mode, accumulated over the past executions. Buffers are usually retrieved in consistent mode for queries.                                                                                                                                                                                        |
| LAST_CU_BUFFER_GETS  | NUMBER     | Number of buffers retrieved in current mode, during the last execution. Buffers are retrieved in current mode for statements such as INSERT, UPDATE, and DELETE.                                                                                                                                                                           |
| CU_BUFFER_GETS       | NUMBER     | Number of buffers retrieved in current mode, accumulated over the past executions. Buffers are retrieved in current mode for statements such as INSERT, UPDATE, and DELETE.                                                                                                                                                                |
| LAST_DISK_READS      | NUMBER     | Number of physical disk reads performed by the operation, during the last execution                                                                                                                                                                                                                                                        |
| DISK_READS           | NUMBER     | Number of physical disk reads performed by the operation, accumulated over the past executions                                                                                                                                                                                                                                             |
| LAST_DISK_WRITES     | NUMBER     | Number of physical disk writes performed by the operation, during the last execution                                                                                                                                                                                                                                                       |
| DISK_WRITES          | NUMBER     | Number of physical disk writes performed by the operation, accumulated over the past executions                                                                                                                                                                                                                                            |
| LAST_ELAPSED_TIME    | NUMBER     | Elapsed time (in microseconds) corresponding to this operation, during the last execution                                                                                                                                                                                                                                                  |
| ELAPSED_TIME         | NUMBER     | Elapsed time (in microseconds) corresponding to this operation, accumulated over the past executions                                                                                                                                                                                                                                       |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.61 V\$SQL\_PLAN\_STATISTICS\_ALL

V\$SQL\_PLAN\_STATISTICS\_ALL contains memory usage statistics for row sources that use SQL memory (sort or hash-join). This view concatenates information in V\$SQL\_PLAN with execution statistics from V\$SQL\_PLAN\_STATISTICS and V\$SQL\_WORKAREA.

| Column               | Datatype      | Description                                                                                                                                                                                                                                                                                                                                |
|----------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS              | RAW(4   8)    | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                        |
| HASH_VALUE           | NUMBER        | Hash value of the parent statement in the library cache. The two columns ADDRESS and HASH_VALUE can be used to join with V\$SQLAREA to add the cursor-specific information.                                                                                                                                                                |
| SQL_ID               | VARCHAR2(13)  | SQL identifier of the parent statement in the library cache                                                                                                                                                                                                                                                                                |
| PLAN_HASH_VALUE      | NUMBER        | Numerical representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line)                                                                                                                      |
| FULL_PLAN_HASH_VALUE | NUMBER        | Numeric representation of the complete SQL plan for this cursor. Comparing one FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible. |
| CHILD_ADDRESS        | RAW(4   8)    | Address of the child cursor                                                                                                                                                                                                                                                                                                                |
| CHILD_NUMBER         | NUMBER        | Number of the child cursor that uses this execution plan. The columns ADDRESS, HASH_VALUE, and CHILD_NUMBER can be used to join with V\$SQL to add the child cursor-specific information.                                                                                                                                                  |
| TIMESTAMP            | DATE          | Date and time when the execution plan was generated                                                                                                                                                                                                                                                                                        |
| OPERATION            | VARCHAR2(120) | Name of the internal operation performed in this step (for example, TABLE ACCESS)                                                                                                                                                                                                                                                          |
| OPTIONS              | VARCHAR2(120) | A variation on the operation described in the OPERATION column (for example, FULL)                                                                                                                                                                                                                                                         |

| Column          | Datatype       | Description                                                                                                                                                                                                                                       |
|-----------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OBJECT_NODE     | VARCHAR2(160)  | Name of the database link used to reference the object (a table name or view name). For local queries that use parallel execution, this column describes the order in which output from operations is consumed.                                   |
| OBJECT#         | NUMBER         | Object number of the table or the index                                                                                                                                                                                                           |
| OBJECT_OWNER    | VARCHAR2(128)  | Name of the user who owns the schema containing the table or index                                                                                                                                                                                |
| OBJECT_NAME     | VARCHAR2(128)  | Name of the table or index                                                                                                                                                                                                                        |
| OBJECT_ALIAS    | VARCHAR2(261)  | Alias for the object                                                                                                                                                                                                                              |
| OBJECT_TYPE     | VARCHAR2(80)   | Type of the object                                                                                                                                                                                                                                |
| OPTIMIZER       | VARCHAR2(80)   | Current mode of the optimizer for the first row in the plan (statement line), for example, CHOOSE. When the operation is a database access (for example, TABLE ACCESS), this column indicates whether or not the object is analyzed.              |
| ID              | NUMBER         | A number assigned to each step in the execution plan                                                                                                                                                                                              |
| PARENT_ID       | NUMBER         | ID of the next execution step that operates on the output of the current step                                                                                                                                                                     |
| DEPTH           | NUMBER         | Depth (or level) of the operation in the tree. It is not necessary to issue a CONNECT BY statement to get the level information, which is generally used to indent the rows from the PLAN_TABLE table. The root operation (statement) is level 0. |
| POSITION        | NUMBER         | Order of processing for all operations that have the same PARENT_ID                                                                                                                                                                               |
| SEARCH_COLUMNS  | NUMBER         | Number of index columns with start and stop keys (that is, the number of columns with matching predicates)                                                                                                                                        |
| COST            | NUMBER         | Cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                  |
| CARDINALITY     | NUMBER         | Estimate, by the cost-based optimizer, of the number of rows produced by the operation                                                                                                                                                            |
| BYTES           | NUMBER         | Estimate, by the cost-based optimizer, of the number of bytes produced by the operation                                                                                                                                                           |
| OTHER_TAG       | VARCHAR2(140)  | Describes the contents of the OTHER column. See EXPLAIN PLAN for values.                                                                                                                                                                          |
| PARTITION_START | VARCHAR2(256)  | Start partition of a range of accessed partitions                                                                                                                                                                                                 |
| PARTITION_STOP  | VARCHAR2(256)  | Stop partition of a range of accessed partitions                                                                                                                                                                                                  |
| PARTITION_ID    | NUMBER         | Step that computes the pair of values of the PARTITION_START and PARTITION_STOP columns                                                                                                                                                           |
| OTHER           | VARCHAR2(4000) | Other information specific to the execution step that users may find useful. See EXPLAIN PLAN for values.                                                                                                                                         |
| DISTRIBUTION    | VARCHAR2(80)   | Stores the method used to distribute rows from producer query servers to consumer query servers                                                                                                                                                   |
| CPU_COST        | NUMBER         | CPU cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                              |

| Column              | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IO_COST             | NUMBER         | I/O cost of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TEMP_SPACE          | NUMBER         | Temporary space usage of the operation (sort or hash-join) as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ACCESS_PREDICATES   | VARCHAR2(4000) | Predicates used to locate rows in an access structure. For example, start or stop predicates for an index range scan.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FILTER_PREDICATES   | VARCHAR2(4000) | Predicates used to filter rows before producing them                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PROJECTION          | VARCHAR2(4000) | Expressions produced by the operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TIME                | NUMBER         | Elapsed time (in seconds) of the operation as estimated by the optimizer's cost-based approach. For statements that use the rule-based approach, this column is null.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| QBLOCK_NAME         | VARCHAR2(128)  | Name of the query block                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| REMARKS             | VARCHAR2(4000) | Remarks                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| OTHER_XML           | CLOB           | Provides extra information specific to an execution step of the execution plan. The content of this column is structured using XML since multiple pieces of information can be stored there. This includes: <ul style="list-style-type: none"> <li>Name of the schema against which the query was parsed</li> <li>Release number of the Oracle Database that produced the explain plan</li> <li>Hash value associated with the execution plan</li> <li>Name (if any) of the outline or the SQL profile used to build the execution plan</li> <li>Indication of whether or not dynamic statistics were used to produce the plan</li> <li>The outline data, a set of optimizer hints that can be used to regenerate the same plan</li> <li>Additional data that describes the relationship between rows in the plan table and subplans of adaptive plans. Note that in Oracle Database 12c, there will be extra rows in the plan table and V\$SQL_PLAN.</li> </ul> |
| EXECUTIONS          | NUMBER         | Number of times this cursor has been executed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| LAST_ELAPSED_TIME      | NUMBER          | Elapsed time (in microseconds) corresponding to this operation, during the last execution                                                                                                          |
| ELAPSED_TIME           | NUMBER          | Elapsed time (in microseconds) corresponding to this operation, accumulated over the past executions                                                                                               |
| POLICY                 | VARCHAR2 ( 40 ) | Sizing policy for this work area: <ul style="list-style-type: none"> <li>• MANUAL</li> <li>• AUTO</li> </ul>                                                                                       |
| ESTIMATED_OPTIMAL_SIZE | NUMBER          | Estimated size (in KB) required by this work area to execute the operation completely in memory (optimal execution). This is either derived from optimizer statistics or from previous executions. |
| ESTIMATED_ONEPASS_SIZE | NUMBER          | Estimated size (in KB) required by this work area to execute the operation in a single pass. This is either derived from optimizer statistics or from previous executions.                         |
| LAST_MEMORY_USED       | NUMBER          | Memory size (in KB) used by this work area during the last execution of the cursor                                                                                                                 |
| LAST_EXECUTION         | VARCHAR2 ( 40 ) | Indicates whether this work area ran using OPTIMAL, ONE PASS, or under ONE PASS memory requirement (MULTI-PASS), during the last execution of the cursor                                           |
| LAST_DEGREE            | NUMBER          | Degree of parallelism used, during the last execution of the cursor                                                                                                                                |
| TOTAL_EXECUTIONS       | NUMBER          | Number of times this work area was active                                                                                                                                                          |
| OPTIMAL_EXECUTIONS     | NUMBER          | Number of times this work area ran in optimal mode                                                                                                                                                 |
| ONEPASS_EXECUTIONS     | NUMBER          | Number of times this work area ran in one pass mode                                                                                                                                                |
| MULTIPASSES_EXECUTIONS | NUMBER          | Number of times this work area ran below the one pass memory requirement                                                                                                                           |
| ACTIVE_TIME            | NUMBER          | Average time this work area is active (in hundredths of a second)                                                                                                                                  |
| MAX_TEMPSEG_SIZE       | NUMBER          | Maximum temporary segment size (in bytes) created by an instantiation of this work area. This column is null if this work area has never spilled to disk.                                          |
| LAST_TEMPSEG_SIZE      | NUMBER          | Temporary segment size (in bytes) created in the last instantiation of this work area. This column is null if the last instantiation of this work area did not spill to disk.                      |

| Column   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| CON_DBID | NUMBER   | The database ID of the PDB                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 10.62 V\$SQL\_REDIRECTION

V\$SQL\_REDIRECTION displays SQL statements that are redirected.

| Column            | Datatype       | Description                                                                                       |
|-------------------|----------------|---------------------------------------------------------------------------------------------------|
| ADDRESS           | RAW(4   8)     | Address of the cursor handle                                                                      |
| PARENT_HANDLE     | RAW(4   8)     | Address of the parent cursor handle                                                               |
| HASH_VALUE        | NUMBER         | Hash value of the SQL statement                                                                   |
| SQL_ID            | VARCHAR2(13)   | SQL identifier of the SQL statement                                                               |
| CHILD_NUMBER      | NUMBER         | Number of the child (instance) for the hash                                                       |
| PARSING_USER_ID   | NUMBER         | Parsing user ID                                                                                   |
| PARSING_SCHEMA_ID | NUMBER         | Parsing schema ID                                                                                 |
| COMMAND_TYPE      | NUMBER         | SELECT, UPDATE, INSERT, MERGE                                                                     |
| REASON            | VARCHAR2(14)   | Reason for redirection ('INVALID OBJECT', 'ROWID', 'QUERY REWRITE', 'READ ONLY')                  |
| ERROR_CODE        | NUMBER         | Error code for local parse                                                                        |
| POSITION          | NUMBER         | Error position, 0 if unknown                                                                      |
| SQL_TEXT_PIECE    | VARCHAR2(1000) | SQL Text containing position, usually a (qualified) identifier                                    |
| ERROR_MESSAGE     | VARCHAR2(1000) | Error code's corresponding error message resolved in the database language, no arguments resolved |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.63 V\$SQL\_SHARD

V\$SQL\_SHARD displays the shard information for a shard query's previous execution. This view uniquely maps a shard SQL fragment of a cross shard query to the target shard database.

| Column             | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_ID             | VARCHAR2(13) | SQL identifier of a cross shard query on the coordinator                                                                                                                                                                                                                                                                                                                                                                                        |
| CHILD_NUMBER       | NUMBER       | Cursor child number of a cross shard query on the coordinator                                                                                                                                                                                                                                                                                                                                                                                   |
| OPERATION_ID       | NUMBER       | Operation ID of a remote node for a shard SQL fragment of a cross shard query                                                                                                                                                                                                                                                                                                                                                                   |
| SHARD_SQL_ID       | VARCHAR2(13) | SQL ID of the SQL segment associated with a remote operation identified by the operation ID in the OPERATION_ID column                                                                                                                                                                                                                                                                                                                          |
| SHARD_ID           | NUMBER       | IDs of shards where the shard SQL fragment was executed                                                                                                                                                                                                                                                                                                                                                                                         |
| SHARD_CHILD_NUMBER | NUMBER       | Cursor child number of a shard SQL fragment on a shard. The default value is 0.                                                                                                                                                                                                                                                                                                                                                                 |
| CON_ID             | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.64 V\$SQL\_SHARED\_CURSOR

V\$SQL\_SHARED\_CURSOR explains why a particular child cursor is not shared with existing child cursors. Each column identifies a specific reason why the cursor cannot be shared.

| Column        | Datatype     | Description                  |
|---------------|--------------|------------------------------|
| SQL_ID        | VARCHAR2(13) | SQL identifier               |
| ADDRESS       | RAW(4   8)   | Address of the parent cursor |
| CHILD_ADDRESS | RAW(4   8)   | Address of the child cursor  |
| CHILD_NUMBER  | NUMBER       | Child number                 |

| Column                    | Datatype    | Description                                                                                                                                                                                     |
|---------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UNBOUND_CURSOR            | VARCHAR2(1) | (Y N) The existing child cursor was not fully built (in other words, it was not optimized)                                                                                                      |
| SQL_TYPE_MISMATCH         | VARCHAR2(1) | (Y N) The SQL type does not match the existing child cursor                                                                                                                                     |
| OPTIMIZER_MISMATCH        | VARCHAR2(1) | (Y N) The optimizer environment does not match the existing child cursor                                                                                                                        |
| OUTLINE_MISMATCH          | VARCHAR2(1) | (Y N) The outlines do not match the existing child cursor                                                                                                                                       |
| STATS_ROW_MISMATCH        | VARCHAR2(1) | (Y N) The existing statistics do not match the existing child cursor                                                                                                                            |
| LITERAL_MISMATCH          | VARCHAR2(1) | (Y N) Non-data literal values do not match the existing child cursor                                                                                                                            |
| FORCE_HARD_PARSE          | VARCHAR2(1) | (Y N) For internal use                                                                                                                                                                          |
| EXPLAIN_PLAN_CURSOR       | VARCHAR2(1) | (Y N) The child cursor is an explain plan cursor and should not be shared                                                                                                                       |
| BUFFERED_DML_MISMATCH     | VARCHAR2(1) | (Y N) Buffered DML does not match the existing child cursor                                                                                                                                     |
| PDML_ENV_MISMATCH         | VARCHAR2(1) | (Y N) PDML environment does not match the existing child cursor                                                                                                                                 |
| INST_DRTLD_MISMATCH       | VARCHAR2(1) | (Y N) Insert direct load does not match the existing child cursor                                                                                                                               |
| SLAVE_QC_MISMATCH         | VARCHAR2(1) | (Y N) The existing child cursor is a slave cursor and the new one was issued by the coordinator (or, the existing child cursor was issued by the coordinator and the new one is a slave cursor) |
| TYPECHECK_MISMATCH        | VARCHAR2(1) | (Y N) The existing child cursor is not fully optimized                                                                                                                                          |
| AUTH_CHECK_MISMATCH       | VARCHAR2(1) | (Y N) Authorization/translation check failed for the existing child cursor                                                                                                                      |
| BIND_MISMATCH             | VARCHAR2(1) | (Y N) The bind metadata does not match the existing child cursor                                                                                                                                |
| DESCRIBE_MISMATCH         | VARCHAR2(1) | (Y N) The typecheck heap is not present during the describe for the child cursor                                                                                                                |
| LANGUAGE_MISMATCH         | VARCHAR2(1) | (Y N) The language handle does not match the existing child cursor                                                                                                                              |
| TRANSLATION_MISMATCH      | VARCHAR2(1) | (Y N) The base objects of the existing child cursor do not match                                                                                                                                |
| BIND_EQUIV_FAILURE        | VARCHAR2(1) | (Y N) The bind value's selectivity does not match that used to optimize the existing child cursor                                                                                               |
| INSUFF_PRIVS              | VARCHAR2(1) | (Y N) Insufficient privileges on objects referenced by the existing child cursor                                                                                                                |
| INSUFF_PRIVS_REM          | VARCHAR2(1) | (Y N) Insufficient privileges on remote objects referenced by the existing child cursor                                                                                                         |
| REMOTE_TRANS_MISMATCH     | VARCHAR2(1) | (Y N) The remote base objects of the existing child cursor do not match                                                                                                                         |
| LOGMINER_SESSION_MISMATCH | VARCHAR2(1) | (Y N) LogMiner Session parameters mismatch                                                                                                                                                      |
| INCOMP_LTRL_MISMATCH      | VARCHAR2(1) | (Y N) Cursor might have some binds (literals) which may be unsafe/non-data. Value mismatch.                                                                                                     |
| OVERLAP_TIME_MISMATCH     | VARCHAR2(1) | (Y N) Mismatch caused by setting session parameter ERROR_ON_OVERLAP_TIME                                                                                                                        |
| EDITION_MISMATCH          | VARCHAR2(1) | (Y N) Cursor edition mismatch                                                                                                                                                                   |
| MV_QUERY_GEN_MISMATCH     | VARCHAR2(1) | (Y N) Internal, used to force a hard-parse when analyzing materialized view queries                                                                                                             |

| Column                        | Datatype    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USER_BIND_PEEK_MISMATCH       | VARCHAR2(1) | (Y N) Cursor is not shared because value of one or more user binds is different and this has a potential to change the execution plan                                                                                                                                                                                                                                                                                                      |
| TYPCHK_DEP_MISMATCH           | VARCHAR2(1) | (Y N) Cursor has typecheck dependencies                                                                                                                                                                                                                                                                                                                                                                                                    |
| NO_TRIGGER_MISMATCH           | VARCHAR2(1) | (Y N) Cursor and child have no trigger mismatch                                                                                                                                                                                                                                                                                                                                                                                            |
| FLASHBACK_CURSOR              | VARCHAR2(1) | (Y N) Cursor non-shareability due to flashback                                                                                                                                                                                                                                                                                                                                                                                             |
| ANYDATA_TRANSFORMATION        | VARCHAR2(1) | (Y N) Is criteria for opaque type transformation and does not match                                                                                                                                                                                                                                                                                                                                                                        |
| PDDL_ENV_MISMATCH             | VARCHAR2(1) | (Y N) Environment setting mismatch for parallel DDL cursor (that is, one or more of the following parameter values have changed: PARALLEL_EXECUTION_ENABLED, PARALLEL_DDL_MODE, PARALLEL_DDL_FORCED_DEGREE, or PARALLEL_DDL_FORCED_INSTANCES)                                                                                                                                                                                              |
| TOP_LEVEL_RPI_CURSOR          | VARCHAR2(1) | (Y N) Is top level RPI cursor                                                                                                                                                                                                                                                                                                                                                                                                              |
| DIFFERENT_LONG_LENGTH         | VARCHAR2(1) | (Y N) Value of LONG does not match                                                                                                                                                                                                                                                                                                                                                                                                         |
| LOGICAL_STANDBY_APPLY         | VARCHAR2(1) | (Y N) Logical standby apply context does not match                                                                                                                                                                                                                                                                                                                                                                                         |
| DIFF_CALL_DURN                | VARCHAR2(1) | (Y N) If Slave SQL cursor/single call                                                                                                                                                                                                                                                                                                                                                                                                      |
| BIND_UACS_DIFF                | VARCHAR2(1) | (Y N) One cursor has bind UACs and one does not                                                                                                                                                                                                                                                                                                                                                                                            |
| PLSQL_CMP_SWITCHS_DIFF        | VARCHAR2(1) | (Y N) PL/SQL anonymous block compiled with different PL/SQL compiler switches                                                                                                                                                                                                                                                                                                                                                              |
| CURSOR_PARTS_MISMATCH         | VARCHAR2(1) | (Y N) Cursor was compiled with subexecution (cursor parts were executed)                                                                                                                                                                                                                                                                                                                                                                   |
| STB_OBJECT_MISMATCH           | VARCHAR2(1) | (Y N) STB is an internal name for a SQL Management Object Mismatch. A SQL Management Object Mismatch means that either a SQL plan baseline, or a SQL profile, or a SQL patch has been created for your SQL statement between the executions. Because a cursor is a read-only entity, a hard parse is forced to be able to create a new cursor that contains information about the new SQL management object related to this SQL statement. |
| CROSSEDITION_TRIGGER_MISMATCH | VARCHAR2(1) | (Y N) The set of crossedition triggers to execute might differ                                                                                                                                                                                                                                                                                                                                                                             |
| PQ_SLAVE_MISMATCH             | VARCHAR2(1) | (Y N) Top-level slave decides not to share cursor                                                                                                                                                                                                                                                                                                                                                                                          |
| TOP_LEVEL_DDL_MISMATCH        | VARCHAR2(1) | (Y N) Is top-level DDL cursor                                                                                                                                                                                                                                                                                                                                                                                                              |
| MULTI_PX_MISMATCH             | VARCHAR2(1) | (Y N) Cursor has multiple parallelizers and is slave-compiled                                                                                                                                                                                                                                                                                                                                                                              |
| BIND_PEEKED_PQ_MISMATCH       | VARCHAR2(1) | (Y N) Cursor based around bind peeked values                                                                                                                                                                                                                                                                                                                                                                                               |
| MV_REWRITE_MISMATCH           | VARCHAR2(1) | (Y N) Cursor needs recompilation because an SCN was used during compile time due to being rewritten by materialized view                                                                                                                                                                                                                                                                                                                   |
| ROLL_INVALID_MISMATCH         | VARCHAR2(1) | (Y N) Marked for rolling invalidation and invalidation window exceeded                                                                                                                                                                                                                                                                                                                                                                     |
| OPTIMIZER_MODE_MISMATCH       | VARCHAR2(1) | (Y N) Parameter OPTIMIZER_MODE mismatch (for example, all_rows versus first_rows_1)                                                                                                                                                                                                                                                                                                                                                        |
| PX_MISMATCH                   | VARCHAR2(1) | (Y N) Mismatch in one parameter affecting the parallelization of a SQL statement. For example, one cursor was compiled with parallel DML enabled while the other was not.                                                                                                                                                                                                                                                                  |

| Column                     | Datatype    | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MV_STALEOBJ_MISMATCH       | VARCHAR2(1) | (Y N) Cursor cannot be shared because there is a mismatch in the list of materialized views which were stale when the cursor was built                                                                                                                                                                                                                                                                                            |
| FLASHBACK_TABLE_MISMATCH   | VARCHAR2(1) | (Y N) Cursor cannot be shared because there is a mismatch with triggers being enabled and/or referential integrity constraints being deferred                                                                                                                                                                                                                                                                                     |
| LITREP_COMP_MISMATCH       | VARCHAR2(1) | (Y N) Mismatch in use of literal replacement                                                                                                                                                                                                                                                                                                                                                                                      |
| PLSQL_DEBUG                | VARCHAR2(1) | (Y N) Value of the PLSQL_DEBUG parameter for the current session does not match the value used to build the cursor                                                                                                                                                                                                                                                                                                                |
| LOAD_OPTIMIZER_STATS       | VARCHAR2(1) | (Y N) A hard parse is forced to initialize extended cursor sharing                                                                                                                                                                                                                                                                                                                                                                |
| ACL_MISMATCH               | VARCHAR2(1) | (Y N) Cached ACL evaluation result stored in the child cursor is not valid for the current session or user                                                                                                                                                                                                                                                                                                                        |
| FLASHBACK_ARCHIVE_MISMATCH | VARCHAR2(1) | (Y N) Value of the FLASHBACK_DATA_ARCHIVE_INTERNAL_CURSOR parameter for the current session does not match the value used to build the cursor                                                                                                                                                                                                                                                                                     |
| LOCK_USER_SCHEMA_FAILED    | VARCHAR2(1) | (Y N) User or schema used to build the cursor no longer exists<br><b>Note:</b> This sharing criterion is deprecated                                                                                                                                                                                                                                                                                                               |
| REMOTE_MAPPING_MISMATCH    | VARCHAR2(1) | (Y N) Reloaded cursor was previously remote-mapped and is currently not remote-mapped. Therefore, the cursor must be reparsed.                                                                                                                                                                                                                                                                                                    |
| LOAD_RUNTIME_HEAP_FAILED   | VARCHAR2(1) | (Y N) Loading of run-time heap for the new cursor (or reload of aged out cursor) failed                                                                                                                                                                                                                                                                                                                                           |
| HASH_MATCH_FAILED          | VARCHAR2(1) | (Y N) No existing child cursors have the unsafe literal bind hash values required by the current cursor                                                                                                                                                                                                                                                                                                                           |
| PURGED_CURSOR              | VARCHAR2(1) | (Y N) Child cursor is marked for purging                                                                                                                                                                                                                                                                                                                                                                                          |
| BIND_LENGTH_UPGRADEABLE    | VARCHAR2(1) | (Y N) Bind length(s) required for the current cursor are longer than the bind length(s) used to build the child cursor                                                                                                                                                                                                                                                                                                            |
| USE_FEEDBACK_STATS         | VARCHAR2(1) | (Y N) A hard parse is forced so that the optimizer can reoptimize the query with improved optimizer inputs (for example, cardinality estimates)                                                                                                                                                                                                                                                                                   |
| REASON                     | CLOB        | Child number, id, and reason the cursor is not shared. The content of this column is structured using XML.<br><br>If this column is null, the FORCE_HARD_PARSE, LOAD_RUNTIME_HEAP_FAILED, and HASH_MATCH_FAILED columns may enable you to determine why the child cursor is not shared.                                                                                                                                           |
| CON_ID                     | NUMBER      | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li>n: Where n is the applicable container ID for the rows containing data</li> </ul> |

## 10.65 V\$SQL\_SHARED\_MEMORY

V\$SQL\_SHARED\_MEMORY displays information about the cursor shared memory snapshot. Each SQL statement stored in the shared pool has one or more child objects

associated with it. Each child object has several parts, one of which is the context heap, which holds, among other things, the query plan.

| Column       | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_TEXT     | VARCHAR2(1000) | SQL text of the shared cursor child object for which this row is displaying information                                                                                                                                                                                                                                                                                                                                                         |
| SQL_FULLTEXT | CLOB           | Full text for the SQL statement exposed as a CLOB column. The full text of a SQL statement can be retrieved using this column instead of joining with the V\$SQLTEXT dynamic performance view.                                                                                                                                                                                                                                                  |
| HASH_VALUE   | NUMBER         | Hash value of the above SQL text in the shared pool                                                                                                                                                                                                                                                                                                                                                                                             |
| SQL_ID       | VARCHAR2(13)   | SQL identifier of the above SQL text in the shared pool                                                                                                                                                                                                                                                                                                                                                                                         |
| HEAP_DESC    | RAW(4   8)     | Address of the descriptor for the context heap of the child cursor described in this row                                                                                                                                                                                                                                                                                                                                                        |
| STRUCTURE    | VARCHAR2(64)   | If the memory chunk described in this row was allocated using a comment of the form "X : Y", then this is the "X" part of the comment                                                                                                                                                                                                                                                                                                           |
| FUNCTION     | VARCHAR2(64)   | Similar to the STRUCTURE column, this is the "Y" field of the comment                                                                                                                                                                                                                                                                                                                                                                           |
| CHUNK_COM    | VARCHAR2(16)   | Whole comment field that was supplied when this memory chunk was allocated                                                                                                                                                                                                                                                                                                                                                                      |
| CHUNK_PTR    | RAW(4   8)     | Starting address of the allocated memory chunk                                                                                                                                                                                                                                                                                                                                                                                                  |
| CHUNK_SIZE   | NUMBER         | Amount of memory allocated for this chunk                                                                                                                                                                                                                                                                                                                                                                                                       |
| ALLOC_CLASS  | VARCHAR2(8)    | Class of memory that this chunk of memory belongs to. It will usually be either FREEABLE or PERMANENT.                                                                                                                                                                                                                                                                                                                                          |
| CHUNK_TYPE   | NUMBER         | An index into a table of callback functions that tell the server how to re-create this chunk of memory should it need to be removed from the shared pool based on an LRU algorithm                                                                                                                                                                                                                                                              |
| SUBHEAP_DESC | RAW(4   8)     | If the parent heap of this context heap is itself a subheap, then this is the address of the descriptor of the parent heap                                                                                                                                                                                                                                                                                                                      |
| CON_ID       | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.66 V\$SQL\_TESTCASES

V\$SQL\_TESTCASES displays information about test cases exported by SQL Test Case Builder.

You can use this view in conjunction with the V\$DIAG\_INCIDENT view. Join the INCIDENT\_ID column in this view with the INCIDENT\_ID column in V\$DIAG\_INCIDENT to view information about the test case associated with a particular incident.

The V\$SQL\_TESTCASES view requires the existence of a TCB root directory named SQL\_TCB\_DIR. This view will not contain any rows if a TCB root directory does not exist, or if the TCB root directory exists with a name other than SQL\_TCB\_DIR. The operating

system directory to which the TCB root directory refers must be writable by the owner of the Oracle Database binaries.

- In Oracle Autonomous Database environments, the TCB root directory is created automatically on each POD during provisioning.
- For on-premise databases, a user who has been granted the DBA role must explicitly create the TCB root directory. See *Oracle Database Administrator's Guide* for more information.

| Column        | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| TESTCASE_NAME | VARCHAR2(512)  | Test case name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| SQL_ID        | VARCHAR2(13)   | SQL identifier of the SQL statement in the test case                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SQL_TEXT      | VARCHAR2(1000) | First 1000 characters of text for the SQL statement in the test case                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SQL_TEXT_FULL | CLOB           | Full text for the SQL statement in the test case, exposed as a CLOB column                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| INCIDENT_ID   | NUMBER         | ID for the incident associated with the test case                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PROBLEM_TYPE  | NUMBER         | Type of problem for the incident associated with the test case.<br>Possible values: <ul style="list-style-type: none"> <li>• 1: Performance problem (PROBLEM_TYPE_PERFORMANCE)</li> <li>• 2: Inconsistent results (PROBLEM_TYPE_WRONG_RESULTS)</li> <li>• 3: Crash in compilation (PROBLEM_TYPE_COMPILATION_ERROR)</li> <li>• 4: Crash in execution (PROBLEM_TYPE_EXECUTION_ERROR)</li> </ul> These numeric values, and their associated constant values shown in parentheses, correspond to the numeric and constant values for problem type constants in the DBMS_SQLDIAG package. See <i>Oracle Database PL/SQL Packages and Types Reference</i> for more information. |
| CREATION_DATE | TIMESTAMP(6)   | Creation time for the incident associated with the test case                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| STATUS        | VARCHAR2(10)   | Current status for the incident associated with the test case.<br>Possible values: <ul style="list-style-type: none"> <li>• COMPLETE: The test case export completed successfully</li> <li>• INCOMPLETE: The test case export failed due to an error</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID        | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul>                                                                                                                                                                                                                     |

## 10.67 V\$SQL\_WORKAREA

V\$SQL\_WORKAREA displays information about work areas used by SQL cursors. Each SQL statement stored in the shared pool has one or more child cursors that are listed in the V\$SQL view. V\$SQL\_WORKAREA lists all work areas needed by these child cursors; V\$SQL\_WORKAREA can be joined with V\$SQLAREA on (ADDRESS, HASH\_VALUE) and with V\$SQL on (ADDRESS, HASH\_VALUE, CHILD\_NUMBER).

You can use this view to find out answers to the following questions:

- What are the top 10 work areas that require the most cache area?
- For work areas allocated in AUTO mode, what percentage of work areas are running using maximum memory?

| Column                 | Datatype      | Description                                                                                                                                                                              |
|------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS                | RAW(4   8)    | Address of the parent cursor handle                                                                                                                                                      |
| HASH_VALUE             | NUMBER        | Hash value of the parent statement in the library cache. Two columns PARENT_HANDLE and HASH_VALUE can be used to join with V\$SQLAREA to locate the parent cursor.                       |
| SQL_ID                 | VARCHAR2(13)  | SQL identifier of the parent statement in the library cache                                                                                                                              |
| CHILD_NUMBER           | NUMBER        | Number of the child cursor that uses this work area. The columns PARENT_HANDLE, HASH_VALUE, and CHILD_NUMBER can be used to join with V\$SQL to locate the child cursor using this area. |
| WORKAREA_ADDRESS       | RAW(4   8)    | Address of the work area handle. This is the primary key for the view.                                                                                                                   |
| OPERATION_TYPE         | VARCHAR2(160) | Type of operation using the work area. Can include values such as SORT, HASH JOIN, GROUP BY, BUFFER, BITMAP MERGE, and BITMAP CONSTRUCTION.                                              |
| OPERATION_ID           | NUMBER        | A unique number used to identify the operation in the execution plan. This identifier can be joined to V\$SQL_PLAN to locate the operation that uses this work area.                     |
| POLICY                 | VARCHAR2(40)  | Sizing policy for this work area (MANUAL or AUTO)                                                                                                                                        |
| ESTIMATED_OPTIMAL_SIZE | NUMBER        | Estimated size (in bytes) required by this work area to execute the operation completely in memory (optimal execution). Derived from either optimizer statistics or previous executions. |
| ESTIMATED_ONEPASS_SIZE | NUMBER        | Estimated size (in bytes) required by this work area to execute the operation in a single pass. Derived from either optimizer statistics or previous executions.                         |
| LAST_MEMORY_USED       | NUMBER        | Memory (in bytes) used by this work area during the last execution of the cursor                                                                                                         |
| LAST_EXECUTION         | VARCHAR2(40)  | Indicates whether this work area runs using OPTIMAL, ONE PASS, or ONE PASS memory requirement (or MULTI-PASS), during the last execution of the cursor                                   |
| LAST_DEGREE            | NUMBER        | Degree of parallelism used during the last execution of this operation                                                                                                                   |
| TOTAL_EXECUTIONS       | NUMBER        | Number of times this work area was active                                                                                                                                                |
| OPTIMAL_EXECUTIONS     | NUMBER        | Number of times this work area ran in optimal mode                                                                                                                                       |
| ONEPASS_EXECUTIONS     | NUMBER        | Number of times this work area ran in one-pass mode                                                                                                                                      |

| Column                 | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MULTIPASSES_EXECUTIONS | NUMBER   | Number of times this work area ran below the one-pass memory requirement                                                                                                                                                                                                                                                                                                                                                                        |
| ACTIVE_TIME            | NUMBER   | Average time this work area is active (in hundredths of a second)                                                                                                                                                                                                                                                                                                                                                                               |
| MAX_TEMPSEG_SIZE       | NUMBER   | Maximum temporary segment size (in bytes) created by an instantiation of this work area. This column is NULL if this work area has never spilled to disk.                                                                                                                                                                                                                                                                                       |
| LAST_TEMPSEG_SIZE      | NUMBER   | Temporary segment size (in bytes) created in the last instantiation of this work area. This column is NULL if the last instantiation of this work area did not spill to disk.                                                                                                                                                                                                                                                                   |
| CON_ID                 | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.68 V\$SQL\_WORKAREA\_ACTIVE

V\$SQL\_WORKAREA\_ACTIVE contains an instantaneous view of the work areas currently allocated by the system. You can join this view against V\$SQL\_WORKAREA on WORKAREA\_ADDRESS to access the definition of that work area. If a work area spills to disk, then this view contains information for the temporary segment created on behalf of this work area.

The last three columns are included to enable joining V\$SQL\_WORKAREA\_ACTIVE with V\$TEMPSEG\_USAGE to retrieve more information on this temporary segment.

You can use this view to answer the following:

- What are the top 10 largest work areas currently allocated in the system?
- What percentage of memory is over-allocated ( $EXPECTED\_SIZE < ACTUAL\_MEM\_USED$ ) and under-allocated ( $EXPECTED\_SIZE > ACTUAL\_MEM\_USED$ )?
- What are the active work areas using more memory than what is expected by the memory manager?
- What are the active work areas that have spilled to disk?

| Column         | Datatype | Description                                                      |
|----------------|----------|------------------------------------------------------------------|
| SQL_HASH_VALUE | NUMBER   | Hash value of the SQL statement that is currently being executed |

| Column           | Datatype      | Description                                                                                                                                                                                                                                                                                        |
|------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_ID           | VARCHAR2(13)  | SQL identifier of the SQL statement that is currently being executed                                                                                                                                                                                                                               |
| SQL_EXEC_START   | DATE          | Time when the execution of the SQL currently executed by this session started                                                                                                                                                                                                                      |
| SQL_EXEC_ID      | NUMBER        | SQL execution identifier (see V\$SQL_MONITOR)                                                                                                                                                                                                                                                      |
| WORKAREA_ADDRESS | RAW(4   8)    | Address of the work area handle. This is the primary key for the view.                                                                                                                                                                                                                             |
| OPERATION_TYPE   | VARCHAR2(160) | Type of operation using the work area. Can include values such as SORT, HASH JOIN, GROUP BY, BUFFER, BITMAP MERGE, and BITMAP CONSTRUCTION.                                                                                                                                                        |
| OPERATION_ID     | NUMBER        | A unique number used to identify the operation in the execution plan. This identifier can be joined to V\$SQL_PLAN to locate the operation that uses this work area.                                                                                                                               |
| POLICY           | VARCHAR2(24)  | Sizing policy for this work area (MANUAL or AUTO)                                                                                                                                                                                                                                                  |
| SID              | NUMBER        | Session identifier                                                                                                                                                                                                                                                                                 |
| QCINST_ID        | NUMBER        | Query coordinator instance identifier. Along with QCSID, enables you to uniquely identify the query coordinator.                                                                                                                                                                                   |
| QCSID            | NUMBER        | Query coordinator session identifier. This is the same as the SID if the work area is allocated by a serial cursor.                                                                                                                                                                                |
| ACTIVE_TIME      | NUMBER        | Average time this work area is active (in microseconds)                                                                                                                                                                                                                                            |
| WORK_AREA_SIZE   | NUMBER        | Maximum size (in bytes) of the work area as it is currently used by the operation                                                                                                                                                                                                                  |
| EXPECTED_SIZE    | NUMBER        | Expected size (in bytes) for this work area. EXPECTED_SIZE is set on behalf of the operation by the memory manager. Memory can be over-allocated when WORK_AREA_SIZE has a higher value than EXPECTED_SIZE. This can occur when the operation using this work area takes a long time to resize it. |
| ACTUAL_MEM_USED  | NUMBER        | Amount of PGA memory (in bytes) currently allocated on behalf of this work area. This value should range between 0 and WORK_AREA_SIZE.                                                                                                                                                             |
| MAX_MEM_USED     | NUMBER        | Maximum memory amount (in bytes) used by this work area                                                                                                                                                                                                                                            |
| NUMBER_PASSES    | NUMBER        | Number of passes corresponding to this work area (0 if running in OPTIMAL mode)                                                                                                                                                                                                                    |
| TEMPSEG_SIZE     | NUMBER        | Size (in bytes) of the temporary segment used on behalf of this work area. This column is NULL if this work area has not (yet) spilled to disk.                                                                                                                                                    |
| TABLESPACE       | VARCHAR2(128) | Tablespace name for the temporary segment created on behalf of this work area. This column is NULL if this work area has not (yet) spilled to disk.                                                                                                                                                |
| SEGRFNO#         | NUMBER        | Relative file number within the tablespace for the temporary segment created on behalf of this work area. This column is NULL if this work area has not (yet) spilled to disk.                                                                                                                     |
| SEGBLK#          | NUMBER        | Block number for the temporary segment created on behalf of this work area. This column is NULL if this work area has not (yet) spilled to disk.                                                                                                                                                   |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.69 V\$SQL\_WORKAREA\_HISTOGRAM

V\$SQL\_WORKAREA\_HISTOGRAM displays the cumulative work area execution statistics (cumulated since instance startup) for different work area groups. The work areas are split into 33 groups based on their optimal memory requirements with the requirements increasing in powers of two. That is, work areas whose optimal requirement varies from 0 KB to 1 KB, 1 KB to 2 KB, 2 KB to 4 KB, ... and 2 TB to 4 TB.

For each work area group, the V\$SQL\_WORKAREA\_HISTOGRAM view shows how many work areas in that group were able to run in optimal mode, how many were able to run in one-pass mode, and finally how many ran in multi-pass mode. The DBA can take a snapshot at the beginning and the end of a desired time interval to derive the same statistics for that interval.

| Column                 | Datatype | Description                                                                                                                                                                         |
|------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOW_OPTIMAL_SIZE       | NUMBER   | Lower bound for the optimal memory requirement of work areas included in this row (bytes)                                                                                           |
| HIGH_OPTIMAL_SIZE      | NUMBER   | Upper bound for the optimal memory requirement of work areas included in this row (bytes)                                                                                           |
| OPTIMAL_EXECUTIONS     | NUMBER   | Number of work areas with an optimal memory requirement comprised between LOW_OPTIMAL_SIZE and HIGH_OPTIMAL_SIZE which have been executed in optimal mode since instance startup    |
| ONEPASS_EXECUTIONS     | NUMBER   | Number of work areas with an optimal memory requirement comprised between LOW_OPTIMAL_SIZE and HIGH_OPTIMAL_SIZE which have been executed in one-pass mode since instance startup   |
| MULTIPASSES_EXECUTIONS | NUMBER   | Number of work areas with an optimal memory requirement comprised between LOW_OPTIMAL_SIZE and HIGH_OPTIMAL_SIZE which have been executed in multi-pass mode since instance startup |
| TOTAL_EXECUTIONS       | NUMBER   | Sum of OPTIMAL_EXECUTIONS, ONEPASS_EXECUTIONS, and MULTIPASSES_EXECUTIONS                                                                                                           |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.70 V\$SQLAREA

V\$SQLAREA displays statistics on shared SQL areas and contains one row per SQL string. It provides statistics on SQL statements that are in memory, parsed, and ready for execution.

| Column          | Datatype       | Description                                                                                                                                                                         |
|-----------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_TEXT        | VARCHAR2(1000) | First thousand characters of the SQL text for the current cursor                                                                                                                    |
| SQL_FULLTEXT    | CLOB           | All characters of the SQL text for the current cursor                                                                                                                               |
| SQL_ID          | VARCHAR2(13)   | SQL identifier of the parent cursor in the library cache                                                                                                                            |
| SHARABLE_MEM    | NUMBER         | Amount of shared memory used by a cursor. If multiple child cursors exist, then the sum of all shared memory used by all child cursors.                                             |
| PERSISTENT_MEM  | NUMBER         | Fixed amount of memory used for the lifetime of an open cursor. If multiple child cursors exist, then the fixed sum of memory used for the lifetime of all the child cursors.       |
| RUNTIME_MEM     | NUMBER         | Fixed amount of memory required during execution of a cursor. If multiple child cursors exist, then the fixed sum of all memory required during execution of all the child cursors. |
| SORTS           | NUMBER         | Sum of the number of sorts that were done for all the child cursors                                                                                                                 |
| VERSION_COUNT   | NUMBER         | Number of child cursors that are present in the cache under this parent                                                                                                             |
| LOADED_VERSIONS | NUMBER         | Number of child cursors that are present in the cache and have their context heap loaded                                                                                            |
| OPEN_VERSIONS   | NUMBER         | Number of child cursors that are currently open under this current parent                                                                                                           |
| USERS_OPENING   | NUMBER         | Number of users that have any of the child cursors open                                                                                                                             |
| FETCHES         | NUMBER         | Number of fetches associated with the SQL statement                                                                                                                                 |
| EXECUTIONS      | NUMBER         | Total number of executions, totalled over all the child cursors                                                                                                                     |

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PX_SERVERS_EXECUTIONS    | NUMBER        | Total number of executions performed by parallel execution servers (0 when the statement has never been executed in parallel)                                                                                                                                                                                                                                                                                                                                                       |
| END_OF_FETCH_COUNT       | NUMBER        | Number of times this cursor was fully executed since the cursor was brought into the library cache. The value of this statistic is not incremented when the cursor is partially executed, either because it failed during the execution or because only the first few rows produced by this cursor are fetched before the cursor is closed or re-executed. By definition, the value of the END_OF_FETCH_COUNT column should be less or equal to the value of the EXECUTIONS column. |
| USERS_EXECUTING          | NUMBER        | Total number of users executing the statement over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                |
| LOADS                    | NUMBER        | Number of times the object was loaded or reloaded                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| FIRST_LOAD_TIME          | VARCHAR2(76)  | Timestamp of the parent creation time                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| INVALIDATIONS            | NUMBER        | Total number of invalidations over all the child cursors                                                                                                                                                                                                                                                                                                                                                                                                                            |
| PARSE_CALLS              | NUMBER        | Sum of all parse calls to all the child cursors under this parent                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DISK_READS               | NUMBER        | Sum of the number of disk reads over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DIRECT_WRITES            | NUMBER        | Sum of the number of direct writes over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DIRECT_READS             | NUMBER        | Sum of the number of direct reads over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                            |
| BUFFER_GETS              | NUMBER        | Sum of buffer gets over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| APPLICATION_WAIT_TIME    | NUMBER        | Application wait time (in microseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Column                    | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLAN_HASH_VALUE           | NUMBER       | Numeric representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line).                                                                                                                                                                                                          |
| FULL_PLAN_HASH_VALUE      | NUMBER       | Numeric representation of the complete SQL plan for this cursor. Comparing one FULL_PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line). Note that the FULL_PLAN_HASH_VALUE cannot be compared across databases releases. It is not backward compatible.                                                                                    |
| MODULE                    | VARCHAR2(64) | Contains the name of the module that was executing when the SQL statement was first parsed as set by calling DBMS_APPLICATION_INFO.SET_MODULE                                                                                                                                                                                                                                                                                 |
| MODULE_HASH               | NUMBER       | Hash value of the module that is named in the MODULE column                                                                                                                                                                                                                                                                                                                                                                   |
| ACTION                    | VARCHAR2(64) | Contains the name of the action that was executing when the SQL statement was first parsed as set by calling DBMS_APPLICATION_INFO.SET_ACTION                                                                                                                                                                                                                                                                                 |
| ACTION_HASH               | NUMBER       | Hash value of the action that is named in the ACTION column                                                                                                                                                                                                                                                                                                                                                                   |
| SERIALIZABLE_ABORTS       | NUMBER       | Number of times the transaction failed to serialize, producing ORA-08177 errors, totalled over all the child cursors                                                                                                                                                                                                                                                                                                          |
| OUTLINE_CATEGORY          | VARCHAR2(64) | If an outline was applied during construction of the cursor, then this column displays the category of that outline. Otherwise the column is left blank.                                                                                                                                                                                                                                                                      |
| CPU_TIME                  | NUMBER       | CPU time (in microseconds) used by this cursor for parsing, executing, and fetching                                                                                                                                                                                                                                                                                                                                           |
| ELAPSED_TIME              | NUMBER       | Elapsed time (in microseconds) used by this cursor for parsing, executing, and fetching. If the cursor uses parallel execution, then ELAPSED_TIME is the cumulative time for the query coordinator, plus all parallel query slave processes.                                                                                                                                                                                  |
| OUTLINE_SID               | VARCHAR2(40) | Outline session identifier                                                                                                                                                                                                                                                                                                                                                                                                    |
| LAST_ACTIVE_CHILD_ADDRESS | RAW(4   8)   | Address (identifier) of the child cursor that was the last to be active in the group (that is, the child cursor on behalf of which statistics in V\$SQL were updated)                                                                                                                                                                                                                                                         |
| REMOTE                    | VARCHAR2(1)  | Indicates whether the cursor is remote mapped (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                  |
| OBJECT_STATUS             | VARCHAR2(19) | Status of the cursor: <ul style="list-style-type: none"> <li>VALID - Valid, authorized without errors</li> <li>VALID_AUTH_ERROR - Valid, authorized with authorization errors</li> <li>VALID_COMPILE_ERROR - Valid, authorized with compilation errors</li> <li>VALID_UNAUTH - Valid, unauthorized</li> <li>INVALID_UNAUTH - Invalid, unauthorized</li> <li>INVALID - Invalid, unauthorized but keep the timestamp</li> </ul> |
| LITERAL_HASH_VALUE        | NUMBER       | Hash value of the literals which are replaced with system-generated bind variables and are to be matched, when CURSOR_SHARING is used. This is not the hash value for the SQL statement. If CURSOR_SHARING is not used, then the value is 0.                                                                                                                                                                                  |
| LAST_LOAD_TIME            | DATE         | Time at which the query plan was loaded into the library cache                                                                                                                                                                                                                                                                                                                                                                |

| Column                         | Datatype      | Description                                                                                                                                                                                                                                                                                             |
|--------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IS_OBSOLETE                    | VARCHAR2(1)   | Indicates whether the cursor has become obsolete (Y) or not (N). This can happen if the number of child cursors is too large.                                                                                                                                                                           |
| IS_BIND_SENSITIVE              | VARCHAR2(1)   | Indicates whether the cursor is bind sensitive (Y) or not (N). A query is considered bind-sensitive if the optimizer peeked at one of its bind variable values when computing predicate selectivities and where a change in a bind variable value may cause the optimizer to generate a different plan. |
| IS_BIND_AWARE                  | VARCHAR2(1)   | Indicates whether the cursor is bind aware (Y) or not (N). A query is considered bind-aware if it has been marked to use extended cursor sharing. The query would already have been marked as bind-sensitive.                                                                                           |
| CHILD_LATCH                    | NUMBER        | Child latch number that is protecting the cursor. This column is obsolete and maintained for backward compatibility.                                                                                                                                                                                    |
| SQL_PROFILE                    | VARCHAR2(64)  | SQL profile used for this statement, if any                                                                                                                                                                                                                                                             |
| SQL_PATCH                      | VARCHAR2(128) | SQL patch used for this statement, if any                                                                                                                                                                                                                                                               |
| SQL_PLAN_BASELINE              | VARCHAR2(128) | SQL plan baseline used for this statement, if any                                                                                                                                                                                                                                                       |
| PROGRAM_ID                     | NUMBER        | Program identifier                                                                                                                                                                                                                                                                                      |
| PROGRAM_LINE#                  | NUMBER        | Program line number                                                                                                                                                                                                                                                                                     |
| EXACT_MATCHING_SIGNATURE       | NUMBER        | Signature used when the <code>CURSOR_SHARING</code> parameter is set to <code>EXACT</code>                                                                                                                                                                                                              |
| FORCE_MATCHING_SIGNATURE       | NUMBER        | Signature used when the <code>CURSOR_SHARING</code> parameter is set to <code>FORCE</code>                                                                                                                                                                                                              |
| LAST_ACTIVE_TIME               | DATE          | Time at which the query plan was last active                                                                                                                                                                                                                                                            |
| BIND_DATA                      | RAW(2000)     | Bind data                                                                                                                                                                                                                                                                                               |
| TYPECHECK_MEM                  | NUMBER        | Typecheck memory                                                                                                                                                                                                                                                                                        |
| IO_CELL_OFFLOAD_ELIGIBLE_BYTES | NUMBER        | Number of I/O bytes which can be filtered by the Exadata storage system<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                   |
| IO_INTERCONNECT_BYTES          | NUMBER        | Number of I/O bytes exchanged between Oracle Database and the storage system                                                                                                                                                                                                                            |
| PHYSICAL_READ_REQUESTS         | NUMBER        | Number of physical read I/O requests issued by the monitored SQL                                                                                                                                                                                                                                        |
| PHYSICAL_READ_BYTES            | NUMBER        | Number of bytes read from disks by the monitored SQL                                                                                                                                                                                                                                                    |
| PHYSICAL_WRITE_REQUESTS        | NUMBER        | Number of physical write I/O requests issued by the monitored SQL                                                                                                                                                                                                                                       |
| PHYSICAL_WRITE_BYTES           | NUMBER        | Number of bytes written to disks by the monitored SQL                                                                                                                                                                                                                                                   |
| OPTIMIZED_PHY_READ_REQUESTS    | NUMBER        | Number of physical read I/O requests from Database Smart Flash Cache issued by the monitored SQL                                                                                                                                                                                                        |
| LOCKED_TOTAL                   | NUMBER        | Total number of times the child cursor has been locked                                                                                                                                                                                                                                                  |
| PINNED_TOTAL                   | NUMBER        | Total number of times the child cursor has been pinned                                                                                                                                                                                                                                                  |
| IO_CELL_UNCOMPRESSED_BYTES     | NUMBER        | Number of uncompressed bytes (that is, size after decompression) that are offloaded to the Exadata cells<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                  |

| Column                         | Datatype    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IO_CELL_OFFLOAD_RETURNED_BYTES | NUMBER      | Number of bytes that are returned by Exadata cell through the regular I/O path<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                                                                                                                                                                                 |
| CON_ID                         | NUMBER      | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul>                                                                                                                              |
| IS_REOPTIMIZABLE               | VARCHAR2(1) | This column shows whether the next execution matching this child cursor will trigger a reoptimization. The values are: <ul style="list-style-type: none"> <li>Y: If the next execution will trigger a reoptimization</li> <li>R: If the child cursor contains reoptimization information, but will not trigger reoptimization because the cursor was compiled in reporting mode</li> <li>N: If the child cursor has no reoptimization information</li> </ul>                                                                                                                 |
| IS_RESOLVED_ADAPTIVE_PLAN      | VARCHAR2(1) | This column shows whether all of the adaptive parts of a plan have been resolved to the final plan. Once the plan is resolved, the plan hash value and the plan displayed by DBMS_XPLAN will not change through the end of execution. The values for this column are: <ul style="list-style-type: none"> <li>NULL: If the plan is not adaptive</li> <li>Y: If the plan is fully resolved</li> <li>N: If the plan is not yet fully resolved</li> </ul> <b>See Also:</b> Oracle Database PL/SQL Packages and Types Reference for more information about the DBMS_XPLAN package |

## 10.71 V\$SQLAREA\_PLAN\_HASH

V\$SQLAREA\_PLAN\_HASH displays statistics on shared SQL areas (V\$SQL) by grouping on the SQL\_ID and PLAN\_HASH\_VALUE columns. It can potentially create several rows for one parent cursor, one for each distinct value of the column PLAN\_HASH\_VALUE.

