1 System Stored Procedures

SAP Adaptive Server Enterprise system stored procedures are similar to the stored procedures that you create using the Transact-SQL language, but are supplied in SAP ASE to use for updating and getting reports from system tables.

System stored procedures are created by installmaster at installation. They are located in the sybsystemprocs database, and owned by the system administrator. Use sp_version to determine which version of installmaster was most recently run.

Some system stored procedures can only run in a specific database, but many of them can run in any database. You can create your own system procedures to execute from any database.

You can declare up to 10,000 variables in a stored procedure.

All system stored procedures:

- Execute at isolation level 1.
- Report a return status that indicates whether or not they completed successfully, and if they did not, the reasons for failure.

The following example means that the procedure executed successfully:

```
return status = 0
```

The examples in this book do not include the return status.

See the following for more information:

- Creating your own stored procedures: System Administration Guide.
- Return values for system stored procedures: Return Values in the Transact-SQL User's Guide.

1.1 Permissions on System Stored Procedures

Set permissions for system stored procedures in the sybsystemprocs database.

Some system stored procedures can run only by a user with specific privileges or roles. Permission check for a system procedure may differ based on the granular permissions setting. Check the permission information for each system stored procedure for details. See *Using Granular Permissions* in the *Security Administration Guide* for more information on granular permissions.

Other system procedures (for example, all the sp_help procedures) can be executed by any user, provided that the execute permission on the procedure was granted to public in sybsystemprocs.

To deny a user permission on a system stored procedure, the system administrator must add the user to sybsystemprocs..sysusers and write a revoke statement that applies to that procedure. The owner of a user database can directly control permissions on the system stored procedures within his or her own database.

1.2 Auditing Stored Procedures

In general, you can audit execution of stored procedures by enabling the <code>exec_procedure</code> audit option, which generates an audit record containing the name of the stored procedure and the parameters.

In addition, the audit option <code>sproc_auth</code> enables auditing for authorization checks that are performed inside system stored procedures.

Some system stored procedures can be audited after enabling specific audit options. See procedure-specific documentation in the reference manual.

For more information, see the Security Administration Guide > Auditing.

1.3 Executing System Stored Procedures

If a system stored procedure is executed in a database other than sybsystemprocs, it operates on the system tables in the database in which it was executed.

For example, if the database owner of pubs2 runs sp_adduser in pubs2, the new user is added to pubs2..sysusers.

Run a system procedure in a specific database by either of the following:

- Opening that database with the use command and execute the procedure
- Qualifying the procedure name with the database name

For example, the user-defined system procedure sp_foo , which executes the db_name system function, returns the name of the database in which it is executed. When executed in the pubs2 database, it returns the value "pubs2":

```
exec pubs2..sp_foo

pubs2
(1 row affected, return status = 0)
```

When executed in sybsystemprocs, it returns the value "sybsystemprocs":

```
exec sybsystemprocs..sp_foo

------
sybsystemprocs
(1 row affected, return status = 0)
```

See sybsystemprocs in Reference Manual: Tables.

1.4 Entering Parameter Values

If a parameter value for a system procedure contains punctuation or embedded blanks, or is a reserved word, you must enclose it in single or double quotes. If the parameter is an object name qualified by a database name or owner name, enclose the entire name in single or double quotes.

i Note

Do not use delimited identifiers as system procedure parameters; they may produce unexpected results.

If a procedure has multiple optional parameters, you can supply parameters in the following form instead of supplying all the parameters:

```
@<parametername> = <value>
```

You can also use "null" as a placeholder for a parameter. Do not enclose "null" in quotes.

SQL has no rules about the number of words you can put on a line or where you must break a line. If you issue a system procedure followed by a command, the SAP ASE server attempts to execute the system procedure, then the command. For example, if you execute the following command, the SAP ASE server returns the output from sp help, then runs the checkpoint command:

```
sp help checkpoint
```

If you specify more parameters than the number of parameters expected by the system procedure, the extra parameters are ignored by the SAP ASE server.

1.5 Messages

System procedures return informational and error messages. System procedure error messages start at error number 17000.

Error messages from the functions and commands included in a procedure are documented in *Troubleshooting* and *Error Messages Guide*.

1.6 System Procedure Tables

Several system procedure tables in the master database, such as spt_values, spt_committab, spt_monitor, and spt_limit_types, are used by system stored procedures to convert internal system values (for example, status bits) into human-readable format.

spt_values is never updated. To see how it is used, execute sp_helptext to look at the text for one of the system stored procedures that references it.

In addition, some system stored procedures create and then drop temporary tables.

Related Information

sp_helptext [page 486]

1.7 sp_activeroles

Displays all active roles.

Syntax

```
sp_activeroles [expand_down]
```

Parameters

expand_down

shows the hierarchy tree of all active roles contained by your roles.

Examples

Example 1

Displays all active roles.

```
Role Name
-----sa_role
sso_role
oper_role
replication_role
```

Example 2

Displays active roles and their hierarchy tree:

```
Role Name Parent Role Name Level
-----sa_role NULL 1
doctor_role NULL 1
```

oper_role NULL 1

Usage

sp activeroles displays all your active roles and all roles contained by those roles.

See also:

- alter role, create role, drop role, grant, revoke, set in Reference Manual: Commands
- For information about creating, managing, and using roles, see the System Administration Guide.
- mut_excl_roles, proc_role, role_contain, role_name in *Reference Manual: Building Blocks*

Permissions

Any user can execute $sp_activeroles$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_displayroles [page 276]

1.8 sp_add_qpgroup

Adds an abstract plan group.

Syntax

sp_add_qpgroup <new_name>

Parameters

<new name>

is the name of the new abstract plan group. Group names must be valid identifiers.

Examples

Example 1

Creates a new abstract plan group named dev plans:

sp add qpgroup dev plans

Usage

Use sp_add_qpgroup to add abstract plan groups for use in capturing or creating abstract plans. The abstract plan group must exist before you can create, save, or copy plans into a group.

You cannot run sp_add_qpgroup in a transaction.

See also set in Reference Manual: Commands.

Permissions

The permission checks for sp_add_qpgroup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_help_qpgroup [page 410]

1.9 sp_add_resource_limit

Creates a limit on the number of server resources that can be used by an SAP ASE login, or by an application, or both, to execute a query, query batch, or transaction.

Syntax

Parameters

<name>

is the SAP ASE login to which the limit applies. To create a limit that applies to all users:

- Of a particular application, specify NULL for <name>.
- Using any application, specify NULL for both <name> and <appname>.

<appname>

is the name of the application to which the limit applies. To create a limit that applies to:

- All applications used by an SAP ASE login, specify NULL for <appname>.
- A particular application, specify the application name that the client program passes to the SAP ASE server in the login packet.
- All users using any application, specify NULL for both <name> and <appname>.

<rangename>

is the time range during which the limit is enforced. The time range must exist in the systimeranges system table of the master database at the time you create the limit.

<limittype>

is the type of resource to limit. This must be one of the following:

- row_count limits the number of rows a query can return.
- elapsed_time limits the number of seconds, in wall-clock time, that a query batch or transaction can run.
- io_cost limits either the actual cost or the optimizer's cost estimate for processing a query.

- tempdb_space limits the number of pages a tempdb database can have during a single session.
- lock_count limits the number of logical locks held simultaneously by a user process.
- idle time number of seconds connections can be idle before they are released.
- cpu_time limits the number of seconds of CPU time that a query batch or transaction can use.

<limitvalue>

is the maximum amount of the server resource (I/O cost, elapsed time in seconds, row count, or tempdb space) that can be used by the login or application before the SAP ASE server enforces the limit. This must be a positive, nonzero integer that is less than or equal to 2^{31} . The following table indicates what value to specify for each limit type:

- row_count the maximum number of rows that can be returned by a query before the limit is enforced.
- elapsed_time the number of seconds, in wall-clock time, that a query batch or transaction can run before the limit is enforced.
- io_cost a unitless measure derived from the optimizer's costing formula.
- tempdb space the number of pages used in tempdb per session.
- lock_count limits the number of logical locks held simultaneously by a user process.

<enforced>

determines whether the limit is enforced prior to or during query execution. The following table lists the valid values for each limit type:

enforced

Code	Description	Limit Type
1	Action is taken when the estimated I/O cost of execution exceeds the specified limit.	io_cost
2	Action is taken when the actual row count, elapsed time, or	row_count
	I/O cost of execution exceeds the specified limit.	elapsed_time
		io_cost
		lock_count
3	Action is taken when either the estimated cost or the actual cost exceeds the specified limit.	io_cost

If you specify an <enforced> value of 3, the SAP ASE server performs a logical "or" of 1 and 2. For example, assume <enforced> is set to 3. If you run a query with io_cost that exceeds the estimated cost, the specified <action> is executed. If the query is within the limits specified for estimated cost but exceeds the actual cost, the specified <action> is also executed.

If you do not specify an <enforced> value, the SAP ASE server enforces limit 2 for row_count and $elapsed_time$ and limit 3 for io_cost . In other words, if the limit

type is io_cost, the specified action is executed if the query exceeds either the estimated or actual cost.

<action>

is the action to take when the limit is exceeded. The following action codes are valid for all limit types:

- 1 issues a warning
- 2 aborts the query batch (not supported for lock_limit)
- 3 aborts the transaction
- 4 kills the session
- 5 records the resource limit violations in the monThresholdEvent table

If you do not specify an <action> value, the SAP ASE server uses a default value of 2 (abort the query batch).

<scope>

is the scope of the limit. Specify one of the following codes appropriate to the type of limit:

- 1 Query
- 2 Query batch (one or more SQL statements sent by the client to the server)
- 4 Transaction
- 6 Query batch and transaction
- 8 Session scope (always 8 for idle time)

If you do not specify a <scope> value, the limit applies to all possible scopes for the limit type.

Examples

Example 1

Creates a resource limit that applies to all users of the payroll application during the early_morning time range. If the query batch takes more than 120 seconds to execute, the SAP ASE server issues a warning:

```
sp add resource limit NULL, payroll, early morning, elapsed time, 120, 2, 1, 2
```

Example 2

Creates a resource limit that applies to all ad hoc queries and applications run by "joe_user" during the midday time range. When a query returns more than 5000 rows, the SAP ASE server aborts the transaction:

```
sp add resource limit joe user, NULL, midday, row count, 5000, 2, 3, 1
```

Example 3

Creates a resource limit that applies to all ad hoc queries and applications run by "joe_user" during the midday time range. When the optimizer estimates that the I/O cost would exceed 650, the SAP ASE server aborts the transaction:

```
sp_add_resource_limit joe_user, NULL, midday, io_cost, 650, 1, 3, 1
```

Example 4

Sets the number of locks to 10000 that all users can simultaneously have open for a session:

```
sp_add_resource_limit NULL, NULL, "at all times", "lock_count", 10000
```

Example 5

Sets the length of idle time to 10 seconds before queries are released for user sa and application isql; at all times indicates the time range encompasses all hours of the day, 2 indicates the limit is enforced prior to execution time, 4 indicates the action is taken when the 10 seconds expires, and 8 indicates the scope of the limit is for the session:

```
sp_add_resource_limit sa, isql, 'at all times', idle_time, 10, 2, 4, 8
```

Usage

Additional considerations for using sp add resource limit.

- You must enable sp configure "allow resource limits" for resource limits to take effect.
- Multiple resource limits can exist for a given user, application, limit type, scope, and enforcement time, as long as their time ranges do not overlap.
- All limits for the currently active named time ranges and the "at all times" range for a login and/or
 application name are bound to the user's session at login time. Therefore, if a user logs into the SAP ASE
 server independently of a given application, resource limits that restrict the user in combination with that
 application do not apply. To guarantee restrictions on that user, create a resource limit that is specific to
 the user and independent of any application.
- Since either the user login name or application name, or both, are used to identify a resource limit, the SAP ASE server observes a predefined search precedence while scanning the sysresourcelimits table for applicable limits for a login session. The following table describes the precedence of matching ordered pairs of login name and application name:

Level	Login Name	Application Name
1	"joe_user"	payroll
2	NULL	payroll
3	"joe_user"	NULL
4	NULL	NULL

If one or more matches are found for a given precedence level, no further levels are searched. This prevents conflicts regarding similar limits for different login/application combinations.

If no match is found at any level, no limit is imposed on the session.

- When you add, delete, or modify resource limits, the SAP ASE server rebinds the limits for each session for that login and/or application at the beginning of the next query batch for that session.
- When you change the currently active time ranges, the SAP ASE server rebinds limits for the session. This rebinding occurs at the beginning of the next query batch.
- You cannot associate the limits for a particular login, application, or login/application combination with named time ranges that overlap (except for limits that share the same time range). For example, if a user is limited to retrieving 50 rows between 9:00 a.m. and 1:00 p.m., you cannot create a second resource limit for the same user that limits him to retrieving 100 rows between 10:00 a.m. and 12:00 noon. However, you can create a resource hierarchy by assigning the 100-row limit to the *user* between 10:00 a.m. and 12:00 noon and assigning the 50-row limit to an **application**, like isql, between 9:00 a.m. and 1:00 p.m.
- Setting a value for lock_count requires that you set the enable monitoring configuration parameter to 1: sp configure 'enable monitoring', 1
- lock count does not support the abort_batch action.
- lock count limit is not inherited by child threads and is not applicable for DTM environment.

i Note

Although the SAP ASE server terminates the current transaction when it reaches its time limit, you receive no 11005 error message until you issue another SQL command or batch; in other words, the message appears only when you attempt to use the connection again.

For more information on resource limits, see the System Administration Guide.

See also isql in the Utility Guide.

Permissions

The permission checks for $sp_add_resource_limitSystem$ Administration differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```

1.10 sp_add_time_range

Adds a named time range to an SAP ASE server.

Syntax

```
sp_add_time_range <name>, <startday>, <endday>, <starttime>, <endtime>
```

Parameters

<name>

is the name of the time range. Time range names must be 255 characters or fewer. The name cannot already exist in the systimeranges system table of the master database.

<startday>

is the day of the week on which the time range begins. This must be the full weekday name for the default server language, as stored in the syslanguages system table of the master database.

<endday>

is the day of the week on which the time range ends. This must be the full weekday name for the default server language, as stored in the syslanguages system table of the master database. The <endday> can fall either earlier or later in the week than the <startday> or can be the same day as the <startday>.

<starttime>

is the time of day when the time range begins. Specify the <starttime> in terms of a 24-hour clock, with a value between "00:00" (midnight) and "23:59" (11:59 p.m.). Use the following form:

"<HH>:<MM>"

<endtime>

is the time of day when the time range ends. Specify the <endtime> in terms of a 24-hour clock, with a value between "00:00" (midnight) and "23:59" (11:59 p.m.). Use the following form:

```
"<HH>:<MM>"
```

i Note

To create a time range that spans the entire day, specify both a start time and an end time of "00:00".

The <endtime> must occur later in the day than the < starttime>, unless <endtime> is "00:00".

Examples

Example 1

Creates the business_hours time range, which is active Monday through Friday, from 9:00 a.m. to 5:00 p.m.:

```
sp_add_time_range business_hours, monday, Friday, "09:00", "17:00"
```

Example 2

Creates two time ranges, before_hours and after_hours, that, together, span all non-business hours Monday through Friday. The before_hours time range covers the period from 12:00 midnight to 9:00 a.m., Monday through Friday. The after_hours time range covers the period from 6:00 p.m. through 12:00 midnight, Monday through Friday:

```
sp_add_time_range before_hours, Monday, Friday, "00:00", "09:00"
sp_add_time_range after_hours, Monday, Friday, "18:00", "00:00"
```

Example 3

Creates the weekends time range, which is 12:00 midnight Saturday to 12:00 midnight Sunday:

```
sp_add_time_range weekends, Saturday, Sunday, "00:00", "00:00"
```

Example 4

Creates the Fri_thru_Mon time range, which is 9:00 a.m. to 5:00 p.m., Friday, Saturday, Sunday, and Monday:

```
sp_add_time_range Fri_thru_Mon, Friday, Monday, "09:00", "17:00"
```

Example 5

 $Creates \ the \ {\tt Wednesday_night}\ time\ range,\ which\ is\ Wednesday\ from\ 5:00\ p.m.\ to\ 12:00\ midnight:$

```
sp_add_time_range Wednesday_night, Wednesday, Wednesday, "17:00", "00:00"
```

Usage

There are additional considerations when using sp add time range:

- The SAP ASE server includes one named time range, the "at all times" time range. This time range covers all times, from the first day through the last of the week, from 00:00 through 23:59. It cannot be modified or deleted.
- The SAP ASE server generates a unique ID number for each named time range and inserts it into the systimeranges system table,
- When storing a time range in the systimeranges system table, the SAP ASE server converts its <startday> and <endday> values into integers. For servers with a default language of us_english, the week begins on Monday (day 1) and ends on Sunday (day 7).
- You can create a time range that overlaps with one or more other time ranges.
- Range days are contiguous, so the days of the week can wrap around the end to the beginning of the week. In other words, Sunday and Monday are contiguous days, as are Tuesday and Wednesday.
- The active time ranges are bound to a session at the beginning of each query batch. A change in the server's active time ranges due to a change in actual time has no effect on a session during the processing of a query batch. In other words, if a resource limit restricts a query batch during a given time range but a query batch begins before that time range becomes active, the query batch that is already running is not affected by the resource limit.
- The addition, modification, and deletion of time ranges using the system procedures does not affect the active time ranges for sessions currently in progress.
- If a resource limit has a transaction as its scope, and a change occurs in the server's active time ranges while a transaction is running, the newly active time range does not affect the transaction currently in progress.
- Changes to a resource limit that has a transaction as its scope does not affect any transactions currently in progress.
- For more information on time ranges, see the System Administration Guide.

Permissions

The permission checks for sp add time range differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```

sp_modify_time_range [page 590]
```

1.11 sp_addalias

Allows an SAP ASE user to be known in a database as another user.

Syntax

```
sp addalias <loginame>, <name_in_db>
```

Parameters

<loginame>

is the master.dbo.syslogins name of the user who wants an alternate identity in the current database.

<name_in_db>

is the database user name to alias <loginame> to. The name must exist in both master.dbo.syslogins and in the sysusers table of the current database.

Examples

Example 1

There is a user named "albert" in the database's sysusers table and a login for a user named "victoria" in master.dbo.syslogins. This command allows "victoria" to use the current database by assuming the name "albert":

```
sp addalias victoria, albert
```

Usage

There are additional considerations when using sp addalias:

- Executing sp_addalias maps one user to another in the current database. The mapping is shown in sysalternates, where the two users' suids (system user IDs) are connected.
- A user can be aliased to only one database user at a time.
- A report on any users mapped to a specified user can be generated with sp_helpuser, giving the specified user's name as an argument.
- When a user tries to use a database, the SAP ASE server checks <code>sysusers</code> to confirm that the user is listed there. If the user is not listed there, the SAP ASE server then checks <code>sysalternates</code>. If the user's <code>suid</code> is listed in <code>sysalternates</code>, mapped to a database user's <code>suid</code>, the SAP ASE server treats the first user as the second user while using the database.

If the user named in <loginame> is in the database's sysusers table, the SAP ASE server does not use the user's alias identity, because it checks sysusers and finds the loginame before checking sysulternates, where the alias is listed.

See also use in Reference Manual: Commands.

Permissions

The permission checks for sp addalias differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addlogin [page 47] sp_adduser [page 73] sp_dropalias [page 281] sp_helpuser [page 495]

1.12 sp_addauditrecord

Allows users to enter user-defined audit records (comments) into the audit trail.

Syntax

Parameters

<text>

is the text of the message to add to the current audit table. The text is inserted into the extrainfo field of the table.

<db name>

is the name of the database referred to in the record. The name is inserted into the dbname field of the current audit table.

<obj_name>

is the name of the object referred to in the record. The name is inserted into the objname field of the current audit table.

<owner_name>

is the owner of the object referred to in the record. The name is inserted into the objowner field of the current audit table.

<dbid>

is the database ID number of db_name. Do not enclose this integer value in quotes. <dbid> is inserted into the dbid field of the current audit table.

<objid>

is the object ID number of obj_name. Do not enclose this integer value in quotes. <objid> is inserted into the objid field of the current audit table.

Examples

Example 1

Adds "I gave A. Smith permission to view the payroll table in the corporate database. This permission was in effect from 3:10 to 3:30 pm on 9/22/92." to the extrainfo field; "corporate" to the dbname field;

"payroll" to the objname field; "dbo" to the objowner field; "10" to the dbid field, and "1004738270" to the objid field of the current audit table:

```
sp_addauditrecord "I gave A. Smith permission to view the payroll table in the corporate database. This permission was in effect from 3:10 to 3:30 pm on 9/22/92.", "corporate", "payroll", "dbo", 10, 1004738270
```

Example 2

Adds this record to the audit trail. This example uses parameter names with the @ prefix, which allows you to leave some fields empty:

```
sp_addauditrecord @text="I am disabling auditing briefly while we reconfigure the system", @db_name="corporate"
```

Usage

The SAP ASE server writes all audit records to the current audit table. The current audit table is determined by the value of the current audit table configuration parameter, set with <code>sp_configure</code>. An installation can have up to eight system audit tables, named <code>sysaudits_01</code>, <code>sysaudits_02</code>, and so forth, through <code>sysaudits_08</code>.

i Note

The records actually are first stored in the in-memory audit queue, and the audit process later writes the records from the audit queue to the current audit table. Therefore, you cannot count on an audit record being stored immediately in the audit table.

You can use sp_addauditrecord if:

- You have been granted execute permission on sp addauditrecord no special role is required
- Auditing is enabled a system security officer used sp_configure to turn on the auditing configuration parameter
- The adhoc option of sp_audit is set to on

Permissions

The permission checks for sp addauditrecord differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled:

- Users with execute permission on the procedure can execute sp addauditrecord.
- By default, sso_role has execute permission.

Disabled With granular permissions disabled:

Setting Description

- Users with execute permission on the procedure can execute <code>sp_addauditrecord</code>.
- By default sso_role has execute permission.
- Users with sa_role can grant execute permission.
- The database owner of sybsystemprocs can grant execute permission to other users.

Auditing

You can enable adhoc auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	adhoc
Event	1
Command or access audited	User-defined audit record
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL
	Other information – text parameter value
	 Other information – Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_audit [page 77]

1.13 sp_addaudittable

Adds another system audit table after auditing is installed.

Syntax

sp addaudittable <devname>

Parameters

<devname>

is the name of the device for the audit table. Specify a device name or specify "default". If you specify "default", the SAP ASE server creates the audit table on the same device as the sybsecurity database. Otherwise, the SAP ASE server creates the table on the device you specify.

Examples

Example 1

Creates a system audit table on auditdev2. If only one system audit table (sysaudits_01) exists when you execute the procedure, the SAP ASE server names the new audit table sysaudits_02 and places it on its own segment, called aud seg 02, on auditdev2:

sp addaudittable auditdev2

Example 2

Creates a system audit table on the same device as the sybsecurity database. If two system audit tables ($sysaudits_01$ and $sysaudits_02$) exist when you execute the procedure, the SAP ASE server names the new audit table $sysaudits_03$ and places it on its own segment, called aud_seg_03 , on the same device as the sybsecurity database:

sp_addaudittable "default"

Usage

There are additional considerations when using sp_addaudittable:

- Auditing must already be installed when you run sp addaudittable. To add a system audit table:
 - 1. Create the device for the audit table, using disk init. For example, run a command like this for UNIX:

```
disk init name = "auditdev2",
physname = "/dev/rxyla",
size = "5K"
```

2. Add the device to the sybsecurity database with the alter database command. For example, to add auditdev2 to the sybsecurity database, use:

```
alter database sybsecurity on auditdev2
```

- 3. Execute sp addaudittable to create the table.
- The SAP ASE server names the new system audit table and the new segment according to how many audit tables are already defined. For example, if five audit tables are defined before you execute the procedure, the SAP ASE server names the new audit table sysaudits_06 and the new segment aud_seg_06. If you specify "default", the SAP ASE server places the segment on the same device as the sybsecurity database. Otherwise, the SAP ASE server places the segment on the device you name.
- A maximum of eight audit tables is allowed. If you already have eight audit tables, and you attempt to execute sp addaudittable to add another one, the SAP ASE server displays an error message.
- For information about how to install auditing, see the installation documentation for your platform. See the *System Administration Guide* for information on how to use auditing.

See also alter database and disk init in Reference Manual: Commands.

Permissions

The permission checks for sp addaudittable differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage auditing privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_audit [page 77]

1.14 sp_addengine

Adds an engine to an existing engine group or, if the group does not exist, creates an engine group and adds the engine.

Considerations for Process Mode

sp addengine does not run in threaded mode.

Syntax

```
sp_addengine <engine_number>, <engine_group> [, <instance_id>]
```

Parameters

<engine_number>

is the number of the engine you are adding to the group. Legal values are between 0 and a maximum equal to the number of configured online engines minus one.

<engine_group>

is the name of the engine group to which you are adding the engine. If <code>engine_group</code> does not exist, the SAP ASE server creates it and adds the engine to it. Engine group names must conform to the rules for identifiers. For details, see *Reference Manual: Building Blocks > Expressions, Identifiers, and Wildcard Characters*.

<instance id>

(in cluster environments) ID of the instance to which you are adding an engine or engine group.

Examples

Example 1

If no engine group is called DS_GROUP , this statement establishes the group. If DS_GROUP already exists, this statement adds engine number 2 to that group:

```
sp_addengine 2, DS_GROUP
```

Example 2

Adds engine number 5 to instance ID 8:

sp addengine 5, 8

Usage

There are additional considerations when using sp_addengine:

- sp addengine creates a new engine group if the value of engine group does not already exist.
- If sp_cluster set <system_view> is set to cluster, you can add an engine or engine group to any instance in the cluster. If <system_view> is set to instance, you can add and engine or engine group only to a local instance.
- The engine groups ANYENGINE and LASTONLINE are predefined. ANYENGINE includes all existing engines. LASTONLINE specifies the engine with highest engine number. A system administrator can create additional engine groups. You cannot modify predefined engine groups.
- As soon as you use sp_bindexeclass to bind applications or logins to an execution class associated with engine group, the associated process may start running on engine number.
- sp_engine can run in sessions using chained transactions after you use sp_procxmode to change the transaction mode to anymode.
- Prior to making engine affinity assignments, study the environment and consider the number of nonpreferred applications and the number of SAP ASE engines available. See the *Performance and Tuning Guide* for more information about non-preferred applications.

Permissions

The permission checks for sp addengine differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_showexeclass [page 744]
sp_showpsexe [page 764]
sp_unbindexeclass [page 825]
```

1.14.1 sp_addexeclass

Creates or updates a user-defined execution class that you can bind to client applications, logins, and stored procedures.

Considerations for Process Mode

The predefined engine group parameter ANYENGINE and LASTONLINE are valid only in process mode.

Syntax

```
sp_addexeclass <classname>, <priority>, <timeslice>, <engine_group> [,
<instance_id>]
```

Parameters

<classname>

is the name of the new execution class.

<priority>

is the priority value with which to run the client application, login, or stored procedure after it is associated with this execution class. Legal values are HIGH, LOW, and MEDIUM.

<timeslice>

is the time unit assigned to processes associated with this class. The SAP ASE server currently ignores this parameter.

<engine_group>

identifies an existing group of engines on which processes associated with this class can run.

<instance id>

(in cluster environments) ID of the instance to which you are binding a user-defined execution class.

Examples

Example 1

Defines a new execution class called DS with a <pri>priority> value of LOW and associates it with the engine group DS GROUP:

```
sp_addexeclass "DS", "LOW", 0, "DS_GROUP"
```

Example 2

(Cluster Edition) Defines a new execution class called DS with a priority value of LOW and associates it with the engine group DS_GROUP on instance number 8, enter:

```
sp_addexeclass "DS", "LOW", 0, "DS_GROUP", 8
```

Usage

There are additional considerations when using sp addexeclass:

- sp_addexeclass creates or updates a user-defined execution class that you can bind to client applications, logins, and stored procedures. If the class already exists, the class attribute values are updated with the values supplied by the user.
- When you run sp_addexeclass in threaded mode, the SAP ASE server uses <engine_group> for the name of a thread pool.
- (In cluster environments) If <code>sp_cluster set <system_view></code> is set to <code>cluster</code>, you can add an execution class on any instance in the cluster. If the <code><system_view></code> is set to <code>instance</code>, you can add an execution class only to a local instance.
- Use the predefined engine group parameter ANYENGINE if you do not want to restrict the execution object to an engine group.
- Use sp_addengine to define engine groups. Use sp_showexeclass to display execution class attributes and the engines in any engine group associated with the specified execution class. sp_showcontrolinfo lists the existing engine groups.

Permissions

The permission checks for sp addexeclass differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class

privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.15 sp_addextendedproc

Creates an extended stored procedure (ESP) in the master database.

Syntax

```
sp addextendedproc <esp name>, <dll name>
```

Parameters

<esp name>

is the name of the extended stored procedure. This name must be identical to the name of the procedural language function that implements the ESP. <esp_name> must be a valid SAP ASE identifier.

<dll name>

is the name of the dynamic link library (DLL) file containing the function specified by <esp_name>. The <dll_name> can be specified with no extension or with its platform-specific extension, such as .dll on Windows or .so on Solaris. If an extension is specified, the <dll_name> must be enclosed in quotation marks.

Examples

Example 1

Registers an ESP for the function named my_esp, which is in the sqlsrvdll.dll file. The name of the resulting ESP database object is also my_esp:

```
sp_addextendedproc my_esp, "sqlsrvdll.dll"
```

Usage

There are additional considerations when using sp addextendedproc:

- Execute sp addextendedproc from the master database.
- You can only use sp_addextendedproc to add extended stored procedures that take no parameters. If your extended stored procedure requires a formal parameter list, you must use the create procedure command with the as external name option, together with the complete parameter list.
- The <esp name > is case sensitive. It must match the name of the function in the DLL.
- The DLL represented by <dll_name> must reside on the server machine on which the ESP is being created and the DLL directory must be in:
 - O (Windows) \$PATH
 - (Compaq Tru64) \$LD LIBRARY PATH
 - (HP) \$SH_LIBRARY_PATH

If the file is not found, the search mechanism also searches \$SYBASE/lib (\$SYBASE/dll on Windows).

• (Windows) An ESP function should not call a C run-time signal routine. This can cause XP Server to fail, because Open Server does not support signal handling on Windows.

See also create procedure in Reference Manual: Commands.

Permissions

The permission checks for sp addextendedproc differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any ESP privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dropextendedproc [page 297] sp_helpextendedproc [page 448]

1.16 sp_addexternlogin

(Component Integration Services only) Creates an alternate login account and password to use when communicating with a remote server through Component Integration Services.

Syntax

```
sp_addexternlogin <server>, <loginame>, <externname>
    [, <externpasswd>] [<rolename>]
```

Parameters

<server>

is the name of the remote server. The remote_server> must be known to the local server by an entry in the master.dbo.sysservers table.

<loginame>

is an account known to the local server. <loginame> must be represented by an entry in the master.dbo.syslogins table. The "sa" account, the "sso" account, and the

<loginame> account are the only users authorized to modify remote access for a given local user.

<externname>

is an account known to the <server> and must be a valid account on the node where the <server> runs. This is the account used for logging into the <server>.

<externpasswd>

is the password for <externname>.

<rolename>

is the SAP ASE user's assigned role. If <rolename> is specified, <login_name> is ignored.

Examples

Example 1

Tells the local server that when the login name "bobj" logs in, access to the remote server OMNI1012 is by the remote name "jordan" and the remote password "hitchpost". Only the "bobj" account, the "sa" account, and the "sso" account have the authority to add or modify a remote login for the login name "bobj":

```
sp addexternlogin OMNI1012, bobj, jordan, hitchpost
```

Example 2

Shows a many-to-one mapping so that all SAP ASE users that need a connection to DB2 can be assigned the same name and password:

```
sp_addexternlogin DB2, NULL, login2, password2
```

Example 3

SAP ASE roles can also be assigned remote logins. With this capability, anyone with a particular role can be assigned a corresponding login name and password for a given remote server:

```
sp_addexternlogin DB2, NULL, login3, password3, role
```

Usage

There are additional considerations when using sp_addexternlogin:

• sp_addexternlogin assigns an alternate login name and password to be used when communicating with a remote server. It stores the password internally in encrypted form.

i Note

You can use sp addexternlogin only when Component Integration Services is configured.

• Mappings can be one-to-one (for specific users), role-to-one (role-based), many-to-one (server-based), or based on the client login and password from the TDS loginrec.

- The login and password have a many to one mapping. That is, you can assign all the users who need to log into a remote server the same name and password.
- When several external logins are set for a user, the following precedence is followed for user connections to a remote server.
 - 1. One-to-one mapping.
 - 2. If there is no one-to-one mapping, active role is used.
 - 3. If neither one-to-one mapping nor active role is present, then many-to-one mapping.
 - 4. If none of the above is used then SAP ASE login and password.
- You can assign external logins to SAP ASE roles. You can assign anyone with a particular role a corresponding login name and password for any given remote server.
- When you establish a connection to a remote server for a user that has more than one role active, each role is searched for an external login mapping and uses the first mapping it finds to establish the login. This is the same order as displayed by the stored procedure sp activeroles.
- If you perform role mapping, and a user's role is changed (using set role), any connections made to remote servers that used role mapping must be disconnected. You cannot do this if a transaction is pending. You cannot use set role if a transaction is active and remote connections are present that used role mapping.
- Before running sp addexternlogin, add the remote server to the SAP ASE server with sp addserver.
- <externname> and <externpasswd> must be a valid user and password combination on the node where the <server> runs.
- Sites with automatic password expiration need to plan for periodic updates of passwords for external logins.
- Use sp dropexternlogin to remove the definition of the external login.
- sp addexternlogin cannot be used from within a transaction.
- The "sa" account and the <loginame> account are the only users who can modify remote access for a given local user.

Permissions

The permission checks for sp addexternlogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any remote login privilege. Any user can execute sp addexternlogin for their own login.

Disabled With granular permissions disabled, you must be a user with sa_role or sso_role. Any user can execute sp_addexternlogin for their own login.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpexternlogin [page 450]
sp_helpserver [page 482]
```

1.17 sp_addgroup

Adds a group to a database. Groups are used as collective names in granting and revoking privileges.

Syntax

sp_addgroup <grpname>

Parameters

<grpname>

is the name of the group. Group names must conform to the rules for identifiers.

Examples

Example 1

Creates a group named accounting in the current database:

sp addgroup accounting

Usage

There are additional considerations when using sp_addgroup:

- sp_addgroup adds the new group to a database's sysusers table. Each group's user ID (uid) is 16384 or larger (except "public," which is always 0).
- A group and a user cannot have the same name.

- Once a group has been created, add new users with sp_adduser. To add an existing user to a group, use sp_changegroup.
- Every database is created with a group named "public". Every user is automatically a member of "public". Each user can be a member of one additional group.

See also grant, revoke in Reference Manual: Commands.

Permissions

The permission checks for sp addgroup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sso_role, or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_adduser [page 73] sp_changegroup [page 135] sp_dropgroup [page 304] sp_helpgroup [page 452]

1.18 sp_addlanguage

Defines the names of the months and days for an alternate language and its date format.

Syntax

```
sp addlanguage <language>, <alias>, <months>, <shortmons>,
```

Parameters

<language>

is the official language name for the language, entered in 7-bit ASCII characters only.

<alias>

substitutes for the alternate language's official name. Enter either "null", to make the alias the same as the official language name, or a name you prefer. You can use 8-bit ASCII characters in an alias—"français", for example—if your terminal supports them.

<months>

is a list of the full names of the 12 months, ordered from January through December, separated only by commas (no spaces allowed). Month names can be up to 20 characters long and can contain 8-bit ASCII characters.

<shortmons>

is a list of the abbreviated names of the 12 months, ordered from January through December, separated only by commas (no spaces allowed). Month abbreviations can be up to 9 characters long and can contain 8-bit ASCII characters.

<days>

is a list of the full names of the seven days, ordered from Monday through Sunday, separated only by commas (no spaces allowed). Day names can be up to 30 characters long and can contain 8-bit ASCII characters.

<datefmt>

is the date order of the date parts month/day/year for entering datetime, smalldatetime, date, or time data. Valid arguments are mdy, dmy, ymd, ydm, myd, or dym. "dmy" indicates that dates are in day/month/year order.

<datefirst>

sets the number of the first weekday for date calculations. For example, Monday is 1, Tuesday is 2, and so on.

Examples

Example 1

This stored procedure adds French to the languages available on the server. "null" makes the alias the same as the official name, "french". Date order is "dmy" – day/month/year. "1" specifies that lundi, the first item in the <days> list, is the first weekday. Because the French do not capitalize the names of the days and months except when they appear at the beginning of a sentence, this example shows them being added in lowercase:

```
sp_addlanguage french, null,
   "janvier, fevrier, mars, avril, mai, juin, juillet,
   aout, septembre, octobre, novembre, decembre",
```

```
"jan, fev, mars, avr, mai, juin, jui, aout, sept, oct, nov, dec", "lundi, mardi, mercredi, jeudi, vendredi, samedi, dimanche", dmy, 1
```

Usage

Usually, you add alternate languages from one of SAP ASE's Language Modules using the langinstall utility or the SAP ASE installation program. A Language Module supplies the names of the dates and translated error messages for that language. However, if a Language Module is not provided with your server, use sp addlanguage to define the date names and format.

Use alter login to change a user's default language. If you set a user's default language to a language added with sp_addlanguage, and there are no localization files for the language, the users receive an informational message when they log in, indicating that their client software could not open the localization files.

See also:

- set in Reference Manual: Commands
- langinstall in the Utility Guide

Permissions

The permission checks for sp addlanguage differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_droplanguage [page 308] sp_helplanguage [page 465] sp_modifylogin [page 593]

1.18.1 Changing System Tables With sp_addlanguage

The sp addlanguage system procedure performs changes to system tables.

- sp_addlanguage creates an entry in master.dbo.syslanguages, inserting a unique numeric value in the langid column for each alternate language. langid 0 is reserved for U.S. English.
- The The Tanguage parameter becomes the official language name, stored in the name column of
 master.dbo.syslanguages. Language names must be unique. Use sp_helplanguage to display a list
 of the alternate languages available on SAP ASE.
- sp_addlanguage sets the alias column in master.dbo.syslanguages to the official language name if NULL is entered for alias, but system administrators can change the value of syslanguage.alias with sp setlanalias.
- sp addlanguage sets the upgrade column in master.dbo.syslanguages to 0.

1.18.2 Dates for Languages Added with sp_addlanguage

For alternate languages added with Language Modules, the SAP ASE server sends date values to clients as datetime datatype, and the clients use localization files to display the dates in the user's current language.

For date strings added with sp_addlanguage, use the convert function to convert the dates to character data in the server, where <pubdate> is datetime data and is any table:

```
select convert(char, <pubdate>) from
```

When users perform data entry on date values and need to use date names created with sp_addlanguage, the client must have these values input as character data, and sent to the server as character data.

1.19 sp_addlogin

Deprecated by SAP ASE versions 15.7 and later. To add a login account in SAP ASE, use the create login command. See Reference Manual: Commands > Commands > create login.

1.20 sp_addmessage

Adds user-defined messages to sysusermessages for use by stored procedure print and raiserror calls and by sp bindmsg.

Syntax

```
sp_addmessage <message_num>, <message_text>
    [,<language>[, <with_log>[, replace]]]
```

Parameters

<message num>

is the message number of the message to add. The message number for a user-defined message must be 20000 or greater.

<message text>

is the text of the message to add. The maximum length is 1024 bytes.

<language>

is the language of the message to add. This must be a valid language name in the syslanguages table. If this parameter is missing, the SAP ASE server assumes that messages are in the default session language indicated by <code>@elangid</code>.

<with_log>

specifies whether the message is logged in the SAP ASE error log as well as in the Windows Event Log on Windows servers, if logging is enabled. Valid values are:

- TRUE the message is logged, regardless of the severity of the error
- FALSE the message may or may not be logged, depending on the severity of the error.

If you do not specify a value for <with_log>, the default is FALSE.

replace

specifies whether to overwrite an existing message of the same number and<languid>. If replace is specified, the existing message is overwritten; if

replace is omitted, it is not. If you do not specify a value for replace, the parameter's default behavior specifies that the existing message is not overwritten.

Examples

Example 1

Adds a message with the number 20001 to sysusermessages:

```
sp_addmessage 20001, "The table '%1!' is not owned by the user '%2!'."
```

Example 2

Adds a message with the number 20002 to sysusermessages. This message is logged in the SAP ASE error log, as well as in the Windows Event Log on Windows servers, if event logging is enabled. If a message numbered 20002 exists in the default session language, this message overwrites the old message:

```
sp_addmessage 20002, "The procedure'%1!' is not owned
by the user '%2!'.", NULL, TRUE, "replace"
```

Usage

sp_addmessage does not overwrite an existing message of the same number and <langid> unless you
specify @replace = "replace".

print and raiserror recognize placeholders in the message text to print out. A single message can contain up to 20 unique placeholders in any order. These placeholders are replaced with the formatted contents of any arguments that follow the message when the text of the message is sent to the client.

The placeholders are numbered to allow reordering of the arguments when the SAP ASE server is translating a message to a language with a different grammatical structure. A placeholder for an argument appears as "%<nn>!", a percent sign (%), followed by an integer from 1 to 20, followed by an exclamation point (!). The integer represents the argument number in the string in the argument list. "%1!" is the first argument in the original version, "%2!" is the second argument, and so on.

Only the user who created a message can execute $sp_addmessage$ with the replace option to replace that original message.

See also print, raiserror in Reference Manual: Commands.

Permissions

The permission checks for sp addmessage differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, any user can execute $sp_addmessage$.

To add a message with with log, you must be the database owner or a user with own database privilege on the database.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, any user can execute $\tt sp_addmessage.}$

To add a message with with log, you must be the database owner or a user with sa_role.

Only the user who created the message can execute sp addmessage with the replace option to replace that original message.

Auditing

You can enable create auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	create
Event	15
Command or access audited	sp_addmessage
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL
	 Previous value – NULL
	Current value – NULL
	Other information – Message number
	• Proxy information – Original login name, if set proxy in effect

Example of extrainfo after executing sp addmessage:

```
sa role sso role oper role sybase ts role mon role; ; ; ; 210002; ; s
         a/ase;
```

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_altermessage [page 75]
sp_bindmsg [page 113]
sp_dropmessage [page 309]
```

1.21 sp_addobjectdef

(Component Integration Services only) Specifies the mapping between a local table and an external storage location.

Syntax

```
sp_addobjectdef <tablename>, <objectdef>[, "<objecttype>"]
```

Parameters

<tablename>

is the name of the object as it is defined in a local table. The <tablename> can be in any of the following forms:

- <dbname>.<owner>.<object>
- <dbname>..<object>
- < <owner>.<object>
- <object>

<dbname> and <owner> are optional. <object> is required. If you do not specify an
<owner>, the default (current user name) is used. If you specify a <dbname>, it must
be the current database name, and you must specify <owner> or mark the owner with
a placeholder in the format <dbname>..<object>. Enclose any multipart
<tablename> values in quotes.

<objectdef>

is a string naming the external storage location of the object. The <objecttype> at <objectdef> can be a table, view, or read-only remote procedure call (RPC) result set accessible to a remote server. A table, view, or RPC uses the following format for <objectdef>:

```
<server_name>.<dbname>.<owner>.<object>
```

<server_name> and <object> are required. <dbname> and <owner> are optional,
but if they are not supplied, a placeholder in the format <dbname>..<object>, is
required.

<objecttype>

is one of the values that specify the format of the object named by <objectdef>. Valid values are:

- table indicates that the object named by <objectdef> is a table accessible to a remote server. This value is the default for <objecttype>.
- view indicates that the object named by <objectdef> is a view managed by a remote server and processed as a table.
- rpc indicates that the object named by <objectdef> is an RPC managed by a
 remote server. The SAP ASE server processes the result set from the RPC as a
 read-only table.

Enclose the <objecttype> value in quotes.