| Column                    | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_TEXT                  | VARCHAR2(1000) | First thousand characters of the SQL text for the current cursor                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SQL_FULLTEXT              | CLOB           | All characters of the SQL text for the current cursor                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ADDRESS                   | RAW(4   8)     | Address of the handle to the parent for this cursor                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| HASH_VALUE                | NUMBER         | Hash value of the parent statement in the library cache                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SQL_ID                    | VARCHAR2(13)   | SQL identifier of the parent cursor in the library cache                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PLAN_HASH_VALUE           | NUMBER         | Numeric representation of the current SQL plan for this cursor. Comparing one <code>PLAN_HASH_VALUE</code> to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line).                                                                                                                                                                                                                                                                             |
| VERSION_COUNT             | NUMBER         | Number of child cursors that are present in the cache under this parent                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| LAST_ACTIVE_CHILD_ADDRESS | RAW(4   8)     | Address (identifier) of the child cursor that was the last to be active in the group (that is, the child cursor on behalf of which statistics in <code>V\$SQL</code> were updated)                                                                                                                                                                                                                                                                                                                            |
| SHARABLE_MEM              | NUMBER         | Amount of shared memory used by a cursor. If multiple child cursors exist, then it is the sum of all shared memory used by all child cursors.                                                                                                                                                                                                                                                                                                                                                                 |
| PERSISTENT_MEM            | NUMBER         | Fixed amount of memory used for the lifetime of an open cursor. If multiple child cursors exist, then it is the fixed sum of memory used for the lifetime of all the child cursors.                                                                                                                                                                                                                                                                                                                           |
| RUNTIME_MEM               | NUMBER         | Fixed amount of memory required during execution of a cursor. If multiple child cursors exist, then the fixed sum of all memory required during execution of all the child cursors.                                                                                                                                                                                                                                                                                                                           |
| SORTS                     | NUMBER         | Sum of the number of sorts that were done for all the child cursors                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| LOADED_VERSIONS           | NUMBER         | Number of child cursors that are present in the cache and that have their context heap loaded                                                                                                                                                                                                                                                                                                                                                                                                                 |
| OPEN_VERSIONS             | NUMBER         | Number of child cursors that are currently open under this parent                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| USERS_OPENING             | NUMBER         | Number of users that have any of the child cursors open                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| USERS_EXECUTING           | NUMBER         | Total number of users executing the statement over all child cursors                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FETCHES                   | NUMBER         | Number of fetches associated with the SQL statement                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| EXECUTIONS                | NUMBER         | Total number of executions, totalled over all the child cursors                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PX_SERVERS_EXECUTIONS     | NUMBER         | Total number of executions performed by parallel execution servers (0 when the statement has never been executed in parallel)                                                                                                                                                                                                                                                                                                                                                                                 |
| END_OF_FETCH_COUNT        | NUMBER         | Number of times this cursor was fully executed since the cursor was brought into the library cache. The value of this statistic is not incremented when the cursor is partially executed, either because it failed during the execution or because only the first few rows produced by this cursor are fetched before the cursor is closed or re-executed. By definition, the value of the <code>END_OF_FETCH_COUNT</code> column should be less or equal to the value of the <code>EXECUTIONS</code> column. |
| LOADS                     | NUMBER         | Number of times the object was loaded or reloaded                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FIRST_LOAD_TIME           | DATE           | Timestamp of the parent creation time                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LAST_LOAD_TIME            | DATE           | Time at which the query plan was loaded into the library cache                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Column                   | Datatype      | Description                                                                                                                                               |
|--------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAST_ACTIVE_TIME         | DATE          | Time at which the query plan was last active                                                                                                              |
| LAST_EXEC_START_TIME     | DATE          | Time at which the most recent execution of this SQL started                                                                                               |
| INVALIDATIONS            | NUMBER        | Total number of invalidations over all the child cursors                                                                                                  |
| PARSE_CALLS              | NUMBER        | Sum of all parse calls to all the child cursors under this parent                                                                                         |
| DISK_READS               | NUMBER        | Sum of the number of disk reads over all child cursors                                                                                                    |
| DIRECT_WRITES            | NUMBER        | Sum of the number of direct writes over all child cursors                                                                                                 |
| BUFFER_GETS              | NUMBER        | Sum of buffer gets over all child cursors                                                                                                                 |
| CPU_TIME                 | NUMBER        | CPU time (in microseconds) used by this cursor for parsing, executing, and fetching                                                                       |
| ELAPSED_TIME             | NUMBER        | Elapsed time (in microseconds) used by this cursor for parsing, executing, and fetching                                                                   |
| APPLICATION_WAIT_TIME    | NUMBER        | Application wait time (in microseconds)                                                                                                                   |
| CONCURRENCY_WAIT_TIME    | NUMBER        | Concurrency wait time (in microseconds)                                                                                                                   |
| CLUSTER_WAIT_TIME        | NUMBER        | Cluster wait time (in microseconds)                                                                                                                       |
| USER_IO_WAIT_TIME        | NUMBER        | User I/O wait time (in microseconds)                                                                                                                      |
| PLSQL_EXEC_TIME          | NUMBER        | PL/SQL execution time (in microseconds)                                                                                                                   |
| JAVA_EXEC_TIME           | NUMBER        | Java execution time (in microseconds)                                                                                                                     |
| ROWS_PROCESSED           | NUMBER        | Total number of rows processed on behalf of this SQL statement                                                                                            |
| COMMAND_TYPE             | NUMBER        | Oracle command type definition                                                                                                                            |
| OPTIMIZER_MODE           | VARCHAR2(10)  | Mode under which the SQL statement was executed                                                                                                           |
| OPTIMIZER_COST           | NUMBER        | Cost of this query given by the optimizer                                                                                                                 |
| OPTIMIZER_ENV            | RAW(2000)     | Optimizer environment                                                                                                                                     |
| OPTIMIZER_ENV_HASH_VALUE | NUMBER        | Hash value for the optimizer environment                                                                                                                  |
| PARSING_USER_ID          | NUMBER        | User ID of the user that has parsed the very first cursor under this parent                                                                               |
| PARSING_SCHEMA_ID        | NUMBER        | Schema ID that was used to parse this child cursor                                                                                                        |
| PARSING_SCHEMA_NAME      | VARCHAR2(128) | Schema name that was used to parse this child cursor                                                                                                      |
| KEPT_VERSIONS            | NUMBER        | Number of child cursors that have been marked to be kept using the DBMS_SHARED_POOL package                                                               |
| MODULE                   | VARCHAR2(64)  | Contains the name of the module that was executing when the SQL statement was first parsed as set by calling DBMS_APPLICATION_INFO.SET_MODULE             |
| MODULE_HASH              | NUMBER        | Hash value of the module that is named in the MODULE column                                                                                               |
| ACTION                   | VARCHAR2(64)  | Contains the name of the action that was executing when the SQL statement was first parsed as set by calling DBMS_APPLICATION_INFO.SET_ACTION             |
| ACTION_HASH              | NUMBER        | Hash value of the action that is named in the ACTION column                                                                                               |
| SERIALIZABLE_ABORTS      | NUMBER        | Number of times the transaction failed to serialize, producing ORA-08177 errors, totalled over all the child cursors                                      |
| OUTLINE_CATEGORY         | VARCHAR2(64)  | If an outline was applied during construction of the cursor, then this column displays the category of that outline. Otherwise, the column is left blank. |

| Column                         | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OUTLINE_SID                    | VARCHAR2(40) | Outline session identifier                                                                                                                                                                                                                                                                                                                                                                                                    |
| REMOTE                         | VARCHAR2(1)  | Indicates whether the cursor is remote mapped (Y) or not (N)                                                                                                                                                                                                                                                                                                                                                                  |
| OBJECT_STATUS                  | VARCHAR2(19) | Status of the cursor: <ul style="list-style-type: none"> <li>VALID - Valid, authorized without errors</li> <li>VALID_AUTH_ERROR - Valid, authorized with authorization errors</li> <li>VALID_COMPILE_ERROR - Valid, authorized with compilation errors</li> <li>VALID_UNAUTH - Valid, unauthorized</li> <li>INVALID_UNAUTH - Invalid, unauthorized</li> <li>INVALID - Invalid, unauthorized but keep the timestamp</li> </ul> |
| LITERAL_HASH_VALUE             | NUMBER       | Hash value of the literals which are replaced with system-generated bind variables and are to be matched, when CURSOR_SHARING is used. This is not the hash value for the SQL statement. If CURSOR_SHARING is not used, then the value is 0.                                                                                                                                                                                  |
| SQL_PROFILE                    | VARCHAR2(64) | SQL profile used for this statement, if any                                                                                                                                                                                                                                                                                                                                                                                   |
| PROGRAM_ID                     | NUMBER       | Program identifier                                                                                                                                                                                                                                                                                                                                                                                                            |
| PROGRAM_LINE#                  | NUMBER       | Program line number                                                                                                                                                                                                                                                                                                                                                                                                           |
| EXACT_MATCHING_SIGNATURE       | NUMBER       | Signature used when the CURSOR_SHARING parameter is set to EXACT                                                                                                                                                                                                                                                                                                                                                              |
| FORCE_MATCHING_SIGNATURE       | NUMBER       | Signature used when the CURSOR_SHARING parameter is set to FORCE                                                                                                                                                                                                                                                                                                                                                              |
| BIND_DATA                      | RAW(2000)    | Bind data                                                                                                                                                                                                                                                                                                                                                                                                                     |
| TYPECHECK_MEM                  | NUMBER       | Typecheck memory                                                                                                                                                                                                                                                                                                                                                                                                              |
| IO_CELL_OFFLOAD_ELIGIBLE_BYTES | NUMBER       | Number of I/O bytes which can be filtered by the Exadata storage system<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                                         |
| IO_INTERCONNECT_BYTES          | NUMBER       | Number of I/O bytes exchanged between Oracle Database and the storage system                                                                                                                                                                                                                                                                                                                                                  |
| PHYSICAL_READ_REQUESTS         | NUMBER       | Number of physical read I/O requests issued by the monitored SQL                                                                                                                                                                                                                                                                                                                                                              |
| PHYSICAL_READ_BYTES            | NUMBER       | Number of bytes read from disks by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                          |
| PHYSICAL_WRITE_REQUESTS        | NUMBER       | Number of physical write I/O requests issued by the monitored SQL                                                                                                                                                                                                                                                                                                                                                             |
| PHYSICAL_WRITE_BYTES           | NUMBER       | Number of bytes written to disks by the monitored SQL                                                                                                                                                                                                                                                                                                                                                                         |
| OPTIMIZED_PHY_READ_REQUESTS    | NUMBER       | Number of physical read I/O requests from Database Smart Flash Cache issued by the monitored SQL                                                                                                                                                                                                                                                                                                                              |
| IO_CELL_UNCOMPRESSED_BYTES     | NUMBER       | Number of uncompressed bytes (that is, size after decompression) that are offloaded to the Exadata cells<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                        |
| IO_CELL_OFFLOAD_RETURNED_BYTES | NUMBER       | Number of bytes that are returned by Exadata cell through the regular I/O path<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                                                                                                                                                                                                                                  |

| Column   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| CON_DBID | NUMBER   | The database ID of the PDB                                                                                                                                                                                                                                                                                                                                                                                                                      |

| COMMAND_TYPE | NUMBER       | SQL command number                                                                                                                                                                                                                                                                                                                                                                                                                              |
| COMMAND_NAME | VARCHAR2(64) | SQL command name                                                                                                                                                                                                                                                                                                                                                                                                                                |
| CON_ID       | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.73 V\$SQLFN\_ARG\_METADATA

V\$SQLFN\_ARG\_METADATA contains metadata about function arguments. There is one row for each argument of every function found in V\$SQLFN\_METADATA. There are no rows for functions that do not have any arguments.

| Column   | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FUNC_ID  | NUMBER        | Internal function identification number. This column can be used to join with the V\$SQLFN_METADATA view.                                                                                                                                                                                                                                                                                                                         |
| ARGNUM   | NUMBER        | Argument number                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DATATYPE | VARCHAR2(8)   | Data type of the argument. The value is NULL if this argument is not used. Otherwise, it can take values of any Oracle data type, family data type, or EXPR data type.                                                                                                                                                                                                                                                            |
| DESCR    | VARCHAR2(128) | This column is reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID   | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li>n: Where n is the applicable container ID for the rows containing data</li> </ul> |

## 10.74 V\$SQLFN\_METADATA

V\$SQLFN\_METADATA contains metadata about operators and built-in functions. Note that this view does not contain information about arguments because the number of arguments will be different for various functions. Information about arguments is contained in V\$SQLFN\_ARG\_METADATA, which can be joined with V\$SQLFN\_METADATA to get information about any function and its arguments.

| Column      | Datatype      | Description                                                                                                                                                                                                       |
|-------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FUNC_ID     | NUMBER        | Internal function identification number                                                                                                                                                                           |
| NAME        | VARCHAR2(128) | Name of the built-in function                                                                                                                                                                                     |
| MINARGS     | NUMBER        | Minimum number of arguments for the function                                                                                                                                                                      |
| MAXARGS     | NUMBER        | Maximum number of arguments for the function                                                                                                                                                                      |
| DATATYPE    | VARCHAR2(8)   | Return data type, which can take any Oracle data type values, data type family values, or ARG[n] data types                                                                                                       |
| VERSION     | VARCHAR2(12)  | Minimum version of the database that has this function                                                                                                                                                            |
| ANALYTIC    | VARCHAR2(3)   | Indicates whether the function is an analytic function (YES) or not (NO)                                                                                                                                          |
| AGGREGATE   | VARCHAR2(3)   | Indicates whether the function is an aggregate function (YES) or not (NO)                                                                                                                                         |
| OFFLOADABLE | VARCHAR2(3)   | Indicates whether execution of the function can be offloaded to the Oracle Exadata Storage Server (YES) or not (NO)<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information |

| Column    | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DISP_TYPE | VARCHAR2(13)   | Function display type: <ul style="list-style-type: none"> <li>NORMAL</li> <li>ARITHMETIC</li> <li>PARENTHESIS</li> <li>REL-OP</li> <li>CASELIKE</li> <li>NOPARENTHESIS</li> </ul>                                                                                                                                                                                                                                                               |
| USAGE     | VARCHAR2(128)  | A text explanation of how to use this function. The text is based on the syntax diagram for the function in the <i>Oracle Database SQL Language Reference</i> .                                                                                                                                                                                                                                                                                 |
| DESCR     | VARCHAR2(4000) | Description of the function                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CON_ID    | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.75 V\$SQLSTATS

V\$SQLSTATS displays basic performance statistics for SQL cursors and contains one row per SQL statement (that is, one row per unique value of SQL\_ID). The column definitions for columns in V\$SQLSTATS are identical to those in the V\$SQL and V\$SQLAREA views. However, the V\$SQLSTATS view differs from V\$SQL and V\$SQLAREA in that it is faster, more scalable, and has a greater data retention (the statistics may still appear in this view, even after the cursor has been aged out of the shared pool). Note that V\$SQLSTATS contains a subset of columns that appear in V\$SQL and V\$SQLAREA.

| Column                    | Datatype       | Description                                                                                                                                                                |
|---------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL_TEXT                  | VARCHAR2(1000) | First thousand characters of the SQL text for the current cursor                                                                                                           |
| SQL_FULLTEXT              | CLOB           | Full text for the SQL statement exposed as a CLOB column. THE full text of a SQL statement can be retrieved using this column instead of joining with the V\$SQLTEXT view. |
| SQL_ID                    | VARCHAR2(13)   | SQL identifier of the parent cursor in the library cache                                                                                                                   |
| LAST_ACTIVE_TIME          | DATE           | Last time the statistics of a contributing cursor were updated                                                                                                             |
| LAST_ACTIVE_CHILD_ADDRESS | RAW(4   8)     | Address of the contributing cursor that last updated these statistics                                                                                                      |

| Column                | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLAN_HASH_VALUE       | NUMBER   | Numeric representation of the current SQL plan for this cursor. Comparing one PLAN_HASH_VALUE to another easily identifies whether or not two plans are the same (rather than comparing the two plans line by line).                                                                                                                                                                                                                                                                |
| PARSE_CALLS           | NUMBER   | Number of parse calls for all cursors with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DISK_READS            | NUMBER   | Number of disk reads for all cursors with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DIRECT_WRITES         | NUMBER   | Number of direct writes for all cursors with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DIRECT_READS          | NUMBER   | Number of direct reads for all cursors with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                  |
| BUFFER_GETS           | NUMBER   | Number of buffer gets for all cursors with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ROWS_PROCESSED        | NUMBER   | Total number of rows the parsed SQL statement returns                                                                                                                                                                                                                                                                                                                                                                                                                               |
| SERIALIZABLE_ABORTS   | NUMBER   | Number of times the transaction failed to serialize, producing ORA-08177 errors, per cursor                                                                                                                                                                                                                                                                                                                                                                                         |
| FETCHES               | NUMBER   | Number of fetches associated with the SQL statement                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| EXECUTIONS            | NUMBER   | Number of executions that took place on this object since it was brought into the library cache                                                                                                                                                                                                                                                                                                                                                                                     |
| END_OF_FETCH_COUNT    | NUMBER   | Number of times this cursor was fully executed since the cursor was brought into the library cache. The value of this statistic is not incremented when the cursor is partially executed, either because it failed during the execution or because only the first few rows produced by this cursor are fetched before the cursor is closed or re-executed. By definition, the value of the END_OF_FETCH_COUNT column should be less or equal to the value of the EXECUTIONS column. |
| LOADS                 | NUMBER   | Number of times the object was either loaded or reloaded                                                                                                                                                                                                                                                                                                                                                                                                                            |
| VERSION_COUNT         | NUMBER   | number of cursors present in the cache with this SQL text and plan                                                                                                                                                                                                                                                                                                                                                                                                                  |
| INVALIDATIONS         | NUMBER   | Number of times this child cursor has been invalidated                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PX_SERVERS_EXECUTIONS | NUMBER   | Total number of executions performed by parallel execution servers (0 when the statement has never been executed in parallel)                                                                                                                                                                                                                                                                                                                                                       |
| CPU_TIME              | NUMBER   | CPU time (in microseconds) used by this cursor for parsing, executing, and fetching                                                                                                                                                                                                                                                                                                                                                                                                 |
| ELAPSED_TIME          | NUMBER   | Elapsed time (in microseconds) used by this cursor for parsing, executing, and fetching. If the cursor uses parallel execution, then ELAPSED_TIME is the cumulative time for the query coordinator, plus all parallel query slave processes.                                                                                                                                                                                                                                        |
| AVG_HARD_PARSE_TIME   | NUMBER   | Average hard parse time (in microseconds) used by this cursor                                                                                                                                                                                                                                                                                                                                                                                                                       |
| APPLICATION_WAIT_TIME | NUMBER   | Application wait time (in microseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CONCURRENCY_WAIT_TIME | NUMBER   | Concurrency wait time (in microseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CLUSTER_WAIT_TIME     | NUMBER   | Cluster wait time (in microseconds). This value is specific to Oracle RAC. It shows the total time spent waiting for all waits that are categorized under the cluster class of wait events. The value in this column is an accumulated wait time spent waiting for Oracle RAC cluster resources.                                                                                                                                                                                    |
| USER_IO_WAIT_TIME     | NUMBER   | User I/O wait time (in microseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PLSQL_EXEC_TIME       | NUMBER   | PL/SQL execution time (in microseconds)                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Column                         | Datatype | Description                                                                                                                                                                                            |
|--------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JAVA_EXEC_TIME                 | NUMBER   | Java execution time (in microseconds)                                                                                                                                                                  |
| SORTS                          | NUMBER   | Number of sorts that were done for the child cursor                                                                                                                                                    |
| SHARABLE_MEM                   | NUMBER   | Total shared memory (in bytes) currently occupied by all cursors with this SQL text and plan                                                                                                           |
| TOTAL_SHARABLE_MEM             | NUMBER   | Total shared memory (in bytes) occupied by all cursors with this SQL text and plan if they were to be fully loaded in the shared pool (that is, cursor size)                                           |
| TYPECHECK_MEM                  | NUMBER   | Typecheck memory                                                                                                                                                                                       |
| IO_CELL_OFFLOAD_ELIGIBLE_BYTES | NUMBER   | Number of I/O bytes which can be filtered by the Exadata storage system<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                                  |
| IO_INTERCONNECT_BYTES          | NUMBER   | Number of I/O bytes exchanged between Oracle Database and the storage system. Typically used for Cache Fusion or parallel queries.                                                                     |
| PHYSICAL_READ_REQUESTS         | NUMBER   | Number of physical read I/O requests issued by the monitored SQL. The requests may not be disk reads.                                                                                                  |
| PHYSICAL_READ_BYTES            | NUMBER   | Number of bytes read from disks by the monitored SQL                                                                                                                                                   |
| PHYSICAL_WRITE_REQUESTS        | NUMBER   | Number of physical write I/O requests issued by the monitored SQL                                                                                                                                      |
| PHYSICAL_WRITE_BYTES           | NUMBER   | Number of bytes written to disks by the monitored SQL                                                                                                                                                  |
| EXACT_MATCHING_SIGNATURE       | NUMBER   | Signature used when the <code>CURSOR_SHARING</code> parameter is set to <code>EXACT</code>                                                                                                             |
| FORCE_MATCHING_SIGNATURE       | NUMBER   | Signature used when the <code>CURSOR_SHARING</code> parameter is set to <code>FORCE</code>                                                                                                             |
| IO_CELL_UNCOMPRESSED_BYTES     | NUMBER   | Number of uncompressed bytes (that is, size after decompression) that are offloaded to the Exadata cells<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information |
| IO_CELL_OFFLOAD_RETURNED_BYTES | NUMBER   | Number of bytes that are returned by Exadata cell through the regular I/O path<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information                           |
| DELTA_PARSE_CALLS              | NUMBER   | Number of parse calls for the cursor since the last Automatic Workload Repository (AWR) snapshot<br><b>See Also:</b> <i>Oracle Database Performance Tuning Guide</i> for an introduction to AWR        |
| DELTA_DISK_READS               | NUMBER   | Number of disk reads for the cursor since the last AWR snapshot                                                                                                                                        |
| DELTA_DIRECT_WRITES            | NUMBER   | Number of direct writes for the cursor since the last AWR snapshot                                                                                                                                     |
| DELTA_DIRECT_READS             | NUMBER   | Number of direct reads for the cursor since the last AWR snapshot                                                                                                                                      |
| DELTA_BUFFER_GETS              | NUMBER   | Number of buffer gets for the cursor since the last AWR snapshot                                                                                                                                       |
| DELTA_ROWS_PROCESSED           | NUMBER   | Number of rows returned by the cursor since the last AWR snapshot                                                                                                                                      |
| DELTA_FETCH_COUNT              | NUMBER   | Number of fetches for the cursor since the last AWR snapshot                                                                                                                                           |
| DELTA_EXECUTION_COUNT          | NUMBER   | Number of executions for the cursor since the last AWR snapshot                                                                                                                                        |

| Column                            | Datatype | Description                                                                                                                                                                                                      |
|-----------------------------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DELTA_PX_SERVERS_EXECUTIONS       | NUMBER   | Number of executions performed by parallel execution servers since the last AWR snapshot                                                                                                                         |
| DELTA_END_OF_FETCH_COUNT          | NUMBER   | Number of times the cursor was fully executed since the last AWR snapshot                                                                                                                                        |
| DELTA_CPU_TIME                    | NUMBER   | CPU time (in microseconds) for the cursor since the last AWR snapshot                                                                                                                                            |
| DELTA_ELAPSED_TIME                | NUMBER   | Database time (in microseconds) for the cursor since the last AWR snapshot                                                                                                                                       |
| DELTA_APPLICATION_WAIT_TIME       | NUMBER   | Time spent by the cursor (in microseconds) in the Application wait class since the last AWR snapshot                                                                                                             |
| DELTA_CONCURRENCY_TIME            | NUMBER   | Time spent by the cursor (in microseconds) in the Concurrency wait class since the last AWR snapshot                                                                                                             |
| DELTA_CLUSTER_WAIT_TIME           | NUMBER   | Time spent by the cursor (in microseconds) in the Cluster wait class since the last AWR snapshot                                                                                                                 |
| DELTA_USER_IO_WAIT_TIME           | NUMBER   | Time spent by the cursor (in microseconds) in the User I/O wait class since the last AWR snapshot                                                                                                                |
| DELTA_PLSQL_EXEC_TIME             | NUMBER   | Time spent by the cursor (in microseconds) executing PL/SQL since the last AWR snapshot                                                                                                                          |
| DELTA_JAVA_EXEC_TIME              | NUMBER   | Time spent by the cursor (in microseconds) executing Java since the last AWR snapshot                                                                                                                            |
| DELTA_SORTS                       | NUMBER   | Number of sorts for the cursor since the last AWR snapshot                                                                                                                                                       |
| DELTA_LOADS                       | NUMBER   | Number of times the cursor was loaded since the last AWR snapshot                                                                                                                                                |
| DELTA_INVALIDATIONS               | NUMBER   | Number of times the cursor was invalidated since the last AWR snapshot                                                                                                                                           |
| DELTA_PHYSICAL_READ_REQUESTS      | NUMBER   | Number of physical read I/O requests for the cursor since the last AWR snapshot                                                                                                                                  |
| DELTA_PHYSICAL_READ_BYTES         | NUMBER   | Number of bytes read from disk for the cursor since the last AWR snapshot                                                                                                                                        |
| DELTA_PHYSICAL_WRITE_REQUESTS     | NUMBER   | Number of physical write I/O requests for the cursor since the last AWR snapshot                                                                                                                                 |
| DELTA_PHYSICAL_WRITE_BYTES        | NUMBER   | Number of bytes written to disk for the cursor since the last AWR snapshot                                                                                                                                       |
| DELTA_IO_INTERCONNECT_BYTES       | NUMBER   | Number of I/O bytes exchanged between the Oracle database and the storage system for the cursor since the last AWR snapshot                                                                                      |
| DELTA_CELL_OFFLOAD_ELIGIBLE_BYTES | NUMBER   | Number of I/O bytes which can be filtered by the Exadata storage system for the cursor since the last AWR snapshot<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information |
| DELTA_CELL_UNCOMPRESSED_BYTES     | NUMBER   | Number of uncompressed bytes that are offloaded to the Exadata cell for the cursor since the last AWR snapshot<br><b>See Also:</b> Oracle Exadata Storage Server Software documentation for more information     |

| Column                   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID                   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| CON_DBID                 | NUMBER   | The database ID of the PDB                                                                                                                                                                                                                                                                                                                                                                                                                      |
| OBSOLETE_COUNT           | NUMBER   | Number of times that a parent cursor became obsolete                                                                                                                                                                                                                                                                                                                                                                                            |
| AVOIDED_EXECUTIONS       | NUMBER   | Number of executions attempted on this object, but prevented due to the SQL statement being in quarantine                                                                                                                                                                                                                                                                                                                                       |
| DELTA_AVOIDED_EXECUTIONS | NUMBER   | Number of executions attempted on this object, but prevented due to the SQL statement being in quarantine, since the last AWR snapshot                                                                                                                                                                                                                                                                                                          |

## 10.76 V\$SQLSTATS\_PLAN\_HASH

V\$SQLSTATS\_PLAN\_HASH displays basic performance statistics for SQL cursors and contains one row per execution plan of a SQL statement (that is, one row per unique combination of SQL\_ID and PLAN\_HASH\_VALUE).

The columns for V\$SQLSTATS\_PLAN\_HASH are the same as those for V\$SQLSTATS.

## 10.77 V\$SQLTEXT

V\$SQLTEXT displays the text of SQL statements belonging to shared SQL cursors in the SGA.

| Column     | Datatype     | Description                                               |
|------------|--------------|-----------------------------------------------------------|
| ADDRESS    | RAW(4   8)   | Used with HASH_VALUE to uniquely identify a cached cursor |
| HASH_VALUE | NUMBER       | Used with ADDRESS to uniquely identify a cached cursor    |
| SQL_ID     | VARCHAR2(13) | SQL identifier of a cached cursor                         |

| Column       | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMMAND_TYPE | NUMBER       | Code for the type of SQL statement (SELECT, INSERT, and so on)                                                                                                                                                                                                                                                                                                                                                                                  |
| PIECE        | NUMBER       | Number used to order the pieces of SQL text                                                                                                                                                                                                                                                                                                                                                                                                     |
| SQL_TEXT     | VARCHAR2(64) | A column containing one piece of the SQL text                                                                                                                                                                                                                                                                                                                                                                                                   |
| CON_ID       | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.78 V\$SQLTEXT\_WITH\_NEWLINES

V\$SQLTEXT\_WITH\_NEWLINES is identical to the V\$SQLTEXT view except that, to improve legibility, V\$SQLTEXT\_WITH\_NEWLINES does not replace newlines and tabs in the SQL statement with spaces.

| Column       | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDRESS      | RAW(4   8)   | Used with HASH_VALUE to uniquely identify a cached cursor                                                                                                                                                                                                                                                                                                                                                                                       |
| HASH_VALUE   | NUMBER       | Used with ADDRESS to uniquely identify a cached cursor                                                                                                                                                                                                                                                                                                                                                                                          |
| SQL_ID       | VARCHAR2(13) | SQL identifier of a cached cursor                                                                                                                                                                                                                                                                                                                                                                                                               |
| COMMAND_TYPE | NUMBER       | Code for the type of SQL statement (SELECT, INSERT, and so on)                                                                                                                                                                                                                                                                                                                                                                                  |
| PIECE        | NUMBER       | Number used to order the pieces of SQL text                                                                                                                                                                                                                                                                                                                                                                                                     |
| SQL_TEXT     | VARCHAR2(64) | A column containing one piece of the SQL text                                                                                                                                                                                                                                                                                                                                                                                                   |
| CON_ID       | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.79 V\$STANDBY\_EVENT\_HISTOGRAM

V\$STANDBY\_EVENT\_HISTOGRAM displays the histogram of apply lag on the physical standby. Each distinct value of apply lag has its own bucket and the count in the corresponding bucket represents the number of occurrences so far. The physical

standby samples the apply lag every second and increments the corresponding bucket in the histogram.

| Column            | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME              | VARCHAR2(64) | Name of the event (currently APPLY_LAG is the only valid value)                                                                                                                                                                                                                                                                                                                                                                   |
| TIME              | NUMBER       | Time duration that the bucket represents                                                                                                                                                                                                                                                                                                                                                                                          |
| UNIT              | VARCHAR2(16) | Time unit (seconds, minutes, hours, or days)                                                                                                                                                                                                                                                                                                                                                                                      |
| COUNT             | NUMBER       | Each row is a histogram bucket for apply lag. COUNT is the number of occurrences the apply lag falls into the histogram bucket.                                                                                                                                                                                                                                                                                                   |
| LAST_TIME_UPDATED | VARCHAR2(20) | Last time the bucket was updated by an event falling into that time duration                                                                                                                                                                                                                                                                                                                                                      |
| CON_ID            | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li>n: Where n is the applicable container ID for the rows containing data</li> </ul> |

## 10.80 V\$STANDBY\_LOG

V\$STANDBY\_LOG displays information about standby redo logs. Standby redo logs are similar to online redo logs, but standby redo logs are only used on a standby database that is receiving redo data from the primary database.

| Column        | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GROUP#        | NUMBER       | Log group number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DBID          | VARCHAR2(40) | Database ID of the primary database to which the standby redo logfile is assigned. If the standby redo logfile is unassigned, the value UNASSIGNED will be displayed.                                                                                                                                                                                                                                                                                                                                                                      |
| THREAD#       | NUMBER       | Log thread number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SEQUENCE#     | NUMBER       | Log sequence number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| BYTES         | NUMBER       | Size of the log (in bytes)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| BLOCKSIZE     | NUMBER       | Block size of the logfile (512 or 4096)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| USED          | NUMBER       | Number of bytes used in the log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ARCHIVED      | VARCHAR2(3)  | Archive status (YES) or (NO). See the STATUS column for further details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| STATUS        | VARCHAR2(10) | Log status: <ul style="list-style-type: none"> <li>UNASSIGNED - If ARCHIVED is NO, then the standby redo log has been archived and is again available. If ARCHIVED is YES, then the standby redo log has never been used and is available.</li> <li>ACTIVE - If ARCHIVED is NO, then the standby redo log is complete and waiting to be archived. If ARCHIVED is YES, then the standby redo log is currently being written to and is therefore not ready to be archived. For a given thread, there should be only one such log.</li> </ul> |
| FIRST_CHANGE# | NUMBER       | Lowest SCN in the log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Column       | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FIRST_TIME   | DATE     | Time of the first SCN in the log                                                                                                                                                                                                                                                                                                                                                                                                  |
| NEXT_CHANGE# | NUMBER   | All redo records contained within this log will have an SCN lower than NEXT_CHANGE#. Only filled in once the log is complete. Also the lowest SCN of any redo record in the next log.                                                                                                                                                                                                                                             |
| NEXT_TIME    | DATE     | All redo records contained within this log will have a timestamp lower than NEXT_TIME. Only filled in once the log is complete. Also the lowest timestamp of any redo record in the next log.                                                                                                                                                                                                                                     |
| LAST_CHANGE# | NUMBER   | All redo records contained within this log will have an SCN lower than LAST_CHANGE#. Only filled in once the log is complete. Also the lowest SCN of any redo record in the next log.<br>LAST_CHANGE# is deprecated. Use NEXT_CHANGE# instead.                                                                                                                                                                                    |
| LAST_TIME    | DATE     | All redo records contained within this log will have a timestamp lower than LAST_TIME. Only filled in once the log is complete. Also the lowest timestamp of any redo record in the next log.<br>LAST_TIME is deprecated. Use NEXT_TIME instead.                                                                                                                                                                                  |
| CON_ID       | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li>n: Where n is the applicable container ID for the rows containing data</li> </ul> |

## 10.81 V\$STATISTICS\_LEVEL

V\$STATISTICS\_LEVEL displays the status of the statistics/advisories controlled by STATISTICS\_LEVEL.

| Column               | Datatype       | Description                                                                                                                                                                                                                                                     |
|----------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATISTICS_NAME      | VARCHAR2(64)   | Name of the statistic/advisory                                                                                                                                                                                                                                  |
| DESCRIPTION          | VARCHAR2(4000) | Description of the statistic/advisory                                                                                                                                                                                                                           |
| SESSION_STATUS       | VARCHAR2(8)    | Status of the statistic/advisory for the session: <ul style="list-style-type: none"> <li>ENABLED</li> <li>DISABLED</li> </ul>                                                                                                                                   |
| SYSTEM_STATUS        | VARCHAR2(8)    | System-wide status of the statistic/advisory: <ul style="list-style-type: none"> <li>ENABLED</li> <li>DISABLED</li> </ul>                                                                                                                                       |
| ACTIVATION_LEVEL     | VARCHAR2(7)    | Indicates the level of STATISTICS_LEVEL that enables the statistic/advisory: <ul style="list-style-type: none"> <li>BASIC</li> <li>TYPICAL</li> <li>ALL</li> </ul>                                                                                              |
| STATISTICS_VIEW_NAME | VARCHAR2(64)   | If there is a single view externalizing the statistic/advisory, then this column contains the name of that view. If there is no such view, then this column is null. If there are multiple views involved, then the DESCRIPTION column mentions the view names. |

| Column           | Datatype    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SESSION_SETTABLE | VARCHAR2(3) | Indicates whether the statistic/advisory can be set at the session level (YES) or not (NO)                                                                                                                                                                                                                                                                                                                                                      |
| CON_ID           | NUMBER      | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.82 V\$STATNAME

V\$STATNAME displays decoded statistic names for the statistics shown in the V\$SESSTAT and V\$SYSSTAT tables.

On some platforms, the NAME and CLASS columns contain additional operating system-specific statistics.

| Column       | Datatype     | Description                                                                                                                                                                                                                                                                                                          |
|--------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATISTIC#   | NUMBER       | Statistic number<br><b>Note:</b> Statistics numbers are not guaranteed to remain constant from one release to another. Therefore, you should rely on the statistics name rather than its number in your applications.                                                                                                |
| NAME         | VARCHAR2(64) | Statistic name. Names that appear in this column remain stable across Oracle Database releases, and they can be relied on by customer scripts.                                                                                                                                                                       |
| CLASS        | NUMBER       | A number representing one or more statistics classes. The following class numbers are additive: <ul style="list-style-type: none"> <li>1 - User</li> <li>2 - Redo</li> <li>4 - Enqueue</li> <li>8 - Cache</li> <li>16 - OS</li> <li>32 - Real Application Clusters</li> <li>64 - SQL</li> <li>128 - Debug</li> </ul> |
| STAT_ID      | NUMBER       | Identifier of the statistic                                                                                                                                                                                                                                                                                          |
| DISPLAY_NAME | VARCHAR2(64) | A clearer and more descriptive name for the statistic that appears in the NAME column. Names that appear in the DISPLAY_NAME column can change across Oracle Database releases, therefore customer scripts should not rely on names that appear in the DISPLAY_NAME column across releases.                          |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.83 V\$STATS\_ADVISOR\_RULES

V\$STATS\_ADVISOR\_RULES displays the rule definition information for each Optimizer Statistics Advisor rule.

| Column      | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RULE_ID     | NUMBER       | ID of the rule                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| NAME        | VARCHAR2(64) | Name of the rule                                                                                                                                                                                                                                                                                                                                                                                                                                |
| RULE_TYPE   | VARCHAR2(9)  | Type of the rule: <ul style="list-style-type: none"> <li>• OBJECT</li> <li>• OPERATION</li> <li>• SYSTEM</li> </ul>                                                                                                                                                                                                                                                                                                                             |
| DESCRIPTION | VARCHAR2(64) | Description of the rule                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CON_ID      | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.84 V\$STREAMS\_APPLY\_COORDINATOR

V\$STREAMS\_APPLY\_COORDINATOR displays information about each apply process coordinator. The coordinator for an apply process gets transactions from the apply process reader and passes them to apply servers. An apply process coordinator is a subcomponent of an apply process, outbound server, or inbound server.

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                                                                                     |
|--------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID                      | NUMBER        | Session ID of the coordinator's session                                                                                                                                                                                                                                                                                         |
| SERIAL#                  | NUMBER        | Serial number of the coordinator's session                                                                                                                                                                                                                                                                                      |
| STATE                    | VARCHAR2(21)  | State of the coordinator: <ul style="list-style-type: none"> <li>• INITIALIZING - Starting up</li> <li>• IDLE - Performing no work</li> <li>• APPLYING - Passing transactions to apply servers</li> <li>• SHUTTING DOWN CLEANLY - Stopping without an error</li> <li>• ABORTING - Stopping because of an apply error</li> </ul> |
| APPLY#                   | NUMBER        | Apply process number. An apply process coordinator is an Oracle background process, prefixed by <code>ap</code> .                                                                                                                                                                                                               |
| APPLY_NAME               | VARCHAR2(128) | Name of the apply process                                                                                                                                                                                                                                                                                                       |
| TOTAL_APPLIED            | NUMBER        | Total number of transactions applied by the apply process since the apply process was last started                                                                                                                                                                                                                              |
| TOTAL_WAIT_DEPS          | NUMBER        | Number of times since the apply process was last started that an apply server waited to apply a logical change record (LCR) in a transaction until another apply server applied a transaction because of a dependency between the transactions                                                                                  |
| TOTAL_WAIT_COMMITS       | NUMBER        | Number of times since the apply process was last started that an apply server waited to commit a transaction until another apply server committed a transaction to serialize commits                                                                                                                                            |
| TOTAL_ADMIN              | NUMBER        | Number of administrative jobs issued since the apply process was last started                                                                                                                                                                                                                                                   |
| TOTAL_ASSIGNED           | NUMBER        | Number of transactions assigned to apply servers since the apply process was last started                                                                                                                                                                                                                                       |
| TOTAL_RECEIVED           | NUMBER        | Total number of transactions received by the coordinator process since the apply process was last started                                                                                                                                                                                                                       |
| TOTAL_IGNORED            | NUMBER        | Number of transactions which were received by the coordinator but were ignored because they had been previously applied                                                                                                                                                                                                         |
| TOTAL_ROLLBACKS          | NUMBER        | Number of transactions which were rolled back due to unexpected contention                                                                                                                                                                                                                                                      |
| TOTAL_ERRORS             | NUMBER        | Number of transactions applied by the apply process that resulted in an apply error since the apply process was last started                                                                                                                                                                                                    |
| UNASSIGNED_COMPLETE_TXNS | NUMBER        | Total number of complete transactions that the coordinator has not assigned to any apply servers                                                                                                                                                                                                                                |
| AUTO_TXN_BUFFER_SIZE     | NUMBER        | Current value of transaction buffer size. Transaction buffer size refers to the number of transactions that the apply reader can assemble ahead of apply servers. The apply process periodically adjusts the transaction buffer size.                                                                                           |
| LWM_TIME                 | DATE          | Time when the message with the lowest message number was recorded. The creation time of the message with the lowest message number was also recorded at this time.                                                                                                                                                              |

| Column                   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LWM_MESSAGE_NUMBER       | NUMBER   | Number of the message corresponding to the low watermark. That is, messages with a commit message number less than or equal to this message number have definitely been applied, but some messages with a higher commit message number also may have been applied.                                                                                                                                                                              |
| LWM_MESSAGE_CREATE_TIME  | DATE     | For captured messages, creation time at the source database of the message corresponding to the low watermark. For user-enqueued messages, time when the message corresponding to the low watermark was enqueued into the queue at the local database.                                                                                                                                                                                          |
| HWM_TIME                 | DATE     | Time when the message with the highest message number was recorded. The creation time of the message with the highest message number was also recorded at this time.                                                                                                                                                                                                                                                                            |
| HWM_MESSAGE_NUMBER       | NUMBER   | Number of the message corresponding to the high watermark. That is, no messages with a commit message number greater than this message number have been applied.                                                                                                                                                                                                                                                                                |
| HWM_MESSAGE_CREATE_TIME  | DATE     | For captured messages, creation time at the source database of the message corresponding to the high watermark. For user-enqueued messages, time when the message corresponding to the high watermark was enqueued into the queue at the local database.                                                                                                                                                                                        |
| STARTUP_TIME             | DATE     | Time when the apply process was last started                                                                                                                                                                                                                                                                                                                                                                                                    |
| ELAPSED_SCHEDULE_TIME    | NUMBER   | Time elapsed (in hundredths of a second) scheduling messages since the apply process was last started                                                                                                                                                                                                                                                                                                                                           |
| ELAPSED_IDLE_TIME        | NUMBER   | Elapsed idle time                                                                                                                                                                                                                                                                                                                                                                                                                               |
| LWM_POSITION             | RAW(64)  | Position of the low-watermark LCR                                                                                                                                                                                                                                                                                                                                                                                                               |
| HWM_POSITION             | RAW(64)  | Position of the high-watermark LCR                                                                                                                                                                                                                                                                                                                                                                                                              |
| PROCESSED_MESSAGE_NUMBER | NUMBER   | Message number currently processed by the apply coordinator                                                                                                                                                                                                                                                                                                                                                                                     |
| CON_ID                   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| ACTIVE_SERVER_COUNT      | NUMBER   | Active server count                                                                                                                                                                                                                                                                                                                                                                                                                             |

#### Note:

The `ELAPSED_SCHEDULE_TIME` column is only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

## 10.85 V\$STREAMS\_APPLY\_READER

V\$STREAMS\_APPLY\_READER displays information about each apply reader. The apply reader is a process which reads (dequeues) messages from the queue, computes message dependencies, and builds transactions. It passes the transactions on to the coordinator in commit order for assignment to the apply servers. An apply reader is a subcomponent of an apply process, outbound server, or inbound server.

| Column                           | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| OLDEST_XIDUSN          | NUMBER        | Transaction ID undo segment number of the oldest transaction that either has been applied or is being applied                                                                                                                                                                      |
| OLDEST_XIDSLT          | NUMBER        | Transaction ID slot number of the oldest transaction that either has been applied or is being applied                                                                                                                                                                              |
| OLDEST_XIDSQN          | NUMBER        | Transaction ID sequence number of the oldest transaction that either has been applied or is being applied                                                                                                                                                                          |
| SPILL_LWM_SCN          | NUMBER        | Spill low-watermark SCN                                                                                                                                                                                                                                                            |
| PROXY_SID              | NUMBER        | When the apply process uses combined capture and apply, the session ID of the propagation receiver that is responsible for direct communication between capture and apply. If the apply process does not use combined capture and apply, then this column is 0.                    |
| PROXY_SERIAL           | NUMBER        | When the apply process uses combined capture and apply, the serial number of the propagation receiver that is responsible for direct communication between capture and apply. If the apply process does not use combined capture and apply, then this column is 0.                 |
| PROXY_SPID             | VARCHAR2(12)  | When the apply process uses combined capture and apply, the process identification number of the propagation receiver that is responsible for direct communication between capture and apply. If the apply process does not use combined capture and apply, then this column is 0. |
| CAPTURE_BYTES_RECEIVED | NUMBER        | When the apply process uses combined capture and apply, the number of bytes received by the apply process from the capture process since the apply process last started. If the apply process does not use combined capture and apply, then this column is not populated.          |
| DEQUEUED_POSITION      | RAW(64)       | Dequeued position. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                            |
| LAST_BROWSE_POSITION   | RAW(64)       | Reserved for internal use                                                                                                                                                                                                                                                          |
| OLDEST_POSITION        | RAW(64)       | The earliest position of the transactions currently being dequeued and applied. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                               |
| SPILL_LWM_POSITION     | RAW(64)       | Spill low-watermark position. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                 |
| OLDEST_TRANSACTION_ID  | VARCHAR2(128) | Oldest transaction ID                                                                                                                                                                                                                                                              |
| TOTAL_LCRS_WITH_DEP    | NUMBER        | Total number of LCRs with row-level dependencies since the apply process last started                                                                                                                                                                                              |

| Column                | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_LCRS_WITH_WMDEP | NUMBER   | Total number of LCRs with watermark dependencies since the apply process last started.<br>A watermark dependency occurs when an apply process must wait until the apply process's low watermark reaches a particular threshold.                                                                                                                                                                                                                 |
| TOTAL_IN_MEMORY_LCRS  | NUMBER   | Total number of LCRs currently in memory                                                                                                                                                                                                                                                                                                                                                                                                        |
| SGA_ALLOCATED         | NUMBER   | The total amount of shared memory (in bytes) allocated from the Streams pool for the apply process since the apply process last started                                                                                                                                                                                                                                                                                                         |
| CON_ID                | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

The `ELAPSED_DEQUEUE_TIME` and `ELAPSED_SCHEDULE_TIME` columns are only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

 **See Also:**

- "TIMED\_STATISTICS"
- "STATISTICS\_LEVEL"

## 10.86 V\$STREAMS\_APPLY\_SERVER

`V$STREAMS_APPLY_SERVER` displays information about each apply server and its activities. An apply server receives messages from the apply coordinator for an apply process. For each message received, an apply server either applies the message or sends the message to the appropriate apply handler. An apply server is a subcomponent of an apply process, outbound server, or inbound server.

| Column     | Datatype      | Description                                                                                           |
|------------|---------------|-------------------------------------------------------------------------------------------------------|
| SID        | NUMBER        | Session ID of the apply server's session                                                              |
| SERIAL#    | NUMBER        | Serial number of the apply server's session                                                           |
| APPLY#     | NUMBER        | Apply process number. An apply process is an Oracle background process, prefixed by <code>ap</code> . |
| APPLY_NAME | VARCHAR2(128) | Name of the apply process                                                                             |

| Column        | Datatype        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| COMMIT_POSITION             | RAW(64)       | Commit position of the transaction. This column is populated only for an apply process that is functioning as an XStream outbound server or inbound server.                                                                                                                                                                                                                                                                                     |
| DEP_COMMIT_POSITION         | RAW(64)       | Commit position of the transaction the slave depends on. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                   |
| LAST_APPLY_POSITION         | RAW(64)       | For inbound servers, the position of the last message applied; for outbound servers, the position of the last message sent to the XStream client application. This column is populated only for an apply process that is functioning as an XStream outbound server or inbound server.                                                                                                                                                           |
| TRANSACTION_ID              | VARCHAR2(128) | Transaction ID that the slave is applying. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                                 |
| DEP_TRANSACTION_ID          | VARCHAR2(128) | Transaction ID of the transaction the slave depends on. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                    |
| CON_ID                      | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| TOTAL_LCRS_RETRIED          | NUMBER        | Total number of LCRs retried by this server                                                                                                                                                                                                                                                                                                                                                                                                     |
| LCR_RETRY_ITERATION         | NUMBER        | Retry iteration for this transaction by this server                                                                                                                                                                                                                                                                                                                                                                                             |
| TOTAL_TXNS_RETRIED          | NUMBER        | Total transactions retried by this server                                                                                                                                                                                                                                                                                                                                                                                                       |

| Column              | Datatype | Description                                               |
|---------------------|----------|-----------------------------------------------------------|
| TXN_RETRY_ITERATION | NUMBER   | Total retry iterations by this server                     |
| TOTAL_TXNS_RECORDED | NUMBER   | Total transactions recorded in error queue by this server |

**Note:**

The `ELAPSED_DEQUEUE_TIME` and `ELAPSED_APPLY_TIME` columns are only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

- "STATISTICS\_LEVEL"

## 10.87 V\$STREAMS\_POOL\_ADVICE

`V$STREAMS_POOL_ADVICE` displays information about the estimated count of spilled or unspilled messages and the associated time spent in the spill or unspill activity for different Streams pool sizes. The sizes range from 10% to 200% of the current Streams pool size, in equal intervals. The value of the interval depends on the current size of the Streams pool.

| Column                         | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STREAMS_POOL_SIZE_FOR_ESTIMATE | NUMBER   | Streams pool size (in megabytes) for the estimate. The size ranges from values smaller than the current Streams pool size to values larger than the current Streams pool size, and there is a separate row for each increment. There is always an entry that shows the current Streams pool size, and there are always 20 increments. The range and the size of the increments depend on the current size of the Streams pool. |
| STREAMS_POOL_SIZE_FACTOR       | NUMBER   | Size factor with respect to the current Streams pool size                                                                                                                                                                                                                                                                                                                                                                      |
| ESTD_SPILL_COUNT               | NUMBER   | Estimated count of messages spilled from the Streams pool                                                                                                                                                                                                                                                                                                                                                                      |
| ESTD_SPILL_TIME                | NUMBER   | Estimated elapsed time (in seconds) to spill                                                                                                                                                                                                                                                                                                                                                                                   |
| ESTD_UNSPILL_COUNT             | NUMBER   | Estimated count of unspills (read back from disk)                                                                                                                                                                                                                                                                                                                                                                              |
| ESTD_UNSPILL_TIME              | NUMBER   | Estimated elapsed time (in seconds) to unspill                                                                                                                                                                                                                                                                                                                                                                                 |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.88 V\$STREAMS\_POOL\_STATISTICS

V\$STREAMS\_POOL\_STATISTICS displays information about the current Streams pool usage percentage.

| Column                 | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOTAL_MEMORY_ALLOCATED | NUMBER   | Total memory allocated to the Streams pool (in bytes). It should always be less than the current size of the Streams pool. You can get the percentage of the Streams pool used by dividing TOTAL_MEMORY_ALLOCATED by CURRENT_SIZE.                                                                                                                                                                                                              |
| CURRENT_SIZE           | NUMBER   | Current size of the Streams pool (in bytes)                                                                                                                                                                                                                                                                                                                                                                                                     |
| SGA_TARGET_VALUE       | NUMBER   | Value of SGA_TARGET. Used to determine whether or not streams pool automatic tuning is enabled. This should be set even if MEMORY_TARGET is set and SGA_TARGET is not set.                                                                                                                                                                                                                                                                      |
| SHRINK_PHASE           | NUMBER   | This only pertains to the Streams pool in an automatic tuning environment (SGA_TARGET and MEMORY_TARGET set). In this case, this shows whether or not the Streams pool is being asked to shrink. During the shrink phase, enqueues are blocked, flow control is enabled for all components, and cached memory is returned to the SGA.                                                                                                           |
| ADVICE_DISABLED        | NUMBER   | This determines whether or not Streams pool advice in V\$STREAMS_POOL_ADVICE as well as all statistics gathering related to auto-tuning the Streams pool have been disabled.                                                                                                                                                                                                                                                                    |
| CON_ID                 | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.89 V\$SUBCACHE

V\$SUBCACHE displays information about the subordinate caches currently loaded into library cache memory. The view walks through the library cache, printing out a row for each loaded subordinate cache per library cache object.

| Column     | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OWNER_NAME | VARCHAR2(64)   | Owner of the object containing these cache entries                                                                                                                                                                                                                                                                                                                                                                                              |
| NAME       | VARCHAR2(1000) | Object Name                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| TYPE       | NUMBER         | Object Type                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| HEAP_NUM   | NUMBER         | Heap number containing this subordinate cache                                                                                                                                                                                                                                                                                                                                                                                                   |
| CACHE_ID   | NUMBER         | Subordinate cache ID                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CACHE_CNT  | NUMBER         | Number of entries for this cache in this object                                                                                                                                                                                                                                                                                                                                                                                                 |
| HEAP_SZ    | NUMBER         | Amount of extent space allocated to this heap                                                                                                                                                                                                                                                                                                                                                                                                   |
| HEAP_ALOC  | NUMBER         | Amount of extent space allocated from this heap                                                                                                                                                                                                                                                                                                                                                                                                 |
| HEAP_USED  | NUMBER         | Amount of space utilized in this heap                                                                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID     | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.90 V\$SUBSCR\_REGISTRATION\_STATS

V\$SUBSCR\_REGISTRATION\_STATS displays information for diagnosability of notifications.

| Column                   | Datatype                       | Description                                                                   |
|--------------------------|--------------------------------|-------------------------------------------------------------------------------|
| REG_ID                   | NUMBER                         | Registration identifier                                                       |
| NUM_NTFNS                | NUMBER                         | Number of notifications                                                       |
| NUM_GROUPING_NTFNS       | NUMBER                         | Number of grouping notifications                                              |
| NUM_NTFNS_CURRENT_GROUP  | NUMBER                         | Number of events received in the current group                                |
| LAST_NTFN_START_TIME     | TIMESTAMP(3)<br>WITH TIME ZONE | Time when the last notification was started                                   |
| LAST_NTFN_SENT_TIME      | TIMESTAMP(3)<br>WITH TIME ZONE | Time when the last notification was sent                                      |
| TOTAL_EMON_LATENCY       | NUMBER                         | Total EMON latency (time taken by the EMON slave to process notifications)    |
| EMON#                    | NUMBER                         | Active EMON slave serving the registration                                    |
| ALL_EMON_SERVERS         | RAW(2000)                      | EMON slaves that served the registration                                      |
| TOTAL_PAYLOAD_BYTES_SENT | NUMBER                         | Total payload bytes sent                                                      |
| SHARD_ID                 | NUMBER                         | Shard number for current registration used for Key Based Messaging            |
| NUM_RETRIES              | NUMBER                         | Number of retries in sending notifications                                    |
| TOTAL_PLSQL_EXEC_TIME    | NUMBER                         | Total PL/SQL callback execution time (relevant only for PL/SQL notifications) |

| Column                   | Datatype                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LAST_ERR                 | VARCHAR2(90)                   | Last error message                                                                                                                                                                                                                                                                                                                                                                                                                              |

This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.91 V\$SYS\_OPTIMIZER\_ENV

V\$SYS\_OPTIMIZER\_ENV displays the contents of the optimizer environment for the instance. The optimizer environment stores the value of the main parameters used by the Oracle optimizer when building the execution plan of a SQL statement. Hence, modifying the value of one or more of these parameters (for example, by issuing an ALTER SYSTEM statement) could lead to plan changes.