This table summarizes how each <objecttype> is used:

Table 1: Summary of objecttype Uses

objecttype	create table	create existing table	Write to table	Read from table
table	Yes	Yes	Yes	Yes
view	No	Yes	Yes	Yes
rpc	No	Yes	No	Yes

Examples

Example 1

Maps the local table accounts in the database finance to the remote object pubs.dbo.accounts in the remote server named MYSERVER. The current database must be finance:

```
sp_addobjectdef "finance.dbo.accounts", "MYSERVER.pubs.dbo.accounts", "table"
```

A subsequent create table creates a table in the pubs database. If pubs.dbo.accounts is an existing table, a create existing table statement populates the table finance.dbo.accounts with information about the remote table.

Example 2

Maps the local table stockcheck to an RPC named stockcheck on remote server NEWYORK in the database wallstreet with owner "kelly". The result set from RPC stockcheck is seen as a read-only table:

```
sp_addobjectdef stockcheck, "NEWYORK.wallstreet.kelly.stockcheck", "rpc"
```

Typically, the next operation would be a create existing table statement for the object stockcheck.

Usage

There are additional considerations when using sp addobjectdef:

- sp_addobjectdef specifies the mapping between a local table and an external storage location. It identifies the format of the object at that location. You can use sp_addobjectdef only when Component Integration Services is installed and configured.
- sp_addobjectdef replaces the sp_addtabledef command. sp_addobjectdef allows existing scripts to run without modification. Internally, sp_addtabledef invokes sp_addobjectdef.
- Only the system administrator can provide the name of another user as a table owner.
- When <objecttype> is table, view, or rpc, the <objectdef> parameter takes the following form:

```
"<server name>.<database>.<owner>.<tablename>"
```

- <server_name> represents a server that has already been added to sysservers by sp addserver.
- o <database> may not be required. Some server classes do not support it.
- <owner> should always be provided, to avoid ambiguity. If you do not specify <owner>, the remote
 object referenced may vary, depending on whether or not the external login corresponds to the remote
 object owner.
- <tablename> is the name of a remote server table.
- Use sp_addobjectdef before issuing any create table or create existing table commands. However, if a remote table exists, you need not use sp_addobjectdef before executing create proxy table.
 - create table is valid only for the <objecttype> values table and file. When either create table or create existing table is used, the SAP ASE server checks sysattributes to determine whether any table mapping has been specified for the object. Follow the <objecttype> values view and rpc with create existing table statements.
- After the table has been created, all future references to the local table name (by select, insert, delete, and update) are mapped to the correct location.

See also:

- create existing table, create table, drop table in Reference Manual: Commands
- Component Integration Services User's Guide > Server Classes.

Permissions

The permission checks for sp addobjectdef differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the table owner or a user with manage database privilege.

Disabled With granular permissions disabled, you must be the table owner, the database owner, or a user with sa role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_defaultloc [page 247]
sp_dropobjectdef [page 311]
sp_helpserver [page 482]
```

1.22 sp_addremotelogin

Authorizes a new remote server user by adding an entry to master.dbo.sysremotelogins.

Syntax

```
sp_addremotelogin <remoteserver>[,< loginame>[, <remotename>] ]
```

Parameters

<remoteserver>

is the name of the remote server to which the remote login applies. This server must be known to the local server by an entry in the master.dbo.sysservers table, which was created with sp addserver.

i Note

This manual page uses the term "local server" to refer to the server that is executing the remote procedures run from a "remote server."

<loginame>

is the login name of the user on the local server. <loginame> must already exist in the master.dbo.syslogins table.

<remotename>

is the name used by the remote server when logging into the local server. All <remotenames> that are not explicitly matched to a local <loginame> are
automatically matched to a local name. In Example 1, the local name is the remote
name that is used to log in. In Example 2, the local name is "albert."

Examples

Example 1

Creates an entry in the sysremotelogins table for the remote server GATEWAY, for purposes of login validation. This is a simple way to map remote names to local names when the local and remote servers have the same users:

```
sp addremotelogin GATEWAY
```

This example results in a value of -1 for the suid column and a value of NULL for the remoteusername in a row of sysremotelogins.

Example 2

Creates an entry that maps all logins from the remote server GATEWAY to the local user name "albert". The SAP ASE server adds a row to sysremotelogins with Albert's server user ID in the suid column and a null value for the remoteusername:

```
sp\_addremotelogin GATEWAY, albert
```

For these logins to be able to run RPCs on the local server, they must specify a password for the RPC connection when they log into the local server, or they must be "trusted" on the local server. To define these logins as "trusted", use <code>sp_remotelogin</code>.

Example 3

Maps a remote login from the remote user "pogo" on the remote server GATEWAY to the local user "ralph". The SAP ASE server adds a row to sysremotelogins with Ralph's server user ID in the suid column and "pogo" in the remoteusername column:

```
sp addremotelogin GATEWAY, ralph, pogo
```

Usage

There are additional considerations when using ${\tt sp_addremotelogin}$:

- When a remote login is received, the local server tries to map the remote user to a local user in three different ways:
 - First, the local server looks for a row in sysremotelogins that matches the remote server name and the remote user name. If the local server finds a matching row, the local server user ID for that row is used to log in the remote user. This applies to mappings from a specified remote user.
 - o If no matching row is found, the local server searches for a row that has a null remote name and a local server user ID other than -1. If such a row is found, the remote user is mapped to the local server user

- ID in that row. This applies to mappings from any remote user from the remote server to a specific local name.
- Finally, if the previous attempts failed, the local server checks the sysremotelogins table for an
 entry that has a null remote name and a local server user ID of -1. If such a row is found, the local server
 uses the remote name supplied by the remote server to look for a local server user ID in the
 syslogins table. This applies when login names from the remote server and the local server are the
 same.
- The name of the local user may be different on the remote server.
- If you use sp_addremotelogin to map all users from a remote server to the same local name, use sp_remotelogin to specify the "trusted" option for those users. For example, if all users from the server GOODSRV that are mapped to "albert" are to be "trusted", use sp_remotelogin as follows:

```
sp remoteoption GOODSRV, albert, NULL, trusted, true
```

Logins that are not specified as "trusted" cannot execute RPCs on the local server unless they specify passwords for the local server when they log into the remote server. In Open Client Client-Library, the user can use the ct_remote_pwd routine to specify a password for server-to-server connections. isql and bcp do not permit users to specify a password for RPC connections.

If users are logged into the remote server using "unified login", these logins are already authenticated by a security mechanism. These logins must also be trusted on the local server, or the users must specify passwords for the server when they log into the remote server.

• Every remote login entry has a status. The default status for the trusted option is false (not trusted). This means that when a remote login comes in using that entry, the password is checked. If you do not want the password to be checked, change the status of the trusted option to true with sp remotelogin.

See also:

- System Administration Guide for more information about setting up servers for remote procedure calls and for using "unified login."
- isql in the Utility Guide

Permissions

The permission checks for sp addremotelogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any remote login privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_remoteoption [page 688]
```

1.23 sp_addsegment

Defines a segment on a database device in a database.

Syntax

```
sp_addsegment <segname>, <dbname>, <devname>
```

Parameters

<segname>

is the name of the new segment to add to the syssegments table of the database. Segment names are unique in each database.

<dbname>

specifies the name of the database in which to define the segment. <dbname> must be the name of the current database or match the database name qualifying sp_addsegment.

<devname>

is the name of the database device in which to locate < segname >. A database device can have more than one segment associated with it.

Examples

Example 1

Creates a segment named indexes for the database pubs 2 on the database device named dev1:

```
sp_addsegment indexes, pubs2, dev1
```

Example 2

Creates a segment named indexes for the pubs2 database on the database device named pubs2 dev:

```
disk init
   name = "pubs2_dev",
   physname = "/dev/pubs_2_dev",
   vdevno = 9, size = 5120

go
alter database pubs2 on pubs2_dev = 2
go
pubs2..sp_addsegment indexes, pubs2, dev1
```

Usage

There are additional considerations when using sp addsegment:

• You cannot create a segment on a device that already has an exclusive segment. If you attempt to do so, you see an error message similar to:

```
A segment with a virtually hashed table exists on device orders_dat.
```

- sp_addsegment defines segment names for database devices created with disk init and assigned to a specific database with an alter database or create database command.
- After defining a segment, use it in create table and create index commands and in the sp_placeobject procedure to place a table or index on the segment.
 When a table or index is created on a particular segment, all subsequent data for the table or index is located on the segment.
- Use the system procedure sp_extendsegment to extend the range of a segment to another database device used by the same database.
- If a database is extended with alter database on a device used by that database, the segments mapped to that device are also extended.
- The system and default segments are mapped to each database device included in a create database or alter database command. The logsegment is also mapped to each device, unless you place it on a separate device with the log on extension to create database or with sp_logdevice. See the System Administration Guide for more information.
- Although you can use sp_addsegment in a database that has both data and the log on the same device, such as when the database is created without the log on option, the SAP ASE server returns an error message if you create a database using:

```
create database <dbname> on <devicename> log on <devicename> with override
```

See alsoalter database, create index, create table, and disk init in *Reference Manual:* Commands.

Permissions

The permission checks for sp addsegment differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database permission

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

1.24 sp_addserver

Defines a remote server, or the name of the local server; specifies the server for remote procedure calls (RPCs) when using the host and port parameters.

Syntax

```
sp addserver <lname>[, <class>[,< pname>]]
```

Component Integration Services (CIS) only:

```
sp addserver '<logical server name>', ASEnterprise, '<host>:<port>:<filter>
```

Parameters

<lname>

is the name used to address the server on your system. sp_addserver adds a row to the sysservers table if there is no entry already present for <lname>. Server names must be unique and must conform to the rules for identifiers.

<class>

identifies the category of server being added. A server <class> of "null" defaults to "ASEnterprise". Allowable values for the <class> parameter are:

- local local server (there can be only one) used only once after start-up, or after restarting the SAP ASE server, to identify the local server name so that it can appear in messages printed by the SAP ASE server
- null remote server with no category defined
- ASEnterprise all versions of SAP ASE; support for SQL Server 4.9 is not provided.
- ASAnywhere Adaptive Server Anywhere version 6.0 or later.
- ASIQ a server with server class ASIQ is any version of Adaptive Server IQ of 12.0 or later.
- direct_connect (Component Integration Services only) an Open Server-based application that conforms to the direct_connect interface specification.
- sds- conforms to the interface requirements of a Specialty Data Store™ as described in the SAP ASE Specialty Data Store Developer's Kit manual.

i Note

The SAP ASE server does not support server class db2. To use db2, migrate your db2 server class to direct connect class.

<pname>

is the name in the interfaces file for the server named <lname>. This enables you to establish local aliases for other SAP ASE servers or Backup Servers that you may need to communicate with. If you do not specify a <pname>, <lname> is used.

(Component Integration Services only) You can use to specify the hostname or IP address and the port of the server you wish to connect to. This enables you to bypass the need for directory services (such as LDAP or an interfaces file) for the server when using the CT-Library. Use the following format:

- "hostname:port"
- "ipaddr:port"

i Note

You must enclose the hostname and port with single or double quotes to use this option.

<filter>

in cluster environments – adds a remote server for remote procedure calls (RPCs).

```
<filter> = ssl [= 'CN = <common_name>']
```

Use this format to declare the <host:port> number:

```
ip address:port
```

Examples

Example 1

(In cluster environments) Adds a remote server named big_logical_server:

```
sp_addserver 'big_logical_server', ASEntrprise,
    'maynard:23954:ssl= "CN=ase1.big server 1.com"'
```

The rules for common names are the same as those used for dynamic listeners and the directory service entries.

Example 2

Adds an entry for a remote server named GATEWAY in master.dbo.sysservers. The <pname> is also GATEWAY:

```
sp_addserver GATEWAY
```

Example 3

Adds an entry for a remote server named GATEWAY in master.dbo.sysservers. The <pname> is VIOLET. If there is already a sysservers entry for GATEWAY with a different <pname>, the <pname> of server GATEWAY changes to VIOLET:

```
sp_addserver GATEWAY, null, VIOLET
```

Example 4

Adds an entry for the local server named PRODUCTION:

```
sp_addserver PRODUCTION, local
```

Example 5

(Component Integration Services only) Adds an entry for a remote SAP ASE server with the host name "myhost" with port number 10224:

```
sp_addserver S1, ASEnterprise, "myhost:10224"
```

i Note

If you use this syntax for <pname>, the SAP ASE site handler cannot successfully connect to this server; only CIS connections recognize this syntax for <pname>.

Example 6

(Component Integration Services only) Adds an entry for a remote SAP ASE server with the host IP 192.123.456.010 with port number 11222:

sp_addserver S3, direct_connect, "192.123.456.010:11222"

Usage

There are additional considerations when using sp addserver:

- The sysservers table identifies the name of the local server and its options, and any remote servers that the local server can communicate with.
 - To execute a remote procedure call on a remote server, the remote server must exist in the sysservers table.
- If <1name> already exists as a server name in the sysservers table, sp_addserver changes the remote server's srvnetname to the name specified by <pname>. When it does this, sp_addserver reports which server it changed, what the old network name was, and what the new network name is.
- The installation or upgrade process for your server adds an entry in sysservers for a Backup Server. If you remove this entry, you cannot back up your databases.
- If you specify an <lname>, <pname> and <class> that already exist in sysservers, sp_addserver prints an error message and does not update sysservers.
- Use sp_serveroption to set or clear server options.

See also Component Integration Services User's Guide > Remote Servers.

Permissions

The permission checks for $sp_addserver$ differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage server privilege.

To execute $sp_addserver$ for a server that is a shared disk cluster, you must be a user with manage cluster privilege and manage server privilege.

Setting Description

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sso_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

```

sp_helpremotelogin [page 471]

sp_helpserver [page 482]

sp_serveroption [page 711]

1.25 sp_addthreshold

Creates a threshold to monitor space on a database segment. When free space on the segment falls below the specified level, the SAP ASE server executes the associated stored procedure.

Syntax

```
sp_addthreshold <dbname>, <segname>, <free_space>, <proc_name>
```

Parameters

<dbname>

is the database for which to add the threshold. This must be the name of the current database.

<segname>

is the segment for which to monitor free space. Use quotes when specifying the "default" segment.

<free_space>

is the number of free pages at which the threshold is crossed. When free space in the segment falls below this level, the SAP ASE server executes the associated stored procedure.

c_name>

is the stored procedure to be executed when the amount of free space on <segname> drops below <free_space>. The procedure can be located in any database on the current SAP ASE server or on an Open Server. Thresholds cannot execute procedures on remote SAP ASE servers.

Examples

Example 1

Creates a threshold for segment1. When the free space on segment1 drops below 200 pages, the SAP ASE server executes the procedure pr warning:

```
sp addthreshold mydb, segment1, 200, pr warning
```

Example 2

Creates a threshold for the user_data segment. When the free space on user_data falls below 100 pages, the SAP ASE server executes a remote procedure call to the Open Server mail me procedure:

```
sp addthreshold userdb, user data, 100, "o server...mail me"
```

Example 3

Creates a threshold on the indexes segment of the pubs 2 database. You can issue this command from any database:

```
pubs2..sp_addthreshold pubs2, indexes, 100, pr_warning
```

Usage

When a threshold is crossed, the SAP ASE server executes the associated stored procedure. The SAP ASE server uses the following search path for the threshold procedure:

- If the procedure name does not specify a database, the SAP ASE server looks in the database in which the threshold was crossed.
- If the procedure is not found in this database, and the procedure name begins with "sp_", the SAP ASE server looks in the sybsystemprocs database.

If the procedure is not found in either database, the SAP ASE server sends an error message to the error log.

The SAP ASE server uses a **hysteresis value**, the global variable <code>@@thresh_hysteresis</code>, to determine how sensitive thresholds are to variations in free space. Once a threshold executes its procedure, it is deactivated.

The threshold remains inactive until the amount of free space in the segment rises to <code>@@thresh_hysteresis</code> pages above the threshold. This prevents thresholds from executing their procedures repeatedly in response to minor fluctuations in free space.

See also:

- create procedure and dump transaction in Reference Manual: Commands
- System Administration Guide for more information about using thresholds
- lct admin in Reference Manual: Building Blocks

Permissions

The permission checks for sp addthreshold differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dboption [page 228]

sp_dropthreshold [page 323]

sp_helpthreshold [page 493]

sp_modifythreshold [page 598]

sp_thresholdaction [page 809]

1.25.1 Creating Additional Thresholds

Each database can have up to 256 thresholds, including the last-chance threshold.

When you add a threshold, it must be at least twice the size of the <code>@@thresh_hysteresis</code> pages from the closest threshold.

1.25.2 Executing Threshold Procedures

Tasks initiated when a threshold is crossed execute as background tasks. These tasks do not have an associated terminal or user session. If you execute sp_who while these tasks are running, the status column shows "background."

The SAP ASE server executes the threshold procedure with the permissions the user had at the time he or she added the threshold, minus any permissions that have since been revoked.

Each threshold procedure uses one user connection, for as long as it takes for the procedure to execute.

1.25.3 Changing or Deleting Thresholds

 $To \ change \ or \ delete \ thresholds, \ use \ sp_helpthreshold, \ sp_modify threshold, \ and \ sp_drop threshold.$

Procedure	Description
sp_helpthreshold	For information about existing thresholds.
sp_modifythreshold	To associate a threshold with a new threshold procedure, free-space value, or segment (you cannot change the free-space value or segment name associated with the last-chance threshold).
	Each time a user modifies a threshold, that user becomes the threshold owner. When the threshold is crossed, the SAP ASE server executes the threshold with the permissions the owner had at the time he or she modified the threshold, minus any permissions that have since been revoked.
sp_dropthreshold	To drop a threshold from a segment.

1.25.4 Disabling Free-Space Accounting

Use the no free space acctg option of $sp_dboption$ to disable free-space accounting on non-log segments.

System procedures cannot provide accurate information about space allocation when free-space accounting is disabled.

You cannot disable free-space accounting on log segments.

1.25.5 The Last-Chance Threshold

By default, the SAP ASE server monitors the free space on the segment where the log resides and executes $sp_thresholdaction$ when the amount of free space is less than that required to permit a successful dump

of the transaction log. This amount of free space, called the last-chance threshold, is calculated by the SAP ASE server and cannot be changed by users.

If the last-chance threshold is crossed before a transaction is logged, the SAP ASE server suspends the transaction until log space is freed. Use <code>sp_dboption</code> to change this behavior for a particular database <code>sp_dboption</code> "abort tran on log full", true causes the SAP ASE server to roll back all transactions that have not yet been logged when the last-chance threshold is crossed.

All databases have a last-chance threshold, including master. The threshold is an estimate of the number of free log pages that are required to back up the transaction log. As you allocate more space to the log segment, the SAP ASE server automatically adjusts the last-chance threshold.

1.25.6 Creating Threshold Procedures

Any user with create procedure privilege can create a threshold procedure in a database. Usually, a system administrator creates <code>sp_thresholdaction</code> in the <code>sybsystemprocs</code> database, and the database owners create threshold procedures in user databases.

sp_addthreshold does not verify that the specified procedure exists. It is possible to add a threshold before creating the procedure it executes.

sp_addthreshold checks to ensure that the user adding the threshold procedure has been granted the "sa_role". All system roles active when the threshold procedure is created are entered in systhresholds as valid roles for the user writing the procedure.

The SAP ASE server passes four parameters to a threshold procedure:

- ullet <@dbname>, varchar(30), which identifies the database
- <@segmentname>, varchar(30), which identifies the segment
- <@space_left>, int, which indicates the number of free pages associated with the threshold
- <@status>, int, which has a value of 1 for last-chance thresholds and 0 for other thresholds

These parameters are passed by position rather than by name; your threshold procedure can use other names for them, but it must declare them in the order shown and with the correct datatypes.

It is not necessary to create a different procedure for each threshold. To minimize maintenance, you can create a single threshold procedure in the sybsystemprocs database that is executed for all thresholds in the SAP ASE server.

Include print and raiserror statements in the threshold procedure to send output to the error log.

1.26 sp_addtype

Creates a user-defined datatype.

Syntax

Parameters

<typename>

is the name of the user-defined datatype. Type names must conform to the rules for identifiers and must be unique in each database.

<phystype>

is the physical or SAP ASE server-supplied datatype on which to base the user-defined datatype. You can specify any SAP ASE datatype except timestamp.

The char, varchar, unichar, univarchar, nchar, nvarchar, binary, and varbinary datatypes expect a <length> in parentheses. If you do not supply one, the SAP ASE server uses the default length of 1 character.

The numeric and decimal datatypes expect a decimal precision> and <scale>, in parentheses and separated by a comma. If you do not supply them, the SAP ASE server uses a default precision of 18 and a scale of 0.

Enclose physical types that include punctuation, such as parentheses or commas, within single or double quotes.

identity

indicates that the user-defined datatype has the IDENTITY property. Enclose the identity keyword within single or double quotes. You can specify the IDENTITY property only for numeric datatypes with a scale of 0.

IDENTITY columns store sequential numbers, such as invoice numbers or employee numbers, that are generated by the SAP ASE server. The value of the IDENTITY column uniquely identifies each row in a table. IDENTITY columns are not updatable and do not allow null values.

<nulltype>

indicates how the user-defined datatype handles null value entries. Acceptable values for this parameter are null, NULL, nonull, NONULL, "not null", and "NOT NULL".

Any <nulltype> that includes a blank space must be enclosed in single or double quotes.

If you omit both the IDENTITY property and the <nulltype>, the SAP ASE server creates the datatype using the null mode defined for the database. By default, datatypes for which no <nulltype> is specified are created NOT NULL (that is, null values are not allowed and explicit entries are required). For compliance to the SQL standards, use the sp_dboption system procedure to set the allow nulls by default option to true. This changes the database's null mode to NULL.

Examples

Example 1

Creates a user-defined datatype called ssn to be used for columns that hold social security numbers. Since the <nulltype> parameter is not specified, the SAP ASE server creates the datatype using the database's default null mode. Notice that varchar(11) is enclosed in quotation marks, because it contains punctuation (parentheses):

```
sp_addtype ssn, "varchar(11)"
```

Example 2

Creates a user-defined datatype called birthday that allows null values:

```
sp_addtype birthday, "datetime", null
```

Example 3

Creates a user-defined datatype called temp52 used to store temperatures of up to 5 significant digits with 2 places to the right of the decimal point:

```
sp_addtype temp52, "numeric(5,2)"
```

Example 4

Creates a user-defined datatype called row_id with the IDENTITY property, to be used as a unique row identifier. Columns created with this datatype store system-generated values of up to 10 digits in length:

```
sp_addtype "row_id", "numeric(10,0)", "identity"
```

Example 5

Creates a user-defined datatype with an underlying type of sysname:

```
sp_addtype systype, sysname
```

Although you cannot use the sysname datatype in a create table, alter table, or create procedure statement, you can use a user-defined datatype that is based on sysname.

Usage

- sp_addtype creates a user-defined datatype and adds it to the systypes system table. Once a user-defined datatype is created, you can use it in create table and alter table statements and bind defaults and rules to it.
- Build each user-defined datatype in terms of one of the SAP ASE-supplied datatypes, specifying the length or the precision and scale, as appropriate. You cannot override the length, precision, or scale in a create table or alter table statement.
- A user-defined datatype name must be unique in the database, but user-defined datatypes with different names can have the same definitions.
- If nchar or nvarchar is specified as the <phystype>, the maximum length of columns created with the new type is the length specified in sp_addtype multiplied by the value of <@@ncharsize> at the time the type was added.
- If unichar or univarchar is specified as the <phystype>, the maximum length of columns created with the new type is the length specified in sp_addtype multiplied by the value of 2 at the time the type was added
- Each system type has a hierarchy, stored in the systypes system table. User-defined datatypes have the same datatype hierarchy as the physical types on which they are based. In a mixed-mode expression, all types are converted to a common type, the type with the lowest hierarchy.

 Use the following query to list the hierarchy for each system-supplied and user-defined type in your

```
select name, hierarchy
from systypes
order by hierarchy
```

database:

• If a user-defined datatype is defined with the IDENTITY property, all columns created from it are IDENTITY columns. You can specify IDENTITY, NOT NULL, or neither in the create or alter table statement. Following are three different ways to create an IDENTITY column from a user-defined datatype with the IDENTITY property:

```
create table new_table (id_col IdentType)

create table new_table (id_col IdentType identity)

create table new_table (id_col IdentType not null)
```

When you create a column with the create table or alter table statement, you can override the null type specified with the sp addtype system procedure:

- Types specified as NOT NULL can be used to create NULL or IDENTITY columns.
- Types specified as NULL can be used to create NOT NULL columns, but not to create IDENTITY columns.

i Note

If you try to create a null column from an IDENTITY type, the create or alter table statement fails.

See also:

• create default, create rule, create table in Reference Manual: Commands

• User-Defined Datatypes in Reference Manual: Building Blocks

Permissions

Any user can execute $sp_addtype$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_unbindefault [page 822]
sp_unbindrule [page 829]
```

1.27 sp_addumpdevice

Adds a dump device to the SAP ASE server.

Syntax

Parameters

"tape"

for tape drives. Enclose tape in quotes.

"disk"

is for a disk or a file device. Enclose disk in quotes.

<logicalname>

is the "logicalF dump device name. It must be a valid identifier. Once you add a dump device to sysdevices, you can specify its logical name in the load and dump commands.

<physicalname>

is the physical name of the device. You can specify either an absolute path name or a relative path name. During dumps and loads, the Backup Server resolves relative path names by looking in the SAP ASE server's current working directory. Enclose names containing non-alphanumeric characters in quotation marks. For UNIX platforms, specify a non-rewinding tape device name.

<tapesize>

is the capacity of the tape dump device, specified in megabytes. Platforms require this parameter for tape devices but ignore it for disk devices. The <tapesize> should be at least five database pages (each page requires 2048 bytes). You should specify a capacity that is slightly below the rated capacity for your device.

Examples

Example 1

Adds a 40 MB tape device. Dump and load commands can reference the device by its physical name, /dev/nrmt8, or its logical name, mytapedump:

```
sp_addumpdevice "tape", mytapedump, "/dev/nrmt8", 40
```

Example 2

Adds a disk device named mydiskdump. Specify an absolute or relative path name and a file name:

```
sp addumpdevice "disk", mydiskdump, "/dev/rxyld/dump.dat"
```

Usage

There are additional considerations when using sp addumpdevice:

• sp_addumpdevice adds a dump device to the master.dbo.sysdevices table. Tape devices are assigned a cntrltype of 3; disk devices are assigned a cntrltype of 2.

- To use an operating system file as a dump device, specify a device of type disk and an absolute or relative path name for the <physicalname>. Omit the <tapesize> parameter. If you specify a relative path name, dumps are made to or loaded from the current SAP ASE server working directory at the time the dump or load command executes.
- Ownership and permission problems can interfere with the use of disk or file dump devices. sp_addumpdevice adds the device to the sysdevices table, but does not guarantee that you can create a file as a dump device or that users can dump to a particular device.
- The with capacity = <megabytes> clause of the dump database and dump transaction commands can override the <tapesize> specified with sp_addumpdevice. On platforms that do not reliably detect the end-of-tape marker, the Backup Server issues a volume change request after the specified number of megabytes have been dumped.
- When a dump device fails, use sp_dropdevice to drop it from sysdevices. After replacing the device, use sp_addumpdevice to associate the logical device name with the new physical device. This avoids updating backup scripts and threshold procedures each time a dump device fails.
- To add database devices to sysdevices, use the disk init command.

See also disk init, dump database, dump transaction, load database, load transaction in Reference Manual: Commands.

Permissions

The permission checks for sp addumpdevice differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage disk privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dropdevice [page 292] sp_helpdevice [page 446]

1.28 sp_adduser

Adds a new user to the current database.

Syntax

```
sp adduser <loginame> [, <name in db> [, <grpname>]]
```

Parameters

```
<loginame>
```

is the user's name in master.dbo.syslogins.

<name_in_db>

is a new name for the user in the current database.

<grpname>

adds the user to an existing group in the database.

Examples

Example 1

Adds "margaret" to the database. Her database user name is the same as her SAP ASE login name, and she belongs to the default group, "public":

```
sp adduser margaret
```

Example 2

Adds "haroldq" to the database. When "haroldq" uses the current database, his name is "harold." He belongs to the fort_mudge group, as well as to the default group "public":

```
sp_adduser haroldq, harold, fort_mudge
```

Usage

There are additional considerations when using sp adduser:

• The database owner executes sp_adduser to add a user name to the sysusers table of the current database, enabling the user to access the current database under his or her own name.

- Specifying a <name_in_db> parameter gives the new user a name in the database that is different from his or her login name in SAP ASE. The ability to assign a user a different name is provided as a convenience. It is not an alias, as provided by sp_addalias, since it is not mapped to the identity and privileges of another user.
- A user and a group cannot have the same name.
- A user can be a member of only one group other than the default group, "public". Every user is a member of the default group, "public". Use sp changegroup to change a user's group.
- In order to access a database, a user must either be listed in sysusers (with sp_adduser) or mapped to another user in sysalternates (with sp_addalias), or there must be a "guest" entry in sysusers.

See also grant, revoke, and use in Reference Manual: Commands.

Permissions

The permission checks for sp adduser differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_dropgroup [page 304]

sp_helpuser [page 495]

1.29 sp_altermessage

Enables and, possibly, disables the logging of a system-defined or user-defined message in the SAP ASE error log.

Syntax

```
sp_altermessage {<message_id | severity_level>}, <parameter>, <parameter_value>
```

Parameters

<message_id | severity_level>

is the message number of the message to be altered, or the severity level at which you want messages sent to the error log. The <message_id> is the number of the message as it is recorded in the error column in the sysmessages or sysusermessages system table. Indicate the <severity_level> by including a negative sign before the number. That is, -16 indicates that all error messages of severity level 16 that are displayed to the client are included in the error log as well.

<parameter>

is the message parameter to be altered. The maximum length is 30 bytes. The only valid parameter is with log.

<parameter_value>

is the new value for the parameter specified in <parameter>. Valid values are true and false.

Examples

Example 1

Specifies that message number 2000 in sysmessages should be logged in the SAP ASE error log and also in the Windows Event Log (if logging is enabled):

```
sp_altermessage 2000, 'with_log', 'TRUE'
```

Example 2

Specifies that error messages of severity level 16 are included in the error log:

```
sp_altermessage -16, "with_log", true
go
3611 Messages altered.
(return status = 0)
```

For example, after this change running the non-existent sp_test system procedure results in a severity-level 16 error message:

```
sp_test
go
Msg 2812, Level 16, State 5:
Line 1:
Stored procedure 'sp_test' not found. Specify owner.objectname or use sp_help
to check whether the object
exists (sp_help may produce lots of output).
```

This results in the server writing error message 2812 (severity level 16) to the error log:

```
00:0006:00000:00023:2018/02/02 13:19:29.10 server Error: 2812, Severity: 16, State: 5
00:0006:00000:00023:2018/02/02 13:19:29.10 server Stored procedure 'sp_test' not found. Specify owner.objectname or use sp_help to check whether the object exists (sp_help may produce lots of output).
```

Usage

If the <parameter_value> is true, the specified message is always logged. If it is false, the default logging behavior is used; the message may or may not be logged, depending on the severity of the error and other factors. Setting the <parameter_value> to false produces the same behavior that would occur if sp altermessage had not been called.

On Windows servers, sp altermessage also enables and disables logging in the Windows Event Log.

Permissions

The permission checks for sp altermessage differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addmessage [page 47] sp_dropmessage [page 309]

1.30 sp_audit

Allows a system security officer to configure auditing options.

Syntax

```
sp_audit <option>, <login_role_name>, <object_name> [,<setting>]
```

The syntax for manually restarting auditing is:

```
sp_audit restart
```

Parameters

<option>

is a global, user-specific, database-specific, or object-specific option.

Table 2: Auditing Options

Option	Description
adhoc	Allows users to use sp_addauditrecord to add their own user-defined audit records to the audit trail.

Option	Description
all	Audits all actions.
allow	Audits the command allow.
alter	Audits the execution of the commands: alter database, alter index, alter role, alter table, altermodify owner (including alter encryption key modify owner)
bcp	Audits the execution of the bcp in utility.
bind	Audits the execution of: sp_bindefault, sp_bindmsg, sp_bindrule
cluster	Audits cluster commands.
cmdtext	Audits the SQL text entered by a user. System stored procedures and command password parameters can be replaced with a fixed-length string of asterisks for security purposes.
config_h istory	Audits configuration history.
create	Audits the create commands: create database, create default, create function, create index, create procedure, create role, create rule, create service, create table, create trigger, create view
dbaccess	Audits access to the database from another database.
dbcc	Audits the execution of all dbcc commands.
delete	Audits the deletion of rows from a table or view.
deny	Audits the deny command.
disk	Audits the execution of these commands: disk init, disk mirror, disk refit, disk reinit, disk remirror, disk resize, disk unmirror
drop	Audits the executions of the commands: drop database, drop default, drop function, drop index, drop procedure, drop role, drop rule, drop service, drop table, drop trigger, drop view, sp_dropmessage
dump	Audits the execution of the commands: dump database, dump databasecumulative, dump transaction
dump_con fig	Audits the execution of the dump configuration tocommand.
encrypti on_key	Audits the execution of the commands: alter encryption key, create encryption key, drop encryption key, sp_encryption
errors	Audits fatal error and non-fatal errors.
errorlog	Audits changes to the error log.
exec_pro cedure	Audits the execution of a stored procedure.

Option	Description
exec_tri gger	Audits any command that fires the trigger.
func_dba	Audits access to a database using built-in functions.
func_obj _access	Audits access to an object using built-in functions.
grant	Audits the execution of the grant, and grant rolecommands.
insert	Audits the insertion of rows into a table or view using the insert command.
install	Audits the installation of Java classes using the installjava command.
load	load database. Audits the execution of the commands: load databasecumulative load transaction
login	Audits the execution of Audits a login attempt to the server for all logins or roles, a specific login, or a specific role (both system defined and user defined roles).
login_ad min	Audits the execution of the commands alter login, create login, drop login by login administrators.
login_lo	Audits the host name and network IP address when a login account is locked due to exceeding the configured number of failed login attempts.
logout	Audits any logout from an SAP ASE server.
mount	Audits the execution of the mount database command.
password	Audits the events for global password and login policy options.
quiesce	Audits the execution of the quiesce database, prepare database commands. $ \\$
referenc e	Audits the references between tables using the create table or alter table commands.
remove	Audits the removal of Java classes.
revoke	Audits the execution of the revoke, revoke role commands.
role	Audits the execution of the alter role, create role, drop role, grant role, revoke role, set role commands.
role_loc ked	Audits the alter rolelock command.
rpc	Audits remote procedure calls (either in or out)
security	Audits the server-wide security-relevant events.
_	Audits the alter login profile, create login profile, drop login profile commands.
select	Audits the execution of the select command for a table or view.
setuser	Audits the execution of the setuser command.

Option	Description
sproc_au	Audits the authorization checks that are done inside system stored procedures.
table_ac	Audits access to any table by a specific user for the select, delete, update, or insert commands.
thread_p	Audits the execution of the alter thread pool, create thread pool, drop thread pool commands.
transfer _table	Audits the execution of the transfer table command.
truncate	Audits the execution of the truncate table command.
unbind	Audits the execution of the sp_unbindefault, sp_unbindrule, sp_unbindmsg commands.
unmount	Audits the execution of the unmount database commands.
update	Audits updates to rows in a table or view.
view_acc ess	Audits the access to any view by a specific user using the select, delete, insert, or update commands.

<login_role_name>

determines the logins or roles to audit.

<object_name>

valid objects to audit.

default	<pre>is valid when you specify the exec_procedure for <option></option></pre>			
procedure	as the first parameter.			
default trigger	is valid when you specify the $\mathtt{exec_trigger}$ for $\texttt{}$ as the first parameter.			
<object name=""></object>	is the name of a specific object to be audited. Valid values			

depend on the value you specified for the global option.

You can specify the object name and include the owner's name if you do not own the object. For example, to audit a table named inventory that is owned by Joe, you would specify joe.inventory for <object name>.

<setting>

determines the settings for the audit events. The server generates audit records for events controlled by this option, whether the event passes or fails permission checks.

]

off deactivates auditing for the specified option.

on activates auditing for the specified option.

pass activates auditing for events that pass permission checks.

fail activates auditing for events that fail permission checks.

restart

If the audit process is forced to terminate due to an error, you can manually restart auditing by using the restart option.

The audit process can be restarted provided that no audit was currently running, but that the audit process has been configured to run by entering <code>sp_configure</code> "auditing" 1.

Examples

Example 1

Sets the $login_locked$ audit option to initiate auditing of hostname and network IP addresses when a login account is locked due to exceeding the configured number of failed login attempts:

```
sp_audit "login_locked","all","all","on"
```

If the audit tables are full and the event cannot be logged, a message with the information is sent to the errorlog.

Monitoring the audit logs for the Locked Login event (112) helps to identify attacks on login accounts.

Initiates auditing for SSL security-relevant events. Both successful and failed events are audited:

```
sp_audit "security", "all", "all", "on"
sample records added:
```

To view the events from sybsecurity:

```
select * from sybsecurity..sysaudits_01 where event=99
```

Example 3

Displays the setting of the security auditing option:

```
sp_audit "security", "all", "all"
```

Example 4

Initiates auditing for the creation of objects in the master database, including create database.

```
sp_audit "create", "all", master, "on"
```

Example 5

Audits commands in the pubs2 database:

```
sp_audit "encryption_key", "all", pubs2, "on"
```

Example 6

Initiates auditing for the creation of all objects in the db1database:

```
sp_audit "create", "all", db1, "on"
```

Example 7

Initiates auditing for all failed executions by a system administrator.

```
sp_audit "all", "sa_role", "all", "fail"
```

Example 8

Initiates auditing for all updates to future tables in the current database. For example, if the current database is utility, all new tables created in utility are audited for updates. The auditing for existing tables is not affected.

```
sp_audit "update", "all", "default table", "on"
```

Example 9

Initiates auditing for all transfer table commands entered for the titles table:

```
use pubs2
sp_audit "transfer_table", "all", titles, "on"
```

Initiates auditing for the deny command:

```
sp_audit "deny", "all", "master", "on"
```

Example 11

Audits all attempts to unmount or create a manifest file with any database:

```
sp_audit "unmount", "all", "all", "on"
```

Example 12

Turns on auditing for successful and failed role creations in the master database:

```
sp_audit "alter", "all", "master", "on"
```

Example 13

This example turns on auditing for successful role alterations in the master database:

```
sp_audit "alter", "all", "master", "pass"
```

Example 14

This example turns off auditing for dropping roles in the master database:

```
sp_audit "drop", "all", "master", "off"
```

Example 15

This example turns off auditing for granting roles and permissions in the master database:

```
sp_audit "grant", "all", "master", "off"
```

Auditing is performed using the grant or role audit option generating event 85 audit record.

Example 16

This example turns on auditing for revoking roles:

```
sp_audit "revoke", "all", "master", "on"
```

Auditing is performed using the revoke or role audit option generating event 85 audit record.

Example 17

This example shows how to audit all failed deletions on the projects table in the <code>company_operations</code> database and for all new tables in the database. You can use the object-specific <code>delete</code> option for the <code>projects</code> table and use <code>default table</code> for all future tables in the database. You must be in the object's database before you execute <code>sp_audit</code> to set object-specific auditing options:

```
use company_operations
go
sp_audit "delete", "all", "projects", "fail"
go
sp_audit "delete", "all", "default table", "fail"
go
```

This example audits all table accesses by the login "tonyb":

```
sp_audit "table_access", "tonyb", "all", "on"
```

Example 19

This example audits the procedure sp addlogin:

```
use sybsystemprocs
go
sp_audit "exec_procedure", "all", "sp_addlogin", "on"
go
```

Example 20

Initiates auditing for all login attempts for logins with roles: doc role and nurse role.

```
sp_audit "login", "doc_role", "all", "on"
sp_audit "login", "nurse_role", "all", "on"
```

Example 21

Initiates auditing for all logins with the role doc role.

```
sp_audit "all", "doc_role", "all", "on"
```

Usage

- sp_audit determines what is audited when auditing is enabled. No actual auditing takes place until you use sp_configure to set the auditing parameter to on. Then, all auditing options that have been configured with sp_audit take effect. For more information, see sp_configure.
- If you are not the owner of the object being specified, qualify the <object_name> parameter value with the owner's name, in the following format:

```
"<ownername>.<objname>"
```

- You cannot activate default auditing for the following options in the tempdb database:
 - o delete
 - o exec_procedure
 - o exec trigger
 - o insert
 - o select
 - o update
- The configuration parameters that control auditing are:
 - auditing enables or disables auditing for the server.
 - o audit queue size establishes the size of the audit queue.
 - current audit table sets the current audit table. The SAP ASE server writes all audit records to that table.

- suspend auditing when full controls the behavior of the audit process when an audit device becomes full.
- All auditing configuration parameters are dynamic and take effect immediately.
- If you do not specify a value for the forth parameter, SAP ASE displays the current auditing setting for the option. If you specify pass for an option and later specify fail for the same option, or vice versa, the result is equivalent to specifying on. The SAP ASE server generates audit records regardless of whether events pass or fail permission checks.
 - on or off apply to all auditing options
 - o pass and fail apply to all options except cmdtext, errors, and adhoc. For these options, only on or off applies. The initial, default value of all options is off. If you select the cmdtext option to either pass or fail, the SAP ASE server replaces the value with on.

Permissions

The permission checks for sp audit differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage auditing privilege.
Disabled	With granular permissions disabled, you must be a user with sso role.

Auditing

You can enable <code>config_history</code> auditing option to audit this procedure. Values in <code>event</code> and <code>extrainfo</code> columns from the <code>sysaudits</code> table are:

Audit option	Event	Command or access audited	Information in extrainfo:	
config_history	154	sp_audit	 Roles - Current active roles Keywords or options - NULL Previous value - NULL Current value - NULL Other information - Includes procedure name, parameter name, old value, new value, mode (static or active), and instance ID Proxy information - Original login name, if set proxy in effect 	

Example of extrainfo after executing sp_configure "auditing", 1 and sp_configure "enable granular permissions", 1:

```
select event, extrainfo from sybsecurity..sysaudits_01 where event = 154
go
event extrainfo
```

```
154 ;;; ^01^1AUDIT^2config history auditing^3^4^5off^6on^7^8^9;;
154 ;;; ^01^1SERVER^2sp_configure^3^4enable granular permissions^50^61^7dynamic^8^9;;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_configure [page 203]
sp_addauditrecord [page 28]
```

1.30.1 Auditing Options

Specify values for auditing options and requirements.

The values you can specify for the <login_role_name> and <object_name> parameters to sp_audit depend on the type of auditing option you specify:

- Global options apply to commands that affect the entire server, such as booting the server, disk
 commands, and allowing ad hoc, user-defined audit records. Option settings for global events are stored in
 the sybsecurity..sysauditoptions system table.
 All global audit options support auditing at the login and role level (both system defined and user defined
 roles).
- Database-specific options apply to a database. Examples include altering a database, bulk copy (bcp in) of data into a database, granting or revoking access to objects in a database, and creating objects in a database. Option settings for database-specific events are stored in the master..sysdatabases system table
- Object-specific options apply to a specific object. Examples include selecting, inserting, updating, or
 deleting rows of a particular table or view and the execution of a particular trigger or procedure. Option
 settings for object-specific events are stored in the sysobjects system table in the relevant database.
- User-specific options apply to a specific user or system role. Examples include accesses by a particular user to any table or view or all actions performed when a particular system role, such as sa_role, is active. Option settings for individual users are stored in master..syslogins. The settings for system roles are stored in master..sysauditoptions.
 - The all option supports a specific login, logins granted a user defined role, or logins granted a system role.
- The role audit option audits all role-related commands, and audit options create, alter, and drop are used to audit role-definition commands, while grant and revoke are used to audit the granting/revoking of roles to/from subjects. The settings for role-specific option are stored in master..sysauditoptions. The master database is specified for audit options that require an object name parameter.
- Granular auditing is supported for all global options (with the exception of cluster), and the user-specific option all. Granular auditing provides fine-grained security-related auditing and is used to generate audit records only for the specified logins and roles. Both system roles and user defined roles can be specified.

The default value for all options is off.

The Auditing Options, Requirements, and Examples table shows:

- Valid values for the <option> and the type of each option global, database-specific, object-specific, or user-specific
- Valid values for the <login_role_name> and object_name> parameters for each option
- The database to be in when you set the auditing option
- The command or access that is audited when you set the option
- An example for each option

Table 3: Auditing Options, Requirements, and Examples

Option (op- tion type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited	
adhoc (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	Allows users to use sp_addauditrecord	
		This example e	enables ad hoc user-	defined auditing records:	
		sp_audit	"adhoc", "all	", "all", "on"	
	Thise	example enables ad	l hoc user-defined au	uditing records for intern_role:	
		sp_audit "a	dhoc", "intern	n_role", "all", "on"	
all (user-specific)	, <login>,Or <role></role></login>	all	Any	A particular login or logins granted to a role	
	This	example turns aud	liting on for all action	s in which the sa_role is active:	
		sp_audit	"all", "sa_ro	le", "all", "on"	
allow	all	all	Any	allow	
(database-specific)		This example	turns auditing on fo	r the command allow:	
		sp_audit	"allow", "all"	', "master", "on"	
alter (database-specific)	all	Database to be audited	Any	alter database, alter index, alter role, alter table, altermodify owner(including alter encryption key modify owner)	
	This example turns auditing on for all executions of alter commands in the master database:				
	S	p_audit @opti @object_na:	<pre>ton = "alter", me = "master",</pre>	<pre>@login_name = "all", @setting = "on"</pre>	
bcp (database-specific)	all	Database to be audited	Any	bcp in	

Option (op- tion type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited	
	This example returns the status of bcp auditing in the pubs 2 database:				
		sp_aı	ndit "bcp", "al	11", "pubs2"	
	If you do not s	pecify a value for <	setting>, SAP ASE you specify	returns the status of auditing for the option	
bind	all	Database to be audited	Any	sp_bindefault	
(database-specific)				sp_bindmsg	
				sp_bindrule	
		This example turn	ns bind auditing off fo	or the planning database:	
		sp_audit "	bind", "all",	"planning", "off"	
cluster	<pre>all, <login>, or <role></role></login></pre>	all	Any	Cluster commands	
(global)	This example turns on auditing for cluster commands:				
	sp audit "cluster", "all", "all", "on"				
		_			
cmdtext (user-specific)	Login name of the user to be audited	all	Any	SQL text entered by a user. (Does not reflect whether or not the text in question passed permission checks or not. <pre><eventmod> always has a value of 1.)</eventmod></pre>	
		This example	turns text auditing o	off for database owners:	
		sp_audit	"cmdtext", "sa	a", "all", "off"	
config_history (global)	all, <login>, or <role></role></login>	all	Any	Configuration history	
(0)	This example turns on auditing for configuration history:				
		sp_audit "co	nfig_history",	"all", "all", "on"	
create (database-specific)	all	Database to be audited	Any	create database, create default, create function, create index, create procedure, create role, create rule, create service, create table, create trigger, create view, sp_addmessage	

Option (option type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited		
	Specify mas	_	i Note	ate database. You are also auditing the ts in master.		
	This examp	ole turns on auditin	g of successful objec	et creations in the planning database:		
		sp_audit "cr	reate", "all",	"planning", "pass"		
	The current sta	The current status of auditing create database is not affected because you did not specify the master database.)				
dbaccess (database-specific)	all	Database to be audited	Any	Any access to the database from another database		
	This example audits all external accesses to the project database:					
		sp_audit "d	baccess", "all	", "project", "on"		
dbcc	<pre>all, <login>, or <role></role></login></pre>	all	Any	All dbcc commands		
(global)	This example audits all executions of the dbcc command:					
	sp_audit "dbcc", "all", "all", "on"					
delete (object-specific)	all	Name of the ta- ble or view to be audited, or default view or default table	The database of the table or view (except tempdb)	delete from a table, delete from a view		
	This example audits all delete actions for all future tables in the current database:					
	sp_audit "delete", "all", "default table", "on"					
deny	all	all	Any	deny		
(database-specific)		This example	e turns auditing on fo	or the command deny:		
		sp_audit	"deny", "all",	, "master", "on"		

Option (option type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited		
disk (global)	all, <login>, or<role></role></login>	all	Any	disk init, disk mirror, disk refit, disk reinit, disk remirror, disk resize, disk unmirror		
		This exam	nple audits all disk ac	ctions for the server:		
		sp_audi	t "disk", "all	", "all", "on"		
drop (database-specific)	all	Database to be audited	Any	drop database, drop default, drop function, drop index, drop procedure, drop role, drop rule, drop service, drop table, drop trigger, drop view, sp_dropmessage		
	This example a	This example audits all drop commands in the financial database that fail permission checks:				
		sp_audit "d:	rop", "all", "	financial", "fail"		
dump (database-specific)	all	Database to be audited	Any	dump database, dump databasecumulative, dump transaction		
		This example au	dits dump command	ds in the pubs2 database:		
		sp_audit	"dump", "all"	, "pubs2", "on"		
dump_config (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	dump configuration to		
(0)	This example enables auditing for dump configuration to command:					
		sp_audit "du	ump_config", "a	all", "all", "pass"		
encryption_key (database-specific)	all	Database to be audited	Any	alter encryption key create encryption key drop encryption key sp_encryption		
	1	This example audits	s all the above comm	nands in the pubs 2 database:		
	S	sp_audit "enc:	ryption_key",	"all", "pubs2", "on"		

Option (option type)	login_role_nam e	object_name	Database to be in to set the option	
errors (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	Fatal error, non-fatal error
,		This exan	nple audits errors thi	roughout the server:
		sp_audit	"errors", "al	l", "all", "on"
		This example	e audits errors for th	eroleintern_role:
		sp_audit "er	rrors", "inter	n_role", "all", "on"
errorlog (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	sp_errorlog
,	This exar	mple audits attemp	ots to "change log" to	nove to a new SAP ASE error log file:
		sp_audit	"errorlog", "a	all", "all", "on"
exec_procedure (object-specific)	all	Name of the procedure to be audited or default procedure	The database of the procedure (ex- cept tempdb)	execute
	This exar	nple turns automa	tic auditing off for ne	ew procedures in the current database:
	sp_audi	t "exec_proce	edure", "all",	"default procedure", "off"
exec_trigger (object-specific)	all	Name of the trig- ger to be audited or default trigger	The database of the trigger (except tempdb)	Any command that fires the trigger
	This example a	udits all failed exec	cutions of the trig_	_fix_plan trigger in the current database:
	sp_au	dit "exec_tri	gger", "all",	"trig_fix_plan", "fail"
func_dbaccess (database-specific)	all	Name of the da- tabase you are auditing	Any	Access to a database using built-in functions.
	This e	xample audits acce	esses to the strate	egy database via built-in functions:
	sp_a	audit @option: @object_nam	="func_dbacces ne = "strategy	ss", @login_name="all", ", @setting = "on"
func_obj_acces s (object-specific)	all	Name of any object that has an entry in sysobjects	Any	Access to an object using built-in functions.

Option (option type)	login_role_nam e object_na	Database to be to set the option			
	This example a	udits accesses to the cu	stomer table via built-in functions:		
	sp_audit @op @objec	tion="func_obj_ac ct_name = "custom	ccess", @login_name="all", er", @setting = "on"		
grant	all Name of t	•	grant,grant role		
(database-specific)	audited	De .			
	This ex	xample audits all grants i	n the planning database:		
	sp_audit @optic	on="grant", @logi "planning", @se	n_name="all", @object_name = etting = "on"		
insert (object-specific)	all Name of t view or ta which you serting ro default view or default table	ble to the object (exce are in-tempdb) ws, or			
			101_view view in the current database: , "dpt_101_view", "on"		
install (database-specific)	all Database audited	to be Any	installjava		
(uatabase-specific)	This example a	nudits the installation of ja	ava classes in database planning:		
	sp_aud	it "install", "al	l", "planning", "on"		
load	all Database audited	to be Any	load database, load		
(database-specific)	addited		databasecumulative load transaction		
	This example audits all failed executions of database and transaction loads in the projects_db database:				
	sp_audi	t "load", "all",	"projects_db", "fail"		
login	all, <login>, all</login>	Any	Any login attempt to SAP ASE.		
(global)	or <role></role>				

Option (option type)	login_role_nam e	object_name	Database to be			
	This exar	nple audits all f	ailed attempts to log	in to the server by logins granted to role1:		
		sp_audi	t "login", "ro	lel", "all", "fail"		
		This examp	ole audits all logins w	with the role intern_role:		
		sp_audit	"all", "inter	n_role", "all", "on"		
login_admin (global)	<pre>all,<login>, or<role></role></login></pre>	all	Any	alter login, create login, drop login		
		This exa	mple enables auditir	ng for login administration:		
		sp_audit	"login_admin"	, "all", "all", "on"		
login_locked (global)	all, <login>, or <role></role></login>	all	Any	The host name and network IP address when a login account is locked due to exceeding the configured number of failed login attempts		
	This example shows that the login is locked because of exceeding the configured number of failed login attempts:					
		sp_audit	"login_locked'	", "all", "all", "on"		
logout (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	Any logout from SAP ASE		
	This example turns auditing off of logouts from the server:					
	sp_audit "logout", "all", "all", "off"					
mount (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	mount database		
	This example audits all mount database commands issued:					
		sp_au	dit "mount", "	all", "all", "on"		
password (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	Setting of global password and login policy options		
	This example turns auditing on for passwords:					
		sp_audi	t "password",	"all", "all", "on"		
quiesce (global)	all, <login>, Or <role></role></login>	all	Any	quiesce database,prepare database		

Option (op- tion type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited		
	Т	his example turns a	auditing on for quie	esce database commands:		
		sp_audit	"quiesce", "a	ll", "all", "on"		
reference (object-specific)	all	Name of the view or table to which you are inserting rows, or default view or default table	Any	Referencing a table with create table or alter table		
	This ex			n of references to the titles table: l", "titles", "off"		
remove	all	all	Any	The removal of Java classes		
(database-specific)	This			sses in the planning database: , "planning", "on"		
revoke (database-specific)	all	Database to be audited	Any	revoke, revoke role		
	This example turns off auditing of the execution of revoke in the payments_db database:					
		sp_audit "rev	voke", "all",	"payments_db", "off"		
role (global)	all, <login>, or <role></role></login>	all	Any	alter role, create role, drop role, grant role, revoke role, set role		
	This example turns on auditing for role-related commands:					
	sp_audit "role", "all", "all", "on"					
role_locked (global)	all, <login>, or <role></role></login>	all	Any	alter rolelock		
		This exa	mple turns on auditi	ng for locking roles:		
		sp_audit "r	cole_locked",	"all", "all", "on"		

Option (op- tion type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited
rpc (global)	all, <login>, Or <role></role></login>	all	Any	Remote procedure calls (either in or out)
	Т	his example audits	all remote procedur	re calls out of or into the server:
		sp_audi	it "rpc", "all	", "all", "on"
security (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	Server-wide security-relevant events.
(8.000)	Т	his example audits	s server-wide securit	y-relevant events in the server:
		sp_audit	"security", "a	all", "all", "on"
security_profile (global)	all, <login>, or<role></role></login>	all	Any	alter login profile,create login profile,drop login profile
		This example	enables auditing for	login profile commands:
	5	sp_audit "sec	urity_profile'	', "all", "all", "on"
select (object-specific)	all	Name of the view or table to which you are inserting rows, or default view or default table	The database of the object (except tempdb)	select from a table, select from a view
	This exam	nple audits all failed	I selects from the cu	stomer table in the current database:
		sp_audit "se	elect", "all",	"customer", "fail"
setuser	all	all	Any	setuser
(database-specific)	Thi	s example audits a	ll executions of set	user in the projdb database:
	sp_audit "setuser", "all", "projdb", "on"			
sproc_auth (global)	all, <login>, Or<role></role></login>	all	Any	Auditing for authorization checks that are done inside system stored procedures.

Option (op- tion type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited		
		This	s example enables s	proc_auth:		
		sp_audit	'sproc_auth',	'all','all','on'		
table_access (user-specific)	Login name of the user to be audited.	all	Any	select, delete, update, or insert		
	Т	his example audits	all table accesses by	y the login named "smithson":		
	S	p_audit "tabl	e_access", "sr	mithson", "all", "on"		
thread_pool (global)	<pre>all, <login>, or <role></role></login></pre>	all	Any	alter thread pool, create thread pool, drop thread pool		
		This example	enables auditing for	thread pool commands:		
		sp_audit "t	hread pool", '	"all", "all", "on"		
transfer_table (object-specific)	all	Table to be audited	Any	transfer table.		
	This example audits transfer-relevant events in the server:					
		sp_audit "tr	ansfer_table",	, "all", "t1", "on"		
truncate (database-specific)	all	Database to be audited	Any	truncate table		
(**************************************	This example audits all table truncations in the customer database:					
		sp_audit "tr	runcate", "all'	", "customer", "on"		
unbind (database-specific)	all	Database to be audited	Any	<pre>sp_unbindefault,sp_unbindrule, sp_unbindmsg</pre>		
	This example audits all failed attempts of unbinding in the master database:					
		sp_audit "u	nbind", "all",	, "master", "fail"		
unmount	<pre>all, <login>, or <role></role></login></pre>	all	Any	unmount database		
(global)	This exam	ple audits all attem	npts to unmount or c	reate a manifest file with any database:		
		sp_audit	"unmount", "al	ll", "all", "on"		

Option (option type)	login_role_nam e	object_name	Database to be in to set the option	Command or access being audited		
update (object-specific)	This example a		the object (except tempdb)	update to a table, update to a view		
		sp_audit u	ipuate, aii ,	, "projects", "on"		
view_access (user-specific)	Login name of the user to be audited	all	Any	select, delete, insert, or update to a view		
	This example turns off view auditing of user "joe":					
		sp_audit "v	iew_access", "	joe", "all", "off"		

1.31 sp_autoconnect

(Component Integration Services only) Defines a passthrough connection to a remote server for a specific user, which allows the named user to enter passthrough mode automatically at login.

Syntax

```
sp_autoconnect <server>, {true | false}[, <loginame>]
```

Parameters

<server>

is the name of a server to which an automatic passthrough connection is made. <server> must be the name of a remote server already added by sp_addserver. This server cannot be the local server.

true | false

determines whether the automatic passthrough connection is enabled or disabled for <server>. true enables the automatic connection. false disables it.

<loginame>

specifies the name of the user for which automatic connection is required. If no <loginame> is supplied, the autoconnect status is modified for the current user.

Examples

Example 1

The current user is automatically connected to the server MYSERVER the next time that user logs in. The user's connection is placed in passthrough mode:

```
sp_autoconnect MYSERVER, true
```

Example 2

Disables the autoconnect feature for the user "steve":

```
sp autoconnect MYSERVER, false, steve
```

Usage

- sp_autoconnect defines a passthrough connection to a remote server for a specific user, which allows the named user to enter passthrough mode automatically at login.
- Use sp autoconnect only when Component Integration Services is installed and configured.
- Do not change the autoconnect status of the "sa" login account.
- Changing the autoconnect status does not occur immediately for users who are currently connected. They must disconnect from the local server, then reconnect before the change is made.
- Use disconnect to exit passthrough mode.

See also connect to...disconnect, grant in Reference Manual: Commands.

Permissions

The permission checks for sp_autoconnect differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage any login privilege.
	Any user can execute sp_autoconnect for themselves.
Disabled	With granular permissions disabled, you must be a user with sa_role.

Setting Description

Any user can execute sp autoconnect for themselves.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_passthru [page 645]
sp_remotesql [page 690]
```

1.32 sp_autoformat

A utility stored procedure that produces readable result set data, sp_autoformat reformats the width of variable-length character data to display only non-blank characters. Trailing blanks are truncated in the output.

Syntax

```
sp_autoformat <fulltabname>[, <selectlist>, <whereclause>, <orderby>]
```

Parameters

<fulltabname>

specifies the name of table from which data is being selected. Use owner names if the object owner is not the user running the command.

<selectlist>

specifies the comma-separated list of columns to be selected in the result set. Columns in the table can be renamed using the <name> = <column> notation. See examples. If

<selectlist> is not provided, all columns in the table specified are output in column
ID order.

<whereclause>

is a search predicate, specified as a where clause, that filters out rows from the table being selected.

<orderby>

is an optional order by clause that specifies the order in which the output result set is presented.

Examples

Example 1

Returns a result set from a select statement similar to select id, colid, name from syscolumns where id = 3, where the character columns are autoformatted:

```
1> sp_autoformat "syscolumns", "id, colid, name", "where id = 3"
2> go
```

```
id
             colid name
                 1 id
           3
           3
                   2 number
           3
                  3 colid
           3
                  4 status
           3
                  5 type
                  6 length
           3
           3
                  7 offset
                 8 usertype
           3
           3
                  9 cdefault
           3
                 10 domain
           3
                 11 name
                 12 printfmt
13 prec
           3
           3
           3
                 14 scale
                 15 remote_type
16 remote_name
           3
           3
           3
                 17 xstatus
           3
                 18 xtype
           3
                  19 xdbid
           3
                  21 accessrule
                  22 status2
```

Example 2

Renames the output columns using the following syntax:

```
[ <AS-Name label of Column> ][ ]*=[ ]*<column name>
```

<AS-Name label of Column> is optional, and you can use white spaces around the = separator:

```
_____
        3 id
         3 number
         3 status
         3 type
         3 length
         3 offset
         3 usertype
3 cdefault
         3 domain
                           10
         3 name
                           11
         3 printfmt
                           12
         3 prec
3 scale
                           14
         3 remote_type
3 remote_name
                          15
                           16
                           17
         3 xstatus
         3 xtype
                           18
                           19
21
         3 xdbid
         3 accessrule
         3 status2
                           22
(1 row affected)
```

Uses the <orderby> parameter to specify an ordering in the result output:

Example 4

Generates an autoformatted result when you select from multiple tables, or if you have a complex SQL select statement with expressions in the select list, you must:

1. Use temporary tables to generate the result set:

The following generates the list of the columns with the highest column ID on all system catalogs:

The following generates the same result set with auto-formatting of character data using a temporary table to produce readable output, and includes minor changes to provide column names in the temporary table:

2. Use sp autoformat on that temporary table to produce formatted output:

```
1> exec sp_autoformat @fulltabname = #result, @orderby = "order by
    ObjectName"
2> go
```

```
11 sysalternates 2 altsuid
21 sysattributes 13 comments
55 syscertificates 6 suid
45 syscharsets 8 sortfile
3 syscolumns 22 status2
6 syscomments 8 status
37 sysconfigures 9 value4
17 sysconstraints 7 spare2
38 syscurconfigs 15 type
30 sysdatabases 19 status4
12 sysdepends 10 readobj
35 sysdevices 7 mirrorname
43 sysengines 12 starttime
...
(1 row affected)
(return status = 0)
```

The order by clause in the original select statement is skipped when generating the temporary table, and is instead added to the call to sp_autoformat when generating the output result You can further process the temporary table to report only on the required output for selected tables, as shown below:

Usage

- In SAP ASE version 15.0.3 and higher, sp_autoformat accepts columns of datatypes int (smallint, bigint, tinyint, unsigned int), numeric, money, date/time, and float, real, and double precision.
- sp_autoformat looks for an object only in the current database. To use sp_autoformat on temporary tables, issue the procedure from tempdb.
- sp_autoformat does not validate that the columns referenced in any of the parameters actually exist in the table specified by the <fulltabname> parameter. sp_autoformat fails if you reference any nonexistent columns.
- Provide only one instance of a column in the select list.

Return codes are:

- 0 successful completion
- 1 internal error, or usage error in invocation
- Other any other errors raised by the SAP ASE server during the execution of the generated SQL statement are returned back to the caller.

Restrictions for sp autoformat are:

- sp_autoformat uses internal SQL variables to generate SQL statements that are then executed using execute immediate. The length of the generated SQL statement is limited to 2K bytes. Auto-formatting result sets for a large column list, or columns with long names can sometimes cause an error due to insufficient size of the buffer for the generated SQL statement.
- Quoted identifiers are not supported for either the table or column names. If you have result sets that use quoted identifiers and that need autoformatting:
 - 1. Generate the required data in a temporary table, where the columns in the temporary table do not have any quoted identifiers.
 - 2. Use sp autoformat to produce the required output using the temporary table.
 - 3. Rename the columns in the <selectlist> in the desired output format.

Permissions

No permission checks are performed for sp_autoformat. Permission checks do not differ based on the granular permissions settings. Users selecting from the tables must have appropriate select privileges.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.33 sp_bindcache

Binds a database, table, index, text object, or image object to a data cache.

Syntax

```
sp_bindcache <cachename>, <dbname>
   [, [<ownername>.]<tablename>
       [, <indexname> | "text only"]]
```

Parameters

<cachename>

is the name of an active data cache.

<dbname>

is the name of the database to be bound to the cache or the name of the database containing the table, index, text or image object to be bound to the cache.

<ownername>

is the name of the table's owner. If the table is owned by "dbo", the owner name is optional.

<tablename>

is the name of the table to be bound to the cache, or the name of the table with an index, text object, or image object that is to be bound to the cache.

<indexname>

is the name of the index to be bound to the cache.

text only

binds text or image objects to a cache. When this parameter is used, you cannot give an index name at the same time.

Examples

Example 1

Binds the titles table to the cache named pub cache:

```
sp bindcache pub cache, pubs2, titles
```

Example 2

Binds the clustered index titles.title id cix to the pub ix cache:

```
sp_bindcache pub_ix_cache, pubs2, titles, title_id_cix
```

Example 3

Binds pubs2 to the tempdb cache:

```
sp_bindcache tempdb_cache, pubs2
```

Example 4

Binds the pubs2 transaction log, syslogs, to the cache named logcache:

```
sp_bindcache logcache, pubs2, syslogs
```

Example 5

Binds the image chain for the au pix table to the cache named pub cache:

```
sp_bindcache pub_cache, pubs2, au_pix, "text only"
```

Usage

- A database or database object can be bound to only one cache. You can bind a database to one cache and bind individual tables, indexes, text objects, or image objects in the database to other caches. The database binding serves as the default binding for all objects in the database that have no other binding. The data cache hierarchy for a table or index is as follows:
 - If the object is bound to a cache, the object binding is used.
 - If the object is not bound to a cache, but the object's database is bound to a cache, the database binding is used.
 - o If neither the object nor its database is bound to a cache, the default data cache is used.
- The cache and the object or database being bound to it must exist before you can execute sp_bindcache. Create a cache with sp_cacheconfig and, if the operation is not dynamic, restart the SAP ASE server before binding objects to the cache.
- Cache bindings take effect immediately, and do not require a restart of the server. When you bind an object to a data cache:
 - Any pages for the object that are currently in memory are cleared.
 - When the object is used in queries, its pages are read into the bound cache.
- You can bind an index to a different cache than the table it references. If you bind a clustered index to a cache, the binding affects only the root and intermediate pages of the index. It does not affect the data pages (which are, by definition, the leaf pages of the index).
- To bind a database, you must be using the master database. To bind tables, indexes, text objects, or image objects, you must be using the database where the objects are stored.
- To bind any system tables in a database, you must be using the database and the database must be in single-user mode. Use the command:

```
sp dboption <db name>, "single user", true
```

For more information, see sp dboption.

- You do not have to unbind objects or databases in order to bind them to a different cache. Issuing sp_bindcache on an object that is already bound drops the old binding and creates the new one.
- sp_bindcache needs to acquire an exclusive table lock when you are binding a table or its indexes to a cache so that no pages can be read while the binding is taking place. If a user holds locks on a table, and you issue sp_bindcache on that object, the task doing the binding sleeps until the locks are released.
- When you bind or unbind an object, all stored procedures that reference the object are recompiled the next time they are executed. When you change the binding for a database, all stored procedures that reference objects in the bound database are recompiled the next time they are executed.
- When you drop a table, index, or database, all associated cache bindings are dropped. If you re-create the table, index, or database, you must use sp bindcache again if you want it bound to a cache.
- If a database or a database object is bound to a cache, and the cache is dropped, the cache bindings are marked invalid, but remain stored in the sysattributes system table(s). Warnings are printed in the error log when the SAP ASE server is restarted. If a cache of the same name is created, the bindings become valid when the SAP ASE server is restarted.
- The following procedures provide information about the bindings for their respective objects: sp_helpdb for databases, sp_help for tables, and sp_helpindex for indexes. sp_helpcache provides information about all objects bound to a particular cache.

- Use sp_spaceused to see the current size of tables and indexes, and sp_estspace to estimate the size of tables that you expect to grow. Use sp_cacheconfig to see information about cache size and status, and to configure and reconfigure caches.
- Although you can still use sp_bindcache on a system tempdb, the binding of the system tempdb is now non-dynamic. Until you restart the server:
 - The changes do not take effect
 - o sp_helpcache reports a status of "P" for pending, unless you have explicitly bound the system tempdb to the default data cache, in which case the status as "V" for valid, because by default the system tempdb is already bound to the default datacache.

Restrictions for sp bindcache are:

• The sysattributes system table cannot be bound to a named cache. For example:

```
1> sp_bindcache 'systables_cache', pubs2, sysattributes
2> go
Msg 867, Level 16, State 1:
Server 'marina_157', Procedure 'sp_bindcache', Line 409:
The system table Sysattributes or its indices may not be bound to a named cache.
(1 row affected)
Msg 19828, Level 16, State 1:
Server 'marina_157', Procedure 'sp_bindcache', Line 416:
Cache binding failed for database 'pubs2'.
(return status = 1)
```

- The master database, the system tables in master, and the indexes on the system tables in master cannot be bound to a cache. You can bind non-system tables from master, and their indexes, to caches.
- You cannot bind a database or an object to a cache if:
 - Isolation level 0 reads are active on the table
 - The task doing the binding currently has a cursor open on the table
- If a cache has the type log only, you can bind a syslogs table only to that cache. Use sp_cacheconfig to see a cache's type.

Permissions

The permission checks for sp bindcache differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage data cache privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

```

1.34 sp_bindefault

Binds a user-defined default to a column or user-defined datatype.

Syntax

```
sp_bindefault <defname>, <objname> [, futureonly]
```

Parameters

<defname>

is the name of a default created with create default statements to bind to specific columns or user-defined datatypes.

<objname>

is the name of the table and column, or user-defined datatype, to which the default is to be bound. If the <objname> parameter is not of the form ".<column>", it is assumed to be a user-defined datatype. If the object name includes embedded blanks or punctuation, or is a reserved word, enclose it in quotation marks.

Existing columns of the user-defined datatype inherit the default <defname>, unless you specify futureonly.

You cannot bind defaults to computed columns.

futureonly

prevents existing columns of a user-defined datatype from acquiring the new default. This parameter is optional when you are binding a default to a user-defined datatype. It is never used to bind a default to a column.

Examples

Example 1

Assuming that a default named today has been defined in the current database with create default, this command binds it to the startdate column of the employees table:

```
sp_bindefault today, "employees.startdate"
```

Each new row added to the employees table has the value of the today default in the startdate column, unless another value is supplied.

Example 2

Assuming that a default named def_ssn and a user-defined datatype named ssn exist, this command binds def ssn to ssn:

```
sp_bindefault def_ssn, ssn
```

The default is inherited by all columns that are assigned the user-defined datatype ssn when a table is created. Existing columns of type ssn also inherit the default def_ssn, unless you specify futureonly (which prevents existing columns of that user-defined datatype from inheriting the default), or unless the column's default has previously been changed (in which case the changed default is maintained).

Example 3

Binds the default def ssn to the user-defined datatype ssn:

```
sp_bindefault def_ssn, ssn, futureonly
```

Because the future only parameter is included, no existing columns of type ssn are affected.

Usage

There are additional considerations when using sp_bindefault:

- You can create column defaults in two ways: by declaring the default as a column constraint in the create table or alter table statement or by creating the default using the create default statement and binding it to a column using sp_bindefault. Using create default, you can bind that default to more than one column in the database.
- You cannot bind a default to an SAP ASE server-supplied datatype.
- You cannot bind a default to a system table.
- Defaults bound to a column or user-defined datatype with the IDENTITY property have no effect on column values. Each time you insert a row into the table, the SAP ASE server assigns the next sequential number to the IDENTITY column.

- If binding a default to a column, give the <objname> argument in the form ".<column>". Any other format is assumed to be the name of a user-defined datatype.
- If a default already exists on a column, you must remove it before binding a new default. Use sp_unbindefault to remove defaults created with sp_bindefault. To remove defaults created with create table or alter table, use alter table to replace the default with NULL.
- Existing columns of the user-defined datatype inherit the new default unless you specify futureonly.
 New columns of the user-defined datatype always inherit the default. Binding a default to a user-defined datatype overrides defaults bound to columns of that type; to restore column bindings, unbind and rebind the column default.
- Statements that use a default cannot be in the same batch as their sp bindefault statement.

See also create default, create table, drop default in Reference Manual: Commands.

Permissions

You must be the table owner or the user datatype owner to execute <code>sp_bindefault</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

You can enable bind auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	bind
Event	6
Command or access audited	sp_bindefault
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Name of the default Other information – Original login name, if set proxy in effect

Example of extrainfo for after executing sp_bindefault:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; test_default; ; s
     a/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_unbindefault [page 822]

1.35 sp_bindexeclass

Associates an execution class with a client application, login, stored procedure, or default execution class.

Syntax

```
sp bindexeclass "<object name>", "<object type>", "<scope>", "<classname>"
```

Parameters

<object name>

is the name of the client application, login, or stored procedure to be associated with the execution class, classname. If <object type> is df, it should be null.

<object_type>

identifies the type of object_name. Use:

- ap for application
- df for user-defined default execution class
- 1g for login
- pr for stored procedure
- sv for a service task (valid only in threaded mode)

<scope>

is the name of a client application or login, or it can be NULL for ap, df, lg, or sv objects. For objects, scope is the name of the stored procedure owner (user name). When the object with object_name interacts with the application or login, classname attributes apply for the <scope> you set.

<classname>

specifies the type of class to associate with object name. Values are:

- EC1, EC2, or EC3
- The name of a user-defined execution class
- ANYENGINE

Examples

Example 1

This statement specifies that Transact-SQL applications execute with EC3 attributes for any login or application process (because the value of <scope> is NULL) that invokes isql, unless the login or application is bound to a higher execution class:

```
sp_bindexeclass 'isql', 'ap', NULL, 'EC3'
```

Example 2

This statement specifies that when a login with the system administrator role executes Transact-SQL applications, the login process executes with EC1 attributes. If you have already executed the statement in the first example, then any other login or client application that invokes isql executes with EC3 attributes:

```
sp_bindexeclass 'sa', 'lg', 'isql', 'EC1'
```

Example 3

This statement assigns EC3 attributes to the stored procedure named my proc owned by user kundu:

```
sp_bindexeclass 'my_proc', 'PR', 'kundu', 'EC3'
```

Example 4

This statement assigns CLASS1 attributes to all tasks that are running with default execution attributes:

```
sp_bindexeclass NULL, 'DF', NULL, 'CLASS1'
```

Example 5

Binds the license heartbeat operation to the core execution task:

```
sp_bindexeclass "License Heartbeat", sv, NULL, core
```

Usage

There are additional considerations when using <code>sp_bindexeclass</code>:

- When binding an execution class to a default execution class, all tasks running with default execution attributes run with attributes of the new class.
- You can bind service tasks to existing execution classes created to manage user tasks. That is, service tasks and user tasks can coexist in the same execution class.
- The monServiceTask monitoring table includes all services tasks, including their name and current binding.
- sp_bindexeclass associates an execution class with a client application, login, or stored procedure. It can also associate an execution class to the default execution class. Use sp_addexeclass to create execution classes.
- When scope is NULL, object_name has no scope. classname's execution attributes apply to all of its interactions. For example, if object_name is an application name, the attributes apply to any login process that invokes the application. If object_name is a login name, the attributes apply to a particular login process for any application invoked by the login process.

- When binding a stored procedure to an execution class, you must use the name of the stored procedure owner (user name) for the scope parameter. This narrows the identity of a stored procedure when there are multiple invocations of it in the same database.
- Due to precedence and scoping rules, the execution class being bound may or may not have been in effect for the object called object name. The object automatically binds itself to another execution class, depending on other binding specifications, precedence, and scoping rules. If no other binding is applicable, the object binds to the default execution class. If you do not specify a user-defined default execution class, then the object binds to the system-defined execution class EC2.
- You can use sp bindexeclass to bind a RepAgent thread to an execution class using rep agent as the application without generating an error. However, because of restrictions in the SAP ASE server, the priority attribute is set to medium, and the binding has no effect.
- Binding fails when you attempt to bind an active process to an engine group with no online engines.
- The SAP ASE server creates a row in the sysattributes table containing the object ID and user ID in the row that stores data for the binding.
- A stored procedure must exist before it can be bound.
- Stored procedure bindings must be done in the database in which the stored procedure resides. Therefore, when binding system procedures, execute sp bindexeclass from within the sybsystemprocs database.
- Only the "priority attribute" of the execution class is used when you bind the class to a stored procedure.
- The name of the owner of a stored procedure must be supplied as the scope parameter when you are binding a stored procedure to an execution class. This helps to uniquely identify a stored procedure when multiple stored procedures with the same name (but different owners) exist in the database.

See also isql in the Utility Guide.

Permissions

The permission checks for sp bindexeclass differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage any execution class privilege.

For ECO, you must be a user with manage any execution class and sybase_ts_role.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

For ECO, you must be a user with sa_role and sybase_ts_role.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addexeclass [page 35]
sp_showexeclass [page 744]
sp_unbindexeclass [page 825]

1.36 sp_bindmsg

Binds a user message to a referential integrity constraint or check constraint.

Syntax

sp_bindmsg <constrname>, <msgid>

Parameters

<constrname>

is the name of the integrity constraint to which you are binding a message. Use the constraint clause of the create table command, or the add constraint clause of the alter table command to create and name constraints.

<msgid>

is the number of the user message to be bound to an integrity constraint. The message must exist in the sysusermessages table in the local database prior to calling sp_bindmsg.

Examples

Example 1

Binds user message number 20100 to the positive balance constraint:

sp_bindmsg positive_balance, 20100

Usage

There are additional considerations when using sp bindmsg:

- sp_bindmsg binds a user message to an integrity constraint by adding the message number to the constraint row in the sysconstraints table.
- Only one message can be bound to a constraint. To change the message for a constraint, just bind a new message. The new message number replaces the old message number in the sysconstraints table.
- You cannot bind a message to a unique constraint because a unique constraint does not have a constraint row in sysconstraints (a unique constraint is a unique index).
- Use the sp addmessage procedure to insert user messages into the sysusermessages table.
- The sp getmessage procedure retrieves message text from the sysusermessages table.
- sp help <tablename> displays all constraint names declared on <tablename>.

See also alter table, create table in Reference Manual: Commands.

Permissions

You must be the constraint owner to execute $sp_bindmsg$. Permission checks do not differ based on the granular permissions settings.

Auditing

You can enable bind auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value	
Audit option	bind	
Event	7	
Command or access audited	sp_bindmsg	
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Message ID Proxy information – Original login name, if set proxy in effect 	

Example of extrainfo after executing sp bindmsg:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; 21000; ; s
    a/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addmessage [page 47]
sp_getmessage [page 390]
sp_unbindmsg [page 827]
```

1.37 sp_bindrule

Binds a rule to a column or user-defined datatype.

Syntax

sp_bindrule <rulename>, <objname>[, futureonly]

Parameters

<rulename>

is the name of a rule. Create rules with create rule statements and bind rules to specific columns or user-defined datatypes with sp_bindrule.

<objname>

is the name of the table and column, or user-defined datatype, to which the rule is to be bound. If <objname> is not of the form ".<column>", it is assumed to be a user-defined datatype. If the object name has embedded blanks or punctuation, or is a reserved word, enclose it in quotation marks.

futureonly

prevents existing columns of a user-defined datatype from inheriting the new rule. This parameter is optional when you bind a rule to a user-defined datatype. It is meaningless when you bind a rule to a column.

Examples

Example 1

Assuming that a rule named today has been created in the current database with create rule, this command binds it to the startdate column of the employees table. When a row is added to employees, the data for the startdate column is checked against the rule today:

```
sp bindrule today, "employees.startdate"
```

Example 2

Assuming the existence of a rule named rule_ssn and a user-defined datatype named ssn, this command binds rule_ssn to ssn. In a create table statement, columns of type ssn inherit the rule rule_ssn. Existing columns of type ssn also inherit the rule rule_ssn, unless ssn's rule was previously changed (in which case the changed rule is maintained in the future only):

```
sp_bindrule rule_ssn, ssn
```

Example 3

The rule rule_ssn is bound to the user-defined datatype ssn, but no existing columns of type ssn are affected. futureonly prevents existing columns of type ssn from inheriting the rule:

```
sp_bindrule rule_ssn, ssn, futureonly
```

Usage

There are additional considerations when using sp bindrule:

- Create a rule using the create rule statement. Then execute sp_bindrule to bind it to a column or user-defined datatype in the current database.
- Rules are enforced when an insert is attempted, not when sp_bindrule is executed. You can bind a character rule to a column with an exact or approximate numeric datatype, even though such an insert is illegal.
- You cannot use sp bindrule to bind a check constraint for a column in a create table statement.
- You cannot bind a rule to an SAP ASE server-supplied datatype or to a text or an image column.
- You cannot bind a rule to a system table.
- You cannot bind a rule to a computed column.
- If you are binding to a column, the <objname> argument must be of the form ".<column>". Any other format is assumed to be the name of a user-defined datatype.
- Statements that use a rule cannot be in the same batch as their sp bindrule statement.
- You can bind a rule to a column or user-defined datatype without unbinding an existing rule. Rules bound to columns always take precedence over rules bound to datatypes. Binding a rule to a column replaces a rule bound to the datatype of that column; however, binding a rule to a datatype does not replace a rule bound to a column of that user-defined datatype.
- Existing columns of the user-defined datatype inherit the new rule unless their rule was previously changed, or the value of the optional third parameter is futureonly. New columns of the user-defined datatype always inherit the rule.

See also create rule, drop rule in Reference Manual: Commands.

Permissions

You must be the table owner or user datatype owner to execute <code>sp_bindmsg</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

You can enable bind auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	bind
Event	8
Command or access audited	sp_bindrule
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Name of the rule Proxy information – Original login name, if set proxy in effect

Example of extrainfo after executing sp_bindrule:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; test_rule; ; s
    a/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_unbindrule [page 829]

1.38 sp_cacheconfig

Creates, configures, reconfigures, and drops data caches, and provides information about them.

Syntax

Parameters

<cachename>

is the name of the data cache to be created or configured. Cache names must be unique, and can be up to 30 characters long. A cache name does not have to be a valid SAP ASE identifier, that is, it can contain spaces and other special characters.

<cache_size>[P|K|M|G]

is the size of the data cache to be created or, if the cache already exists, it is the new size of the data cache. The minimum size of a row_cache is 265 times the logical page size of the server. Size units can be specified with P for pages, K for kilobytes (the default), M for megabytes, or G for gigabytes. For megabytes and gigabytes, you can specify floating-point values. The cache size is in multiples of the logical page size.

- logonly indicates the cache is only for log.
- mixed indicates the cache is for log and data.
- inmemory_storage indicates that you are creating a cache for an in-memory or relaxed-durability database.
- lockless data cache indicates that you are creating a lockless cache with relaxed cache replacement policy.
- row_storage indicates you are creating a cache for in-memory row storage and storing data as rows, rather than in pages or buffers

strict | relaxed

specifies the cache replacement policy.

```
cache_partition=[1 | 2 | 4 | 8 | 16 | 32 | 64 | 128 | 256]
```

specifies the number of partitions to create in the cache.

instance <instance_name>

(in cluster environments) is the name of the instance with a cache that you are adjusting.

Examples

Example 1

Creates the data cache pub_cache with 10 MB of space. All space is in the default logical page size memory pool:

```
sp_cacheconfig pub_cache, "10M"
```

Example 2

Reports the current configuration of pub_cache and any memory pools in the cache:

```
sp_cacheconfig pub_cache
```

Example 3

Drops pub_cache at the next start of the SAP ASE server:

```
sp_cacheconfig pub_cache, "0"
```

Example 4

Creates pub log cache and sets its type to logonly in a single step:

```
sp_cacheconfig pub_log_cache, "2000K", logonly
```

Example 5

The first command creates the cache pub_log_cache with the default type mixed. The second command changes its status to logonly. The resulting configuration is the same as that in example 4:

```
sp_cacheconfig pub_log_cache, "2000K"
sp_cacheconfig pub_log_cache, logonly
```

Example 6

Creates a cache and sets the size, type, replacement policy and number of cache partitions:

```
sp_cacheconfig 'newcache', '50M', mixed, strict, "cache_partition=2"
```

Example 7

Creates an in-memory storage named pubs3_imdb:

```
sp_cacheconfig pubs_imdb, '500M', inmemory_storage
```

Example 8

(In cluster environments) Displays the cache for instance blade1:

```
sp_cacheconfig 'instance blade1'
```

Example 9

(In cluster environments) Sets the size of the Sales Cache size on blade1 to 100 MB:

```
sp_cacheconfig 'Sales Cache', '100M', 'instance blade1'
```

Example 10

(In cluster environments) Sets the size of the Sales Cache size on blade1 to 0 megabytes, effectively dropping the cache.