The parameters displayed by this view are either regular initialization parameters (such as OPTIMIZER\_FEATURES\_ENABLE) or pseudo parameters (such as ACTIVE\_INSTANCE\_COUNT).

| Column        | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID            | NUMBER       | Unique identifier of the parameter in the optimizer environment                                                                                                                                                                                                                                                                                                                                                                                 |
| NAME          | VARCHAR2(40) | Name of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                           |
| SQL_FEATURE   | VARCHAR2(64) | Associated feature control ID                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ISDEFAULT     | VARCHAR2(3)  | Indicates whether the parameter is set to the default value (YES) or not (NO)                                                                                                                                                                                                                                                                                                                                                                   |
| VALUE         | VARCHAR2(25) | Value of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DEFAULT_VALUE | VARCHAR2(25) | Default value of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CON_ID        | NUMBER       | The ID of the container to which the data pertains. ## 10.92 V\$SYS\_TIME\_MODEL

V\$SYS\_TIME\_MODEL displays the system-wide accumulated times for various operations. The time reported is the total elapsed or CPU time (in microseconds). Any timed operation will buffer at most 5 seconds of time data. Specifically, this means that if a timed operation (such as SQL execution) takes a long period of time to perform, the data published to this view is at most missing 5 seconds of the time accumulated for the operation.

The time values are 8-byte integers and can therefore hold approximately 580,000 years worth of time before wrapping. Background process time is not included in a statistic value unless the statistic is specifically for background processes.

| Column    | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAT_ID   | NUMBER       | Statistic identifier for the time statistic                                                                                                                                                                                                                                                                                                                                                                                                           |
| STAT_NAME | VARCHAR2(64) | Name of the statistic (see <a href="#">Table 10-1</a> )                                                                                                                                                                                                                                                                                                                                                                                               |
| VALUE     | NUMBER       | Amount of time (in microseconds) that the system has spent in this operation                                                                                                                                                                                                                                                                                                                                                                          |
| CON_ID    | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

This view returns instance-wide data and a value of 0 in the CON\_ID column when queried from the root of a CDB.

## 10.93 V\$SYSAUX\_OCCUPANTS

V\$SYSAUX\_OCCUPANTS displays SYSAUX tablespace occupant information.

| Column        | Datatype     | Description                  |
|---------------|--------------|------------------------------|
| OCCUPANT_NAME | VARCHAR2(64) | Occupant name                |
| OCCUPANT_DESC | VARCHAR2(64) | Occupant description         |
| SCHEMA_NAME   | VARCHAR2(64) | Schema name for the occupant |

This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.94 V\$SYSMETRIC

V\$SYSMETRIC displays the system metric values captured for the most current time interval for both the long duration (60-second) and short duration (15-second) system metrics.

| Column       | Datatype        | Description                                                                                                                                                                                                                                                                                                                                               |

## 10.95 V\$SYSMETRIC\_HISTORY

V\$SYSMETRIC\_HISTORY displays all system metric values available in the database. Both long duration (60-second with 1 hour history) and short duration (15-second with one-interval only) metrics are displayed by this view.

| Column       | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                   |

## 10.96 V\$SYSMETRIC\_SUMMARY

V\$SYSMETRIC\_SUMMARY displays a summary of all system metric values for the long-duration system metrics. The average, maximum value, minimum value, and the value of one standard deviation for the last hour are displayed for each metric item.

| Column       | Datatype     | Description                               |
|--------------|--------------|-------------------------------------------|
| BEGIN_TIME   | DATE         | Begin time of the interval                |
| END_TIME     | DATE         | End time of the interval                  |
| INTSIZE_CSEC | NUMBER       | Interval size (in hundredths of a second) |
| GROUP_ID     | NUMBER       | Metric group ID                           |
| METRIC_ID    | NUMBER       | Metric ID                                 |
| METRIC_NAME  | VARCHAR2(64) | Metric name                               |
| NUM_INTERVAL | NUMBER       | Number of intervals observed              |

| Column             | Datatype        | Description                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAXVAL             | NUMBER          | Maximum value observed                                                                                                                                                                                                                                                                                                                                    |
| MINVAL             | NUMBER          | Minimum value observed                                                                                                                                                                                                                                                                                                                                    |
| AVERAGE            | NUMBER          | Average value over the period                                                                                                                                                                                                                                                                                                                             |
| STANDARD_DEVIATION | NUMBER          | One standard deviation                                                                                                                                                                                                                                                                                                                                    |
| METRIC_UNIT        | VARCHAR2 ( 64 ) | Metric unit description                                                                                                                                                                                                                                                                                                                                   |
| CON_ID             | NUMBER          | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.97 V\$SYSSTAT

V\$SYSSTAT displays system statistics. To find the name of the statistic associated with each statistic number (STATISTIC#), query the V\$STATNAME view.

| Column     | Datatype        | Description                                                                                                                                                                                                                                                                                                        |
|------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATISTIC# | NUMBER          | Statistic number<br><b>Note:</b> Statistics numbers are not guaranteed to remain constant from one release to another. Therefore, you should rely on the statistics name rather than its number in your applications.                                                                                              |
| NAME       | VARCHAR2 ( 64 ) | Statistic name. You can get a complete listing of statistic names by querying the V\$STATNAME view.                                                                                                                                                                                                                |
| CLASS      | NUMBER          | A number representing one or more statistics class. The following class numbers are additive: <ul style="list-style-type: none"> <li>1 - User</li> <li>2 - Redo</li> <li>4 - Enqueue</li> <li>8 - Cache</li> <li>16 - OS</li> <li>32 - Real Application Clusters</li> <li>64 - SQL</li> <li>128 - Debug</li> </ul> |
| VALUE      | NUMBER          | Statistic value                                                                                                                                                                                                                                                                                                    |
| STAT_ID    | NUMBER          | Identifier of the statistic                                                                                                                                                                                                                                                                                        |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

This view returns instance-wide data and a value of 0 in the CON\_ID column when queried from the root of a CDB.

## 10.98 V\$SYSTEM\_CURSOR\_CACHE

V\$SYSTEM\_CURSOR\_CACHE displays system wide information on cursor usage.

 **See Also:**

"V\$SESSION\_CURSOR\_CACHE"

| Column    | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OPENS     | NUMBER   | Cumulative total of cursor opens                                                                                                                                                                                                                                                                                                                                                                                                                |
| HITS      | NUMBER   | Cumulative total of cursor open hits                                                                                                                                                                                                                                                                                                                                                                                                            |
| HIT_RATIO | NUMBER   | Ratio of the number of times an open cursor was found divided by the number of times a cursor was sought                                                                                                                                                                                                                                                                                                                                        |
| CON_ID    | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.99 V\$SYSTEM\_EVENT

V\$SYSTEM\_EVENT displays information on total waits for an event. Note that the TIME\_WAITED and AVERAGE\_WAIT columns will contain a value of zero on those platforms that do not support a fast timing mechanism. If you are running on one of these platforms and you want this column to reflect true wait times, then you must set TIMED\_STATISTICS to TRUE in the parameter file; doing this will have a small negative effect on system performance.

 **See Also:**  
"TIMED\_STATISTICS"

| Column               | Datatype        | Description                                                                                                                  |
|----------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| EVENT                | VARCHAR2 ( 64 ) | Name of the wait event; derived statistic name from V\$EVENT_NAME<br><b>See Also:</b> " <a href="#">Oracle Wait Events</a> " |
| TOTAL_WAITS          | NUMBER          | Total number of waits for the event                                                                                          |
| TOTAL_TIMEOUTS       | NUMBER          | Total number of timeouts for the event                                                                                       |
| TIME_WAITED          | NUMBER          | Total amount of time waited for the event (in hundredths of a second)                                                        |
| AVERAGE_WAIT         | NUMBER          | Average amount of time waited for the event (in hundredths of a second)                                                      |
| TIME_WAITED_MICRO    | NUMBER          | Total amount of time waited for the event (in microseconds)                                                                  |
| CPU                  | NUMBER          | Total amount of CPU time consumed while implementing the wait event itself (in microseconds)                                 |
| TOTAL_WAITS_FG       | NUMBER          | Total number of waits for the event, from foreground sessions                                                                |
| TOTAL_TIMEOUTS_FG    | NUMBER          | Total number of timeouts for the event, from foreground sessions                                                             |
| TIME_WAITED_FG       | NUMBER          | Total amount of time waited for the event, from foreground sessions (in hundredths of a second)                              |
| AVERAGE_WAIT_FG      | NUMBER          | Average amount of time waited for the event, from foreground sessions (in hundredths of a second)                            |
| TIME_WAITED_MICRO_FG | NUMBER          | Total amount of time waited for the event, from foreground sessions (in microseconds)                                        |
| CPU_FG               | NUMBER          | Total amount of CPU time consumed while implementing the wait event itself, from foreground sessions (in microseconds)       |
| EVENT_ID             | NUMBER          | Identifier of the wait event                                                                                                 |
| WAIT_CLASS_ID        | NUMBER          | Identifier of the wait class of the wait event                                                                               |
| WAIT_CLASS#          | NUMBER          | Number of the wait class of the wait event                                                                                   |
| WAIT_CLASS           | VARCHAR2 ( 64 ) | Name of the wait class of the wait event                                                                                     |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

**Note:**

This view returns instance-wide data and a value of 0 in the CON\_ID column when queried from the root of a CDB.

## 10.100 V\$SYSTEM\_FIX\_CONTROL

V\$SYSTEM\_FIX\_CONTROL displays information about Fix Control (enabled/disabled) at the system level.

| Column                   | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BUGNO                    | NUMBER       | Bug number (as fix control identifier)                                                                                                                                                                                                                                                                                                                                                                                                          |
| VALUE                    | NUMBER       | Current value set for the fix control                                                                                                                                                                                                                                                                                                                                                                                                           |
| SQL_FEATURE              | VARCHAR2(64) | Feature control ID                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DESCRIPTION              | VARCHAR2(64) | Description of the fix control                                                                                                                                                                                                                                                                                                                                                                                                                  |
| OPTIMIZER_FEATURE_ENABLE | VARCHAR2(25) | Version on (and after) which the fix is enabled by default                                                                                                                                                                                                                                                                                                                                                                                      |
| EVENT                    | NUMBER       | Event formerly used to control this fix                                                                                                                                                                                                                                                                                                                                                                                                         |
| IS_DEFAULT               | NUMBER       | Indicates whether the current value is the same as the default (1) or not (0)                                                                                                                                                                                                                                                                                                                                                                   |
| CON_ID                   | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.101 V\$SYSTEM\_PARAMETER

V\$SYSTEM\_PARAMETER displays information about the initialization parameters that are currently in effect for the instance. A new session inherits parameter values from the instance-wide values.

| Column                | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NUM                   | NUMBER         | Parameter number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NAME                  | VARCHAR2(80)   | Name of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| TYPE                  | NUMBER         | Parameter type: <ul style="list-style-type: none"> <li>• 1 - Boolean</li> <li>• 2 - String</li> <li>• 3 - Integer</li> <li>• 4 - Parameter file</li> <li>• 5 - Reserved</li> <li>• 6 - Big integer</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| VALUE                 | VARCHAR2(4000) | Instance-wide parameter value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DISPLAY_VALUE         | VARCHAR2(4000) | Parameter value in a user-friendly format. For example, if the VALUE column shows the value 262144 for a big integer parameter, then the DISPLAY_VALUE column will show the value 256K.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DEFAULT_VALUE         | VARCHAR2(255)  | The default value for this parameter. This is the value of the parameter if a value is not explicitly specified for the parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ISDEFAULT             | VARCHAR2(9)    | Indicates whether the parameter is set to the default value (TRUE) or the parameter value was specified in the parameter file (FALSE).<br>The database sets the value of the ISDEFAULT column to TRUE for parameters that are not specified in the init.ora or server parameter file (SPFILE).                                                                                                                                                                                                                                                                                                                                                                                                 |
| ISSES_MODIFIABLE      | VARCHAR2(5)    | Indicates whether the parameter can be changed with ALTER SESSION (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ISSYS_MODIFIABLE      | VARCHAR2(9)    | Indicates whether the parameter can be changed with ALTER SYSTEM and when the change takes effect: <ul style="list-style-type: none"> <li>• IMMEDIATE - Parameter can be changed with ALTER SYSTEM regardless of the type of parameter file used to start the instance. The change takes effect immediately.</li> <li>• DEFERRED - Parameter can be changed with ALTER SYSTEM regardless of the type of parameter file used to start the instance. The change takes effect in subsequent sessions.</li> <li>• FALSE - Parameter cannot be changed with ALTER SYSTEM unless a server parameter file was used to start the instance. The change takes effect in subsequent instances.</li> </ul> |
| ISPDB_MODIFIABLE      | VARCHAR2(5)    | Indicates whether the parameter can be modified inside a PDB (TRUE) or not (FALSE).<br>In a non-CDB, the value of this column is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ISINSTANCE_MODIFIABLE | VARCHAR2(5)    | For parameters that can be changed with ALTER SYSTEM, indicates whether the value of the parameter can be different for every instance (TRUE) or whether the parameter must have the same value for all Real Application Clusters instances (FALSE). If the ISSYS_MODIFIABLE column is FALSE, then this column is always FALSE.                                                                                                                                                                                                                                                                                                                                                                |
| ISMODIFIED            | VARCHAR2(8)    | Indicates how the parameter was modified. If an ALTER SYSTEM was performed, the value will be MODIFIED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ISADJUSTED            | VARCHAR2(5)    | Indicates whether Oracle adjusted the input value to a more suitable value (for example, the parameter value should be prime, but the user input a non-prime number, so Oracle adjusted the value to the next prime number)                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Column         | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ISDEPRECATED   | VARCHAR2(5)   | Indicates whether the parameter has been deprecated (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                       |
| ISBASIC        | VARCHAR2(5)   | Indicates whether the parameter is a basic parameter (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                      |
| DESCRIPTION    | VARCHAR2(255) | Description of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                    |
| UPDATE_COMMENT | VARCHAR2(255) | Comments associated with the most recent update                                                                                                                                                                                                                                                                                                                                                                                                 |
| HASH           | NUMBER        | Hash value for the parameter name                                                                                                                                                                                                                                                                                                                                                                                                               |
| CON_ID         | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

"V\$PARAMETER" for information about initialization parameters that are currently in effect for a session

## 10.102 V\$SYSTEM\_PARAMETER2

V\$SYSTEM\_PARAMETER2 displays information about the initialization parameters that are currently in effect for the instance, with each list parameter value appearing as a row in the view. A new session inherits parameter values from the instance-wide values.

Presenting the list parameter values in this format enables you to quickly determine the values for a list parameter. For example, if a parameter value is *a*, *b*, then the V\$SYSTEM\_PARAMETER view does not tell you if the parameter has two values (both *a* and *b*) or one value (*a*, *b*). V\$SYSTEM\_PARAMETER2 makes the distinction between the list parameter values clear.

| Column | Datatype       | Description                                                                                                                                                                                       |

|-----------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DISPLAY_VALUE         | VARCHAR2(4000) | Parameter value in a user-friendly format. For example, if the VALUE column shows the value 262144 for a big integer parameter, then the DISPLAY_VALUE column will show the value 256K.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ISDEFAULT             | VARCHAR2(6)    | Indicates whether the parameter is set to the default value (TRUE) or the parameter value was specified in the parameter file (FALSE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ISSES_MODIFIABLE      | VARCHAR2(5)    | Indicates whether the parameter can be changed with ALTER SESSION (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ISSYS_MODIFIABLE      | VARCHAR2(9)    | Indicates whether the parameter can be changed with ALTER SYSTEM and when the change takes effect: <ul style="list-style-type: none"> <li>IMMEDIATE - Parameter can be changed with ALTER SYSTEM regardless of the type of parameter file used to start the instance. The change takes effect immediately.</li> <li>DEFERRED - Parameter can be changed with ALTER SYSTEM regardless of the type of parameter file used to start the instance. The change takes effect in subsequent sessions.</li> <li>FALSE - Parameter cannot be changed with ALTER SYSTEM unless a server parameter file was used to start the instance. The change takes effect in subsequent instances.</li> </ul> |
| ISPDB_MODIFIABLE      | VARCHAR2(5)    | Indicates whether the parameter can be modified on a per-PDB basis (TRUE) or not (FALSE).<br>In a non-CDB, the value of this column is NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ISINSTANCE_MODIFIABLE | VARCHAR2(5)    | For parameters that can be changed with ALTER SYSTEM, indicates whether the value of the parameter can be different for every instance (TRUE) or whether the parameter must have the same value for all Real Application Clusters instances (FALSE). If the ISSYS_MODIFIABLE column is FALSE, then this column is always FALSE.                                                                                                                                                                                                                                                                                                                                                          |
| ISMODIFIED            | VARCHAR2(8)    | Indicates how the parameter was modified. If an ALTER SYSTEM was performed, the value will be MODIFIED.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ISADJUSTED            | VARCHAR2(5)    | Indicates whether Oracle adjusted the input value to a more suitable value (for example, the parameter value should be prime, but the user input a non-prime number, so Oracle adjusted the value to the next prime number)                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ISDEPRECATED          | VARCHAR2(5)    | Indicates whether the parameter has been deprecated (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ISBASIC               | VARCHAR2(5)    | Indicates whether the parameter is a basic parameter (TRUE) or not (FALSE)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DESCRIPTION           | VARCHAR2(255)  | Description of the parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ORDINAL               | NUMBER         | Position (ordinal number) of the parameter value. Useful only for parameters whose values are lists of strings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| UPDATE_COMMENT        | VARCHAR2(255)  | Comments associated with the most recent update                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| HASH                  | NUMBER         | Hash value for the parameter name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| CPU                  | NUMBER       | Total amount of CPU time consumed while implementing waits from this wait class (in microseconds)                                                                                                                                                                                                                                                                                                                                               |
| TOTAL_WAITS_FG       | NUMBER       | Total number of waits for this wait class, from foreground sessions                                                                                                                                                                                                                                                                                                                                                                             |
| TIME_WAITED_FG       | NUMBER       | Total amount of time spent in waits from this wait class, from foreground sessions (in hundredths of a second)                                                                                                                                                                                                                                                                                                                                  |
| TIME_WAITED_MICRO_FG | NUMBER       | Total amount of time spent in waits from this wait class, from foreground sessions (in microseconds)                                                                                                                                                                                                                                                                                                                                            |
| CPU_FG               | NUMBER       | Total amount of CPU time consumed while implementing waits from this wait class, from foreground sessions (in microseconds)                                                                                                                                                                                                                                                                                                                     |
| CON_ID               | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

This view returns instance-wide data and a value of 0 in the `CON_ID` column when queried from the root of a CDB.

## 10.104 V\$TABLESPACE

V\$TABLESPACE displays tablespace information from the control file.

| Column                      | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TS#                         | NUMBER       | Tablespace number                                                                                                                                                                                                                                                                                                                                                                                                                 |
| NAME                        | VARCHAR2(30) | Tablespace name                                                                                                                                                                                                                                                                                                                                                                                                                   |
| INCLUDED_IN_DATABASE_BACKUP | VARCHAR2(3)  | Indicates whether the tablespace is included in full database backups using the <code>BACKUP DATABASE RMAN</code> command (YES) or not (NO); NO only if the <code>CONFIGURE EXCLUDE RMAN</code> command was used for this tablespace                                                                                                                                                                                              |
| BIGFILE                     | VARCHAR2(3)  | Indicates whether the tablespace is a bigfile tablespace (YES) or a smallfile tablespace (NO)                                                                                                                                                                                                                                                                                                                                     |
| FLASHBACK_ON                | VARCHAR2(3)  | Indicates whether the tablespace participates in FLASHBACK DATABASE operations (YES) or not (NO)                                                                                                                                                                                                                                                                                                                                  |
| ENCRYPT_IN_BACKUP           | VARCHAR2(3)  | Indicates whether encryption is turned ON or off at the tablespace level: <ul style="list-style-type: none"> <li>ON - Encryption is turned ON at the tablespace level</li> <li>OFF - Encryption is turned OFF at the tablespace level</li> <li>NULL - Encryption is neither explicitly turned on nor off at the tablespace level (default or when cleared)</li> </ul>                                                             |
| CON_ID                      | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li>n: Where n is the applicable container ID for the rows containing data</li> </ul> |

## 10.105 V\$TEMP\_CACHE\_TRANSFER

V\$TEMP\_CACHE\_TRANSFER is deprecated. The information that was provided in this view is now provided in the V\$INSTANCE\_CACHE\_TRANSFER and V\$SEGMENT\_STATISTICS views.

| Column                | Datatype | Description                                                   |
|-----------------------|----------|---------------------------------------------------------------|
| FILE_NUMBER           | NUMBER   | Number of the temp file                                       |
| X_2_NULL              | NUMBER   | Number of blocks with Exclusive-to-NULL conversions; always 0 |
| X_2_NULL_FORCED_WRITE | NUMBER   | Number of Exclusive-to-NULL forced writes; always 0           |
| X_2_NULL_FORCED_STALE | NUMBER   | Number of Exclusive-to-NULL blocks converted to CR; always 0  |

| Column                | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X_2_S                 | NUMBER   | Number of blocks with Exclusive-to-Shared conversions; always 0                                                                                                                                                                                                                                                                                                                                                                                 |

This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.107 V\$temp\_extent\_pool

V\$temp\_extent\_pool displays the state of temporary space cached and used for the instance. Note that loading of the temporary space cache is lazy and that instances can be dormant.

| Column          | Datatype     | NULL     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| RELATIVE_FNO    | NUMBER       |          | Relative file number                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CON_ID          | NUMBER       |          | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.108 V\$temp\_space\_header

V\$temp\_space\_header displays aggregate information per file per LOCALLY MANAGED temporary tablespace regarding how much space is currently being used and how much is free as identified in the space header.

| Column          | Datatype     | NULL     | Description                      |
|-----------------|--------------|----------|----------------------------------|
| TABLESPACE_NAME | VARCHAR2(30) | NOT NULL | Name of the temporary tablespace |

| Column       | Datatype | NULL | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILE_ID      | NUMBER   |      | Absolute file number                                                                                                                                                                                                                                                                                                                                                                                                                               |

## 10.111 V\$TEMPSEG\_USAGE

V\$TEMPSEG\_USAGE describes temporary segment usage.

| Column       | Datatype      | Description                                                                                                                                                  |
|--------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USERNAME     | VARCHAR2(128) | User who requested temporary space                                                                                                                           |
| USER         | VARCHAR2(128) | This column is obsolete and maintained for backward compatibility. The value of this column is always equal to the value in USERNAME.                        |
| SESSION_ADDR | RAW(4   8)    | Session address                                                                                                                                              |
| SESSION_NUM  | NUMBER        | Serial number of session                                                                                                                                     |
| SQLADDR      | RAW(4   8)    | Address of SQL statement                                                                                                                                     |
| SQLHASH      | NUMBER        | Hash value of SQL statement                                                                                                                                  |
| SQL_ID       | VARCHAR2(13)  | SQL identifier of SQL statement                                                                                                                              |
| TABLESPACE   | VARCHAR2(30)  | Tablespace in which space is allocated                                                                                                                       |
| CONTENTS     | VARCHAR2(9)   | Indicates whether tablespace is TEMPORARY or PERMANENT                                                                                                       |
| SEGTYPE      | VARCHAR2(9)   | Type of sort segment: <ul style="list-style-type: none"> <li>SORT</li> <li>HASH</li> <li>DATA</li> <li>INDEX</li> <li>LOB_DATA</li> <li>LOB_INDEX</li> </ul> |
| SEGFILE#     | NUMBER        | File number of initial extent                                                                                                                                |
| SEGBLK#      | NUMBER        | Block number of the initial extent                                                                                                                           |
| EXTENTS      | NUMBER        | Extents allocated to the sort                                                                                                                                |

| Column         | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BLOCKS         | NUMBER       | Extents in blocks allocated to the sort                                                                                                                                                                                                                                                                                                                                                                                                         |
| SEGRFNO#       | NUMBER       | Relative file number of initial extent                                                                                                                                                                                                                                                                                                                                                                                                          |
| TS#            | NUMBER       | Tablespace number                                                                                                                                                                                                                                                                                                                                                                                                                               |
| CON_ID         | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| SQL_ID_TEMPSEG | VARCHAR2(13) | SQL identifier of the SQL statement that created the temporary segment                                                                                                                                                                                                                                                                                                                                                                          |

## 10.112 V\$TEMPSTAT

V\$TEMPSTAT displays information about file read/write statistics.

| Column         | Datatype | Description                                                                                                                |
|----------------|----------|----------------------------------------------------------------------------------------------------------------------------|
| FILE#          | NUMBER   | Number of the file                                                                                                         |
| PHYRDS         | NUMBER   | Number of physical reads done                                                                                              |
| PHYWRTS        | NUMBER   | Number of times DBWR is required to write                                                                                  |
| PHYBLKRD       | NUMBER   | Number of physical blocks read                                                                                             |
| PHYBLKWRT      | NUMBER   | Number of blocks written to disk, which may be the same as PHYWRTS if all writes are single blocks                         |
| SINGLEBLKRDS   | NUMBER   | Number of single block reads                                                                                               |
| READTIM        | NUMBER   | Time (in hundredths of a second) spent doing reads if the TIMED_STATISTICS parameter is true; 0 if false                   |
| WRITETIM       | NUMBER   | Time (in hundredths of a second) spent doing writes if the TIMED_STATISTICS parameter is true; 0 if false                  |
| SINGLEBLKRDTIM | NUMBER   | Cumulative single block read time (in hundredths of a second)                                                              |
| AVGIOTIM       | NUMBER   | Average time (in hundredths of a second) spent on I/O, if the TIMED_STATISTICS parameter is true; 0 if false               |
| LSTIOTIM       | NUMBER   | Time (in hundredths of a second) spent doing the last I/O, if the TIMED_STATISTICS parameter is true; 0 if false           |
| MINIOTIM       | NUMBER   | Minimum time (in hundredths of a second) spent on a single I/O, if the TIMED_STATISTICS parameter is true; 0 if false      |
| MAXIORTM       | NUMBER   | Maximum time (in hundredths of a second) spent doing a single read, if the TIMED_STATISTICS parameter is true; 0 if false  |
| MAXIOWTM       | NUMBER   | Maximum time (in hundredths of a second) spent doing a single write, if the TIMED_STATISTICS parameter is true; 0 if false |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.113 V\$TEMPUNDOSTAT

V\$TEMPUNDOSTAT shows various statistics related to the temporary undo log for this database instance. It displays a histogram of statistical data to show how the system is working. Each row in the view keeps statistics collected in the instance for a 10-minute interval. The rows are in the descending order of the BEGIN\_TIME column value. This view contains a total of 576 rows, spanning a 4-day cycle. This view is similar to the V\$UNDOSTAT view.

| Column         | Datatype     | Description                                                                                                                                                                                                                                                                                         |
|----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BEGIN_TIME     | DATE         | Identifies the beginning of the time interval                                                                                                                                                                                                                                                       |
| END_TIME       | DATE         | Identifies the end of the time interval                                                                                                                                                                                                                                                             |
| UNDOTSN        | NUMBER       | Represents the last active undo tablespace in the duration of time. The tablespace ID of the active undo tablespace is returned in this column. If more than one undo tablespace was active in that period, the active undo tablespace that was active at the end of the period is reported.        |
| TXNCOUNT       | NUMBER       | Total number of transaction that have bound to the temp undo segment contained in above tablespace within the interval period                                                                                                                                                                       |
| MAXCONCURRENCY | NUMBER       | Highest number of transactions executed concurrently which modified temporary objects within the interval period                                                                                                                                                                                    |
| MAXQUERYLEN    | NUMBER       | Reserved for future use                                                                                                                                                                                                                                                                             |
| MAXQUERYID     | VARCHAR2(13) | Reserved for future use                                                                                                                                                                                                                                                                             |
| UNDOBLKCNT     | NUMBER       | Total number of temporary undo blocks consumed                                                                                                                                                                                                                                                      |
| EXTCNT         | NUMBER       | Total number of extents consumed                                                                                                                                                                                                                                                                    |
| USCOUNT        | NUMBER       | Temp undo segments created in this period                                                                                                                                                                                                                                                           |
| SSOLDERRCNT    | NUMBER       | Identifies the number of times the error ORA-01555 occurred. You can use this statistic to decide whether or not the UNDO_RETENTION initialization parameter is set properly given the size of the undo tablespace. Increasing the value of UNDO_RETENTION can reduce the occurrence of this error. |

| Column        | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NOSPACEERRCNT | NUMBER   | Total number of times the error 'no space left for temporary undo' was raised                                                                                                                                                                                                                                                                                                                                                                   |
| CON_ID        | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.114 V\$THREAD

V\$THREAD displays thread information from the control file. This view does not return meaningful results on a physical standby database.

| Column              | Datatype     | Description                                                      |
|---------------------|--------------|------------------------------------------------------------------|
| THREAD#             | NUMBER       | Thread number                                                    |
| STATUS              | VARCHAR2(6)  | Thread status (OPEN CLOSED)                                      |
| ENABLED             | VARCHAR2(8)  | Enabled status: DISABLED, (enabled) PRIVATE, or (enabled) PUBLIC |
| GROUPS              | NUMBER       | Number of log groups assigned to this thread                     |
| INSTANCE            | VARCHAR2(80) | Instance name, if available                                      |
| OPEN_TIME           | DATE         | Last time the thread was opened                                  |
| CURRENT_GROUP#      | NUMBER       | Current log group                                                |
| SEQUENCE#           | NUMBER       | Sequence number of current log                                   |
| CHECKPOINT_CHANGE#  | NUMBER       | SCN at last checkpoint                                           |
| CHECKPOINT_TIME     | DATE         | Time of last checkpoint                                          |
| ENABLE_CHANGE#      | NUMBER       | SCN at which thread was enabled                                  |
| ENABLE_TIME         | DATE         | Time of enable SCN                                               |
| DISABLE_CHANGE#     | NUMBER       | SCN at which thread was disabled                                 |
| DISABLE_TIME        | DATE         | Time of disable SCN                                              |
| LAST_REDO_SEQUENCE# | NUMBER       | Last redo sequence number written by LGWR                        |
| LAST_REDO_BLOCK     | NUMBER       | Last redo block written by LGWR                                  |
| LAST_REDO_CHANGE#   | NUMBER       | SCN of last redo for the thread                                  |
| LAST_REDO_TIME      | DATE         | Time of last redo for the thread                                 |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.115 V\$THRESHOLD\_TYPES

V\$THRESHOLD\_TYPES displays information about threshold types.

| Column            | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| METRICS_ID        | NUMBER       | Metrics ID                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| METRICS_GROUP_ID  | NUMBER       | Metrics group ID                                                                                                                                                                                                                                                                                                                                                                                                                                |
| OPERATOR_MASK     | NUMBER       | Operator mask                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| OBJECT_TYPE       | VARCHAR2(64) | Object type: <ul style="list-style-type: none"> <li>SYSTEM</li> <li>FILE</li> <li>SERVICE</li> <li>EVENT_CLASS</li> <li>TABLESPACE</li> <li>SESSION</li> </ul>                                                                                                                                                                                                                                                                                  |
| ALERT_REASON_ID   | NUMBER       | ID of the alert reason                                                                                                                                                                                                                                                                                                                                                                                                                          |
| METRIC_VALUE_TYPE | NUMBER       | Metric value type                                                                                                                                                                                                                                                                                                                                                                                                                               |
| CON_ID            | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.116 V\$TIMER

V\$TIMER displays the elapsed time in hundredths of a second. Time is measured since the beginning of the epoch, which is operating system specific, and wraps around to 0 again whenever the value overflows four bytes (roughly 497 days).

| Column | Datatype | Description                              |
|--------|----------|------------------------------------------|
| HSECS  | NUMBER   | Elapsed time (in hundredths of a second) |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.117 V\$TIMEZONE\_NAMES

V\$TIMEZONE\_NAMES displays valid time zone names.

| Column   | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TZNAME   | VARCHAR2(64) | Time zone region (for example, US/Pacific)                                                                                                                                                                                                                                                                                                                                                                                                      |
| TZABBREV | VARCHAR2(64) | Corresponding daylight abbreviation (for example, PDT)                                                                                                                                                                                                                                                                                                                                                                                          |
| CON_ID   | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.118 V\$TOPLEVELCALL

V\$TOPLEVELCALL displays the mapping between Oracle top level calls and names.

| Column              | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TOP_LEVEL_CALL#     | NUMBER       | Oracle top level call number                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TOP_LEVEL_CALL_NAME | VARCHAR2(64) | Oracle top level call name                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CON_ID              | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.119 V\$TRANSACTION

V\$TRANSACTION lists the active transactions in the system.

| Column       | Datatype      | Description                                                                                                                            |
|--------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| ADDR         | RAW(4   8)    | Address of the transaction state object                                                                                                |
| XIDUSN       | NUMBER        | Undo segment number                                                                                                                    |
| XIDSLOT      | NUMBER        | Slot number                                                                                                                            |
| XIDSQN       | NUMBER        | Sequence number                                                                                                                        |
| UBAFIL       | NUMBER        | Undo block address (UBA) filenum                                                                                                       |
| UBABLK       | NUMBER        | UBA block number                                                                                                                       |
| UBASQN       | NUMBER        | UBA sequence number                                                                                                                    |
| UBAREC       | NUMBER        | UBA record number                                                                                                                      |
| STATUS       | VARCHAR2(16)  | Status                                                                                                                                 |
| START_TIME   | VARCHAR2(20)  | Start time (wall clock)                                                                                                                |
| START_SCNB   | NUMBER        | Start system change number (SCN) base                                                                                                  |
| START_SCNW   | NUMBER        | Start SCN wrap                                                                                                                         |
| START_UEXT   | NUMBER        | Start extent number                                                                                                                    |
| START_UBAFIL | NUMBER        | Start UBA file number                                                                                                                  |
| START_UBABLK | NUMBER        | Start UBA block number                                                                                                                 |
| START_UBASQN | NUMBER        | Start UBA sequence number                                                                                                              |
| START_UBAREC | NUMBER        | Start UBA record number                                                                                                                |
| SES_ADDR     | RAW(4   8)    | User session object address                                                                                                            |

|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REQUEST | NUMBER   | Lock mode in which the process requests the lock: <ul style="list-style-type: none"> <li>• 0 - none</li> <li>• 1 - null (NULL)</li> <li>• 2 - row-S (SS)</li> <li>• 3 - row-X (SX)</li> <li>• 4 - share (S)</li> <li>• 5 - S/Row-X (SSX)</li> <li>• 6 - exclusive (X)</li> </ul>                                                                                                                                                                      |
| CTIME   | NUMBER   | Time since current mode was granted                                                                                                                                                                                                                                                                                                                                                                                                                   |
| BLOCK   | NUMBER   | The lock is blocking another lock                                                                                                                                                                                                                                                                                                                                                                                                                     |
| CON_ID  | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.121 V\$TRANSPORTABLE\_PLATFORM

V\$TRANSPORTABLE\_PLATFORM displays all platforms that support cross-platform tablespace transport. Specifically, it lists all platforms supported by the RMAN CONVERT TABLESPACE command, along with the endianness of each platform.

| Column        | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLATFORM_ID   | NUMBER        | Platform identification number                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PLATFORM_NAME | VARCHAR2(101) | Platform name                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ENDIAN_FORMAT | VARCHAR2(14)  | Platform endian format: <ul style="list-style-type: none"> <li>• Big</li> <li>• Little</li> <li>• UNKNOWN FORMAT</li> </ul>                                                                                                                                                                                                                                                                                                                           |
| CON_ID        | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.122 V\$TSDP\_SUPPORTED\_FEATURE

V\$TSDP\_SUPPORTED\_FEATURE displays information about the features supported by Transparent Sensitive Data Protection (TSDP).

| Column        | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEATURE_NAME  | VARCHAR2(200)  | The name of the supported feature                                                                                                                                                                                                                                                                                                                                                                                                               |
| FUNCTIONALITY | VARCHAR2(200)  | The functionality that is supported within the feature. If all of the functionality of the feature is supported, the value is ALL, otherwise the value will show the specific functionality that is supported.                                                                                                                                                                                                                                  |
| COMMENT\$\$   | VARCHAR2(4000) | More information regarding the support for the feature and the specific functionality                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID        | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.123 V\$TYPE\_SIZE

V\$TYPE\_SIZE displays the sizes of various database components for use in estimating data block capacity.

| Column      | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMPONENT   | VARCHAR2(8)  | Component name, such as segment or buffer header                                                                                                                                                                                                                                                                                                                                                                                                |
| TYPE        | VARCHAR2(8)  | Component type                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DESCRIPTION | VARCHAR2(32) | Description of the component                                                                                                                                                                                                                                                                                                                                                                                                                    |
| TYPE_SIZE   | NUMBER       | Size of the component                                                                                                                                                                                                                                                                                                                                                                                                                           |
| CON_ID      | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.124 V\$UNDOSTAT

V\$UNDOSTAT displays a histogram of statistical data to show how well the system is working. The available statistics include undo space consumption, transaction concurrency, and length of queries executed in the instance. You can use this view to estimate the amount of undo space required for the current workload. Oracle uses

this view to tune undo usage in the system. The view returns NULL values if the system is in manual undo management mode. Each row in the view keeps statistics collected in the instance for a 10-minute interval. The rows are in descending order by the `BEGIN_TIME` column value. Each row belongs to the time interval marked by (`BEGIN_TIME`, `END_TIME`). Each column represents the data collected for the particular statistic in that time interval. The first row of the view contains statistics for the (partial) current time period. The view contains a total of 576 rows, spanning a 4 day cycle.

| Column                      | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BEGIN_TIME</code>     | DATE         | Identifies the beginning of the time interval                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>END_TIME</code>       | DATE         | Identifies the end of the time interval                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>UNDOTSN</code>        | NUMBER       | Represents the last active undo tablespace in the duration of time. The tablespace ID of the active undo tablespace is returned in this column. If more than one undo tablespace was active in that period, the active undo tablespace that was active at the end of the period is reported.                                                                                                                                                       |
| <code>UNDOBLKS</code>       | NUMBER       | Represents the total number of undo blocks consumed. You can use this column to obtain the consumption rate of undo blocks, and thereby estimate the size of the undo tablespace needed to handle the workload on your system.                                                                                                                                                                                                                     |
| <code>TXNCOUNT</code>       | NUMBER       | Identifies the total number of transactions executed within the period                                                                                                                                                                                                                                                                                                                                                                             |
| <code>MAXQUERYLEN</code>    | NUMBER       | Identifies the length of the longest query (in seconds) executed in the instance during the period. You can use this statistic to estimate the proper setting of the <code>UNDO_RETENTION</code> initialization parameter. The length of a query is measured from the cursor open time to the last fetch/execute time of the cursor. Only the length of those cursors that have been fetched/executed during the period are reflected in the view. |
| <code>MAXQUERYID</code>     | VARCHAR2(13) | SQL identifier of the longest running SQL statement in the period                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>MAXCONCURRENCY</code> | NUMBER       | Identifies the highest number of transactions executed concurrently within the period                                                                                                                                                                                                                                                                                                                                                              |
| <code>UNXPSTEALCNT</code>   | NUMBER       | Number of attempts to obtain undo space by stealing unexpired extents from other transactions                                                                                                                                                                                                                                                                                                                                                      |
| <code>UNXPBLKRELCNT</code>  | NUMBER       | Number of unexpired blocks removed from certain undo segments so they can be used by other transactions                                                                                                                                                                                                                                                                                                                                            |
| <code>UNXPBLKREUCNT</code>  | NUMBER       | Number of unexpired undo blocks reused by transactions                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>EXPSTEALCNT</code>    | NUMBER       | Number of attempts to steal expired undo blocks from other undo segments                                                                                                                                                                                                                                                                                                                                                                           |
| <code>EXPBLKRELCNT</code>   | NUMBER       | Number of expired undo blocks stolen from other undo segments                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>EXPBLKREUCNT</code>   | NUMBER       | Number of expired undo blocks reused within the same undo segments                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>SSOLDERRCNT</code>    | NUMBER       | Identifies the number of times the error <code>ORA-01555</code> occurred. You can use this statistic to decide whether or not the <code>UNDO_RETENTION</code> initialization parameter is set properly given the size of the undo tablespace. Increasing the value of <code>UNDO_RETENTION</code> can reduce the occurrence of this error.                                                                                                         |

| Column              | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NOSPACEERRCNT       | NUMBER   | Identifies the number of times space was requested in the undo tablespace and there was no free space available. That is, all of the space in the undo tablespace was in use by active transactions. The corrective action is to add more space to the undo tablespace.                                                                                                                                                                         |
| ACTIVEBLKS          | NUMBER   | Total number of blocks in the active extents of the undo tablespace for the instance at the sampled time in the period                                                                                                                                                                                                                                                                                                                          |
| UNEXPIREDBLKS       | NUMBER   | Total number of blocks in the unexpired extents of the undo tablespace for the instance at the sampled time in the period                                                                                                                                                                                                                                                                                                                       |
| EXPIREDBLKS         | NUMBER   | Total number of blocks in the expired extents of the undo tablespace for the instance at the sampled time in the period                                                                                                                                                                                                                                                                                                                         |
| TUNED_UNDORETENTION | NUMBER   | Amount of time (in seconds) for which undo will not be recycled from the time it was committed. At any point in time, the latest value of TUNED_UNDORETENTION is used to determine whether data committed at a particular time in the past can be recycled.                                                                                                                                                                                     |
| CON_ID              | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.125 V\$UNUSABLE\_BACKUPFILE\_DETAILS

V\$UNUSABLE\_BACKUPFILE\_DETAILS displays information about all backup files (backup pieces, proxy copies, or copies) that are marked unavailable and expired. You can select one of the rows and use BTYPE\_KEY or FILETYPE\_KEY to change the status of a backup file set or a specific file to available.

| Column            | Datatype | Description                                                                  |
|-------------------|----------|------------------------------------------------------------------------------|
| SESSION_KEY       | NUMBER   | Session identifier                                                           |
| SESSION_RECID     | NUMBER   | Session record ID                                                            |
| SESSION_STAMP     | NUMBER   | Session stamp                                                                |
| RMAN_STATUS_RECID | NUMBER   | Record ID of the corresponding row in the control file                       |
| RMAN_STATUS_STAMP | NUMBER   | Timestamp of the row in the controlfile                                      |
| BTYPE             | CHAR(9)  | Backup type container. Possible values are: BACKUPSET, IMAGECOPY, PROXYCOPY. |
| BTYPE_KEY         | NUMBER   | Unique identifier for the backup type, either BS_KEY or COPY_KEY.            |

| Column       | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID1          | NUMBER        | If BACKUPSET, it contains SET_STAMP.<br>If IMAGECOPY or PROXYCOPY, it is RECID from the control file.                                                                                                                                                                                                                                                                                                                                           |
| ID2          | NUMBER        | If BACKUPSET, it contains SET_COUNT.<br>If IMAGECOPY or PROXYCOPY, it is STAMP.                                                                                                                                                                                                                                                                                                                                                                 |
| FILETYPE     | VARCHAR2(15)  | Type of file. Possible values are: BACKUPPIECE, COPY, PROXYCOPY.                                                                                                                                                                                                                                                                                                                                                                                |
| FILETYPE_KEY | NUMBER        | Backup piece key if the file is a backup piece; otherwise COPY_KEY.                                                                                                                                                                                                                                                                                                                                                                             |
| STATUS       | VARCHAR2(1)   | Status of the backup file, either U (unavailable) or X (expired)                                                                                                                                                                                                                                                                                                                                                                                |
| FILESIZE     | NUMBER        | Size of the file                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DEVICE_TYPE  | VARCHAR2(17)  | Type of device on which the file resides                                                                                                                                                                                                                                                                                                                                                                                                        |
| FILENAME     | VARCHAR2(513) | Name of the file                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MEDIA        | VARCHAR2(65)  | Name of the media on which the copy resides. This value is informational only. It is not needed for restore.                                                                                                                                                                                                                                                                                                                                    |
| MEDIA_POOL   | NUMBER        | Media pool in which the copy resides. This is the same value that was entered in the POOL operand of the Recovery Manager BACKUP command.                                                                                                                                                                                                                                                                                                       |
| CON_ID       | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.126 V\$VERSION

V\$VERSION displays the version number of Oracle Database. The database components have the same version number as the database, so the version number is returned only once.

| Column        | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BANNER        | VARCHAR2(80)  | Component name and version number                                                                                                                                                                                                                                                                                                                                                                                                               |
| BANNER_FULL   | VARCHAR2(160) | The new 2 line banner format introduced in Oracle Database 18c. The banner displays the database release and version number.                                                                                                                                                                                                                                                                                                                    |
| BANNER_LEGACY | VARCHAR2(80)  | The legacy 1 line banner used before Oracle Database 18c. This column displays the same value as the BANNER column.                                                                                                                                                                                                                                                                                                                             |
| CON_ID        | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.127 V\$VPD\_POLICY

V\$VPD\_POLICY displays all the fine-grained security policies and predicates associated with the cursors currently in the library cache.

| Column                | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| POLICY_FUNCTION_OWNER | VARCHAR2(128)  | Owner of the policy function                                                                                                                                                                                                                                                                                                                                                                                                                    |
| PREDICATE             | VARCHAR2(4000) | Predicate for the policy (truncated to 4000 bytes in length)                                                                                                                                                                                                                                                                                                                                                                                    |
| CON_ID                | NUMBER         | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.128 V\$WAIT\_CHAINS

V\$WAIT\_CHAINS displays information about blocked sessions. A wait chain is composed of sessions that are blocked by one another. Each row represents a blocked and blocker session pair. If a wait chain is not a cyclical wait chain, then the last row for the chain does not have a blocker.

| Column               | Datatype      | Description                                                                                                                   |
|----------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| CHAIN_ID             | NUMBER        | A number identifying the wait chain                                                                                           |
| CHAIN_IS_CYCLE       | VARCHAR2(5)   | Indicates whether the final blocked session in the wait chain is blocked by the initial blocked session (TRUE) or not (FALSE) |
| CHAIN_SIGNATURE      | VARCHAR2(801) | An Oracle-specific text signature of the wait chain. This signature can be used to identify similar wait chains.              |
| CHAIN_SIGNATURE_HASH | NUMBER        | A numeric representation of CHAIN_SIGNATURE                                                                                   |
| INSTANCE             | NUMBER        | Blocked session's instance identifier                                                                                         |
| OSID                 | VARCHAR2(25)  | Blocked session's operating system process identifier                                                                         |
| PID                  | NUMBER        | Blocked session's Oracle process identifier                                                                                   |
| SID                  | NUMBER        | Blocked session's Oracle session identifier                                                                                   |

| Column                       | Datatype     | Description                                                                                                                                                                                      |

| P3                           | NUMBER       | Third additional wait parameter; NULL if IN_WAIT is FALSE                                                                                                                                        |
| P3_TEXT                      | VARCHAR2(64) | Description of the third additional wait parameter; NULL if IN_WAIT is FALSE                                                                                                                     |
| IN_WAIT_SECS                 | NUMBER       | Seconds the blocked session has been in the current wait; NULL if IN_WAIT is FALSE                                                                                                               |
| TIME_REMAINING_SECS          | NUMBER       | Seconds remaining until the blocked session ends its wait (-1 if the blocked session can indefinitely wait); NULL if IN_WAIT is FALSE                                                            |
| NUM_WAITERS                  | NUMBER       | Number of sessions waiting for the blocked session                                                                                                                                               |

| Column          | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ROW_WAIT_OBJ#   | NUMBER   | Object ID for the table containing the row specified in ROW_WAIT_ROW#; NULL if IN_WAIT is FALSE                                                                                                                                                                                                                                                                                                                                                 |
| ROW_WAIT_FILE#  | NUMBER   | Identifier for the data file containing the row specified in ROW_WAIT_ROW#; NULL if IN_WAIT is FALSE. This column is valid only if the blocked session is currently waiting for another transaction to commit and the value of ROW_WAIT_OBJ# is not -1.                                                                                                                                                                                         |
| ROW_WAIT_BLOCK# | NUMBER   | Identifier for the block containing the row specified in ROW_WAIT_ROW#; NULL if IN_WAIT is FALSE. This column is valid only if the blocked session is currently waiting for another transaction to commit and the value of ROW_WAIT_OBJ# is not -1.                                                                                                                                                                                             |
| ROW_WAIT_ROW#   | NUMBER   | Current row being locked; NULL if IN_WAIT is FALSE. This column is valid only if the blocked session is currently waiting for another transaction to commit and the value of ROW_WAIT_OBJ# is not -1.                                                                                                                                                                                                                                           |
| CON_ID          | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.129 V\$WAITCLASSMETRIC

V\$WAITCLASSMETRIC displays metric values of wait classes for the most recent 60-second interval. A history of the last one hour will be kept in the system.

| Column               | Datatype | Description                                                                                           |
|----------------------|----------|-------------------------------------------------------------------------------------------------------|
| BEGIN_TIME           | DATE     | Begin time of the interval                                                                            |
| END_TIME             | DATE     | End time of the interval                                                                              |
| INTSIZE_CSEC         | NUMBER   | Interval size (in hundredths of a second)                                                             |
| WAIT_CLASS#          | NUMBER   | Number of the class of the wait event                                                                 |
| WAIT_CLASS_ID        | NUMBER   | Identifier of the class of the wait event                                                             |
| AVERAGE_WAITER_COUNT | NUMBER   | Average waiter count                                                                                  |
| DBTIME_IN_WAIT       | NUMBER   | Percent of database time spent in the wait                                                            |
| TIME_WAITED          | NUMBER   | Time waited during the interval (in hundredths of a second)                                           |
| WAIT_COUNT           | NUMBER   | Number of times waited                                                                                |
| TIME_WAITED_FG       | NUMBER   | Amount of time (in hundredths of a second) spent in waits from this wait class in foreground sessions |
| WAIT_COUNT_FG        | NUMBER   | Number of times foreground processes waited                                                           |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.130 V\$WAITCLASSMETRIC\_HISTORY

V\$WAITCLASSMETRIC\_HISTORY displays metric values of wait classes for all intervals in the last one hour.

The columns for V\$WAITCLASSMETRIC\_HISTORY are the same as those for V\$WAITCLASSMETRIC.

**See Also:**

"V\$WAITCLASSMETRIC"

## 10.131 V\$WAITSTAT

V\$WAITSTAT displays block contention statistics. This table is only updated when timed statistics are enabled.

| Column | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLASS  | VARCHAR2(18) | Class of the block                                                                                                                                                                                                                                                                                                                                                                                                                              |
| COUNT  | NUMBER       | Number of waits by this OPERATION for this CLASS of block                                                                                                                                                                                                                                                                                                                                                                                       |
| TIME   | NUMBER       | Sum of all wait times for all the waits by this OPERATION for this CLASS of block (in centiseconds)                                                                                                                                                                                                                                                                                                                                             |
| CON_ID | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.132 V\$WALLET

V\$WALLET displays metadata of certificates that may be used as a master key for Transparent Data Encryption.