```
sp_cacheconfig 'Sales Cache', 'OM', 'instance blade1'
```

Example 11

Creates a 20-gigabyte row storage cache for the pubs2 database:

```
sp_cacheconfig "pubs2_row_cache", "20G", "row_storage"
```

Example 12

Reports on the imrs pub cache:

```
sp cacheconfig imrs_pub_cache
      Config Value
Cache Name
                              Run Value
       ------
imrs_pub_cache
          500.00 Mb
                           Active
                                            Row Storage
                                      500.00 Mb
(1 row affected)
                   Total 500.00 Mb 500.00 Mb
Cache: imrs_pub_cache, Status: Active, Type: Row Storage
     Config Size: 500.00 Mb, Run Size: 500.00 Mb
Config Replacement: none, Run Replacement: none
Config Partition: 1, Run Partition:
                                                                1
(return status = 0)
```

Example 13

Increases the size of the pubs2 row cache:

```
sp_cacheconfig "pubs2_row_cache", "30g"
```

Example 14

Decreases the size of the pubs2 row cache (requires a server restart to take effect):

```
sp_cacheconfig "pubs2_row_cache", "10g"
```

26 sp_cacheconfig "pubs2_vlink_cache", "10g"

Example 15

Grows the imrs pub cache to 500MB:

```
sp_cacheconfig imrs_pub_cache, "500M", "row_storage"
```

Example 16

Creates a 1-gigabyte lockless data cache named sys_cache:

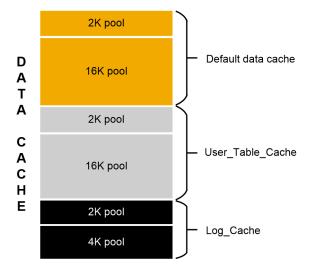

```
sp_cacheconfig "sys_cache", "1G", "lockless data cache", "relaxed"
```

Usage

- The minimum cache size of the row_cache is 265MB.
- If the SAP ASE server is unable to allocate all the memory requested while you are creating a new cache or adding memory to an existing cache, it allocates all the available memory. However, this additional memory is allocated at the next restart of the SAP ASE server.
- If there are objects bound to cache (including the default cache), you cannot delete the cache until you unbind the objects.
- (In cluster environments) If you do not specify an instance_name, the cache for the cluster is displayed.
- Some of the actions you perform with sp_cacheconfig are dynamic (do not require a restart of the SAP ASE server) and some are static (require a reboot). The dynamic and static actions are:

Dynamic sp_cacheconfig Actions	Static sp_cacheconfig Actions
Adding a new cache	Changing the number of cache partitions
Adding memory to an existing cache	Reducing a cache size
Deleting a cache	Changing the replacement policy
Changing a cache type	

- When you first create a data cache:
 - All space is allocated to the logical page size memory pool.
 - The default type is mixed.
- This figure shows a data cache for a 2K server with two user-defined data caches configured and the following pools:
 - The default data cache with a 2K pool and a 16K pool
 - o A user cache with a 2K pool and a 16K pool
 - A log cache with a 2K pool and a 4K pool

- The default data cache must always have the type default, and no other cache can have the type default.
- The SAP ASE housekeeper task does not do any buffer washing in caches with a type of logonly or in caches with a relaxed LRU replacement policy.
- The following commands perform only 2K I/O: disk init, some dbcc commands, and drop table. The dbcc checkdb and dbcc checktable commands can perform large I/O for tables, but perform 2K I/O on indexes. Cache usage for Transact-SQL commands, depending on the binding of the database or object, are:

Command	Database Bound	Table or Index is Bound	Database or Object Not Bound
create index	Bound cache	N/A	Default data cache
disk init	N/A	N/A	Default data cache
dbcc checkdb	Bound cache	N/A	Default data cache
dbcc checktable, indexalloc, tablealloc	Bound cache	Bound cache	Default data cache
drop table	Bound cache	Bound cache	Default data cache

- Recovery uses only the logical page size pool of the default data cache. All pages for all transactions that
 must be rolled back or rolled forward are read into and changed in this pool. Be sure that your default
 logical page size pool is large enough for these transactions.
- When you use sp_cacheconfig with no parameters, it reports information about all of the caches on the server. If you specify only a cache name, it reports information about only the specified cache. If you use a fragment of a cache name, it reports information for all names matching "%<fragment>%".
 All reports include a block of information that reports information about caches, and a separate block of data for each cache that provides information about the pools within the cache.
 The output below, from a server using 2K, shows the configuration for:

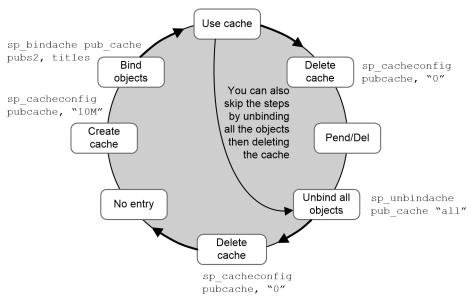

- The default data cache with two pools: a 2K pool and a 16K pool. The default data cache has 2 partitions.
- $\circ\ \ \text{pubs_cache}$ with two pools: 2K and 16K
- o pubs_log, with the type set to logonly and cache replacement policy set to relaxed, with a 2K pool
 and a 4K pool

Cache Name	Status	Type	Config Value	Run Value
default data cache pubs_cache pubs_log	Active Active Active	Default Mixed Log Only	0.00 Mb 10.00 Mb 2.40 Mb	26.09 Mb 10.00 Mb 2.40 M

The meaning of the columns in the output are:

Column	Meaning	
Cache Name	The name of the cache.	
Status	One of the following: o "Active" o "Pend/Act" The status "Pend" is short for pending. It always occurs in combination with either "Act" for Active or "Del" for Delete. It indicates that a configuration action has taken place, but that the server must be restarted in order for the changes to take effect.	
Туре	"Mixed" or "Log Only" for user-defined caches, "Default" for the default data cache.	
I/O Size	The size of I/O for a memory pool. This column is blank on the line that shows that cache configuration.	

Column	Meaning
Wash Size	The size of the wash area for the pool. As pages enter the wash area of the cache, they are written to disk. This column is blank on the line that shows the cache configuration.
Config Value or Config Size	The size that the cache or pool. If the value is 0, the size has not been explicitly configured, and a default value is used.
Run Value or Run Size	The size of the cache or pool now in use on the SAP ASE server.
Config/ Run Replacement	The cache policy (strict or relaxed) that is used for the cache after the next restart, and the current replacement policy. These differ only if the policy has been changed since the last reboot.
Config/Run Partition	The number of cache partitions that is used for the cache, and the current number of partitions. These differ if <code>sp_cacheconfig</code> has been used to change the number of partitions since the last reboot.
APF Percent	The percentage of buffers in the pool that can hold buffers that have been fetched by asynchronous prefetch, but have not been used.
Total	The total size of data cache, if the report covers all caches, or the current size of the particular cache, if you specify a cache name. The following figure illustrates the effects of restarts and ${\tt sp_cacheconfig}$ on Cache Status:

• You can also configure caches and pools by editing the configuration file. For more information, see the System Administration Guide.

Permissions

The permission checks for $sp_cacheconfig$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage data cache privilege.

Any user can execute sp_cacheconfig to view cache configurations

Disabled With granular permissions disabled, you must be a user with sa_role.

Any user can execute sp_cacheconfig to view cache configurations

Auditing

You can enable $config_history$ auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value	
Audit option	config history	
Event	154	
Command or access audited	sp_cacheconfig	
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Includes procedure name, parameter name, old value, new value, mode (static or active), and instance ID Proxy information – Original login name, if set proxy in effect 	

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_bindcache [page 103] sp_helpcache [page 420] sp_poolconfig [page 670] sp_unbindcache [page 818] sp_unbindcache_all [page 821]

1.38.1 Data Cache Memory

When the SAP ASE server is first installed, all data cache memory is assigned to the logical page size pool of the cache named default data cache. The default data cache is used by all objects that are not explicitly bound to a data cache with sp bindcache or with databases that are not bound to a cache.

- When you create data caches, the memory allocation is validated against max memory. Memory for caches is allocated out of the memory allocated to the SAP ASE server with the total logical_memory configuration parameter. To increase the amount of space available for caches, increase total logical memory, or decrease other configuration settings that use memory. If the sum of total logical memory and additional memory requested is greater than max memory, then the SAP ASE server issues and error and does not perform the changes.
 - The default cache is used for all objects, including system tables, that are not bound to another cache, and is the only cache used during recovery. For more information, see the System Administration Guide.
- A data cache requires a small percentage of overhead for structures that manage the cache. All cache overhead is taken from free memory. To see the amount of overhead required for a specific size of cache, use sp helpcache, giving the size:

```
sp_helpcache "200M"

10.38Mb of overhead memory will be needed to manage
a cache of size 200M
```

This is only an estimate of the overhead. The actual overhead may be larger because of runtime issues.

1.38.2 Creating Cache for In-Memory Databases

Information about creating cache for in-memory databases.

- The cache name cannot be longer than 127 bytes.
- The minimum size of in-memory storage cache is 256 logical pages (512K on a server using 2K logical pages).
- You cannot:
 - o Include the strict or relaxed replacement strategies for in-memory storage. By default, sp cacheconfig uses a replacement strategy of none for in-memory storage cache.
 - Create large I/O pools for in-memory storage cache (in-memory databases do not perform I/O). The SAP ASE server issues an error if you use sp_poolconfig to create buffer pools an in-memory storage cache.
 - Change the cache type from mixed to logonly, or vice versa.
 - Each cachlet in an in-memory cache must contain a full allocation unit of 256 pages. If the amount of space you request does not completely full all the allocation units, the server reduces the amount of space allocated until all remaining cachlets are full. The page size of the server determines the amount of space reduced. For example, on a server using 2K logical pages, sp_cacheconfig allocates 96MB of 100MB requested:

```
sp_cacheconfig tempdb_user_cache, "100M", "inmemory_storage",
"cache_partition=32"
go
```

```
sp cacheconfig tempdb user cache
go
Cache Name
                                     Status
                                             Config Value
         Type
        Run Value
        user_cache Active In-Memory Storage
 tempdb user cache
                                               100.00 Mb
             96.00 Mb
(1 row affected)
                          Total 100.00 Mb 96.00 Mb
______
Cache: tempdb_user_cache, Status: Active, Type: In-Memory Storage
     config Size: 100.00 Mb, Run Size: 96.00 Mb

Config Replacement: none, Run Replacement: none

Config Partition: 32, Run Partition:

ize Wash Size Config Size

Run Size APF Percent
            96.00 Mb 0
                                                 96.00 Mb
(return status = 0)
```

However, on a server that uses 8K logical pages, sp_cacheconfig allocates 64MB of the 100MB requested:

```
sp cacheconfig tempdb user cache, "100M", "inmemory storage",
"cache_partition=32"
sp_cacheconfig tempdb_user cache
go
Cache Name
       Type
                                       Config Value
       Run Value
                       Active
tempdb_user cache
       In-Memory Storage
                                          100.00 Mb
           64.00 Mb
(1 row affected)
                      Total 100.00 Mb 64.00 Mb
_____
Cache: tempdb_user_cache, Status: Active, Type: In-Memory Storage
     Config Size: 100.00 Mb, Run Size: 64.00 Mb

Config Replacement: none, Run Replacement: none
Config Partition: 32, Run Partition:
ize Wash Size Config Size
Run Size APF Percent
IO Size
                                     Config Size
       _____
           0 Kb
    8 Kb
                                            64.00 Mb
(return status = 0)
```

Consequently, if you issue a command to create a 100MB cache: For this issue to show up, it requires larger page size and large cache partition values. in this example, for an 8K server, 2M of space is needed for an allocation unit of 256 pages. With 32 cache partitions, that means that the the inmemory cache has to be divisible by $64 (32 \times 2)$. Hence the 100M is rounded down to 64M.

1.38.3 Creating Cache for In-Memory Row Storage

Information on creating cache for in-memory row storage.

- Creating in-memory row storage reserves system memory, so you must configure max memory to provide an adequate amount of memory. If the system has insufficient space to create an in-memory row storage for the specified size, it issues an error message prompting the user to increase the value for max memory.
- If you specify <cache_size> as a number of pages, sp_cacheconfig converts this page number to an amount of memory using the @@maxpagesize variable for the current installation.

Creating caches for in-memory row storage includes these restrictions:

- The cache name must be unique within the server installation (including across all other caches of any type).
- You cannot change an in-memory row storage cache to another type of cache. Instead, drop and then
 redeploy the memory to another cache type. Similarly, you cannot change other caches types to inmemory row storage caches.
- You can increase the size of an in-memory row storage cache, subject to available system memory.

 However, you cannot decrease its size without restarting the server, at which time the cache is resized to the lower limit.

i Note

Avoid storing a large number of rows in the cache and then reducing its size as there may not be sufficient memory when the server attempts to instantiate the contents of the in-memory row storage when the server restarts.

- You may dedicate a row storage cache exclusively to one database, and vice-versa. That is, you can create multiple in-memory row storage caches in a server, but they cannot be shared across databases.
- You cannot use the cache_partition or instance arguments when you create in-memory row storage caches.
- Each cachlet in an in-memory cache must contain a full allocation unit of 256 pages. If the amount of space you request does not completely full all the allocation units, the server reduces the amount of space allocated until all remaining cachlets are full. The page size of the server determines the amount of space reduced. For example, on a server using 2K logical pages, sp_cacheconfig allocates 96MB of 100MB requested:

```
sp_cacheconfig tempdb_user_cache, "100M", "inmemory_storage",
"cache_partition=32"
go
sp_cacheconfig tempdb_user_cache
go
Cache Name
Status
Type
Config Value
Run Value

Config Size: 100.00 Mb, Run Size: 96.00 Mb
```

```
Config Replacement: none, Run Replacement: none
Config Partition: 32, Run Partition: 32

IO Size Wash Size Config Size
Run Size APF Percent

2 Kb 0 Kb 96.00 Mb
96.00 Mb 0

(return status = 0)
```

However, on a server that uses 8K logical pages, sp_cacheconfig allocates 64MB of the 100MB requested:

```
sp cacheconfig tempdb user cache, "100M", "inmemory storage",
"cache_partition=32"
sp cacheconfig tempdb user cache
go
Cache Name
        Type
                                           Config Value
        Run Value
 tempdb_user_cache
                                   Active
      In-Memory Storage
                                              100.00 Mb
            64.00 Mb
(1 row affected)
                          Total 100.00 Mb 64.00 Mb
______
Cache: tempdb_user_cache, Status: Active, Type: In-Memory Storage
Config Size: 100.00 Mb, Run Size: 64.00 Mb
Config Replacement: none, Run Replacement: none
Config Partition: 32, Run Partition:
IO Size Wash Size Config Size
Run Size APF Percent
            0 Kb
64.00 Mb
     8 Kb
                                                64.00 Mb
(return status = 0)
```

Consequently, if you issue a command to create a 100MB cache: For this issue to show up, it requires larger page size and large cache partition values. in this example, for an 8K server, 2M of space is needed for an allocation unit of 256 pages. With 32 cache partitions, that means that the the inmemory cache has to be divisible by $64 (32 \times 2)$. Hence the 100M is rounded down to 64M.

1.38.4 Changing Existing Caches

To change the size of an existing cache, specify the cache's name and the new size.

If you increase the size of an existing cache, all of the added space is placed in the smallest pool.

To reduce the size of an existing cache, all of the space must be available in the logical page size pool. You may need to use sp_poolconfig to move space from other pools to this pool.

If you have a database or any nonlog objects bound to a cache, you cannot change its type to logonly.

1.38.5 Using Cache Partitions

Cache partitions can be used to reduce cache spinlock contention without needing to create separate caches and bind database objects to them.

For more information on monitoring cache spinlock contention, see the Performance and Tuning Guide.

You can set the default number of cache partitions for all caches with the configuration parameter global cache partition number. See the System Administration Guide.

1.38.6 Dropping Caches

To drop or delete a data cache, change its size to 0. When you set a cache's size to 0, the cache is marked for deletion. The cache remains active, and all objects that are bound to that cache continue to use it.

- You cannot drop the default data cache.
- If you delete a data cache, and there are objects bound to the cache, the cache is left as-is in memory and the SAP ASE server issues the following message:

```
Cache (nmc3) not deleted dynamically. Objects are bound to the cache. Use sp_unbindcache_all to unbind all objects bound to the cache.
```

The entry corresponding to the cache in the configuration file is deleted, as well as the entries corresponding to the cache in sysconfigures, and the cache is deleted the next time the SAP ASE server is restarted.

• You cannot run sp cacheconfig within a transaction.

1.39 sp_cachestrategy

Enables or disables prefetching (large I/O) and MRU cache replacement strategy for a table, index, text object, or image object.

Syntax

```
sp_cachestrategy <dbname>, [<ownername>.]<tablename>
  [, <indexname> | "text only" | "table only"
  [, {prefetch | mru}, {"on" | "off"}]]
```

Parameters

<dbname>

is the name of the database where the object is stored.

<ownername>

is the name of the table's owner. If the table is owned by "dbo", the owner name is optional.

<tablename>

is the name of the table.

<indexname>

is the name of the index on the table.

text only

changes the cache strategy for a text or image object.

table only

changes the cache strategy for a table.

prefetch | mru

is prefetch or mru, and specifies which setting to change. Use the mru strategy in all caches, regardless of available I/O size. Setting prefetch "on" has no effect on tables or indexes that are read into a cache that allows only 2K I/O.

on | off

specifies the setting, "on" or "off", enclosed in quotes.

Examples

Example 1

Displays information about cache strategies for the titles table:

```
object name index name large IO MRU
dbo.titles titleidind ON ON
```

When you use $sp_cachestrategy$ without specifying the strategy and setting, it reports the current settings for the object.

Example 2

Displays information about cache strategies for the titleind index:

```
sp_cachestrategy pubs2, titles, titleind
```

Example 3

Disables prefetch on the titleind index of the titles table:

```
sp_cachestrategy pubs2, titles, titleind, prefetch, "off"
```

Example 4

Re-enables MRU replacement strategy on the authors table:

```
sp_cachestrategy pubs2, authors, "table only", mru, "on"
```

Example 5

Re-enables prefetching on the text pages of the blurbs table:

```
sp cachestrategy pubs2, blurbs, "text only", prefetch, "on"
```

Usage

- If memory pools for large I/O are configured for the cache used by a table or an index, the optimizer can choose to prefetch data or index pages by performing large I/Os of up to eight data pages at a time. This prefetch strategy can be used on the data pages of a table or on the leaf-level pages of a nonclustered index. By default, prefetching is enabled for all tables, indexes, and text or image objects. Setting the prefetch option to "off" disables prefetch for the specified object.
- The optimizer can choose to use MRU replacement strategy to fetch and discard buffers in cache for table scans and index scans for I/O of any size. By default, this strategy is enabled for all objects. Setting mru to "off" disables this strategy. If you turn mru off for an object, all pages are read into the MRU/LRU chain in cache, and they remain in the cache until they are flushed by additional I/O. For more information on cache strategies, see the *Performance and Tuning Guide*.
- You can change the cache strategy only for objects in the current database.
- To see the size, status and I/O size of all data caches on the server, use sp cacheconfig.

See also delete, select, set, update in Reference Manual: Commands.

Permissions

The permission checks for sp cachestrategy differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the object owner or a user with manage data cache privilege.

Disabled With granular permissions disabled, you must be the object owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_cacheconfig [page 118]
sp_poolconfig [page 670]

1.39.1 Overrides

If prefetching is turned on for a table or an index, you can override the prefetching for a session with set prefetch "off". If prefetching is turned off for an object, you cannot override that setting.

The prefetch, 1ru, and mru options to the select, delete, and update commands suggest the I/O size and cache strategy for individual statements. If prefetching or MRU strategy is enabled for a table or an index, you can override it for a query by specifying I/O the size of the logical page size for prefetch, and by specifying 1ru strategy. For example, the following command forces LRU strategy, logical page size I/O, and a table scan of the titles table:

```
select avg(advance) from titles (index titles prefetch 2 lru)
```

If you request a prefetch size, and the object's cache is not configured for I/O of the requested size, the optimizer chooses the best available I/O size.

If prefetching is enabled for an object with <code>sp_cachestrategy</code>, using a <code>prefetch</code> specification of the logical page size in a <code>select</code>, <code>delete</code>, or <code>update</code> command overrides an earlier <code>set prefetch "on"</code> statement. Specifying a larger I/O size in a <code>select</code>, <code>delete</code>, or <code>update</code> command does not override a <code>set prefetch "off"</code> command.

1.40 sp_changedbowner

Changes the owner of a user database.

Syntax

```
sp_changedbowner <loginame>[, true]
```

Parameters

<loginame>

is the login name of the new owner of the current database.

true

transfers aliases and their permissions to the new database owner. Values are "true" and "true".

Examples

Example 1

Makes the user "albert" the owner of the current database:

sp changedbowner albert

Usage

There are additional considerations when using sp changedbowner:

- The new owner must not already be known as either a user or alias (that is, the new owner must not already be listed in sysusers or sysalternates). Executing sp_changedbowner with the single parameter <loginame> changes the database ownership to <loginame> and drops aliases of users who could act as the old "dbo."
- After executing sp_changedbowner, the new owner is known as the database owner inside the database.
- sp changedbowner cannot transfer ownership of the system databases.
- The new owner must already have a login name in the SAP ASE server, but **cannot** have a database user name or alias name in the database. To assign database ownership to such a user, drop the user name or alias entry before executing sp_changedbowner.
- To grant permissions to the new owner, a system administrator must grant them to the database owner, since the user is no longer known inside the database under any other name.

See also create database in Reference Manual: Commands.

Permissions

The permission checks for sp changedbowner differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with \mathtt{own} any database privilege.
Disabled	With granular permissions disabled, you must be a user with sa role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addlogin [page 47]
sp_dropalias [page 281]
sp_dropuser [page 326]
sp_helpdb [page 438]
```

1.41 sp_changegroup

Changes a user's group.

Syntax

sp_changegroup <grpname>, <username>

Parameters

<grpname>

is the name of the group. The group must already exist in the current database. If you use "public" as the <grpname>, enclose it in quotes, because it is a keyword.

<username>

is the name of the user to be added to the group. The user must already exist in the current database.

Examples

Example 1

The user "albert" is now a member of the "fort_mudge" group, regardless of what group "albert" belonged to before:

```
sp changegroup fort mudge, albert
```

Example 2

To remove someone from a group without making that user a member of a new group, use sp_changegroup to change the user's group to "public". For example, the following removes "albert" from the group he belonged to without making him a member of a new group (all users are always members of "public"):

```
sp changegroup "public", albert
```

Usage

There are additional considerations when using sp changegroup:

- Executing sp_changegroup adds the specified user to the specified group. The user is dropped from the group he or she previously belonged to and is added to the one specified by <grpname>.
- New database users can be added to groups at the same time they are given access to the database with sp adduser.
- Groups are used as a collective name for granting and revoking privileges. Every user is always a member of the default group, "public", and can belong to only one other group.
- When a user changes from one group to another, the user loses all permissions that he or she had as a result of belonging to the old group and gains the permissions granted to the new group.

See also grant, revoke in Reference Manual: Commands.

Permissions

The permission checks for $sp_changegroup$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addgroup [page 42]
sp_adduser [page 73]
sp_dropgroup [page 304]
sp_helpgroup [page 452]
```

1.42 sp_checknames

Checks the current database for names that contain characters not in the 7-bit ASCII set.

Syntax

```
sp_checknames [help | silent]
```

Parameters

help

shows information about the system tables that are scanned.

silent

checks the current database in a silent mode, returning one of the following:

- 0 if there are no names with non-7 bit ASCII characters
- 1 if there is at least one name with a non-7 bit ASCII character

Examples

Example 1

Checks the master database for names that contain characters not in the 7-bit ASCII set:

Example 2

Displays information about the system tables scanned:

sysremotelogins.remoteusername

sysdatabases.name sysdevices.name syslogins.name syslogins.dbname syslogins.password

sysservers.srvname
sysservers.srvnetname

In all databases:
 syscolumns.name
 sysindexes.name
 sysobjects.name
 syssegments.name
 systypes.name
 sysusers.name
(return status = 0)

```
1> sp_checknames help
2> go

sp_checknames is used to search for non 7-bit ASCII characters
several important columns of system tables. The following
columns are searched:
In "master":
```

```
Example 3
```

1>

Suppresses the output of system table names, and displays just the return status:

```
1> sp_checknames silent
2> go

(return status = 1)
```

Usage

There are additional considerations when using sp checknames:

- sp_checknames examines the names of all objects, columns, indexes, user names, group names, and other elements in the current database for characters outside of the 7-bit ASCII set. It reports illegal names and gives instructions to make them compatible with the 7-bit ASCII set.
- Run sp_checknames in every database on your server after upgrading from a SQL Server of release 4.0.x or 4.2.x, and after using a default character set that was not 7-bit ASCII.
- Follow the instructions in the sp_checknames report to correct all non-ASCII names.

See also update in Reference Manual: Commands.

Permissions

Any user can execute $sp_checknames$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_password [page 647] sp_rename [page 693] sp_renamedb [page 697]

1.43 sp_checkreswords

Detects and displays identifiers that are Transact-SQL reserved words. Checks server names, device names, database names, segment names, user-defined datatypes, object names, column names, user names, login names, and remote login names.

Syntax

```
sp_checkreswords [<user_name_param>]
```

Parameters

<user name param>

is the name of a user in the current database. If you supply <user_name_param>, sp checkreswords checks only for objects that are owned by the specified user.

Examples

Example 1

Shows the results if ${\tt sp_checkreswords}$ is executed in the master database:

```
1> /* executed in the master database */
2> sp checkreswords
Reserved Words Used as Database Object Names for Database master
Upgrade renames sysobjects.schema to sysobjects.schemacnt.

Database-wide Objects	
Found no reserved words used a	s names for database-wide objects.

Usage

• sp_checkreswords reports the names of existing objects that are reserved words. Transact-SQL does not allow words that are part of any command syntax to be used as identifiers, unless you are using delimited identifiers. Reserved words are pieces of SQL syntax, and they have special meaning when you use them as part of a command. For example, in pre-release 10.0 SQL Server, you could have a table called work, and select data from it with this query:

```
select * from work
```

work was a new reserved word in SQL Server release 10.0, part of the command <code>commit work</code>. Issuing the same <code>select</code> statement in release 10.0 or later causes a syntax error. <code>sp_checkreswords</code> finds identifiers that would cause these problems.

- sp_checkreswords also finds reserved words, used as identifiers, that were created using the set quoted identifier option.
- Use sp_checkreswords before or immediately after upgrading to a new release of SAP ASE. For information on installing and running this procedure before performing the upgrade, see the installation documentation for your platform.
 - Run sp_checkreswords in the master database and in each user database. Also run it in model and sybsystemprocs, if you have added users or objects to those databases.
- The return status indicates the number of items found.
- If you supply a user name, sp_checkreswords checks for all of the objects that can be owned by a user tables, indexes, views, procedures, triggers, rules, defaults, and user-defined datatypes. It reports all identifiers that are reserved words.
- If your current database is not the master database, and you do not provide a user name, sp_checkreswords checks for all of the objects above, with a separate section in the report for each user name. It also checks sysusers and syssegments for user names and segment names that are reserved words. You only need to check model and sybsystemprocs if you have added objects, users, or userdefined datatypes.
- If your current database is master, and you do not provide a user name, sp_checkreswords performs all of the checks above and also checks sysdatabases, syslogins, syscharsets, sysservers, sysremotelogins, sysdevices, and syslanguages for reserved words used as the names of databases, local or remote logins, local and remote servers, character sets, and languages.

To change the name of a database, use <code>sp_renamedb</code>. The database must be in single-user mode. Drop and recreate any procedures, triggers, and views that explicitly reference the database name. For more information, <code>see sp_renamedb</code>.

See also:

- set in Reference Manual: Commands
- defincopy in the Utility Guide

Permissions

Any user can execute $sp_checkreswords$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_renamedb [page 697]
```

1.43.1 Handling Reported Instances of Reserved Words

If sp checkreswords reports that reserved words are used as identifiers, you have two options.

- Use sp_rename, sp_renamedb, or update the system tables to change the name of the identifier.
- Use set <code>quoted_identifier</code> on if the reserved word is a table name, view name, or column name. If most of your applications use stored procedures, you can drop and re-create these procedures with <code>set quoted_identifier</code> on, and quote all identifiers. All users can run the procedures, without having to use <code>set quoted_identifier</code> on for their session. You can use <code>set quoted_identifier</code> on, create views that give alternative names to tables or columns, and change your applications to reference the view instead.

The following example provides alternatives for the new reserved words "key", "level", and "work":

```
create view keyview
```

```
as
select lvl = "level", wrk = "work"
from "key"
```

The syntax for the set command is:

```
set quoted_identifier on
```

If you do not either change the identifiers or use delimited identifiers, any query that uses the reserved words as identifiers reports an error, usually a syntax error. For example:

```
Msg 156, Level 15, State 1:
Server 'rosie', Line 1:
Incorrect syntax near the keyword 'level'.
```

i Note

The quoted identifier option is a SQL92 option and may not be supported by many client products that support other SAP ASE features. For example, you cannot use bcp on tables with names that are reserved words.

Before choosing the quoted identifier option, perform a test on various objects using all the tools you use to access the SAP ASE server. Use set quoted_identifier on, create a table with a reserved word for a name and reserved words for column names. If the client product generates SQL code, it must enclose identifiers in double quotes (if they are reserved words) and character constants in single quotes.

Procedures, triggers, and views that depend on objects with names that have been changed may work after the name change, but stop working when the query plan is recompiled. Recompilation takes place for many reasons, without notification to the user. To avoid unsuspected loss of functionality, change the names of objects in procedures, triggers, and views immediately after you change the object name.

Whether you change the object names or use delimited identifiers, you must change all stored procedures, views, triggers, and applications that include the reserved word. If you change object names, you must change identifiers; if you use delimited identifiers, you must add the set quoted_identifier option and quotation marks.

If you do not have the text of your procedures, triggers, views, rules, and defaults saved in operating system files, you can use defncopy to copy the definitions from the server to files. See defncopy in the *Utility Guide*.

1.43.2 Changing Identifiers

If you change the names of the items reported by sp_checkreswords, you must change the names in all procedures, triggers, views, and applications that reference the object using the reserved word.

Dump your database before changing identifier names. After you change the identifier names, run dbcc to determine that there are no problems, and dump the database again.

If you are changing identifiers on an active production database:

• Perform the changes when the system is least busy, so that you disrupt as few users as possible.

• Prepare carefully by finding all Open Client DB-Library programs, windowing applications, stored procedures, triggers, and scripts that use a particular identifier. This way, you can make the edits needed in the source code, then change the identifiers and replace the procedures and code as quickly as possible.

The procedure sp depends can help find procedures, views, and triggers that use table and view names.

1.43.3 Using sp_rename to Change Identifiers

The system procedure sp_rename renames tables, indexes, views, procedures, triggers, rule, defaults, user-defined datatypes, and columns. Use $sp_renamedb$ to rename databases.

The types of identifiers that you can change with sp_rename and the changes you need to make on the server and in your application programs are:

Types Changes to Make

Table name

- Drop all procedures, triggers and views that reference the table, and re-create them with the new name. Use sp depends to find the objects that depend on the table.
- Change all applications or SQL source scripts that reference the table to use the new table name.
- Change dbcc scripts that perform table-level checks using table names.

Index name

- Drop any stored procedures that create or drop the index, and re-create them with the new name.
- Change all applications or SQL source scripts that create or drop the index.
- Change dbcc scripts that perform index-level checks using index names.

View name

- Drop all procedures, triggers, and views that reference the view, and re-create them with the new name. Use sp_depends to find the objects that depend on the view.
- Change all applications or SQL source scripts that reference the view to use the new view name.

Procedure name

- Drop and re-create with the new procedure name all procedures and triggers that reference the procedure.
- Change all applications or SQL source scripts that execute the procedure to use the new name.
- If another server remotely calls the procedure, change applications on the remote server to use the new procedure name.

Trigger name – change any SQL source scripts that create the trigger.

Rule name – change any SQL source scripts that create the rule.

Default name

Change any SQL source scripts that create the default.

User-defined datatype name

- Drop all procedures that create tables with user-defined datatypes, and re-create them with the new name.
- Change any applications that create tables with user-defined datatypes.

Types Changes to Make

Column name

• Drop all procedures, triggers and views that reference the column, and re-create them with the new column name.

sp_depends cannot find column name references. The following query displays the names of procedures, triggers, and views that reference a column named "key":

```
select distinct sysobjects.name
from sysobjects, syscomments
where sysobjects.id = syscomments.id
and syscomments.text like "%key%"
```

• Change all applications and SQL source scripts that reference the column by name.

To change the name of the view isolation to isolated, use:

```
sp_rename "isolation", isolated
```

To change the name of a column in the renamed view isolated, use:

```
sp_rename "isolated.key", keyname
```

Use sp_depends to get a list of all views, procedures, and triggers that references a view, procedure, or table that is renamed. To use sp_depends after renaming an object, give the new name. For example:

```
sp_depends <new_name>
```

1.43.4 Changing Other Identifiers

To change user names, login names, device names, remote server names, remote server user names, segment names, and character set and language names, determine whether you can drop the object or user, then add or create it again.

If you cannot drop the object or user, issue the following to allow direct updates to system tables:

```
sp_configure "allow updates to system tables", 1
```

Only a system security officer can set the allow updates to system tables configuration parameter.

Errors during direct updates to system tables can create severe problems in the SAP ASE server. Determine whether you can drop the objects or user, then re-create them:

Identifier Type Suggested Actions to Avoid Updates to System Tables

User names and login names

To change the name of a user with no objects:

- 1. Use sp_helprotect <username> in each database to record the user's permissions.
- 2. Drop the user from all of the databases (sp_dropuser).
- 3. Drop the login (drop login).
- 4. Add the new login name (create login).

Identifier Type	Suggested Actions to Avoid Updates to System Tables					
	5. Add the new user name to the databases (sp_adduser).6. Restore the user's permissions with grant.					
Device names	If this device is completely allocated, you need not use its name in a create database command, so you can leave the name unchanged.					
Remote server names	Unless there are large numbers of remote login names from the remote server, drop the remote server (sp_dropserver) and add it with a new name (sp_addserver).					
Remote server logins	Drop the remote login with sp_dropremotelogin, add it with a new name using sp_addremotelogin, and restore the user's permission to execute procedures with grant.					
Segment names	These are rarely used, once objects have been created on the segments.					
Character set and language names	Languages and character sets have reserved words as identifiers only if a system administrator has created alternative languages with <code>sp_addlanguage</code> . Drop the language with <code>sp_droplanguage</code> , and add it with a new name.					

This table shows possible dependencies on this set of identifiers. See this table for possible dependencies, whether you choose to upgrade by dropping and re-creating objects, by using delimited identifiers, or by performing direct updates to system tables.

Direct updates to system tables can be very dangerous. You can make mistakes that make it impossible for the SAP ASE server to run or make it impossible to access objects in your databases. Undertake this effort when you are calm and collected, and when little or no production activity is taking place on the server. If possible, use the alternative methods described in the following table.

Considerations when changing identifiers:

Identifier	Remember To
Login name	Change the user name in each database where this person is a user.
User name	Drop, edit, and re-create all procedures, triggers, and views that use qualified (<owner_name>.<object_name>) references to objects owned by this user. Change all applications and SQL source scripts that use qualified object names to use the new user name. You do not have to drop the objects themselves; sysusers is linked to sysobjects by the column that stores the user's ID, not the user's name.</object_name></owner_name>
Device name	Change any SQL source scripts or applications that reference the device name to use the new name.
Remote server name	Change the name on the remote server. If the name that <code>sp_checkreswords</code> reports is the name of the local server, you must restart the server before you can issue or receive remote procedure calls.

Identifier	Remember To
Remote server network name	Change the server's name in the interfaces files.
Remote server login name	Change the name on the remote server.
Segment name	Drop and re-create all procedures that create tables or indexes on the segment name. Change all applications that create objects on segments to use the new segment name.
Character set name	None.
Language name	Change both master.dbo.syslanguages and master.dbo.syslogins. The update to syslogins may involve many rows. Also, change the names of your localization files.

This example shows a "safe" procedure for updating a user name, with all data modification preceded by a begin transaction command. The system security officer executes:

```
sp_configure "allow updates to system tables", 1
```

Then you can execute:

```
begin transaction
update sysusers
set name = "workerbee"
where name = "work"
```

At this point, run the query, and check to be sure that the command affected only the row that you intended to change. The only identifier change that affects more than one row is changing the language name in syslogins. If the query affected:

- Only the correct row use commit transaction.
- More than one row or the incorrect row use rollback transaction, determine the source of the problem, and execute the command correctly.

When you are finished, the system security officer turns off the allow updates to system tables configuration parameter with this command:

```
sp_configure "allow updates to system tables", 0
```

Only update system tables in a single database in each user defined transaction. Do not issue a begin transaction command and then update tables in several databases. Such actions can make recovery extremely difficult.

The following table shows the system tables and columns that you should update to change reserved words. The tables preceded by "master.dbo." occur only in the master database. All other tables occur in master and in user databases. Be certain you are using the correct database before you attempt the update. You can check for the current database name with this command:

```
select db_name()
```

Table 4: System Table Columns to Update When Changing Identifiers

Type of identifier	Table to update	Column name
User name	sysusers	name
Login names	master.dbo.syslogins	name
Segment names	syssegments	name
Device name	sysdevices	name
Remote server name	sysservers	srvname
Remote server network name	sysservers	srvnetname
Character set names	master.dbo.syscharsets	name
Language name	master.dbo.syslanguages	name
	master.dbo.syslogins	language

1.43.5 Using Delimited Identifiers

Consideration for using delimited identifiers.

- You can use delimited identifiers for table names, column names, and view names. You cannot use delimited identifiers for other object names.
- If you choose to use delimited identifiers, use set quoted_identifier on, and drop and re-create all the procedures, triggers, and views that use the identifier. Edit the text for those objects, enclosing the reserved words in double quotes and enclosing all character strings in single quotes.

The following example shows the changes to make to queries in order to use delimited identifiers. This example updates a table named work, with columns named key and level. Here is the pre-release 10.0 query, which encloses character literals in double quotes, and the edited version of the query for use with delimited identifiers:

```
/* pre-release 10.0 version of query */
update work set level = "novice"
   where key = "19-732"

/* 10.0 or later version of query, using
** the quoted identifier option
*/
update "work" set "level" = 'novice'
   where "key" = '19-732'
```

- All applications that use the reserved word as an identifier must be changed as follows:
 - The application must set the quoted identifier option on.
 - All uses of the reserved word must be enclosed in double quotes.
 - All character literals used by the application while the quoted identifier option is turned on must be enclosed in single quotes. Otherwise, the SAP ASE server attempts to interpret them as object names.

In the following example, this query results in an error message:

```
set quoted_identifier on
select * from titles where title_id like "BU%"
```

The correct query is:

```
select * from titles where title_id like 'BU%'
```

• Stored procedures that you create while the delimited identifiers are in effect can be run without turning on the option. (The allow updates to system tables option also works this way.) This means that you can turn on quoted identifier mode, drop a stored procedure, edit it to insert quotation marks around reserved words used as identifiers, and re-create the procedure. All users can execute the procedure without using set quoted_identifier.

1.44 sp_checksource

Checks for the existence of the source text of compiled objects such as views, defaults, rules, triggers, procedures, declarative defaults, check constraints, computed columns, function-based indexes and predicates. The predicate name may be a user-defined or internal name.

Syntax

```
sp_checksource [<objname>[, <tabname>[, <username>]]]
```

Parameters

<objname>

is the compiled object to be checked for the existence of its source text.

<tabname>

is the name of the table or view to be checked for the existence of all check constraints, defaults, and triggers defined on it.

<username>

is the name of the user who owns the compiled objects to be checked for the existence of the source text.

Example 1

Checks for the existence of the source text of all compiled objects in the current database:

```
sp_checksource
```

Example 2

Checks for the existence of the source text of the view named titleview:

```
sp_checksource titleview
```

Example 3

Checks for the existence of the source text of the view named titls vu that is owned by Mary:

```
sp checksource title vu, @username = Mary
```

Example 4

Checks for the existence of the source text of the custom stored procedure list phone proc:

```
sp_checksource list_phone_proc
```

Example 5

Checks for the existence of the source text of all the check constraints, triggers, and declarative defaults defined on the table named my_tab :

```
sp_checksource @tabname = "my_tab"
```

Example 6

Checks for the existence of the source text of the view my_vu and all check constraints, triggers, and defaults defined on the table my_tab :

```
sp_checksource @objname = "my_vu", @tabname = "my_tab"
```

Example 7

Checks for the existence of the source text of all compiled objects owned by Tom:

```
sp_checksource @username = "Tom"
```

Example 8

Checks for the existence of the source text for the "pred1" predicate:

```
sp checksource pred1
```

Usage

There are additional considerations when using sp checksource:

- sp checksource checks for the existence of the source text of the specified compiled object. If the source text exists for the specified object, sp checksource returns 0. If the source text does not exist for the specified object, sp checksource returns 1.
- If you do not provide any parameters, sp checksource checks the existence of the source text for all compiled objects in the current database.
- To use sp checksource with no parameters, you must be the database owner or system administrator.
- sp checksource encrypts the text of user-defined functions.

Permissions

The permission checks for sp checksource differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage database privilege to check for the existence of the source text of compiled objects that are owned by another user.

Any user can execute sp checksource to check for the existence of the source text for his or her own compiled objects.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role to check for the existence of the source text of compiled objects that are owned by another user.

Any user can execute sp checksource to check for the existence of the source text for his or her own compiled objects.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_hidetext [page 497]

1.45 sp_chgattribute

Changes the max_rows_per_page, fillfactor, reservepagegap, or exp_row_size value for future space allocations of a table or an index; sets the concurrency_opt_threshold for a table. Provides the user interface for optimistic index locking.

Syntax

Parameters

<objname>

is the name of the table or index for which you want to change attributes.

max rows per page

specifies the row size. Use this for tables with variable-length columns.

fillfactor

value for future spacespecifies how full the SAP ASE server makes each page when it is re-creating an index or copying table pages as a result of a reorg rebuild command or an alter table command to change the locking scheme. The fillfactor percentage is relevant only at the time the index is rebuilt. Valid values are 0–100.

reservepagegap

specifies the ratio of filled pages to empty pages that are to be left during extent I/O allocation operations. For each specified <num_pages>, an empty page is left for future expansion of the table. Valid values are 0–255. The default value is 0.

recompile factor

sets a factor for row growth that, when reached, triggers the server to recompile the query plan. For example, if you set recompile_factor to 20, the query plan is recompiled every factor of 20. That is, the first recompile is at 20 rows, the next at 400 rows, the third at 8,000 row, the next 160,000 rows, and so on.

exp_row_size

reserves a specified amount of space for the rows in data-only locked tables. Use this option to reduce the number of rows being forwarded, which can be expensive during updates. Valid values are 0, 1, and any value between the minimum and maximum row

length for the table. O means a server-wide setting is applied, and 1 means to fully pack the rows on the data pages.

concurrency opt threshold

specifies the table size, in pages, at which access to a data-only-locked table should begin optimizing for reducing I/O, rather than for concurrency. If the table is smaller than the number of pages specified by concurrency_opt_threshold, the query is optimized for concurrency by always using available indexes; if the table is larger than the number of pages specified by concurrency_opt_threshold, the query is optimized for I/O instead. Valid values are -1 to 32767. Setting the value to 0 disables concurrency optimization. Use -1 to enforce concurrency optimization for tables larger than 32767 pages. The default is 15 pages.

optimistic_index_lock

enables a performance optimization that eliminates contention on the root page of an index. If the root page must change because of index splits, an exclusive table is acquired. For this reason, <code>optimistic_index_lock</code> is appropriate for tables where the number of modifications is relatively small. Valid values are 1 to turn on optimistic index locking or 0 to turn off optimistic index locking which is the default.

fact min

Used on table objects in conjunction with fact_table hint to filter the number of rows on hinted fact tables. You can use fact_min in an abstract plan clause to configure a fact table hint to be applied only if the row count of the fact table is greater than the value of fact_min (boundary points not included). If the value is less than fact_min, the reason for failure is returned as FACTTBL_REASON_SMALLTBL. The default value is 1. The value of fact_min is scaled by a factor specified by fact_unit.

fact max

Used on table objects in conjunction with fact_table hint to filter the number of rows on hinted fact tables. You can use fact_max in an abstract plan clause to configure the fact table hint to be applied only if the row count of the fact table is less than the value of fact_max (boundary points not included). If the value is greater than fact_max, the reason for failure is returned as FACTTBL_REASON_HUGETBL. The default value is 1000000. The value of fact_max is scaled by a factor specified by fact_unit.

fact_unit

fact_unit is used as a scaling factor for fact_min and fact_max. fact_unit can also be used to forcibly reject the fact_table hint by setting the fact_unit value to -1. The reason for rejection is returned as FACTTBL_REASON_FORCEDREJECT. The default value is 1000

optimistic_LFB

configures the index to use only delta updates for non-leaf pages.

identity burn max

allows you to reset the internal counter for the identity column. The value set represents the highest value already generated; the next automatically generated value is one larger than the value you specify. The value is passed as a varchar datatype in the fourth parameter.

identity gap

indicates that you want to change the identity gap.

<value>

is the numeric input value for the various options you specify in the sp_chgattribute.

<optvalue>

is the new value. Valid values and default values depend on which parameter is specified. This parameter is only used by the identity_burn_max parameter. For other parameters, this value is NULL.

<set number>

is the new size of the identity gap.

dealloc_first_txtpg

updates a text or image column to null. Sets the corresponding text pointer to null after deallocating the previously referenced text or image pages. This result in reduced space allocation for null text/images columns. Valid values are:

- O default, existing value, if either the table option setting is 1, or the database option deallocate first text page is TRUE, then deallocate the first text page after NULL update; otherwise, do not deallocate the first text page.
- 1 deallocate the first text page after NULL update (overriding the setting of the database option deallocate first text page).
- 2 do not deallocate the first text page after NULL update (overriding the setting of the database option deallocate first text page).

Whether the first text page will be deallocated after NULL update depends on the combination of this table parameter and the database option deallocate first text page.