### Note:

The use of PKI encryption with Transparent Data Encryption is deprecated. To configure Transparent Data Encryption, use the `ADMINISTER KEY MANAGEMENT` SQL statement. See *Oracle Database Advanced Security Guide* for more information.

| Column     | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CERT_ID    | VARCHAR2(52)  | A unique certificate identifier value used to specify a particular PKI certificate for use as the master key                                                                                                                                                                                                                                                                                                                                          |
| DN         | VARCHAR2(255) | Distinguished name of a particular PKI certificate                                                                                                                                                                                                                                                                                                                                                                                                    |
| SERIAL_NUM | VARCHAR2(40)  | Unique serial number assigned to a certificate by the issuer or signer                                                                                                                                                                                                                                                                                                                                                                                |
| ISSUER     | VARCHAR2(255) | Distinguished name of the Certificate Authority or issuer that issued and signed the certificate                                                                                                                                                                                                                                                                                                                                                      |
| KEYSIZE    | NUMBER        | Size of the PKI key associated with the certificate                                                                                                                                                                                                                                                                                                                                                                                                   |
| STATUS     | VARCHAR2(16)  | Current status of the certificate: <ul style="list-style-type: none"> <li>• UNUSED</li> <li>• IN USE</li> <li>• USED</li> </ul> This column allows the user to identify whether a certificate is currently in use or has already been used for Transparent Data Encryption.                                                                                                                                                                           |
| CON_ID     | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>• 1: This value is used for rows containing data that pertain to only the root</li> <li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.133 V\$WORKLOAD\_REPLAY\_THREAD

V\$WORKLOAD\_REPLAY\_THREAD displays information for all the different types of replay sessions.

| Column | Datatype | Description                                                     |
|--------|----------|-----------------------------------------------------------------|
| CLOCK  | NUMBER   | Current simulated SCN based on the SCN recorded at capture time |

| Column          | Datatype      | Description                                                                                                                                                                                                      |
|-----------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NEXT_TICKER     | NUMBER        | Next stream ID that will increment the <code>CLOCK</code> after a commit action                                                                                                                                  |
| SID             | NUMBER        | Session ID of the replay session                                                                                                                                                                                 |
| SERIAL#         | NUMBER        | Session serial number of the replay session                                                                                                                                                                      |
| SPID            | VARCHAR2(24)  | The server process ID of the replay session                                                                                                                                                                      |
| LOGON_USER      | VARCHAR2(128) | Logon username of the replay session                                                                                                                                                                             |
| LOGON_TIME      | DATE          | Logon time of the replay session                                                                                                                                                                                 |
| EVENT           | VARCHAR2(64)  | Event name                                                                                                                                                                                                       |
| EVENT_ID        | NUMBER        | Event identifier                                                                                                                                                                                                 |
| EVENT#          | NUMBER        | Event operation code                                                                                                                                                                                             |
| P1TEXT          | VARCHAR2(64)  | Text for event parameter 1                                                                                                                                                                                       |
| P1              | NUMBER        | Value of event parameter 1                                                                                                                                                                                       |
| P2TEXT          | VARCHAR2(64)  | Text for event parameter 2                                                                                                                                                                                       |
| P2              | NUMBER        | Value of event parameter 2                                                                                                                                                                                       |
| P3TEXT          | VARCHAR2(64)  | Text for event parameter 3                                                                                                                                                                                       |
| P3              | NUMBER        | Value of event parameter 3                                                                                                                                                                                       |
| WAIT_FOR_SCN    | NUMBER        | The captured SCN for which the current user call should wait                                                                                                                                                     |
| FILE_ID         | NUMBER        | The stream ID that is being replayed                                                                                                                                                                             |
| CALL_COUNTER    | NUMBER        | The call counter of the user call that is being replayed                                                                                                                                                         |
| DEPENDENT_SCN   | NUMBER        | The dependent SCN, captured to order the commit actions using block-level dependencies                                                                                                                           |
| STATEMENT_SCN   | NUMBER        | Statement SCN                                                                                                                                                                                                    |
| COMMIT_WAIT_SCN | NUMBER        | The (maximum) SCN that the current commit should wait for                                                                                                                                                        |
| POST_COMMIT_SCN | NUMBER        | The next SCN after the current commit                                                                                                                                                                            |
| ACTION_TYPE     | NUMBER        | The type of commits. The possible values are: <code>COMMIT</code> , <code>ROLLBACK</code> , <code>FAKED_COMMIT</code> , and <code>NULL</code> . A value of <code>NULL</code> means it is not a commit operation. |
| SESSION_TYPE    | VARCHAR2(13)  | The type of replay session:<br>LOGON<br>ADMIN<br>DISPATCHER<br>REPLAY                                                                                                                                            |
| WRC_ID          | NUMBER        | Unique replay client ID assigned by the server to all participating replay clients when replay starts                                                                                                            |
| SCHEDULE_CAP_ID | NUMBER        | An unique identifier for a workload capture added to a replay schedule. A value of 0 is used for a non-consolidated replay.                                                                                      |
| FILE_NAME       | VARCHAR2(51)  | File name of the captured stream                                                                                                                                                                                 |
| SKIP_IT         | VARCHAR2(1)   | Whether or not the current replayed user call is skipped or not                                                                                                                                                  |
| DIRTY_BUFFERS   | VARCHAR2(1)   | Reserved for internal use                                                                                                                                                                                        |
| DBTIME          | NUMBER        | Accumulated database time for the replay session                                                                                                                                                                 |
| NETWORK_TIME    | NUMBER        | Accumulated network time for the replay session                                                                                                                                                                  |
| THINK_TIME      | NUMBER        | Accumulated think time for the replay session                                                                                                                                                                    |

---

| Column               | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIME_GAIN            | NUMBER       | If nonzero, the accumulated time in macro seconds indicating how fast the replay is                                                                                                                                                                                                                                                                                                                                                               |
| TIME_LOSS            | NUMBER       | If nonzero, the accumulated time in macro seconds indicating how slow the replay is                                                                                                                                                                                                                                                                                                                                                               |
| USER_CALLS           | NUMBER       | Total number of user calls                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PLSQL_CALLS          | NUMBER       | Total number of PL/SQL calls recorded in the workload capture                                                                                                                                                                                                                                                                                                                                                                                     |
| PLSQL_SUBCALLS       | NUMBER       | Total number of calls recorded in the workload capture for SQL executed from PL/SQL                                                                                                                                                                                                                                                                                                                                                               |
| PLSQL_DBTIME         | NUMBER       | Total amount of database time in microseconds from PL/SQL calls that have been recorded in the workload capture                                                                                                                                                                                                                                                                                                                                   |
| CLIENT_OS_USER       | VARCHAR2(15) | Operating system username of the replay client                                                                                                                                                                                                                                                                                                                                                                                                    |
| CLIENT_HOST          | VARCHAR2(64) | Host name of the replay client                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CLIENT_PID           | VARCHAR2(24) | Process ID of the replay client                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PROGRAM              | VARCHAR2(84) | Program name of the replay client                                                                                                                                                                                                                                                                                                                                                                                                                 |
| CAPTURE_ELAPSED_TIME | NUMBER       | Total amount of elapsed time of a session since capture starts (in seconds)                                                                                                                                                                                                                                                                                                                                                                       |
| REPLAY_ELAPSED_TIME  | NUMBER       | Total amount of elapsed time of a session since replay starts (in seconds)                                                                                                                                                                                                                                                                                                                                                                        |
| CON_ID               | NUMBER       | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"><li>• 0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li><li>• 1: This value is used for rows containing data that pertain to only the root</li><li>• <i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li></ul> |

---

## 10.134 V\$XML\_AUDIT\_TRAIL

V\$XML\_AUDIT\_TRAIL shows standard, fine-grained, SYS, and mandatory audit records written in XML format files.

### Note:

This view is relevant when using traditional auditing. Traditional auditing is deprecated in Oracle Database 21c. Oracle recommends that you instead use unified auditing, which enables selective and more effective auditing inside Oracle Database.

- See *Oracle Database Security Guide* for more information about unified auditing.
- See *Oracle Database Upgrade Guide* for more information about migrating to unified auditing.

This view is populated only in an Oracle Database where unified auditing is not enabled. When unified auditing is enabled in Oracle Database, the audit records are populated in the new audit trail and can be viewed from UNIFIED\_AUDIT\_TRAIL.

| Column             | Datatype                       | Description                                                                                                                                                                                         |
|--------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AUDIT_TYPE         | NUMBER                         | Type of audit row: <ul style="list-style-type: none"> <li>• 1 = Standard XML Audit</li> <li>• 2 = Fine Grained XML Audit</li> <li>• 4 = SYS XML Audit</li> <li>• 8 = Mandatory XML Audit</li> </ul> |
| SESSION_ID         | NUMBER                         | Numeric ID for the Oracle session                                                                                                                                                                   |
| PROXY_SESSIONID    | NUMBER                         | Proxy session serial number, if an enterprise user has logged in through a proxy mechanism                                                                                                          |
| STATEMENTID        | NUMBER                         | Numeric ID for the statement run (a statement may cause multiple audit records)                                                                                                                     |
| ENTRYID            | NUMBER                         | Numeric ID for the audit trail entry in the session                                                                                                                                                 |
| EXTENDED_TIMESTAMP | TIMESTAMP(6)<br>WITH TIME ZONE | Timestamp of the audited operation (the timestamp of the user's logon for entries is created by AUDIT SESSION)                                                                                      |
| GLOBAL_UID         | VARCHAR2(32)                   | Global user identifier for the user, if the user has logged in as an enterprise user                                                                                                                |
| DB_USER            | VARCHAR2(128)                  | Database username of the user whose actions were audited                                                                                                                                            |
| CLIENTIDENTIFIER   | VARCHAR2(64)                   | Client identifier in the Oracle session                                                                                                                                                             |
| EXT_NAME           | VARCHAR2(1024)                 | User's external name                                                                                                                                                                                |
| OS_USER            | VARCHAR2(128)                  | Operating system logon user name of the user whose actions were audited                                                                                                                             |
| OS_HOST            | VARCHAR2(128)                  | Client host system name                                                                                                                                                                             |
| OS_PROCESS         | VARCHAR2(16)                   | Operating system process identifier of the Oracle server process                                                                                                                                    |
| TERMINAL           | VARCHAR2(30)                   | Identifier for the user's terminal                                                                                                                                                                  |

| Column           | Datatype       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INSTANCE_NUMBER  | NUMBER         | Instance number as specified by the <code>INSTANCE_NUMBER</code> initialization parameter                                                                                                                                                                                                                                                                                                                                                                      |
| OBJECT_SCHEMA    | VARCHAR2(128)  | Owner of the audited object                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| OBJECT_NAME      | VARCHAR2(128)  | Name of the object affected by the action                                                                                                                                                                                                                                                                                                                                                                                                                      |
| POLICY_NAME      | VARCHAR2(128)  | Name of the fine-grained auditing policy                                                                                                                                                                                                                                                                                                                                                                                                                       |
| NEW_OWNER        | VARCHAR2(128)  | Owner of the object named in the <code>NEW_NAME</code> column                                                                                                                                                                                                                                                                                                                                                                                                  |
| NEW_NAME         | VARCHAR2(128)  | New name of object after renaming, or the name of an underlying object (for example, <code>CREATE INDEX owner.obj_name ON new_owner.new_name</code> )                                                                                                                                                                                                                                                                                                          |
| ACTION           | NUMBER         | Numeric code for the action type                                                                                                                                                                                                                                                                                                                                                                                                                               |
| STATEMENT_TYPE   | NUMBER         | Description of the action                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| TRANSACTIONID    | RAW(8)         | Identifier of the transaction in which the object is accessed or modified                                                                                                                                                                                                                                                                                                                                                                                      |
| RETURNCODE       | NUMBER         | Oracle error code generated by the action. Zero if the action succeeded.                                                                                                                                                                                                                                                                                                                                                                                       |
| SCN              | NUMBER         | System change number (SCN) of the query                                                                                                                                                                                                                                                                                                                                                                                                                        |
| COMMENT_TEXT     | VARCHAR2(4000) | Text comments on standard audit entries. Also indicates how the user was authenticated - the method can be one of the following: <ul style="list-style-type: none"> <li>• DATABASE - authentication was done by password</li> <li>• NETWORK - authentication was done by Oracle Net Services or the Advanced Networking Option</li> <li>• PROXY - the client was authenticated by another user. The name of the proxy user follows the method type.</li> </ul> |
| AUTH_PRIVILEGES  | VARCHAR2(32)   | Privileges granted and revoked in <code>GRANT</code> and <code>REVOKE</code> statements recorded for standard audit trail entry                                                                                                                                                                                                                                                                                                                                |
| GRANTEE          | VARCHAR2(128)  | User who granted or revoked the privilege                                                                                                                                                                                                                                                                                                                                                                                                                      |
| PRIV_USED        | NUMBER         | Numerical code of privileges, if any, used in the action                                                                                                                                                                                                                                                                                                                                                                                                       |
| SES_ACTIONS      | VARCHAR2(16)   | Session summary for standard audit records. A string of 12 characters, one for each action type, in the following order: Alter, Audit, Comment, Delete, Grant, Index, Insert, Lock, Rename, Select, Update, Flashback.<br>Values: - = None, S=Success, F=Failure, B=Both                                                                                                                                                                                       |
| OS_PRIVILEGE     | VARCHAR2(7)    | This column is populated only for administrative authentication audit records. It contains the administrative privilege used (for example, <code>SYSDBA</code> , <code>SYSOPER</code> , <code>NONE</code> ).<br>For all other types of audit records, the value of this column is null.                                                                                                                                                                        |
| ECONTEXT_ID      | VARCHAR2(64)   | Application execution context identifier                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SQL_BIND         | VARCHAR2(4000) | List of bind variables used in the statement                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SQL_TEXT         | VARCHAR2(4000) | The statement or command that triggered the audit event                                                                                                                                                                                                                                                                                                                                                                                                        |
| OBJ_EDITION_NAME | VARCHAR2(128)  | Name of the edition containing the audited object                                                                                                                                                                                                                                                                                                                                                                                                              |
| DBID             | NUMBER         | Database identifier of the audited database                                                                                                                                                                                                                                                                                                                                                                                                                    |
| RLS_INFO         | VARCHAR2(4000) | Stores virtual private database (VPD) policy names and predicates separated by delimiter.<br>To format the output into individual rows, use the <code>DBMS_AUDIT_UTIL.DECODE_RLS_INFO_ATRAIL_XML</code> function.                                                                                                                                                                                                                                              |

| Column       | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CURRENT_USER | VARCHAR2(128) | Effective user for the statement execution                                                                                                                                                                                                                                                                                                                                                                                                      |
| CON_ID       | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

The `SQL_BIND` and `SQL_TEXT` columns are only populated if the `AUDIT_TRAIL` initialization parameter is set to `xml`, `extended` or if the `AUDIT_SYS_OPERATIONS` initialization parameter is set to `TRUE`.

## 10.135 V\$XSTREAM\_APPLY\_COORDINATOR

`V$XSTREAM_APPLY_COORDINATOR` displays information about each XStream apply process coordinator. The coordinator for an apply process gets transactions from the apply process reader and passes them to apply servers. An apply process coordinator is a subcomponent of an apply process, outbound server, or inbound server.

| Column  | Datatype     | Description                                                                                                                                                                                                                                                                                                           |
|---------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID     | NUMBER       | Session ID of the coordinator's session                                                                                                                                                                                                                                                                               |
| SERIAL# | NUMBER       | Serial number of the coordinator's session                                                                                                                                                                                                                                                                            |
| STATE   | VARCHAR2(21) | State of the coordinator: <ul style="list-style-type: none"> <li>INITIALIZING - Starting up</li> <li>IDLE - Performing no work</li> <li>APPLYING - Passing transactions to apply servers</li> <li>SHUTTING DOWN CLEANLY - Stopping without an error</li> <li>ABORTING - Stopping because of an apply error</li> </ul> |

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                        |
|--------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APPLY#                   | NUMBER        | Apply process number. An apply process coordinator is an Oracle background process, prefixed by <code>ap</code> .                                                                                                                                                  |
| APPLY_NAME               | VARCHAR2(128) | Name of the apply process                                                                                                                                                                                                                                          |
| TOTAL_APPLIED            | NUMBER        | Total number of transactions applied by the apply process since the apply process was last started                                                                                                                                                                 |
| TOTAL_WAIT_DEPS          | NUMBER        | Number of times since the apply process was last started that an apply server waited to apply a logical change record (LCR) in a transaction until another apply server applied a transaction because of a dependency between the transactions                     |
| TOTAL_WAIT_COMMITS       | NUMBER        | Number of times since the apply process was last started that an apply server waited to commit a transaction until another apply server committed a transaction to serialize commits                                                                               |
| TOTAL_ADMIN              | NUMBER        | Number of administrative jobs issued since the apply process was last started                                                                                                                                                                                      |
| TOTAL_ASSIGNED           | NUMBER        | Number of transactions assigned to apply servers since the apply process was last started                                                                                                                                                                          |
| TOTAL_RECEIVED           | NUMBER        | Total number of transactions received by the coordinator process since the apply process was last started                                                                                                                                                          |
| TOTAL_IGNORED            | NUMBER        | Number of transactions which were received by the coordinator but were ignored because they had been previously applied                                                                                                                                            |
| TOTAL_ROLLBACKS          | NUMBER        | Number of transactions which were rolled back due to unexpected contention                                                                                                                                                                                         |
| TOTAL_ERRORS             | NUMBER        | Number of transactions applied by the apply process that resulted in an apply error since the apply process was last started                                                                                                                                       |
| UNASSIGNED_COMPLETE_TXNS | NUMBER        | Total number of complete transactions that the coordinator has not assigned to any apply servers                                                                                                                                                                   |
| LWM_TIME                 | DATE          | Time when the message with the lowest message number was recorded. The creation time of the message with the lowest message number was also recorded at this time.                                                                                                 |
| LWM_MESSAGE_NUMBER       | NUMBER        | Number of the message corresponding to the low watermark. That is, messages with a commit message number less than or equal to this message number have definitely been applied, but some messages with a higher commit message number also may have been applied. |
| LWM_MESSAGE_CREATE_TIME  | DATE          | For captured messages, creation time at the source database of the message corresponding to the low watermark. For user-enqueued messages, time when the message corresponding to the low watermark was enqueued into the queue at the local database.             |
| HWM_TIME                 | DATE          | Time when the message with the highest message number was recorded. The creation time of the message with the highest message number was also recorded at this time.                                                                                               |
| HWM_MESSAGE_NUMBER       | NUMBER        | Number of the message corresponding to the high watermark. That is, no messages with a commit message number greater than this message number have been applied.                                                                                                   |
| HWM_MESSAGE_CREATE_TIME  | DATE          | For captured messages, creation time at the source database of the message corresponding to the high watermark. For user-enqueued messages, time when the message corresponding to the high watermark was enqueued into the queue at the local database.           |

| Column                   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STARTUP_TIME             | DATE     | Time when the apply process was last started                                                                                                                                                                                                                                                                                                                                                                                                    |
| ELAPSED_SCHEDULE_TIME    | NUMBER   | Time elapsed (in hundredths of a second) scheduling messages since the apply process was last started                                                                                                                                                                                                                                                                                                                                           |
| ELAPSED_IDLE_TIME        | NUMBER   | Elapsed idle time                                                                                                                                                                                                                                                                                                                                                                                                                               |
| LWM_POSITION             | RAW(64)  | Position of the low-watermark LCR                                                                                                                                                                                                                                                                                                                                                                                                               |
| HWM_POSITION             | RAW(64)  | Position of the high-watermark LCR                                                                                                                                                                                                                                                                                                                                                                                                              |
| PROCESSED_MESSAGE_NUMBER | NUMBER   | Message number currently processed by the apply coordinator                                                                                                                                                                                                                                                                                                                                                                                     |
| CON_ID                   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| ACTIVE_SERVER_COUNT      | NUMBER   | Active server count                                                                                                                                                                                                                                                                                                                                                                                                                             |

 **Note:**

The `ELAPSED_SCHEDULE_TIME` column is only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

## 10.136 V\$XSTREAM\_APPLY\_READER

`V$XSTREAM_APPLY_READER` displays information about each XStream apply reader. The apply reader is a process which reads (dequeues) messages from the queue, computes message dependencies, and builds transactions. It passes the transactions on to the coordinator in commit order for assignment to the apply servers. An apply reader is a subcomponent of an apply process, outbound server, or inbound server.

| Column  | Datatype | Description                           |
|---------|----------|---------------------------------------|
| SID     | NUMBER   | Session ID of the reader's session    |
| SERIAL# | NUMBER   | Serial number of the reader's session |

| Column                         | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| APPLY#                         | NUMBER        | Apply process number. An apply process is an Oracle background process, prefixed by <code>ap</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| APPLY_NAME                     | VARCHAR2(128) | Name of the apply process                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| STATE                          | VARCHAR2(36)  | Shows the state of the apply reader and the hash server. The possible values include: <ul style="list-style-type: none"> <li>INITIALIZING - Starting up</li> <li>IDLE - Performing no work</li> <li>DEQUEUE MESSAGES - Dequeuing messages from the queue</li> <li>SCHEDULE MESSAGES - Computing dependencies between messages and assembling messages into transactions</li> <li>SPILLING - Spilling unapplied messages from memory to hard disk</li> <li>PAUSED - WAITING FOR DDL TO COMPLETE - Waiting for a data definition language (DDL) logical change record (LCR) to be applied</li> </ul> The state of the apply reader is displayed first, followed by the state of the hash server. A semicolon separates the apply reader state from the hash server state. |
| TOTAL_MESSAGES_DEQUEUED        | NUMBER        | Total number of messages dequeued since the apply process was last started                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| TOTAL_MESSAGES_SPILLED         | NUMBER        | Number of messages spilled by the reader since the apply process was last started                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DEQUEUE_TIME                   | DATE          | Time when the last message was received                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DEQUEUED_MESSAGE_NUMBER        | NUMBER        | Number of the last message received                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| DEQUEUED_MESSAGE_CREATION_TIME | DATE          | For captured messages, creation time at the source database of the last message received. For user-enqueued messages, time when the message was enqueued into the queue at the local database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SGA_USED                       | NUMBER        | Amount (in bytes) of SGA memory used by the apply process since it was last started                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ELAPSED_DEQUEUE_TIME           | NUMBER        | Time elapsed (in hundredths of a second) dequeuing messages since the apply process was last started                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ELAPSED_SCHEDULE_TIME          | NUMBER        | Time elapsed (in hundredths of a second) scheduling messages since the apply process was last started. Scheduling includes computing dependencies between messages and assembling messages into transactions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                                                         |
| SPILL_LWM_POSITION    | RAW(64)       | Spill low-watermark position. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                                              |
| OLDEST_TRANSACTION_ID | VARCHAR2(128) | Oldest transaction ID                                                                                                                                                                                                                                                                                                                                                                                                                           |
| TOTAL_LCRS_WITH_DEP   | NUMBER        | Total number of LCRs with row-level dependencies since the apply process last started                                                                                                                                                                                                                                                                                                                                                           |
| TOTAL_LCRS_WITH_WMDEP | NUMBER        | Total number of LCRs with watermark dependencies since the apply process last started.<br>A watermark dependency occurs when an apply process must wait until the apply process's low watermark reaches a particular threshold.                                                                                                                                                                                                                 |
| TOTAL_IN_MEMORY_LCRS  | NUMBER        | Total number of LCRs currently in memory                                                                                                                                                                                                                                                                                                                                                                                                        |
| SGA_ALLOCATED         | NUMBER        | The total amount of shared memory (in bytes) allocated from the XStreams pool for the apply process since the apply process last started                                                                                                                                                                                                                                                                                                        |
| CON_ID                | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

The `ELAPSED_SCHEDULE_TIME` column is only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

## 10.137 V\$XSTREAM\_APPLY\_RECEIVER

`V$XSTREAM_APPLY_RECEIVER` displays information about the message receiver of the apply process. The values are reset to zero when the database (or instance in an Oracle Real Application Clusters (Oracle RAC) environment) restarts, when apply migrates to another instance, or when the XStream process is stopped.

| Column                                  | Datatype                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Column                   | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACKNOWLEDGEMENT_POSITION | RAW(64)  | Acknowledgement position of the messages received by the receiver. Corresponds to ACKNOWLEDGEMENT, except the value is in position rather than SCN.                                                                                                                                                                                                                                                                                             |
| CON_ID                   | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.138 V\$XSTREAM\_APPLY\_SERVER

V\$XSTREAM\_APPLY\_SERVER displays information about each XStream apply server and its activities. An apply server receives messages from the apply coordinator for an apply process. For each message received, an apply server either applies the message or sends the message to the appropriate apply handler. An apply server is a subcomponent of an apply process, outbound server, or inbound server.

| Column     | Datatype      | Description                                                                                     |
|------------|---------------|-------------------------------------------------------------------------------------------------|
| SID        | NUMBER        | Session ID of the apply server's session                                                        |
| SERIAL#    | NUMBER        | Serial number of the apply server's session                                                     |
| APPLY#     | NUMBER        | Apply process number. An apply process is an Oracle background process, prefixed by <i>ap</i> . |
| APPLY_NAME | VARCHAR2(128) | Name of the apply process                                                                       |
| SERVER_ID  | NUMBER        | Parallel execution server number of the apply server                                            |

| Column           | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE            | VARCHAR2(20) | <p>State of the apply server:</p> <ul style="list-style-type: none"> <li>INITIALIZING - Starting up</li> <li>IDLE - Performing no work</li> <li>RECORD LOW-WATERMARK - Performing an administrative job that maintains information about the apply progress, which is used in the ALL_APPLY_PROGRESS and DBA_APPLY_PROGRESS data dictionary views</li> <li>ADD PARTITION - Performing an administrative job that adds a partition that is used for recording information about in-progress transactions</li> <li>DROP PARTITION - Performing an administrative job that purges rows that were used to record information about in-progress transactions</li> <li>EXECUTE TRANSACTION - Applying a transaction</li> <li>WAIT COMMIT - Waiting to commit a transaction until all other transactions with a lower commit SCN are applied. This state is possible only if the COMMIT_SERIALIZATION apply process parameter is set to a value other than DEPENDENT_TRANSACTIONS and the PARALLELISM apply process parameter is set to a value greater than 1.</li> <li>WAIT DEPENDENCY - Waiting to apply a logical change record (LCR) in a transaction until another transaction, on which it has a dependency, is applied. This state is possible only if the PARALLELISM apply process parameter is set to a value greater than 1.</li> <li>ROLLBACK TRANSACTION - Rolling back a transaction</li> <li>TRANSACTION CLEANUP - Cleaning up an applied transaction, which includes removing LCRs from the apply process's queue</li> <li>WAIT FOR CLIENT - Waiting for an XStream client application to request more LCRs</li> <li>WAIT FOR NEXT CHUNK - Waiting for the next set of LCRs for a large transaction</li> </ul> |
| XIDUSN           | NUMBER       | Transaction ID undo segment number of the transaction currently being applied                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| XIDSLT           | NUMBER       | Transaction ID slot number of the transaction currently being applied                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| COMMIT_POSITION             | RAW(64)       | Commit position of the transaction. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                                        |
| DEP_COMMIT_POSITION         | RAW(64)       | Commit position of the transaction the slave depends on. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                   |
| LAST_APPLY_POSITION         | RAW(64)       | For inbound servers, the position of the last message applied; for outbound servers, the position of the last message sent to the XStream client application. This column is populated only for an apply process that is functioning as an XStream outbound server or inbound server.                                                                                                                                                           |
| TRANSACTION_ID              | VARCHAR2(128) | Transaction ID that the slave is applying. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                                 |
| DEP_TRANSACTION_ID          | VARCHAR2(128) | Transaction ID of the transaction the slave depends on. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                                                                                                                                                                    |
| CON_ID                      | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| TOTAL_LCRS_RETRIED          | NUMBER        | Total number of LCRs retried by this server                                                                                                                                                                                                                                                                                                                                                                                                     |
| LCR_RETRY_ITERATION         | NUMBER        | Retry iteration for this transaction by this server                                                                                                                                                                                                                                                                                                                                                                                             |
| TOTAL_TXNS_RETRIED          | NUMBER        | Total transactions retried by this server                                                                                                                                                                                                                                                                                                                                                                                                       |
| TXN_RETRY_ITERATION         | NUMBER        | Retry iteration for this transaction by this server                                                                                                                                                                                                                                                                                                                                                                                             |
| TOTAL_TXNS_RECORDED         | NUMBER        | Total transactions recorded in error queue by this server                                                                                                                                                                                                                                                                                                                                                                                       |

 **Note:**

The `ELAPSED_SCHEDULE_TIME` column is only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

## 10.139 V\$XSTREAM\_CAPTURE

`V$XSTREAM_CAPTURE` displays information about each capture process that sends LCRs to an XStream outbound server.

| Column                    | Datatype                   | Description                                                                                           |
|---------------------------|----------------------------|-------------------------------------------------------------------------------------------------------|
| <code>SID</code>          | <code>NUMBER</code>        | Session identifier of the capture process                                                             |
| <code>SERIAL#</code>      | <code>NUMBER</code>        | Session serial number of the capture process session                                                  |
| <code>CAPTURE#</code>     | <code>NUMBER</code>        | Capture process number. A capture process is an Oracle background process prefixed by <code>cp</code> |
| <code>CAPTURE_NAME</code> | <code>VARCHAR2(128)</code> | Name of the capture process                                                                           |
| <code>LOGMINER_ID</code>  | <code>NUMBER</code>        | Session ID of the Oracle LogMiner session associated with the capture process                         |
| <code>STARTUP_TIME</code> | <code>DATE</code>          | Time when the capture process was last started                                                        |

| Column                    | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE                     | VARCHAR2(551) | <p>State of the capture process:</p> <ul style="list-style-type: none"> <li>INITIALIZING - Starting up.</li> <li>WAITING FOR DICTIONARY REDO - Waiting for redo log files containing the dictionary build related to the first SCN to be added to the capture process session. A capture process cannot begin to scan the redo log files until all of the log files containing the dictionary build have been added.</li> <li>DICTIONARY INITIALIZATION - Processing a dictionary build.</li> <li>MINING (PROCESSED SCN = <i>scn_value</i>) - Mining a dictionary build at the SCN <i>scn_value</i>.</li> <li>LOADING (step <i>X</i> of <i>Y</i>) - Processing information from a dictionary build and currently at step <i>X</i> in a process that involves <i>Y</i> steps, where <i>X</i> and <i>Y</i> are numbers.</li> <li>CAPTURING CHANGES - Scanning the redo log for changes that satisfy the capture process rule sets.</li> <li>WAITING FOR REDO - Waiting for new redo log files to be added to the capture process session. The capture process has finished processing all of the redo log files added to its session. This state is possible if there is no activity at a source database. For a downstream capture process, this state is possible if the capture process is waiting for new log files to be added to its session.</li> <li>EVALUATING RULE - Evaluating a change against a capture process rule set.</li> <li>CREATING LCR - Converting a change into an LCR.</li> <li>ENQUEUEING MESSAGE - Enqueueing an LCR that satisfies the capture process rule sets into the capture process queue.</li> <li>PAUSED FOR FLOW CONTROL - Unable to enqueue LCRs either because of low memory or because propagations and outbound servers are consuming messages slower than the capture process is creating them. This state indicates flow control that is used to reduce spilling of captured LCRs when propagation or apply has fallen behind or is unavailable.</li> <li>WAITING FOR THE BUFFERED QUEUE TO SHRINK - Waiting for the buffered queue to change to a smaller size. The buffered queue shrinks when there is a memory limitation or when an administrator reduces its size.</li> <li>WAITING FOR <i>n</i> SUBSCRIBER(S) INITIALIZING - Waiting for outbound servers that receive LCRs from the capture process to start, where <i>n</i> is the number of apply processes.</li> <li>WAITING FOR TRANSACTION - Waiting for LogMiner to provide more transactions.</li> <li>WAITING FOR INACTIVE DEQUEUEERS - Waiting for the capture process's queue subscribers to start. The capture process stops enqueueing LCRs if there are no active subscribers to the queue.</li> <li>SUSPENDED FOR AUTO SPLIT/MERGE - Waiting for a merge operation to complete.</li> <li>SHUTTING DOWN - Stopping.</li> <li>ABORTING - Aborting.</li> </ul> |
| TOTAL_PREFILTER_DISCARDED | NUMBER        | Total number of prefiltered messages discarded                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| TOTAL_PREFILTER_EVALUATIONS   | NUMBER       | Total number of prefilter evaluations                                                                                                                                                                                                                                                                                |
| TOTAL_MESSAGES_CAPTURED       | NUMBER       | Total number of redo entries passed by LogMiner to the capture process for detailed rule evaluation since the capture process last started. A capture process converts a redo entry into a message and performs detailed rule evaluation on the message when capture process prefiltering cannot discard the change. |
| CAPTURE_TIME                  | DATE         | Time when the most recent message was captured                                                                                                                                                                                                                                                                       |

| CAPTURE_MESSAGE_CREATE_TIME   | DATE         | Creation time of the most recently captured message                                                                                                                                                                                                                                                                  |
| TOTAL_MESSAGES_CREATED        | NUMBER       | Count associated with ELAPSED_LCR_TIME to calculate rate                                                                                                                                                                                                                                                             |
| TOTAL_FULL_EVALUATIONS        | NUMBER       | Count associated with ELAPSED_RULE_TIME to calculate rate                                                                                                                                                                                                                                                            |
| TOTAL_MESSAGES_ENQUEUE_D      | NUMBER       | Total number of messages enqueued since the capture process was last started                                                                                                                                                                                                                                         |
| ENQUEUE_TIME                  | DATE         | Time when the last message was enqueued                                                                                                                                                                                                                                                                              |
| ENQUEUE_MESSAGE_NUMBER        | NUMBER       | Number of the last enqueued message                                                                                                                                                                                                                                                                                  |
| ENQUEUE_MESSAGE_CREATE_TIME   | DATE         | Creation time of the last enqueued message                                                                                                                                                                                                                                                                           |
| AVAILABLE_MESSAGE_NUMBER      | NUMBER       | For local capture, the last redo SCN flushed to the log files. For downstream capture, the last SCN added to LogMiner through the archived redo log files.                                                                                                                                                           |
| AVAILABLE_MESSAGE_CREATE_TIME | DATE         | For local capture, the time the SCN was written to the log file. For downstream capture, the time the most recent archived redo log file (containing the most recent SCN) was added to LogMiner.                                                                                                                     |
| ELAPSED_CAPTURE_TIME          | NUMBER       | Elapsed time (in hundredths of a second) scanning for changes in the redo log since the capture process was last started                                                                                                                                                                                             |
| ELAPSED_RULE_TIME             | NUMBER       | Elapsed time (in hundredths of a second) evaluating rules since the capture process was last started                                                                                                                                                                                                                 |
| ELAPSED_ENQUEUE_TIME          | NUMBER       | Elapsed time (in hundredths of a second) enqueueing messages since the capture process was last started                                                                                                                                                                                                              |
| ELAPSED_LCR_TIME              | NUMBER       | Elapsed time (in hundredths of a second) creating LCRs since the capture process was last started                                                                                                                                                                                                                    |
| ELAPSED_REDO_WAIT_TIME        | NUMBER       | Elapsed time (in hundredths of a second) spent by the capture process in the WAITING FOR REDO state                                                                                                                                                                                                                  |
| ELAPSED_PAUSE_TIME            | NUMBER       | Elapsed flow control pause time (in hundredths of a second)                                                                                                                                                                                                                                                          |
| STATE_CHANGED_TIME            | DATE         | Time at which the state of the capture process changed                                                                                                                                                                                                                                                               |
| SGA_USED                      | NUMBER       | The total amount of shared memory (in bytes) currently used by the capture process out of the amount allocated (SGA_ALLOCATED)                                                                                                                                                                                       |
| SGA_ALLOCATED                 | NUMBER       | The total amount of shared memory (in bytes) allocated from the Streams pool for the capture process                                                                                                                                                                                                                 |
| BYTES_OF_REDO_MINED           | VARCHAR2(64) | The total amount of redo data mined (in bytes) since the capture process last started                                                                                                                                                                                                                                |
| SESSION_RESTART_SCN           | VARCHAR2(64) | The SCN from which the capture process started mining redo data when it was last started                                                                                                                                                                                                                             |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

 **Note:**

The `ELAPSED_CAPTURE_TIME`, `ELAPSED_RULE_TIME`, `ELAPSED_ENQUEUE_TIME`, `ELAPSED_LCR_TIME`, and `ELAPSED_REDO_WAIT_TIME` columns are only populated if the `TIMED_STATISTICS` initialization parameter is set to `true`, or if the `STATISTICS_LEVEL` initialization parameter is set to `TYPICAL` or `ALL`.

 **See Also:**

- "TIMED\_STATISTICS"
- "STATISTICS\_LEVEL"

## 10.140 V\$XSTREAM\_MESSAGE\_TRACKING

`V$XSTREAM_MESSAGE_TRACKING` displays information about LCRs tracked through the stream that are processed by XStream components.

You can track an LCR through a stream using one of the following methods:

- Set the `message_tracking_frequency` capture process parameter to 1 or another relatively low value for XStream Outbound processes.
- Set the `message_tracking_frequency` apply process parameter to 1 or another relatively low value for XStream Inbound processes.
- Use the `DBMS_XSTREAM_ADM.SET_MESSAGE_TRACKING` procedure to specify a tracking label that becomes part of each LCR generated by the current session.

When the `actions` parameter in the `DBMS_XSTREAM_ADM.SET_MESSAGE_TRACKING` procedure is set to `DBMS_XSTREAM_ADM.ACTION_MEMORY`, information about the LCRs is tracked in memory, and this view is populated with information about the LCRs. Currently, `DBMS_XSTREAM_ADM.ACTION_MEMORY` is the only valid setting for the `actions` parameter in the procedure.

 **Note:**

This view does not display information about messages flowing in an Oracle GoldenGate configuration. To view information about such message streams, query the V\$GOLDENGATE\_MESSAGE\_TRACKING view.

| Column                | Datatype                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRACKING_LABEL        | VARCHAR2(128)                  | User-specified tracking label                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TAG                   | RAW(30)                        | First 30 bytes of the tag of the LCR                                                                                                                                                                                                                                                                                                                                                                                                            |
| COMPONENT_NAME        | VARCHAR2(128)                  | Name of the component that processed the LCR                                                                                                                                                                                                                                                                                                                                                                                                    |
| COMPONENT_TYPE        | VARCHAR2(128)                  | Type of the component that processed the LCR                                                                                                                                                                                                                                                                                                                                                                                                    |

## 10.141 V\$XSTREAM\_OUTBOUND\_SERVER

V\$XSTREAM\_OUTBOUND\_SERVER displays statistics about an outbound server. An outbound server sends LCRs to the XStream client application.

 **Note:**

When the COMMITTED\_DATA\_ONLY column is YES in the V\$XSTREAM\_OUTBOUND\_SERVER view, the V\$STREAMS\_APPLY\_SERVER view provides additional information about the outbound server process, and information about the apply server background processes used by the outbound server.

| Column       | Datatype      | Description                                                                                             |
|--------------|---------------|---------------------------------------------------------------------------------------------------------|
| SID          | NUMBER        | Session ID of the outbound server's session                                                             |
| SERIAL#      | NUMBER        | Serial number of the outbound server's session                                                          |
| SPID         | VARCHAR2(12)  | Process identification number of the operating-system process that sends LCRs to the client application |
| SERVER_NAME  | VARCHAR2(128) | Name of the outbound server                                                                             |
| STARTUP_TIME | DATE          | Time when the client application attached to the outbound server                                        |

| Column | Datatype     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE  | VARCHAR2(19) | <p>State of the outbound server</p> <p>When the <code>COMMITTED_DATA_ONLY</code> column shows YES, the following states are possible:</p> <ul style="list-style-type: none"> <li>INITIALIZING - Starting up the outbound server.</li> <li>IDLE - Performing no work because there are no LCRs to send to the XStream client application.</li> <li>GET TRANSACTIONS - Receiving transactions from the outbound server's apply coordinator.</li> <li>SEND TRANSACTION - Sending a transaction to an XStream client application.</li> <li>WAIT FOR NEXT CHUNK - Waiting for the next set of LCRs for a large transaction.</li> <li>TRANSACTION CLEANUP - Cleaning up an applied transaction, which includes removing LCRs from the outbound server's queue.</li> <li>WAIT FOR CLIENT - Waiting for an XStream client application to request more LCRs.</li> </ul> <p>When the <code>COMMITTED_DATA_ONLY</code> column shows NO, the following states are possible:</p> <ul style="list-style-type: none"> <li>INITIALIZING - Starting up the outbound server.</li> <li>INITIALIZING RULE EVALUATION CONTEXT - Initializing the context to evaluate the outbound server's rules.</li> <li>IDLE - Performing no work because there is no LCR to send to the XStream client application.</li> <li>BROWSING LCR - Browsing the outbound server's queue for next LCR.</li> <li>EVALUATING RULES - Evaluating an LCR against a rule set.</li> <li>DEQUEUEING LCR - Dequeueing an LCR from the outbound server's queue.</li> <li>SENDING LCR - Sending an LCR to an XStream client application.</li> <li>WAITING FOR CAPTURE TO TERMINATE - Waiting for the capture process to become disabled.</li> <li>SUSPENDED DUE TO A DROPPED SUBSCRIBER - Suspended because a connected subscriber was dropped. For example, a subscriber can be dropped during a split or merge operation.</li> <li>SUSPENDED FOR AUTO SPLIT/MERGE - Suspended because an automatic split or merge operation is being performed.</li> <li>WAITING ON EMPTY QUEUE - Waiting for more LCRs from the capture process.</li> <li>WAITING FOR CLIENT - Waiting for the XStream client application to request more LCRs.</li> <li>WAITING FOR CAPTURE TO INITIALIZE - Waiting for the capture process to finish the data dictionary build.</li> <li>WAITING TO ATTACH TO CAPTURE - Waiting for the outbound server to attach to the capture process.</li> </ul> <p>When a state refers to a capture process, it is the capture process that captures changes for the outbound server. When a state refers to a propagation, it is the outbound server that sends LCRs to the XStream client application.</p> |

| Column                          | Datatype | Description                                                                                                                                                                                                                                                                                                          |
|---------------------------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XIDUSN                          | NUMBER   | Transaction ID undo segment number of the transaction currently being processed. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                       |
| XIDSLT                          | NUMBER   | Transaction ID slot number of the transaction currently being processed. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                               |
| XIDSQN                          | NUMBER   | Transaction ID sequence number of the transaction currently being processed. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                           |
| COMMITSCN                       | NUMBER   | Commit SCN of the transaction currently being processed. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                                               |
| TOTAL_TRANSACTIONS_SENT         | NUMBER   | Total number of transactions sent by the outbound server to the XStream client application since the last time the client application attached to the outbound server. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL. |
| MESSAGE_SEQUENCE                | NUMBER   | Number of the current LCR being processed by the outbound server. This value is reset to 1 at the beginning of each transaction. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                       |
| TOTAL_MESSAGES_SENT             | NUMBER   | Total number of LCRs sent by the outbound server to the XStream client application since the last time the client application attached to the outbound server                                                                                                                                                        |
| SEND_TIME                       | DATE     | Time the last LCR was sent by the outbound server to the XStream client application                                                                                                                                                                                                                                  |
| LAST_SENT_MESSAGE_NUMBER        | NUMBER   | Message number of the last LCR sent by the outbound server to the XStream client application                                                                                                                                                                                                                         |
| LAST_SENT_MESSAGE_CREATION_TIME | DATE     | Creation time at the source database of the last LCR sent by the outbound server to the client application                                                                                                                                                                                                           |
| ELAPSED_SEND_TIME               | NUMBER   | Time elapsed (in hundredths of a second) sending LCRs to the XStream client application since the last time the client application attached to the outbound server                                                                                                                                                   |
| COMMIT_POSITION                 | RAW(64)  | Commit position of the transaction currently being processed. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                                          |
| LAST_SENT_POSITION              | RAW(64)  | Position of the last LCR sent to the XStream client application. This column is populated only if the COMMITTED_DATA_ONLY column shows YES. When the COMMITTED_DATA_ONLY column shows NO, this column is NULL.                                                                                                       |
| BYTES_SENT                      | NUMBER   | Total number of bytes sent by the outbound server to the XStream client application since the last time the client application attached to the outbound server                                                                                                                                                       |

| Column              | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMMITTED_DATA_ONLY | CHAR(3)  | <p>YES if the outbound server can send only LCRs in committed transactions to the XStream client application. A committed transaction is an assembled, noninterleaving transaction with no rollbacks.</p> <p>NO if the outbound server can send LCRs in transactions that have not yet committed to the XStream client application. This mode is for internal Oracle use only.</p>                                                                     |
| CON_ID              | NUMBER   | <p>The ID of the container to which the data pertains. Possible values include:</p> <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.142 V\$XSTREAM\_TABLE\_STATS

V\$XSTREAM\_TABLE\_STATS shows the statistics for all the tables processed by each apply server for the XStream session.

| Column                  | Datatype      | Description                                                                                                                                                                     |
|-------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APPLY_NAME              | VARCHAR2(128) | Name of XStream Out or XStream In process                                                                                                                                       |
| SERVER_ID               | NUMBER        | Parallel apply server slave ID. If the server ID is 0, then this is an aggregate of statistics for servers that may have been automatically shutdown due to session inactivity. |
| SOURCE_TABLE_OWNER      | VARCHAR2(128) | Source owner of the captured or replicated table                                                                                                                                |
| SOURCE_TABLE_NAME       | VARCHAR2(128) | Source name of the captured or replicated table                                                                                                                                 |
| DESTINATION_TABLE_OWNER | VARCHAR2(128) | Target owner of the captured or replicated table                                                                                                                                |
| DESTINATION_TABLE_NAME  | VARCHAR2(128) | Target name of the captured or replicated table                                                                                                                                 |
| LAST_UPDATE             | DATE          | Time of last update                                                                                                                                                             |
| TOTAL_INSERTS           | NUMBER        | Number of insert operations on this table processed by this apply server for the current session                                                                                |
| TOTAL_UPDATES           | NUMBER        | Number of update operations on this table processed by this apply server for the current session                                                                                |
| TOTAL_DELETES           | NUMBER        | Number of delete operations on this table processed by this apply server for the current session                                                                                |
| INSERT_COLLISIONS       | NUMBER        | Number of insert collisions on this table encountered by this apply server for the current session                                                                              |

| Column                     | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UPDATE_COLLISIONS          | NUMBER   | Number of update collisions on this table encountered by this apply server for the current session                                                                                                                                                                                                                                                                                                                                              |
| DELETE_COLLISIONS          | NUMBER   | Number of delete collisions on this table encountered by this apply server for the current session                                                                                                                                                                                                                                                                                                                                              |
| REPERROR_RECORDS           | NUMBER   | Number of change records that were recorded on this table by this apply server for the current session                                                                                                                                                                                                                                                                                                                                          |
| REPERROR_IGNORES           | NUMBER   | Number of ignored change records on this table by this apply server for the current session                                                                                                                                                                                                                                                                                                                                                     |
| WAIT_DEPENDENCIES          | NUMBER   | Number of waits for this table due to dependency for the current session                                                                                                                                                                                                                                                                                                                                                                        |
| CON_ID                     | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |
| CDR_INSERT_ROW_EXISTS      | NUMBER   | Number of conflicts where an insert gets an ORA-00001 error                                                                                                                                                                                                                                                                                                                                                                                     |
| CDR_UPDATE_ROW_EXISTS      | NUMBER   | Number of conflicts where an update gets an ORA-26786 error                                                                                                                                                                                                                                                                                                                                                                                     |
| CDR_UPDATE_ROW_MISSING     | NUMBER   | Number of conflicts where an update gets an ORA-26787 error                                                                                                                                                                                                                                                                                                                                                                                     |
| CDR_DELETE_ROW_EXISTS      | NUMBER   | Number of conflicts where a delete gets an ORA-26786 error                                                                                                                                                                                                                                                                                                                                                                                      |
| CDR_DELETE_ROW_MISSING     | NUMBER   | Number of conflicts where a delete gets an ORA-26787 error                                                                                                                                                                                                                                                                                                                                                                                      |
| CDR_SUCCESSFUL_RESOLUTIONS | NUMBER   | Number of successfully resolved conflicts                                                                                                                                                                                                                                                                                                                                                                                                       |
| CDR_FAILED_RESOLUTIONS     | NUMBER   | Number of conflicts that could not be resolved due to an error during resolution                                                                                                                                                                                                                                                                                                                                                                |
| LOB_OPERATIONS             | NUMBER   | The number of LOB updates (LOB writes, LOB trims, and LOB erases) applied by the inbound server.                                                                                                                                                                                                                                                                                                                                                |

## 10.143 V\$XSTREAM\_TRANSACTION

V\$XSTREAM\_TRANSACTION displays information about transactions that are being processed by capture processes, outbound servers, and inbound servers. This view can identify long running transactions and to display how many LCRs are being processed in each transaction. This view only contains information about captured LCRs. It does not contain information about user-enqueued LCRs or user messages. This view only shows information about LCRs that are being processed because they satisfied the rule sets for the component at the time of the query. For capture processes, this view only shows information about changes in transactions that the

capture process has converted into LCRs. It does not show information about all the active transactions present in the redo log.

For outbound servers, this view only shows information about LCRs that the outbound server has dequeued. It does not show information about LCRs in the outbound server's queue. For outbound servers, information about a transaction remains in the view until the transaction is sent to the XStream client application.

For inbound servers, information about a transaction remains in the view until the transaction commits or until the entire transaction is rolled back.

| Column                   | Datatype      | Description                                                                                                                                                                                                                                                                                    |

| COMPONENT_NAME           | VARCHAR2(128) | Name of the component                                                                                                                                                                                                                                                                          |
| COMPONENT_TYPE           | VARCHAR2(20)  | Type of component <ul style="list-style-type: none"> <li>CAPTURE - Capture process</li> <li>APPLY - Apply reader subcomponent in an outbound server or inbound server</li> <li>PROPAGATION_SENDER - Propagation sender that sends LCRs from a capture process to an outbound server</li> </ul> |
| XIDUSN                   | NUMBER        | Transaction ID undo segment number of the transaction                                                                                                                                                                                                                                          |
| XIDSLT                   | NUMBER        | Transaction ID slot number of the transaction                                                                                                                                                                                                                                                  |
| XIDSQN                   | NUMBER        | Transaction ID sequence number of the transaction                                                                                                                                                                                                                                              |
| CUMULATIVE_MESSAGE_COUNT | NUMBER        | Number of LCRs processed in the transaction. If a component is restarted while the transaction is being processed, then this column shows the number of LCRs processed in the transaction since the component was started.                                                                     |
| TOTAL_MESSAGE_COUNT      | NUMBER        | Total number of LCRs processed in the transaction by an outbound server or inbound server. This column does not pertain to capture processes.                                                                                                                                                  |
| FIRST_MESSAGE_TIME       | DATE          | Time stamp of the first LCR processed in the transaction. If a capture process is restarted while the transaction is being processed, then this column shows the time stamp of the first LCR processed after the capture process was started.                                                  |
| FIRST_MESSAGE_NUMBER     | NUMBER        | SCN of the first message in the transaction. If a capture process is restarted while the transaction is being processed, then this column shows the SCN of the first message processed after the capture process was started.                                                                  |
| LAST_MESSAGE_TIME        | DATE          | Time stamp of the last LCR processed in the transaction                                                                                                                                                                                                                                        |
| LAST_MESSAGE_NUMBER      | NUMBER        | SCN of the most recent message encountered for the transaction                                                                                                                                                                                                                                 |
| FIRST_MESSAGE_POSITION   | RAW(64)       | Position of the first message seen by an XStream inbound server<br>This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                        |
| LAST_MESSAGE_POSITION    | RAW(64)       | Position of the last message seen by an XStream inbound server.<br>This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                        |
| TRANSACTION_ID           | VARCHAR2(128) | Transaction ID for an XStream inbound server. This column is populated only for an apply process that is functioning as an XStream inbound server.                                                                                                                                             |

| Column | Datatype | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CON_ID | NUMBER   | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

## 10.144 V\$ZONEMAP\_USAGE\_STATS

V\$ZONEMAP\_USAGE\_STATS displays zone map usage statistics.

| Column       | Datatype      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ZONEMAP      | VARCHAR2(257) | Name of the zone map in the form of <i>owner.name</i>                                                                                                                                                                                                                                                                                                                                                                                           |
| PRUNING_TYPE | VARCHAR2(11)  | Type of data pruning performed using the zone map                                                                                                                                                                                                                                                                                                                                                                                               |
| EXECUTIONS   | NUMBER        | Number of executions, including parallel slave executions                                                                                                                                                                                                                                                                                                                                                                                       |
| BASE_COUNT   | NUMBER        | Base count accumulated over number of executions                                                                                                                                                                                                                                                                                                                                                                                                |
| PRUNED_COUNT | NUMBER        | Pruned count accumulated over number of executions                                                                                                                                                                                                                                                                                                                                                                                              |
| CON_ID       | NUMBER        | The ID of the container to which the data pertains. Possible values include: <ul style="list-style-type: none"> <li>0: This value is used for rows containing data that pertain to the entire CDB. This value is also used for rows in non-CDBs.</li> <li>1: This value is used for rows containing data that pertain to only the root</li> <li><i>n</i>: Where <i>n</i> is the applicable container ID for the rows containing data</li> </ul> |

The ratio ( $\text{PRUNED\_COUNT} / \text{BASE\_COUNT}$ ) shows the fraction of data pruned by the zone map.

# Part IV

## Appendixes

This part includes the following appendixes:

- [Database Limits](#)
- [SQL Scripts](#)
- [Oracle Wait Events](#)
- [Oracle Enqueue Names](#)
- [Statistics Descriptions](#)
- [Background Processes](#)

# A

## Database Limits

This appendix lists the limits of values associated with database functions and objects. Limits exist on several levels in the database. There is usually a hard-coded limit in the database that cannot be exceeded. This value may be further restricted for any given operating system.

Database limits are divided into four categories:

- [Datatype Limits](#)
- [Physical Database Limits](#)
- [Logical Database Limits](#)
- [Process and Runtime Limits](#)

<sup>1</sup> The absolute maximum number of columns in a table is 1000. However, when you create an object table (or a relational table with columns of object, nested table, varray, or REF type), Oracle maps the columns of the user-defined types to relational columns, creating in effect hidden columns that count toward the 1000-column limit. For details on how Oracle calculates the total number of columns in such a table, refer to *Oracle Database Administrator's Guide*.

## A.2 Physical Database Limits

This table describes limit types and limit values for physical database items.

| Item                | Type of Limit                                    | Limit Value                                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Database Block Size | Minimum                                          | 2048 bytes; must be a multiple of operating system physical block size                                                                                                                                                                                     |
| Database Block Size | Maximum                                          | Operating system dependent; never more than 32 KB                                                                                                                                                                                                          |
| Database Blocks     | Minimum in initial extent of a segment           | 2 blocks                                                                                                                                                                                                                                                   |
| Database Blocks     | Maximum per datafile                             | Platform dependent; typically $2^{22} - 1$ blocks                                                                                                                                                                                                          |
| Controlfiles        | Number of control files                          | 1 minimum; 2 or more (on separate devices) strongly recommended                                                                                                                                                                                            |
| Controlfiles        | Size of a control file                           | Maximum of 201031680 logical blocks                                                                                                                                                                                                                        |
| Database files      | Maximum per tablespace                           | Operating system dependent; usually 1022                                                                                                                                                                                                                   |
| Database files      | Maximum per database                             | 65533<br>May be less on some operating systems<br>Limited also by size of database blocks and by the DB_FILES initialization parameter for a particular instance                                                                                           |
| Database extents    | Maximum per dictionary managed tablespace        | 4 GB * physical block size (with K/M modifier); 4 GB (without K/M modifier)                                                                                                                                                                                |
| Database extents    | Maximum per locally managed (uniform) tablespace | 2 GB * physical block size (with K/M modifier); 2 GB (without K/M modifier)                                                                                                                                                                                |
| Database file size  | Maximum                                          | Operating system dependent. Limited by maximum operating system file size. See the <b>Bigfile Tablespaces</b> and <b>Smallfile (traditional) Tablespaces</b> rows for more information about the maximum database file size in these types of tablespaces. |
| MAXEXTENTS          | Default value                                    | Derived from tablespace default storage or DB_BLOCK_SIZE initialization parameter                                                                                                                                                                          |
| MAXEXTENTS          | Maximum                                          | Unlimited                                                                                                                                                                                                                                                  |
| Redo Log Files      | Maximum number of logfiles                       | Limited by value of MAXLOGFILES parameter in the CREATE DATABASE statement<br>Control file can be resized to allow more entries; ultimately an operating system limit                                                                                      |
| Redo Log Files      | Maximum number of logfiles per group             | Unlimited                                                                                                                                                                                                                                                  |
| Redo Log File Size  | Minimum size                                     | 4 MB                                                                                                                                                                                                                                                       |
| Redo Log File Size  | Maximum Size                                     | Operating system limit; typically 2 TB                                                                                                                                                                                                                     |
| Tablespaces         | Maximum number per database                      | 64 K<br>Number of tablespaces cannot exceed the number of database files because each tablespace must include at least one file                                                                                                                            |

| Item                                | Type of Limit    | Limit Value                                                                                                                                                                                                                                                                               |
|-------------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bigfile Tablespaces                 | Number of blocks | A bigfile tablespace contains only one datafile or tempfile, which can contain up to approximately 4 billion ( $2^{32}$ ) blocks. The maximum size of the single datafile or tempfile is 128 terabytes (TB) for a tablespace with 32 K blocks and 32 TB for a tablespace with 8 K blocks. |
| Smallfile (traditional) Tablespaces | Number of blocks | A smallfile tablespace is a traditional Oracle tablespace, which can contain 1022 datafiles or tempfiles, each of which can contain up to approximately 4 million ( $2^{22}$ ) blocks.                                                                                                    |
| External Tables file                | Maximum size     | Dependent on the operating system.<br>An external table can be composed of multiple files.                                                                                                                                                                                                |

## A.3 Logical Database Limits

This table describes limit types and limit values for logical database items.

| Item                                | Type of Limit                                                    | Limit Value                                                                                                             |
|-------------------------------------|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Columns                             | Maximum per table                                                | 1000                                                                                                                    |
| Columns                             | Maximum per index (or clustered index)                           | 32                                                                                                                      |
| Columns                             | Maximum per bitmapped index                                      | 30                                                                                                                      |
| Constraints                         | Maximum per column                                               | Unlimited                                                                                                               |
| Constraints                         | Maximum per database                                             | 4,294,967,293                                                                                                           |
| Database users                      | Maximum per database                                             | 4,294,967,293                                                                                                           |
| Dictionary-managed database objects | Maximum per database                                             | 4,254,950,911 - overhead                                                                                                |
| Indexes                             | Maximum per table                                                | Unlimited                                                                                                               |
| Indexes                             | Total size of indexed column                                     | 75% of the database block size minus some overhead                                                                      |
| Partitions                          | Maximum length of linear partitioning key                        | 4 KB - overhead                                                                                                         |
| Partitions                          | Maximum number of columns in partition key                       | 16 columns                                                                                                              |
| Partitions                          | Maximum number of partitions allowed per table or index          | 1024K - 1                                                                                                               |
| Rows                                | Maximum number per table                                         | Unlimited                                                                                                               |
| Stored Packages                     | Maximum size                                                     | Approximately 6,000,000 lines of code.<br><b>See Also:</b> <i>Oracle Database PL/SQL Language Reference</i> for details |
| Subpartitions                       | Maximum number of subpartitions in a composite partitioned table | 1024K - 1                                                                                                               |
| Subqueries                          | Maximum levels of subqueries in a SQL statement                  | Unlimited in the FROM clause of the top-level query<br>255 subqueries in the WHERE clause                               |

| Item                         | Type of Limit               | Limit Value                                                                                                                                                                                                                                                                                            |
|------------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Change Numbers (SCNs) | Maximum                     | 281,474,976,710,656, which is 281 trillion SCNs                                                                                                                                                                                                                                                        |
| Tables                       | Maximum per clustered table | 32 tables                                                                                                                                                                                                                                                                                              |
| Tables                       | Maximum per database        | Unlimited<br>Oracle does not define a limit on the number of tables per database. However, tables are subject to the limit on the maximum number of dictionary-managed database objects allowed per database. See the entry for " <a href="#">Dictionary-managed database objects</a> " in this table. |
| Trigger Cascade Limit        | Maximum value               | Operating system-dependent, typically 32                                                                                                                                                                                                                                                               |
| Users and Roles              | Maximum                     | 2,147,483,638                                                                                                                                                                                                                                                                                          |

 **Note:**

The limit on how long a SQL statement can be depends on many factors, including database configuration, disk space, and memory

 **Note:**

When an object instance exists in memory, there is no fixed limit on the number of attributes in the object. But the maximum total amount of memory consumed by an object instance is 4 GB. When an object instance is inserted into a table, the attributes are exploded into separate columns in the table, and the Oracle 1000-column limit applies.

## A.4 Process and Runtime Limits

This table describes limit types and limit values for process and runtime items.

| Item                       | Type of Limit                                             | Limit Value                                                                                                           |
|----------------------------|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Instances per database     | Maximum number of cluster database instances per database | Operating system-dependent                                                                                            |
| Locks                      | Row-level                                                 | Unlimited                                                                                                             |
| Locks                      | Distributed Lock Manager                                  | Operating system dependent                                                                                            |
| SGA size                   | Maximum value                                             | Operating system-dependent; typically 2 to 4 GB for 32-bit operating systems, and > 4 GB for 64-bit operating systems |
| Advanced Queuing Processes | Maximum per instance                                      | 10                                                                                                                    |
| Job Queue Processes        | Maximum per instance                                      | 1000                                                                                                                  |

| Item                           | Type of Limit                                          | Limit Value                                                                                                  |
|--------------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| I/O Slave Processes            | Maximum per background process (DBWR, LGWR, and so on) | 15                                                                                                           |
| I/O Slave Processes            | Maximum per Backup session                             | 15                                                                                                           |
| Sessions                       | Maximum per instance                                   | 2 <sup>16</sup> ; limited by the PROCESSES and SESSIONS initialization parameters. 2 <sup>16</sup> is 65536. |
| Global Cache Service Processes | Maximum per instance                                   | 10                                                                                                           |
| Shared Servers                 | Maximum per instance                                   | Unlimited within constraints set by the PROCESSES and SESSIONS initialization parameters, for instance       |
| Dispatchers                    | Maximum per instance                                   | Unlimited within constraints set by PROCESSES and SESSIONS initialization parameters, for instance           |
| Parallel Execution Slaves      | Maximum per instance                                   | Unlimited within constraints set by PROCESSES and SESSIONS initialization parameters, for instance           |
| Backup Sessions                | Maximum per instance                                   | Unlimited within constraints set by PROCESSES and SESSIONS initialization parameters, for instance           |
| Services                       | Maximum per instance                                   | 8200                                                                                                         |

# B

## SQL Scripts

This appendix describes SQL scripts that are required for optimal operation of the Oracle Database.

The SQL scripts are described in the following sections:

- [Creating the Data Dictionary](#)
- [Creating Additional Data Dictionary Structures](#)
- [The "NO" Scripts](#)
- [Upgrade Scripts](#)
- [Java Scripts](#)

 **Note:**

Comments within the SQL scripts themselves contain more detailed information and examples.

 **Note:**

To run scripts in a pluggable database (PDB), connect to the PDB before running the script. For more information about running scripts in a multitenant container database (CDB), see *Oracle Multitenant Administrator's Guide*.

### B.1 Creating the Data Dictionary

When you use the Database Configuration Assistant to create a database, Oracle automatically creates the data dictionary. Thereafter, whenever the database is in operation, Oracle updates the data dictionary in response to every DDL statement. The data dictionary base tables are the first objects created in any Oracle database. They are created in the `SYSTEM` tablespace and must remain there. The data dictionary base tables store information about all user-defined objects in the database.

[Table B-1](#) lists required scripts, which are run automatically when you create a database using the Database Configuration Assistant. They are described here because you might need to run them if you create a database manually. To run these scripts, you must be connected to Oracle as a user with `SYSDBA` privileges.

**Table B-1 Creating the Data Dictionary Scripts**

| Script Name  | Needed For                       | Description                                                                                                                                                                                                                                              |
|--------------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| catalog.sql  | All databases                    | Creates the data dictionary and public synonyms for many of its views<br>Grants PUBLIC access to the synonyms                                                                                                                                            |
| catproc.sql  | All databases                    | Runs all scripts required for, or used with, PL/SQL                                                                                                                                                                                                      |
| catpcat.sql  | All databases                    | Runs the catalog.sql and catproc.sql scripts as parallel processes, which can speed up database creation<br><b>Note:</b> You must run catpcat.sql by using the catctl.pl program. See <i>Oracle Database Administrator's Guide</i> for more information. |
| catclust.sql | Oracle Real Application Clusters | Creates Oracle Real Application Clusters data dictionary views                                                                                                                                                                                           |

 **See Also:**

- *Oracle Real Application Clusters Administration and Deployment Guide* for more information about creating Oracle Real Application Cluster views

## B.2 Creating Additional Data Dictionary Structures

Oracle Database supplies other scripts that create additional structures you can use in managing your database and creating database applications. These scripts are listed in [Table B-2](#).

 **See Also:**

Your operating system-specific Oracle documentation for the exact names and locations of these scripts on your operating system

**Table B-2 Creating Additional Data Dictionary Structures**

| Script Name                   | Needed For             | Run By        | Description                                                                                                                                                                                                                                |
|-------------------------------|------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| catblock.sql                  | Performance management | SYS           | Creates views that can dynamically display lock dependency graphs<br><b>See Also:</b> <i>Oracle Database Administrator's Guide</i>                                                                                                         |
| caths.sql                     | Heterogeneous Services | SYS           | Installs packages for administering heterogeneous services<br><b>See Also:</b> <i>Oracle Database Gateway for APCC Installation and Configuration Guide for Microsoft Windows</i>                                                          |
| catio.sql                     | Performance management | SYS           | Allows I/O to be traced on a table-by-table basis                                                                                                                                                                                          |
| catqueue.sql                  | Advanced Queuing       |               | Creates the dictionary objects required for Advanced Queuing                                                                                                                                                                               |
| catrep.sql                    | Oracle Replication     | SYS           | Runs all SQL scripts for enabling database replication                                                                                                                                                                                     |
| catwrr.sql                    | Database Replay        | SYS           | Master script that creates the entire schema related to Database Replay - calls the create schema scripts for Workload Capture, Database Replay, Workload Replay, and Workload Intelligence                                                |
| catwrrwithb.sql               | Database Replay        | SYS           | Creates the schema for Workload Intelligence                                                                                                                                                                                               |
| dbmsiotc.sql                  | Storage management     | Any user      | Analyzes chained rows in index-organized tables                                                                                                                                                                                            |
| dbmspool.sql                  | Performance management | SYS or SYSDBA | Enables DBA to lock PL/SQL packages, SQL statements, and triggers into the shared pool<br><b>See Also:</b> <i>Oracle Database PL/SQL Packages and Types Reference</i>                                                                      |
| userlock.sql                  | Concurrency control    | SYS or SYSDBA | Provides a facility for user-named locks that can be used in a local or clustered environment to aid in sequencing application actions                                                                                                     |
| utlbstat.sql and utlestat.sql | Performance monitoring | SYS           | Respectively start and stop collecting performance tuning statistics                                                                                                                                                                       |
| utlchnl.sql                   | Storage management     | Any user      | For use with the Oracle Database. Creates tables for storing the output of the ANALYZE command with the CHAINED ROWS option. Can handle both physical and logical rowids.<br><b>See Also:</b> <i>Oracle Database Administrator's Guide</i> |
| utlconst.sql                  | Year 2000 compliance   | Any user      | Provides functions to validate that CHECK constraints on date columns are year 2000 compliant                                                                                                                                              |

**Table B-2 (Cont.) Creating Additional Data Dictionary Structures**

| Script Name    | Needed For                             | Run By        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| utldtree.sql   | Metadata management                    | Any user      | Creates tables and views that show dependencies between objects<br><br><b>See Also:</b> <i>Oracle Database SecureFiles and Large Objects Developer's Guide</i>                                                                                                                                                                                                                                                                                                                                               |
| utlexpt1.sql   | Constraints                            | Any user      | For use with the Oracle Database. Creates the default table (EXCEPTIONS) for storing exceptions from enabling constraints. Can handle both physical and logical rowids.<br><br><b>See Also:</b> <i>Oracle Database Administrator's Guide</i>                                                                                                                                                                                                                                                                 |
| utlfixdirs.sql | Moving a database to a new Oracle home | SYS           | Used after moving a database to a new Oracle home. Updates directory objects to use the new path names for the Oracle home and Oracle base directories, as defined by the new values for the ORACLE_HOME and ORACLE_BASE environment variables.<br><br>When you run this script in the root container of a CDB, it updates directory objects in the root, as well as any Oracle-maintained directory objects in the PDBs; you must manually update any PDB directory objects that are not Oracle-maintained. |
| utlip.sql      | PL/SQL                                 | SYS           | Used primarily for upgrade and downgrade operations. It invalidates all existing PL/SQL modules by altering certain dictionary tables so that subsequent recompilations will occur in the format required by the database. It also reloads the packages STANDARD and DBMS_STANDARD, which are necessary for any PL/SQL compilations.                                                                                                                                                                         |
| utlirp.sql     | PL/SQL                                 | SYS           | Used to change from 32-bit to 64-bit word size or vice versa. This script recompiles existing PL/SQL modules in the format required by the new database. It first alters some data dictionary tables. Then it reloads the packages STANDARD and DBMS_STANDARD, which are necessary for using PL/SQL. Finally, it triggers a recompilation of all PL/SQL modules, such as packages, procedures, and types.                                                                                                    |
| utllockt.sql   | Performance monitoring                 | SYS or SYSDBA | Displays a lock wait-for graph, in tree structure format<br><br><b>See Also:</b> <i>Oracle Database Administrator's Guide</i>                                                                                                                                                                                                                                                                                                                                                                                |

**Table B-2 (Cont.) Creating Additional Data Dictionary Structures**

| Script Name  | Needed For             | Run By                        | Description                                                                                                                                                                                                                 |

| utlxplan.sql | Performance management | Any user                      | Creates the table PLAN_TABLE, which holds output from the EXPLAIN PLAN statement<br><br><b>See Also:</b> <i>Oracle Database Data Warehousing Guide</i>                                                                      |

## B.3 The "NO" Scripts

These scripts are used to remove dictionary information for various optional services or components.

**Table B-3 The NO Scripts**

| Script Name     | Needed For                | Run By | Description                                                                    |
|-----------------|---------------------------|--------|--------------------------------------------------------------------------------|
| catnoadt.sql    | Objects                   | SYS    | Drops views and synonyms on dictionary metadata that relate to object types    |
| catnoaud.sql    | Security                  | SYS    | Drops views and synonyms on auditing metadata                                  |
| catnoclust.sql  | Real Application Clusters | SYS    | Drops views that are specific to Oracle Real Application Clusters (Oracle RAC) |
| catnodrdaas.sql | DRDA Application Server   | SYS    | Drops all DRDA Application Server objects from the database                    |
| catnogwm.sql    | Global Data Services      | SYS    | Drops users, roles, and other objects created for Global Data Services.        |
| catnohs.sql     | Heterogeneous Services    | SYS    | Removes Heterogeneous Services dictionary metadata                             |

Table B-3 (Cont.) The NO Scripts

| Script Name      | Needed For             | Run By | Description                                                                                                                                                                             |
|------------------|------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| catnojav.sql     | Java                   | SYS    | Drops the RDBMS Java classes and system triggers created by the <code>catjava.sql</code> script.                                                                                        |
| catnoprt.sql     | Partitioning           | SYS    | Drops views and synonyms on dictionary metadata that relate to partitioned tables and indexes                                                                                           |
| catnosvm.sql     | Server Manager         | SYS    | Removes Oracle7 Server Manager views and synonyms                                                                                                                                       |
| catnowrr.sql     | Database Replay        | SYS    | Master script that drops the entire schema related to Database Replay - calls the drop schema scripts for Workload Capture, Database Replay, Workload Replay, and Workload Intelligence |
| catnowrrc.sql    | Database Replay        | SYS    | Drops the schema related to Workload Capture                                                                                                                                            |
| catnowrrp.sql    | Database Replay        | SYS    | Drops the schema related to Workload Replay                                                                                                                                             |
| catnowrrwitb.sql | Database Replay        | SYS    | Drops the schema related to Workload Intelligence                                                                                                                                       |
| catnsnmp.sql     | Distributed management | SYS    | Drops the DBSNMP user and SNMPAGENT role                                                                                                                                                |

## B.4 Upgrade Scripts

Upgrade scripts are used when upgrading to another release of Oracle.

### See Also:

*Oracle Database Upgrade Guide* for information about upgrade scripts

## B.5 Java Scripts

The Java scripts are useful only if the JServer option is installed.

Table B-4 Java Scripts

| Script Name | Description                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------|
| initjvm.sql | Initializes JServer by installing core Java class libraries and Oracle-specific Java classes          |
| rmjvm.sql   | Removes all elements of the JServer<br><b>See Also:</b> <i>Oracle Database Java Developer's Guide</i> |
| catjava.sql | Installs Java-related packages and classes                                                            |

# C

## Oracle Wait Events

This appendix describes Oracle wait events.

It includes these topics:

- [Classes of Wait Events](#)
- [Descriptions of Common Wait Event Parameters](#)
- [Descriptions of Wait Events](#)

Information about wait events is displayed in three dynamic performance views:

- `V$SESSION_WAIT` displays the events for which sessions have just completed waiting or are currently waiting.
- `V$SYSTEM_EVENT` displays the total number of times all the sessions have waited for the events in that view.
- `V$SESSION_EVENT` is similar to `V$SYSTEM_EVENT`, but displays all waits for each session.

### See Also:

["V\\$SESSION\\_EVENT"](#), ["V\\$SESSION\\_WAIT"](#), and ["V\\$SYSTEM\\_EVENT"](#)

Many of these wait events are tied to the internal implementation of Oracle and therefore are subject to change or deletion without notice. Application developers should be aware of this and write their code to tolerate missing or extra wait events.

The following SQL statement displays an alphabetical list of all Oracle wait events and the wait class to which they belong:

```
SQL> SELECT name, wait_class FROM V$EVENT_NAME ORDER BY name;
```

### C.1 Classes of Wait Events

Every wait event belongs to a class of wait event.

The following list describes each of the wait classes.

#### Administrative

Waits resulting from DBA commands that cause users to wait (for example, an index rebuild)

#### Application

Waits resulting from user application code (for example, lock waits caused by row level locking or explicit lock commands)

### **Cluster**

Waits related to Oracle Real Application Clusters resources (for example, global cache resources such as 'gc cr block busy')

### **Commit**

This wait class only comprises one wait event - wait for redo log write confirmation after a commit (that is, 'log file sync')

### **Concurrency**

Waits for internal database resources (for example, latches)

### **Configuration**

Waits caused by inadequate configuration of database or instance resources (for example, undersized log file sizes, shared pool size)

### **Idle**

Waits that signify the session is inactive, waiting for work (for example, 'SQL\*Net message from client')

### **Network**

Waits related to network messaging (for example, 'SQL\*Net more data to dblink')

### **Other**

Waits which should not typically occur on a system (for example, 'wait for EMON to spawn')

### **Queue**

Contains events that signify delays in obtaining additional data in a pipelined environment. The time spent on these wait events indicates inefficiency or other problems in the pipeline. It affects features such as parallel queries or `DBMS_PIPE` PL/SQL packages.

### **Scheduler**

Resource Manager related waits (for example, 'resmgr: become active')

### **System I/O**

Waits for background process I/O (for example, DBWR wait for 'db file parallel write')

### **User I/O**

Waits for user I/O (for example 'db file sequential read')

## C.2 Descriptions of Common Wait Event Parameters

This section describes some of the common wait event parameters.

### **block#**

This is the block number of the block for which Oracle needs to wait. The block number is relative to the start of the file. To find the object to which this block belongs, issue the following SQL statement:

```
select segment_name, segment_type, owner, tablespace_name
from dba_extents
where file_id = file#
 and block#
 between block_id and block_id + blocks - 1;
```

### **blocks**

The number of blocks that is being either read from or written to the file. The block size depends on the file type:

- Database files have a block size of `DB_BLOCK_SIZE`
- Logfiles and control files have a block size that is equivalent to the physical block size of the platform

### **break?**

If the value for this parameter equals 0, a reset was sent to the client. A nonzero value indicates that a break was sent to the client.

### **class**

The class of the block describes how the contents of the block are used. For example, class 1 represents data block, and class 2 represents sort block. Use this SQL query to see the block classes:

```
SELECT view_definition FROM V_$FIXED_VIEW_DEFINITION WHERE
view_name='GV$WAITSTAT';
```

### **dba**

The initials "dba" represents the data block address, which consists of a file number and a block number.

### **driver id**

The address of the disconnect function of the driver that is currently being used.

### **file#**

The following query returns the name of the database file:

```
select *
from v$datafile
where file# = file#;
```

**id1**

The first identifier (*id1*) of the enqueue or global lock takes its value from P2 or P2RAW. The meaning of the identifier depends on the name (P1).

**id2**

The second identifier (*id2*) of the enqueue or global lock takes its value from P3 or P3RAW. The meaning of the identifier depends on the name (P1).

**le**

The relative index number into V\$GC\_ELEMENT.

**mode**

The *mode* is usually stored in the low order bytes of P1 or P1RAW and indicates the mode of the enqueue or global lock request. This parameter has one of the following values:

**Table C-1 Lock Mode Values**

| Mode Value | Description         |
|------------|---------------------|
| 1          | Null mode           |
| 2          | Sub-Share           |
| 3          | Sub-Exclusive       |
| 4          | Share               |
| 5          | Share/Sub-Exclusive |
| 6          | Exclusive           |

Use the following SQL statement to retrieve the name of the lock and the mode of the lock request:

```
select chr(bitand(p1,-16777216)/16777215)||
 chr(bitand(p1, 16711680)/65535) "Lock",
 bitand(p1, 65535) "Mode"
from v$session_wait
where event = 'DFS enqueue lock acquisition';
```

**name and type**

The name or "type" of the enqueue or global lock can be determined by looking at the two high order bytes of P1 or P1RAW. The name is always two characters. Use the following SQL statement to retrieve the lock name.

```
select chr(bitand(p1,-16777216)/16777215)||
 chr(bitand(p1,16711680)/65535) "Lock"
from v$session_wait
where event = 'DFS enqueue lock acquisition';
```

**namespace**

The name of the object namespace as it is displayed in V\$DB\_OBJECT\_CACHE view.

**requests**

The number of I/Os that are "requested." This differs from the number of blocks in that one request could potentially contain multiple blocks.

**session#**

The number of the inactive session. Use the following SQL statement to find more information about the session:

```
select *
from v$session
where sid = session#;
```

**waited**

This is the total amount of time the session has waited for this session to terminate.

## C.3 Descriptions of Wait Events

This section provides detailed descriptions for those wait events of greatest interest.

Where appropriate, pointers are provided to further information elsewhere in Oracle Database documentation. For a complete listing of wait events, in alphabetical order, you can issue the following SQL statement:

```
SQL> SELECT name FROM V$EVENT_NAME ORDER BY name;
```

### C.3.1 alter system set dispatcher

A session has issued a statement `ALTER SYSTEM SET DISPATCHER = string` and is waiting for the dispatchers to get started.

**Wait Time:** The session will wait 1 / 100 of a second and verify if the new dispatchers have started, else the session will wait again

| Parameter     | Description                                                     |
|---------------|-----------------------------------------------------------------|
| <i>waited</i> | Number of times that the session has waited 1 / 100 of a second |

### C.3.2 ARCH Remote Write

Used to track the time (in centiseconds) that `ARCn` background processes spend blocked waiting for network write operations to complete.

### C.3.3 ASYNC Remote Write

Used to track the time (in centiseconds) for asynchronous streaming RFSWRITE operations. This includes stall reaps and streaming network submission time. This time is accumulated by *TTnn* (Redo Transport Slave) background processes.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

### C.3.4 batched allocate scn lock request

A session is waiting on another process to allocate a system change number (SCN). If the foreground timed out waiting on a process to get the SCN, the foreground will get the SCN.

**Wait Time:** The wait time is 1 second on the assumption that an SCN allocation should normally need much less than that

**Parameters:** None

### C.3.5 BFILE check if exists

The session waits to check if an external large object (LOB) exists.

**Wait Time:** The total elapsed time for the **exists** call

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

### C.3.6 BFILE check if open

The session waits for an external large object (LOB) to open.

**Wait Time:** The total elapsed time for the **isopen** call

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

### C.3.7 BFILE closure

The session waits for an external large object (LOB) to close.

**Wait Time:** The total elapsed time for the **close** call

---

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

---

### C.3.8 BFILE get length

The session waits on a call to check the size of an external large object (LOB).

**Wait Time:** The total elapsed time for the call to check the LOB size

---

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

---

### C.3.9 BFILE get name object

The session waits on a call to find or generate the external name of a external large object.

**Wait Time:** The total elapsed time for **make external file name** to complete

---

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

---

### C.3.10 BFILE get path object

The session is waiting on a call to find or generate the external path name of an external large object (LOB).

**Wait Time:** The total elapsed time for **make external path** to complete

---

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

---

### C.3.11 BFILE internal seek

The session waits for a positioning call within the external large object (LOB) to complete.

**Wait Time:** The total elapsed time for the **seek** to complete

---

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

---

## C.3.12 BFILE open

The session waits for an external large object (LOB) to open.

**Wait Time:** The total elapsed time for the **isopen** call

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

## C.3.13 BFILE read

The session waits for a read from a external large object (LOB) to complete.

**Wait Time:** The total elapsed time for the **read** to complete

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

## C.3.14 broadcast mesg queue transition

Processes enter "wait for broadcast mesg queue transition" when cleaning up a publisher channel handle to a RELIABLE broadcast channel. The publisher is responsible for moving the message to the free queue, but it cannot do so until the message is in the done queue. If the message is still not in the done queue, process enters this wait. This wait event will most likely appear when an Oracle process is about to exit normally, or when PMON cleans up a dead process.

**Wait Time:** Varies

| Parameter             | Description                                                          |
|-----------------------|----------------------------------------------------------------------|
| <i>channel handle</i> | publisher channel handle pointer                                     |
| <i>message</i>        | broadcast message pointer                                            |
| <i>location</i>       | A number indicating the function in KSR where the process is waiting |

## C.3.15 broadcast mesg recovery queue transition

Processes enter "wait for broadcast mesg recovery queue transition" when cleaning up a publisher channel handle to a RELIABLE broadcast channel. The broadcasted message is in the recovery queue of another channel handle (for example, ch2). Process enters this wait, if the message is yet to be removed from the recovery queue of the ch2 channel handle. This wait event will most likely appear when an Oracle process is about to exit normally, or when PMON cleans up a dead process.

**Wait Time:** Varies

| Parameter             | Description                      |
|-----------------------|----------------------------------|
| <i>channel handle</i> | Publisher channel handle pointer |

| Parameter       | Description                                                          |
|-----------------|----------------------------------------------------------------------|
| <i>message</i>  | Broadcast message pointer                                            |
| <i>location</i> | A number indicating the function in KSR where the process is waiting |

### C.3.16 buffer busy waits

Wait until a buffer becomes available.

There are four reasons that a session cannot pin a buffer in the buffer cache, and a separate wait event exists for each reason:

1. "buffer busy waits": A session cannot pin the buffer in the buffer cache because another session has the buffer pinned.
2. "read by other session": A session cannot pin the buffer in the buffer cache because another session is reading the buffer from disk.
3. "gc buffer busy acquire": A session cannot pin the buffer in the buffer cache because another session is reading the buffer from the cache of another instance.
4. "gc buffer busy release": A session cannot pin the buffer in the buffer cache because another session on another instance is taking the buffer from this cache into its own cache so it can pin it.

Prior to release 10.1, all four reasons were covered by "buffer busy waits." In release 10.1, the "gc buffer busy" wait event covered both the "gc buffer busy acquire" and "gc buffer busy release" wait events.

**Wait Time:** Normal wait time is 1 second. If the session was waiting for a buffer during the last wait, then the next wait will be 3 seconds.

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>class#</i> | See " <a href="#">class</a> "  |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about the potential causes of the buffer busy waits wait event

### C.3.17 buffer deadlock

Oracle does not really wait on this event; the foreground only yields the CPU. Thus, the chances of catching this event are very low. This is not an application induced deadlock, but an assumed deadlock by the cache layer. The cache layer cannot get a buffer in a certain mode within a certain amount of time.

**Wait Time:** 0 seconds. The foreground process only yields the CPU and will usually be placed at the end of the CPU run queue.

| Parameter    | Description                                                                 |
|--------------|-----------------------------------------------------------------------------|
| <i>class</i> | See " <a href="#">class</a> "                                               |
| <i>mode</i>  | See " <a href="#">mode</a> "                                                |
| <i>flag</i>  | The flag points to the internal flags used by the session to get this block |
| <i>dba</i>   | See " <a href="#">dba</a> "                                                 |

### C.3.18 buffer latch

The session waits on the buffer hash chain latch. Primarily used in the dump routines.

**Wait Time:** 1 second

| Parameter         | Description                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>latch addr</i> | The virtual address in the SGA where this latch is located. Use the following statement to find the name of this latch:<br><br><pre>select * from v\$latch a, v\$latchname b where addr = <i>latch addr</i> and a.latch# = b.latch#;</pre> |
| <i>chain#</i>     | The index into array of buffer hash chains. When the chain is 0xffffffff, the foreground waits on the LRU latch.                                                                                                                           |

### C.3.19 buffer read retry

This event occurs only if the instance is mounted in shared mode (Oracle Real Application Cluster).

During the read of the buffer, the contents changed. This means that either:

- The version number, dba, or the incarnation and sequence number stored in the block no longer match
- The checksum on the block does not match the checksum in the block

The block will be reread (this may fail up to 3 times), then corruption is assumed and the corrupt block is dumped in the trace file.

**Wait Time:** The wait time is the elapsed time of the read

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |

### C.3.20 checkpoint completed

A session waits for a checkpoint to complete. This could happen, for example, during a close database or a local checkpoint.

**Wait Time:** 5 seconds

**Parameters:** None

## C.3.21 cleanup of aborted processes

When a process spawn is aborted while the process spawning background is in the middle of spawning, the current session must wait until the pid of the new process is filled in. Once the pid is filled in, then the process spawn can be actually aborted.

**Wait Time:** Usually 3 seconds

| Parameter       | Description          |
|-----------------|----------------------|
| <i>location</i> | Location of the wait |

## C.3.22 control file parallel write

This event occurs while the session is writing physical blocks to all control files. This happens when:

- The session starts a control file transaction (to ensure the control files are up to date in case the session crashes before committing the control file transaction)
- The session commits a transaction to a control file
- Changing a generic entry in the control file, the new value is being written to all control files

**Wait Time:** The wait time is the time it takes to finish all writes to all control files

| Parameter       | Description                                                          |
|-----------------|----------------------------------------------------------------------|
| <i>files</i>    | The number of control files to which the session is writing          |
| <i>blocks</i>   | The number of blocks that the session is writing to the control file |
| <i>requests</i> | The number of I/O requests which the session wants to write          |

## C.3.23 control file sequential read

Reading from the control file. This happens often. For example, while:

- Making a backup of the control files
- Sharing information (between instances) from the control file
- Reading other blocks from the control files
- Reading the header block

**Wait Time:** The wait time is the elapsed time of the read

| Parameter     | Description                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file#</i>  | The control file from which the session is reading                                                                                                                                        |
| <i>block#</i> | Block number in the control file from where the session starts to read. The block size is the physical block size of the port (usually 512 bytes, some UNIX ports have 1 or 2 Kilobytes). |
| <i>blocks</i> | The number of blocks that the session is trying to read                                                                                                                                   |

## C.3.24 control file single write

This wait is signaled while the control file's shared information is written to disk. This is an atomic operation protected by an enqueue (CF), so that only one session at a time can write to the entire database.

**Wait Time:** The wait time is the elapsed time of the write

| Parameter     | Description                                                                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file#</i>  | This identifies the control file to which the session is currently writing                                                                                                        |
| <i>block#</i> | Block number in the control file where the write begins. The block size is the as the physical block size of the port (usually 512 bytes, some UNIX ports have 1 or 2 Kilobytes). |
| <i>blocks</i> | The number of blocks that the session is trying to write                                                                                                                          |

## C.3.25 cursor: mutex S

A session waits on this event when it is requesting a mutex in shared mode, when another session is currently holding a this mutex in exclusive mode on the same cursor object.

| Parameter | Description                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Hash value of cursor                                                                                                 |
| <i>P2</i> | Mutex value (top 2 bytes contain SID holding mutex in exclusive mode, and bottom two bytes usually hold the value 0) |
| <i>P3</i> | Mutex where (an internal code locator) OR'd with Mutex Sleeps                                                        |

## C.3.26 cursor: mutex X

The session requests the mutex for a cursor object in exclusive mode, and it must wait because the resource is busy. The mutex is busy because either the mutex is being held in exclusive mode by another session or the mutex is being held shared by one or more sessions. The existing mutex holder(s) must release the mutex before the mutex can be granted exclusively.

| Parameter | Description                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Hash value of cursor                                                                                                 |
| <i>P2</i> | Mutex value (top 2 bytes contain SID holding mutex in exclusive mode, and bottom two bytes usually hold the value 0) |
| <i>P3</i> | Mutex where (an internal code locator) OR'd with Mutex Sleeps                                                        |

## C.3.27 cursor: pin S

A session waits on this event when it wants to update a shared mutex pin and another session is currently in the process of updating a shared mutex pin for the same cursor object. This wait event should rarely be seen because a shared mutex pin update is very fast.

**Wait Time:** Microseconds

| Parameter | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Hash value of cursor                                                                                                  |
| <i>P2</i> | Mutex value (top 2 bytes contains SID holding mutex in exclusive mode, and bottom two bytes usually hold the value 0) |
| <i>P3</i> | Mutex where (an internal code locator) OR'd with Mutex Sleeps                                                         |

### C.3.28 cursor: pin S wait on X

A session waits for this event when it is requesting a shared mutex pin and another session is holding an exclusive mutex pin on the same cursor object.

**Wait Time:** Microseconds

| Parameter | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Hash value of cursor                                                                                                  |
| <i>P2</i> | Mutex value (top 2 bytes contains SID holding mutex in exclusive mode, and bottom two bytes usually hold the value 0) |
| <i>P3</i> | Mutex where (an internal code locator) OR'd with Mutex Sleeps                                                         |

### C.3.29 cursor: pin X

A session waits on this event when it is requesting an exclusive mutex pin for a cursor object and it must wait because the resource is busy. The mutex pin for a cursor object can be busy either because a session is already holding it exclusive, or there are one or more sessions which are holding shared mutex pin(s). The exclusive waiter must wait until all holders of the pin for that cursor object have released it, before it can be granted.

**Wait Time:** Microseconds

| Parameter | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Hash value of cursor                                                                                                  |
| <i>P2</i> | Mutex value (top 2 bytes contains SID holding mutex in exclusive mode, and bottom two bytes usually hold the value 0) |
| <i>P3</i> | Mutex where (an internal code locator) OR'd with Mutex Sleeps                                                         |

### C.3.30 Data Guard: process clean up

During Data Guard process termination, Data Guard will wait for one second for process cleanup to complete.

### C.3.31 Data Guard: process exit

During Data Guard process termination, Data Guard will wait for a process to exit before attempting any process cleanup that may be required. It will sleep for one second between each check for process exit.

## C.3.32 Data Guard Broker: single instance

The Data Guard Broker (DMON) process waits for the other instances in this cluster to complete shutdown before continuing with the broker operation.

**Wait Time:** Depends on the number of instances, but not exceeding 30 seconds times the number of instances

## C.3.33 db file asynch I/O submit

When asynchronous I/O is available, this wait event captures any time spent in submitting I/Os to the underlying storage.

**See Also:**

"db file parallel write"

## C.3.34 db file parallel read

This happens during recovery. It can also happen during buffer prefetching, as an optimization (rather than performing multiple single-block reads). Database blocks that must be changed as part of recovery are read in parallel from the database.

**Wait Time:** Wait until all of the I/Os are completed

| Parameter       | Description                                                                       |
|-----------------|-----------------------------------------------------------------------------------|
| <i>files</i>    | This indicates the number of files to which the session is reading                |
| <i>blocks</i>   | This indicates the total number of blocks to be read                              |
| <i>requests</i> | This indicates the total number of I/O requests, which will be the same as blocks |

## C.3.35 db file parallel write

This event occurs in the DBWR. It indicates the time that DBWR spends waiting for I/O completion.

If asynchronous I/O is available, then the db file asynch I/O submit wait event captures any time spent in submitting I/Os to the underlying storage.

When asynchronous I/O is not available, db file parallel write captures the time spent during submit and reap.

**Wait Time:** While there are outstanding I/Os, DBWR waits for some of the writes to complete. DBWR does not wait for all of the outstanding I/Os to complete.

| Parameter        | Description                                                                       |
|------------------|-----------------------------------------------------------------------------------|
| <i>requests</i>  | This indicates the total number of I/O requests, which will be the same as blocks |
| <i>interrupt</i> |                                                                                   |

| Parameter      | Description                                                                                |
|----------------|--------------------------------------------------------------------------------------------|
| <i>timeout</i> | This indicates the timeout value in hundredths of a second to wait for the I/O completion. |

 **See Also:**

- *Oracle Database Performance Tuning Guide* about how this wait event can help identify I/O problems
- ["db file asynch I/O submit"](#)

### C.3.36 db file scattered read

Similar to the "db file sequential read" wait event, except that the session is reading multiple data blocks.

**Wait Time:** The wait time is the actual time it takes to do all of the I/Os

| Parameter     | Description                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "                                                                           |
| <i>block#</i> | See " <a href="#">block#</a> "                                                                          |
| <i>blocks</i> | The number of blocks that the session is trying to read from the <i>file#</i> starting at <i>block#</i> |

 **See Also:**

- *Oracle Database Performance Tuning Guide* for more information about this wait event
- *Oracle Database Performance Tuning Guide* about how this wait event can help identify I/O problems
- *Oracle Database Performance Tuning Guide* about potential causes for this wait event

### C.3.37 db file sequential read

The session waits while a sequential read from the database is performed. This event is also used for rebuilding the control file, dumping data file headers, and getting the database file headers.

**Wait Time:** The wait time is the actual time it takes to do the I/O

| Parameter    | Description                   |
|--------------|-------------------------------|
| <i>file#</i> | See " <a href="#">file#</a> " |

| Parameter     | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| <i>block#</i> | See " <a href="#">block#</a> "                                                |
| <i>blocks</i> | This is the number of blocks that the session is trying to read (should be 1) |

### C.3.38 db file single write

This event is used to wait for the writing of the file headers.

**Wait Time:** The wait time is the actual time it takes to do the I/O

| Parameter     | Description                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "                                                                              |
| <i>block#</i> | See " <a href="#">block#</a> "                                                                             |
| <i>blocks</i> | This is the number of blocks that the session is trying to write in <i>file#</i> starting at <i>block#</i> |

 **See Also:**

- *Oracle Database Performance Tuning Guide* about how this wait event can help identify I/O problems

### C.3.39 DFS db file lock

This event occurs only for the DBWR in Real Application Clusters. Each DBWR of every instance holds a global lock on each file in shared mode. The instance that is trying to offline the file will escalate the global lock from shared to exclusive. This signals the other instances to synchronize their SGAs with the control file before the file can be taken offline.

The name of this lock is **DF** (see [Oracle Enqueue Names](#) for more information).

**Wait Time:** 1 second in loop. The DBWR is waiting in a loop (sleep, check) for the other instances to downgrade to NULL mode. During this time, the DBWR cannot perform other tasks such as writing buffers.

| Parameter   | Description                   |
|-------------|-------------------------------|
| <i>file</i> | See " <a href="#">file#</a> " |

### C.3.40 DFS lock handle

The session waits for the lock handle of a global lock request. The lock handle identifies a global lock. With this lock handle, other operations can be performed on this global lock (to identify the global lock in future operations such as conversions or release). The global lock is maintained by the DLM.

**Wait Time:** The session waits in a loop until it has obtained the lock handle from the DLM. Inside the loop there is a wait of 0.5 seconds.

| Parameter   | Description                           |
|-------------|---------------------------------------|
| <i>name</i> | See " <a href="#">name and type</a> " |
| <i>mode</i> | See " <a href="#">mode</a> "          |
| <i>id1</i>  | See " <a href="#">id1</a> "           |
| <i>id2</i>  | See " <a href="#">id2</a> "           |

The session needs to get the lock handle.

### C.3.41 direct path read

During Direct Path operations the data is asynchronously read from the database files. At some stage the session needs to make sure that all outstanding asynchronous I/O have been completed to disk. This can also happen if during a direct read no more slots are available to store outstanding load requests (a load request could consist of multiple I/Os).

**Wait Time:** 10 seconds. The session will be posted by the completing asynchronous I/O. It will never wait the entire 10 seconds. The session waits in a tight loop until all outstanding I/Os have completed.

| Parameter                 | Description                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>descriptor address</i> | This is a pointer to the I/O context of outstanding direct I/Os on which the session is currently waiting |
| <i>first dba</i>          | The dba of the oldest I/O in the context referenced by the descriptor address                             |
| <i>block cnt</i>          | Number of valid buffers in the context referenced by the descriptor address                               |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

## C.3.42 direct path sync

During Direct Path write operations the data is asynchronously written to the database files. At some point the session needs to ensure that all outstanding asynchronous I/O have been completed to disk. On UNIX the `fsync` command, which synchronizes data to disk, is issued to confirm that all the writes have completed and the data is all on disk.

**Wait Time:** The time taken for the `fsync` operation to complete, which normally is the time taken to complete the outstanding I/Os.

| Parameters   | Description                       |
|--------------|-----------------------------------|
| <i>file#</i> | See " <i>file#</i> "              |
| <i>flags</i> | Flags used for debugging purposes |

## C.3.43 direct path write

During Direct Path operations, the data is asynchronously written to the database files. At some stage the session needs to make sure that all outstanding asynchronous I/O have been completed to disk. This can also happen if, during a direct write, no more slots are available to store outstanding load requests (a load request could consist of multiple I/Os).

**Wait Time:** 10 seconds. The session will be posted by the completing asynchronous I/O. It will never wait the entire 10 seconds. The session waits in a tight loop until all outstanding I/Os have completed.

| Parameter                 | Description                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>descriptor address</i> | This is a pointer to the I/O context of outstanding direct I/Os on which the session is currently waiting |
| <i>first dba</i>          | The dba of the oldest I/O in the context referenced by the descriptor address                             |
| <i>block cnt</i>          | Number of valid buffers in the context referenced by the descriptor address                               |

### See Also:

*Oracle Database Performance Tuning Guide* for more information about this parameter

## C.3.44 Disk file operations I/O

This event is used to wait for disk file operations (for example, open, close, seek, and resize). It is also used for miscellaneous I/O operations such as block dumps and password file accesses.

**Wait Time:** The wait time is the actual time it takes to do the I/O

| Parameter            | Description                                                |
|----------------------|------------------------------------------------------------|
| <i>FileOperation</i> | Type of file operation                                     |
| <i>fileno</i>        | File identification number                                 |
| <i>filetype</i>      | Type of file (for example, log file, data file, and so on) |

### C.3.45 dispatcher shutdown

During shutdown immediate or normal, the shutdown process must wait for all the dispatchers to shutdown. As each dispatcher is signaled, the session that causes the shutdown is waits on this event until the requested dispatcher is no longer alive.

**Wait Time:** 1 second

| Parameter     | Description                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>waited</i> | Indicates the cumulative wait time. After 5 minutes, the session writes to the alert and trace files to indicate that there might be a problem. |

#### See Also:

*Oracle Database SQL Language Reference* for information about shutting down a dispatcher using `SHUTDOWN` clause of the `SQL ALTER SYSTEM` statement

### C.3.46 dispatcher timer

This basically means that the dispatcher is idle and waiting for some work to arrive.

**Wait Time:** 60 seconds

| Parameter         | Description                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>sleep time</i> | The intended sleep time. The dispatcher will return to work sooner if it is posted by either data arriving on the network or by a post from a shared server process to send data back to the client. |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

## C.3.47 duplicate cluster key

It is possible for a race condition to occur when creating a new cluster key. If it is found that another process has put the cluster key into the data/index block, then the session waits and retries. The retry should then find a valid cluster key.

**Wait Time:** 0.01 seconds

| Parameter  | Description                                                                   |
|------------|-------------------------------------------------------------------------------|
| <i>dba</i> | The dba of the block into which the session is trying to insert a cluster key |

## C.3.48 enq: OW - initialization

A session will wait on this event if it is trying to initialize the database wallet, and another session has already begun an initialization.

**Wait Time:** Total time necessary to initialize the wallet context

**Parameters:** None

### See Also:

*Oracle Database Performance Tuning Guide* for more information about the potential causes of an enqueue wait event

## C.3.49 enq: OW - termination

A session will wait on this event if it is trying to terminate the database wallet, and another session has already begun a termination.

**Wait Time:** Total time necessary to deallocate memory used by the wallet context and terminate the context.

**Parameters:** None

### See Also:

*Oracle Database Performance Tuning Guide* for more information about the potential causes of an enqueue wait event

## C.3.50 enq: TX - index contention

Occurs when a transaction inserting a row in an index has to wait for the end of an index block split being done by another transaction.

### C.3.51 enq: TX - row lock contention

This wait event can occur for several reasons.

- If one user is wanting to update or delete a row or rows that another session is modifying. The session holding the lock will release it when it performs a COMMIT or ROLLBACK.
- If a session is waiting due to potential duplicates in a UNIQUE index. If two sessions try to insert the same key value, the second session has to wait to see if an ORA-0001 should be raised or not. The session holding the lock will release it when it performs a COMMIT or ROLLBACK.
- If a session is waiting due to a shared bitmap index fragment. Bitmap indexes index key values and a range of rowids. Each entry in a bitmap index can cover many rows in the actual table. If two sessions want to update rows covered by the same bitmap index fragment, then the second session waits for the first transaction to either COMMIT or ROLLBACK by waiting for the TX lock.

### C.3.52 enqueue

The session is waiting for a local enqueue.

The wait depends on the name of the enqueue (see [Oracle Enqueue Names](#)).

**Wait Time:** Depends on the enqueue name

| Parameter   | Description                           |
|-------------|---------------------------------------|
| <i>name</i> | See " <a href="#">name and type</a> " |
| <i>mode</i> | See " <a href="#">mode</a> "          |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about the potential causes of an enqueue wait event

### C.3.53 flashback buf free by RVWR

This wait event only occurs when Flashback Database is turned on. A session waits for recovery writer (RVWR) to write flashback data to the flashback logs on disk because the buffers are full. Until RVWR can free up the buffers, the session may need to wait.

If this event becomes a top wait event for the database, it is typically because the file system or storage system for the Fast Recovery Area does not support enough bandwidth for Oracle to write the flashback database logs. Refer to the Flashback Database section in *Oracle Database Backup and Recovery User's Guide* for tuning considerations.

**Wait Time:** 1 second

**Parameters:** None

## C.3.54 flashback logfile sync

Waits for flashback database data to be written to disk.

**Wait Time:** Includes RVWR writing the flashback database data and posting this process

**Parameters:** None

## C.3.55 free buffer waits

This wait event can occur for several reasons.

- All buffer gets have been suspended. This could happen when a file was read-only and is now read/write. All the existing buffers must be invalidated since they are not linked to lock elements (needed when mounted parallel (shared)). So cache buffers are not assigned to data block addresses until the invalidation is finished.
- The session moved some dirty buffers to the dirty queue and now this dirty queue is full. The dirty queue must be written first. The session will wait on this event and try again to find a free buffer
- This also happens after inspecting **free buffer inspected** buffers. If no free buffer is found, Oracle waits for one second, and then tries to get the buffer again (depends on the context). For more information, see [free buffer inspected](#).

**Wait Time:** 1 second

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |

### See Also:

- *Oracle Database Performance Tuning Guide* for more information about this wait event
- *Oracle Database Performance Tuning Guide* about potential causes of this wait event

## C.3.56 free global transaction table entry

The session is waiting for a free slot in the global transaction table (used by the Distributed Database option). It will wait for 1 second and try again.

**Wait Time:** 1 second

| Parameter    | Description                                                                               |
|--------------|-------------------------------------------------------------------------------------------|
| <i>tries</i> | The number of times the session tried to find a free slot in the global transaction table |

### C.3.57 free process state object

Used during the creation of a process. The session will scan the process table and look for a free process slot. If none can be found, PMON is posted to check if all the processes currently in the process table are still alive. If there are dead processes, then PMON will clean them and make the process slot available to new processes. The waiting process will then rescan the process table to find the new slot.

**Wait Time:** 1 second

**Parameters:** None

### C.3.58 gc recovery quiesce

Instance recovery is waiting for a global cache operation to complete.

**Wait Time:** The total elapsed time for the global cache operation to complete

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>class</i>  | See " <a href="#">class</a> "  |

### C.3.59 GCS lock open S

The session waits for a resource get in SHARED mode on the block identified by *file#* and *block#*.

**Wait Time:** 1 second

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>class</i>  | See " <a href="#">class</a> "  |

### C.3.60 GCS lock open X

The session waits for a resource get in EXCLUSIVE mode on the block identified by *file#* and *block#*.

**Wait Time:** 1 second

| Parameter    | Description                   |
|--------------|-------------------------------|
| <i>file#</i> | See " <a href="#">file#</a> " |

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>lenum</i>  | See " <a href="#">le</a> "     |

### C.3.61 gcs remastering wait for drop pkey

A session dropping an object waits on the lock manager daemon (LMD) to remove the object's affinity to an instance.

Wait Time: 20 hundredths of a second

| Parameter   | Description                                        |
|-------------|----------------------------------------------------|
| <i>pkey</i> | The object id of the database object being dropped |

### C.3.62 global cache busy

The session waits to convert a buffer from Shared Current to Exclusive Current status.

Wait Time: 1 second

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>le</i>     | See " <a href="#">le</a> "     |

### C.3.63 global cache lock cleanup

PMON is waiting for an LCK process to cleanup the lock context after a foreground process died while doing a global cache lock operation.

Wait Time: 1 second

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>lenum</i>  | See " <a href="#">le</a> "     |

### C.3.64 global cache freelist

All releasable locks are used and a new one has been requested. To make a resource element available, a resource element is pinged.

Wait Time: The duration of the resource get operation to ping the resource element

Parameters: None

## C.3.65 inactive session

This event is used for switching and killing sessions.

- Switching sessions  
If a timeout period has been specified, then wait that amount of time for the session to be detached.
- Killing sessions  
From either `KILL SESSION` or internal request. Having posted a session that it should kill itself, wait for up to 1 minute for the session to terminate.

**Wait Time:** 1 second

| Parameter       | Description                      |
|-----------------|----------------------------------|
| <i>session#</i> | See " <a href="#">session#</a> " |
| <i>waited</i>   | See " <a href="#">waited</a> "   |

## C.3.66 inactive transaction branch

The session waits for a transaction branch that is currently used by another session.

**Wait Time:** 1 second

| Parameter      | Description                                                           |
|----------------|-----------------------------------------------------------------------|
| <i>branch#</i> | The serial number of the transaction for which the session is waiting |
| <i>waited</i>  | See " <a href="#">waited</a> "                                        |

## C.3.67 index block split

While trying to find an index key in an index block, Oracle noticed that the index block was being split. Oracle will wait for the split to finish and try to find the key again.

**Wait Time:** The session will yield the CPU, so there is no actual waiting time

| Parameter      | Description                                                                                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rootdba</i> | The root of the index                                                                                                                                                                                               |
| <i>level</i>   | This is the level of the block that the session is trying to split in the index. The leaf blocks are level 0. If the level is > 0, it is a branch block. (The root block can be considered a special branch block). |
| <i>childdb</i> | The block that the session is trying to split                                                                                                                                                                       |

## C.3.68 instance state change

The session waits for SMON to enable or disable cache or transaction recovery. This usually happens during `ALTER DATABASE OPEN` or `CLOSE`.

**Wait Time:** Wait time depends on the amount of time the action takes (that is, the amount of recovery needed)

| Parameter     | Description                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>layer</i>  | This value can be 1 or 2. If 1, it means that the transaction layer wants transaction recovery to be performed. If 2, it means that cache recovery will be performed. |
| <i>value</i>  | This value can be 0 (disable) or 1 (enable)                                                                                                                           |
| <i>waited</i> | The number of seconds waited so far                                                                                                                                   |

### C.3.69 io done

The session waits for an I/O to complete or it waits for a slave process to become available to submit the I/O request. This event occurs on platforms that do not support asynchronous I/O.

**Wait Time:** 50 milliseconds

| Parameter      | Description                  |
|----------------|------------------------------|
| <i>msg ptr</i> | A pointer to the I/O request |

### C.3.70 kcl bg acks

The session waits for the background LCK process(es) to finish what they are doing. For example:

- Lock recovery
- Initializing the locks (start up)
- Finalizing the locks (shut down)

**Wait Time:** 10 seconds

| Parameter    | Description                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------|
| <i>count</i> | The number of LCK processes that have finished                                                |
| <i>loops</i> | The number times the process had to wait for the LCK processes to finish what they were doing |

### C.3.71 ksxr wait for mount shared

The cross instance broadcast facility of this Oracle instance is waiting for the database mount in shared mode to complete.

**Wait Time:** The time taken for the instance to mount. An indefinite wait on this event implies that the instance startup is hanging.

### C.3.72 ktm: instance recovery

The session waits for SMON to finish the instance, transaction recovery, or sort segment cleanup.

**Wait Time:** The wait time can vary and depends on the amount of recovery needed

| Parameter            | Description                                                                                                                                                                                  |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>undo segment#</i> | If the value is 0, SMON is probably performing instance recovery. If P1 > 0, use this query to find the undo segment:<br><br><pre>select * from v\$rollstat where usn = undo segment#;</pre> |

### C.3.73 latch activity

This event is used as part of the process of determining whether a latch must be cleaned.

**Wait Time:** 0.05 to 0.1 seconds

| Parameter       | Description                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address</i>  | The address of the latch that is being checked                                                                                                                                               |
| <i>number</i>   | The latch number of the latch that has activity. To find more information on the latch, use the following SQL statement:<br><br><pre>select * from v\$latchname where latch# = number;</pre> |
| <i>process#</i> | If this is 0, it is the first phase of the in-flux tests                                                                                                                                     |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about latch wait events

### C.3.74 latch free

The process waits for a latch that is currently busy (held by another process).

**Wait Time:** The wait time increases exponentially and does not include spinning on the latch (active waiting). The maximum wait time also depends on the number of latches that the process is holding. There is an incremental wait of up to 2 seconds.

| Parameter      | Description                                                                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address</i> | The address of the latch for which the process is waiting                                                                                                                                           |
| <i>number</i>  | The latch number that indexes in the V\$LATCHNAME view. To find more information on the latch, use the following SQL statement:<br><br><pre>select * from v\$latchname where latch# = number;</pre> |

| Parameter    | Description                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------|
| <i>tries</i> | A count of the number of times the process tried to get the latch (slow with spinning) and the process has to sleep |

**See Also:**

*Oracle Database Performance Tuning Guide* for more information about latch wait events

### C.3.75 latch: redo copy

Redo copy latches are acquired by sessions in order to write changes into the redo log buffer and by the LGWR process to ensure that there are no current writers before it copies data from the buffer to the redo log.

### C.3.76 latch: row cache objects

This event occurs when another session is modifying the contents of part of the dictionary cache (or row cache). This event is often associated with high parse activity but may occur for other reasons, such as manipulation of rollback segments. *V\$ROWCACHE* may indicate which part of the row cache is being contended.

### C.3.77 library cache load lock

The session tries to find the load lock for the database object so that it can load the object. The load lock is always obtained in Exclusive mode, so that no other process can load the same object. If the load lock is busy the session will wait on this event until the lock becomes available.

**Wait Time:** 3 seconds (1 second for PMON)

| Parameter             | Description                                                |
|-----------------------|------------------------------------------------------------|
| <i>object address</i> | Address of the object being loaded                         |
| <i>lock address</i>   | Address of load lock being used                            |
| <i>mask</i>           | Indicates which data pieces of the object that must loaded |

### C.3.78 library cache lock

This event controls the concurrency between clients of the library cache. It acquires a lock on the object handle so that either:

- One client can prevent other clients from accessing the same object
- The client can maintain a dependency for a long time (for example, no other client can change the object)

This lock is also obtained to locate an object in the library cache.