```
DB setting (deallocate first text page) | 0 1 2

dealloc_first_txtp - true | Y Y N N N N N
```

- Y deallocate first text page after null update
- N not deallocate first text page after null update

The output from sp help indicates whether first text page will be deallocated.

plldegree

specifies the maximum number of threads the query optimizer can use.

ptn_locking

specifies whether to enable (1) or disable (0) locking at the partition level. By default, partition locking is disabled.

'<view_name>', 'materialize', 1 | 0]

Enables or disables forced view materialization. Where:

- <view_name> name of the view on which you are enabling or disabling forced materialization.
- materialize indicates you are enabling or disabling forced materialization.
- 0 | 1 a value of 0 disables forced view materialization; a value of 1 forces view materialization.

Example 1

Sets the max rows per page to 1 for the authors table for all future space allocations:

```
sp_chgattribute authors, "max_rows_per_page", 1
```

Example 2

Sets the max rows per page to 4 for the titleidind index for all future space allocations:

```
sp_chgattribute "titles.titleidind", "max_rows_per_page", 4
```

Example 3

Specifies a fillfactor of 90 percent for pages in title_ix:

```
sp_chgattribute "titles.title_ix", "fillfactor", 90
```

Example 4

Sets the exp row size to 120 for the authors table for all future space allocations:

```
sp_chgattribute "authors", "exp_row_size", 120
```

Example 5

Sets the reservepagegap to 16 for the titleidind index for all future space allocations:

```
sp_chgattribute "titles.titleidind", "reservepagegap", 16
```

Example 6

Turns off concurrency optimization for the titles table:

```
sp_chgattribute "titles", "concurrency_opt_threshold", 0
```

Example 7

Sets the identity gap for mytable to 20:

```
sp_chgattribute "mytable", "identity_gap", 20
```

Example 8

Changes mytable to use the identity burning set factor setting instead of the identity gap setting:

```
sp_chgattribute "mytable", "identity_gap", 0
```

Example 9

Sets the value of $sp_chgattribute$ to 1, turning the optimistic index locking feature on.

```
sp_chgattribute "mytable", "optimistic_index_lock", 1
```

Example 10

Sets the value of $sp_chgattribute$ to 0, turning the optimistic index locking feature off.

```
sp_chgattribute "mytable", "optimistic_index_lock", 0
```

Switches the deallocation for text and image space on using dealloc first txtpq:

```
sp_chgattribute "mytable", "dealloc_first_txtpg", 1
```

To switch the feature off:

```
sp_chgattribute "mytable", "dealloc_first_txtpg", 0
```

Example 12

The output from sp help indicates whether the first text page will be deallocated:

Example 13

Changes the identity burn max value for the authors table to 5:

```
sp_chgattribute "authors", "identity_burn_max", 0, "5"
```

Example 14

Tells the query optimizer to use a maximum of four threads:

```
sp_chgattribute my_table, "plldegree", 4
```

The query optimizer may choose less than four threads if it does not find enough resources. The same mechanism can be applied to an index. For example, the following example uses an index called auth_ind exists on authors to use two threads to access it:

```
sp_chgattribute "authors.auth_ind", "plldegree", 4
```

You must run sp chgatttribute from the current database.

Example 15

Enables partition-level locking for the authors table:

```
sp_chgattribute authors, "ptn_locking", 1
```

To disable partition-level locking:

```
sp_chgattribute authors, "ptn_locking", 0
```

For the fact_table hint to be successfully applied, both the conditions on fact_min and on fact_max need to be fulfilled.

With these values, the fact_table hint will depend on the row count from the table as follows:

```
sp_chgattribute myTable, fact_min, 100
sp_chgattribute myTable, fact_max, 4000
sp_chgattribute myTable, fact_unit, 500
```

Table Row Countfact_table hintrow_count <= 100 * 500</td>Not applied (reason: FACTTBL_REASON_SMALLTBL)100 * 500 < row_count < 4000 * 500</td>Appliedrow_count => 4000 * 500Not applied (reason: FACTTBL_REASON_HUGETBL)

Example 17

Sets fact unit to -1 to force the fact_table hint rejection.

```
sp_chgattribute myTable, fact_unit, -1
```

The fact_table hint is rejected with FACTTBL_REASON_FORCEDREJECT.

Example 18

Enables forced view materialization for view big important view:

```
sp_chgattribute 'big_important_view', 'materialize', 1
```

Example 19

Sets the recompile factor for the titles table to 12:

```
sp_chgattribute titles, recompile_factor, 0, '12'
```

Example 20

Configures the pubs2 database to use delta updates for non-leaf pages on the titleind index of the titles table:

```
sp_chgattribute 'titles.titleind', 'optimistic_LFB', 1
```

Usage

There are additional considerations when using sp chgattribute:

You cannot change attributes for virtually hashed tables. For example, if you attempt to change the
attributes for table order_line (a virtually-hashed table) like this:

```
sp_chgattribute 'order_line', 'exp_row_size', 1
```

The SAP ASE server issues an error message similar to:

sp_chgattribute is not allowed for order_line, as it is a virtually hashed table.

- (Cluster Edition only) You cannot use sp_chgattribute to change the value of <identity_gap> at runtime
- sp_chgattribute changes the max_rows_per_page, fillfactor, reservepagegap, exp_row_size, or dealloc_first_txtpg value for future space allocations or data modifications of the table or index. It does not affect the space allocations of existing data pages. You can change these values for an object only in the current database.
- Use sp_help to see the stored space management values for a table. Use sp_helpindex to see the stored space management values for an index.
- Setting max_rows_per_page to 0 tells the SAP ASE server to fill the data or index pages and not to limit the number of rows—this is the default behavior of the SAP ASE server if you do not set max rows per page.
- Both the identity_burn_max value stored in sysobjects and the current identity value are set to the new value.
- If the table is:
 - Not empty the new value of identity_burn_max must be greater than or equal to the current maximum value of the identity column.
 - Empty you can set the value to any positive value in the valid range.
- Low values of max_rows_per page cause page splits. Page splits occur when new data or index rows need to be added to a page, and there is not enough room for the new row. Usually, the data on the existing page is split fairly evenly between the newly allocated page and the existing page.

To approximate the maximum value for a nonclustered index, subtract 32 from the page size and divide the resulting number by the index key size. The following statement calculates the maximum value of max rows per page for the nonclustered index titleind:

```
select
  (select @@pagesize - 32) / minlen
  from sysindexes where name = "titleind"

------
288
```

- If you specify an incorrect value for max_rows_per_page, fillfactor, reservepagegap, or exp_row_size, sp_chgattribute returns an error message specifying the valid values.
- You cannot run this stored procedure from within a transaction.
- Only a user with sa role privileges can execute this stored procedure.
- You cannot set the optimistic index locking option for tables with datapages or datarow locking schemes.
- You cannot set the optimistic index locking option for tables in system databases, such as master or tempdb. You can set it only on user-defined tables.
- text and image pages are allocated space even when you perform a NULL update. You can use dealloc_first_txtpg to remove these empty text pages from the table.
 A new update to the column results in reallocation of a text or image page.

See also:

• alter table create index create table in Reference Manual: Commands

• For more information on max_rows_per_page, fillfactor, reservepagegap, exp_row_size, and concurrency_opt_threshold, see the *Performance and Tuning Guide*.

For more information about identity gaps, see *Transact-SQL User's Guide > Managing Identity Gaps in Tables*.

Permissions

The permission checks for sp chgattribute differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the object owner.

Disabled With granular permissions disabled, you must be the object owner.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpindex [page 454]

1.46 sp_cleanpwdchecks

sp_cleanpwdchecks is a custom stored procedure that allows you to define when and how to remove login and password-related attributes stored in user-defined tables.

Syntax

sp_cleanpwdchecks, <login_name>

Parameters

<login_name>

specifies the login name of the cleanup to be performed.

Usage

 $sp_cleanpwdchecks$ is user-defined, and is dynamically called in the master database when you drop a login.

Permissions

 $sp_cleanpwdchecks$ is not executed directly. It is a custom stored procedure and executed by the SAP ASE server internally.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.47 sp_clearpsexe

Clears the execution attributes of an SAP ASE session that was set by sp setpsexe.

Syntax

sp_clearpsexe <spid>, <exeattr>

Parameters

<spid>

is the process ID of the session for which execution attributes are to be cleared.

<exeattr>

identifies the execution attributes to be cleared. Values for exeattr are "priority" and "enginegroup".

Examples

Example 1

Drops the engine group entry for process 12.

sp_clearpsexe 12, 'enginegroup'

Usage

There are additional considerations when using sp clearpsexe:

- If the execution attributes are not cleared during the lifetime of the session, they are cleared when the session exits or terminates abnormally.
- sp clearpsexe fails if there are no online engines in the associated engine group.
- When you drop an engine group entry, the session executes on an engine group determined by a class definition or by the default class.
- Use sp who to list process IDs (spids).

See also Performance and Tuning Guide.

Permissions

 $The \ permission \ checks \ for \ \verb|sp_clearpsex| e \ differ \ based \ on \ your \ granular \ permissions \ settings.$

Setting	Description				
Enabled	With granular permissions enabled, you must be a user with manage any execution class privilege.				
	Any user can execute $sp_clearpsexe$ to clear the priority attributes of tasks owned by that user.				
Disabled	With granular permissions disabled, you must be a user with sa_role.				
	Any user can execute sp_clearpsexe to clear the priority attributes of tasks owned by that user.				

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_unbindexeclass [page 825]
```

1.48 sp_clearstats

Initiates a new accounting period for all server users or for a specified user. Prints statistics for the previous period by executing sp_reportstats.

Syntax

```
sp_clearstats [<loginame>]
```

Parameters

<loginame>

is the user's login name.

Examples

Example 1

Initiates a new accounting period for all users:

sp_clearstats

Name	Since	CPU	Percent CPU	I/O	Percent I/O
probe	Jun 19 1990	0	0%	0	0%
julie	Jun 19 1990	10000	24.9962%	5000	24.325%
_					
jason	Jun 19 1990	10002	25.0013%	5321	25.8866%
ken	Jun 19 1990	10001	24.9987%	5123	24.9234%
kathy	Jun 19 1990	10003	25.0038%	5111	24.865%
(5 rows	affected)				
Total C	PU Total I/	0			
40006	20555 accounts cle	arod			

Initiates a new accounting period for the user "kathy":

Usage

sp_clearstats creates an accounting period and should be run only at the end of a period.

Because $sp_clearstats$ clears out the accounting statistics, you must record the statistics **before** running the procedure.

 $\verb|sp_clearstats| updates| the \verb|syslogins| field| accdate| and clears| the \verb|syslogins| fields| to topu| and to tio.$

Permissions

The permission checks for $sp_clearstats$ differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with ${\tt manage}\ {\tt server}\ {\tt privilege}.$
Disabled	With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_reportstats [page 700]

1.49 sp_client_addr

Displays the IP (Internet Protocol) address of every SAP ASE task with an attached client application, including the spid and the client host name.

Syntax

```
sp_client addr [<spid>]
```

Parameters

<spid>

specifies one task for which you require an IP address.

Examples

Example 1

Lists IP addresses for all tasks:

```
sp_client_addr

-----
spid hostname ipaddr
-------
11 FRED 162.66.131.36
21 BARNEY 162.66.100.233
```

```
22 WILMA 162.66.100.206

23 BETTY 162.66.100.119

24 PEBBLES 162.66.100.125

25 BAMBAM 162.66.100.124

(6 rows affected)

(return status = 0)
```

Shows IP addresses for spid 21:

Example 3

Shows the result when a client application is not connected via IP:

```
sp_client_addr 11

-----
spid hostname ipaddr
-------
11 FRED 0.0.0.0
(1 row affected)
(return status = 0)
```

Example 4

Shows the result of a task with no attached client; for example, Housekeeper:

```
sp_client_addr 9

------
spid hostname ipaddr
--------
9 NULL
(1 row affected)
(return status = 0)
```

Example 5

Shows the result when an incorrect spid is specified:

```
sp_client_addr 99

-----
Msg 18934, Level 16, State 1:
Procedure "sp_client_addr", Line 32:
spid not found
(return status = 1)
```

Usage

If the client application is not attached by IP, the address appears as 0.0.0.0. The SAP ASE server does not support display of addresses of protocols other than IP.

If a task has no attached client (Housekeeper, for instance), the IP address appears as "NULL". Tasks with no attached client are not listed when you use sp client addr with no parameter.

Permissions

Any user can execute sp_client_addr . Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_who [page 847]

1.50 sp_cluster

(Cluster environments only) Performs a number of procedures related to clusters.

Syntax

• To migrate a connection to a different logical cluster or instance:

```
sp_cluster connection, migrate, <lc_name>, <instance_name>, "<spid_list>"
```

• To determine if previous connection migrations to a new instance are pending, and terminates the migrations if they are:

```
sp_cluster connection, ["migrate_status" | "migrate_cancel'"][, "<spid_list>"]
```

• To modify an outstanding action, such as canceling the action or changing the timing of the action:

```
sp_cluster logical, "action", <lc_name>, {
   cancel, <action_handle> |
   modify_time, <action_handle>, <wait_option>[, <timeout> ] |
   release, <action_handle }>
```

• To add a resource or one or more routes to the logical cluster:

```
sp_cluster logical, "add", <lc_name>, {
    route, <route_type>, <key_list> |
    instance, <instance_list> | failover, <instance_list |>
    database, <database_name> [, with nowait] }
```

• To move a route from one logical cluster to another:

```
sp_cluster logical, "alter", <lc_name>, route, <route_type>, <key_list>
```

• To create a new logical cluster:

```
sp_cluster logical, "create", <lc_name> [, for single instance access]
```

• To stop the logical cluster on one or more instances or the entire logical cluster, and places the instances or the cluster in the inactive state:

```
sp_cluster logical, "deactivate", <lc_name>, {
    "cluster" | "instance", <instance_list> }
    [, <wait_option>[, <timeout>,[, @handle output ]]]
```

• To drop a logical cluster, or one or more resources from the logical cluster:

• To reverse a manual failover, reinstating the original base instances:

```
sp_cluster logical, "failback", <lc_name>, {
    cluster<[, wait_option>[, <timeout>[, @handle output ]]] |
    instance, <from_instance_list>, <to_instance_list>[, <wait_option>[,
        <timeout>[, @handle output ]]] }
```

• To initiate a manual failover from base instances to failover instances.

```
sp_cluster logical, "failover", <lc_name>, {cluster
    [, <to_instance_list[, wait_option>[, <timeout>[, @handle output ]]]
    | instance, <from_instance_list>, <to_instance_list>[, <wait_option>[, <timeout>[, "sync" [, @handle output ]]]] }
```

To manually gather and migrate a group of connections to a different logical cluster:

```
sp_cluster logical, "gather", <lc_name>
```

• To display complete syntax for sp cluster logical:

```
sp_cluster logical, "help"
```

• To stop the logical cluster on one or more instances or the entire logical cluster:

• To start the default logical cluster on one or more instances:

```
sp_cluster logical, "online", {<lc_name>[, <instance_list>]}
```

• To set logical cluster rules: the open logical cluster, the failover mode, the system view, the start-up mode, and the load profile:

• To display information about a logical cluster:

```
sp_cluster logical, "show"
[, <lc_name>[, {<action>[, <state>] | route[, <type>[, <key>]]}]]
```

To set up and manage the load profile for the logical cluster:

• To set up and manage the load profile for the logical cluster:

```
sp_cluster profile, [ "show"[, <profile_name>] | "create", <profile_name> |
"drop", <profile_name> | "set", <profile_name> [, weight [, <wt_metric> [,
<wt_value> ] | threshold [, <thr_metric> [, <thr_value> ] ] ]
```

Parameters

sp_cluster connection, migrate, <lc_name>, <instance_name>, "<spid_list>"

- <lc name> is the name of the logical cluster.
- <instance name> is the name of the instance.
- <spid_list> is the list of spids you are migrating. Separate multiple spids with semicolons.

sp_cluster connection, ['migrate_status' | 'migrate_cancel'][, '<spid_list>']

- <spid_list> is the list of spids you are investigating.
- migrate cancel indicates you are terminating the connection migrations.
- migrate_status indicates you are investigating the status of connection migrations.

sp_cluster logical, "action", <lc_name>, {cancel, <action_handle> |
modify_time, <action_handle>, <wait_option>[, <timeout>] | release,
<action handle>}

- cancel specifies an action to be canceled.
- <action handle> is the action identifier.
- modify time specifies that the time of the action is to be modified.
- <wait option> is how the time of the action is to be modified. Values are:

- wait indicates that existing connections are given a specified amount of time (or an infinite amount of time if no <timeout> is given) to migrate or disconnect.
- nowait indicates that existing connections are migrated or disconnected immediately.
- until indicates that existing connections are given until a specific time of day to migrate or disconnect.
- <timeout> is a specific amount of time (when used with wait) or a specific time (when used with until). The format is "hh:mm:ss" according to a 24-hour clock. For example, <timeout> records "11:30 p.m" (or "11:30pm") as "23:30:00".
- release specifies that all resources held by a completed action are to be released.

sp_cluster logical, "add", <lc_name>, { route, <route_type>, <key_list> |
instance, <instance_list> | failover, <instance_list> | database
<database name> [, with nowait]}

- <1c name> is the name of a logical cluster.
- route specifies that one or more routes are to be added to the logical cluster
- <route type> is the type of route to be added. Values are:
 - o application specifies a route for an application name to the logical cluster.
 - login specifies a route for a login name to the logical cluster.
 - o alias specifies a route for a server name alias to the logical cluster.
- <key_list> is a list of applications, logins, or aliases, depending on the route type. Elements in the key list are delimited by semicolons.
- instance specifies that one or more base instances are to be added to the logical cluster.
- <instance_list> is the list of instances to be added. Separate multiple instances with semicolons.
- failover specifies that one or more failover instances are to be added to the logical cluster.
- database specifies a database to be added to the logical cluster.
- <database_name> is the name of the database.
- with nowait indicates that existing connections are migrated or disconnected immediately.

sp_cluster logical, "alter", <lc_name>, route, <route_type>, <key_list>

- <lc_name> is the name of a logical cluster.
- route specifies a route is to be altered.
- <route type> is the type of route to be altered. Values are:
 - application specifies a route for an application name to the logical cluster.
 - login specifies a route for a login name to the logical cluster.
 - o alias specifies a route for a server name alias to the logical cluster.
- <key_list> is a list of applications, logins, or aliases, depending on the route type. Elements in a key list are delimited with semicolons.

sp_cluster logical, "create", <lc_name>[, for single instance access]

- <1c name> is name of the logical cluster.
- for single instance access creates a single-instance logical cluster. By default, creating the logical clusters sets these parameters:
 - o down routing-"disconnect"
 - failover "instance"
 - o fail to any-"off"

sp_cluster logical, "deactivate", <lc_name>, { "cluster" | "instance",
<instance_list> } [, <wait_option>[, <timeout>,[, @handle output]]]

- <1c name> name of a logical cluster.
- cluster specifies the entire cluster.
- instance specifies that only certain instances in the logical cluster are to be placed in the inactive state.
- <instance list> list of selected instances in the logical cluster.
- <wait option> the valid options are:
 - wait indicates that existing connections are given a specified amount of time (or an infinite amount of time if no <timeout> is given) to migrate or disconnect.
 - nowait indicates that existing connections are migrated or disconnected immediately.
 - until indicates that existing connections are given until a specific time of day to migrate or disconnect.
- <timeout> a specific amount of time (when used with wait) or a specific time (when used with until). The format is "hh:mm:ss" according to a 24-hour clock. For example, <timeout> records 11:30 p.m. as 23:30:00.
- @handle output specifies that an action handle is to be retrieved for the action.

sp_cluster logical, "drop", <lc_name>, { cluster | instance, <instance_list> |
failover, <instance_list> | route, <route_type>, <key_list> | database
<database name>}

- <lc name> name of a logical cluster.
- cluster specifies the entire cluster.
- instance specifies that only certain instances in the logical cluster are to be placed in the inactive state.
- <instance_list> list of selected instances in the logical cluster.
- database specifies a database to be added to the logical cluster.
- <database name> is the name of the database.

sp_cluster logical, "failback", <lc_name>, { cluster[, <wait_option>[,
<timeout>[, @handle output]]] | instance, <from_instance_list>,
<to_instance_list>[, <wait_option>[, <timeout>[, @handle output]]] }

- <1c name> name of a logical cluster.
- cluster specifies the entire cluster.
- <to_instance_list> list of predefined failover instances. A value of NULL activates the first failover group.
- <from_instance_list> list of instances that are to be taken offline.

- <wait option> where the valid options are:
 - wait indicates that existing connections are given a specified amount of time (or an infinite amount of time if no <timeout> is given) to migrate or disconnect.
 - nowait indicates that existing connections are migrated or disconnected immediately.
 - until indicates that existing connections are given until a specific time of day to migrate or disconnect.
- <timeout> a specific amount of time (when used with wait) or a specific time (when used with until). The format is "hh:mm:ss" according to a 24-hour clock.
 For example, <timeout> records 11:30 p.m. as 23:30:00.
- @handle output specifies that an action handle is to be retrieved for the action.

sp_cluster logical, "failover", <lc_name>, {cluster[, <to_instance_list[,
wait_option>[, <timeout>[, @handle output]]] | instance, <from_instance_list>,
<to_instance_list>[, <wait_option>[,<timeout>[, "sync"[, @handle
output]]]] }

- <1c name> name of a logical cluster.
- cluster specifies the failover of the entire logical cluster.
- <to_instance_list> list of predefined failover instances. A value of NULL activates the first failover group.
- <wait option> how the time of the action is to be recorded. Values are:
 - wait indicates that existing connections are given a specified amount of time (or an infinite amount of time if no <timeout> is given) to migrate or disconnect.
 - nowait indicates that existing connections are migrated or disconnected immediately.
 - until indicates that existing connections are given until a specific time of day to migrate or disconnect.
- <timeout> is a specific amount of time (when used with wait) or a specific time (when used with until). The format is "hh:mm:ss" according to a 24-hour clock.
 For example, <timeout> records 11:30 pm as 23:30:00.
- @handle output specifies that an action handle is to be retrieved for the failover.
- instance specifies that only selected instances in the logical cluster are to fail over.
- <from instance list> list of instances that are to be taken offline

sp cluster logical, "gather", <lc name>

- gather indicates you are gathering a set of qualified connections to migrate them to another logical cluster.
- <lc name> name of a logical cluster to which you are migrating the connections.

sp_cluster logical, "offline", <lc_name>, { cluster | instance,
<instance_list> } [, <wait_option>[, <timeout>[, @handle output]]]

- < lc name> name of a logical cluster.
- cluster specifies the entire cluster.

- instance specifies that only selected instances in the logical cluster are to taken offline.
- <instance list> list of selected instances in the logical cluster.
- <wait option> how the time of the action is to be specified. Values are:
 - wait indicates that existing connections are given a specified amount of time (or an infinite amount of time if no <timeout> is given) to migrate or
 - nowait indicates that existing connections are migrated or disconnected immediately.
 - until indicates that existing connections are given until a specific time of day to migrate or disconnect.
- <timeout> is a specific amount of time (when used with wait) or a specific time (when used with until). The format is "hh:mm:ss" according to a 24-hour clock.
 For example, <timeout> records 11:30 pm as 23:30:00.
- @handle output specifies that an action handle is to be retrieved for the action.
- <from instance list> list of instances that are to be taken offline

sp_cluster logical, "online", { <lc_name>[, <instance_list>]}

- <1c name> name of a logical cluster.
- <instance list> list of selected instances in the logical cluster.

sp_cluster logical, "set", <lc_name>, {open | failover, <failover_mode> |
system_view, <view_mode> | startup, { automatic | manual } | load_profile,
<profile_name> | action_release, { automatic | manual } | gather, { automatic |
manual } | login distribution, { affinity | "round-robin" }

- <1c name> name of a logical cluster.
- open sets the open logical cluster. Unrouted connections are sent to the open logical cluster.
- failover <failover_mode> sets the failover mode of the logical cluster. Values for <failover_mode> are:
 - instance specifies a 1:1 failover strategy; every time a base instance fails, a failover resource is brought online.
 - group specifies that failover resources are brought online only after all base instances in the cluster fail.
- system_view <view_mode> sets the default system view for tasks running in the logical cluster. Values for <view mode> are:
 - instance specifies that monitoring and informational tools such as sp_who, sp_lock, and monitoring tables describe an instance.
 - cluster specifies that monitoring and informational tools such as sp_who,
 sp_lock, and monitoring tables describe the whole cluster.
- startup { automatic | manual} sets the start-up mode of the logical cluster.
 - automatic specifies that the logical cluster is started automatically when the cluster starts.
 - manual specifies that the logical cluster must be started manually.

- login_distribution specifies how the Cluster Edition distributes connections when a logical cluster spans multiple instances.
- action_release enables or disables the automatic releasing and clearing of these logical cluster actions—online, offline, failover, and failback—after they are completed or cancelled.
 - automatic specifies that logical cluster actions are cleared automatically.
 - manual specifies that logical cluster actions are not cleared after they are completed or cancelled. This is the default.
- gather enables or disables the movement of groups of connections to a different logical cluster when one of these predefined actions occurs—online, add route, alter route, Or drop route.
 - automatic specifies that the connections are moved automatically.
 - manual specifies that the connections are not moved automatically. This is the default.
- @handle output specifies that an action handle is to be retrieved for the action.
- <from instance list> list of instances that are to be taken offline

sp_cluster logical, "show"[, <lc_name>[, {<action>[, <state>] | route[,
<type>[, <key>]]}]]

- <lc_name> name of the logical cluster. If NULL is entered, summary information for all logical clusters is displayed.
- action specifies information about administrative actions: failover, failback, online, offline, deactivate.
- <state> one of: cancelled, complete, or active.
- route specifies information about routes.
- <type> is one of: application, alias, or login.
- <key> a specific login, alias, or application name.

sp_cluster profile, ["show" [, <profile_name>] | "create", <profile_name> |
"drop", <profile_name> | "set", <profile_name>[, weight[, <wt_metric>[,
<wt_value>] | threshold[, <thr_metric> [, <thr_value>]]

- show displays configured load profiles and their settings.
- <profile_name> name of a load profile.
- creates creates a new load profile.
- drop drops a load profile.
- set specifies attributes of a load profile. You must set each attribute individually.
- weight specifies a weight attribute.
- <wt metric> specifies an individual weight metric. Values are:
 - user connections the capacity of an instance to accept a new connection, based on resource availability.
 - cpu utilization the capacity of an instance to accept a new connection, based on resource availability.
 - run queue the capacity of an instance to accept a new connection, based on resource availability.
 - o io load outstanding asynchronous I/Os.

• engine deficit – the difference in the number of online engines among instances in the cluster.

i Note

engine deficit is measurable only when instances in the cluster have unequal numbers of engines. engine deficit adds a metric for maximum relative capacity to the load score.

- user metric an optional, user-supplied metric.
- <wt_value> specifies a weight value. Valid values are 0 to 255. A weight of zero
 (0) excludes the metric from calculation.
- threshold specifies a threshold attribute.
- <thr metric> specifies a particular threshold attribute. Values are:
 - o dynamic specifies a threshold for dynamic load distribution.
 - o login specifies a threshold for login redirection
 - hysteresis specifies a minimum load score for any connection redirection.
- <thr value> depends on value of <thr metric>. When <thr metric> is:
 - dynamic or login <thr_value> is the percentage difference between the load scores of two instances. Valid values are 0 to 100. A weight of zero (0) disables this form of load distribution.
 - hysteresis <thr_value> is the minimum load score for the target instance that must be met before dynamic load distribution or login redirection can occur.

Examples

Example 1

Moves the connection with a spid of 73 into the ${\tt SalesLC}$ cluster:

```
sp_cluster connection, migrate, SalesLC, NULL, '73'
```

Example 2

Moves the current connection to the "ase3" instance:

```
sp cluster connection, migrate, NULL, ase3
```

Example 3

Moves connections with spid values of 73 and 75 into "ase3" instance and the SalesLC cluster:

```
sp cluster connection, migrate, SalesLC, ase3, '73;75'
```

Example 4

Determines if there is a connection migration occurring on spid 73; if there is, the Cluster Edition cancels the migration:

```
sp_cluster connection, 'migrate_cancel', '73'
```

Checks the status of migrated connections for connections with a spid value of 73:

Example 6

Cancels a timed action on the "SalesLC" logical cluster. The action handle is 4390.

```
sp_cluster logical, "action", SalesLC, cancel, "4390"
```

Example 7

Changes the wait option for existing action 5364 to nowait.

```
sp_cluster logical, "action", SalesLC, modify_time, "5364", nowait
```

Example 8

Releases action 3456 for the "SalesLC" logical cluster.

```
sp_cluster logical, "action", SalesLC, release, "3456"
```

Example 9

Releases all completed or cancelled actions for the "SalesLC" logical cluster.

```
sp_cluster logical, "action", SalesLC, release, "all"
```

Example 10

Adds instances "ase1" and "ase2" to the "SalesLC" logical cluster.

```
sp_cluster logical, "add", SalesLC, instance, "ase1;ase2"
```

Example 11

Creates one failover group with "ase3" for "SalesLC".

```
sp_cluster logical, "add", SalesLC, failover, ase3
```

Example 12

Routes the logins "tom", "dick", and "harry" to the "SalesLC" logical cluster

```
sp_cluster logical, "add", SalesLC, route, login, "tom;dick;harry"
```

Example 13

Routes the field_sales application to the "SalesLC" logical cluster.

```
sp_cluster logical, "add", SalesLC, route, application, field_sales
```

Creates a route of type alias to logical cluster "lc1" with the alias "SalesLC". Then, changes the logical cluster association of the route from "lc1" to "lc2". The route is identified by its route type (alias) and its key (SalesLC).

```
sp_cluster logical, "add", "lc1", "route", "alias", "SalesLC"
sp_cluster logical, "alter", "lc2", "route", "alias", "SalesLC"
```

Example 15

Creates a logical cluster named "SalesLC":

```
sp_cluster logical, "create", SalesLC
```

Example 16

Immediately stops all instances in the "SalesLC" logical cluster, and places "SalesLC" in the inactive state:

```
sp cluster logical, "deactivate", SalesLC, cluster, nowait
```

Example 17

Stops the "ase1" and "ase2" instances, and places "SalesLC" in the inactive state:

```
sp_cluster logical, "deactivate", SalesLC, instance, "ase1;ase2"
```

Example 18

Drops the "SalesLC" logical cluster:

```
sp_cluster logical, "drop", SalesLC, cluster
```

Example 19

Drops the base instances "ase1" and "ase2" from the "SalesLC" logical cluster.

```
sp_cluster logical, "drop", SalesLC, instance, "ase1;ase2"
```

Example 20

Drops the routes from the applications field_sales and web_sales from the "SalesLC" logical cluster.

```
sp_cluster logical "drop", SalesLC, route, application,
    "field_sales;web_sales"
```

Example 21

Fails back the "SalesLC" logical cluster:

```
sp_cluster logical, "failback", SalesLC, cluster
```

Example 22

"SalesLC" is running on "ase3" and "ase1". In this example, "ase3" fails back to "ase1", and "SalesLC" continues to run on "ase2". The action takes place in two minutes:

```
declare @out_handle varchar(15)
execute
sp_cluster logical, "failback", SalesLC, instance,
ase3, ase1, wait, "00:02:00", @handle = @out_handle
output
```

Fails over the "SalesLC" logical cluster to the first group of predefined failover resources. The failover waits 2 minutes before terminating connections.

```
declare @out_handle varchar(15)
execute
sp_cluster logical, "failover", SalesLC, cluster, NULL, wait, "00:02:00",
@handle = @out_handle output
```

```
Action '2' has been issued for the 'failover cluster' command.Logical Cluster Handle Action From To

State InstancesWaiting ConnectionsRemaining WaitType StartTime Deadline CompleteTime

SalesLC 2 failover cluster 2, 4 NULL complete

Nov 15 2007 3:23PM Nov 15 2007 3:25PM Nov 15 2007 3:23PM Remember to issue the 'sp_cluster logical, action, <logical cluster name>, release, <handle>' command for any cancelled or completed actions.
```

Example 24

"SalesLC" is running on "ase1" and "ase2". In this example, "ase1" fails over to "ase3", and "SalesLC" continues to run on "ase2". No wait option is specified, so it defaults to an indefinite wait.

```
Action '1' has been issued for the 'failover instance' command.
Logical Cluster Handle Action From

To State InstancesWaiting
ConnectionsRemaining WaitType StartTime Deadline CompleteTi

me

SalesLC 1 failover
instance 1 4 complete 0
0 infinite Nov 15 2007 3:06PM NULL Nov 15 2007

3:06PM
Remember to issue the `sp_cluster logical, action, <logical cluster name>, release, <handle>' command for any cancelled or completed actions.
```

Example 25

Gathers and migrates a group of connections to the "new_stores" logical cluster:

```
sp_cluster logical, 'gather', new_stores
```

Example 26

Displays syntax for the sp cluster logical stored procedures.

```
Usage for sp_cluster 'logical':
    sp_cluster 'logical', 'help' [, <module>]
    To show the logical cluster configuration:
    sp_cluster 'logical', 'show'
    sp_cluster 'logical', 'show', <lcname>
```

```
sp_cluster 'logical', 'show', <lcname> | NULL, 'action' [, <state>]
sp_cluster 'logical', 'show', <lcname> | NULL, 'route' [, <type [, <key>]]
To create a logical cluster:
sp_cluster 'logical', 'create', <lcname>
To add resources to a logical cluster:
sp_cluster 'logical', 'add', <lcname>, 'failover', <instance_list> [,<group>]
sp_cluster 'logical', 'add', <lcname>, 'instance', <instance_list
sp_cluster 'logical', 'add', <lcname>, 'route', <route_type>, <key_list>
To drop resources from a logical cluster:
sp_cluster 'logical', 'drop', <lcname>, 'cluster'
sp_cluster 'logical', 'drop', <lcname>, 'failover', <instance_list>
sp_cluster 'logical', 'drop', <lcname>, 'instance', <instance_list>
sp_cluster 'logical', 'drop', <lcname>, 'route', <route_type>, <key_list>
Argument details:
<lcname> is a logical cluster nam
 <instance list> is a ';' separated list of instance
To set attributes of a logical cluster:
sp_cluster 'logical', 'set', <lcname>, 'open'
sp_cluster 'logical', 'set', <lcname>, 'down_routing', 'disconnect' |
'system' |
     'open'
sp_cluster 'logical', 'online', <lcname>[, <instance_list>]
sp_cluster 'logical', 'offline', <lcname>, 'cluster'[, <wait_option>[,<time>[,
     @handle output]]]
sp_cluster 'logical', 'offline', <lcname>, 'instance',
    <instance_list>[,<wait_option>[, <time>[, @handle output]]]
To failover and failback a logical cluster:
sp_cluster 'logical', 'failover', <lcname>, 'cluster'[, <instance_list>[,
     <wait option>[, <time>[, @handle output]]]]
To work with action handles:
sp_cluster 'logical', 'action', <lcname>, 'cancel', <handle>
sp_cluster 'logical', 'action', <lcname>, 'modify_time', <handle>,
<wait option>[,
     \langle \overline{t}ime \rangle]
sp cluster 'logical', 'action', <lcname>, 'release', <handle>
Argument details:
<wait_option> is one of {'nowait', 'wait', 'until'}
<time> is a time in hh:mm:ss format
<handle> is an action handle
```

Immediately stops all instances in the "SalesLC", and places "SalesLC" in the offline state.

```
sp_cluster logical, "offline", SalesLC, cluster, nowait
```

Example 28

Stops the "ase1" and "ase2" instances in "SalesLC", and places "SalesLC" in the offline state.

```
sp_cluster logical, "offline", SalesLC, instance, "ase1;ase2"
```

Starts all base instances in the "SalesLC" logical cluster, and brings the cluster online.

```
sp_cluster logical, "online", SalesLC
```

Example 30

Starts the "ase1" instance in "SalesLC", and brings the cluster online.

```
sp_cluster logical, "online", SalesLC, ase1
```

Example 31

Sets the load profile for the "SalesLC" logical cluster to the Sybase profile sybase profile oltp:

```
sp_cluster logical, "set", SalesLC, load_profile,
sybase_profile_oltp
```

Example 32

Sets the default system view to cluster:

```
sp_cluster logical, "set", SalesLC, system_view, cluster
```

Example 33

Displays summary information for all configured logical clusters.

```
sp_cluster logical, "show", NULL
```

ID Name	State	Online Ins	stances	Connections	
1 2 SalesLC	mycluster online offline 'mycluster' 'CatchallLC Instance	online online online online online	tem logic cype	4 0 0 0 cal cluster. al cluster. Connections 0 er 0	1
mycluster	wool	online	base	1	0.01

Example 34

Displays a list of all outstanding actions.

```
sp_cluster logical, "show", NULL, action
```

Example 35

Displays information for the SalesLC logical cluster.

```
sp_cluster logical, "show", SalesLC
```

ID	Name	State	Online Instances	Connections
		online Type	1 0 Connections Load Score	Failover Gro

<pre>application</pre>				

Example 36

Creates the load profile "my_profile":

```
sp_cluster profile, "create", my_profile
```

Example 37

Specifies the metric weights for "my_profile." "user connections" is set to zero, which excludes that metric from the profile:

```
sp_cluster profile, "set", my_profile, weight, "user connections", '0' sp_cluster profile, "set", my_profile, weight, cpu utilization, '20' sp_cluster profile, "set", my_profile, weight, runqueue, '30' sp_cluster profile, "set", my_profile, weight, io load, '10' sp_cluster profile, "set", my_profile, weight, engine deficit, '10' sp_cluster profile, "set", my_profile, weight, user metric, '30'
```

Example 38

Sets the login redirection threshold to 80 and the hysteresis value to 10 for "my_profile:"

```
sp_cluster profile, "set", my_profile, threshold, login, '80'
sp_cluster profile, "set", my_profile, threshold, hysteresis, '10'
```

Example 39

Displays information about a configured profile:

```
sp_cluster profile, "show", my_profile

ID Profile Type Connections CPU Run Queue

Example 40

Creates a single-instance logical cluster named "tech":

```
sp_cluster logical, "create", tech, for single instance access
```

Example 41

Removes the binding between a single-instance database named "automotive" and a single-instance logical cluster named "tech":

```
sp_cluster logical, "drop", tech, database automotive
```

Usage

The parameter usage for sp_cluster is:

Parameter

Usage Consideration

sp_cluster
connection

• To migrate the current spid, omit <spid_list> from sp_cluster connection, migrate.

sp_cluster
logical,
action

• Retrieve an action handle by querying the monLogicalClusterAction table or executing:

```
sp_cluster logical, "show", NULL, action
```

- Any client that does not support migration is disconnected when it completes a SQL batch and has no open transactions, or when the <timeout> period expires, which ever comes first.
- Any client remaining at the end of the <timeout> period is disconnected.

Parameter

Usage Consideration

- Cancelling an action does not roll back the action. Additional tasks may be necessary to restore the configuration to the original state.
- Only completed actions can be released. Releasing an action removes the completed action from the system and from the monLogicalClusterAction table.

sp_cluster logical, 'add'

- You cannot add a base instance or a failover resource to the system logical cluster.
- Separate multiple instance, failover resources, or applications with semicolons.
- Create multiple failover groups by enclosing the group in parenthesis, and separating groups with a comma. If you do not specify group, a new group is created and the instances are added to that group. You can specify a group into which the instances are placed (the group number must be quoted).
 For example:

```
1> sp_cluster logical, 'add', tempLC, failover,
"asedemo3;asedemo2"
2> go
```

```
Added failover instance 'asedemo3' to group 1 for logical cluster 'tempLC'. Added failover instance 'asedemo2' to group 1 for logical cluster 'tempLC'.
```

And then add the instances to the group:

```
1> sp_cluster logical, 'add', tempLC, failover, asedemo4, "4"
2> go
```

Added failover instance 'asedemo4' to group 4 for logical cluster 'tempLC'.

sp_cluster logical, "deactivate"

- You cannot use the deactivate command for the system logical cluster.
- offline is identical to the deactivate, except deactivate places stopped instances or clusters in the inactive state and offline places them in the offline state.

sp_cluster logical "drop"

- You must place an instance or failover resource in the offline state before dropping it.
- Dropping a cluster also drops all routes, resources, and settings associated with the cluster.

sp_cluster logical "failback"

• To initiate a failback, the logical cluster must first be failed over.

sp_cluster logical "gather"

- The logical cluster must be online to gather connections manually
- The logical cluster must have defined routes to gather connections

Parameter

Usage Consideration

sp_cluster logical, "offline"

- You cannot use the offline command for the system logical cluster.
- offline is identical to deactivate, except deactivate places stopped instances or clusters in the inactive state.

sp_cluster logical "online"

• You cannot use the online command for the system logical cluster.

sp_cluster logical "set"

Only one logical cluster can have the open property. When you set the open property
to a new logical cluster, the open property is removed from the previous open logical
cluster.

sp_cluster profile

- The user metric value must be normalized so that it is compatible with values for metrics provided by SAP. Consider a user metric that measures response times. If the maximum acceptable response time is 10 seconds and the measured value is 5, the metric value is 50 (5/10 x 100 = 50).
- Threshold metrics let you configure at what point a load imbalance should cause connections to be redirected from one instance to another. The workload manager redirects connections when the load score difference (as a percent) between the target instance and the least loaded instance meets or exceeds the threshold value. The hysteresis value guards against redirection when the load score difference meets the threshold value, but the instance load scores (for example, 2 and 8) are so low that redirection is not appropriate.

Adding or dropping single-instance databases

- The single-instance logical cluster definitions must exist before issuing sp_cluster logical 'drop' | 'add'.
- All logical clusters to which you are adding and dropping single-instance databases must be single-instance logical clusters. You cannot use single-instance databases with regular logical clusters.
- performs a database migration when you change a database's bindings to another
 logical cluster that uses a different node. This migration may take significantly
 longer than without database migration because sp_cluster must drain the
 connections on the present node and migrate them to the new node. However, if it is
 acceptable to drop client connections, you may use the with nowait parameter
 for better performance.
- Connections from one logical cluster are not migrated to another. If both single-instance logical clusters have the same base node, connections from either logical cluster can access the single-instance database. However, if they have different base nodes, once the database has been migrated to the second logical clusters base node, the first logical cluster cannot access the single-instance database.
- All connections to the host node may access its single-instance database.

Permissions

The permission checks for sp cluster differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage cluster privilege or ha_role.

Disabled With granular permissions disabled, you must be a user with sa_role or ha_role.

1.51 sp_clusterlockusage

(Cluster environments only) Reports on the free, used, and retained locks in the cluster.

Syntax

sp_clusterlockusage

Examples

Example 1

Reports the locks currently used in the cluster:

Lock Usage	count	% of total
Total Locks	95039	n/a
Free Locks	85807	90.29 %
Used Locks	9232	90.29 %
	4032	4.24 %
Object Locks		
Physical Locks	233	0.25 %
Partition Locks	9	0.00 %
Table Locks	0	0.00 %
Page Locks	0	0.00 %
Row Locks	17	0.02 %
Others	501	0.53 %
Retention Used	0	0.00 %

Usage

Retention Used reports on the number of locks that are not owned by any task, but are owned at the cluster level because of lock retention.

Permissions

The permission checks for sp clusterlockusage differ based on your granular permissions settings.

Setting Description

 $\textbf{Enabled} \quad \text{With granular permissions enabled, you must be a user with \mathtt{manage} cluster $\mathtt{privilege}$ or a supervised for the property of the propert$

user with ha_role.

Disabled With granular permissions disabled, you must be a user with sa_role or ha_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.52 sp_cmp_all_qplans

Compares all abstract plans in two abstract plan groups.

Syntax

```
sp_cmp_all_qplans <group1>, <group2>[, <mode>]
```

Parameters

<group1>, <group2>

are the names of the two abstract plan groups.

<mode>

is the display option. The modes and what information they report are:

- counts the default mode, this option reports plans that:
 - o Are the same
 - Have the same association key, but different groups
 - o Exist in one group, but not the other
- brief the information provided by counts, plus:

- The IDs of the abstract plans in each group where the plans are different, but the association key is the same
- The IDs of plans that are in one group, but not in the other.
- same all counts, plus the IDs, queries, and plans for all abstract plans where the queries and plans match.
- diff all counts, plus the IDs, queries, and plans for all abstract plans where the queries and plans are different.
- first all counts, plus the IDs, queries, and plans for all abstract plans that are in the first plan group, but not in the second plan group.
- second all counts, plus the IDs, queries, and plans for all abstract plans that are in the second plan group, but not in the first plan group.
- offending all counts, plus the IDs, queries, and plans for all abstract plans that have different association keys or that do not exist in both groups. This is the combination of the diff, first, and second modes
- full all counts, plus the IDs, queries, and plans for all abstract plans. This is the combination of same and offending modes.

Examples

Example 1

Generates a default report on two abstract plan groups:

```
sp_cmp_all_qplans dev_plans, prod_plans
```

```
If the two query plans groups are large, this might take some time.