**Wait Time:** 3 seconds (1 second for PMON)

| Parameter             | Description                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------|
| <i>handle address</i> | Address of the object being loaded                                                                              |
| <i>lock address</i>   | Address of the load lock being used. This is not the same thing as a latch or an enqueue, it is a State Object. |
| <i>mode</i>           | Indicates the data pieces of the object which must be loaded                                                    |
| <i>namespace</i>      | See " <a href="#">namespace</a> "                                                                               |

 **See Also:**

- *Oracle Database Performance Tuning Guide* for more information about this wait event
- *Oracle Database Performance Tuning Guide* for more information about potential causes of this wait event

## C.3.79 library cache pin

This event manages library cache concurrency. Pinning an object causes the heaps to be loaded into memory. If a client wants to modify or examine the object, the client must acquire a pin after the lock.

**Wait Time:** 3 seconds (1 second for PMON)

| Parameter             | Description                                                                                                               |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <i>handle address</i> | Address of the object being loaded                                                                                        |
| <i>pin address</i>    | Address of the load lock being used. This is not the same thing as a latch or an enqueue, it is basically a State Object. |
| <i>mode</i>           | Indicates which data pieces of the object that must be loaded                                                             |
| <i>namespace</i>      | See " <a href="#">namespace</a> "                                                                                         |

 **See Also:**

## C.3.80 library cache shutdown

The process shutting down the instance waits for sessions to complete before proceeding with library cache shutdown.

### C.3.81 library cache: mutex X

Library cache mutexes protect hash buckets within the shared pool. Each hash bucket contains a number of cursors. The mutex must be held in exclusive mode before any of the structures that it protects can be changed. This wait event is often associated with high parse activity.

### C.3.82 LMON global data update

The rolling migration operation is waiting for a response from LMON to acknowledge the global data was updated.

**Wait Time:** The time it takes for LMON to publish/retrieve the global data associated with a

**Parameters:** None

### C.3.83 lock manager wait for remote message

The lock manager waits for a message from a remote lock manager in the same configuration.

**Wait Time:** The elapsed time of the wait

| Parameter       | Description                         |
|-----------------|-------------------------------------|
| <i>waittime</i> | The elapsed time of the actual wait |

### C.3.84 Log archive I/O

Used local archiving of online redo logs (for a production database) or standby redo logs (for a standby database). When the archiving process exhausts its I/O buffers because all of them are being used for on-going I/O's, the wait for an available I/O buffer is captured in this system wait event.

**Wait Time:** Depends on the speed of the disks

**Parameters:** None

### C.3.85 log buffer space

Waiting for space in the log buffer because the session is writing data into the log buffer faster than LGWR can write it out. Consider making the log buffer bigger if it is small, or moving the log files to faster disks such as striped disks.

**Wait Time:** Usually 1 second, but 5 seconds if it is waiting for a Switch Logfile to complete

**Parameters:** None

 **See Also:**

- *Oracle Database Performance Tuning Guide* for more information about this wait event
- *Oracle Database Performance Tuning Guide* for more information about potential causes of this wait event

## C.3.86 log file parallel write

Writing redo records to the redo log files from the log buffer.

**Wait Time:** Time it takes for the I/Os to complete. Even though redo records are written in parallel, the parallel write is not complete until the last I/O is on disk.

| Parameter       | Description                    |
|-----------------|--------------------------------|
| <i>files</i>    | Number of files to be written  |
| <i>blocks</i>   | Number of blocks to be written |
| <i>requests</i> | Number of I/O requests         |

 **See Also:**

*Oracle Database Performance Tuning Guide* for information about how this wait event can help identify I/O problems

## C.3.87 log file sequential read

Waiting for the read from this logfile to return. This is used to read redo records from the log file.

**Wait Time:** Time it takes to complete the physical I/O (read)

| Parameter     | Description                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------|
| <i>log#</i>   | The relative sequence number of the logfiles within a log group (used only when dumping the logfiles) |
| <i>block#</i> | See " <a href="#">block#</a> "                                                                        |
| <i>blocks</i> | The number of blocks to read                                                                          |

## C.3.88 log file single write

Waiting for the write to this logfile to complete. This event is used while updating the header of the logfile. It is signaled when adding a log file member and when incrementing sequence numbers.

**Wait Time:** Time it takes for the physical I/O (write) to complete

---

| Parameter     | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| <i>log#</i>   | This is the number of the group/log to which the session is currently writing |
| <i>block#</i> | See " <a href="#">block#</a> "                                                |
| <i>blocks</i> | The number of blocks to write                                                 |

---

### C.3.89 log file switch (archiving needed)

Waiting for a log switch because the log that the LGWR will be switching into has not been archived yet. Check the alert log to ensure that archiving has not stopped due to a failed archive write. To speed archiving, consider adding more archive processes or putting the archive files on striped disks.

**Wait Time:** 1 second

**Parameters:** None

### C.3.90 log file switch (checkpoint incomplete)

Waiting for a log switch because the session cannot wrap into the next log. Wrapping cannot be performed because the checkpoint for that log has not completed.

**Wait Time:** 1 second

**Parameters:** None

### C.3.91 log file switch (clearing log file)

Waiting for a log switch because the log is being cleared due to a `CLEAR LOGFILE` command or implicit clear logfile executed by recovery.

**Wait Time:** 1 second

**Parameters:** None

### C.3.92 log file switch (private strand flush incomplete)

User sessions trying to generate redo, wait on this event when LGWR waits for DBWR to complete flushing redo from IMU buffers into the log buffer; when DBWR is complete LGWR can then finish writing the current log, and then switch log files.

**Wait Time:** 1 second

**Parameters:** None

### C.3.93 log file switch completion

Waiting for a log switch to complete.

**Wait Time:** 1 second

**Parameters:** None

### C.3.94 log file sync

When a user session commits, the session's redo information must be flushed to the redo logfile. The user session will post the LGWR to write the log buffer to the redo log file. When the LGWR has finished writing, it will post the user session.

**Wait Time:** The wait time includes the writing of the log buffer and the post.

| Parameter      | Description                                                                        |
|----------------|------------------------------------------------------------------------------------|
| <i>buffer#</i> | The number of the physical buffer in the redo log buffer that must be synchronized |

#### See Also:

- *Oracle Database Performance Tuning Guide* for more information about this wait event
- *Oracle Database Performance Tuning Guide* for information about potential causes of this wait event

### C.3.95 log switch/archive

Used as part of the `ALTER SYSTEM ARCHIVE LOG CHANGE scn` statement. The session waits for the current log from all open threads to be archived.

**Wait Time:** Wait for up to 10 seconds

| Parameter      | Description                                                                 |
|----------------|-----------------------------------------------------------------------------|
| <i>thread#</i> | The thread number of the thread that is currently archiving its current log |

### C.3.96 optimizer stats update retry

When concurrent sessions try to update optimizer statistics for the same object, all of them except the one that successfully acquired all necessary locks/pins on the library/row cache entries, wait on this wait event and then retry locking after a short period of time. In addition to explicit statistics gathering and maintenance operations using the `DBMS_STATS` package, Oracle database itself may try to update statistics for some objects, either on behalf of the user or for its own maintenance purposes.

**Wait Time:** 10 ms

**Parameters:** None

### C.3.97 parallel recovery change buffer free

The parallel recovery coordinator is waiting for a change mapping buffer to be released by one of the recovery slaves.

**Wait Time:** 100ms

**Parameters:** None

### C.3.98 parallel recovery control message reply

The parallel recovery coordinator is waiting for all recovery slaves to respond to a synchronous control message.

**Wait Time:** 100ms

**Parameters:** None

### C.3.99 parallel recovery coord send blocked

The parallel recovery coordinator cannot send a redo change message because the recovery slave is still actively applying redo that it has already received and has not yet released the channel.

**Wait Time:** 100ms

**Parameters:** None

### C.3.100 parallel recovery coord wait for reply

The parallel recovery coordinator is waiting for all recovery slaves to exit.

**Wait Time:** 100ms

**Parameters:** None

### C.3.101 parallel recovery coordinator waits for slave cleanup

The parallel recovery coordinator is waiting for all recovery slaves to exit gracefully.

**Wait Time:** 10ms

**Parameters:** None

### C.3.102 parallel recovery read buffer free

The parallel recovery coordinator is waiting for a log read buffer to be released by all recovery slaves. Only after every recovery slave finishes applying redo from a log read buffer, can the buffer be used by the coordinator to issue the next log read.

**Wait Time:** 100ms

**Parameters:** None

### C.3.103 parallel recovery slave next change

A parallel recovery slave is idle and waiting for the next change message from the coordinator.

**Wait Time:** 100ms

**Parameters:** None

### C.3.104 pending global transaction(s)

This event should happen only during testing. The session waits for pending transactions to clear.

**Wait Time:** 30 seconds

| Parameter    | Description                                                                    |
|--------------|--------------------------------------------------------------------------------|
| <i>scans</i> | Number of times the session has scanned the <code>PENDING_TRANS\$</code> table |

### C.3.105 pipe get

The session waits for a message to be received on the pipe or for the pipe timer to expire.

**Wait Time:** There is a 5 second wake up (check) and the pipe timer set by the user

| Parameter             | Description                                   |
|-----------------------|-----------------------------------------------|
| <i>handle address</i> | The library cache object handle for this pipe |
| <i>buffer length</i>  | The length of the buffer                      |
| <i>timeout</i>        | The pipe timer set by the user                |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.106 pipe put

The session waits for the pipe send timer to expire or for space to be made available in the pipe.

**Wait Time:** There is the 5 second wakeup (check) and the user-supplied timeout value

| Parameter             | Description                                                        |
|-----------------------|--------------------------------------------------------------------|
| <i>handle address</i> | The library cache object handle for this pipe                      |
| <i>record length</i>  | The length of the record or buffer that has been put into the pipe |
| <i>timeout</i>        | The pipe timer set by the user                                     |

### C.3.107 PL/SQL lock timer

This event is called through the `DBMS_LOCK.SLEEP` procedure. This event will most likely originate from procedures written by a user.

**Wait Time:** The wait time is in hundredths of seconds and depends on the user context

| Parameter       | Description                                                                        |
|-----------------|------------------------------------------------------------------------------------|
| <i>duration</i> | The duration that the user specified in the <code>DBMS_LOCK.SLEEP</code> procedure |

### C.3.108 pmon timer

This is the main wait event for PMON. When PMON is idle, it is waiting on this event.

**Wait Time:** Up to 3 seconds, if not posted before

| Parameter       | Description                                                |
|-----------------|------------------------------------------------------------|
| <i>duration</i> | The actual amount of time that the PMON is trying to sleep |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.109 prewarm transfer retry

Release a hash latch, then wait under this event before attempting to re-acquire the hash latch.

**Wait Time:** 10ms

**Parameters:** None

### C.3.110 prior process spawner to be cleaned up

When a prior process has died while spawning a background, the current process which is trying to spawn new a background must wait until the prior process state is cleaned up.

**Wait Time:** Usually 3 - 10 seconds

| Parameter          | Description                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <i>process_pid</i> | process identifier (see <code>V\$PROCESS.PID</code> ) of the process whose state must be cleaned up.        |
| <i>process_sno</i> | process serial number (see <code>V\$PROCESS.SERIAL#</code> ) of the process whose state must be cleaned up. |

### C.3.111 process startup

Wait for a shared server, Dispatcher, or other background process to start.

**Wait Time:** Wait up to 1 second for a background process to start. If timed out, then re-wait until 5 minutes have passed and signal an error. If the process has started, the event will acknowledge this.

| Parameter       | Description                                     |
|-----------------|-------------------------------------------------|
| <i>type</i>     | The process type that was started               |
| <i>process#</i> | The process number of the process being started |
| <i>waited</i>   | Cumulative time waited for the process to start |

### C.3.112 PX Deque wait

The process is waiting for a message during a parallel execute.

**Wait Time:** The wait time depends on how quickly the message arrives. Wait times can vary, but it will normally be a short period of time.

| Parameter        | Description                                          |
|------------------|------------------------------------------------------|
| <i>reason</i>    | The reason for dequeuing                             |
| <i>sleeptime</i> | The amount of time that the session slept            |
| <i>loop</i>      | The total number of times that the session has slept |

### C.3.113 PX qref latch

Each parallel execution process has a parallel execution qref latch, which must be acquired before the queue buffers can be manipulated.

**Wait Time:** Wait up to 1 second

| Parameter        | Description                                                           |
|------------------|-----------------------------------------------------------------------|
| <i>function</i>  | Indicates the type of wait that the session is doing                  |
| <i>sleeptime</i> | The amount of time that the session waits (in hundredths of a second) |
| <i>qref</i>      | The address of the process queue for which the session is waits       |

### C.3.114 PX server shutdown

During normal or immediate shutdown the parallel execution slaves are posted to shutdown cleanly. If any parallel execution slaves are still alive after 10 seconds, they are killed.

**Wait Time:** Wait up to 0.5 seconds

| Parameter     | Description                                                    |
|---------------|----------------------------------------------------------------|
| <i>nalive</i> | The number of parallel execution slaves that are still running |

| Parameter        | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <i>sleeptime</i> | The total sleeptime since the session started to wait on this event |
| <i>loop</i>      | The number of times the session waited for this event               |

### C.3.115 PX signal server

This event occurs only in Exclusive mode. The query coordinator is signalling the Query Slaves that an error has occurred.

**Wait Time:** 0.5 seconds

| Parameter     | Description                                       |
|---------------|---------------------------------------------------|
| <i>serial</i> | The serial number of the slave process queue      |
| <i>error</i>  | The error that has occurred                       |
| <i>nbusy</i>  | The number of slave processes that are still busy |

### C.3.116 rdbms ipc message

The background processes (LGWR, DBWR, LMS0) use this event to indicate that they are idle and are waiting for the foreground processes to send them an IPC message to do some work.

**Wait Time:** Up to 3 seconds. The parameter *timeout* shows the true sleep time.

| Parameter      | Description                                                  |
|----------------|--------------------------------------------------------------|
| <i>timeout</i> | The amount of time that the session waits for an IPC message |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.117 rdbms ipc message block

This event indicates that all message blocks are in use and that the session had to wait for a message block to become available.

**Wait Time:** Wait up to 60 seconds

**Parameters:** None

### C.3.118 rdbms ipc reply

This event is used to wait for a reply from one of the background processes.

**Wait Time:** The wait time is specified by the user and is indicated by the parameter *timeout*.

| Parameter           | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>from_process</i> | The background process for which the session is waiting. The wait is for a reply to an IPC message sent by the session. |
| <i>timeout</i>      | The amount of time in seconds that this process will wait for a reply                                                   |

### C.3.119 read by other session

This event occurs when a session requests a buffer that is currently being read into the buffer cache by another session. Prior to release 10.1, waits for this event were grouped with the other reasons for waiting for buffers under the 'buffer busy waits' event.

**Wait Time:** Time waited for the buffer to be read by the other session (in microseconds)

| Parameter     | Description                    |
|---------------|--------------------------------|
| <i>file#</i>  | See " <a href="#">file#</a> "  |
| <i>block#</i> | See " <a href="#">block#</a> " |
| <i>class#</i> | See " <a href="#">class</a> "  |

### C.3.120 recovery active instance mapping setup

This event is used to track the time taken (in centiseconds) to set up recovery context on remote instances.

### C.3.121 recovery apply pending

This event tracks the time the logmerger process waited (in centiseconds) for apply slaves to apply all pending changes up to a certain SCN.

### C.3.122 recovery cancel

This wait event is used to track the time taken (in centiseconds) to cancel multi instance media recovery.

### C.3.123 recovery checkpoint

This wait event tracks the time (in centiseconds) spent waiting for DBWR processes on all instances to write dirty buffers to disk up to a certain SCN.

### C.3.124 recovery file header update for checkpoint

This wait event tracks the time (in centiseconds) spent by MRP0 process waiting on master logmerger to update file headers to record the latest checkpoint.

### C.3.125 recovery file header update for fuzziness

This wait event tracks the time taken (in centiseconds) to update file headers to record media recovery fuzziness.

### C.3.126 recovery marker apply

This wait event is used to track the time (in centiseconds) taken to process a recovery marker.

### C.3.127 recovery merge pending

This wait event is used to track the time spent (in centiseconds) by the MRP0 process waiting for remote logmergers to merge changes up to a certain SCN.

### C.3.128 recovery metadata latch

This wait event tracks the time taken (in centiseconds) to get the active DataGuard metadata update latch to advance a query SCN.

### C.3.129 recovery move influx buffers

This wait event is used to track the time spent (in centiseconds) waiting for all apply slaves to move their influx buffers to the dirty queue.

### C.3.130 recovery read

A parallel recovery slave (or serial recovery process) is waiting for a batch of data block reads to complete.

**Wait Time:** Time it takes to complete the physical I/O (read)

**Parameters:** None

### C.3.131 recovery receive buffer free

This wait event is used to track the time (in centiseconds) spent by the receiver process on instance waiting for apply slaves to apply changes from received buffers so that they can be freed for the next change.

### C.3.132 recovery remote file verification

This wait event tracks the time spent (in centiseconds) by the MRP0 process waiting for remote logmergers to finish file verification on remote instances.

### C.3.133 recovery send buffer free

This wait event is used to track the time spent (in centiseconds) by the sender process waiting for apply slaves to apply changes from the local instance so that the buffer can be reused for new changes.

### C.3.134 recovery shutdown

This wait event is used to track the time (in centiseconds) taken for remote logmergers to shut down.

### C.3.135 Redo Transport Attach

Used to track the time spent (in centiseconds) doing Connect, Logon, and RFSATTACH for *any* network process.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

### C.3.136 Redo Transport Close

Used to track the time spent (in centiseconds) by *ARCn*, *NSSn*, and *TTnn* processes doing RFSCLOSE and RFSRGSTR operations.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

### C.3.137 Redo Transport Detach

Used to track the time spent (in centiseconds) doing RFSDETACH and Disconnect for *any* network process.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

## C.3.138 Redo Transport Open

Used to track the time spent (in centiseconds) by *ARCn*, *NSSn*, and *TTnn* background processes doing *RFSCREAT* and *RFSANNCE* operations.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

## C.3.139 Redo Transport Ping

Used to track the time spent (in centiseconds) by *ARCn* background processes doing *RFSPING* operations.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

## C.3.140 Redo Transport Slave Shutdown

Used to track the time spent (in centiseconds) by *LGWR* doing *NSSn* and *TTnn* process shutdown and termination.

## C.3.141 Redo Transport Slave Startup

Used to track the time spent (in centiseconds) by *LGWR* doing *NSSn* and *TTnn* process startup and initialization.

## C.3.142 Redo Writer Remote Sync Complete

Used to track the time spent (in centiseconds) by *LGWR* reaping completed network writes to remote destinations.

## C.3.143 Redo Write Remote Sync Notify

Used to track the time spent (in centiseconds) by *LGWR* issuing network writes to remote destinations.

## C.3.144 Remote Sync Ping

Used to track the time spent (in centiseconds) by the *LGWR* and *NSSn* background processes doing synchronous *PING* operations.

### C.3.145 resmgr:become active

The session is waiting for a resource manager active session slot. This event occurs when the resource manager is enabled and the number of active sessions in the session's current consumer group exceeds the current resource plan's active session limit for the consumer group. To reduce the occurrence of this wait event, increase the active session limit for the session's current consumer group.

**Wait Time:** The time the session waited to be allocated an active session slot

| Parameter       | Description          |
|-----------------|----------------------|
| <i>location</i> | location of the wait |

### C.3.146 resmgr:cpu quantum

The session is waiting to be allocated a quantum of CPU. This event occurs when the resource manager is enabled and is throttling CPU consumption. To reduce the occurrence of this wait event, increase the CPU allocation for the sessions's current consumer group.

**Wait Time:** The time the session waited to acquire a CPU quantum

| Parameter                | Description                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>location</i>          | Location of the wait                                                                                                            |
| <i>Consumer Group ID</i> | Consumer group ID of the session waiting. This value is from the CONSUMER_GROUP_ID column in the DBA_RSRC_CONSUMER_GROUPS view. |

#### See Also:

"DBA\_RSRC\_CONSUMER\_GROUPS"

### C.3.147 resmgr: I/O rate limit

The session is waiting for I/O bandwidth to be available to issue I/Os. This event occurs when PDB I/O rate limits are enabled by setting the MAX\_IOPS and/or MAX\_MBPS parameters. To reduce the occurrence of this wait event, the PDB I/O rate limit values need to be increased. This can be achieved by increasing the values of MAX\_IOPS and MAX\_MBPS or by removing the limits altogether by setting the parameter value to 0.

**Wait Time:** The time the session waited for the I/O bandwidth to become available.

| Parameter         | Description                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------|
| <i>P1: PDB_ID</i> | This the PDB ID of the PDB that has its I/O throttled because the MAX_IOPS or MAX_MBPS parameter was set for it. |

 See Also:

- "MAX\_IOPS"
- "MAX\_MBPS"

### C.3.148 resmgr:pq queued

The session is waiting in the parallel statement queue.

**Wait Time:** The time the session waited for sufficient parallel query processes to become available to run this session with the requested degree of parallelism

| Parameter       | Description          |
|-----------------|----------------------|
| <i>location</i> | Location of the wait |

 See Also:

*Oracle Database VLDB and Partitioning Guide* for more information about this wait event

### C.3.149 rolling migration: cluster quiesce

This is the wait event that instances wait on when cluster is about to start a rolling migration. The instances are waiting for any privileged operations that blocks rolling migration to complete before allowing rolling migration.

**Wait Time:** 1 second

| Parameter       | Description                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>location</i> | Its value will be 1 if the wait is for completion of the privileged operations so that a rolling upgrade/downgrade can start. Its value will be 2 if the wait is for completion of the rolling upgrade/downgrade on all the nodes in the cluster. |
| <i>waits</i>    | The number of seconds spent waiting at the current location.                                                                                                                                                                                      |

### C.3.150 row cache lock

The session is trying to get a data dictionary lock.

**Wait Time:** Wait up to 60 seconds.

| Parameter       | Description                                     |
|-----------------|-------------------------------------------------|
| <i>cache id</i> | The CACHE# column value in the V\$ROWCACHE view |
| <i>mode</i>     | See " <a href="#">mode</a> "                    |

| Parameter      | Description                    |
|----------------|--------------------------------|
| <i>request</i> | The pipe timer set by the user |

 **See Also:**

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.151 RVWR wait for flashback copy

Waits for a process to copy flashback database data into the flashback buffer, in order to write out the requested flashback data.

**Wait Time:** 10 milliseconds

| Parameter           | Description                                           |
|---------------------|-------------------------------------------------------|
| <i>copy latch #</i> | The number of flashback copy latch RVWR is waiting on |

### C.3.152 sbtbufinfo

This function is called when Oracle needs to discover the size, and number, of I/O buffers that have been allocated by the SBT layer. It should be very fast and never block.

**Wait Time:** Less than one millisecond

**Parameters:** None

### C.3.153 sbtgetbuf

This function obtains one I/O buffer that Oracle will use for I/O during a backup job.

**Wait Time:** Less than one millisecond

**Parameters:** None

### C.3.154 sbtmapbuf

This is an internal function used to facilitate multi-process buffer management. It should be very fast and never block.

**Wait Time:** Less than one millisecond

**Parameters:** None

### C.3.155 sbtrelbuf

This function releases an I/O buffer that has been already processed during a restore job, so that the SBT layer can fill it with more data. It should be very fast and never block.

**Wait Time:** Less than one millisecond

**Parameters:** None

### C.3.156 scging AST call

Called by the session to find the highest lock mode that is held on a resource.

**Wait Time:** Wait up to 0.2 seconds, but the wait will continue until the NULL mode Acquisition AST has fired.

**Parameters:** None

### C.3.157 SGA: allocation forcing component growth

Process waiting on an immediate mode memory transfer with auto-tune SGA after a 4031 for MMAN to get the memory and post it.

**Wait Time:** 10 msec

**Parameters:** None

### C.3.158 SGA: MMAN sleep for component shrink

MMAN to wait and post itself for satisfying an auto-tuned memory request while trying to fully free a component's quiesced granules. In Release 10.1, the name of this event was 'wait for SGA component shrink'.

**Wait Time:** 10 msec

| Parameter | Description                                     |
|-----------|-------------------------------------------------|
| <i>P1</i> | component_id (corresponding to the memory pool) |
| <i>P2</i> | Current size in granules                        |
| <i>P3</i> | Target size in granules                         |

### C.3.159 SGA: sga\_target resize

Memory resize requests wait while sga target is being resized. In Release 10.1, the name of this event was 'wait for sga\_target resize'.

**Wait Time:** 10 msec

**Parameters:** None

## C.3.160 Shared IO Pool Memory

Wait until a shared I/O pool buffer becomes available. This happens when processes are using these buffers for I/O and the current process needs to wait for the release of any one of the buffers to the shared I/O pool.

**Wait Time:** 10msec

**Parameters:** None

## C.3.161 shared server idle wait

Idle wait event for a shared server. The server waits on the common queue for a virtual circuit. (See also "[virtual circuit wait](#)".)

**Wait Time:** 30 seconds

**Parameters:** None

### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

## C.3.162 single-task message

When running single task, this event indicates that the session waits for the client side of the executable.

**Wait Time:** Total elapsed time that this session spent in the user application

**Parameters:** None

## C.3.163 smon timer

This is the main idle event for SMON. SMON will be waiting on this event most of the time until it times out or is posted by another process.

**Wait Time:** 5 minutes (300 seconds)

| Parameter        | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <i>sleeptime</i> | The amount of time that SMON tries to wait on this event in seconds |
| <i>failed</i>    | The number of times SMON was posted when there some kind of error   |

### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.164 SQL\*Net break/reset to client

The server sends a break or reset message to the client. The session running on the server waits for a reply from the client.

**Wait Time:** The actual time it takes for the break or reset message to return from the client

| Parameter        | Description                       |
|------------------|-----------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> " |
| <i>break?</i>    | See " <a href="#">break?</a> "    |

### C.3.165 SQL\*Net break/reset to dblink

Same as **SQL\*Net break/reset to client**, but in this case, the break/reset message is sent to another server process over a database link.

**Wait Time:** The actual time it takes for the break or reset message to return from the other server process

| Parameter        | Description                       |
|------------------|-----------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> " |
| <i>break?</i>    | See " <a href="#">break?</a> "    |

### C.3.166 SQL\*Net message from client

The server process (foreground process) waits for a message from the client process to arrive.

**Wait Time:** The time it took for a message to arrive from the client since the last message was sent to the client

| Parameter        | Description                                                                      |
|------------------|----------------------------------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                                                |
| <i>#bytes</i>    | The number of bytes received by the server (foreground process) from the client. |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.167 SQL\*Net message from dblink

The session waits while the server process (foreground process) receives messages over a database link from another server process.

**Wait Time:** The time it took for a message to arrive from another server (foreground process) since a message was sent to the other foreground process.

| Parameter        | Description                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                                                                                     |
| <i>#bytes</i>    | The number of bytes received by the server (foreground process) from another foreground process over a database link. |

 **See Also:**

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.168 SQL\*Net message to client

The server (foreground process) is sending a message to the client.

**Wait Time:** The actual time the **send** takes

| Parameter        | Description                                                  |
|------------------|--------------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                            |
| <i>#bytes</i>    | The number of bytes sent by the server process to the client |

### C.3.169 SQL\*Net message to dblink

The server process (foreground process) is sending a message over a database link to another server process.

**Wait Time:** The actual time the **send** takes

| Parameter        | Description                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                                                             |
| <i>#bytes</i>    | The number of bytes sent by the server process to another server process over a database link |

 **See Also:**

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.170 SQL\*Net more data from client

The server is waiting on the client to send more data to its client shadow process, in an already initiated operation.

**Wait Time:** The time waited depends on the time it took to receive the data (including the waiting time)

| Parameter        | Description                                  |
|------------------|----------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "            |
| <i>#bytes</i>    | The number of bytes received from the client |

### C.3.171 SQL\*Net more data from dblink

The foreground process is expecting more data from a data base link.

**Wait Time:** The total time it takes to read the data from the database link (including the waiting time for the data to arrive)

| Parameter        | Description                       |
|------------------|-----------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> " |
| <i>#bytes</i>    | The number of bytes received      |

### C.3.172 SQL\*Net more data to client

The server process is sending more data/messages to the client. The previous operation to the client was also a **send**.

**Wait Time:** The actual time it took for the **send** to complete

| Parameter        | Description                                           |
|------------------|-------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                     |
| <i>#bytes</i>    | The number of bytes that are being sent to the client |

#### See Also:

*Oracle Database Performance Tuning Guide* for more information about this wait event

### C.3.173 SQL\*Net more data to dblink

The event indicates that the server is sending data over a database link again. The previous operation over this database link was also a **send**.

**Wait Time:** The actual time it takes to send the data to the other server

| Parameter        | Description                                                                          |
|------------------|--------------------------------------------------------------------------------------|
| <i>driver id</i> | See " <a href="#">driver id</a> "                                                    |
| <i>#bytes</i>    | The number of bytes that are sent over the database link to the other server process |

### C.3.174 Streams AQ: waiting for messages in the queue

The session is waiting on an empty OLTP queue (Advanced Queuing) for a message to arrive so that the session can dequeue that message.

**Wait Time:** The amount of time that the session wants to wait is determined by the parameter *wait time*

| Parameter        | Description                                                  |
|------------------|--------------------------------------------------------------|
| <i>queue id</i>  | The ID of the OLTP queue for which this session is waiting   |
| <i>process#</i>  | The process number of the process in which this session runs |
| <i>wait time</i> | The intended wait time for this session                      |

### C.3.175 switch logfile command

The session waits on the user command `SWITCH LOGFILE` to complete.

**Wait Time:** 5 seconds

**Parameters:** None

### C.3.176 SYNC Remote Write

Used to track the time spent by LGWR doing SYNC RFSWRITE operations.

#### See Also:

*Oracle Data Guard Concepts and Administration* for more information about using RFS to manage standby redo logs.

### C.3.177 TCP Socket (KGAS)

A session is waiting for an external host to provide requested data over a network socket. The time that this wait event tracks does not indicate a problem, and even a long wait time is not a reason to contact Oracle Support. It naturally takes time for data to flow between hosts over a network, and for the remote aspect of an application to process any request made to it. An application that communicates with a remote host must wait until the data it will read has arrived. In addition, on Microsoft Windows, a separate thread monitors the arrival of traffic. This thread spends most of its life in waits tracked by the TCP Socket (KGAS) wait event.

**Wait Time:** The total elapsed time for the network connection to be established or for data to arrive from over the network

| Parameter | Description                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>P0</i> | For Oracle internal use only. Values 8, 9, and 10 occur within the special thread present on Microsoft Windows; other P0 values occur in normal user sessions. |
| <i>P1</i> | For Oracle internal use only                                                                                                                                   |

### C.3.178 timer in sksawat

The session waits for the Archiver (ARC*n*) asynchronous I/O to complete.

**Wait Time:** 0.01 seconds

**Parameters:** None

### C.3.179 transaction

Wait for a blocking transaction to be rolled back. Continue waiting until the transaction has been rolled back.

**Wait Time:** 1 second

| Parameter        | Description                                                         |
|------------------|---------------------------------------------------------------------|
| <i>undo seg#</i> | The rollback segment ID                                             |
| <i>slot#</i>     | The slot ID inside the rollback segment                             |
| <i>wrap#</i>     | The sequence number that is incremented for each transaction        |
| <i>count</i>     | The number of times that the session has waited on this transaction |

### C.3.180 unbound tx

The session waits to see if there are any transactions that have been started but do not have a Rollback Segment associated with them.

**Wait Time:** 1 second

**Parameters:** None

### C.3.181 undo\_retention publish retry

This wait can occur for two reasons. A session issuing an `ALTER SYSTEM SET UNDO_RETENTION` may wait on this event wait while a cluster reconfiguration takes place. Or the background process MMNL may wait for cluster reconfiguration while attempting to determine the `max UNDO_RETENTION`.

**Wait time:** 1 second

| Parameter | Description                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>P1</i> | Identifies where the retry is happening. Id = 1 retry while publishing into the <code>max undo_retention</code> namespace. Id = 2 retry while iterator accessing the <code>max undo_retention</code> namespace |
| <i>P2</i> | Retry count (maximum number of retries is 5)                                                                                                                                                                   |

### C.3.182 undo segment extension

The undo segment is being extended or shrunk. The session must wait until the operation on the undo segment has finished.

**Wait Time:** 0.01 seconds

| Parameter       | Description                                                     |
|-----------------|-----------------------------------------------------------------|
| <i>segment#</i> | The ID of the rollback segment that is being extended or shrunk |

### C.3.183 undo segment recovery

PMON is rolling back a dead transaction. The wait continues until rollback finishes.

**Wait Time:** 3 seconds

| Parameter       | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| <i>segment#</i> | The ID of the rollback segment that contains the transaction that is being rolled back |
| <i>tx flags</i> | The transaction flags (options) set for the transaction that is being rolled back      |

### C.3.184 undo segment tx slot

Wait for a transaction slot to become available within the selected rollback segment. Continue waiting until the slot is available.

**Wait Time:** 1 second

| Parameter       | Description                                                                            |
|-----------------|----------------------------------------------------------------------------------------|
| <i>segment#</i> | The ID of the rollback segment that contains the transaction that is being rolled back |

### C.3.185 utl\_file I/O

Waits associated with operations performed using the `UTL_FILE` package.

### C.3.186 virtual circuit status

The session waits for a virtual circuit to return a message type indicated by status.

**Wait Time:** 30 seconds

| Parameter       | Description                                    |
|-----------------|------------------------------------------------|
| <i>circuit#</i> | Indicates the virtual circuit# being waited on |
| <i>status</i>   | Indicates what the session is waiting for      |

**Note:**

The virtual circuit status wait event has been deprecated. It is replaced by the virtual circuit wait event.

### C.3.187 virtual circuit wait

The session waits for a virtual circuit operation to complete.

**Wait Time:** 30 seconds

| Parameter       | Description                                                |
|-----------------|------------------------------------------------------------|
| <i>circuit#</i> | Indicates the virtual circuit# being waited on             |
| <i>type</i>     | Indicates the type of operation the session is waiting for |

### C.3.188 WCR: replay client notify

During replay, the Workload Replay Client always keeps an open connection to the database to detect some special errors. This session will normally be in the wait state until some specific replay-related exception occurs.

**Wait Time:** Waits until notified. Times out every 30 seconds.

| Parameter       | Description                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>who am I</i> | Identifies the reason for wait for the admin thread.<br>1 - waiting for REPLAY.START() to be issued.<br>2 - waiting for the replay to run to completion or REPLAY.CANCEL() to be issued. |

### C.3.189 WCR: replay clock

A session will wait on this event during replay if it has some logical dependencies on another session that has not yet committed its work.

**Wait Time:** Depends upon the amount of row lock contention in the original capture

| Parameter                        | Description                                                          |
|----------------------------------|----------------------------------------------------------------------|
| <i>wait for scn's hi 4 bytes</i> | High 4 bytes of the 8-byte replay SCN that the session is waiting on |
| <i>wait for scn's lo 4 bytes</i> | Low 4 bytes of the 8-byte replay SCN that the session is waiting on  |

### C.3.190 WCR: replay lock order

A session will wait on this event during replay if it saw some lock contention during capture.

**Wait Time:** Depends upon the amount of row lock contention in the original capture

| Parameter                        | Description                                                          |
|----------------------------------|----------------------------------------------------------------------|
| <i>wait for scn's hi 4 bytes</i> | High 4 bytes of the 8-byte replay SCN that the session is waiting on |
| <i>wait for scn's lo 4 bytes</i> | Low 4 bytes of the 8-byte replay SCN that the session is waiting on  |

### C.3.191 WCR: replay paused

When the user issues a `DBMS_WORKLOAD_REPLAY.PAUSE_REPLAY` command, all the replayed sessions are waiting on this wait event until replay is resumed.

**Parameters:** None

### C.3.192 WCR: Sync context busy

In the default replay mode, commits during replay are synchronized to follow the same order as capture. All commits are serialized using the Sync context. A replayed session will wait on this event if it is trying to commit at the same time as another replayed session.

**Parameters:** None

### C.3.193 WMON goes to sleep

WMON is the UNIX-specific Wait Monitor, that can be used to reduce the number of system calls related to setting timers for posting or waiting in Oracle. You must set an initialization parameter that enables the WMON process.

**Wait Time:** Depends on the next timeout

**Parameters:** None

### C.3.194 write complete waits

The session waits for a buffer to be written. The write is caused by normal aging or by a cross-instance call.

**Wait Time:** 1 second

| Parameter     | Description                                                                       |
|---------------|-----------------------------------------------------------------------------------|
| <i>file#</i>  | The rollback segment id that contains the transaction that is being rolled back   |
| <i>block#</i> | The transaction flags (options) set for the transaction that is being rolled back |
| <i>id</i>     | Identifies the reason for waiting                                                 |

### C.3.195 writes stopped by instance recovery or database suspension

The session is blocked until the instance that started Instance Recovery is finished.

**Wait Time:** 5 seconds

| <b>Parameter</b>  | <b>Description</b>                                                              |
|-------------------|---------------------------------------------------------------------------------|
| <i>bythread#</i>  | The rollback segment id that contains the transaction that is being rolled back |
| <i>ourthread#</i> | The current instance thread number                                              |

# D

## Oracle Enqueue Names

This appendix lists Oracle enqueues. **Enqueues** are shared memory structures (locks) that serialize access to database resources. They can be associated with a session or transaction. Enqueue names are displayed in the `LOCK_TYPE` column of the `DBA_LOCK` and `DBA_LOCK_INTERNAL` data dictionary views.

A **resource** uniquely identifies an object that can be locked by different sessions within an instance (local resource) or between instances (global resource). Each session that tries to lock the resource will have an **enqueue** on the resource.

### Note:

The names of enqueues and their definitions may change from release to release.

### See Also:

["DBA\\_LOCK\\_INTERNAL"](#) and ["DBA\\_LOCK"](#)

The Oracle enqueues are:

- BL, Buffer Cache Management
- BR, Backup/Restore
- CF, Controlfile Transaction
- CI, Cross-instance Call Invocation
- CU, Bind Enqueue
- DF, Datafile
- DL, Direct Loader Index Creation
- DM, Database Mount
- DR, Distributed Recovery Process
- DW, SecureFiles
- DX, Distributed Transaction
- FP, File Object
- FS, File Set
- HW, High-Water Lock
- IN, Instance Number
- IR, Instance Recovery

- IS, Instance State
- IV, Library Cache Invalidation
- JI, Enqueue used during AJV snapshot refresh
- JQ, Job Queue
- KK, Redo Log "Kick"
- KP, contention in Oracle Data Pump startup and shutdown processes
- KO, Multiple Object Checkpoint
- L[A-P], Library Cache Lock
- LS, Log Start or Switch
- MM, Mount Definition
- MR, Media Recovery
- N[A-Z], Library Cache Pin
- PE, ALTER SYSTEM SET PARAMETER = VALUE
- PF, Password File
- PI, Parallel Slaves
- PR, Process Startup
- PS, Parallel Slave Synchronization
- Q[A-Z], Row Cache
- RO, Object Reuse
- RT, Redo Thread
- RW, Row Wait
- SC, System Change Number
- SM, SMON
- SN, Sequence Number
- SQ, Sequence Number Enqueue
- SR, Synchronized Replication
- SS, Sort Segment
- ST, Space Management Transaction
- SV, Sequence Number Value
- TA, Transaction Recovery
- TC, Thread Checkpoint
- TE, Extend Table
- TM, DML Enqueue
- TO, Temporary Table Object Enqueue
- TS, Temporary Segment (also TableSpace)
- TT, Temporary Table
- TX, Transaction

- UL, User-defined Locks
- UN, User Name
- US, Undo Segment, Serialization
- WL, Being Written Redo Log
- XA, Instance Attribute Lock
- XI, Instance Registration Lock
- ZA, Exclusive Lock When Moving Audit Table

## Statistics Descriptions

This appendix describes the statistics stored in the `V$SESSTAT` and `V$SYSSTAT` dynamic performance tables. These statistics are useful in identifying and correcting performance problems.

This appendix contains the following topics:

- [Displaying Statistics](#)
- [Statistics Descriptions](#)

### E.1 Displaying Statistics

The `V$SESSTAT` view displays statistics on a per-session basis and is valid only for the session currently connected. When a session disconnects, all statistics for the session are updated in `V$SYSSTAT`. The values for the statistics are cleared until the next session uses them.

The `V$STATNAME` view contains all of the statistics for an Oracle release.

Many of these statistics are tied to the internal implementation of Oracle and therefore are subject to change or deletion without notice, even between patch releases. Application developers should be aware of this and write their code to tolerate missing or extra statistics.

#### See Also:

["V\\$SESSTAT"](#), ["V\\$STATNAME"](#), and ["V\\$SYSSTAT"](#) for more information on these views

### E.2 Statistics Descriptions

This section describes some of the statistics stored in the `V$SESSTAT` and `V$SYSSTAT` views. The statistics are listed in alphabetical order.

The `CLASS` column contains a number representing one or more statistics classes. The following class numbers are additive:

- 1, User
- 2, Redo
- 4, Enqueue
- 8, Cache
- 16, OS
- 32, Real Application Clusters
- 64, SQL

- 128, Debug
- 256, Instance level

For example, a class value of 72 represents a statistic that relates to SQL statements and caching.

Some statistics are populated only if the `TIMED_STATISTICS` initialization parameter is set to `true`. Those statistics are flagged with a `Y` in the right-hand column.

**Table E-1 Database Statistics Descriptions**

| Name                                   | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | TIMED_STATISTICS |
|----------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| application wait time                  | 1     | The total wait time (in centiseconds) for waits that belong to the Application wait class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |
| background checkpoints completed       | 8     | Number of checkpoints completed by the background process. This statistic is incremented when the background process successfully advances the thread checkpoint.                                                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| background checkpoints started         | 8     | Number of checkpoints started by the background process. This statistic can be larger than "background checkpoints completed" if a new checkpoint overrides an incomplete checkpoint or if a checkpoint is currently under way. This statistic includes only checkpoints of the redo thread. It does not include: <ul style="list-style-type: none"> <li>• Individual file checkpoints for operations such as offline or begin backup</li> <li>• Foreground (user-requested) checkpoints (for example, performed by <code>ALTER SYSTEM CHECKPOINT LOCAL</code> statements)</li> </ul> |                  |
| background timeouts                    | 128   | This is a count of the times where a background process has set an alarm for itself and the alarm has timed out rather than the background process being posted by another process to do some work.                                                                                                                                                                                                                                                                                                                                                                                   |                  |
| branch node splits                     | 128   | Number of times an index branch block was split because of the insertion of an additional value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |
| buffer is not pinned count             | 72    | Number of times a buffer was free when visited. | commit nowait requested          | 1     | The number of no-wait commit or asynchronous commit requests that were made either using SQL or the OCI transaction control API                                                                                                                                                                        |                  |
| Commit SCN cached                | 128   | Number of times the system change number of a commit operation was cached                                                                                                                                                                                                                              |                  |
| commit wait/nowait performed     | 1     | The number of asynchronous/synchronous commits that were actually performed                                                                                                                                                                                                                            |                  |
| commit wait/nowait requested     | 1     | The number of no-wait or wait commits that were made either using SQL or the OCI transaction control API                                                                                                                                                                                               |                  |
| commit wait performed            | 1     | The number of synchronous commits that were actually performed. These commits waited for the commit redo to be flushed and be present on disk before returning.                                                                                                                                        |                  |
| commit wait requested            | 1     | The number of waiting or synchronous commit requests that were made either using SQL or the OCI transaction control API                                                                                                                                                                                |                  |
| concurrency wait time            | 1     | The total wait time (in centiseconds) for waits that belong to the Concurrency wait class                                                                                                                                                                                                              |                  |
| consistent changes               | 8     | Number of times a user process has applied rollback entries to perform a consistent read on the block<br>Work loads that produce a great deal of consistent changes can consume a great deal of resources. The value of this statistic should be small in relation to the "consistent gets" statistic. |                  |
| consistent gets                  | 8     | Number of times a consistent read was requested for a block.<br><b>See Also:</b> <a href="#">"consistent changes"</a> and <a href="#">"session logical reads"</a> statistics                                                                                                                           |                  |
| consistent gets direct           | 8     | Number of times a consistent read was requested for a block bypassing the buffer cache (for example, direct load operation). This is a subset of "consistent gets" statistics value.                                                                                                                   |                  |
| consistent gets from cache       | 8     | Number of times a consistent read was requested for a block from buffer cache. This is a subset of "consistent gets" statistics value.                                                                                                                                                                 |                  |
| consistent gets from pmem        | 8     | Number of direct-mapped blocks accessed in CR (consistent read) mode from PMEM. This is a subset of "consistent gets" statistics value.                                                                                                                                                                |                  |
| consistent gets pmem direct      | 8     | Number of CR gets from pmem in direct read (e.g. tablescan) code path. This is a subset of "consistent gets from pmem" statistics value.                                                                                                                                                               |                  |
| consistent gets pmem examination | 8     | Number of direct-mapped blocks accessed and examined in CR mode from PMEM, via regular path. This is a subset of "consistent gets from pmem" statistics value.                                                                                                                                         |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                        | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | TIMED_STATISTICS |
|---------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| consistent gets pmem examination (fastpath) | 8     | Number of direct-mapped blocks accessed and examined in CR mode from PMEM, via fast path. This is a subset of both "consistent gets from pmem" and "consistent gets pmem examination" statistics values.                                                                                                                                                                                                                                                                                           |                  |
| consistent gets pmem pin                    | 8     | Number of direct-mapped blocks accessed and pinned in CR mode from PMEM, via regular path. This is a subset of "consistent gets from pmem" statistics value.                                                                                                                                                                                                                                                                                                                                       |                  |
| consistent gets pmem pin (fastpath)         | 8     | Number of direct-mapped blocks accessed and pinned in CR mode from PMEM, via fast path. This is a subset of both "consistent gets from pmem" and "consistent gets pmem pin" statistics values.                                                                                                                                                                                                                                                                                                     |                  |
| CPU used by this session                    | 1     | Amount of CPU time (in 10s of milliseconds) used by a session from the time a user call starts until it ends. If a user call completes within 10 milliseconds, the start and end user-call time are the same for purposes of this statistics, and 0 milliseconds are added.<br><br>A similar problem can exist in the reporting by the operating system, especially on systems that suffer from many context switches.                                                                             | Y                |
| CPU used when call started                  | 128   | The CPU time used when the call is started<br><br><b>See Also:</b> " <a href="#">CPU used by this session</a> "                                                                                                                                                                                                                                                                                                                                                                                    | Y                |
| CR blocks created                           | 8     | Number of CURRENT blocks cloned to create CR (consistent read) blocks. The most common reason for cloning is that the buffer is held in a incompatible mode.                                                                                                                                                                                                                                                                                                                                       |                  |
| cumulative begin requests                   | 32    | Total number of begin requests received by the Oracle database allowing the database to detect and process requests                                                                                                                                                                                                                                                                                                                                                                                |                  |
| cumulative DB time in requests              | 288   | Total database time DB Time (in microseconds) within requests to the Oracle database, measuring DB time used from the beginning to the end of each request. (See also DB time statistic.)                                                                                                                                                                                                                                                                                                          |                  |
| cumulative DB time protected in requests    | 288   | Total database time DB Time (in microseconds) within requests to the Oracle database protected by Application Continuity or Transparent Application Continuity, measuring DB time used from the beginning to the end of each request. (See also DB time statistic.)<br><br>This is a subset of "cumulative DB time in requests" value, which enables you to calculate the ratio of total time in requests to protected time in requests. See also Application Continuity Protection Check (ACCHK). |                  |
| cumulative end requests                     | 32    | Total number of end requests received by the Oracle database allowing the database to detect and process requests                                                                                                                                                                                                                                                                                                                                                                                  |                  |
| cumulative time in requests                 | 32    | Total wall clock time (in microseconds) within requests to the Oracle database, measuring time spent from the beginning to the end of each request. This statistic is used by draining and planned failover. (See <code>drain_timeout</code> .)                                                                                                                                                                                                                                                    |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                                      | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | TIMED_STATISTICS |
|-----------------------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| cumulative user calls in requests                         | 32    | Total number of user calls received by the Oracle database within requests to the Oracle database                                                                                                                                                                                                                                                                                                                                                                                                            |                  |
| cumulative user calls protected by Application Continuity | 32    | Total number of user calls received by the Oracle database within requests to the Oracle database that were protected by Application Continuity or Transparent Application Continuity                                                                                                                                                                                                                                                                                                                        |                  |
| current blocks converted for CR                           | 8     | Number CURRENT blocks converted to CR state                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                  |
| cursor authentications                                    | 128   | Number of privilege checks conducted during execution of an operation                                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| data blocks consistent reads - undo records applied       | 128   | Number of undo records applied to data blocks that have been rolled back for consistent read purposes                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| data warehousing cooling action                           | 8     | Number of times that cooling occurred on this instance                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |
| data warehousing evicted objects                          | 8     | Number of times that objects got evicted by automatic big table caching on this instance                                                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| data warehousing evicted objects - cooling                | 8     | Number of times that objects got evicted on this instance due to a cooling action                                                                                                                                                                                                                                                                                                                                                                                                                            |                  |
| data warehousing evicted objects - replace                | 8     | Number of times that objects got evicted due to caching replacement, that is, when an object is evicted because a hotter object forces it to be evicted from the cache                                                                                                                                                                                                                                                                                                                                       |                  |
| data warehousing scanned blocks                           | 8     | Number of blocks scanned by automatic big table caching on this instance using parallel query                                                                                                                                                                                                                                                                                                                                                                                                                |                  |
| data warehousing scanned blocks - disk                    | 8     | Number of blocks scanned by automatic big table caching on this instance by direct read from disk                                                                                                                                                                                                                                                                                                                                                                                                            |                  |
| data warehousing scanned blocks - memory                  | 8     | Number of blocks scanned by automatic big table caching on this instance by cache read from memory                                                                                                                                                                                                                                                                                                                                                                                                           |                  |
| data warehousing scanned blocks - offload                 | 8     | Number of blocks scanned by automatic big table caching on this instance by Exadata offloading                                                                                                                                                                                                                                                                                                                                                                                                               |                  |
| data warehousing scanned objects                          | 8     | Number of times the objects in automatic big table caching are scanned using parallel query                                                                                                                                                                                                                                                                                                                                                                                                                  |                  |
| db block changes                                          | 8     | Closely related to " <a href="#">consistent changes</a> ", this statistic counts the total number of changes that were part of an update or delete operation that were made to all blocks in the SGA. Such changes generate redo log entries and hence become permanent changes to the database if the transaction is committed.<br><br>This approximates total database work. This statistic indicates the rate at which buffers are being dirtied (on a per-transaction or per-second basis, for example). |                  |
| db block gets                                             | 8     | Number of times a CURRENT block was requested<br><b>See Also:</b> " <a href="#">consistent gets</a> "                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| db block gets direct                                      | 8     | Number of times a CURRENT block was requested bypassing the buffer cache (for example, a direct load operation). This is a subset of "db block gets" statistics value.                                                                                                                                                                                                                                                                                                                                       |                  |

| Name                                           | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          | TIMED_STATISTICS |
|------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| db block gets from cache                       | 8     | Number of times a CURRENT block was requested from the buffer cache. This is a subset of "db block gets" statistics value.                                                                                                                                                                                                                                                                                                                                           |                  |
| db block gets from pmem                        | 8     | Number of direct-mapped blocks accessed in CURRENT mode from PMEM, via regular path                                                                                                                                                                                                                                                                                                                                                                                  |                  |
| db block gets from pmem (fastpath)             | 8     | Number of direct-mapped blocks accessed in CURRENT mode from PMEM, via fast path                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| DBWR checkpoint buffers written                | 8     | Number of buffers that were written for checkpoints                                                                                                                                                                                                                                                                                                                                                                                                                  |                  |
| DBWR checkpoints                               | 8     | Number of times the DBWR was asked to scan the cache and write all blocks marked for a checkpoint or the end of recovery. This statistic is always larger than "background checkpoints completed".                                                                                                                                                                                                                                                                   |                  |
| DBWR lru scans                                 | 8     | Number of times that DBWR scans the LRU queue looking for buffers to write. This count includes scans to fill a batch being written for another purpose (such as a checkpoint).                                                                                                                                                                                                                                                                                      |                  |
| DBWR revisited being-written buffer            | 8     | Number of times that DBWR tried to save a buffer for writing and found that it was already in the write batch. This statistic measures the amount of "useless" work that DBWR had to do in trying to fill the batch.<br><br>Many sources contribute to a write batch. If the same buffer from different sources is considered for adding to the write batch, then all but the first attempt will be "useless" because the buffer is already marked as being written. |                  |
| DBWR transaction table writes                  | 8     | Number of rollback segment headers written by DBWR. This statistic indicates how many "hot" buffers were written, causing a user process to wait while the write completed.                                                                                                                                                                                                                                                                                          |                  |
| DBWR undo block writes                         | 8     | Number of rollback segment blocks written by DBWR                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |
| DDL statements parallelized                    | 32    | Number of DDL statements that were executed in parallel                                                                                                                                                                                                                                                                                                                                                                                                              |                  |
| deferred (CURRENT) block cleanout applications | 128   | Number of times cleanout records are deferred, piggyback with changes, always current get                                                                                                                                                                                                                                                                                                                                                                            |                  |
| DFO trees parallelized                         | 32    | Number of times a serial execution plan was converted to a parallel plan                                                                                                                                                                                                                                                                                                                                                                                             |                  |
| dirty buffers inspected                        | 8     | Number of dirty buffers found by the user process while it is looking for a buffer to reuse                                                                                                                                                                                                                                                                                                                                                                          |                  |
| DML statements parallelized                    | 32    | Number of DML statements that were executed in parallel                                                                                                                                                                                                                                                                                                                                                                                                              |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | TIMED_STATISTICS |
|-------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| DML statements retried              | 64    | <p>When a long-running DML is executing, the cursor may get invalidated due to some concurrent DDL on one of the cursor's dependencies. In this case, an internal ORA-14403 error is thrown and is caught and cleared in one of the calling functions. The current work is rolled back and the DML is restarted without the user being notified of this.</p> <p>The statistic counts the number of times that the thrown, caught, and cleared (ORA-14403) sequence occurred for DML statements. Should a DML vary widely in execution time, check this statistic to see if it increments during the DML execution. If so, then concurrent DDL may be the cause of the extra elapsed time.</p> |                  |

| file io wait time                   | 1     | Total time spent in wait (in microseconds) for I/O to datafiles, excluding the service time for such I/O. This is cumulative for all I/Os for all datafiles. The service time for one I/O operation is estimated as the minimum time spent in the I/O call seen so far. This service time is subtracted from the time spent in each I/O call to get the wait time for that I/O.                                                                                                                                                                                                                                                                                                               |                  |

| flash cache eviction: buffer pinned | 8     | Database Smart Flash Cache buffer is invalidated due to object or range reuse, and so on. The Database Flash Cache Buffer was in use at the time of eviction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                  |
| flash cache eviction: invalidated   | 8     | Database Smart Flash Cache buffer is invalidated due to object or range reuse, and so on. The Database Smart Flash Cache buffer was not in use at the time of eviction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                                       | Class | Description                                                                                                                                                                                                                                                                                                                                           | TIMED_STATISTICS |
|--------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| flash cache insert skip: corrupt           | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because the buffer was corrupted                                                                                                                                                                                                                                       |                  |
| flash cache insert skip: DBWR overloaded   | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because DBWR was busy writing other buffers                                                                                                                                                                                                                            |                  |
| flash cache insert skip: exists            | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because it was already in the flash cache                                                                                                                                                                                                                              |                  |
| flash cache insert skip: modification      | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because it was being modified                                                                                                                                                                                                                                          |                  |
| flash cache insert skip: not current       | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because it was not current                                                                                                                                                                                                                                             |                  |
| flash cache insert skip: not useful        | 8     | In-memory buffer was skipped for insertion into the Database Smart Flash Cache because the type of buffer was not useful to keep                                                                                                                                                                                                                      |                  |
| flash cache inserts                        | 8     | Total number of in-memory buffers inserted into the Database Smart Flash Cache                                                                                                                                                                                                                                                                        |                  |
| flashback log write bytes                  | 2     | Total size in bytes of flashback database data written by RVWR to flashback database logs                                                                                                                                                                                                                                                             |                  |
| flashback log writes                       | 2     | Total number of writes by RVWR to flashback database logs                                                                                                                                                                                                                                                                                             |                  |
| foreground propagated tracked transactions | 128   | Number of transactions modifying tables enabled for flashback data archive which were archived by a foreground process                                                                                                                                                                                                                                |                  |
| free buffer inspected                      | 8     | Number of buffers skipped over from the end of an LRU queue to find a reusable buffer. The difference between this statistic and "dirty buffers inspected" is the number of buffers that could not be used because they had a user, a waiter, or were being read or written, or because they were busy or needed to be written after rapid aging out. |                  |
| free buffer inspected for pmem             | 8     | Number of PMEM buffers skipped over from the end of an LRU queue to find a reusable PMEM buffer                                                                                                                                                                                                                                                       |                  |
| free buffer requested                      | 8     | Number of times a reusable buffer or a free buffer was requested to create or load a block                                                                                                                                                                                                                                                            |                  |
| free buffer requested for pmem             | 8     | Number of times a reusable PMEM buffer or a free PMEM buffer was requested to directly access a block                                                                                                                                                                                                                                                 |                  |
| gc read wait failures                      | 40    | A read wait is when a CR server waits for a disk read to complete before serving a block to another instance. This statistic displays the number of times a read wait ended in failure, that is, after waiting it was unable to serve a block.                                                                                                        |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                                            | Class | Description                                                                                                                                                                                                                                                                                                                         | TIMED_STATISTICS |
|-------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| gc read wait timeouts                           | 40    | A read wait is when a CR server waits for a disk read to complete before serving a block to another instance. This statistic displays the number of times a read wait timed out, that is, the disk read did not complete in time, so the wait was aborted.                                                                          |                  |
| gc read waits                                   | 40    | The number of times a CR server waited for a disk read, and then successfully served a block                                                                                                                                                                                                                                        |                  |
| global enqueue CPU used by this session         | 32    | Amount of CPU time (in 10s of milliseconds) used by synchronous and asynchronous global enqueue activity in a session from the time a user call starts until it ends. If a user call completes within 10 milliseconds, the start and end user-call time are the same for purposes of this statistics, and 0 milliseconds are added. |                  |
| global enqueue get time                         | 32    | Total elapsed time in 10s of milliseconds of all synchronous and asynchronous global enqueue gets and converts                                                                                                                                                                                                                      |                  |
| global enqueue gets async                       | 32    | Total number of asynchronous global enqueue gets and converts                                                                                                                                                                                                                                                                       |                  |
| global enqueue gets sync                        | 32    | Total number of synchronous global enqueue gets and converts                                                                                                                                                                                                                                                                        |                  |
| global enqueue releases                         | 32    | Total number of synchronous global enqueue releases                                                                                                                                                                                                                                                                                 |                  |
| hot buffers moved to head of LRU                | 8     | When a hot buffer reaches the tail of its replacement list, Oracle moves it back to the head of the list to keep it from being reused. This statistic counts such moves.                                                                                                                                                            |                  |
| hot buffers moved to head of LRU for pmem       | 8     | When a hot PMEM buffer reaches the tail of its replacement list, Oracle moves it back to the head of the list to keep it from being reused. This statistic counts such moves.                                                                                                                                                       |                  |
| hot pmem block exchange with dram attempts      | 264   | Number of hot PMEM buffers that were attempted to be exchanged with colder DRAM buffers, to ensure both blocks are still cached                                                                                                                                                                                                     |                  |
| hot pmem block exchange with dram successes     | 264   | Number of hot PMEM buffers that were successfully exchanged with colder DRAM buffers, with both blocks still cached                                                                                                                                                                                                                 |                  |
| hot pmem block migration to dram attempts       | 8     | Number of hot PMEM buffer cache blocks that were attempted to be migrated to DREM to reduce access latency                                                                                                                                                                                                                          |                  |
| hot pmem block migration to dram successes      | 264   | Number of hot PMEM buffer cache blocks that were successfully migrated to DRAM to reduce access latency                                                                                                                                                                                                                             |                  |
| immediate (CR) block cleanout applications      | 128   | Number of times cleanout records are applied immediately during consistent-read requests                                                                                                                                                                                                                                            |                  |
| immediate (CURRENT) block cleanout applications | 128   | Number of times cleanout records are applied immediately during current gets. Compare this statistic with " <a href="#">deferred (CURRENT) block cleanout applications</a> "                                                                                                                                                        |                  |
| IM (HPK4SQL) hash joins attempted               | 384   | Number of in-memory vectorized hash joins attempted                                                                                                                                                                                                                                                                                 |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

|-----------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------|------------------|
| IM (HPK4SQL) hash joins completed             | 384   | Number of in-memory vectorized hash joins completed                                                          |                  |
| IM (hybrid) scan blocks on hybrid list        | 384   | Number of blocks on the hybrid In-Memory scan list                                                           |                  |
| IM (hybrid) scan rows on hybrid list          | 384   | Number of rows on the hybrid In-Memory scan list                                                             |                  |
| IM default area resized                       | 128   | The amount of memory by which the column store got resized                                                   |                  |
| IM populate accumulated time (ms)             | 128   | Total amount of DB time (in milliseconds) spent populating CUs into the IM column store due to segment scans |                  |
| IM populate bytes in-memory EU data           | 128   | Size in bytes of in-memory EU data populated due to segment scans                                            |                  |
| IM populate bytes uncompressed EU data        | 128   | Uncompressed size in bytes of in-memory EU data populated due to segment scans                               |                  |
| IM populate CUs                               | 128   | Number of CUs populated in the IM column store due to segment scans                                          |                  |
| IM populate CUs memcompress for capacity high | 128   | Number of CUs populated in the IM column store due to segment scans using memcompress for capacity high      |                  |
| IM populate CUs memcompress for capacity low  | 128   | Number of CUs populated in the IM column store due to segment scans using memcompress for capacity low       |                  |
| IM populate CUs memcompress for dml           | 128   | Number of CUs populated in the IM column store due to segment scans using memcompress for DML                |                  |
| IM populate CUs memcompress for query high    | 128   | Number of CUs populated in the IM column store due to segment scans using memcompress for query high         |                  |
| IM populate CUs memcompress for query low     | 128   | Number of CUs populated in the IM column store due to segment scans using memcompress for query low          |                  |
| IM populate CUs no memcompress                | 128   | Number of CUs populated in the IM column store due to segment scans without compression                      |                  |
| IM populate CUs requested                     | 128   | Number of CUs requested to be populated due to segment scans                                                 |                  |
| IM populate EUs                               | 128   | Number of EUs populated in the IM column store due to segment scans                                          |                  |
| IM populate EUs accumulated time (ms)         | 128   | Total amount of DB time (in milliseconds) spent populating EUs into the IM column store due to segment scans |                  |
| IM populate EUs columns                       | 128   | Number of columns populated in EUs due to segment scans                                                      |                  |
| IM populate EUs memcompress for capacity high | 128   | Number of EUs populated in the IM column store due to segment scans at memcompress for capacity high         |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                                             | Class | Description                                                                                                          | TIMED_STATISTICS |
|--------------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------|------------------|
| IM populate EUs memcompress for capacity low     | 128   | Number of EUs populated in the IM column store due to segment scans at memcompress for capacity low                  |                  |
| IM populate EUs memcompress for dml              | 128   | Number of EUs populated in the IM column store due to segment scans at memcompress for dml                           |                  |
| IM populate EUs memcompress for query high       | 128   | Number of EUs populated in the IM column store due to segment scans at memcompress for query high                    |                  |
| IM populate EUs memcompress for query low        | 128   | Number of EUs populated in the IM column store due to segment scans at memcompress for query low                     |                  |
| IM populate EUs no memcompress                   | 128   | Number of EUs populated in the IM column store without compression due to segment scans                              |                  |
| IM populate EUs requested                        | 128   | Number of EUs requested to be populated in the IM column store due to segment scans                                  |                  |
| IM populate (faststart) CUs read                 | 128   | Number of CUs read from the IM FastStart tablespace                                                                  |                  |
| IM populate no contiguous inmemory space         | 128   | Number of CUs that fail to populate due to lack of contiguous space in In-Memory area                                |                  |
| IM populate segments                             | 128   | Number of segments populated due to segment scan                                                                     |                  |
| IM populate segments requested                   | 128   | Number of segments requested to be populated due to segment scan                                                     |                  |
| IM populate segments wall clock time (ms)        | 128   | Total amount of wall clock time (in milliseconds) spent populating CUs into the IM column store due to segment scans |                  |
| IM prepopulate accumulated time (ms)             | 128   | Total amount of DB time (in milliseconds) spent prepopulating CUs into the IM column store priority                  |                  |
| IM prepopulate bytes in-memory EU data           | 128   | Size in bytes of in-memory EU data populated due to priority                                                         |                  |
| IM prepopulate bytes uncompressed EU data        | 128   | Uncompressed size in bytes of in-memory EU data populated due to priority                                            |                  |
| IM prepopulate CUs                               | 128   | Number of CUs prepopulated in the IM column store due to priority                                                    |                  |
| IM prepopulate CUs memcompress for capacity high | 128   | Number of CUs prepopulated in the IM column store due to priority using memcompress for capacity high                |                  |
| IM prepopulate CUs memcompress for capacity low  | 128   | Number of CUs prepopulated in the IM column store due to priority using memcompress for capacity low                 |                  |
| IM prepopulate CUs memcompress for dml           | 128   | Number of CUs prepopulated in the IM column store due to priority using memcompress for DML                          |                  |
| IM prepopulate CUs memcompress for query high    | 128   | Number of CUs prepopulated in the IM column store due to priority using memcompress for query high                   |                  |
| IM prepopulate CUs memcompress for query low     | 128   | Number of CUs prepopulated in the IM column store due to priority using memcompress for query low                    |                  |
| IM prepopulate CUs no memcompress                | 128   | Number of CUs prepopulated in the IM column store due to priority without compression                                |                  |

| IM repopulate (trickle) EUs requested                     | 128   | Number of EUs requested to be trickle repopulated in the IM column store due to DML changes                                                                                  |                  |
| IM scan CUs column not in memory                          | 128   | Number of extents that could not be read from the IM column store because one of the columns required was not in memory                                                      |                  |
| IM scan CUs invalid                                       | 128   | Number of extents that could not be services from the IM column store even though a CU existed for these extents. Possible cause SCN of CU higher than the SCN of the query. |                  |
| IM scan CUs invalid (all rows are invalid)                | 128   | Number of CUs where none of the rows were returned after a valid vector was applied                                                                                          |                  |
| IM scan CUs invalid or missing revert to on disk extent   | 128   | Number of extents where no IMCU exists                                                                                                                                       |                  |
| IM scan CUs memcompress for query low                     | 128   | Number of memcompress for query high CUs scanned in the IM column store                                                                                                      |                  |
| IM scan CUs memcompress for query high                    | 128   | Number of memcompress for query high CUs scanned in the IM column store                                                                                                      |                  |
| IM scan CUs memcompress for capacity low                  | 128   | Number of memcompress for capacity low CUs scanned in the IM column store                                                                                                    |                  |
| IM scan CUs memcompress for capacity high                 | 128   | Number of memcompress for capacity high CUs scanned in the IM column store                                                                                                   |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                        | Class | Description                                                                                                                                                                    | TIMED_STATISTICS |
|---------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| IM scan CUs memcompress for dml             | 128   | Number of memcompress for DML CUs scanned in the IM column store                                                                                                               |                  |
| IM scan CUs predicates applied              | 128   | Number of where clause predicates applied to the In-Memory storage index                                                                                                       |                  |
| IM scan CUs predicates optimized            | 128   | Number of where clause predicates applied to the IM column store for which either all rows pass min/max pruning via an In-Memory storage index or no rows pass min/max pruning |                  |
| IM scan CUs pruned                          | 128   | Number of CUs pruned by the storage index                                                                                                                                      |                  |
| IM scan (dynamic) multi-threaded scans      | 128   | Number of In-Memory table scans which benefited from In-Memory dynamic scans                                                                                                   |                  |
| IM scan (dynamic) tasks processed by parent | 128   | Number of IMCUs processed normally because of Resource Manager limit                                                                                                           |                  |
| IM scan (dynamic) tasks processed by thread | 128   | Number of IMCUs processed in parallel by a worker thread                                                                                                                       |                  |
| IM scan (dynamic) rows                      | 128   | Number of rows processed by In-Memory dynamic scans                                                                                                                            |                  |
| IM scan EU bytes in-memory                  | 128   | Size in bytes of in-memory EU data accessed by scans                                                                                                                           |                  |
| IM scan EU bytes uncompressed               | 128   | Uncompressed size in bytes of in-memory EU data accessed by scans                                                                                                              |                  |
| IM scan EU rows                             | 128   | Number of rows scanned from EUs in the IM column store before where clause predicate applied                                                                                   |                  |
| IM scan EUs columns accessed                | 128   | Number of columns in the EUs accessed by scans                                                                                                                                 |                  |
| IM scan EUs columns decompressed            | 128   | Number of columns in the EUs decompressed by scans                                                                                                                             |                  |
| IM scan EUs columns theoretical max         | 128   | Number of columns that would have been accessed from the EU if the scans looked at all columns                                                                                 |                  |
| IM scan EUs memcompress for capacity high   | 128   | Number of memcompress for capacity high EUs scanned in the IM column store                                                                                                     |                  |
| IM scan EUs memcompress for capacity low    | 128   | Number of memcompress for capacity low EUs scanned in the IM column store                                                                                                      |                  |
| IM scan EUs memcompress for dml             | 128   | Number of memcompress for DML EUs scanned in the IM column store                                                                                                               |                  |
| IM scan EUs memcompress for query high      | 128   | Number of memcompress for query high EUs scanned in the IM column store                                                                                                        |                  |
| IM scan EUs memcompress for query low       | 128   | Number of memcompress for query low EUs scanned in the IM column store                                                                                                         |                  |
| IM scan EUs no memcompress                  | 128   | Number of uncompressed EUs scanned in the IM column store                                                                                                                      |                  |
| IM scan EUs split pieces                    | 128   | Number of split EU pieces among all IM EUs                                                                                                                                     |                  |
| IM scan rows                                | 128   | Number of rows in scanned In-Memory Compression Units (IMCUs)                                                                                                                  |                  |
| IM scan rows cache                          | 128   | Number of rows retrieved from the buffer cache because they were invalid in the IM column store                                                                                |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                                    | Class | Description                                                                                                                                                         | TIMED_STATISTICS |
|-----------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| IM scan rows journal                    | 128   | Number of rows scanned from the transaction journal in IM column store                                                                                              |                  |
| IM scan rows optimized                  | 128   | Number of rows that were not scanned in the IM column store as they were pruned via a number of optimizations such as min/max pruning via In-Memory storage indexes |                  |
| IM scan rows projected                  | 128   | Number of rows returned from the IM column store                                                                                                                    |                  |
| IM scan rows valid                      | 128   | Number of rows scanned from the IM column store after applying valid vector                                                                                         |                  |
| IM scan segments minmax eligible        | 128   | Number of CUs that are eligible for min/max pruning via storage index                                                                                               |                  |
| IM space CU bytes allocated             | 128   | Number of In-Memory bytes allocated                                                                                                                                 |                  |
| IM space CU creations initiated         | 128   | Number of space requests for CUs                                                                                                                                    |                  |
| IM space CU extents allocated           | 128   | Number of In-Memory extents allocated                                                                                                                               |                  |
| IM space segments allocated             | 128   | Number of snapshot segments created                                                                                                                                 |                  |
| IM space segments freed                 | 128   | Number of snapshot segments deleted                                                                                                                                 |                  |
| IM transactions                         | 128   | Number of transactions that triggered data to be journaled in the IM column store                                                                                   |                  |
| IM transactions CUs invalid             | 128   | Number of CUs in the IM column store invalidated by transactions                                                                                                    |                  |
| IM transactions rows invalidated        | 128   | Number of rows in the IM column store invalidated by transactions                                                                                                   |                  |
| IM transactions rows journaled          | 128   | Number of rows logged in the transaction journal                                                                                                                    |                  |
| in call idle wait time                  | 1     | The total wait time (in microseconds) for waits that belong to the Idle wait class.<br><b>See Also:</b> "non-idle wait count" and "non-idle wait time"              |                  |
| index cmph cu, uncomp sentinels         | 128   | Number of CUs created with uncompressed sentinels                                                                                                                   |                  |
| index cmph dm, cu lock expand           | 128   | Number of times CU lock structure expanded                                                                                                                          |                  |
| index cmph dm, cu migrate row           | 128   | Number of times a row migrated from a CU                                                                                                                            |                  |
| index cmph dm, insert unpurge CU row    | 128   | Number of times a CU row was unpurged during insert                                                                                                                 |                  |
| index cmph dm, purge dummy CU           | 128   | Number of times dummy CU purged from leaf block                                                                                                                     |                  |
| index cmph dm, split for cu lock expand | 128   | Number of times leaf block split for CU lock expansion                                                                                                              |                  |
| index cmph dm, split for cu migrate row | 128   | Number of leaf block splits due to CU row migration                                                                                                                 |                  |

| index fast full scans (full)              | 64    | Number of fast full scans initiated for full segments                                                                                                                                                                                                                                                            |                  |
| index fast full scans (rowid ranges)      | 64    | Number of fast full scans initiated with rowid endpoints specified                                                                                                                                                                                                                                               |                  |
| large tracked transactions                | 128   | For tables tracked by flashback data archive, the number of transactions modifying rows in those tables which are large in terms of size or number of changes                                                                                                                                                    |                  |
| leaf node splits                          | 128   | Number of times an index leaf node was split because of the insertion of an additional value                                                                                                                                                                                                                     |                  |
| lob reads                                 | 8     | Number of LOB API read operations performed in the session/system. A single LOB API read may correspond to multiple physical/logical disk block reads.                                                                                                                                                           |                  |
| lob writes                                | 8     | Number of LOB API write operations performed in the session/system. A single LOB API write may correspond to multiple physical/logical disk block writes.                                                                                                                                                        |                  |
| lob writes unaligned                      | 8     | Number of LOB API write operations whose start offset or buffer size is not aligned to the internal chunk size of the LOB. Writes aligned to chunk boundaries are the most efficient write operations. The internal chunk size of a LOB is available through the LOB API (for example, DBMS_LOB.GETCHUNKSIZE()). |                  |
| logons cumulative                         | 1     | Total number of logons since the instance started. Useful only in V\$SYSSTAT. It gives an instance overview of all processes that logged on.                                                                                                                                                                     |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                               | Class | Description                                                                                                                                                                                                                | TIMED_STATISTICS |
|------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| logons current                     | 1     | Total number of current logons. Useful only in V\$SYSSTAT.                                                                                                                                                                 |                  |
| memopt r failed puts               | 128   | Total failed puts on hash index                                                                                                                                                                                            |                  |
| memopt r failed reads on blocks    | 128   | Total lookup failures due to read failure on blocks because of concurrent changes                                                                                                                                          |                  |
| memopt r failed reads on buckets   | 128   | Total lookup failures due to concurrent hash bucket changes                                                                                                                                                                |                  |
| memopt r hits                      | 128   | Total hits on hash index – primary key found                                                                                                                                                                               |                  |
| memopt r lookup detected CR buffer | 128   | Total lookup failures due to block pointed to by hash index being no longer the current version                                                                                                                            |                  |
| memopt r lookups                   | 128   | Total number of lookups on hash index                                                                                                                                                                                      |                  |
| memopt r misses                    | 128   | Total misses on hash index due to primary key not found                                                                                                                                                                    |                  |
| memopt r puts                      | 128   | Total puts on hash index                                                                                                                                                                                                   |                  |
| memopt r successful puts           | 128   | Total successful puts on hash index                                                                                                                                                                                        |                  |
| messages received                  | 128   | Number of messages sent and received between background processes                                                                                                                                                          |                  |
| messages sent                      | 128   | Number of messages sent and received between background processes                                                                                                                                                          |                  |
| no buffer to keep pinned count     | 72    | Number of times a visit to a buffer attempted, but the buffer was not found where expected. Like "buffer is not pinned count" and "buffer is pinned count", this statistic is useful only for internal debugging purposes. |                  |
| no work - consistent read gets     | 128   | Number consistent gets that require neither block cleanouts nor rollbacks.<br><b>See Also:</b> "consistent gets"                                                                                                           |                  |
| non-idle wait count                | 1     | The total number of waits performed with wait events that were not part of the Idle wait class.<br><b>See Also:</b> "in call idle wait time" and "non-idle wait time"                                                      |                  |
| non-idle wait time                 | 1     | The total wait time (in microseconds) for waits that do not belong to the Idle wait class.<br><b>See Also:</b> "in call idle wait time" and "non-idle wait count"                                                          |                  |
| OLAP Aggregate Function Calc       | 64    | The number of times the AGGREGATE function computes a parent value based on the values of its children.                                                                                                                    |                  |
| OLAP Aggregate Function Logical NA | 64    | The number of times an AGGREGATE function evaluates to a logical NA value. This could be because the AGGINDEX is on and the composite tuple does not exist.                                                                |                  |
| OLAP Aggregate Function Precompute | 64    | The number of times the AGGREGATE function is to compute a value and finds it precomputed in the cube.                                                                                                                     |                  |
| OLAP Custom Member Limit           | 64    | The number of times an OLAP table function issues a custom member limit                                                                                                                                                    |                  |
| OLAP Engine Calls                  | 64    | The total number of OLAP transactions executed within the session. This value provides a general indication of the level of OLAP activity in the session.                                                                  |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                                   | Class | Description                                                                                                                                                                                                                                                                              | TIMED_STATISTICS |
|----------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| OLAP Fast Limit                        | 64    | The number of times an OLAP table function issues a fast limit                                                                                                                                                                                                                           |                  |
| OLAP Full Limit                        | 64    | The number of times an OLAP table function issues a full limit                                                                                                                                                                                                                           |                  |
| OLAP GID Limit                         | 64    | The number of times an OLAP table function issues a Cube Grouping ID (CGID) limit. Typically, this type of limit occurs for query rewrite transformations that resolve to a cube organized materialized view.                                                                            |                  |
| OLAP Import Rows Loaded                | 64    | The number of OLAP import rows loaded. This statistic provides the number of rows of the source cursor that are actually loaded into an Analytic Workspace (AW).<br>The difference between the OLAP Import Rows Pushed and OLAP Import Rows Loaded provides the number of rejected rows. |                  |
| OLAP Import Rows Pushed                | 64    | The number of OLAP import rows pushed. This statistic refers to the number of rows encountered from a source cursor and is useful during cube build operations.                                                                                                                          |                  |
| OLAP INHIER Limit                      | 64    | The number of times an OLAP table function issues an in-hierarchy limit. This type of limit can occur when you use cube dimension hierarchy views.                                                                                                                                       |                  |
| OLAP Limit Time                        | 64    | The total time taken by all the OLAP Limit operations that were performed during the last call to the OLAP table function                                                                                                                                                                |                  |
| OLAP Paging Manager Cache Changed Page | 64    | The number of times the OLAP page pool is changed for any attached AW.                                                                                                                                                                                                                   |                  |
| OLAP Paging Manager Cache Hit          | 64    | The number of times a requested page is found in the OLAP page pool. Use this statistic in conjunction with <a href="#">OLAP Paging Manager Cache Miss</a> to determine the OLAP page pool efficiency ratio.                                                                             |                  |
| OLAP Paging Manager Cache Miss         | 64    | The number of times a requested page is not found in the OLAP page pool. Use this statistic in conjunction with OLAP Paging Manager Cache Hit to determine the OLAP page pool efficiency ratio.                                                                                          |                  |
| OLAP Paging Manager Cache Write        | 64    | The number of times the OLAP paging manager writes to a page in the OLAP page pool.                                                                                                                                                                                                      |                  |
| OLAP Paging Manager New Page           | 64    | The number of newly-created pages in the OLAP page pool that have not yet been written to the workspace LOB                                                                                                                                                                              |                  |
| OLAP Paging Manager Pool Size          | 64    | Size, in bytes, of the OLAP page pool allocated to a session and the sum of all OLAP page pools in the system.                                                                                                                                                                           |                  |
| OLAP Perm LOB Read                     | 64    | The number of times data was read from the table where the AW is stored. These are permanent LOB reads.                                                                                                                                                                                  |                  |
| OLAP Row Id Limit                      | 64    | The number of times an OLAP table function issues a row Id limit.                                                                                                                                                                                                                        |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                            | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | TIMED_STATISTICS |
|---------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| OLAP Row Load Time              | 64    | <p>The total time spent loading rows into an AW during cube build and OLAP SQL import operations.</p> <p>Use this statistic along with the <a href="#">OLAP engine elapsed time</a> to measure time spent running OLAP engine routines that involve loading data into AWs from a SQL source.</p> <p>This statistic has the following levels of precision:</p> <ul style="list-style-type: none"> <li>• Low precision timer<br/>This captures the elapsed time of the entire fetch phase of the SQL cursor that is being loaded into AWs. It includes the SQL execution time that occurs during a fetch operation from a source cursor and time taken by the OLAP engine to populate AWs.</li> <li>• High precision timer<br/>This captures the elapsed time, excluding the SQL processing of the cursor being loaded. It records the time spent in the OLAP engine only.</li> <li>• Default timer precision:<br/>This is based on the <code>STATISTIC_LEVEL</code> parameter. If the low precision is used, then <code>STATISTICS_LEVEL</code> is <code>TYPICAL</code>. The high precision timer is used when <code>STATISTIC_LEVEL</code> is set to <code>ALL</code>. No timing is captured when <code>STATISTICS_LEVEL</code> is <code>BASIC</code>.</li> </ul> |                  |
| OLAP Row Source Rows Processed  | 64    | The number of rows processed by the OLAP row source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                  |
| OLAP Session Cache Hit          | 64    | The number of times the requested, dynamically-aggregated value of an AW object, was found in the OLAP session cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |
| OLAP Session Cache Miss         | 64    | The number of times the requested, dynamically-aggregated value of an AW object, was not found in the OLAP session cache.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                  |

| OS CPU Qt wait time             | 1     | The time a session spends on the CPU run queue (in microseconds), waiting to get the CPU to run                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                  |
| OS Involuntary context switches | 16    | Number of context switches that were enforced by the operating system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                        | Class | Description                                                                                                                                                                                                              | TIMED_STATISTICS |
|---------------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| OS Signals received                         | 16    | Number of signals received                                                                                                                                                                                               |                  |
| OS Swaps                                    | 16    | Number of swap pages                                                                                                                                                                                                     |                  |
| OS Voluntary context switches               | 16    | Number of voluntary context switches (for example, when a process gives up the CPU by a SLEEP() system call)                                                                                                             |                  |
| Parallel operations downgraded 1 to 25 pct  | 32    | Number of times parallel execution was requested and the degree of parallelism was reduced because of insufficient parallel execution servers                                                                            |                  |
| Parallel operations downgraded 25 to 50 pct | 32    | Number of times parallel execution was requested and the degree of parallelism was reduced because of insufficient parallel execution servers                                                                            |                  |
| Parallel operations downgraded 50 to 75 pct | 32    | Number of times parallel execution was requested and the degree of parallelism was reduced because of insufficient parallel execution servers                                                                            |                  |
| Parallel operations downgraded 75 to 99 pct | 32    | Number of times parallel execution was requested and the degree of parallelism was reduced because of insufficient parallel execution servers                                                                            |                  |
| Parallel operations downgraded to serial    | 32    | Number of times parallel execution was requested but execution was serial because of insufficient parallel execution servers                                                                                             |                  |
| Parallel operations not downgraded          | 32    | Number of times parallel execution was executed at the requested degree of parallelism                                                                                                                                   |                  |
| parse count (describe)                      | 64    | Total number of parse calls on a describe cursor. This operation is a less expensive than a hard parse and more expensive than a soft parse.                                                                             |                  |
| parse count (hard)                          | 64    | Total number of parse calls (real parses). A hard parse is a very expensive operation in terms of memory use, because it requires Oracle to allocate a workheap and other memory structures and then build a parse tree. |                  |
| parse count (total)                         | 64    | Total number of parse calls (hard, soft, and describe). A soft parse is a check on an object already in the shared pool, to verify that the permissions on the underlying object have not changed.                       |                  |
| parse time cpu                              | 64    | Total CPU time used for parsing (hard and soft) in 10s of milliseconds                                                                                                                                                   | Y                |
| parse time elapsed                          | 64    | Total elapsed time for parsing, in 10s of milliseconds. Subtract " <a href="#">parse time cpu</a> " from this statistic to determine the total waiting time for parse resources.                                         | Y                |
| physical maps pmem                          | 264   | Number of direct-mapped references acquired from FsDirect. Note that in steady state this is approximately the same as the number of unmaps, because each map requires an unmap (e.g. reuses a PMEM buffer).             |                  |
| physical read bytes                         | 8     | Total size in bytes of all disk reads by application activity (and not other instance activity) only.                                                                                                                    |                  |
| physical read flash cache hits              | 8     | Total number of reads from flash cache instead of disk                                                                                                                                                                   |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                       | Class | Description                                                                                                                                                                                                                                                                                                                                                   | TIMED_STATISTICS |
|--------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| physical read IO requests                  | 8     | Number of read requests for application activity (mainly buffer cache and direct load operation) which read one or more database blocks per request. This is a subset of "physical read total IO requests" statistic.                                                                                                                                         |                  |
| physical read requests optimized           | 8     | Number of read requests that read one or more database blocks from the Database Smart Flash Cache or the Exadata Smart Flash Cache.                                                                                                                                                                                                                           |                  |
| physical read total bytes                  | 8     | Total size in bytes of disk reads by all database instance activity including application reads, backup and recovery, and other utilities. The difference between this value and "physical read bytes" gives the total read size in bytes by non-application workload.                                                                                        |                  |
| physical read total IO requests            | 8     | Number of read requests which read one or more database blocks for all instance activity including application, backup and recovery, and other utilities. The difference between this value and "physical read total multi block requests" gives the total number of small I/O requests which are less than 128 kilobytes down to single block read requests. |                  |
| physical read total multi block requests   | 8     | Total number of Oracle instance read requests which read 128 kilobytes or more in two or more database blocks per request for all instance activity including application, backup and recovery, and other utilities.                                                                                                                                          |                  |
| physical reads                             | 8     | Total number of data blocks read from disk. This value can be greater than the value of "physical reads direct" plus "physical reads cache" as reads into process private buffers also included in this statistic.                                                                                                                                            |                  |
| physical reads cache                       | 8     | Total number of data blocks read from disk into the buffer cache. This is a subset of "physical reads" statistic.                                                                                                                                                                                                                                             |                  |
| physical reads cache prefetch              | 8     | Number of contiguous and noncontiguous blocks that were prefetched.                                                                                                                                                                                                                                                                                           |                  |
| physical reads direct                      | 8     | Number of reads directly from disk, bypassing the buffer cache. For example, in high bandwidth, data-intensive operations such as parallel query, reads of disk blocks bypass the buffer cache to maximize transfer rates and to prevent the premature aging of shared data blocks resident in the buffer cache.                                              |                  |
| physical reads direct (lob)                | 8     | Number of buffers that were read directly for LOBs                                                                                                                                                                                                                                                                                                            |                  |
| physical reads direct temporary tablespace | 8     | Number of buffers that were read directly from temporary tablespaces                                                                                                                                                                                                                                                                                          |                  |
| physical reads for flashback new           | 8     | Number of blocks read for newing (that is, preparing a data block for a completely new change) blocks while flashback database is enabled                                                                                                                                                                                                                     |                  |
| physical reads pmem                        | 8     | Number of blocks read/copied from PMEM into DRAM cache                                                                                                                                                                                                                                                                                                        |                  |
| physical reads pmem decrypt                | 8     | Number of blocks read/copied from PMEM into DRAM cache due to the need for decryption. This is a subset of "physical reads pmem" statistics value.                                                                                                                                                                                                            |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                      | Class | Description                                                                                                                                                                                                                                                                                             | TIMED_STATISTICS |
|-------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| physical reads pmem direct path           | 8     | Number of blocks read from PMEM into PGA memory due to direct path access. This is a subset of "physical reads pmem" statistics value.                                                                                                                                                                  |                  |
| physical reads pmem exclusive             | 8     | Number of blocks read/copied from PMEM into DRAM cache due to exclusive access requests, which prevents other processes from accessing the block on PMEM directly. This is a subset of "physical reads pmem" statistics value.                                                                          |                  |
| physical reads pmem modification          | 8     | Number of blocks read/copied from PMEM into DRAM cache due to modification. This is a subset of "physical reads pmem" statistics value.                                                                                                                                                                 |                  |
| physical reads pmem promote               | 8     | Number of blocks read/copied from PMEM into DRAM cache due to hot block promotion. This is a subset of "physical reads pmem" statistics value. This statistic is further categorized into "hot pmem block migration to dram successes" and "hot pmem block exchange with dram successes" statistics.    |                  |
| physical reads pmem rollback              | 8     | Number of blocks read/copied from PMEM into DRAM cache due to CR rollback. This is a subset of "physical reads pmem" statistics value.                                                                                                                                                                  |                  |
| physical reads prefetch warmup            | 8     | Number of data blocks that were read from the disk during the automatic prewarming of the buffer cache.                                                                                                                                                                                                 |                  |
| physical unmaps pmem forced               | 264   | Number of forfeited direct-mapped references requested by FsDirect due to PMEM memory pressure                                                                                                                                                                                                          |                  |
| physical write bytes                      | 8     | Total size in bytes of all disk writes from the database application activity (and not other kinds of instance activity).                                                                                                                                                                               |                  |
| physical write IO requests                | 8     | Number of write requests for application activity (mainly buffer cache and direct load operation) which wrote one or more database blocks per request.                                                                                                                                                  |                  |
| physical write total bytes                | 8     | Total size in bytes of all disk writes for the database instance including application activity, backup and recovery, and other utilities. The difference between this value and "physical write bytes" gives the total write size in bytes by non-application workload.                                |                  |
| physical write total IO requests          | 8     | Number of write requests which wrote one or more database blocks from all instance activity including application activity, backup and recovery, and other utilities. The difference between this stat and "physical write total multi block requests" gives the number of single block write requests. |                  |
| physical write total multi block requests | 8     | Total number of Oracle instance write requests which wrote two or more blocks per request to the disk for all instance activity including application activity, recovery and backup, and other utilities.                                                                                               |                  |
| physical writes                           | 8     | Total number of data blocks written to disk. This statistics value equals the sum of "physical writes direct" and "physical writes from cache" values.                                                                                                                                                  |                  |

| Name                                          | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | TIMED_STATISTICS |
|-----------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| physical writes direct                        | 8     | Number of writes directly to disk, bypassing the buffer cache (as in a direct load operation)                                                                                                                                                                                                                                                                                                                                                                                                 |                  |
| physical writes direct (lob)                  | 8     | Number of buffers that were directly written for LOBs                                                                                                                                                                                                                                                                                                                                                                                                                                         |                  |
| physical writes direct temporary tablespace   | 8     | Number of buffers that were directly written for temporary tablespaces                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| physical writes from cache                    | 8     | Total number of data blocks written to disk from the buffer cache. This is a subset of "physical writes" statistic.                                                                                                                                                                                                                                                                                                                                                                           |                  |
| physical writes non checkpoint                | 8     | Number of times a buffer is written for reasons other than advancement of the checkpoint. Used as a metric for determining the I/O overhead imposed by setting the FAST_START_IO_TARGET parameter to limit recovery I/Os. (Note that FAST_START_IO_TARGET is a deprecated parameter.) Essentially this statistic measures the number of writes that would have occurred had there been no checkpointing. Subtracting this value from "physical writes" gives the extra I/O for checkpointing. |                  |
| pinned buffers inspected                      | 8     | Number of times a user process, when scanning the tail of the replacement list looking for a buffer to reuse, encountered a cold buffer that was pinned or had a waiter that was about to pin it. This occurrence is uncommon, because a cold buffer should not be pinned very often.                                                                                                                                                                                                         |                  |
| pinned buffers inspected for pmem             | 8     | Number of times a user process, when scanning the tail of the replacement list looking for a PMEM buffer to reuse in DRAM, encountered a cold buffer that was pinned or had a waiter that was about to pin it. This occurrence is uncommon, because a cold buffer should not be pinned very often.                                                                                                                                                                                            |                  |
| prefetched blocks aged out before use         | 8     | Number of contiguous and noncontiguous blocks that were prefetched but aged out before use                                                                                                                                                                                                                                                                                                                                                                                                    |                  |
| process last non-idle time                    | 128   | The last time this process executed                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Y                |
| PX local messages recv'd                      | 32    | Number of local messages received for parallel execution within the instance local to the current session                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| PX local messages sent                        | 32    | Number of local messages sent for parallel execution within the instance local to the current session                                                                                                                                                                                                                                                                                                                                                                                         |                  |

|-------------------------------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| recovery blocks skipped lost write checks | 8     | Number of Block Read Records that skipped the lost write check during recovery.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| recursive calls                           | 1     | Number of recursive calls generated at both the user and system level. Oracle maintains tables used for internal processing. When Oracle needs to make a change to these tables, it internally generates an internal SQL statement, which in turn generates a recursive call.                                                                                                                                                                                                                                                                                                                                                                                                                                          |                  |
| recursive cpu usage                       | 1     | Total CPU time used by non-user calls (recursive calls). Subtract this value from "CPU used by this session" to determine how much CPU time was used by the user calls.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                  |
| redo blocks checksummed by FG (exclusive) | 2     | Number of exclusive redo blocks that were checksummed by the generating foreground processes. An exclusive redo block is the one whose entire redo content belongs to a single redo entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |
| redo blocks checksummed by LGWR           | 2     | Number of redo blocks that were checksummed by the LGWR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                  |
| redo blocks written                       | 2     | Total number of redo blocks written. This statistic divided by "redo writes" equals number of blocks per write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| redo buffer allocation retries            | 2     | Total number of retries necessary to allocate space in the redo buffer. Retries are needed either because the redo writer has fallen behind or because an event such as a log switch is occurring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| redo entries                              | 2     | Number of times a redo entry is copied into the redo log buffer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                  |
| redo entries for lost write detection     | 2     | Number of times a Block Read Record is copied into the log buffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                  |
| redo log space requests                   | 2     | Number of times the active log file is full and Oracle must wait for disk space to be allocated for the redo log entries. Such space is created by performing a log switch.<br><br>Log files that are small in relation to the size of the SGA or the commit rate of the work load can cause problems. When the log switch occurs, Oracle must ensure that all committed dirty buffers are written to disk before switching to a new log file. If you have a large SGA full of dirty buffers and small redo log files, a log switch must wait for DBWR to write dirty buffers to disk before continuing.<br><br>Also examine the <b>log file space</b> and <b>log file space switch</b> wait events in V\$SESSION_WAIT |                  |
| redo log space wait time                  | 2     | Total time waited in centiseconds for available space in the redo log buffer. See also "redo log space requests"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Y                |
| redo ordering marks                       | 2     | Number of times that a system change number was allocated to force a redo record to have a higher SCN than a record generated in another thread using the same block                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                  |
| redo size                                 | 2     | Total amount of redo generated in bytes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                    | Class | Description                                                                                                                                                                                                                                                                                                       | TIMED_STATISTICS |
|-----------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| redo size for lost write detection      | 2     | Total amount of Block Read Records generated in bytes.                                                                                                                                                                                                                                                            |                  |
| redo synch time                         | 8     | Elapsed time of all "redo synch writes" calls in 10s of milliseconds                                                                                                                                                                                                                                              | Y                |
| redo synch writes                       | 8     | Number of times the redo is forced to disk, usually for a transaction commit. The log buffer is a circular buffer that LGWR periodically flushes. Usually, redo that is generated and copied into the log buffer need not be flushed out to disk immediately.                                                     |                  |
| redo wastage                            | 2     | Number of bytes wasted because redo blocks needed to be written before they are completely full. Early writing may be needed to commit transactions, to be able to write a database buffer, or to switch logs.                                                                                                    |                  |
| redo write broadcast ack count          | 2     | Number of times a commit broadcast acknowledgment has not been received by the time when the corresponding log write is completed. This is only for Oracle RAC.                                                                                                                                                   |                  |
| redo write broadcast ack time           | 2     | Total amount of the latency associated with broadcast on commit beyond the latency of the log write (in microseconds). This is only for Oracle RAC.                                                                                                                                                               | Y                |
| redo write time                         | 2     | Total elapsed time of the write from the redo log buffer to the current redo log file in 10s of milliseconds                                                                                                                                                                                                      | Y                |
| redo writes                             | 2     | Total number of writes by LGWR to the redo log files. "redo blocks written" divided by this statistic equals the number of blocks per write                                                                                                                                                                       |                  |
| rollback changes - undo records applied | 128   | Number of undo records applied to user-requested rollback changes (not consistent-read rollbacks)                                                                                                                                                                                                                 |                  |
| rollbacks only - consistent read gets   | 128   | Number of consistent gets that require only block rollbacks, no block cleanouts.<br><b>See Also:</b> "consistent gets"                                                                                                                                                                                            |                  |
| rows fetched via callback               | 64    | Rows fetched via callback. Useful primarily for internal debugging purposes.                                                                                                                                                                                                                                      |                  |
| scheduler wait time                     | 1     | The total wait time (in microseconds) for waits that belong to the Scheduler wait class                                                                                                                                                                                                                           |                  |
| SCN increments due to another database  | 128   | SCN increments due to communication with another database                                                                                                                                                                                                                                                         |                  |
| serializable aborts                     | 1     | Number of times a SQL statement in a serializable isolation level had to abort                                                                                                                                                                                                                                    |                  |
| session connect time                    | 1     | The connect time for the session in 10s of milliseconds. This value is useful only in V\$SESSTAT. It is the wall clock time since the logon to this session occurred.                                                                                                                                             | Y                |
| session cursor cache count              | 64    | Total number of cursors cached. This statistic is incremented only if SESSION_CACHED_CURSORS > 0. This statistic is the most useful in V\$SESSTAT. If the value for this statistic in V\$SESSTAT is close to the setting of the SESSION_CACHED_CURSORS parameter, the value of the parameter should be increased. |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                  | Class | Description                                                                                                                                                                                                                                              | TIMED_STATISTICS |
|---------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| session cursor cache hits             | 64    | Number of hits in the session cursor cache. A hit means that the SQL (including recursive SQL) or PL/SQL statement did not have to be reparsed. Subtract this statistic from "parse count (total)" to determine the real number of parses that occurred. |                  |
| session logical reads                 | 1     | The sum of "db block gets" plus "consistent gets". This includes logical reads of database blocks from either the buffer cache or process private memory.                                                                                                |                  |
| session logical reads - IM            | 128   | Number of database blocks read from the IM column store (number of blocks in IMCU - number of blocks with invalid rows)                                                                                                                                  |                  |
| session pga memory                    | 1     | Current PGA size for the session. Useful only in V\$SESSTAT; it has no meaning in V\$SYSSTAT.                                                                                                                                                            |                  |
| session pga memory max                | 1     | Peak PGA size for the session. Useful only in V\$SESSTAT; it has no meaning in V\$SYSSTAT.                                                                                                                                                               |                  |
| session stored procedure space        | 1     | Amount of memory this session is using for stored procedures                                                                                                                                                                                             |                  |
| session uga memory                    | 1     | Current UGA size for the session. Useful only in V\$SESSTAT; it has no meaning in V\$SYSSTAT.                                                                                                                                                            |                  |
| session uga memory max                | 1     | Peak UGA size for a session. Useful only in V\$SESSTAT; it has no meaning in V\$SYSSTAT.                                                                                                                                                                 |                  |
| shared hash latch upgrades - no wait  | 8     | A shared hash latch upgrade is when a hash latch is upgraded from shared mode to exclusive mode. This statistic displays the number of times the upgrade completed immediately.                                                                          |                  |
| shared hash latch upgrades - wait     | 8     | A shared hash latch upgrade is when a hash latch is upgraded from shared mode to exclusive mode. This statistics displays the number of times the upgrade did not complete immediately.                                                                  |                  |
| shared io pool buffer get failure     | 128   | Number of unsuccessful buffer gets from the shared I/O pool from instance startup time.                                                                                                                                                                  |                  |
| shared io pool buffer get success     | 128   | Number of successful buffer gets from the shared I/O pool from instance startup time.                                                                                                                                                                    |                  |
| slave propagated tracked transactions | 128   | Number of transactions modifying tables enabled for flashback data archive which were archived by a slave process                                                                                                                                        |                  |
| sorts (disk)                          | 64    | Number of sort operations that required at least one disk write<br><br>Sorts that require I/O to disk are quite resource intensive. Try increasing the size of the initialization parameter SORT_AREA_SIZE. For more information, see "SORT_AREA_SIZE".  |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                              | Class | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | TIMED_STATISTICS |
|-----------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| sorts (memory)                    | 64    | <p>Number of sort operations that were performed completely in memory and did not require any disk writes</p> <p>You cannot do much better than memory sorts, except maybe no sorts at all. Sorting is usually caused by selection criteria specifications within table join SQL operations.</p>                                                                                                                                                                                                                              |                  |
| sorts (rows)                      | 64    | Total number of rows sorted                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                  |
| SQL*Net roundtrips to/from client | 1     | Total number of Oracle Net Services messages sent to and received from the client                                                                                                                                                                                                                                                                                                                                                                                                                                             |                  |
| SQL*Net roundtrips to/from dblink | 1     | Total number of Oracle Net Services messages sent over and received from a database link                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |
| summed dirty queue length         | 8     | <p>The sum of the dirty LRU queue length after every write request. Divide by <b>write requests</b> to get the average queue length after write completion.</p>                                                                                                                                                                                                                                                                                                                                                               |                  |
| switch current from pmem          | 8     | <p>Number of times the CURRENT PMEM block moved to a DRAM buffer, leaving a CR block in the original PMEM buffer. This happens when one Oracle process pins a CURRENT PMEM buffer for read, and another Oracle process wants to pin the same buffer for modification. The latter process clones the PMEM buffer into a new DRAM buffer for modification, while converting the original PMEM current buffer into a PMEM CR buffer.</p>                                                                                         |                  |
| switch current to new buffer      | 8     | Number of times the CURRENT block moved to a different buffer, leaving a CR block in the original buffer                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |
| table fetch by rowid              | 64    | <p>Number of rows that are fetched using a ROWID (usually recovered from an index)</p> <p>This occurrence of table scans usually indicates either non-optimal queries or tables without indexes. Therefore, this statistic should increase as you optimize queries and provide indexes in the application.</p>                                                                                                                                                                                                                |                  |
| table fetch continued row         | 64    | <p>Number of times a chained or migrated row is encountered during a fetch</p> <p>Retrieving rows that span more than one block increases the logical I/O by a factor that corresponds to the number of blocks that need to be accessed. Exporting and re-importing may eliminate this problem. Evaluate the settings for the storage parameters PCTFREE and PCTUSED. This problem cannot be fixed if rows are larger than database blocks (for example, if the LONG data type is used and the rows are extremely large).</p> |                  |
| table scan blocks gotten          | 64    | <p>During scanning operations, each row is retrieved sequentially by Oracle. This statistic counts the number of blocks encountered during the scan.</p> <p>This statistic tells you the number of database blocks that you had to get from the buffer cache for the purpose of scanning. Compare this value with the value of "consistent gets" to determine how much of the consistent read activity can be attributed to scanning.</p>                                                                                     |                  |

**Table E-1 (Cont.) Database Statistics Descriptions**

| Name                                                       | Class | Description                                                                                                                                                                                                                                                         | TIMED_STATISTICS |
|------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| table scan disk IMC fallback                               | 128   | Number of rows fetched from the buffer cache because they were not present in the IM column store (in a scan that was otherwise performed in memory)                                                                                                                |                  |
| table scan disk non-IMC rows gotten                        | 128   | Number of rows fetched during non-In-Memory scan                                                                                                                                                                                                                    |                  |
| table scan rows gotten                                     | 64    | Number of rows that are processed during scanning operations                                                                                                                                                                                                        |                  |
| table scans (cache partitions)                             | 64    | Number of range scans performed on tables that have the CACHE option enabled                                                                                                                                                                                        |                  |
| table scans (direct read)                                  | 64    | Number of table scans performed with direct read (bypassing the buffer cache)                                                                                                                                                                                       |                  |
| table scans (IM)                                           | 128   | Number of segments / granules scanned using In-Memory                                                                                                                                                                                                               |                  |
| table scans (long tables)                                  | 64    | Long (or conversely short) tables can be defined as tables that do not meet the short table criteria as described in " <a href="#">table scans (short tables)</a> "                                                                                                 |                  |
| table scans (rowid ranges)                                 | 64    | During parallel query, the number of table scans conducted with specified ROWID ranges                                                                                                                                                                              |                  |
| table scans (short tables)                                 | 64    | Long (or conversely short) tables can be defined by optimizer hints coming down into the row source access layer of Oracle. The table must have the CACHE option set.                                                                                               |                  |
| tracked rows                                               | 128   | Number of rows modified in tables enabled for flashback data archive                                                                                                                                                                                                |                  |
| tracked transactions                                       | 128   | Number of transactions which modified a table enabled for flashback data archive                                                                                                                                                                                    |                  |
| transaction lock background get time                       | 128   | Useful only for internal debugging purposes                                                                                                                                                                                                                         |                  |
| transaction lock background gets                           | 128   | Useful only for internal debugging purposes                                                                                                                                                                                                                         |                  |
| transaction lock foreground requests                       | 128   | Useful only for internal debugging purposes                                                                                                                                                                                                                         |                  |
| transaction lock foreground wait time                      | 128   | Useful only for internal debugging purposes                                                                                                                                                                                                                         |                  |
| transaction rollbacks                                      | 128   | Number of transactions being successfully rolled back                                                                                                                                                                                                               |                  |
| transaction tables consistent read rollbacks               | 128   | Number of times rollback segment headers are rolled back to create consistent read blocks                                                                                                                                                                           |                  |
| transaction tables consistent reads - undo records applied | 128   | Number of undo records applied to transaction tables that have been rolled back for consistent read purposes                                                                                                                                                        |                  |
| user calls                                                 | 1     | Number of user calls such as login, parse, fetch, or execute<br><br>When determining activity, the ratio of user calls to RPI calls, give you an indication of how much internal work gets generated because of the type of requests the user is sending to Oracle. |                  |

Table E-1 (Cont.) Database Statistics Descriptions

| Name                               | Class | Description                                                                                                                                                                                                                    | TIMED_STATISTICS |
|------------------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| user commits                       | 1     | Number of user commits. When a user commits a transaction, the redo generated that reflects the changes made to database blocks must be written to disk. Commits often represent the closest thing to a user transaction rate. |                  |
| user I/O wait time                 | 1     | The total wait time (in centiseconds) for waits that belong to the User I/O wait class                                                                                                                                         |                  |
| user rollbacks                     | 1     | Number of times users manually issue the ROLLBACK statement or an error occurs during a user's transactions                                                                                                                    |                  |
| very large tracked transactions    | 128   | For tables tracked by flashback data archive, number of transactions modifying those tables which are very large in terms of size or number of changes                                                                         |                  |
| write clones created in background | 8     | Number of times a background or foreground process clones a CURRENT buffer that is being written. The clone becomes the new, accessible CURRENT buffer, leaving the original buffer (now the clone) to complete writing.       |                  |
| write clones created in foreground | 8     | Number of times a background or foreground process clones a CURRENT buffer that is being written. The clone becomes the new, accessible CURRENT buffer, leaving the original buffer (now the clone) to complete writing.       |                  |

# F

## Background Processes

An Oracle Database **background process** is defined as any process that is listed in V\$PROCESS and has a non-null value in the PNAME column.

Table F-1 describes Oracle Database background processes.

The External Properties column lists the type of instance in which the process runs. If the process is specific to a particular feature, then the column names the feature.

### Note:

When the `THREADED_EXECUTION` initialization parameter is set to `TRUE` on Linux and UNIX, the `DBW`, `PMON`, `PSP`, and `VKTM` background processes run as operating system processes, and the other background processes run as operating system threads.

See "[THREADED\\_EXECUTION](#)" for more information about the `THREADED_EXECUTION` initialization parameter.