Query plans that are the same

count

------

49

Different query plans that have the same association key

count

-----

1

Query plans present only in group 'dev_plans':

count

------

1

Query plans present only in group 'prod_plans':

count

------

0
```

Example 2

Generates a report using the brief mode:

```
sp_cmp_all_qplans dev_plans, prod_plans, brief
```

Usage

There are additional considerations when using sp_cmp_all_qplans:

- Use sp cmp all qplans to check for differences in abstract plans in two groups of plans.
- sp cmp all qplans matches pairs of plans where the plans in each group have the same user ID and query text. The plans are classified as follows:
 - o Plans that are the same
 - Plans that have the same association key in both groups, but have different abstract plans. The association key is the group ID, user ID and query text.
 - Plans that exist in one group, but do not exist in the other group
- To compare two individual abstract plans, use sp cmp qplans. To see the names of abstract plan groups, use sp help apgroup.
- When a system administrator or database owner runs sp cmp all qplans, it reports on all plans in the two groups. When another user executes sp cmp all qplans, it reports only on plans that have the user's ID.

Permissions

The permission checks for sp cmp all qplans differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage abstract plans privilege or a user with monitor qp performance privilege.

Any user can compare plans that they own.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user can compare plans that they own.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_cmp_qplans [page 189] sp_help_qpgroup [page 410]

1.53 sp_cmp_qplans

Compares two abstract plans.

Syntax

```
sp_cmp_qplans <id1>, <id2>
```

Parameters

<id1>,<id2>

are the IDs of two abstract plans.

Examples

Example 1

Compares abstract plan 411252620 to 1383780087:

```
sp cmp qplans 411252620, 1383780087
```

```
The queries are the same. The query plans are the same.
```

Example 2

Compares abstract plan 2091258605 to 647777465:

```
sp cmp qplans 2091258605, 647777465
```

```
The queries are the same. The query plans are different.
```

Usage

There are additional considerations when using sp_cmp_qplans :

• sp_cmp_qplans compares the queries, abstract plans, and hash keys of two abstract plans, and reports whether the queries are the same, and whether the plans are the same. It prints one of these messages for the query:

- The gueries are the same.
- The queries are different.
- The queries are different but have the same hash key.

It prints one of these messages for the abstract plan:

- The guery plans are the same.
- The query plans are different.
- sp cmp qplans also prints a return status showing the results of the comparison. The status values 1, 2 and 10 are additive. The status values and their meanings are:
 - 0 The query text and abstract plans are the same.
 - +1 The queries and hash keys are different.
 - +2 The gueries are different, but the hash keys are the same.
 - +10 The abstract plans are different.
 - 100 One or both of the plan IDs does not exist.
- To find the ID of a plan, use <code>sp_help_qpgroup</code> or <code>sp_find_qplan</code>. Plan IDs are also returned by <code>create</code> plan and are included in showplan output.

Permissions

The permission checks for sp cmp qplans differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage abstract plans privilege or monitor qp performance privilege.

Any user can compare plans that they own.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user can compare plans that they own.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_cmp_all_qplans [page 186] sp_help_qpgroup [page 410]

1.54 sp_commonkey

Defines a common key — columns that are frequently joined — between two tables or views.

Syntax

```
sp_commonkey <tabaname>, <tabbname>, <col1a>, <col1b>
    [, <col2a>, <col2b>, ..., <col8a>, <col8b>]
```

Parameters

<tabaname>

is the name of the first table or view to be joined.

<tabbname>

is the name of the second table or view to be joined.

<col1a>

is the name of the first column in the table or view <tabaname> that makes up the common key. Specify at least one pair of columns (one column from the first table or view and one from the second table or view).

<col1b>

is the name of the partner column in the table or view <tabbname> that is joined with <colla> in the table or view <tabaname>.

Examples

Example 1

Defines a common key on titles.titleid and titleauthor.titleid:

```
sp_commonkey titles, titleauthor, title_id, title_id
```

Example 2

Assumes two tables, projects and departments, each with a column named empid. This statement defines a frequently used join on the two columns:

```
sp_commonkey projects, departments, empid, empid
```

Usage

There are additional considerations when using sp commonkey:

- Common keys are created in order to make explicit a logical relationship that is implicit in your database design. The information can be used by an application. sp_commonkey does not enforce referential integrity constraints; use the primary key and foreign key clauses of the create table or alter table command to enforce key relationships.
- Executing sp_commonkey adds the key to the syskeys system table. To display a report on the common keys that have been defined, use sp_helpkey.
- You must be the owner of at least one of the two tables or views in order to define a common key between them
- The number of columns from the first table or view must be the same as the number of columns from the second table or view. Up to eight columns from each table or view can participate in the common key. The datatypes of the common columns must also agree. For columns that take a length specification, the lengths can differ. The null types of the common columns need not agree.
- The installation process runs <code>sp_commonkey</code> on appropriate columns of the system tables.
- You cannot use a Java datatype with sp commonnkey.

See also alter table, create table, create trigger in Reference Manual: Commands.

Permissions

You must be the table owner to execute <code>sp_commonkey</code>. Permission checks do not differ based on the granular permissions settings

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dropkey [page 306] sp_foreignkey [page 387] sp_helpjoins [page 461] sp_helpkey [page 463] sp_primarykey [page 677]

1.55 sp_companion

Run from the secondary companion, sp_companion performs cluster operations such as configuring SAP ASE as a secondary companion in a high availability system and moving a companion server from one failover mode to another.

Syntax

Parameters

<server_name>

is the name of the SAP ASE server on which you are performing a cluster operation.

configure

configures the server specified by <server_name> as the primary companion in a failover configuration.

drop

permanently drops a companion from failover configuration. After the command has completed, the servers are in single-server mode.

suspend

temporarily removes the companions from a failover configuration. After the command is completed, the companions are in suspended mode.

resume

reverses the ${\tt suspend}$ command and resumes normal companion mode between the companions.

prepare failback

prepare the secondary companion to relinquish the primary companion's resources so it can failback.

do advisory

verifies that the secondary companion is compatible for successfully performing the primary companion's functions during failover mode.

- all causes do_advisory the investigate all the parameters.
- help displays information and syntax about the do advisory parameter.
- <group_attribute_name> is the name of the group attribute upon which sp companion reports
- <base_attribute_name> is the name of the base attribute upon which you
 want sp companion do advisory reports.

with proxydb

creates proxy databases on the secondary companion for all database other than the system databases – and all subsequent databases that are added – when this parameter is included in the initial configuration of the companion servers. By default, with proxydb is disabled.

<srvlogin>

is a user's login to access the companion server. By default, the value of srvlogin is "sa".

<srvpassword>

is the user's password to access the companion server. By default, the value of srvpassword is null.

<cluster_login>

is the user's login to log into the cluster. By default, the value of ${\tt cluster_login}$ is "sa".

<cluspassword>

is the user password you must provide to log into the cluster. By default, the value of cluspassword is null.

Examples

Example 1

Configures the SAP ASE MONEY1 as the primary companion:

```
sp_companion "MONEY1", configure
```

Example 2

Configures the SAP ASE MONEY1 as the primary companion and creates proxy databases on the secondary companion:

```
sp_companion "MONEY1", configure, with_proxydb, "sa", "sapsswd"
```

Example 3

Drops the SAP ASE PERSONEL1 from the failover configuration. After the command has completed, both the primary companion and the secondary companion are in single-server mode:

```
sp_companion "PERSONEL1", "drop"
```

Example 4

Resumes normal companion mode for the companion server (in this example, MONEY1):

```
sp_companion "MONEY1", "resume"
```

Example 5

Prepares the primary companion (in this example, PERSONEL1) to change to normal companion mode and resume control of the SAP ASE server that failed over:

```
sp_companion "PERSONEL1", "prepare_failback"
```

Example 6

Checks to make sure a cluster operation with the PERSONEL1 companion is successful. Because $do_advisory$ in this example uses the all parameter, it checks all the $do_advisory$ attributes of PERSONEL1 to make sure that none of them prevent a successful cluster operation, and that the secondary companion can successfully perform the primary companion's operations after failover is complete:

```
sp_companion "PERSONEL1", do_advisory, "all"
```

Example 7

Checks to make sure that none of the attributes for the Component Integration Services (CIS) on the companion server is compatible with the local server:

```
sp_companion "PERSONEL1", do_advisory, "CIS"
```

Usage

sp_companion performs cluster operations such as configuring SAP ASE as a secondary companion in a high availability system. sp_companion also moves companion servers from one failover mode to another (for example, from failover mode back to normal companion mode). sp_companion is run from the secondary companion.

sp_companion is installed with the installhasvss (insthasv on Windows), not the installmaster script. installhasvss is located in the scripts subdirectory in \$SYBASE ASE.

sp_companion automatically disables SAP's mirroring. You should use a third-party mirroring software to protect your data from disk failures.

For complete information, see *Using Failover in A High Availability System*. Before running the do_advisory command, make sure to read the configuration chapter of this book as well as the do_advisory chapter.

Permissions

You must be user with ha_role to execute <code>sp_companion</code>. Permission checks do not differ based on the granular permissions settings

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.56 sp_compatmode

Verifies whether full compatibility mode can be used.

Syntax

sp compatmode

Examples

Example 1

Verifies whether full compatibility mode can be used:

```
1> sp compatmode
```

```
Compatibility mode is enabled.
WARNING: Compatibility mode may not be used when statement cache and literalautoparam are enabled.
WARNING: The configuration option 'histogram tuning factor' is configured with value '20', which is not the default value in ASE 12.5. This may lead to different accuracy of statistics and different query plans.
(return status = 0)
1>
```

Usage

This query reports whether compatibility mode is enabled or not. You see a warning if there are conflicts with the use of enable compatibility mode.

For more information, see the Migration Technology Guide.

Permissions

Any user can execute $sp_compatmode$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.57 sp_config_dump

Allows you to list, add, or change dump configurations.

Syntax

```
sp_config_dump
  [@config_name = '<configuration_name>'
  [, {
        [@stripe_dir = '<stripe_dir_name>',]
        [@ext_api = '<external_api>',]
        [@num_stripes = '<number_of_stripes>',]
        [@retry = '<number_of_retries>',]
        [@blocksize = '<number_of_bytes>',]
        [@compression = '<compression_level>',]
        [@retaindays = '<number_of_days>',]
        [@init = '[noinit | init]',]
        [@verify = '[header | full]',]
        [@notify = '[client | operator_console]',]
        [@backup_srv_name = <backup_server_name>',]
        } | ['delete']
```

Parameters

@config name = '<configuration name>'

is a unique dump configuration name that is required for adding or changing any specific dump configuration. The SAP ASE server lists all dump configurations when you do not include '<configuration_name>'. Additional parameters, when supplied, are changed to new values.

@stripe_dir = '<stripe_dir_name>'

is a file system directory in which files are archived during the dump operation. Archived files are typically named using this format:

```
database_name.dump_type.date-timestamp.stripeID
```

<code>@stripe dir defaults to the directory where the Backup Server is started.</code>

Ostripe dir cannot be a tape device.

@ext api = '<external api>'

is the name of the external API (byte stream device) used for the dump operation. By default, this parameter is unused. Provide <external api> in this format:

```
external_API_name::additional_options
```

@num stripes = '<number of stripes>'

is the number of stripe devices used during the dump operation. The default is 1.

@retry = '<number_of_retries>'

is the number of times the server tries the dump operation for nonfatal errors. Valid values are 0 to 5; the default is 0 (which indicates no retry).

@blocksize = '<number_of_bytes>'

is the block size for the dump device, overriding the default block size for the device. The value must be at least 1 database page (2048 bytes for most systems), and an exact multiple of the database page size. For optimal performance, specify blocksize as a power of 2 (such as 65,536, 131,072, or 262,144).

@compression = '<compression_level>'

is the compression level for compressed dumps. By default, compression is disabled.

@retaindays = '<number of days>'

is the number of days that Backup Server prevents a dump from being overwritten. Backup Server requires you to confirm any overwrite requests on an unexpired volume. By default, value is 0, meaning dumps can be overwritten.

@init = '[noinit | init]'

specifies whether to initialize the volume. The default is noinit.

@verify = '[header | full]'

specifies whether you want Backup Server to perform a minimal page-header or full structural row check on the data pages as they are copied to archives. There is no structural check made to global allocation map (GAM), object allocation map (OAM), allocation pages, indexes, text, or log pages. By default, there is no verification of data pages during archiving.

```
@notify = '[client | operator console]'
```

specifies whether Backup Server routes messages to the client terminal that initiated the dump, or to the operator-console terminal where the Backup Server is running.

```
@backup srv name = '<backup server name>'
```

specifies the network name of the remote Backup Server running on the machine to which the dump device is attached. Do not use backup_server_name to dump to SYB_BACKUP, the default Backup Server. You can specify up to 32 remote Backup Servers using this option.

For platforms that use interfaces files, the Backup Server name must appear in the interfaces file.

'delete'

specifies the dump configuration to be deleted.

Examples

Example 1

Lists all dump configurations:

```
sp_config_dump
go

Configuration name
-----
dmp_cfg1
dmp_cfg2
dmp_cfg3
```

Example 2

Lists parameter values for a dump configuration called dmp cfg1:

Example 3

Creates a new dump configuration called dmp_cfg2 that specifies that a dump operation creates 5 stripes in the $/work1/dmp_dir$ stripe directory, and that retries once if it fails with a nonfatal error:

```
sp_config_dump 'dmp_cfg2',
    @stripe_dir='/work1/dmp_dir', @num_stripes='5',
    @retry='1'
```

Example 4

Changes the stripe directory of an existing dump configuration:

```
sp_config_dump 'dmp_cfg2',
    @stripe_dir='/work2/dmp_dir'
```

Example 5

Deletes a dump configuration:

```
sp_config_dump 'dmp_cfg2', 'delete'
```

Usage

The sp_config_dump procedure does not support tape devices.

See also:

- dump, load, genddlonly in Reference Manual: Commands
- For information about dump operations, see the System Administration Guide.

Permissions

The permission checks for sp_config_dump differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage dump configuration

Disabled With granular permissions disabled, you must be a user with sa_role or oper_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.58 sp_confighistory

Creates the cheevents view and displays changes made to SAP ASE configuration.

Syntax

Parameters

```
create_view
```

indicates you are creating the ch events view.

```
<begin_date>, [<end_date>]
```

displays all items from <begin_date> value to the <end_date> value.

last

displays the latest configuration history items.

<items num>

number of items to show from the list of latest configuration history items.

area | type | target | element

displays items from the specified area:

- area area in which the auditable event occurs. One of:
 - o server server-level events.
 - o database database-level events.
 - o cache cache-level events.
 - $^{\circ}$ traceflag dbcc traceflag and set switch events.
 - SUSD startup/shutdown.
 - o audit auditing state changes.
- type type of auditable event. One of:
 - o sp_configure
 - o sp_serveroption
 - o sp dboption
 - o sp_cacheconfig
 - o sp_poolconfig
 - o create thread pool

- o alter thread pool
- o drop thread pool
- o dbcc traceflag
- o set switch
- o configuration file change
- startup
- shutdown
- o shutdown with wait
- o shutdown with nowait
- abrupt shutdown
- o global auditing
- config history auditing
- target name of the target objects to which the change applies (for example, server, cache, thread pool, and database names, traceflag number, and so on).
- element configuration or other option name (for example, "enable monitoring", "config pool: 4K, option: wash size", and so on).

help

displays usage information for sp confighistory.

Permissions

- Only the system administrator (users with sa_role) can use this procedure to create the ch events view.
- Only the system administrator (users with sa_role) and users with mon_role can use this procedure to query the ch_events view.

The permission checks differ, based on your granular permission settings:

Setting Description

Enabled With granular permissions enabled, only users with:

- select any audit table permission can query against the ch events view.
- manage auditing permission can change the option state of configuration history auditing
- select any audit table permission can query against the ch events view.
- select any audit table permission can query the audit tables.

Disabled With granular permissions disabled, only:

- System security officers (users with sso_role) can change the option state of configuration history auditing
- Only system administrators (users with sa_role) and users with mon_role can query against the ch events view.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.59 sp_configure

Displays configuration parameters by group, their current values, their non-default value settings, the value to which they have most recently been set, and the amount of memory used by this setting. Displays only the parameters with a display level that is the same as or below that of the user.

Syntax

Parameters

<configname>

displays the current value, default value, most recently changed value, and amount of memory used by the setting for all parameters matching parameter>.

<configvalue>

resets <configname> to <configvalue> and displays the current value, default value, configured value, and amount of memory used by <configname>.

sp_configure <configname,> 0, "default" resets <configname> to its
default value and displays current value, default value, configured value, and amount of
memory used by <configname>.

<group_name>

displays all configuration parameters in $<group_name>$, their current values, their default values, the value (if applicable) to which they have most recently been set, and the amount of memory used by this setting.

<non unique parameter fragment>

displays all parameter names that match <non_unique_parameter_fragment>, their current values, default values, configured values, and the amount of memory used.

drop instance

allows you to drop an instance-specific configuration setting

<instance name>

(in cluster environments) indicates the instance for which you are setting the instancespecific options.

snapshot isolation timeout

Allows you to set the upper limit of time (in seconds) until which a statement can remain idle in the system, before it is preempted in a transaction snapshot. The default timeout value is 0 (zero) seconds, which means the statement will *not* be preempted.

For statement snapshot, transactions are preempted after 60 seconds, and such transactions later re-register themselves.

<timeout_value>

the value (in seconds) for the parameter snapshot isolation timeout

display nondefault settings

displays configuration options for which the configuration or run value is different from the default value.

write

creates <file_name> from the current configuration. If <file_name> already exists, a message is written to the error log and the existing file is renamed using the convention <file_name>.001, <file_name>.002, and so on. If you have changed a static parameter but have not restarted your server, "write" gives you the currently running value for that parameter.

read

performs validation checking on values contained in <file_name> and reads those values that pass validation into the server. If any parameters are missing from <file_name>, the current running values for those parameters are used.

verify

performs validation checking on the values in <file name>.

restore

creates <file_name> with the values in sysconfigures. This is useful if all copies of the configuration file have been lost and you need to generate a new copy.

<file_name>

is the name of the file you want to use ${\tt sp_configure}$ on.

Examples

Example 1

Displays all configuration parameters by group, their current values, their default values, the value (if applicable) to which they have most recently been set, and the amount of memory used by this setting:

```
sp_configure
```

Example 2

Displays all configuration parameters that include the word "identity":

```
Sp_configure "identity"

Configuration option is not unique.

Parameter Name Default Memory Used Config Value Run Value Unit Type

identity burning set 1 0 1 1 id static identity grab size 0 0 0 0 id dyna size of auto identit 10 0 10 bytes dyna

. . .
```

Example 3

Sets the system recovery interval in minutes to 3 minutes:

```
Parameter Name Default Memory Used Config Value Run Value Unit Type recovery interval 5 0 3 3 min dyn Configuration option changed. The SQL Server need not be rebooted since the option is dynamic.
```

Example 4

Resets the value for number of devices to the SAP ASE default:

```
sp_configure "number of device", 0, "default"
```

Example 5

Configures four databases to be recovered concurrently:

```
sp_configure "max concurrently recovered db", 4
```

Example 6

Starts four checkpoint tasks:

```
sp_configure "number of checkpoint tasks", 4
```

Example 7

Captures Query Processing metrics (qp metrics) at the server level:

```
sp_configure "enable metrics capture", 1
```

Example 8

Performs validation checking on the values in the file srv.config and reads the parameters that pass validation into the server. Current run values are substituted for values that do not pass validation checking:

Example 9

Runs validation checking on the values in the file restore.config:

Example 10

Creates the file my_server.config and writes the current configuration values the server is using to that file:

Example 11

Performs a validation check on the values in \$SYBASE/backup config.cfg:

```
sp_configure "configuration file", 0, "verify",
    "backup_config.cfg"
```

Example 12

Set the snapshot isolation timeout to 60 seconds. After 60 seconds of idle time, the statement is preempted in the transaction snapshot. The output is illustrated below:

```
sp_configure 'snapshot isolation timeout', 60
Parameter Name
                                      Memory Used Config Value Run Value
                             Default.
Unit Type
snapshot isolation timeout
                            0
                                       0
                                                    60
                                                                  60
seconds dynamic
(1 row affected)
Configuration option changed. ASE need not be rebooted since the option is
dynamic.
Changing the value of 'snapshot isolation timeout' to '60' increases the
amount.
of memory ASE uses by 12 K.
(return status = 0)
```

Usage

 Any user can execute sp_configure to display information about parameters and their current values, but not to modify parameters. System administrators can execute sp_configure to change the values of most configuration parameters. Only system security officers can execute certain parameters. These are listed under "Permissions" in this section.

- sp_configure allows you to specify the value for configuration parameters in unit specifiers. The unit specifiers are p or P for pages, m or M for megabytes, g or G for gigabytes, and t or T for terabytes. If you do not specify a unit, and you are configuring a parameter that controls memory, the SAP ASE server uses the logical page size for the basic unit.
- Files created with sp configure have restricted permissions.
- When you execute sp configure to modify a dynamic parameter:
 - The configuration and run values are updated.
 - The configuration file is updated.
 - The change takes effect immediately.
- When you execute sp configure to modify a static parameter:
 - The configuration value is updated.
 - The configuration file is updated.
 - The change takes effect only when you restart the SAP ASE server.
- When issued with no parameters, sp_configure displays a report of all configuration parameters by group, their current values, their default values, the value (if applicable) to which they have most recently been set, and the amount of memory used by this setting:
 - The default column in the report displays the value SAP ASE is shipped with. If you do not explicitly reconfigure a parameter, it retains its default value.
 - The memory used column displays the amount of memory used by the parameter at its current value in kilobytes. Some related parameters draw from the same memory pool. For instance, the memory used for stack size and stack guard size is already accounted for in the memory used for number of user connections. If you added the memory used by each of these parameters separately, it would total more than the amount actually used. In the memory used column, parameters that "share" memory with other parameters are marked with a hash mark (#).
 - The config_value column displays the most recent value to which the configuration parameter has been set with sp_configure.
 - The run_value column displays the value being used by the SAP ASE server. It changes after you
 modify a parameter's value with sp_configure and, for static parameters, after you restart the SAP
 ASE server. This is the value stored in syscurconfigs.value.

i Note

If the server uses a case-insensitive sort order, <code>sp_configure</code> with no parameters returns a list of all configuration parameters and groups in alphabetical order with no grouping displayed.

- Each configuration parameter has an associated display level. There are three display levels:
 - The "basic" level displays only the most basic parameters. It is appropriate for very general server tuning.
 - The "intermediate" level displays parameters that are somewhat more complex, as well as showing you all the "basic" parameters. This level is appropriate for a moderately complex level of server tuning.
 - The "comprehensive" level (default) displays all parameters, including the most complex ones. This level is appropriate for users who do highly detailed server tuning.
 Setting one of the other display levels lets you work with a subset of the configuration parameter, shortening the amount of information displayed by sp_configure.

The syntax for showing your current display level is:sp_displaylevel.

• sp_configure can run in sessions using chained transaction mode if there are no open transactions.

See also:

- For information on the individual configuration parameters, see the System Administration Guide.
- set in Reference Manual: Commands
- For more information on max concurrently recovered db and number of checkpoint tasks, see System Administration Guide > Backing up and Restoring User Databases.

Permissions

The permission checks for sp_configure differ based on your granular permissions settings. Any user can display information about parameters and their current values.

Setting Description

Enabled

With granular permissions enabled:

- Only a user with manage security configuration privilege can execute sp_configure to modify values for parameters in table .
- You must have the manage server configuration privilege to execute sp_configure to modify values for other configuration parameters.

$\textbf{Disabled} \quad \textbf{With granular permissions disabled:}$

- Only user with sso_role can execute sp_configure to modify values for parameters in table .
- You must have sa_role to execute sp_configure to modify values for other configuration parameters:
 - o allow procedure grouping
 - o allow remote access
 - o allow sendmsg
 - $^{\circ}$ allow updates to system tables
 - o audit queue size
 - o auditing
 - $^{\circ}$ automatic master key access
 - o check password for digit
 - o curread change w/ open cursors
 - o current audit table
 - o enable encrypted columns
 - $^{\circ}\,$ enable granular permissions
 - o enable ldap user auth
 - o enable logins during recovery
 - $^{\circ}$ enable pam user auth
 - o enable predicated privileges
 - o enable ssl
 - O FIPS login password encryption
 - o log audit logon failure

Setting Description

- O log audit logon success
- o maximum failed logins
- \circ minimum password length
- o msg confidentiality reqd
- o msg integrity reqd
- o net password encryption reqd
- o restricted decrypt permission
- o secure default login
- o select on syscomments.text
- O SQL Perfmon Integration
- o suspend auditing when device full
- o syb_sendmsg port number
- o systemwide password expiration
- o unified login required
- o use security services

Auditing

You can enable the following auditing options to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value		
Audit option	config_history		
Event	154		
Command or access audited	sp_configure		
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Includes procedure name, parameter name, old value, new value, mode (static or active), and instance ID Proxy information – Original login name, if set proxy in effect 		

Information Value
Audit option security
Event 82

Command or access sp_configure

audited

Information	Value
-------------	-------

Information in extrainfo

- Roles Current active roles
- Keywords or options Name of the configuration parameter
- Previous value Old parameter value if command is setting a new value
- Current value New parameter value if command is setting a new value
- Other information Number of configuration parameter, if a parameter is being set; name of configuration file, if a configuration file is being used to set parameters
- Proxy information Original login name, if set proxy in effect

Information	Value
-------------	-------

Audit option (Automatically audited event not controlled by an option)

Event 72

Command or access audited sp_configure "auditing", 1

Information in extrainfo

- Roles Current active roles
- Keywords or options NULL
- Keywords or options NULL
- Current value NULL
- Other information NULL
- Proxy information Original login name, if set proxy in effect

Information Value

Audit option (Automatically audited event not controlled by an option)

Event 73

Command or access audited sp_configure "auditing", 0

Information in extrainfo

- Roles Current active roles
- Keywords or options NULL
- Keywords or options NULL
- Current value NULL
- Other information NULL
- Proxy information Original login name, if set proxy in effect

Example of extrainfo for event 72 or 73:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; ; sa/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_dboption [page 228] sp_displaylevel [page 268] sp_helpconfig [page 424] sp_monitorconfig [page 611]

1.59.1 Configuring Parallel Checkpoints

The number of checkpoint tasks parameter configures parallel checkpoints.

Parallel checkpoints depend on the layout of the databases and performance of underlying I/O sybsystems. Tune this parameter depending on the number of active databases and the ability of the I/O subsystem to handle writes.

This configuration parameter is dynamic. When the value for this parameter is reduced, checkpoint tasks drain out, and when the value is increased, additional tasks are created.

1.59.2 Configuring Degree of Parallelism During Database Recovery

The max concurrently recovered db parameter determines the degree of parallelism during database recovery:

When the SAP ASE server is not in recovery, this configuration parameter takes effect statically. However when the SAP ASE server is in recovery, a system administrator can force serial recovery dynamically.

The effectiveness of max concurrently recovered db depends on the database layout and the performance of underlying I/O subsystem.

1.59.3 Setting Configuration Parameters for Clusters Using sp_configure

Considerations for configuring clusters.

- If you do not specify a configuration option or instance name, the information displayed depends on the system view setting.
- If you do not specify a configuration option but specify the instance name, the SAP ASE server displays all instance-specific configuration settings for the specified instance.
- If you specify the configuration option, but not the configuration value and instance name, the SAP ASE
 server displays the current settings for the specified option for all instances under the "cluster" view. If you
 specify the instance name, the SAP ASE server displays configuration information for the specified
 instance.

• If you specify the configuration option and value, but not the instance, the SAP ASE server configures the cluster-wide setting for the option. If, however, you specify the instance name, the SAP ASE server sets the configuration value only for the instance. The syntax is:

```
sp configure <configuration name>, <config value>, NULL, <instance name>
```

- You cannot set configuration options from inside a local temporary database.
- If an instance already has instance-specific setting for a configuration parameter set, you can reconfigure this parameter for a cluster-wide setting.
- A user can reconfigure only those instances to which they are connected.

1.60 sp_copy_all_qplans

Copies all plans for one abstract plan group to another group.

Syntax

```
sp_copy_all_qplans <src_group>, <dest_group>
```

Parameters

```
<src_group>
```

is the name of the source abstract plan group.

<dest_group>

is the name of the abstract plan group to which the plans are to be copied.

Examples

Example 1

Copies all of the abstract plans in the dev_plans group to the ap_stdin group:

```
sp_copy_all_qplans dev_plans, ap_stdin
```

Usage

There are additional considerations when using sp copy all qplans:

- The destination group must exist before you can copy plans into it. It may contain plans.
- sp_copy_all_qplans calls sp_copy_qplan for each plan in the source group. Each plan is copied as a separate transaction, so any problem that keeps sp_copy_all_qplans from completing does not affect the plans that have already been copied.
- sp_copy_qplan prints messages when it cannot copy a particular abstract plan. You also see these messages when running sp_copy_all_qplans.
- If the query text for a plan in the destination group exactly matches the query text in the source group and the user ID is the same, the plan is not copied, and a message giving the plan ID is sent to the user, but the copying process continues with the next plan in the source group.
- Copying a very large number of abstract plans can take considerable time, and also requires space on the system segment in the database and space to log the changes to the database. Use sp_spaceused to check the size of sysqueryplans, and sp_helpsegment for the system and logsegment to check the space available.

Permissions

The permission checks for sp copy all qplans differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Any user can execute sp copy all qplans to copy an abstract plan that they own.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Any user can execute sp copy all qplans to copy an abstract plan that they own.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_copy_qplan [page 214]
sp_help_qpgroup [page 410]

1.61 sp_copy_qplan

Copies one abstract plan to an abstract plan group.

Syntax

```
sp copy qplan <src id>, <dest group>
```

Parameters

```
<src_id>
```

is the ID of the abstract plan to copy.

<dest_group>

is the name of the destination abstract plan group.

Examples

Example 1

Copies the abstract plan with ID 2140534659 to the ap_stdin abstract plan group:

```
sp copy qplan 2140534659, ap stdin
```

Usage

There are additional considerations when using sp_copy_qplan:

- The destination group must exist before you can copy an abstract plan into it. You do not need to specify a source group, since plans are uniquely identified by the plan ID.
- A new plan ID is generated when the plan is copied. The plan retains the ID of the user who created it, even if the system administrator or database owner copies the plan. To assign a different user ID, a system administrator or database owner can use sp_export_qpgroup and sp_import_qpgroup.
- If the query text for a plan in the destination group exactly matches the query text in the source group and the user ID, the plan is not copied, and a message giving the plan IDs is sent to the user.
- To copy all of the plans in an abstract plan group, use sp copy all qplans.

Permissions

The permission checks for sp copy qplans differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Any user execute sp_copy_qplan to copy a plan that they own.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user execute sp_copy_qplan to copy a plan that they own.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_help_qplan [page 412]
sp_import_qpgroup [page 500]
```

1.62 sp_countmetadata

Displays the number of indexes, objects, or databases in the SAP ASE server.

Syntax

```
sp countmetadata "<configname>"[, <dbname>]
```

Parameters

<configname>

is "number of open databases", "number of open objects", "number of open indexes", Or "number of open partitions".

<dbname>

is the name of the database on which to run sp_countmetadata. If no database name is given, sp_countmetadata provides a total count for all databases.

Examples

Example 1

Reports on the number of user objects in the SAP ASE server. Use this value to set the number of objects allowed in the database, plus space for additional objects and temporary tables:

```
sp_configure "number of open objects", 310

sp_countmetadata "open objects"

There are 283 user objects in all database(s), requiring
117.180 Kbytes of memory. The 'open objects'
configuration parameter is currently set to a run value
of 500.
```

Example 2

Reports on the number of indexes in the SAP ASE server:

```
sp_countmetadata "open indexes", pubs2

There are 21 user indexes in pubs2 database(s), requiring 8.613 kbytes of memory. The 'open indexes' configuration parameter is currently set to 600.
```

Usage

There are additional considerations when using sp countmetadata:

- sp_countmetadata displays the number of indexes, objects, databases, or partitions in the SAP ASE server, including the number of system databases such as model and tempdb.
- Avoid running sp_countmetadata during SAP ASE peak times. It can cause contention on the sysindexes, sysobjects, sysdatabases, and syspartitions system tables.
- You can run sp_countmetadata on a specified database if you want information on a particular database. However, when configuring caches for indexes, objects, databases, or partitions, run sp_countmetadata without the <database_name> option.

- The information on memory returned by sp_countmetadata can vary by platform. For example, a database on an SAP ASE server for Windows could have a different sp_countmetadata result than the same database on Sun Solaris. Information on the number of user indexes, objects, databases, or partitions should be consistent, however.
- sp_countmetadata does not include temporary tables in its calculation. Add 5 percent to the open objects value and 10 percent to the open indexes or open partitions value to accommodate temporary tables.
- If you specify a non-unique fragment of "open indexes", "open objects", "open databases", or "open partitions" for <configname>, sp_countmetadata returns a list of matching configuration parameter names with their configured values and current values. For example:

```
sp countmetadata "open"
Configuration option is not unique.
option_name _______
curread change w/ open cursors 1
12
                   config_value run value
                                                      1
number of open databases
                                                      12
                                       500
number of open indexes
                                                     500
number of open objects
                                       500
                                                     500
open index hash spinlock ratio
                                        100
                                                     100
open index spinlock ratio open object spinlock ratio
                                        100
                                                     100
                                        100
                                                     100
```

Permissions

The permission checks for sp countmetadata differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage server privilege.
Disabled	With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_configure [page 203]

sp_monitorconfig [page 611]
```

1.63 sp_cursorinfo

Reports information about a specific cursor or all execute cursors that are active for your session.

Syntax

```
sp_cursorinfo [{<cursor_level> | null}][, <cursor_name>]
```

Parameters

```
<cursor level> | null
```

is the level at which the SAP ASE server returns information for the cursors. You can specify the following for <cursor_level>:

- <N> any cursors declared inside stored procedures at a specific procedure nesting level. You can specify any positive number for its level.
- 0 any cursors declared outside stored procedures.
- 1 any cursors from either of the above. You can substitute any negative number for this level.

For information about cursors with a specific <cursor_name > regardless of cursor level, specify null for this parameter.

<cursor name>

is the specific name for the cursor. The SAP ASE server reports information about all active cursors that use this name at the <cursor_level> you specify. If you omit this parameter, the SAP ASE server reports information about all the cursors at that level.

Examples

Example 1

Displays the information about the cursor named c at level 0:

The cursor has been successfully opened 0 times.

```
1> declare c cursor
2> for select au_id,au_lname, au_fname from authors
3> go
1> sp_cursorinfo
2> go

Cursor name 'c' is declared at nesting level '0'.
The cursor is declared as NON-SCROLLABLE cursor.
```

The cursor id is 917505.

```
The cursor will remain open when a transaction is committed or rolled back.

The number of rows returned for each FETCH is 1.

The cursor is updatable.

This cursor is using 5389 bytes of memory.

(return status = 0)
```

Example 2

Displays information on the cursor's scrollability and sensitivity, in this case a semi-sensitive scrollable cursor css:

```
sp cursorinfo 0, cursor css
Cursor name 'css' is declared at nesting level '0'.
The cursor is declared as SEMI SENSITIVE SCROLLABLE cursor.
The cursor id is 786434.
The cursor has been successfully opened 1 times.
The cursor was compiled at isolation level 1.
The cursor is currently scanning at a nonzero isolation level.
The cursor is positioned on a row.
There have been 1 rows read, 0 rows updated and 0 rows deleted through this
cursor.
The cursor will remain open when a transaction is committed or rolled back.
The number of rows returned for each FETCH is 1.
The cursor is read only.
This cursor is using 19892 bytes of memory.
There are 2 columns returned by this cursor.
The result columns are:
Name = 'c1', Table = 't1', Type = INT, Length = 4 (not updatable)
Name = 'c2', Table = 't1', Type = INT, Length = 4 (not updatable)
```

Usage

There are additional considerations when using sp cursorinfo:

- If you do not specify either <cursor_level> or <cursor_name>, the SAP ASE server displays
 information about all active cursors. Active cursors are those declared by you and allocated by the SAP
 ASE server.
- The SAP ASE server reports the following information about each cursor:
 - The cursor name, its nesting level, its cursor ID, and the procedure name (if it is declared in a stored procedure).
 - The number of times the cursor has been opened.
 - The isolation level (0, 1, or 3) in which it was compiled and in which it is currently scanning (if open).
 - Whether the cursor is open or closed. If the cursor is open, it indicates the current cursor position and the number of rows fetched.
 - Whether the open cursor closes if the cursor's current position is deleted.
 - Whether the cursor remains open or be closed if the cursor's current transaction is committed or rolled back.
 - The number of rows returned for each fetch of that cursor.
 - $\circ\quad$ Whether the cursor is updatable or read-only.
 - The number of columns returned by the cursor. For each column, it displays the column name, the table name or expression result, and whether it is updatable.

The output from <code>sp_cursorinfo</code> varies, depending on the status of the cursor. In addition to the information listed, <code>sp_cursorinfo</code> displays the <code>showplan</code> output for the cursor. For more information about <code>showplan</code>, see the <code>Performance</code> and <code>Tuning</code> Guide.

See also:

• declare cursor, set in Reference Manual: Commands

Permissions

Any user can execute $sp_cursorinfo$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.64 sp_dbextend

Allows you to install automatic database expansion procedures on database/segment pairs and devices; define site-specific policies for individual segments and devices; and simulate execution of the database expansion machinery, to study the operation before engaging large volume loads.

These policies are stored in the sysattributes table in master database.

All arguments are string arguments:

Syntax

Parameters

set

sets the threshold at which a database, segment, or device should fire. The arguments are:

- 'threshold', <dbname>, <segmentname>, <freespace> specifies the free space level at which to install the threshold on a specified database and segment.
 - Specify <freespace> in size unit specifiers, such as megabytes. If you specify no size units, the value of <freespace> is treated as the number of kilobytes in the segment.
- 'database', <dbname>, <segmentname> {[[, <growby>][,</maxsize>]]} specifies the name of the database/segment pair, the size by which to alter the database, and the maximum size of the database, at which the expansion process stops.
 - <growby> is the rate, in unit specifiers or percentage values, at which the database grows at each expansion attempt.
 - <maxsize> is the maximum size of the segment, after which no further expansion occurs. Both are optional parameters.

• 'device', <devicename> { [[, <growby >] [, <maxsize>]] }] - defines the growth rate and maximum size of a device, in unit specifiers or percentage values, at which the device can grow. <maxsize> in devices is subject to OS disk limitations.

clear

clears any previously set rules of expansion for a specified database and segment or for a specified device.

modify

modifies previously set site-specific policies, such as <growby> and <maxsize>, for a database and segment.

Use <newvalue> to specify the new value you set for automatic expansion.

list

lists briefly existing rules for a specified database, segment, device, or thresholds on specified segments, and presents the data from master.dbo.sysattributes in a readable format. Allows you to view rules on a per-database or per-device basis.

Presents the current rules in effect.

Use <order_by_clause> to generate listings in a different order from the default ordering of name, type.

Use threshold to display all the thresholds that are currently installed on the specified database (using the @dbname) and segment (using @segment name).

listfull

lists fully the site-specific policy rules, and includes a comment column in the sysattributes table that displays a datetime stamp for when the rule was set, and when it was last modified.

check

examines current policies and verifies that they are consistent with the current space layout in each segment. If any policy settings appear redundant, ineffective, or incorrect, a warning message appears.

simulate

simulates executing the database or device expansion schemes executed at runtime, according to the set of current policies implemented by the set command.

<iterations> specifies the number of times you simulate the expansion.

execute

performs the actual database/segment, or device, expansion, using the current set of policies.

reload [defaults]

reinitializes sysattributes with the system-supplied defaults for <growby> and <maxsize> in all databases, segments, and devices, and reverts the databases or devices to the original default behavior.

reload does not delete user-specified policies.

help

provides help information for all command parameters, such as set or list, or help information for any single command.

trace

traces the threshold procedure execution logic in all expansion processes.

enable | disable

enables or disables the automatic expansion procedures on a specified database segment or device.

who

shows any active expansion processes running currently. Use:

- '<spid>' restricts the output for a particular spid.
- block shows tasks that currently cause blocking of the expansion process.
- all shows all currently active tasks.

<freespace>

specifies the free space value at which the threshold procedure is installed on the specified segment. Always use size unit specifiers, such as megabytes, to specify <freespace>.

<dbname>

is the name of the database in which the threshold is being installed.

<segmentname>

is the segment contained in database <dbname>.

<devicename>

is the logical name of the affected device.

<newvalue>

specifies the new value you set for automatic expansion when you modify a policy for a database/segment pair or device.

<order by clause>

generates listings in a different order from the default ordering in the t> command. The default order is name, type.

<iterations>

specifies the number of times an expansion is simulated or executed.

<growby>

specifies the rate, in unit specifiers or percentage values, at which a specified database segment or device grows each time the threshold procedures are attempted.

<maxsize>

is the maximum size of a segment/database pair or device, the size at which automatic expansion must stop.

<maxsize> is the maximum size of the segment at which the automatic expansion
process stops, not the maximum size of the database.

You can set <maxsize> to a value larger than the total amount of disk space available on the device, but actual expansion is limited to the available disk space at the time expansion is attempted.

Examples

Set Thresholds

Installs the space expansion threshold on a log segment in the database pubs2 at 100 MB:

```
sp_dbextend 'set', 'thresh', pubs2, logsegment, '100m'
```

Set Database

Installs a policy for the logsegment segment, at a growth rate of 100 MB per expansion attempt:

```
sp_dbextend 'set', 'database', pubs2, logsegment, '100m'
```

Set Device

Expands this device until either the OS disk space limitation or the device size of 4 TB is reached:

```
sp_dbextend 'set', 'device', pubs2-datadev1, '100m'
```

Clear

Shows how to clear all space-expansion thresholds previously installed in pubs2, logsegment:

```
sp_dbextend 'clear', 'thresh', pubs2, logsegment
```

You can also the space-expansion threshold for segment dataseg1 in pubs2, installed at a free space of 200 MB:

```
sp_dbextend 'clear', 'thresh', pubs2, dataseg1, '200m'
```

Modify

Defines the rate of growth as 5% of current value, in each expansion attempt:

```
sp_dbextend 'modify', 'da', pubs2, logsegment, 'growby', '5%'
```

A command can fail when <maxsize> is not previously defined:

```
sp_dbextend 'modify', 'device', pubs2_log_dev, 'maxsize', '2.3g'
```

List

Lists briefly the rules for all databases and devices:

```
sp_dbextend 'list'
```

This lists rules for all databases with names similar to $\verb"pubs\$":$

```
sp_dbextend 'list', 'database', 'pubs%'
```

Listfull

Lists the rules for all databases and devices, including a comment column showing a datetime stamp:

```
sp_dbextend 'listfull'
```

List Threshold

When issued from the pubs2 database, this lists the thresholds setup on various segments in the pubs2 database:

```
sp_dbextend 'list', 'threshold'
```

To examine the thresholds on a particular segment, use as:

```
sp_dbextend 'list', 'threshold', pubs2, 'logsegment'
```

Simulate

Simulates an expansion twice, without tripping the thresholds:

```
sp_dbextend 'simulate', pubs2, logsegment, '2'
```

Execute

Executes an automatic expansion procedure:

```
sp_dbextend 'execute', pubs2, logsegment
```

Help

Obtains help for a specific command:

```
sp_dbextend help, 'set'
```

Usage

There are additional considerations when using sp dbextend:

- You can only set one automatic expansion threshold on any given database/segment pair. If you try to install another instance of the threshold procedure, even at a different free space value, an error is raised.
- You cannot set system-supplied defaults, only modify them. After you modify system defaults you can reset them by re-running the installdbextend script, or by using the reload defaults command.
- To disallow any automatic growth in a particular segment, either specify 0 for <growby> or <maxsize>, or do not install the threshold procedure at all. If you specify NULL for this parameter, defaults to the system-specified default <growby> rate is used.
- By default, if the size of the device is greater than 40MB, the size of the database is increased by 10 percent. If your database is smaller than 40 MB, the size of the database is increased by 4 MB. However, you can specify database resizing limits that match the needs of your site
- There is no system-specified maximum size for the default database. If no <maxsize> value is specified, the size of the database is limited only by the physical limitations of the database device.
- To turn off the automatic growth feature on a particular device, specify 0 for <growby> or <maxsize>. If you do not specify a value for <growby>, the default expansion rate is used.
- When you use this stored procedure to clear a threshold, <dbname> and <segmentname> are required arguments.
- When you use this stored procedure to clear a database, and provide no <dbname> and <segmentname>, all policy rules that is, all the relevant rows in master.dbo.sysattributes for the current database and all segments in it are deleted. This is a good way to reverse all settings to default and restart.

- When you use this stored procedure to clear a device, if you do not provide a value for <devicename>, no policy rules are cleared. You can clear out the policy rules for a single device by providing <devicename >or using "%" to clear policies for all devices.
- You can specify <dbname>, <devicename>, and <segmentname> using patterns, so that names with patterns that match the specified pattern are considered for the clear, enable, disable, and list operations.
- You must have set a value or property before you can modify it. modify fails if no value was previously set. <growby> and <maxsize> are modified to the new value specified by <newvalue>
- The new value specified in <newvalue> remains in effect throughout subsequent attempts to expand either the database or device. Even if <newvalue> is less than the current size of the database, segment, or device, the object does not shrink. <newvalue> specifies only future expansion, and does not affect current sizes.
- Provide <dbname> and <segmentname> to obtain policy rules for individual databases and for the segments inside them.
- When you use list for a database and provide no <dbname> or <segmentname>, all the policy rules (that is, rows in master.dbo.sysattributes) for all segments in the current database are listed.
- When you use list for a device name and provide no <devicename>, default policy rules for all devices are listed. You can filter this to list the policy rules for a single device by providing <devicename> or use pattern specifiers for the <devicename>.
- You can simulate the expansion of only one database/segment pair at a time. Both <dbname> and <segmentname> are required arguments. You cannot use wildcard patterns in <dbname> or <segmentname> for execute or simulate commands.
- The maximum size of a device is 4TB.
- trace turns the trace facility on or off throughout the server. If trace is on, messages appear in the server error log when a threshold fires. Use trace only for troubleshooting.

See also alter database, create database, disk init, and disk resize in Reference Manual: Commands.

Permissions

If the automatic expansion procedures are installed on a segment by a database owner without sa_role privilege, the devices do not expand, because the user cannot run the disk resize command. A user with sa_role privilege should run the set threshold command when installing the threshold procedure.

The following permission checks for sp dbextend differ based on your granular permissions settings

Setting Description

Enabled With granular permissions enabled, you must be:

Setting Description

- sp_dbextend clear database a user with own any database privilege, or for the specified database, be the database owner or a user with own database privilege on the database.
- sp dbextend clear device a user with manage disk privilege.
- sp_dbextend clear threshold the database owner or a user with own database privilege on the database.
- sp_dbextend execute the database owner or be a user with own database privilege on the specified database, and have manage disk privilege.
- sp dbextend simulate the database owner or a user with own database privilege.
- sp_dbextend enable/disable a user with own any database privilege or the database owner or have the own database privilege on the specified database.
- sp_dbextend list database a user with own any database privilege when % pattern is specified.
- sp_dbextend list @ verbose=2 a user with own any database privilege.
- sp_dbextend modify database the database owner or a user with own database privilege on the specified database or a user with own any database privilege for sp dbextend 'modify', 'database', 'default'.
- sp dbextend modify device the database owner or a user with manage disk privilege.
- sp dbextend reload defaults a user with own any database privilege.
- sp_dbextend set database the database owner or a user with own database privilege on the specified database.
- sp_dbextend set device a user with manage disk privilege.
- sp_dbextend set threshold the database owner or a user with own database on the specified database and you must have the manage disk privilege.
- sp dbextend trace a user with set switch privilege.

Disabled With granular permissions disabled, you must be:

- sp dbextend clear database the database owner or a user with sa_role.
- sp_dbextend clear device a user with sa_role.
- sp_dbextend clear threshold the database owner or a user with sa_role.
- sp dbextend execute a user with sa_role.
- sp dbextend simulate the database owner or a user with sa_role.
- sp_dbextend enable/disable the database owner or a user with sa_role.
- sp dbextend list database a user with sa_role permission when % pattern is specified.
- sp dbextend list @ verbose=2 a user with sa_role.
- sp_dbextend modify database the database owner or a user with sa_role if dbname equals default.
- sp dbextend modify device the database owner or a user with sa_role.
- sp_dbextend reload defaults the database owner or a user with sa_role.
- sp dbextend set database the database owner or a user with sa_role.
- sp_dbextend set device the database owner or a user with sa_role.
- sp dbextend set threshold the database owner or a user with sa_role.

Setting Description

• sp dbextend trace - a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dropthreshold [page 323]
sp_modifythreshold [page 598]

1.65 sp_dboption

Displays or changes database options, and enables the asynchronous log service feature.

Syntax

```
sp_dboption [<dbname>, <optname>, <optvalue>[, <dockpt>]]
```

Parameters

<dbname>

is the name of the database in which the option is to be set. You must be using master to execute sp_dboption with parameters (that is, to change a database option). You cannot, however, change option settings in the master database.

<optname>

is the name of the option to be set. The SAP ASE server understands any unique string that is part of the option name. Use quotes around the option name if it is a keyword or includes embedded blanks or punctuation.

You can turn on more than one database option at a time. You cannot change database options inside a user-defined transaction.

<optvalue>

is the value of the setting. true turns the option on, and false turns it off.

<dockpt>

specifies whether sp_dboption performs the checkpoint command on <dbname>. The default value is 1, which automatically performs checkpoint. You can run checkpoint on the <dbname> by manually executing the checkpoint.

Examples

Example 1

Displays list of database options:

```
sp_dboption
```

Settable database options

```
database_options
abort on low memory
abort tran on log full
allow incremental dumps
allow nulls by default
allow wide dol rows
async log service
auto identity
auto imrs partition tuning
dbo use only ddl in tran
deallocate first text page
deferred table allocation
delayed commit
enforce dump tran sequence
erase residual data
full logging for all full logging for alter table
full logging for reorg rebuild
full logging for select into
identity in nonunique index
no chkpt on recovery
no free space acctg
read only
scratch database
select into/bulkcopy/pllsort
single user
trunc log on chkpt
trunc. log on chkpt.
unique auto_identity index
```

Example 2

Makes database pubs2 read-only:

```
1> use pubs2
2> go
```

```
1> master..sp_dboption pubs2, "read", true
2> go

Database option 'read only' turned ON for database 'pubs2'.
Running CHECKPOINT on database 'pubs2' for option 'read only' to take effect.
(return status = 0)
```

The read string uniquely identifies the read only option from among all available database options. Note the use of quotes around the keyword read.

Example 3

Makes the database pubs2 writable again, but by specifying 0 for the <dockpt> option, you see Run the CHECKPOINT command in the database that was changed:

```
1> use pubs2
2> go
1> master..sp_dboption pubs2, "read", false, 0
2> go

Database option 'read only' turned OFF for database 'pubs2'.
Run the CHECKPOINT command in the database that was changed.
(return status = 0)
```

To manually perform a checkpoint on pubs2, enter:

```
1> checkpoint 2> go
```

Example 4

Allows select into, bcp, parallel sort operations on tables in pubs2. The select into string uniquely identifies the select into/bulkcopy option from among all available database options:

```
use pubs2
go
master..sp_dboption pubs2, "select into", true
go
```

i Note

Quotes are required around the option because of the embedded space.

Example 5

Automatically defines 10-digit IDENTITY in new tables created in mydb. The IDENTITY column, $SYB_IDENTITY_COL$, is defined in each new table that is created without specifying either a primary key, a unique constraint, or an IDENTITY column:

```
use mydb
go
master..sp_dboption mydb, "auto identity", true
go
```

Example 6

Automatically includes an IDENTITY column in the index keys of mydb tables, provided these tables already have an IDENTITY column. All indexes created on the tables are internally unique:

```
use master
```

```
go
sp_dboption mydb, "identity in nonunique index", true
go
use mydb
go
```

Example 7

Automatically includes IDENTITY With unique, nonclustered index for new tables in pubs2:

```
use master
go
sp_dboption pubs2, "unique auto_identity index", true
go
use pubs2
go
```

Example 8

Sets asynchronous log service (ALS) in a specified database, enabling the user log cache and the log writer threads.

```
sp_dboption "mydb", "async log service", true
use mydb
```

Example 9

Disables ALS in a specified database:

```
sp_dboption "mydb", "async log service", false
use mydb
```

Example 10

Enforces a dump transaction sequence for big_db:

```
sp_dboption 'big_db', 'enforce dump tran sequence',
true
```

Example 11

Enables full logging for select into and alter table in mydb:

• The create database command creates mydb:

```
create database mydb on datadev=20 log on logdev=10 go
```

```
CREATE DATABASE: allocating 10240 logical pages (20.0 megabytes) on disk 'datadev' (10240 logical pages requested).

CREATE DATABASE: allocating 5120 logical pages (10.0 megabytes) on disk 'logdev' (5120 logical pages requested).

Database 'mydb' is now online.
```

• Turns on the full-logging option for select into in mydb:

```
sp_dboption "mydb", "full logging for select into", "true"
go
```

```
Database option 'full logging for select into' turned ON for database 'mydb'.
Running CHECKPOINT on database 'mydb' for option 'full logging for select into' to take effect.
```

```
(return status = 0)
```

table' to take effect.
(return status = 0)

• Turns on the full-logging option for alter table in mydb:

```
sp_dboption "mydb", "full logging for alter table", "true" go

Database option 'full logging for alter table' turned ON for database 'mydb'.

Running CHECKPOINT on database 'mydb' for option 'full logging for alter
```

• Running sp helpdb shows the settings for mydb:

```
name db_size owner dbid created durability status

mydb 30.0 MB sa 5 Dec 16, 2010 full full logging for select into/alter table

(1 row affected) device_fragments size usage created free kbytes

datadev 20.0 MB data only Dec 16 2010 6:08PM 18696 logdev 10.0 MB log only Dec 16 2010 6:08PM not applicable

log only free kbytes = 10184
```

Example 12

Enables back-up and restoration of cumulative dumps:

```
sp_dboption mydb, "allow incremental dumps", true
```

Example 13

Enables deferred table creation for pubs2:

(return status = 0)

```
sp_dboption pubs2, "deferred table allocation", true
```

Example 14

The syntax to enable the removal of residual data at the database level for these two examples is:

```
sp_dboption <dbname>, "erase residual data", true
```

The first example use these two tables:

- create table t1 (col1 int) with erase residual data on
- create table t2 (col1 int) with erase residual data off

i Note

The $sp_dboption$ procedure requires quote marks for "erase residual data", but create table ... with erase residual data on | off does not use quotes. Using quote marks in create table causes a syntax error.

The option to erase residual data is turned on for table t1 because it is set at the database level, so that both the drop table and truncate table commands for t1 result in the cleanup of all residual data from its pages.

Table t2, however, has the erase residual data option turned off explicitly, as it was created with the erase residual data off clause. Residual data is not removed, even though the "erase residual data" option is set to true at the database level. As a result, residual data remains, even after running drop table and truncate table on t2:

```
create database db1

go
    sp_dboption db1, "erase residual data", true
go
    use db1
go
    create table t1 (col int)
go
    insert t1 values ...
go
    create table t2 (col1 int, col2 char(10)) with erase residual data off
go
    truncate table t1
go
    drop table t1
go
    drop table t2
go
drop table t2
go
```

The second example uses the following:

```
create database db1
go
use db1
go
create table t1 (col int)
go
sp_dboption db1, "erase residual data", true
go
create table t2 (col1 int, col2 char(10))
go
create table t3 (col1 int, col2 char(10)) with erase residual data off
go
truncate table t1
go
truncate table t2
go
truncate table t3
go
```

- Table t1 does not have erase residual data off set explicitly, but does have it set at the database level, resulting in the removal of residual data from t1 when you run truncate table t1.
- Table t2 is set to erase residual data because the option was set at the database level. This results in the removal of residual data from t2 when you run truncate table t2.
- Table t3 is marked with erase residual data off explicitly, so that even though sp_dboption sets "erase residual data" to true, residual data is not removed when SAP ASE runs truncate table t3.

Example 15

Deallocate the first text page after a NULL update:

```
sp_dboption mydb, "deallocate first text page", true
```

Example 16

Configure automatically disabling and re-enabling IMRS usage for an IMRS-enabled table.

```
sp dboption mydb, "auto imrs partition tuning", true
```

Usage

- When you enable the "erase residual data" setting at the database level, any operation that results in deallocation is followed by the cleaning of its pages. By default, this option is disabled
- You cannot change master database option settings.
- If you enter an ambiguous value for <optname>, an error message appears. For example, two of the database options are dbo use only and read only. Using "only" for the <optname> parameter generates a message because it matches both names. The complete names that match the string supplied are printed out so that you can see how to make the <optname> more specific.
- To display a list of database options, execute sp_dboption with no parameters from inside the master database.
- For a report on which database options are set in a particular database, execute sp_helpdb.
- The no chkpt on recovery option disables the trunc log on chkpt option when both are set with sp_dboption for the same database. This conflict is especially possible in the tempdb database which has trunc log on chkpt set to on as the default.
- The database owner or system administrator can set or unset particular database options for all new databases by executing sp dboption on model.
- After sp_dboption has been executed, the change does not take effect until the checkpoint command is issued in the database for which the option was changed.

- alter table, checkpoint, create default, create index, create procedure, create rule, create schema, create table, create trigger, create view, drop default, drop index, drop procedure, drop rule, drop table, drop trigger, drop view, grant, revoke, select in Reference Manual: Commands
- See the System Administration Guide for more information on database options.
- bcp in the Utility Guide
- Using sp_dboption on IMRS-enabled tables:
 - Occasionally, an IMRS-enabled table may consume a large amount of row storage cache without
 improving the performance. When auto imrs partition tuning is enabled, the server internally
 monitors the transaction workload accesses to the data and disables row storage usage for them.
 However, the disabled row storage usage may later improve by using row storage. The server monitors
 these cases and may re-enable the row storage usage if it finds that the performance for the workload
 improves by storing data in row storage.
 - For example, a table that rarely updates may initially load data in row storage. However, since the table is seldom updated, doing so may not improve performance, but may waste row storage cache for the

- partition. When auto imrs partition tuning is enabled, the server disables row storage use for these updates on the partition.
- Use sp imrs or the monIMRSPartitionActivity monitoring table to see when the server decides to disable IMRS usage. For example:

```
sp imrs 'show', 'effectiveness', 'imrscache'
CacheName DBName ObjectName PartitionName
                                                  DisabledRowTypes
             mydb
                          t1
imrscache
                                              p1
                                                            Migrated
```

- You cannot use auto imrs partition tuning on snapshot isolation-enabled tables, which continue to use row storage regardless of their workload access, providing the snapshot isolation required to create versions in row storage for all the DMLs issued against these tables.
- Once auto imrs partition tuning is disabled, the server does not make any new internal decisions to disable or re-enable row storage for different operations on the partitions in the database. However, any decisions made before disabling auto imrs partition tuning are applied to determine if rows storage is used for an operation on the partition.

Permissions

The permission checks for sp dboption differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database privilege on the database.

Any user can display database options.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user can display database options. A user aliased to the database owner cannot execute sp dboption to change database options.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.65.1 Full Logging and sp_dboption

By default, select into, certain types of alter table, and reorg rebuild are run in minimally logged mode. Before executing these commands, first set the select into/bulk copy database option to true to allow the SAP ASE server to break the dump sequence—that is, to perform operations that prevent the ability to use dump transaction.

When you use the full logging for [select into | alter table | reorg rebuild | all] parameters, the command is run with full logging. Any previously set value of select into/bulk copy becomes irrelevant for any of the now-fully logged commands.

Full logging for fast bcp and parallel sort is not supported, and cannot take place unless you set select into/bulk copy to true.

Once the operation is set to run with full logging, you can run dump transaction/load transaction and recovery for these operations, just like any other fully logged operation.

The syntax to fully log commands that are, by default, minimally logged is:

```
sp_dboption <dbname>, "full logging for
   [select into | alter table | reorg rebuild | all]",
   true | false
```

where:

- full logging for select into in order to have a select into proxy table fully logged, set the "full logging for select into" option to true on the remote server that hosts the actual table. If you set the full logging for select into option to false on the server that hosts the actual table, the command is then executed with minimal logging in that database and the dump transaction sequence breaks
- pll create index enables full logging when a parallel sort is done. Parallel sorting is required when you create a clustered index on a round-robin-partitioned table
- full logging for alter table enables full logging for these versions of alter table that require data movement:

```
o alter table add <column> not null
```

- o alter table drop <column> not null
- o alter table modify <datatype> of not null <column>
- o alter table partition

Other variants of alter table are already executed in fully logged mode.

i Note

Changing the locking scheme between an allpages-locked table and a datapages-locked/data rows-locked table by alter table lock requires data movement, however, this behavior is not supported by full logging for alter table.

• full logging for reorg rebuild – involves table data movement. This has no impact on the reorg rebuild index command, which is already fully logged. This parameter enables full logging for

reorg rebuild table statements. When you do not set this option (or set this option to false), the SAP ASE server executes the reorg rebuild table command with minimal logging.

• full logging for all – enables all the above full logging options. Setting all to false disables all the full logging options.

i Note

The syntax requires that you specify what you want to fully log; "full logging" by itself is not a valid option.

When you use any of the full logging for option, the command is run with full logging. Any previously set value of select into/bulk copy/pllsort becomes irrelevant for any of the now-fully logged commands. Full logging for fast bcp and parallel sort is not supported and cannot take place unless you set select into/bulk copy/pllsort to true.

Once the operation is set to run with full logging, you can run dump transaction/load transaction and recovery for these operations, just like any other fully logged operation.

The dboption is "full logging for all" and not just "full logging" on its own.

i Note

The execution of a fully logged select into, alter table, or reorg rebuild command may require a significant amount of log space to accommodate the transaction log.

1.65.2 Shrinking the Log

Issuing select into, alter table, and reorg rebuild when full logging is enabled can greatly increase the demand for log space, particularly for large tables. You may need to increase the size of the log. Once you have completed the command, you may remove the extra log space using the alter database log off command.

See alter database and System Administration Guide Volume I > Shrinking Log Space.

You cannot set full logging for select into, alter database, or reorg rebuild for:

- The master database
- In-memory databases

You can change the settings of:

- Any database that has mixed log and data segments, but the option is ignored until such time as the database is altered to no longer have mixed log and data segments.
- A database that does not have a durability level of full, but the option is ignored until the database is altered to have full durability.

These restrictions apply because none of the databases allow you to execute a dump transaction command. The use of fully recoverable DDLs enables dump transaction.

1.65.3 Allowing Wide Rows Using sp_dboption

allow wide dol rows configures databases to allow wide, variable-length, data-only locked (DOL) rows.

- You must enable allow wide dol rows separately for each database.
- You can set the allow wide dol rows database option in user databases only. You cannot set the allow wide dol rows database option for the master database.
- Enabling allow wide dol rows in an the SAP ASE server configured with page size of 8K or less has no effect.
- Disabling allow wide dol rows prevents SAP ASE from creating wide, variable-length DOL rows; it does not prevent you from selecting data that includes such rows. However, until you enable allow wide dol rows, you cannot change rows that contain wide data, unless the change produces rows that no longer contain wide data.
- Temporary databases cannot use wide DOL worktables until you enable their allow wide dol rows setting. If you use tempdb groups, enable allow wide dol rows either for all databases in the group or for none of them, so worktable and query processing behavior is consistent across the group, regardless of the tempdb to which a particular user session is bound.

1.65.4 Asynchronous Log Service (ALS) Options

Enabling async log service (ALS) allows for greater scalability in the SAP ASE server, providing higher throughput in logging subsystems for high-end symmetric multiprocessor systems.

- The ALS option is disabled by default.
- You cannot enable the ALS option in system databases, such as master or model.
- The ALS option is persistent; once you enable ALS on a specified database, you can dump and reload the database without disabling ALS. To disable this feature, you must use sp_dboption to set the parameter to false.

1.65.5 Using enforce dump tran sequence

enforce dump tran sequence prevents operations that disallow a subsequent dump transaction.

- false (the default) does not affect operations that interfere with dump transactions.
- true disallows operations that prevent a dump transaction.

You can set this option to true, only if the database:

- Is a dedicated log database.
- Is not an archive database.
- Is not a local or global temporary database.
- Is not read-only.
- Was not brought online for standby access.
- Has full durability. Databases with at shutdown and no recovery durability are not allowed.

- Has select into/bulk copy/pllsort or trunc log on chkpt set to false. If any of these options are true, they automatically reset to false.
- Does not need a dump database due to one of the following reasons. Perform a dump database before setting this database option to true.
 - A partially logged update has been done, for example, select into, alter table modify, reorg rebuild, fast bcp, and writetext.
 - The transaction log was truncated.
 - It is a newly created or upgraded database.

If the database option enforce dump tran sequence is true, you cannot:

- Set select into/bulk copy/pllsort to true. Commands with partial logging are not allowed.
- \circ Set trunc log on chkpt to true. The log cannot be truncated by the checkpoint process.
- Execute dump tran with truncate_only or dump tran with no_log. The log cannot be truncated without dumping it to an archive device.
- Mark the database as read-only.
- Change durability from full to at_shutdown or no_recovery.
- Change to be a mixed-log-and-data database. In cases like load database and dbcc findstranded where the database may be changed to mixed log and data.

1.65.6 Database Options and sp_dboption

There are additional considerations when using the database options of sp dboption.

- The abort tran on log full option determines the fate of a transaction that is running when the last-chance threshold is crossed in the log segment of the specified database. The default value is false, meaning that the transaction is suspended and is awakened only when space has been freed. If you change the setting to true, all user queries that need to write to the transaction log are killed until space in the log has been freed.
- Setting the allow nulls by default option to true changes the default value of a column from not null to null, in compliance with the SQL standards. The Transact-SQL default value for a column is not null, meaning that null values are not allowed in a column unless null is specified in the create table or alter table column definition. allow nulls by default true reverses this.

 You cannot use allow nulls by default to change the nullibility of a column during select into statements. Instead, use convert to specify the nullibility of the resulting columns.
- While the auto identity option is set to true (on), a 10-digit IDENTITY column is defined in each new table that is created without specifying either a primary key, a unique constraint, or an IDENTITY column. The column is not visible when you select all columns with the select * statement. To retrieve it, you must explicitly mention the column name, SYB_IDENTITY_COL, in the select list.

 To set the precision of the automatic IDENTITY column, use the size of auto identity column configuration parameter.
 - Though you can set auto identity to true in tempdb, it is not recognized or used, and temporary tables created there do not automatically include an IDENTITY column.
 - For a report on indexes in a particular table that includes the IDENTITY column, execute sp helpindex.
- While the dbo use only option is set to true (on), only the database's owner can use the database.
- When the ddl in tran option is set to true (on), you can use certain data definition language commands in transactions. If ddl in tran is true in a particular database, commands such as create

table, grant, and alter table are allowed inside transactions in that database. If ddl in tran is true in the model database, the commands are allowed inside transactions in all databases created after ddl in tran was set in model.

Data definition language (DDL) commands hold locks on system tables such as sysobjects. Avoid using them inside transactions; if you must use them, keep the transactions short.

Using any DDL commands on tempdb within transactions may cause your system to grind to a halt. Always leave ddl in transet to false in tempdb.

- You can use these commands inside a user-defined transaction when the ddl in tran option is set to true:
 - o alter table clauses other than partition and unpartition are allowed
 - o create default
 - o create index
 - o create procedure
 - o create rule
 - o create schema
 - o create table
 - o create trigger
 - o create view
 - o drop default
 - o drop index
 - o drop procedure
 - o drop rule
 - o drop table
 - o drop trigger
 - o drop view
 - o grant
 - o revoke
- You can never use these commands inside a user-defined transaction:
 - o alter table
 - o alter table...lock
 - \circ alter table...partition
 - o alter table...unpartition
 - o create database
 - o disk init
 - o dump database
 - o dump transaction
 - o drop database
 - o load database
 - o load transaction
 - o select into
 - o truncate table

o update statistics

In addition, system procedures that create temporary tables or change the master database cannot be used inside user-defined transactions.

- You may enable deferred table allocation for the model database, but not for any other system databases, including master, sybsystemprocs, sybsystemdb, or for any temporary databases.
- identity in nonunique index automatically includes an IDENTITY column in a table's index keys, so that all indexes created on the table are unique. This database option makes logically nonunique indexes internally unique, and allows these indexes to be used to process updatable cursors and isolation level 0 reads.

The table must already have an IDENTITY column for the identity in nonunique index option to work, either from a create table statement or by setting the auto identity database option to true before creating the table.

Use identity in nonunique index if you plan to use cursors and isolation level 0 reads on tables with nonunique indexes. A unique index ensures that the cursor is positioned at the correct row the next time a fetch is performed on that cursor. If you plan to use cursors on tables with unique indexes and any isolation level, you may want to use the unique auto identity index option.

Do not confuse the identity in nonunique index option with unique auto_identity index, which is used to add an IDENTITY column with a unique, nonclustered index to new tables.

For a report on indexes in a particular table that includes the IDENTITY column, execute sp helpindex.

- no free space acctg suppresses free-space accounting and execution of threshold actions for data segments. Setting no free space acctg to true speeds recovery time because speeds recovery time because the free-space counts are not recomputed for data segments.
- When the no chkpt on recovery option is enabled, SAP ASE does not issue a checkpoint after performing recovery on an online database, and, as a side effect, prevents the truncate log on chkpt option from working. Prior to the concept of offline databases and the online database command introduced in version 11.0, the no chkpt on recovery option was used to facilitate loading transaction log dumps. Because SAP ASE no longer checkpoints offline databases, this option is no longer needed, but still exists for backward compatibility.
- The read only option means that users can retrieve data from the database, but cannot modify any data.
- select into/bulkcopy/pllsort must be set to on to perform operations that do not keep a complete record of the transaction in the log, which include:
 - Using the writetext utility.
 - o Doing a select into a permanent table.
 - o Doing a "fast" bulk copy with bop. By default, fast bop is used on tables that do not have indexes.
 - Performing a parallel sort.

A transaction log dump cannot recover these minimally logged operations, so dump transaction to a dump device is prohibited. However, you can still use dump transaction...with no_log and dump transaction...with truncate_onlyAfter non-logged operations are completed, set select into/bulk copy/pllsort to false (off) and issue dump database.

Issuing the dump transaction statement after unlogged changes have been made to the database with select into, bulk copy, or parallel sort produces an error message instructing you to use dump database instead. The writetext command does not have this protection.

You do not have to set the select <code>into/bulkcopy/pllsort</code> option to true in order to select <code>into</code> a temporary table, since <code>tempdb</code> is never recovered. The option need not be set to <code>true</code> in order to run <code>bcp</code> on a table that has indexes, because tables with indexes are always copied with the slower version of bulk copy and are logged.

Setting select into/bulkcopy/pllsort does not block log dumping, but making minimally logged changes to data does block the use of a regular dump transaction.

By default, select into/bulkcopy/pllsort is turned off in newly created databases. To change the default, turn this option on in the model database.

- When single user is set to true, only one user at a time can access the database (single-user mode). You cannot set single user to true in a user database from within a stored procedure or while users have the database open. You cannot set single user to true for tempdb.
- The trunc log on chkpt option means that if the transaction log has more than 50 rows of committed transactions, the transaction log is truncated (the committed transactions are removed) every time the checkpoint checking process occurs (usually more than once per minute). When the database owner runs checkpoint manually, however, the log is **not** truncated. It may be useful to turn this option on while doing development work, to prevent the log from growing.

While the trunc log on chkpt option is on, dump transaction to a dump device is prohibited, since dumps from the truncated transaction log cannot be used to recover from a media failure. Issuing the dump transaction statement produces an error message instructing you to use dump database instead. trunc log on chkpt is off in newly created databases. To change the default, turn this option on in the model database.

If you set trunc log on chkpt on in model, and you need to load a set of database and transaction logs into a newly created database, be sure to turn the option off in the new database.

- The delayed commit option is disabled by default. When this is enabled, all local transactions use delayed commits. That is, at the time of commit, control returns to the client without waiting for the I/O on the log pages to complete, and the I/O is not issued on the last log buffer for delayed commit transactions. Delayed commits are not used when both delayed commit and ALS options are enabled for a database.
- When the unique auto_identity index option is set to true, it adds an IDENTITY column with a unique, nonclustered index to new tables. By default, the IDENTITY column is a 10-digit numeric datatype, but you can change this default with the size of auto identity column configuration parameter. As with auto identity, the IDENTITY column is not visible when you select all columns with the select * statement. To retrieve it, you must explicitly mention the column name, SYB_IDENTITY_COL, in the select list.

If you need to use cursors or isolation level 0 reads with nonunique indexes, use the identity in nonunique index option.

Though you can set unique auto_identity index to true in tempdb, it is not recognized or used, and temporary tables created there do not automatically include an IDENTITY column with a unique index. The unique auto_identity index option provides a mechanism for creating tables that have an automatic IDENTITY column with a unique index that can be used with updatable cursors. The unique index on the table ensures that the cursor is positioned at the correct row after a fetch. (If you are using isolation level 0 reads and need to make logically nonunique indexes internally unique so that they can process updatable cursors, use the identity in nonunique index option.)

In some cases, the unique auto_identity index option can avoid the Halloween problem for the following reasons:

- Users cannot update an IDENTITY column; hence, it cannot be used in the cursor update.
- The IDENTITY column is automatically created with a unique, nonclustered index so that it can be used for the updatable cursor scan.

For more information about the Halloween problem, IDENTITY columns, and cursors, see *Transact-SQL Users Guide > Cursors: Accessing Data* and *Performance and Tuning Series: Query Processing and Abstract Plans > Optimization for Cursors.*

Do not confuse the unique auto_identity index option with the identity in nonunique index option, which is used to make all indexes in a table unique by including an IDENTITY column in the table's index keys.

1.65.7 Considerations for In-Memory Row Storage

Setting the sp_dboption ... abort on low memory option allows you to avoid loosing transactions.

Set sp dboption ... abort on low memory to:

- true the statement or transaction is rolled back after the server fails to find free memory for a request.
- false after all attempts to acquire memory fail, the task is suspended, but the statement is not aborted. Once memory is made available to the system, any sleeping tasks are woken up and executed. There are no loss of transactions with this setting.

The default value is set to:

- true for regular, non-in-memory row storage databases, and for in-memory row storage-enabled databases that contain only data-row cached-enabled tables.
- false the database contains any snapshot isolation-enabled tables (that is, rollback are avoided, but tasks are suspended).

Creating an snapshot isolation-enabled table in a database automatically changes abort on low memory to false. However, dropping the last snapshot isolation-enabled table from a database does not change a false abort on low memory value to true. You must manually change the option.

1.66 sp_dbrecovery_order

Specifies the order in which user databases are recovered and lists the user-defined recovery order of a database or all databases.

Syntax

```
sp_dbrecovery_order [<database_name>[, <rec_order>[, force[, relax | strict ]]]]
```

Parameters

<database name>

is the name of the database being assigned a recovery order or the database with a user-defined recovery order that is to be listed.

<rec_order>

is the order in which the database is to be recovered. A <prec_order> of -1 deletes a specified database from the user-defined recovery sequence.

force

allows the user to insert a database into an existing recovery sequence without putting it at the end.

relax

specifies that the databases are made as they recover (default).

The default is relax, which means that databases are brought online immediately when recovery has completed.

strict

specifies that the databases are specified by the recovery order.

Examples

Example 1

Makes the pubs2 database the first user database to be recovered following a system failure:

```
sp_dbrecovery_order pubs2, 1
```

Example 2

Inserts the pubs 3 database into third position in a user-defined recovery sequence. If another database was initially in third position, it is moved to fourth position, and all databases following it are moved accordingly:

```
sp_dbrecovery_order pubs3, 3, force
```

Example 3

Removes the pubs2 database from the user-defined recovery sequence. Subsequently, pubs2 is recovered after all databases with a user-specified recovery order have recovered:

```
sp_dbrecovery_order pubs2, -1
```

Example 4

Lists the current recovery order of all databases with a recovery order assigned through sp_dbrecovery_order:

```
sp_dbrecovery_order
```

Usage

There are additional considerations when using sp dbrecovery order:

- You must be in the master database to use sp_dbrecovery_order to enter or modify a user-specified recovery order. You can list the user-defined recovery order of databases from any database.
- To change the user-defined recovery position of a database, use sp_dbrecovery_order to delete the database from the recovery sequence, then use sp_dbrecovery_order to insert it into a new position.
- System databases are always recovered before user databases. The system databases and their recovery order are:
 - 1. master
 - 2. model
 - 3. tempdb
 - 4. sybsystemdb
 - 5. sybsecurity
 - 6. sybsystemprocs
- If no database is assigned a recovery order through sp_dbrecovery_order, all user databases are recovered in order, by database ID, after system databases.
- If <database name>:
 - Is specified but no rec_order> is given sp_dbrecovery_order shows the user-defined recovery
 position of the specified database.
 - Is not specified sp_dbrecovery_order lists the recovery order of all databases with a user-assigned recovery order.
- The order of recovery assigned through sp_dbrecovery_order must be consecutive, starting with 1 and containing no gaps between values. The first database assigned a recovery order must be assigned a <rec_order> of 1. If three databases have been assigned a recovery order of 1, 2, and 3, you cannot assign the next database a recovery order of 5.

Permissions

The permission checks for <code>sp_dbrecovery_order</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.67 sp_dbremap

Forces the SAP ASE server to recognize changes made by alter database. Run this procedure only when instructed to do so by an SAP ASE message.

Syntax

sp dbremap <dbname>

Parameters

<dbname>

is the name of the database in which the alter database command was interrupted.

Examples

Example 1

An alter database command changed the database sample_db. This command makes the changes visible to the SAP ASE server:

sp dbremap sample db

Usage

There are additional considerations when using sp dbremap:

- If an alter database statement issued on a database that is in the process of being dumped is interrupted, the SAP ASE server prints a message instructing the user to execute sp dbremap.
- Any changes to sysusages during a database or transaction dump are not copied into active memory
 until the dump completes, to ensure that database mapping does not change during the dump. Running
 alter database makes changes to system tables on the disk immediately. In-memory allocations
 cannot be changed until a dump completes. This is why alter database pauses.
 When you execute sp dbremap, it must wait until the dump process completes.
- If you are instructed to run sp_dbremap, but do not do it, the space you have allocated with alter database does not become available to the SAP ASE server until the next restart.

See also alter database, dump database, dump transaction in Reference Manual: Commands

Permissions

The permission checks for sp dbremap differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database

privilege on the database.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.68 sp_defaultloc

(Component Integration Services only) Defines a default storage location for objects in a local database.

Syntax

sp_defaultloc <dbname>, <defaultloc>, <defaulttype>

Parameters

<dbname>

is the name of a database being mapped to a remote storage location. The database must already have been defined by a create database statement. You cannot map system databases to a remote location.

<defaultloc>

is the remote storage location to which the database is being mapped. To direct the server to delete an existing default mapping for a database, supply NULL for this parameter. The value of <defaultloc> must end in a period (.), as follows:

<server>.<dbname>.<owner>.

<defaulttype>

is one of the values that specify the format of the object named by <object_loc>.The valid values are as follows. Enclose the <defaulttype> value in quotes:

- table indicates that the object named by <object_loc> is a table accessible to a remote server. This value is the default for <defaulttype>.
- view indicates that the object named by <object_loc> is a view managed by a remote server, processed as a table.
- rpc indicates that the object named by <object_loc> is an RPC managed by a remote server; processes the result set from the RPC as a read-only table.

Examples

Example 1

sp_defaultloc defines the remote storage location pubs.dbo. in the remote server named MYSERVER. It maps the database pubs to the remote location. A create table book1 statement would create a table named book1 at the remote location. A create existing table statement for bookN would require that pubs.dbo.bookN already exist at the remote location, and information about table bookN would be stored in the local table bookN:

```
sp_defaultloc pubs, MYSERVER.pubs.dbo., table
create table pubs.dbo.book1 (bridges char(15))
```

Example 2

Removes the mapping of the database pubs to a remote location:

```
sp_defaultloc pubs, NULL
```

Example 3

Identifies the remote storage location wallst.nasdaq.dbo where "wallst" is the value provided for <server_name>, "nasdaq" is provided for <database>, and "dbo" is provided for <owner>. The RPC sybase must already exist at the remote location. A create existing table sybase statement would store information about the result set from RPC sybase in local table ticktape. The result set from RPC sybase is regarded as a read-only table. Inserts, updates and deletes are not supported for RPCs:

```
sp_defaultloc ticktape, wallst.nasdaq.dbo., rpc
create existing table sybase (bestbuy integer)
```

Usage

There are additional considerations when using sp defaultloc:

• sp_defaultloc defines a default storage location for tables in a local database. It maps table names in a database to a remote location. It permits the user to establish a default for an entire database, rather than issue an sp_addobjectdef command before every create table and create existing table command.

• When <defaulttype> is table, view, or rpc, the <defaultloc> parameter takes the form:

<server_name>.<dbname>.<owner>.

- The <defaultloc> specification ends in a period (.).
- <server_name> represents a server already added to sysservers by sp_addserver. The <server_name> parameter is required.
- o <dbname> might not be required. Some server classes do not support it.
- <owner> should always be provided to avoid ambiguity. If it is not provided, the remote object actually
 referenced could vary, depending on whether the external login corresponds to the remote object
 owner
- Issue sp_defaultloc before any create table or create existing table statement. When either statement is used, the server uses the sysattributes table to determine whether any table mapping has been specified for the object about to be created or defined. If the mapping has been specified, a create table statement directs the table to be created at the location specified by <object_loc>. A create existing table statement stores information about the existing remote object in the local table.
- If you issue sp_defaultloc on defaulttype view and then issue create table, Component Integration Services creates a new table, not a view, on the remote server.
- Changing the default location for a database does not affect tables that have previously been mapped to a different default location.
- After tables in the database have been created, all future references to tables in <dbname> (by select, insert, delete, and update) are mapped to the correct location.

See also create existing table, create table in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_defaultloc</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addobjectdef [page 50]
sp_addserver [page 58]
sp_helpserver [page 482]

1.69 sp_deferred_index_recovery

Lists indexes in the specified table for which you have specified a deferred index recovery.

Syntax

```
sp_deferred_index_recovery [<option>] [,<database_name>] [,<table_name>]
[,<index_name>]]
```

Parameters

<option>

is one of:

- list lists the set of indexes whose recovery has been deferred. This is the default option.
- create re-creates the set of indexes listed
- drop drops the set of indexes listed
- help prints usage information for sp_deferred_index_recovery

<database name>

Name of the database that contains the indexes. If you do not list a database, sp_deferred_index_recovery

<table_name>

Name of the table that holds the indexes

<index_name>

is the index name.

Examples

Example 1

This example lists the indexes in the titles table of the pubs2 database with deferred recovery:

```
sp deferred index recovery list, pubs2.titles
```

Permissions

Any user can execute sp_deferred_index_recovery.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.70 sp_deletesmobj

(Only when the TSM is licensed at your site) Deletes specified backup objects from the IBM Tivoli Storage Manager (TSM).

Syntax

```
sp_deletesmob "syb_tsm", "<server_name>"{, "<database_name>", "<object_type>",
"<dump_type>", "<until_time>", "<bs_name>"}
```

Parameters

syb_tsm

is the keyword that invokes the libsyb_tsm.so module that enables communication with TSM.

<server_name>

is the name of the SAP ASE server associated with the TSM backup objects to be deleted.

<database name>

is the name of the database associated with the TSM backup objects to be deleted. An asterisk (*) indicates all databases.

<object_name>

is the name of the TSM backup object as provided in the dump database or dump transaction command. If this parameter is omitted, all backup objects are deleted. An asterisk (*) indicates all backup objects.

<dump_type>

is the backup object type to be deleted. Values are:

- DB database backup objects created by the dump database command.
- XACT database backup objects created by the dump transaction command.
- * (default) all database backup objects.

<until_time>

is the date timestamp field. All backup objects matching the specified criteria and created before the <until time> date are deleted.

<bs_name>

is the name of the remote Backup Server. If <bs_name> is omitted, the default is SYB_BACKUP.

Examples

Example 1

Removes all TSM backup objects created at the SAP ASE "svr1."