**Table F-1 Background Processes**

| Name    | Expanded Name                                                       | Short Description                                                                                                                | Long Description                                                                                                                                                                                                                                                                                                                                                                          | External Properties              |
|---------|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| ABMR    | Auto BMR Background Process                                         | Coordinates execution of tasks such as filtering duplicate block media recovery requests and performing flood control            | When a process submits a block media recovery request to ABMR, it dynamically spawns slave processes (BMR $n$ ) to perform the recovery. ABMR and BMR $n$ terminate after being idle for a long time.<br><b>See Also:</b> <i>Oracle Database Backup and Recovery User's Guide</i>                                                                                                         | Database instances               |
| ACFS    | ASM Cluster File System CSS Process                                 | Tracks the cluster membership in CSS and informs the file system driver of membership changes                                    | ACFS delivers CSS membership changes to the Oracle cluster file system. These membership changes are required for the file system to maintain file system consistency within the cluster.                                                                                                                                                                                                 | Oracle ASM instances, Oracle RAC |
| ACMS    | Atomic Control File to Memory Service Process                       | Coordinates consistent updates to a control file resource with its SGA counterpart on all instances in an Oracle RAC environment | The ACMS process works with a coordinating caller to ensure that an operation is executed on every instance in Oracle RAC despite failures. ACMS is the process in which a distributed operation is called. As a result, this process can exhibit a variety of behaviors. In general, ACMS is limited to small, nonblocking state changes for a limited set of cross-instance operations. | Database instances, Oracle RAC   |
| AMB $n$ | <b>See</b> <a href="#">ASMB</a> , <a href="#">AMB<math>n</math></a> |                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                           |                                  |

| ASMB,<br>AMB $n$ | ASM<br>Background<br>Process                   | Communicates with an Oracle ASM instance, managing storage and providing statistics                                                                                                                                                                     | <p>In a database instance, the ASMB and AMB<math>n</math> processes enable the database instance to connect to an Oracle ASM instance in order to access Oracle ASM disk groups. Possible processes are ASMB and AMB1-AMB3.</p> <p>In an Oracle ASM instance, the ASMB process runs when the ASMCMD <code>cp</code> command runs, or when a database instance first starts if the server parameter file is stored in Oracle ASM. ASMB also runs with Oracle Cluster Registry on Oracle ASM. The only possible process is ASMB; AMB<math>n</math> processes do not run in Oracle ASM instances.</p> <p>In an Oracle IO Server (IOS) instance, the ASMB process enables the IOS instance to connect to an Oracle ASM instance in order to access Oracle ASM disk groups. The only possible process is ASMB; AMB<math>n</math> processes do not run in IOS instances.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Database instances, Oracle ASM instances, Oracle IO Server (IOS) instances                            |
| AS $nn$          | Database<br>Apply Reader<br>or Apply<br>Server | <p>Computes dependencies between logical change records (LCRs) and assembles messages into transactions (Reader Server)</p> <p>Applies LCRs to database objects or passes LCRs and user messages to their appropriate apply handlers (Apply Server)</p> | <p>When the reader server finishes computing dependencies between LCRs and assembling transactions, it returns the assembled transactions to the coordinator process. Query <code>V\$STREAMS_APPLY_READER</code>, <code>V\$XSTREAM_APPLY_READER</code>, and <code>V\$GG_APPLY_READER</code> for information about the reader server background process.</p> <p>An apply server receives the transactions from the coordinator background process, and either applies database changes in LCRs or sends LCRs or messages to apply handlers. Apply servers can also enqueue a queue. If an apply server encounters an error, then it then tries to resolve the error with a user-specified conflict handler or error handler. If an apply server cannot resolve an error, then it rolls back the transaction and places the entire transaction, including all of its messages, in the error queue. When an apply server commits a completed transaction, this transaction has been applied. When an apply server places a transaction in the error queue and commits, this transaction also has been applied. Query <code>V\$STREAMS_APPLY_SERVER</code> for information about the apply server background process. For XStream Inbound servers, query <code>V\$XSTREAM_APPLY_SERVER</code>. For GoldenGate Integrated Replicat, query <code>V\$GG_APPLY_SERVER</code>.</p> <p>The coordinator process name is AS<math>nn</math>, where <math>nn</math> can include letters and numbers.</p> | Database instances, XStream Outbound servers, XStream Inbound servers, GoldenGate Integrated Replicat |

| Name    | Expanded Name                                     | Short Description                                                                                                                      | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | External Properties                      |
|---------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| BMR $n$ | Automatic Block Media Recovery Slave Pool Process | Fetches blocks from a real-time readable standby database                                                                              | When a process submits a block media recovery request to ABMR, it dynamically spawns slave processes (BMR $n$ ) to perform the recovery. BMR $n$ processes fetch blocks from a real-time readable standby database. ABMR and BMR $n$ terminate after being idle for a long time.<br><br><b>See Also:</b> <i>Oracle Database Backup and Recovery User's Guide</i>                                                                                                                                                      | Database instances                       |
| B $nnn$ | ASM Blocking Slave Process for GMON               | Performs maintenance actions on Oracle ASM disk groups                                                                                 | B $nnn$ performs actions that require waiting for resources on behalf of GMON. GMON must be highly available and cannot wait.<br><br>A B $nnn$ slave is spawned when a disk is taken offline in an Oracle ASM disk group. Offline timer processing and drop of the disk are performed in this slave. Up to five process (B000 to B004) can exist depending on the load.                                                                                                                                               | Oracle ASM instances                     |
| BW $nn$ | Database Writer Process                           | Writes modified blocks from the database buffer cache to the data files                                                                | See the <b>Long Description</b> for the DBW $n$ process in this table for more information about the BW $nn$ process.                                                                                                                                                                                                                                                                                                                                                                                                 | Database instances                       |
| CJQ0    | Job Queue Coordinator Process                     | Selects jobs that need to be run from the data dictionary and spawns job queue slave processes (J $nnn$ ) to run the jobs              | CJQ0 is automatically started and stopped as needed by Oracle Scheduler.<br><br>The JOB_QUEUE_PROCESSES initialization parameter specifies the maximum number of processes that can be created for the execution of jobs. CJQ0 starts only as many job queue processes as required by the number of jobs to run and available resources.<br><br><b>See Also:</b> <i>Oracle Database Concepts</i> and <i>Oracle Database Administrator's Guide</i>                                                                     | Database instances                       |
| CKPT    | Checkpoint Process                                | Signals DBW $n$ at checkpoints and updates all the data files and control files of the database to indicate the most recent checkpoint | At specific times CKPT starts a checkpoint request by messaging DBW $n$ to begin writing dirty buffers. On completion of individual checkpoint requests, CKPT updates data file headers and control files to record most recent checkpoint.<br><br>CKPT checks every three seconds to see whether the amount of memory exceeds the value of the PGA_AGGREGATE_LIMIT initialization parameter, and if so, takes the action described in "PGA_AGGREGATE_LIMIT".<br><br><b>See Also:</b> <i>Oracle Database Concepts</i> | Database instances, Oracle ASM instances |
| CL $nn$ | Cleanup Slave Process                             | Performs cleanup of dead processes                                                                                                     | Cleanup slaves assist in the cleanup of dead processes and killed sessions. The number of slaves will be proportional to the amount of cleanup work to be done and the current efficiency of cleanup.                                                                                                                                                                                                                                                                                                                 | Database instances, Oracle ASM instances |

Table F-1 (Cont.) Background Processes

| Name    | Expanded Name                                     | Short Description                                                                                                                                                               | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | External Properties                          |
|---------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| CLG     | Persistent Cluster Flash Cache Background Process | For Oracle Data Appliance only, this process performs actions related to recovery of a dead instance's database flash cache                                                     | For Oracle Data Appliance only, in the event of an instance crash, the surviving instance will recover the dead instance's database flash cache. The CLG process will perform actions related to scanning the dead instance's database flash cache and claim flash blocks mastered by the dead instance.                                                                                                                                                                                                                                                                                                                                                       | Database instances, Oracle RAC               |
| CLMN    | Cleanup Main Process                              | Performs cleanup of dead processes, killed sessions, killed transactions, and killed network connections                                                                        | CLMN periodically performs cleanup of all the following: dead processes, killed sessions, transactions, network connections, idle sessions, detached transactions, and detached network connections that have exceeded their idle timeout.                                                                                                                                                                                                                                                                                                                                                                                                                     | Database instances, Oracle ASM instances     |
| CP $nn$ | Database Capture Process                          | Captures database changes from the redo log by using the infrastructure of LogMiner                                                                                             | The capture process name is CP $nn$ , where $nn$ can include letters and numbers. The underlying LogMiner process name is MS $nn$ , where $nn$ can include letters and numbers. The capture process includes one reader server that reads the redo log and divides it into regions, one or more preparer servers that scan the redo log, and one builder server that merges redo records from the preparer servers. Each reader server, preparer server, and builder server is a process. Query the V\$XSTREAM_CAPTURE and V\$GOLDENGATE_CAPTURE views for information about this background process.<br><b>See Also:</b> <i>Oracle Database XStream Guide</i> | Database instances, XStream Outbound Servers |
| CR $nn$ | LMS CR Slave Process                              | Offloads the work from LMS so that blocks that require lots of UNDO to be applied do not block the LMS. Such requests are passed on to the slave so that the LMS is not stalled | There can be a maximum of eight CR processes per LMS process, with names from CR00 to CR07. Each LMS has its own set with similar name. The CR $nn$ processes are threads and the process ID part will be the same as the owning LMS's process ID.<br>The names for CR $nn$ processes will have the format CR0 $n$ _ $\langle$ spawning process id $\rangle$ _ $\langle$ thread id $\rangle$ .                                                                                                                                                                                                                                                                 | Oracle RAC                                   |
| CS $nn$ | I/O Calibration Process                           | Issues I/Os to storage as part of storage calibration.                                                                                                                          | CS $nn$ slave processes are started on execution of the DBMS_RESOURCE_MANAGER.CALIBRATE_IO( ) procedure. There is one slave process per CPU on each node of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Database instances, Oracle RAC               |
| CTWR    | Change Tracking Writer Process                    | Tracks changed data blocks as part of the Recovery Manager block change tracking feature                                                                                        | CTWR tracks changed blocks as redo is generated at a primary database and as redo is applied at a standby database. The process is slightly different depending on the type of database.<br><b>See Also:</b> <i>Oracle Database Backup and Recovery User's Guide</i>                                                                                                                                                                                                                                                                                                                                                                                           | Database instances                           |
| CX $nn$ | Propagation Sender Process                        | Sends LCRs to a propagation receiver                                                                                                                                            | The propagation sender process name is CX $nn$ , where $nn$ can include letters and numbers. Query V\$PROPAGATION_SENDER for information about a propagation sender.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Database instances, XStream Outbound Server  |

| Name | Expanded Name                     | Short Description                                                                                           | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | External Properties                      |
|------|-----------------------------------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| DBRM | Database Resource Manager Process | Sets resource plans and performs other tasks related to the Database Resource Manager                       | If a resource plan is not enabled, then this process is idle.<br><b>See Also:</b> <i>Oracle Database Administrator's Guide</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Database instances                       |
| DBWn | Database Writer Process           | Writes modified blocks from the database buffer cache to the data files                                     | The primary responsibility of the Database Writer Process is to write data blocks to disk. It also handles checkpoints, file open synchronization, and logging of Block Written records.<br><br>In many cases the blocks that the Database Writer Process writes are scattered throughout the disk. Thus, the writes tend to be slower than the sequential writes performed by LGWR. The Database Writer Process performs multiblock writes when possible to improve efficiency. The number of blocks written in a multiblock write varies by operating system.<br><br>The DB_WRITER_PROCESSES initialization parameter specifies the number of Database Writer Processes. There can be 1 to 100 Database Writer Processes. The names of the first 36 Database Writer Processes are DBW0-DBW9 and DBWa-DBWz. The names of the 37th through 100th Database Writer Processes are BW36-BW99. The database selects an appropriate default setting for the DB_WRITER_PROCESSES parameter or adjusts a user-specified setting based on the number of CPUs and processor groups.<br><b>See Also:</b> " <a href="#">DB_WRITER_PROCESSES</a> " | Database instances                       |
| DIA0 | Diagnostic Process                | Detects and resolves hangs and deadlocks                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Database instances, Oracle ASM instances |
| DIAG | Diagnostic Capture Process        | Performs diagnostic dumps                                                                                   | DIAG performs diagnostic dumps requested by other processes and dumps triggered by process or instance termination. In Oracle RAC, DIAG performs global diagnostic dumps requested by remote instances.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Database instances, Oracle ASM instances |
| DMnn | Data Pump Master Process          | Coordinates the Data Pump job tasks performed by Data Pump worker processes and handles client interactions | The Data Pump master (control) process is started during job creation and coordinates all tasks performed by the Data Pump job. It handles all client interactions and communication, establishes all job contexts, and coordinates all worker process activities on behalf of the job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Database instances, Data Pump            |

| DMON | Data Guard Broker Monitor Process | Manages and monitors a database that is part of a Data Guard broker configuration                                                           | <p>When you start the Data Guard broker, a DMON process is created. DMON runs for every database instance that is managed by the broker. DMON interacts with the local database and the DMON processes of the other databases to perform the requested function. DMON also monitors the health of the broker configuration and ensures that every database has a consistent description of the configuration.</p> <p>DMON maintains profiles about all database objects in the broker configuration in a binary configuration file. A copy of this file is maintained by the DMON process for each of the databases that belong to the broker configuration. The process is created when the <code>DG_BROKER_START</code> initialization parameter is set to <code>true</code>.</p> <p><b>See Also:</b> <i>Oracle Data Guard Broker</i></p>                                                                                                                                                                                                                                                                   | Database instances, Data Guard     |
| Dnnn | Dispatcher Process                | Performs network communication in the shared server architecture                                                                            | <p>In the shared server architecture, clients connect to a dispatcher process, which creates a virtual circuit for each connection. When the client sends data to the server, the dispatcher receives the data into the virtual circuit and places the active circuit on the common queue to be picked up by an idle shared server. The shared server then reads the data from the virtual circuit and performs the database work necessary to complete the request. When the shared server must send data to the client, the server writes the data back into the virtual circuit and the dispatcher sends the data to the client. After the shared server completes the client request, the server releases the virtual circuit back to the dispatcher and is free to handle other clients.</p> <p>Several initialization parameters relate to shared servers. The principal parameters are: <code>DISPATCHERS</code>, <code>SHARED_SERVERS</code>, <code>MAX_SHARED_SERVERS</code>, <code>LOCAL_LISTENER</code>, <code>REMOTE_LISTENER</code>.</p> <p><b>See Also:</b> <i>Oracle Database Concepts</i></p> | Database instances, shared servers |
| DSKM | Slave Diskmon Process             | Acts as the conduit between the database, Oracle ASM instances, and the Master Diskmon daemon to communicate information to Exadata storage | This process is active only if Exadata Storage is used. DSKM performs operations related to Exadata I/O fencing and Exadata cell failure handling.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Oracle ASM instances, Exadata      |

Table F-1 (Cont.) Background Processes

| Name | Expanded Name                             | Short Description                                                                                                               | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | External Properties                      |
|------|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| DWnn | Data Pump Worker Process                  | Performs Data Pump tasks as assigned by the Data Pump master process                                                            | The Data Pump worker process is responsible for performing tasks that are assigned by the Data Pump master process, such as the loading and unloading of metadata and data.                                                                                                                                                                                                                                                                                                                                                     | Database instances                       |
| EMNC | EMON Coordinator Process                  | Coordinates database event management and notifications                                                                         | EMNC is a master background process that coordinates event management and notification activity in the database, including Streams Event Notifications, Continuous Query Notifications, and Fast Application Notifications.                                                                                                                                                                                                                                                                                                     | Database instances                       |
| Ennn | EMON Slave Process                        | Performs database event management and notifications                                                                            | The database event management and notification load is distributed among the EMON slave processes. These processes work on the system notifications in parallel, offering a capability to process a larger volume of notifications, a faster response time, and a lower shared memory use for staging notifications.                                                                                                                                                                                                            | Database instances                       |
| FBDA | Flashback Data Archiver Process           | Archives historical rows for tracked tables into flashback data archives and manages archive space, organization, and retention | <p>When a transaction that modifies a tracked table commits, FBDA stores the pre-image of the rows in the archive. FBDA maintains metadata on the current rows and tracks how much data has been archived.</p> <p>FBDA is also responsible for automatically managing the flashback data archive for space, organization (partitioning tablespaces), and retention. FBDA also keeps track of how far the archiving of tracked transactions has progressed.</p> <p><b>See Also:</b> <i>Oracle Database Development Guide</i></p> | Database instances                       |
| FDnn | Oracle ASM Stale FD Cleanup Slave Process | Cleans up Oracle ASM stale file descriptors on foreground processes                                                             | This process cleans up Oracle ASM stale file descriptors on foreground processes if an Oracle ASM disk is globally closed.                                                                                                                                                                                                                                                                                                                                                                                                      | Database and Oracle ASM instances        |
| FENC | Fence Monitor Process                     | Processes fence requests for RDBMS instances which are using Oracle ASM instances                                               | CSS monitors RDBMS instances which are connected to the Oracle ASM instance and constantly doing I/Os. When the RDBMS instance terminates due to a failure, all the outstanding I/O's from the RDBMS instance should be drained and any new I/O's rejected. FENC receives and processes the fence request from CSSD.                                                                                                                                                                                                            | Oracle ASM instances                     |
| FMON | File Mapping Monitor Process              | Manages mapping information for the Oracle Database file mapping interface                                                      | <p>The <code>DBMS_STORAGE_MAP</code> package enables you to control the mapping operations. When instructed by the user, FMON builds mapping information and stores it in the SGA, refreshes the information when a change occurs, saves the information to the data dictionary, and restores it to the SGA at instance startup.</p> <p>FMON is started by the database whenever the <code>FILE_MAPPING</code> initialization parameter is set to true.</p>                                                                     | Database instances, Oracle ASM instances |

Table F-1 (Cont.) Background Processes

| Name    | Expanded Name                                        | Short Description                                                                    | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | External Properties                                                  |
|---------|------------------------------------------------------|--------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| FSFP    | Data Guard Broker Fast Start Failover Pinger Process | Maintains fast-start failover state between the primary and target standby databases | FSFP is created when fast-start failover is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Database instances, Data Guard                                       |
| GCR $n$ | Global Conflict Resolution Slave Process             | Performs synchronous tasks on behalf of LMHB                                         | GCR $n$ processes are transient slaves that are started and stopped as required by LMHB to perform synchronous or resource intensive tasks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Database instances, Oracle ASM instances, Oracle RAC                 |
| GEN0    | General Task Execution Process                       | Performs required tasks including SQL and DML                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances, Oracle ASM instances, Oracle ASM Proxy instances |
| GMON    | ASM Disk Group Monitor Process                       | Monitors all mounted Oracle ASM disk groups                                          | GMON monitors all the disk groups mounted in an Oracle ASM instance and is responsible for maintaining consistent disk membership and status information. Membership changes result from adding and dropping disks, whereas disk status changes result from taking disks offline or bringing them online.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Oracle ASM instances                                                 |
| GTX $n$ | Global Transaction Process                           | Provides transparent support for XA global transactions in an Oracle RAC environment | <p>These processes help maintain the global information about XA global transactions throughout the cluster. Also, the processes help perform two-phase commit for global transactions anywhere in the cluster so that an Oracle RAC database behaves as a single system to the externally coordinated distributed transactions.</p> <p>The GLOBAL_TXN_PROCESSES initialization parameter specifies the number of GTX<math>n</math> processes, where <math>n</math> is 0-9 or a-j. The database automatically tunes the number of these processes based on the workload of XA global transactions. You can disable these processes by setting the parameter to 0. If you try to run XA global transactions with these processes disabled, an error is returned.</p> <p><b>See Also:</b> <i>Oracle Real Application Clusters Administration and Deployment Guide</i></p> | Database instances, Oracle RAC                                       |

Table F-1 (Cont.) Background Processes

| Name        | Expanded Name                              | Short Description                                                                                                    | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | External Properties                                  |
|-------------|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| <i>Innn</i> | Disk and Tape I/O Slave Process            | Serves as an I/O slave process spawned on behalf of DBWR, LGWR, or an RMAN backup session                            | I/O slave process can be configured on platforms where asynchronous I/O support is not available. These slaves are started by setting the corresponding slave enable parameter in the server parameter file. The I/O slaves simulate the asynchronous I/O behavior when the underlying platform does not have native support for asynchronous I/O.                                                                                                                                                                                                                            | Database instances                                   |
| IMCO        | In-Memory Coordinator                      | Initiates background population and repopulation of in-memory enabled objects                                        | The IMCO background process initiates population (prepopulation) of in-memory enabled objects with priority LOW/MEDIUM/HIGH/CRITICAL. In-memory enabled objects with priority NONE will not be prepopulated but will be populated on demand via <i>Wnnn</i> processes when queried. The IMCO background process can also initiate repopulation of in-memory objects.<br><br>Starting with Oracle Database 19c, IMXT (In-Memory External Table) segments are dropped by the IMCO background process. In previous releases, IMXT segments were dropped by foreground processes. | Database instances                                   |
| IMR0        | Instance Membership Recovery Slave Process | Performs synchronous tasks on behalf of LMON                                                                         | The IMR0 background process performs the Instance Member Recovery synchronous operations on behalf of LMON                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Oracle RAC, Database instances, Oracle ASM instances |
| INSV        | Data Guard Broker Instance Slave Process   | Performs Data Guard broker communication among instances in an Oracle RAC environment                                | INSV is created when the <code>DG_BROKER_START</code> initialization parameter is set to <code>true</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Database instances, Data Guard                       |
| IPC0        | IPC Service Background Process             | Common background server for basic messaging and RDMA primitives based on IPC (Inter-process communication) methods. | IPC0 handles very high rates of incoming connect requests, as well as, completing reconfigurations to support basic messaging and RDMA primitives over several transports such as UDP, RDS, InfiniBand and RC.                                                                                                                                                                                                                                                                                                                                                                | Oracle RAC                                           |
| <i>Jnnn</i> | Job Queue Slave Process                    | Executes jobs assigned by the job coordinator                                                                        | Job slave processes are created or awakened by the job coordinator when it is time for a job to be executed.<br><br>Job slaves gather all the metadata required to run the job from the data dictionary. The slave processes start a database session as the owner of the job, execute triggers, and then execute the job. After the job is complete, the slave processes commit and then execute appropriate triggers and close the session. The slave can repeat this operation in case additional jobs need to be run.                                                     | Database instances                                   |

Table F-1 (Cont.) Background Processes

| Name    | Expanded Name                              | Short Description                                              | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                 | External Properties                                  |
|---------|--------------------------------------------|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| JP $n$  | Java Patching Slave Process                | Patches and updates the Java in the database classes           | JP $n$ patches and updates the Java in the database classes. It is only started for Oracle Real Application Clusters (Oracle RAC) databases, and one of the database instances is responsible for patching the Java in the database objects. For multitenant container databases (CDBs), the process updates each pluggable database (PDB) individually. JP $n$ is started automatically and does not require user intervention. | Oracle RAC                                           |
| LCK $n$ | Lock Process                               | Manages global enqueue requests and cross-instance broadcasts  | The process handles all requests for resources other than data blocks. For examples, LCK $n$ manages library and row cache requests. Possible processes are LCK0 and LCK1.                                                                                                                                                                                                                                                       | Database instances, Oracle ASM instances, Oracle RAC |
| LDD $n$ | Global Enqueue Service Daemon Helper Slave | Helps the LMD $n$ processes with various tasks                 | LDD $n$ processes are slave processes spawned on demand by LMD $n$ processes. They are spawned to help the dedicated LMD $n$ processes with various tasks when certain workloads start creating performance bottlenecks. These slave processes are transient as they are started on demand and they can be shutdown when no longer needed. There can be up to 36 of these slave processes (LDD0-LDDz).                           | Database instances, Oracle ASM instances, Oracle RAC |
| LG $nn$ | Log Writer Worker                          | Writes redo log                                                | On multiprocessor systems, LGWR creates worker processes to improve the performance of writing to the redo log. LGWR workers are not used when there is a SYNC standby destination. Possible processes are LG00-LG99.                                                                                                                                                                                                            | Database instances                                   |
| LGWR    | Log Writer Process                         | Writes redo entries to the online redo log                     | Redo log entries are generated in the redo log buffer of the system global area (SGA). LGWR writes the redo log entries sequentially into a redo log file. If the database has a multiplexed redo log, then LGWR writes the redo log entries to a group of redo log files.<br><b>See Also:</b> <i>Oracle Database Concepts</i> and <i>Oracle Database Administrator's Guide</i>                                                  | Database instances, Oracle ASM instances             |
| LM $nn$ | <b>See</b> LMS $n$ , LM $nn$               |                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                      |
| LMD $n$ | Global Enqueue Service Daemon Process      | Manages incoming remote resource requests from other instances | LMD $n$ processes enqueue resources managed under Global Enqueue Service. In particular, they process incoming enqueue request messages and control access to global enqueues. They also perform distributed deadlock detections. There can be up to 36 of these processes (LMD0-LMDz).                                                                                                                                          | Database instances, Oracle ASM instances, Oracle RAC |

| Name       | Expanded Name                                   | Short Description                                                                                                   | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         | External Properties                                  |
|------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| LMFC       | Lock Manager Flash Cache Process                | For Oracle Database Appliance only, performs actions related to recovery of a dead instance's database flash cache. | For Oracle Database Appliance only, in the event of a instance crash, the surviving instance will recover the dead instance's database flash cache. The LMFC process will perform actions related to scanning the dead instance's database flash cache and claim flash blocks mastered by the dead instance.                                                                                                                                                             | Database instances, Oracle RAC                       |
| LMHB       | Global Cache/ Enqueue Service Heartbeat Monitor | Monitor the heartbeat of several processes                                                                          | LMHB monitors the CKPT, DIAn, LCKn, LGnn, LGWR, LMDn, LMON, LMSn, and RMSn processes to ensure they are running normally without blocking or spinning.                                                                                                                                                                                                                                                                                                                   | Database instances, Oracle ASM instances, Oracle RAC |
| LMON       | Global Enqueue Service Monitor Process          | Monitors an Oracle RAC cluster to manage global resources                                                           | LMON maintains instance membership within Oracle RAC. The process detects instance transitions and performs reconfiguration of GES and GCS resources.<br><b>See Also:</b> <i>Oracle Real Application Clusters Administration and Deployment Guide</i>                                                                                                                                                                                                                    | Database instances, Oracle ASM instances, Oracle RAC |
| LMSn, LMnn | Global Cache Service Process                    | Manages resources and provides resource control among Oracle RAC instances                                          | LMSn and LMnn processes maintain a lock database for Global Cache Service (GCS) and buffer cache resources. These processes receive, process, and send GCS requests, block transfers, and other GCS-related messages. There can be up to 100 of these processes, named as follows:<br><br>LMS0-LMS9<br>LMSA-LMSZ<br>LM10-LM19<br>LM1A-LM1Z<br>LM20-LM29<br>LM2A-LM2R<br><br><b>See Also:</b> <i>Oracle Real Application Clusters Administration and Deployment Guide</i> | Database instances, Oracle ASM instances, Oracle RAC |
| LREG       | Listener Registration Process                   | Registers the instance with the listeners                                                                           | LREG notifies the listeners about instances, services, handlers, and endpoint.                                                                                                                                                                                                                                                                                                                                                                                           | Database instances, Oracle ASM instances, Oracle RAC |
| LSP0       | Logical Standby Coordinator Process             | Schedules transactions for Data Guard SQL Apply                                                                     | LSP0 is the initial process created upon startup of Data Guard SQL Apply. In addition to managing LogMiner and Apply processes, LSP0 is responsible for maintaining inter-transaction dependencies and appropriately scheduling transactions with applier processes. LSP0 is also responsible for detecting and enabling run-time parameter changes for the SQL Apply product as a whole.                                                                                | Database instances, Data Guard                       |

Table F-1 (Cont.) Background Processes

| Name | Expanded Name                                     | Short Description                                                                                           | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | External Properties                                      |
|------|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| LSP1 | Logical Standby Dictionary Build Process          | Performs a logical standby dictionary build on a primary database                                           | The LSP1 process is spawned on a logical standby database that is intended to become the new primary database. A logical standby database becomes a primary database because of switchover or failover. The dictionary is necessary for logical standby databases to interpret the redo of the new primary database.                                                                                                                                                                                                                                             | Database instances, Data Guard                           |
| LSP2 | Logical Standby Set Guard Process                 | Determines which database objects will be protected by the database guard                                   | The LSP2 process is created as needed during startup of SQL Apply to update the list of objects that are protected by the database guard.                                                                                                                                                                                                                                                                                                                                                                                                                        | Database instances, Data Guard                           |
| Lnnn | Pooled Server Process                             | Handles client requests in Database Resident Connection Pooling                                             | In Database Resident Connection Pooling, clients connect to a connection broker process. When a connection becomes active, the connection broker hands off the connection to a compatible pooled server process. The pooled server process performs network communication directly on the client connection and processes requests until the client releases the server. After being released, the connection is returned to the broker for monitoring, leaving the server free to handle other clients.<br><br><b>See Also:</b> <i>Oracle Database Concepts</i> | Database instances, Database Resident Connection Pooling |
| MARK | Mark AU for Resynchronization Coordinator Process | Marks ASM allocation units as stale following a missed write to an offline disk                             | MARK essentially tracks which extents require resynchronization for offline disks. This process runs in the database instance and is started when the database instance first begins using the Oracle ASM instance. If required, MARK can also be started on demand when disks go offline in the Oracle ASM redundancy disk group.                                                                                                                                                                                                                               | Database instances, Oracle ASM instances                 |
| MMAN | Memory Manager Process                            | Serves as the instance memory manager                                                                       | This process performs the resizing of memory components on the instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances, Oracle ASM instances                 |
| MMNL | Manageability Monitor Lite Process                | Performs tasks relating to manageability, including active session history sampling and metrics computation | MMNL performs many tasks relating to manageability, including session history capture and metrics computation.                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Database instances, Oracle ASM instances                 |
| MMON | Manageability Monitor Process                     | Performs or schedules many manageability tasks                                                              | MMON performs many tasks related to manageability, including taking Automatic Workload Repository snapshots and performing Automatic Database Diagnostic Monitor analysis.                                                                                                                                                                                                                                                                                                                                                                                       | Database instances, Oracle ASM instances                 |
| Mnnn | Shared MMON Slave Process                         | Performs manageability tasks on behalf of MMON                                                              | The <i>Mnnn</i> processes are a pool of slave processes that can be shared by multiple <i>MZnn</i> processes. See the <b>Long Description</b> for <i>MZnn</i> in this table for more information about the <i>MZnn</i> processes.                                                                                                                                                                                                                                                                                                                                | Database instances, Oracle ASM instances                 |

Table F-1 (Cont.) Background Processes

| Name    | Expanded Name                          | Short Description                                                                                         | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | External Properties                                                              |
|---------|----------------------------------------|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| MRP0    | Managed Standby Recovery Process       | Coordinates the application of redo on a physical standby database                                        | MRP0 is spawned at the start of redo apply on a physical standby database. This process handles the extraction of redo and coordinates the application of that redo on a physical standby database.<br><br><b>See Also:</b> <i>Oracle Data Guard Concepts and Administration</i>                                                                                                                                                                                                                                                                                 | Database instances, Data Guard                                                   |
| MS $nn$ | LogMiner Worker Process                | Reads redo log files and translates and assembles into transactions                                       | Multiple MS $nn$ processes can exist, where $n$ is 0-9 or a-Z. A minimum of three MS $nn$ processes work as a group to provide transactions to a LogMiner client, for example, a logical standby database or a database capture. There may be more than one such group, for example, multiple capture processes configured for either local or downstream capture in a database.                                                                                                                                                                                 | Database instances, Logical Standby, XStream Outbound servers, Oracle GoldenGate |
| MZ $nn$ | Dedicated MMON Slave Process           | Performs manageability tasks on behalf of MMON                                                            | MZ $nn$ is a dedicated process for a single MMON slave action. It performs manageability tasks dispatched by MMON, which include taking Automatic Workload Repository snapshots and performing Automatic Database Diagnostic Monitor analysis.                                                                                                                                                                                                                                                                                                                   | Database instances, Oracle ASM instances                                         |
| N $nnn$ | Connection Broker Process              | Monitors idle connections and hands off active connections in Database Resident Connection Pooling        | In Database Resident Connection Pooling, clients connect to a connection broker process. When a connection becomes active, the connection broker hands off the connection to a compatible pooled server process. The pooled server process performs network communication directly on the client connection and processes requests until the client releases the server. After being released, the connection is returned to the broker for monitoring, leaving the server free to handle other clients.<br><br><b>See Also:</b> <i>Oracle Database Concepts</i> | Database instances, Database Resident Connection Pooling                         |
| NFS $n$ | Direct NFS Dispatcher IO Slave Process | Performs direct NFS I/O for database processes                                                            | The dispatcher slave processes enable scaling of Direct NFS connections to a clustered NAS storage. These dedicated set of slaves will be used to perform Direct NFS I/Os on behalf of database processes. The dispatcher processes are enabled by the ENABLE_DNFS_DISPATCHER initialization parameter. NFS $n$ is spawned only if Direct NFS library is enabled for I/O to NFS servers. The number of slave processes spawned is based on the CPU_COUNT value.<br><br><b>See Also:</b> "ENABLE_DNFS_DISPATCHER"                                                 | Database instances                                                               |
| NSS $n$ | Network Server SYNC Process            | Transfers redo from current online redo logs to remote standby destinations configured for SYNC transport | NSS $n$ can run as multiple processes, where $n$ is 1-9 or A.<br><br><b>See Also:</b> <i>Oracle Data Guard Concepts and Administration</i>                                                                                                                                                                                                                                                                                                                                                                                                                       | Database instances, Data Guard                                                   |

Table F-1 (Cont.) Background Processes

| Name    | Expanded Name                                | Short Description                                                                                      | Long Description                                                                                                                                                                                                                                                                                                                | External Properties                                                  |
|---------|----------------------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| NSV $n$ | Data Guard Broker NetSlave Process           | Performs broker network communications between databases in a Data Guard environment                   | NSV $n$ is created when a Data Guard broker configuration is enabled. There can be as many NSV $n$ processes (where $n$ is 0- 9 and A-U) created as there are databases in the Data Guard broker configuration.                                                                                                                 | Database instances, Data Guard                                       |
| OCF $n$ | ASM CF Connection Pool Process               | Maintains a connection to the Oracle ASM instance for metadata operations                              |                                                                                                                                                                                                                                                                                                                                 | Database instances, Oracle ASM instances                             |
| OFSD    | Oracle File Server Background Process        | Serves file system requests submitted to an Oracle instance                                            | This background process listens for new file system requests, both management (like mount, unmount, and export) and I/O requests, and executes them using Oracle threads.                                                                                                                                                       | Database instances, Oracle RAC                                       |
| OF $nn$ | Oracle File Server Background Process Thread | Serves file system requests submitted to an Oracle instance                                            | This is a thread for the OFSD background process. This background process thread is available only on Linux systems.                                                                                                                                                                                                            | Database instances, Oracle RAC                                       |
| O $nnn$ | ASM Connection Pool Process                  | Maintains a connection to the Oracle ASM instance for metadata operations                              | O $nnn$ slave processes are spawned on demand. These processes communicate with the Oracle ASM instance.                                                                                                                                                                                                                        | Database instances, Oracle ASM instances                             |
| PING    | Interconnect Latency Measurement Process     | Assesses latencies associated with communications for each pair of cluster instances                   | Every few seconds, the process in one instance sends messages to each instance. The message is received by PING on the target instance. The time for the round trip is measured and collected.                                                                                                                                  | Database instances, Oracle ASM instances, Oracle RAC                 |
| PMAN    | Process Manager                              | Manages several background processes including shared servers, pooled servers, and job queue processes | PMAN monitors, spawns, and stops the following as needed: <ul style="list-style-type: none"> <li>• dispatcher and shared server processes</li> <li>• connection broker and pooled server processes for database resident connection pools</li> <li>• job queue processes</li> <li>• restartable background processes</li> </ul> | Database instances, Oracle ASM instances, Oracle ASM Proxy instances |
| PMON    | Process Monitor                              | Scans for dead processes and coordinates cleanup                                                       | PMON periodically scans all processes to find any that have died abnormally. PMON is then responsible for coordinating cleanup performed by the CLMN process and the CL $nn$ slaves.<br><b>See Also:</b> <i>Oracle Database Concepts</i> and <i>Oracle Database Net Services Administrator's Guide</i>                          | Database instances, Oracle ASM instances, Oracle ASM Proxy instances |

Table F-1 (Cont.) Background Processes

| Name        | Expanded Name                    | Short Description                                                                                                           | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | External Properties                      |
|-------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| <i>Pnnn</i> | Parallel Query Slave Process     | Perform parallel execution of a SQL statement (query, DML, or DDL)                                                          | <p>Parallel Query has two components: a foreground process that acts as query coordinator and a set of parallel slaves (<i>Pnnn</i>) that are background processes. These background processes are spawned or reused during the start of a parallel statement. They receive and perform units of work sent from the query coordinator.</p> <p>The maximum number of <i>Pnnn</i> processes is controlled by the initialization parameter <code>PARALLEL_MAX_SERVERS</code>. Slave processes are numbered from 0 to the <code>PARALLEL_MAX_SERVERS</code> setting. If the query is a <code>GV\$</code> query, then these background processes are numbered backward, starting from <code>PPA7</code>.</p> | Database instances, Oracle ASM instances |
| <i>PRnn</i> | Parallel Recovery Process        | Performs tasks assigned by the coordinator process performing parallel recovery                                             | <i>PRnn</i> serves as a slave process for the coordinator process performing parallel media recovery and carries out tasks assigned by the coordinator. The default number of these processes is based on number of CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Database instances                       |
| <i>PSP0</i> | Process Spawner Process          | Spawns Oracle background processes after initial instance startup                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances, Oracle ASM instances |
| <i>PXMN</i> | Parallel Execution Monitor       | Spawns parallel server processes on local instances in an Oracle RAC environment for Query Coordinator in remote instances. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances                       |
| <i>QMNC</i> | Non-sharded queue master process | Monitors AQ                                                                                                                 | <p><i>QMNC</i> is the non-sharded queue master process responsible for facilitating various background activities required by AQ: time management of messages, management of nonpersistent queues, cleanup of resources, and so on. <i>QMNC</i> dynamically spawns <i>Qnnn</i> processes as needed for performing these tasks.</p> <p>Note that if the <code>AQ_TM_PROCESSES</code> initialization parameter is set to 0, this process will not start. The database writes the following message to the alert log: <code>WARNING: AQ_TM_PROCESSES is set to 0. System might be adversely affected.</code></p>                                                                                           | Database instances<br>Advanced Queueing  |
| <i>QMnn</i> | AQ Master Class Process          | Per instance per AQ Master Class Process                                                                                    | Each of this type of process represents a single class of work item such as AQ notification, queue monitors, and cross process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances<br>Advanced Queueing  |

Table F-1 (Cont.) Background Processes

| Name        | Expanded Name                     | Short Description                                                                                                   | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | External Properties                         |
|-------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|
| <i>Qnnn</i> | AQ Server Class Process           | Per AQ Master Class server process                                                                                  | Each server class process acts on behalf of an AQ master class process. This relationship is maintained until the master requires services of a particular service process. Once released, the server class processes are moved to a free server pool.                                                                                                                                                                                                                                                                       | Database instances<br>Advanced Queuing      |
| <i>Rnnn</i> | ASM Block Remap Slave Process     | Remaps a block with a read error                                                                                    | A database instance reading from an Oracle ASM disk group can encounter an error during a read. If possible, Oracle ASM asynchronously schedules a <i>Rnnn</i> slave process to remap this bad block from a mirror copy.                                                                                                                                                                                                                                                                                                     | Oracle ASM instances                        |
| RBAL        | ASM Rebalance Master Process      | Coordinates rebalance activity                                                                                      | In an Oracle ASM instance, it coordinates rebalance activity for disk groups. In a database instance, it manages Oracle ASM disk groups.                                                                                                                                                                                                                                                                                                                                                                                     | Database instances,<br>Oracle ASM instances |
| RCBG        | Result Cache Background Process   | Handles result cache messages                                                                                       | This process is used for handling invalidation and other messages generated by server processes attached to other instances in Oracle RAC.                                                                                                                                                                                                                                                                                                                                                                                   | Database instances,<br>Oracle RAC           |
| RECO        | Recoverer Process                 | Resolves distributed transactions that are pending because of a network or system failure in a distributed database | RECO uses the information in the pending transaction table to finalize the status of in-doubt transactions. At timed intervals, the local RECO attempts to connect to remote databases and automatically complete the commit or rollback of the local portion of any pending distributed transactions. All transactions automatically resolved by RECO are removed from the pending transaction table.<br><br><b>See Also:</b> <i>Oracle Database Concepts</i> and <i>Oracle Database Net Services Administrator's Guide</i> | Database instances                          |
| <i>RLnn</i> | ResetLogs Process                 | Clear online redo logs when performing open resetlogs and converting to physical standby                            | <i>RLnn</i> processes are spawned to clear online redo logs. These slaves are terminated after the online redo logs are cleared, and the session does not persist.<br><br>Possible processes are RL00-RL31.                                                                                                                                                                                                                                                                                                                  | Database instances                          |
| RM          | RAT Masking Slave Process         | Extracts and masks bind values from workloads like SQL tuning sets and DB Replay capture files                      | This background process is used with Data Masking and Real Application Testing.                                                                                                                                                                                                                                                                                                                                                                                                                                              | Database instances                          |
| RMON        | Rolling Migration Monitor Process | Manages the rolling migration procedure for an Oracle ASM cluster                                                   | The RMON process is spawned on demand to run the protocol for transitioning an ASM cluster in and out of rolling migration mode.                                                                                                                                                                                                                                                                                                                                                                                             | Oracle ASM instance,<br>Oracle RAC          |
| <i>RMSn</i> | Oracle RAC Management Process     | Performs manageability tasks for Oracle RAC                                                                         | <i>RMSn</i> performs a variety of tasks, including creating resources related to Oracle RAC when new instances are added to a cluster.<br><br><b>See Also:</b> <i>Oracle Real Application Clusters Administration and Deployment Guide</i>                                                                                                                                                                                                                                                                                   | Database instances,<br>Oracle RAC           |

|------|---------------------------------------|-------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| RPnn | Capture Processing Worker Process     | Processes a set of workload capture files                                                       | <p>RPnn are worker processes spawned by calling <code>DBMS_WORKLOAD_REPLAY.PROCESS_CAPTURE(capture_dir,parallel_level)</code>. Each worker process is assigned a set of workload capture files to process.</p> <p>Worker processes execute in parallel without needing to communicate with each other. After each process is finished processing its assigned files, it exits and informs its parent process.</p> <p>The number of worker processes is controlled by the <code>parallel_level</code> parameter of <code>DBMS_WORKLOAD_REPLAY.PROCESS_CAPTURE</code>. By default, <code>parallel_level</code> is null. Then, the number of worker processes is computed as follows:</p> <pre>SELECT VALUE FROM   V\$PARAMETER WHERE  NAME='cpu_count' ;</pre> <p>When <code>parallel_level</code> is 1, no worker processes are spawned.</p> | Database instances                     |
| RPOP | Instant Recovery Repopulation Daemon  | Responsible for re-creating and/or repopulating data files from snapshot files and backup files | The RPOP process is responsible for re-creating and repopulating data files from snapshots files. It works with the instant recovery feature to ensure immediate data file access. The local instance has immediate access to the remote snapshot file's data, while repopulation of the recovered primary data files happens concurrently. Any changes in the data are managed between the instance's DBW processes and RPOP to ensure the latest copy of the data is returned to the user.                                                                                                                                                                                                                                                                                                                                                | Database instances                     |
| RSnn | Global Cache Service Remaster Process | Performs remastering for cluster reconfiguration and dynamic remastering                        | <p>Each RSnn process is a slave process for LMSn to handle remastering work. They are also helper processes for LMS to handle non-critical work from global cache service.</p> <p>The RSnn processes were named RMVn in Oracle Database 12c and earlier releases.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Database instances, Oracle RAC         |
| RSM0 | Data Guard Broker Worker Process      | Performs monitoring management tasks related to Data Guard on behalf of DMON                    | The process is created when a Data Guard broker configuration is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Database instances, Data Guard         |
| RSMN | Remote Slave Monitor Process          | Manages background slave process creation and communication on remote instances in Oracle RAC   | This background process manages the creation of slave processes and the communication with their coordinators and peers. These background slave processes perform tasks on behalf of a coordinating process running in another cluster instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Database instances, Oracle RAC         |
| RVWR | Recovery Writer Process               | Writes flashback data to the flashback logs in the fast recovery area                           | RVWR writes flashback data from the flashback buffer in the SGA to the flashback logs. RVWR also creates flashback logs and performs some tasks for flashback log automatic management.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Database instances, Flashback Database |

Table F-1 (Cont.) Background Processes

| Name        | Expanded Name                                  | Short Description                                                                                      | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | External Properties                |

| <i>Snnn</i> | Shared Server Process                          | Handles client requests in the shared server architecture                                              | <p>In the shared server architecture, clients connect to a dispatcher process, which creates a virtual circuit for each connection. When the client sends data to the server, the dispatcher receives the data into the virtual circuit and places the active circuit on the common queue to be picked up by an idle shared server. The shared server then reads the data from the virtual circuit and performs the database work necessary to complete the request. When the shared server must send data to the client, the server writes the data back into the virtual circuit and the dispatcher sends the data to the client. After the shared server completes the client request, the server releases the virtual circuit back to the dispatcher and is free to handle other clients.</p> <p>Several initialization parameters relate to shared servers. The principal parameters are: DISPATCHERS, SHARED_SERVERS, MAX_SHARED_SERVERS, LOCAL_LISTENER, REMOTE_LISTENER.</p> <p><b>See Also:</b> <i>Oracle Database Concepts</i></p> | Database instances, shared servers |
| <i>SAnn</i> | SGA Allocator                                  | Allocates SGA                                                                                          | <p>A small fraction of SGA is allocated during instance startup. The <i>SAnn</i> process allocates the rest of SGA in small chunks. The process exits upon completion of SGA allocation.</p> <p>Possible processes are SA00-SAzz.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Database instances                 |
| <i>SCCn</i> | ASM Disk Scrubbing Slave Check Process         | Performs Oracle ASM disk scrubbing check operation                                                     | <p><i>SCCn</i> acts as a slave process for <i>SCRB</i> and performs the checking operations.</p> <p>Possible processes are SCC0-SCC9.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Oracle ASM instances               |
| <i>SCM0</i> | DLM Statistics Collection and Management Slave | Collects and manages statistics related to global enqueue service (GES) and global cache service (GCS) | <p>The DLM Statistics Collection and Management slave (<i>SCM0</i>) is responsible for collecting and managing the statistics related to global enqueue service (GES) and global cache service (GCS). This slave exists only if DLM statistics collection is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Database instances                 |
| <i>SCRB</i> | ASM Disk Scrubbing Master Process              | Coordinates Oracle ASM disk scrubbing operations                                                       | <p><i>SCRB</i> runs in an Oracle ASM instance and coordinates Oracle ASM disk scrubbing operations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Oracle ASM instances               |
| <i>SCRn</i> | ASM Disk Scrubbing Slave Repair Process        | Performs Oracle ASM disk scrubbing repair operation                                                    | <p><i>SCRn</i> acts as a slave process for <i>SCRB</i> and performs the repairing operations.</p> <p>Possible processes are SCR0-SCR9.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Oracle ASM instances               |
| <i>SCVn</i> | ASM Disk Scrubbing Slave Verify Process        | Performs Oracle ASM disk scrubbing verify operation                                                    | <p><i>SCVn</i> acts as a slave process for <i>SCRB</i> and performs the verifying operations.</p> <p>Possible processes are SCV0-SCV9.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Oracle ASM instances               |

|---------|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| SMCO    | Space Management Coordinator Process  | Coordinates the execution of various space management tasks                                                                                                                                         | This background process coordinates the execution of various space management tasks, including proactive space allocation and space reclamation. SMCO dynamically spawns slave processes ( <i>Wnnn</i> ) to implement these tasks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Database instances             |
| SMON    | System Monitor Process                | Performs critical tasks such as instance recovery and dead transaction recovery, and maintenance tasks such as temporary space reclamation, data dictionary cleanup, and undo tablespace management | <p>SMON performs many database maintenance tasks, including the following:</p> <ul style="list-style-type: none"> <li>• Creates and manages the temporary tablespace metadata</li> <li>• Reclaims space used by orphaned temporary segments</li> <li>• Maintains the undo tablespace by online, offlining, and shrinking the undo segments based on undo space usage statistics</li> <li>• Cleans up the data dictionary when it is in a transient and inconsistent state</li> <li>• Maintains the SCN to time mapping table used to support Oracle Flashback features</li> </ul> <p>In an Oracle RAC database, the SMON process of one instance can perform instance recovery for other instances that have failed.</p> <p>SMON is resilient to internal and external errors raised during background activities.</p> <p><b>See Also:</b> <i>Oracle Database Concepts</i></p> | Database instances             |
| SP      | SPA Exec Slave                        | Analyzes single SQL statements sent from SQL Performance Analyzer (SPA)                                                                                                                             | Executions of SPA tasks created from a SQL tuning set use this slave to analyze the SQL statements of the SQL tuning set concurrently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Database instances             |
| SVCB    | Service Background Process            | Provides database service run-time load balancing and topology information to clients.                                                                                                              | Every 30 seconds the process processes and publishes run-time load-balancing information and keeps the topology information current. This process is started only if Oracle Real Application Clusters (Oracle RAC) is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Oracle RAC                     |
| TEM $n$ | ASM disk Test Error Emulation Process | Emulates I/O errors on Oracle ASM disks through named events                                                                                                                                        | I/O errors can be emulated on Oracle ASM disk I/O through named events. The scope can be the process, instance, or even cluster. Optionally, a set of AUs can be chosen for error emulation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Oracle ASM instances           |
| TT $nn$ | Redo Transport Slave Process          | Ships redo from current online and standby redo logs to remote standby destinations configured for ASYNC transport                                                                                  | <p>TT<math>nn</math> can run as multiple processes, where <math>nn</math> is 00 to ZZ.</p> <p><b>See Also:</b> <i>Oracle Data Guard Concepts and Administration</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Database instances, Data Guard |

Table F-1 (Cont.) Background Processes

| Name                   | Expanded Name                                  | Short Description                                                                      | Long Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | External Properties                              |
|------------------------|------------------------------------------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| <i>Unnn</i>            | Container process for threads                  | Host processes where database processes execute as threads.                            | <p><i>Unnn</i> processes are database container operating system processes where database background processes like SMON, CJQO, and database foreground processes run. The <code>V\$PROCESS</code> view lists database processes running in these container processes. These container processes are created only when the <code>THREADED_EXECUTION</code> initialization parameter is set to <code>TRUE</code>. The number of these processes vary depending on the active database processes. On a host with multiple NUMA nodes, there will be at least one <i>Unnn</i> process per NUMA node.</p> <p>These processes are fatal processes, if any of them is killed, it will result in instance termination. These processes exit when the instance is shut down or terminated.</p> | Database instances                               |
| <i>VBGn</i>            | Volume Background Process                      | Communicates between the Oracle ASM instance and the operating system volume driver    | <p><i>VBGn</i> handles messages originating from the volume driver in the operating system and sends them to the Oracle ASM instance.</p> <p><i>VBGn</i> can run as multiple processes, where <i>n</i> is 0-9.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Oracle ASM instances, Oracle ASM Proxy instances |
| <i>VDBG</i>            | Volume Driver Process                          | Forwards Oracle ASM requests to perform various volume-related tasks                   | <i>VDBG</i> handles requests to lock or unlock an extent for rebalancing, volume resize, disk offline, add or drop a disk, force and dismount disk group to the Dynamic Volume Manager driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Oracle ASM instances, Oracle ASM Proxy instances |
| <i>VI<sub>nn</sub></i> | Volume I/O                                     | Route ADV <sub>M</sub> volume I/O for ASM instances on compute nodes within an Exadata | <p>These processes handle requests for I/Os targeted at storage not locally accessible. They are used for Exadata targeted storage as well. These background processes only start when an ASM Volume is created and set up to be used. One process will start for each NUMA node on target machines. Under normal operation on non-Exadata hardware and on Exadata hardware that is not utilizing ASM volumes, these processes will not be started.</p> <p>There can be up to 32 <i>VI</i> processes, and they are named sequentially from <i>VI00</i> to <i>VI31</i>.</p>                                                                                                                                                                                                             | Oracle ASM Proxy instances                       |
| <i>VKRM</i>            | Virtual Scheduler for Resource Manager Process | Serves as centralized scheduler for Resource Manager activity                          | <i>VKRM</i> manages the CPU scheduling for all managed Oracle processes. The process schedules managed processes in accordance with an active resource plan.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Database instances                               |

|------|-----------------------------------|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| VKTM | Virtual Keeper of Time Process    | Provides a wall clock time and reference time for time interval measurements                              | VKTM acts as a time publisher for an Oracle instance. VKTM publishes two sets of time: a wall clock time using a seconds interval and a higher resolution time (which is not wall clock time) for interval measurements. The VKTM timer service centralizes time tracking and offloads multiple timer calls from other clients. | Database instances, Oracle ASM instances         |
| VMB0 | Volume Membership Process         | Maintains cluster membership on behalf of the Oracle ASM volume driver                                    | This process membership in the cluster as an I/O-capable client on behalf of the Oracle ASM volume driver.                                                                                                                                                                                                                      | Oracle ASM instances, Oracle ASM Proxy instances |
| VUBG | Volume drive Umbilicus Background | Relays messages between Oracle ASM instance and Oracle ASM Proxy instance that is used by ADVN (for ACFS) |                                                                                                                                                                                                                                                                                                                                 | Oracle ASM instances, Oracle ASM Proxy instances |

| <i>Wnnn</i> | Space Management Slave Process | Performs various background space management tasks, including proactive space allocation and space reclamation | <p><i>Wnnn</i> slave processes perform work on behalf of Space Management and on behalf of the Oracle Database In-Memory option.</p> <ul style="list-style-type: none"> <li>When performing work on behalf of Space Management, <i>Wnnn</i> processes are slave processes dynamically spawned by SMCO to perform space management tasks in the background. These tasks include preallocating space into locally managed tablespace and SecureFiles segments based on space usage growth analysis, and reclaiming space from dropped segments. After being started, the slave acts as an autonomous agent. After it finishes task execution, it automatically picks up another task from the queue. The process terminates itself after being idle for a long time.</li> <li>When performing work on behalf of the Oracle Database In-Memory option, <i>Wnnn</i> processes execute tasks for population or repopulation of objects that are enabled for the In-Memory column store (IM columns store), and tasks that drop in-memory segments when an object is disabled for the IM columns store.</li> </ul> <p>For in-memory population and repopulation, both the IMCO background process and foreground processes will utilize <i>Wnnn</i> slaves. <i>Wnnn</i> processes are utilized by the IMCO background process for prepopulation of in-memory enabled objects with priority LOW/MEDIUM/HIGH/CRITICAL, and for repopulation of in-memory objects. In-memory populate and repopulate tasks running on <i>Wnnn</i> slaves are also initiated from foreground processes in response to queries and DMLs that reference in-memory enabled objects.</p> | Database instances            |
| XDMG        | Exadata Automation Manager     | Initiates automation tasks involved in managing Exadata storage                                                | XDMG monitors all configured Exadata cells for state changes, such as a bad disk getting replaced, and performs the required tasks for such events. Its primary tasks are to watch for when inaccessible disks and cells become accessible again, and to initiate the ASM ONLINE operation. The ONLINE operation is handled by XDWK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Oracle ASM instances, Exadata |
| XDWK        | Exadata Automation Manager     | Performs automation tasks requested by XDMG                                                                    | XDWK gets started when asynchronous actions such as ONLINE, DROP, and ADD an Oracle ASM disk are requested by XDMG. After a 5 minute period of inactivity, this process will shut itself down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Oracle ASM instances, Exadata |
| <i>Xnnn</i> | ASM Disk Expel Slave Process   | Performs Oracle ASM post-rebalance activities                                                                  | This process expels dropped disks after an Oracle ASM rebalance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Oracle ASM instances          |