```
sp_deletesmobj "syb_tsm", "svr1"
```

Example 2

Removes all backup objects of the testdb database created by "svr1" before May 20, 2009, 10:51:43:866am. The backup object name is "obj1.dmp."

Example 3

Removes all backup objects of the "testdb" database created by "svr1" of dump database type before May 21, 2009, 10:51:43:866 a.m.

Example 4

Removes all backup objects of "testdb" created by "svr1" of dump transaction type before May 20, 2009. 10:51:43:866 a.m.

Usage

See also Using Backup Server with IBM Tivoli Storage Manager.

Permissions

The permission checks for sp dbremap differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with dump any database privilege.

Disabled With granular permissions disabled, you must be a user with sa_role or oper_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_querysmobj [page 682]

1.71 sp_depends

Displays information about database object dependencies — the views, triggers, user-defined functions, procedures, and predicates — in the database that depend on a specified table or view, the tables and views in the database on which the specified view, trigger, procedure, or predicate depends, and multiple triggers associated with a table. Predicates cannot be granted in a view.

Also displays information about table column dependencies—the indexes, defaults, check constraints, rules, precomputed result sets, referential integrity constraints, and predicates—defined in either the column specified, if <column name> is provided, or on all the columns in the table, if <column name> is not provided.

Syntax

sp depends <objname>[, <column name>]

Parameters

<objname>

is the name of the table, view, Transact-SQL stored procedure, SQLJ stored procedure, SQLJ function, or trigger to be examined for dependencies. You cannot specify a database name. Use owner names if the object owner is not the user running the command and is not the database owner.

<column_name>

is the name of the column to be examined for dependencies.

Examples

Objects Dependent on a Table

Lists the database objects that depend on the table sysobjects:

```
sp_depends sysobjects
```

Objects Dependent on a View

Lists the database objects that depend on the titleview view, and the database objects on which the titleview view depends:

```
sp depends titleview
Things that the object references in the current database.
object
                      updated selected
              type
dbo.authors
              user table no
                                 no
dbo.titleauthor user table no
                                no
dbo.titles
              user table no
                                 no
Things inside the current database that reference the object.
object
dbo.tview2
             view
```

Objects Dependent on a Specific Table

Lists the database objects that depend on the titles table owned by the user "mary". The quotes are needed, since the period is a special character:

```
sp_depends "mary.titles"
```

i Note

As this example shows, objects owned by database users other than the user executing a command and the database owner must always be qualified with the owner's name.

Precomputed Result Sets

The following examples assume that prs1 and view1 are created with the following dependency structure:

• prs1 is defined on base table tab1 (with unique constraint on column c1) and view1 is defined on prs1

• prs1 is configured for immediate refresh

This example displays the precomputed result sets that include dependencies for column c1:

```
sp_depends prs1,c1
```

```
Things the object references in the current database.
object type updated selected
dbo.tabl user table no no
Things inside the current database that reference the object.
object type
dbo.view1 view
Dependent objects that reference column c1.
Columns referenced in stored procedures, views or triggers are not
included in this report.
Type Property Object Names or Column Names Also see/Use
command
index constraint prs1 10240036482 (c1)
                                         sp helpindex,
                                         drop index,
                                         sp helpconstraint,
                                         alter table drop
                                         constraint
```

Dependencies Between Predicate and Table

Displays the dependencies between predicate pred1 and any tables it references:

```
Things the object references in the current database.

object type updated selected

dbo.tab1 user table no no dbo.tab2 user table no no
```

Dependencies Between Predicate, Table, and Column

Displays the dependencies between predicates and table tab1 and column col1:

```
sp depends tab1, col1
Things inside the current database that reference the object.
object type
object
dbo.pred1
                predicate
Dependent objects that reference column coll.

```

Usage

- Executing sp_depends lists all objects in the current database that depend on <objname>, and on which <objname> depends. For example, views depend on one or more tables and can have procedures or other views that depend on them. An object that references another object is dependent on that object. References to objects outside the current database are not reported.
- Before you modify or drop a column, use sp_depends to determine if the table contains any dependent objects that could be affected by the modification. For example, if you modify a column to use a new datatype, objects tied to the table may need to be redefined to be consistent with the column's new datatype.
- The sp_depends procedure determines the dependencies by looking at the sysdepends table. If the objects were created out of order (for example, if a procedure that uses a view was created before the view was created), no rows exist in sysdepends for the dependencies, and sp_depends does not report the dependencies.
- The updated and selected columns in the report from sp_depends are meaningful if the object being reported on is a stored procedure or trigger. The values for the updated column indicate whether the stored procedure updates the object. The selected column indicates whether the object is being used for a read cursor or a data modification statement.

 ${\tt sp_depends}$ follows these SAP ASE rules for finding objects:

- If the user does not specify an owner name, and the user executing the command owns an object with the specified name, that object is used.
- If the user does not specify an owner name, and the user does not own an object of that name, but the database owner does, the database owner's object is used.
- If neither the user nor the database owner owns an object of that name, the command reports an error condition, even if an object exists in the database with that object name, but with a different owner.
- If both the user and the database owner own objects with the specified name, and the user wants to access the database owner's object, the name must be specified, as in <dbo.objectname>.

See also create procedure, create table, create view, execute in Reference Manual: Commands.

Permissions

Any user can execute $sp_depends$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_help [page 396]

1.71.1 Java Methods

SQLJ functions and SQLJ stored procedures are Java methods wrapped in SQL wrappers.

- SQLJ functions and SQLJ stored procedures are database objects for which you can list dependencies. The only dependencies of SQLJ stored procedures and SQLJ functions are Java classes.
- If <objname> is a SQLJ stored procedure or SQLJ function, sp_depends lists the Java class in the routine's external name declared in the create statement, not classes specified as the return type or datatypes in the parameter list.
- SQLJ stored procedures and SQLJ functions can be listed as dependencies of other database objects.

See Java in Adaptive Server Enterprise for more information.

1.72 sp_deviceattr

(UNIX platforms only) Changes the device parameter settings of an existing database device file.

Syntax

sp_deviceattr <logicalname>, <optname>, <optvalue>

Parameters

<logicalname>

is the logical name of an existing database device. The device can be stored on either an operating system file or a raw partition, but the dsync setting is ignored for raw partitions.

<optname>

name of the attribute to change. Valid values are directio or dsync:

- directio enables the SAP ASE server to write directly to disk, bypassing the
 operating system's buffer system. The SAP ASE server passes the device options
 to Backup Server, which enables Backup Server to access the database device with
 the appropriate directio option.
- dsync enables updates to the device take place directly on the storage media, or are buffered by the UNIX file system

i Note

The directio and dsync options are mutually exclusive; you cannot specify "true" for both at the same time.

<optvalue>

can be either "true" or "false."

Examples

Example 1

Sets dsync on for the device named "file_device1":

```
sp deviceattr file device1, dsync, true
```

Usage

There are additional considerations when using <code>sp_deviceattr</code>:

- For database devices stored on UNIX files, dsync determines whether updates to the device take place directly on the storage media, or are buffered by the UNIX file system.
 - When dsync is on, writes to the database device occur directly to the physical storage media, and the SAP ASE server can recover data on the device in the event of a system failure.
 - When dsync is off, writes to the database device may be buffered by the UNIX file system. The UNIX file system may mark an update as being completed, even though the physical media has not yet been modified. In the event of a system failure, there is no guarantee that requests to update data have ever taken place on the physical media, and the SAP ASE server may be unable to recover the database.

• (UNIX only) On raw devices, you cannot set directio or dsync via the sp_deviceattr stored procedure to true.

i Note

For HPUX, only the dsync option applies.

Doing so returns a message such as the following:

- You cannot set option dsync for raw device 'dev/raw/raw235'
- O You cannot set attribute dsync for raw device 'myrawdisk1'
- After using sp_deviceattr to change the dsync or directio setting, you must restart the SAP ASE server before the change takes affect.
- sp deviceattr displays a warning message if the dsync option is disabled for a database device file.
- dsync is always on for the master device file. You cannot change the dsync setting for a master device file with sp deviceattr. Therefore, you cannot set the directio option for the master device.
- Turn off the dsync value only when the databases on the device does not need to be recovered after a system failure. For example, you may consider turning dsync off for a device that stores only the tempdb database.
- The SAP ASE server ignores the dsync setting for devices stored on raw partitions; updates to those devices are never buffered, regardless of the dsync setting.
- dsync is not used on the Windows platform.

Permissions

The permission checks for sp deviceattr differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage disk privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpdevice [page 446]

1.73 sp_diskdefault

Specifies whether or not a database device can be used for database storage if the user does not specify a database device or specifies default with the create database or alter database commands.

Syntax

sp diskdefault <logicalname,> {defaulton | defaultoff}

Parameters

<logicalname>

is the logical name of the device as given in master.dbo.sysdevices.name. The device must be a database device rather than a dump device.

defaulton | defaultoff

defaulton designates the database device as a default database device; defaultoff designates that the specified database device is not a default database device.

Use defaulton after adding a database device to the system with disk init. Use defaultoff to change the default status of the master device (which is designated as a default device when SAP ASE is first installed).

Examples

Example 1

The master device is no longer used by create database or alter database for default storage of a database:

sp diskdefault master, defaultoff

Usage

There are additional considerations when using sp_diskdefault:

• A default database device is one that is used for database storage by create database or alter database if the user does not specify a database device name or specifies the keyword default.

- You can have multiple default devices. They are used in the order they appear in the master.dbo.sysdevices table (that is, alphabetical order). When the first default device is filled, the second default device is used, and so on.
- When you first install SAP ASE, the master device is the only default database device.

i Note

Once you initialize devices to store user databases, use $sp_diskdefault$ to turn off the master device's default status. This prevents users from accidentally creating databases on the master device and simplifies recovery of the master database.

• To find out which database devices are default database devices, execute sp helpdevice.

See also alter database, create database, disk init in Reference Manual: Commands.

Permissions

The permission checks for sp diskdefault differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage disk privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpdevice [page 446]

1.74 sp_displayaudit

Displays the status of audit options.

Syntax

```
sp_displayaudit ["procedure" | "object" | "login" | "database" | "global" |
    "default_object" | "default_procedure" | "role" [, "<name>"]]
```

Parameters

procedure

displays the status of audit options for the specified stored procedure or trigger. If you do not specify a value for <name>, the active audit options for all procedures and triggers in the current database are displayed.

object

displays the status of audit options for the specified table or view. If you do not specify a value for <name>, the active audit options for all tables and views in the current database are displayed.

login

displays the status of audit options for the specified user login. If you do not specify a value for <name>, the active audit options for all logins in the master database are displayed.

database

displays the status of audit options for the specified database. If you do not specify a value for <name>, the active audit options for all databases on the server are displayed.

global

displays the status of the specified global audit option. If you do not specify a value for <name>, the active audit options for all procedures and triggers in the current database are displayed.

default_object

displays the default audit options that are used for any new table or view created on the specified database. If you do not specify a value for <name>, the default audit options for all databases with active default audit settings are displayed.

default_procedure

displays the default audit options that are used for any new procedure or trigger created on the specified database. If you do not specify a value for <name>, the default audit options for all databases with active default audit settings are displayed.

role

displays the status of audit options for the specified role name. If you do not specify a value for <name>, the active audit options for all roles are displayed.

<name>

is the information for the specified parameter. The parameters and their values are:

procedure	Procedure or trigger name	
object	Table or view name User login	
login		
database	Database name	
global	Global audit option	
default_object	Database name	
default_procedure	Database name	
role	Role name	

You cannot specify a value for <name> unless you first specify an object type parameter.

Examples

Example 1

Displays the status of each category and all auditing options when you do not specify a parameter:

```
sp_displayaudit
No sprocs/triggers currently have auditing enabled. No databases currently have default sproc/trigger auditing enabled.
No objects currently have auditing enabled.
No databases currently have default table/view auditing enabled.
No logins currently have auditing enabled.
Database Name Audit Option Value
            allow
create
 master
                                        on
  master
                                        on
 pubs2
                     create
  pubs2
                     encryption_key on
(1 row affected)
                  Value Subject Name Type of Subject
 Audit Option
    all on sa_role
login on All
login on sa
login on chris
mount on All
security on All
                                        role
All logins and roles
                                              login
login
                                              All logins and roles
                                               All logins and roles
(1 row affected)
```

```
(return status = 0)
```

Example 2

Displays the status of all global audit options when you do not specify a global audit option:

```
sp_displayaudit "global"
go
```

Audit Option	Value	Subject Name	Type of Subject
all login login login mount security	on on on on on	sa_role All sa chris All All	role All logins and roles login login All logins and roles All logins and roles

Example 3

Displays the status of all procedure audit options when you do not specify a procedure name:

```
use sybsystemprocs
go
sp_displayaudit "procedure"
go
```

```
Procedure/Trigger Audit Option Value Database

dbo.sp_altermessage exec_procedure on sybsystemprocs
dbo.sp_help exec_procedure on sybsystemprocs
dbo.sp_who exec_procedure on sybsystemprocs
```

Example 4

Displays only the status of the procedure when you specify a name for a procedure:

```
use sybsystemprocs
go
sp_displayaudit "procedure", "sp_addlogin"
go
```

```
Procedure/Trigger Audit Option Value Database
------
dbo.sp_addlogin exec_procedure on sybsystemprocs
```

Example 5

Displays the status of the global login option:

Example 6

Displays the status of the audit option for intern role:

```
sp_audit "all", "intern_role", "all", "fail"
go
sp_displayaudit "role", "intern_role"
go
```

```
Role Name Audit Option Value
intern_role all fail
```

Usage

The valid auditing options for each parameter are:

Object Type Parameter Valid Auditing Options

object delete, func obj access, insert, reference, select, update

database alter, bcp, bind, create, dbaccess, drop, dump, dump config,

 $\verb|encryption_key|, \verb|errorlog|, errors|, func_dbaccess|, grant|, load|, revoke|,$

setuser, truncate, unbind

hadr_admin_role, js_admin_role, js_client_role, js_user_role,

keycustodian_role, login, login_admin, login_locked, logout, messaging role, mon_role, mount, navigator_role, oper_role, password, quiesce, replication_maint_role_gp, replication_role, role, role_locked, rpc, sa_role, security, security_profile, sproc_auth, sso_role, thread

pool, unmount, webservices_role

default_procedure
 exec procedure, exec trigger

Permissions

The permission checks for $sp_displayaudit$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage auditing privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_audit [page 77]

1.75 sp_displaylevel

Sets or shows which configuration parameters appear in sp_configure output.

Syntax

sp_displaylevel [<loginame>[, <level>]]

Parameters

<loginame>

is the SAP ASE login of the user for whom you want to set or show the display level.

<level>

sets the display level to one of the following:

- "basic" display level shows just the most basic configuration parameters. This level is appropriate for very general server tuning.
- "intermediate" display level shows configuration parameters that are somewhat more complex, as well as all the "basic" level parameters. This level is appropriate for moderately complex server tuning.

• "comprehensive" display level shows all configuration parameters, including the most complex ones. This level is appropriate for highly detailed server tuning.

Examples

Example 1

Shows the current display level for the user who invoked sp displaylevel:

```
sp_displaylevel
```

```
The current display level for login 'sa' is 'comprehensive'.
```

Example 2

Shows the current display level for the user "jerry":

```
sp_displaylevel jerry
The current display level for login 'jerry' is 'intermediate'.
```

Example 3

Sets the display level to "comprehensive" for the user "jerry":

```
sp_displaylevel jerry, comprehensive

The display level for login 'jerry' has been changed to 'comprehensive'.
```

Usage

See the *System Administration Guide: Volume 1* for details about setting configuration parameters and display levels. See *Reference Manual: Configuration Parameters* for a list of configuration parameters.

Permissions

The permission checks for sp displaylevel differ based on your granular permissions settings.

Setting Description Enabled With granular permissions enabled, you must be a user with manage server configuration privilege. Any user can execute sp_displaylevel to set and show their own configuration parameters. Disabled With granular permissions disabled, you must be a user with sso_role.

Setting Description

Any user can execute sp displaylevel to set and show their own configuration parameters.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_configure [page 203]

1.76 sp_displaylogin

Displays information about a login account. By using a wildcard expression (%), you can also obtain information about matching logins. Also displays the encryption versions of the login password stored on disk.

Syntax

```
sp_displaylogin ['<user_id>' | '[<loginame> | <wildcard>]'
```

Parameters

<user id>

is the server user ID.

<loginame>

is the user login account about which you want information. You must be a system security officer or system administrator to get information about someone else's login account.

<wildcard>

is the wildcard expression you use to obtain information about login accounts.

Examples

Display Information About Server Login Account

The password expiration is set to 0, indicating the password never expires:

```
1> sp displaylogin 'sa'
2> go
Suid: 121
Loginame: sa
Fullname:
Configured Authorization:
        sa_role (default ON)
        sso role (default ON)
        oper role (default ON)
        sybase_ts_role (default ON)
Locked: NO
Date of Last Password Change: Aug 10 2010 11:17AM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 0
Current failed login attempts:
Login password encryption: SYB-PROP, SHA-256
```

Display Information About Login Account "susanne"

Last login date: Aug 17 2010 5:55PM

Login Profile :emp_lp

The information displayed varies, depending on the role of the user executing sp_displaylogin. There is not password expiration set for user "susanne", so the password does not expire:

```
Suid: 12
Loginame: susanne
Fullname:
Configured Authorization:
   supervisor (default OFF)
Locked: NO
Date of Last Password Change: July 26 2010 10:42AM
Login Profile :emp_lp
```

Display Login Security-Related Parameters Configured for a Login

Displays the login security-related parameters configured for a login, as well as a specified authentication mechanism. The password expires on November 29, 2010 at 3:46PM, and expires five days later, on December 5, 2010 at 3:46PM:

```
Suid: 294
Loginame: joe
Fullname: Joseph Resu
Configured Authorization:
    intern_role (default OFF)
Locked: NO
Date of Last Password Change: Nov 24 2010 3:46PM
Password expiration interval: 5
Password expired: NO
Minimum password length:4
```

```
Maximum failed logins: 10
Current failed logins: 3
Login password encryption: SHA-256
Login Profile:emp_lp
```

Display Information About Login Account With Server User ID 1

Use Wildcard to Indicate Any Server Login Account

This example uses a wildcard to indicate any server login account, as opposed to your own server login account:

Display Encrypted and Stored On-disk Login Password

1> sp displaylogin 'mylogin'

The on-disk login password is encrypted and stored, using both the old Sybase proprietary encryption algorithm and the SHA-256 algorithm:

```
Password expired: NO
Minimum password length: 6
Maximum failed logins: 0
Current failed login attempts:
Login password encryption: SYB-PROP, SHA-256
Last login date: Aug 17 2010 5:55PM
Login Profile:emp_lp
(return status = 0)
```

When the login password is stored on disk using the SHA-256 algorithm only, the output of sp displaylogin has the line "Login password encryption: SHA-256":

```
1> sp_displaylogin 'mylogin'
2> go
```

```
Suid: 121
Loginame: mylogin
...
Authenticate with: NONE
Login password encryption: SHA-256
Last login date: Aug 17 2010 5:55PM
Login Profile:emp_lp
(return status = 0)
```

When a login has not occurred after upgrade from SAP ASE versions earlier than 15.0.2, the previous style of encryption is still in place, and the output of $sp_displaylogin$ has the line "Login password encryption: SYB-PROP":

```
1> sp_displaylogin 'mylogin'
2> go

Suid: 121
Loginame: mylogin
...
Authenticate with: NONE
Login password encryption: SYB-PROP
Last login date: Aug 17 2006 5:55PM
(return status = 0)
```

When a login has been locked, sp_displaylogin shows the date, reason, and login that locked the account. The lastlogindate value is also displayed:

```
1> sp_displaylogin 'mylogin'
2> go
```

```
Suid: 121
Loginame: mylogin
Fullname:
Configured Authorization:
        sa_role (default ON)
        sso_role (default ON)
        oper role (default ON)
        sybase_ts_role (default ON)
Locked: YES
        Date when locked: Aug 18 2010 9:15AM
       Reason: Account locked by SAP ASE due to failed login attempts
reaching max failed logins.
       Locking suid: mylogin
Date of Last Password Change: Aug 10 2010 11:17AM
Password expiration interval: 0
Password expired: NO
```

```
Minimum password length: 6
Maximum failed logins: 3
Current failed login attempts: 3
Login password encryption: SYB-PROP, SHA-256
Last login date: Aug 17 2010 5:55PM
Login Profile:emp_lp
(return status = 0)
```

Display Encryption Versions Used for a Login

Displays the encryption versions used for a login; this output includes information about the on-disk login password encryption the SAP ASE server uses:

```
sp displaylogin sa
qo
Suid: 1
Loginame: sa
Fullname:
Configured Authorization:
   sa role (default ON)
    sso_role (default ON)
   oper role (default ON)
   sybase_ts_role (default ON)
Locked: NO
Date of Last Password Change: Mar 8 2010 3:04PM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 0
Current failed login attempts:
Login Password Encryption: SHA-256
Login Profile :emp_lp
```

If the SAP ASE server uses encryption algorithms from SAP ASE versions earlier than 15.0.2 or the current release during a downgrade period, $sp_displaylogin$ displays the earlier Sybase proprietary encryption algorithm and the new algorithm, SHA-256:

```
Login password encryption: SYB-PROP, SHA-256
```

Display Login and Password Policy Options of Current Login Account

```
sp displaylogin
go
Suid: 5
Loginame: tammi
Fullname:
Configured Authorization:
   sa_role (default ON)
    sso_role (default ON)
   oper role (default ON)
   sybase_ts_role (default ON)
Locked: NO
Date of Last Password Change: Mar 8 2010 3:04PM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 0
Current failed login attempts:
Authenticate with: ANY
Login Password Encryption: SHA-256
```

```
Exempt inactive lock: 0

Login Profile: emp_lp
```

Display Login Account for User with Suid 56

```
sp_displaylogin '56'
```

Display Login Account Information for All Users With Logins Begin With "st"

```
sp_displaylogin 'st%'
```

Usage

There are additional considerations when using sp displaylogin:

- The sp_passwordpolicy security options are taken into consideration when displaying login information related to password expiration, maximum failed logins, and password length.
- sp_displaylogin displays the encryption version(s) used for a login. For example, when both old and new encryption is used during the password downgrade period, the output of sp_displaylogin has the new line "Password encryption."
- sp_displaylogin displays configured roles, so even if you have made a role inactive with the set command, it is displayed.
- Login triggers associated with the login in question are specified through a login profile. For more information, see *Managing Login Accounts and Login Profiles* in the *System Administration Guide*.
- When you use sp_displaylogin to get information about your own account, you do not need to use the <loginame> parameter. sp_displaylogin displays your server user ID, login name, login profile, full name, any roles that have been granted to you, date of last password change, and whether your account is locked.
- If you are a system security officer or system administrator, you can use the <loginame> parameter to access information about any account.

Permissions

The permission checks for sp displaylogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any login privilege or manage sever privilege.

Any user can execute sp displaylogin to display information about their own login account.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be a user with sa_role or sso_role.}$

Any user can execute sp displaylogin to display information about their own login account.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_activeroles [page 15] sp_displayroles [page 276] sp_helprotect [page 472]

1.77 sp_displayroles

Displays all roles granted to another role, login or login profile, the entire hierarchy tree of roles in table format, and other login security-related parameters configured for the specified role, including the date when the role was locked, its reason, and the login server user ID (suid) that locked the role. For password-protected roles, also displays the role password encryption version.

Displays roles granted to logins through an associated login profile. A grantee column in the output displays the login profile name as applicable. This column is only displayed if the login has an associated login profile with roles granted to the login. The login profile association could be direct or through a default login profile.

Syntax

```
sp_displayroles [<grantee_name >[, <mode>]]
```

Parameters

<grantee_name>

is the login name of a user or login profile name with roles that you want information about, or the name of a role you want information about.

<mode>

is one of the following:

- expand up shows the role hierarchy tree for the parent levels
- expand down shows the role hierarchy tree for the child levels

• display_info - shows the login security-related parameters configured for the specified role

Examples

Example 1

Displays all roles granted to the user issuing the command:

```
Role Name
-----supervisor_role
```

Example 2

Displays all roles granted to supervisor_role:

sp displayroles susanne, expand down

Example 3

Displays the roles granted to login "susanne" and the roles below it in the hierarchy:

```
Role Name Parent Role Name Level

supervisor_role NULL 1
clerk_role supervisor_role 2
```

Example 4

Displays the roles granted to intern role and the roles above it in the hierarchy:

```
sp_displayroles "intern_role", expand_up
```

Example 5

Shows the login security-related parameters configured for the specified role:

```
Role name = physician_role
Locked : YES
    Date when locked: Jul 14 2007 9:15AM
    Reason: Role locked by SAP ASE due to failed login
    attempts reaching max failed logins.
    Locking suid: dr_john
Date of Last Password Change : Oct 31 1999 3:33PM
Password expiration interval = 5
Password expired : NO
Minimum password length = 4
```

```
Maximum failed logins = 10
Current failed logins = 3
Password encryption version: SHA-256
```

Example 6

Displays the roles granted to login "tom," which is associated with the login profile named "sec_profile":

```
grant role sec_role to sec_profile create login tom with password COmp13x login profile sec_profile grant role emp_role to tom go sp_displayroles tom go
```

Role Name	Grantee
<pre>emp_role sec_role</pre>	tom sec_profile

Usage

When you specify the optional parameter <code>expand_up</code> or <code>expand_down</code> all directly granted roles contained by or containing the specified role name are displayed.

The Grantee column displays only when a login has an associated login profile, or the default login profile is applicable to the login with role(s) granted to it.

See also:

- alter role, create role, drop role, grant, revoke, set in Reference Manual: Commands
- User-Defined Login Security in the System Administration Guide for more information.

Permissions

The permission checks for sp_displayroles differ based on your granular permissions settings.

Setting Description Enabled With granular permissions enabled, you must be a user with manage roles or manage server privilege. Any can execute sp_displayroles to see the roles granted to themselves. Disabled With granular permissions disabled, you must be a user with sso_role.

Any can execute sp displayroles to see the roles granted to themselves.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_activeroles [page 15]
sp_displaylogin [page 270]
sp_helprotect [page 472]
```

1.78 sp_downgrade_esd

Validates readiness for downgrade for service packs and patch levels within the same version of SAP ASE. Also downgrades the system catalog changes that were modified with the current version of SAP ASE. sp_downgrade_esd downgrades a specified individual database to a specified previous version. This supports dumping that database in a form that could be loaded by the older version. The online database command can be used to re-upgrade the database after dump. You cannot downgrade a 16.0 or higher database back to a 15.x version.

Syntax

```
sp_downgrade_esd @<database_name>[, @<target_version>[, @verbose]]
```

Parameters

<@database_name>

is the name of the database you are downgrading.

<@target_version>

is a string that specifies what version of 16.0 to go back to. It accepts values "GA" (the default) or "SPO PLxx" where "xx" is an integer. "GA" is an abbreviation for "SPO PLO". The valid options are:

- "GA" (default) for SAP ASE version 16.0.
- "SP0 PL<xx>" where <xx> is an integer. Specifying "SP0 PL0" is the same as using "GA"

<@verbose>

- is an integer that, when used, displays the output in the verbose mode. Valid values are:
 - 1 the procedure produces extra messages about what it is doing
 - o 0 produces no additional messages

Examples

Downgrades sybsystemprocs

This example downgrades sybsystemprocs:

```
1> sp downgrade esd sybsystemprocs, GA
2> go
Reverting database 'sybsystemprocs' to 'GA'.
Database 'sybsystemprocs' is now suitable for use by GA.
(return status = 0)
2> sp_downgrade_esd sybsystemdb, GA
3> go
Reverting database 'sybsystemdb' to 'GA'.
Database 'sybsystemdb' is now suitable for use by GA.
(return status = 0)
1> sp_downgrade_esd model, GA
2> go
Reverting database 'model' to 'GA'.

Database 'model' is now suitable for use by GA.

(return status = 0)
1> sp downgrade esd MYASE tdb 1, GA
2> go
Reverting database 'MYASE_tdb_1' to 'GA'.
Database 'LUMINOUS_tdb_1' is now suitable for use by GA.
(return status = 0)
1> sp_downgrade_esd master, GA
2> go
Reverting database 'master' to 'GA'.
Database 'master' is now suitable for use by GA.
(return status = 0)
1> shutdown
2> go
```

Permissions

A user must have sa_role and be in the master database to execute sp statistics.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.79 sp_dropalias

Removes the alias user name identity established with sp addalias.

Syntax

sp_dropalias <loginame>[, force]

Parameters

<loginame>

is the name (in master.dbo.syslogins) of the user who was aliased to another user.

force

allows you to drop an alias even if it owns database objects.

Examples

Example 1

Assuming that "victoria" was aliased (for example, to the database owner) in the current database, this statement drops "victoria" as an aliased user from the database:

```
sp dropalias victoria
```

Example 2

Drops the alias "harry," which owns a procedure namelist. The SAP ASE server drops the alias but issues a warning message:

```
sp_dropalias harry, force
Warning: You have forced the drop of the alias for login 'harry' which owns
objects in the database. This may result in errors when those objects are
accessed from or contain references to another database.
Alias user dropped.(return status = 0)
```

Usage

Executing the $sp_dropalias$ procedure deletes an alternate suid mapping for a user from the sysalternates table.

When a user's alias is dropped, he or she no longer has access to the database for which the alias was created.

You can drop the alias of a user who owns objects in the database. You do not need to first drop the objects before dropping the login.

Permissions

The permission checks for sp dropalias differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sso_role, or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addalias [page 26]

sp_adduser [page 73]

sp_droplogin [page 309]

sp_dropuser [page 326]

sp_helpuser [page 495]

1.80 sp_drop_all_qplans

Deletes all abstract plans in an abstract plan group.

Syntax

sp_drop_all_qplans <name>

Parameters

<name>

is the name of the abstract plan group from which to drop all plans.

Examples

Example 1

sp_drop_all_qplans dev_test

Usage

To drop individual plans, use sp_drop_qplan.

To see the names of abstract plan groups in the current database, use <code>sp_help_qpgroup</code>.

sp_drop_all_qplans silently drops all plans in the group that belong to the specified user, or all plans in the group, if it is executed by a system administrator or database owner.

Permissions

The permission checks for $sp_drop_all_qplans$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Any user can execute $sp_drop_all_qplans$ to drop plans that they own.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Any user can execute $sp_drop_all_qplans$ to drop plans that they own.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_drop_qplan [page 285]
sp_drop_qpgroup [page 284]

1.81 sp_drop_qpgroup

Drops an abstract plan group.

Syntax

sp_drop_qpgroup <group>

Parameters

<group>

is the name of the abstract plan group to drop.

Examples

Example 1

Drops the abstract plan group "dev_test":

sp_drop_qpgroup dev_test

Usage

You cannot:

- Drop the default groups, ap_stdin and ap_stdout.
- Drop a group that contains plans. To drop all of the plans in a group, use sp_drop_all_qplans. To see a list of groups and the number of plans they contain, use sp_help_qpgroup.
- Run sp drop qpgroup in a transaction.

Permissions

The permission checks for sp drop qpgroup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_drop_all_qplans [page 282]
sp_help_qpgroup [page 410]

1.82 sp_drop_qplan

Drops an abstract plan.

Syntax

sp_drop_qplan <id>

Parameters

<id>>

is the ID of the abstract plan to drop.

Examples

Example 1

The abstract plan with the specified ID is dropped:

sp drop qplan 1760009301

Usage

To find the ID of a plan, use sp_help_qpgroup, sp_help_qplan, or sp_find_qplan. Plan IDs are also returned by create plan and are included in showplan output.

To drop all abstract plans in a group, use $sp_drop_all_qplans$.

See also create plan in Reference Manual: Commands.

Permissions

The permission checks for sp_drop_qplans differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Any user can execute sp drop qplans to drop plans that they own.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user can execute sp drop qplans to drop plans that they own.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_drop_all_qplans [page 282]
sp_find_qplan [page 374]
sp_help_qpgroup [page 410]

1.83 sp_drop_resource_limit

Removes one or more resource limits from the SAP ASE server.

Syntax

```
sp_drop_resource_limit {<name>, <appname>}
    [, <rangename>, <limittype>, <enforced>, <action>, <scope>]
```

Parameters

<name>

is the SAP ASE login to which the limit applies. To drop resource limits that apply to all users:

- Of a particular application, specify <appname> and NULL for <name>.
- Using any application, specify NULL for both <name> and <appname>.

<appname>

is the application to which the limit applies. To drop resource limits that apply to:

- All applications used by the specified login, specify <name> and NULL for <appname>.
- A particular application, specify the application name that the client program passes to the SAP ASE server in the login packet.
- All users using any application, specify NULL for both <name> and <appname>.

<rangename>

is the time range during which the limit is enforced. This must be an existing time range stored in the systimeranges system table or NULL to delete all resource limits for the specified <name>, <appname>, <limittype>, <action>, and <scope>, without regard to <rangename>.

<limittype>

is the type of resource being limited. Valid values are:

- row count drops only limits that restrict the number of rows a query can return.
- elapsed_time drops only limits that restrict the number of seconds that a query batch or transaction can run.
- io_cost drops only limits that restrict actual or estimated query processing cost.

- tempdb_space drops only the limits of the number of tempdb database pages that a single session used or can have.

<enforced>

determines whether the limit is enforced prior to or during query execution. The valid values for each limit type are:

- 1 drops only limits for which action is taken when the estimated cost of execution exceeds the specified limit.
- 2 drops only limits for which action is taken when the actual row count, elapsed time, or cost of execution exceeds the specified limit.
- 3 drops only limits for which action is taken when either the estimated cost (1) or the actual cost (2) exceeds the specified limit.
- NULL drops all resource limits with the specified <name>, <appname>, <rangename>, <limittype>, and <scope>, without regard to when the <action> is enforced.

<action>

is the action taken when the limit is exceeded, and must be one of these:

- 1 drops only limits that issue a warning.
- 2 drops only limits that abort the query batch.
- 3 drops only limits that abort the transaction.
- 4 drops only limits that kill the session.
- NULL drops all resource limits with the specified <name>, <appname>, <rangename>, <limittype>, enforcement time, and <scope>, without regard to the <action> they take.

<scope>

is the scope of the limit, and must be one of the following:

- 1 drops only limits that apply to queries.
- 2 drops only limits that apply to query batches.
- 4 drops only limits that apply to transactions.
- 6 drops only limits that apply to both query batches and transactions.
- NULL drops all resource limits with the specified <name>, <appname>, <rangename>, dimittype>, enforcement time, and <action>, without regard to their <scope>.

Examples

Example 1

Drops the single resource limit that kills the session whenever joe's use of the payroll application runs a query during the friday afternoon time range that results in excessive execution-time I/O cost:

```
sp_drop_resource_limit joe, payroll, friday_afternoon, io_cost, 2, 4, 1
```

i Note

If no resource limit matches these selection criteria, $sp_drop_resource_limit$ returns without error.

Example 2

Drops all limits that apply to joe's use of the payroll application:

```
sp_drop_resource_limit joe, payroll
```

Example 3

Drops all limits that apply to the user "joe":

```
sp drop resource limit joe
```

Example 4

Drops all resource limits that apply to the payroll application:

```
sp drop resource limit NULL, payroll
```

Example 5

Drops all resource limits on the payroll application with an action that kills the session:

```
sp drop resource limit NULL, payroll, NULL, NULL, NULL, 4, NULL
```

Example 6

Drops a resource limit on all users using any application with an action that kills the session:

```
sp drop resource limit NULL, NULL, NULL, NULL, NULL, 4, NULL
```

Usage

To determine which resource limits apply to a given user, application, or time of day, use sp_help_resource_limit.

When you use drop login to drop an SAP ASE login, all resource limits associated with that login are also dropped.

The deletion of a resource limit causes the limits for each session for that login and/or application to be rebound at the beginning of the next query batch for that session.

See the System Administration Guide for more information on resource limits.

Permissions

The permission checks for <code>sp_drop_resource_limit</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_add_resource_limit [page 18]
sp_droplogin [page 309]
sp_help_resource_limit [page 407]
sp_modify_resource_limit [page 587]
```

1.84 sp_drop_time_range

Removes a user-defined time range from the SAP ASE server.

Syntax

```
sp_drop_time_range <name>
```

Parameters

<name>

is the name of the time range to be dropped.

Examples

Example 1

Removes the "evenings" time range:

```
sp_drop_time_range evenings
```

Usage

There are additional considerations when using <code>sp_drop_time_range</code>:

- You cannot remove the "at all times" time range.
- You cannot drop a time range if a resource limit exists for that time range.
- Dropping a time range does not affect the active time ranges for sessions currently in progress.

For more information on time ranges, see the *System Administration Guide*.

Permissions

The permission checks for <code>sp_drop_time_range</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_add_resource_limit [page 18]
sp_add_time_range [page 23]
sp_modify_time_range [page 590]
```

1.85 sp_dropdevice

Drops an SAP ASE database device or dump device.

Syntax

```
sp_dropdevice <logicalname>[, dropfile]
```

Parameters

<logicalname>

is the name of the device as listed in master.dbo.sysdevices.name.

dropfile

when specified, deletes the underlying operating system file.

Examples

Example 1

Drops the device named tape 5 from SAP ASE:

```
sp_dropdevice tape5
```

Example 2

Drops the database device named fredsdata from SAP ASE. The device must not be in use by any database:

```
sp_dropdevice fredsdata
```

Example 3

Drops the database device named fredsdata from SAP ASE as well as the file. The device must not be in use by any database:

sp dropdevice fredsdata, dropfile

Usage

There are additional considerations when using <code>sp_dropdevice</code>:

- sp_dropdevice drops a device from SAP ASE, deleting the device entry from master.dbo.sysdevices.
- sp_dropdevice without the dropfile flag does not remove a file that is being dropped as a database device; it makes the file inaccessible to SAP ASE.
- To delete a file, either use dropfile or, after using sp dropdevice, use operating system commands.

See also drop database in Reference Manual: Commands.

Permissions

The permission checks for $sp_dropdevice$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage disk privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addumpdevice [page 70]
sp_helpdb [page 438]
sp_helpdevice [page 446]

1.86 sp_dropengine

Drops an engine from a specified engine group or, if the engine is the last one in the group, drops the engine group.

Considerations for Process Mode

 $sp_dropengine does not run in threaded mode.$

Syntax

```
sp dropengine <engine number>[, <engine group>][, <instance id>]
```

Parameters

<engine number>

is the number of the engine you are dropping from the group. Values are between 0 and a maximum equal to the number of configured online engines, minus one.

<engine_group>

is the name of the engine group from which to drop the engine.

<instance id>

(Cluster environments only) is the ID of the instance from which you are dropping an engine or engine group.

Examples

Example 1

Drops engine number 2 from the group called DS_GROUP. If it is the last engine in the group, the group is also dropped:

```
sp dropengine 2, DS GROUP
```

Example 2

(Cluster environments only) Drops engine number 5 from instance ID 8:

```
sp_dropengine 5, 8
```

Usage

There are additional considerations when using sp dropengine:

- You can invoke sp dropengine only from the master database.
- If <engine_number> is the last engine in <engine_group>, SAP ASE also drops <engine_group>.
- (Cluster Edition only) if you set sp cluster set <system view> to:
 - o cluster you can drop an engine or engine group from any instance in the cluster.
 - o instance you can drop an engine or engine group only from a local instance.
- sp_dropengine can run in sessions using chained transactions after you use sp_procxmode to change the transaction mode to anymode.
- The <engine number> you specify must exist in <engine group>.

Permissions

The permission checks for sp dropengine differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class privilege.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be a user with sa_role}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addengine [page 33]

1.87 sp_dropexeclass

Drops a user-defined execution class.

Syntax

sp dropexeclass <classname>

Parameters

<classname>

is the name of the user-defined execution class to be dropped.

Examples

Example 1

This statement drops the user-defined execution class <code>DECISION</code>:

sp dropexeclass 'DECISION'

Usage

An execution class helps define the execution precedence used by the SAP ASE server to process tasks. See the *Performance and Tuning Guide* for more information on execution classes and execution attributes.

<classname> must not be bound to any client application, login, stored procedure, or default execution class.
Unbind the execution class first, using sp_unbindexeclass, then drop the execution class, using sp_dropexeclass.

You cannot drop system-defined execution classes.

Permissions

The permission checks for sp dropexeclass differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class

orivilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addexeclass [page 35]

sp_bindexeclass [page 110]

sp_showexeclass [page 744]

sp_unbindexeclass [page 825]

1.88 sp_dropextendedproc

Removes an extended stored procedure.

Syntax

sp_dropextendedproc <esp_name>

Parameters

<esp_name>

is the name of the extended stored procedure to be dropped. <esp_name> is case-sensitive, and must precisely match the name with which the extended stored procedure was created.

Examples

Example 1

Removes xp_echo:

sp dropextendedproc xp echo

Usage

You can execute ${\tt sp_dropextendedproc}$ only from the master database.

Permissions

The permission checks for $sp_dropextendedproc\ differ\ based\ on\ your\ granular\ permissions\ settings.$

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any ESP privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addextendedproc [page 37]
sp_freedll [page 389]
sp_helpextendedproc [page 448]

1.89 sp_dropexternlogin

(Component Integration Services only) Drops the definition of a remote login previously defined by sp addexternlogin.

Syntax

sp_dropexternlogin <server>[, <loginame>[, <rolename>]]

Parameters

<server>

is the name of the remote server from which the local server is dropping account access. The remote server is known to the local server by an entry in the master.dbo.sysservers table.

<loginame>

is a login account known to the local server. If <loginame> is not specified, the current account is used. <loginame> must exist in the master.dbo.syslogins table.

<rolename>

is the SAP ASE user's assigned role.

Examples

Example 1

Drops the definition of an external login to the remote server CIS1012 from "bobj". Only the "bobj" account and the "sa" account can add or modify a remote login for "bobj":

```
sp_dropexternlogin CIS1012, bobj
```

Example 2

Drops the definition of an external login to the remote server SSB from users with the sa_role:

sp_dropexternlogin SSB, NULL, sa_role

Usage

There are additional considerations when using <code>sp_dropexternlogin</code>:

- sp_dropexternlogin drops the definition of a remote login previously defined to the local server by sp addexternlogin.
- You cannot execute <code>sp_dropexternlogin</code> from within a transaction.
- The remote server must be defined to the local server by sp_addserver.
- To add and drop local server users, use sp addalias, create login, and drop login.

Permissions

The permission checks for sp dropexternlogin differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with $manage\ any\ remote\ login$ privilege.

sp dropexternlogin can be executed by users bound to <loginname>.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

sp dropexternlogin can be executed by users bound to <loginname>.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addexternlogin [page 39]
sp_helpexternlogin [page 450]
sp_addlogin [page 47]
sp_droplogin [page 309]
```

1.90 sp_dropglockpromote

Removes lock promotion values from a table or database.

Syntax

```
sp dropglockpromote {"database" | "table"}, <objname>
```

Parameters

database | table

specifies whether to remove the lock promotion thresholds from a database or table. The quotes are required because these are Transact-SQL keywords.

<objname>

is the name of the table or database from which to remove the lock promotion thresholds.

Examples

Example 1

Removes the lock promotion values from titles. Lock promotion for titles now uses the database or server-wide values:

```
sp_dropglockpromote "table", titles
```

Usage

There are additional considerations when using <code>sp_droplockpromote</code>:

- $\bullet \quad \text{Use } \verb"sp_dropglock" promote to drop lock promotion values set with $\verb"sp_setpglock" promote.$
- When you drop a database's lock promotion thresholds, tables that do not have lock promotion thresholds configured use the server-wide values.
- When a table's values are dropped, the SAP ASE server uses the database's lock promotion thresholds if they are configured or the server-wide values if they are not.
- Server-wide values can be changed with sp setpglockpromote, but cannot be dropped.

Permissions

The permission checks for sp dropglockpromote differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage lock promotion

threshold privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_setpglockpromote [page 719]

1.91 sp_dropglockpromote_ptn

Removes partition lock promotion values.

Syntax

• The syntax for dropping server-wide partition lock promotion settings is:

```
sp dropglockpromote ptn "server"
```

• The syntax for dropping the partition lock promotion threshold at the database or table level is:

```
sp_dropglockpromote_ptn {"database" | "table"}, objname
```

Parameters

server

removes server-wide values for the partition lock promotion thresholds.

"database" | "table"

specifies whether to remove the partition lock promotion thresholds for a database or table. These are Transact-SQL keywords and therefore, require quotes.

<objname>

is the name of the table or database from which to remove the partition lock promotion thresholds.

Examples

Example 1

Removes the partition lock promotion values from titles. Lock promotion for titles now uses the database or server-wide values:

sp_dropglockpromote_ptn "table", titles

Usage

There are additional considerations when using $sp_dropglockpromote_ptn$:

- Use sp_dropglockpromote_ptn to drop partition lock promotion values set with sp setpglockpromote ptn.
- When you drop a database's partition lock promotion thresholds, tables that do not have partition lock promotion thresholds configured use the server-wide values.
- When a table's values are dropped, the SAP ASE server uses the database's lock promotion thresholds if they are configured or the server-wide values if they are not.
- When you drop server-wide partition lock promotion thresholds, partition lock promotion threshold values set at the table level will be used. Otherwise, partition lock promotion threshold values set at the database level will be used. If partition lock promotion threshold values are not set at either database or table level, then partition lock promotion is disabled. It can be enabled again using sp setrowlockpromote ptn.

Permissions

The permission checks for sp dropglockpromote ptn differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage lock promotion

threshold privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.92 sp_dropgroup

Drops a group from a database.

Syntax

sp_dropgroup <grpname>

Parameters

<grpname>

is the name of a group in the current database.

Examples

Example 1

The "purchasing" group has merged with the "accounting" group. These commands move "martha" and "george", members of the "purchasing" group, to other groups before dropping the group. The group name "public" is quoted because "public" is a reserved word:

```
sp_changegroup accounting, martha
sp_changegroup "public", george
sp_dropgroup purchasing
```

Usage

Executing sp dropgroup drops a group name from a database's sysusers table.

You cannot drop a group if it has members. To drop the group, execute $\mathtt{sp_changegroup}$ for each member first.

Permissions

The permission checks for sp dropgroup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the database owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addgroup [page 42]
sp_changegroup [page 135]
sp_helpgroup [page 452]

1.93 sp_dropkey

Removes from the syskeys table a key that had been defined using sp_primarykey, sp_foreignkey, or sp_commonkey.

Syntax

sp_dropkey <keytype>, <tabname>[,< deptabname>]

Parameters

<keytype>

is the type of key to be dropped. The values are: primary, foreign, or common.

<tabname>

is the name of the key table or view that contains the key to be dropped.

<deptabname>

specifies the name of the second table in the relationship, if the <keytype> is foreign or common. If the <keytype> is primary, this parameter is unnecessary, since primary keys have no dependent tables. If the <keytype> is foreign, this is the name of the primary key table. If the <keytype> is foreign, give the two table names in the order in which they appear with sp helpkey.

Examples

Example 1

Drops the primary key for the <code>employees</code> table. Any foreign keys that were dependent on the primary key for <code>employees</code> are also dropped:

```
sp dropkey primary, employees
```

Example 2

Drops the common keys between the employees and projects tables:

```
sp_dropkey common, employees, projects
```

Example 3

Drops the foreign key between the titleauthor and titles tables:

```
sp dropkey foreign, titleauthor, titles
```

Usage

There are additional considerations when using sp dropkey:

- Executing sp_dropkey deletes the specified key from syskeys. Only the owner of a table can drop a key from that table.
- Keys are created to make explicit a logical relationship that is implicit in your database design. This information can be used by an application.
- Dropping a primary key automatically drops any foreign keys associated with it. Dropping a foreign key has no effect on a primary key specified on that table.
- Executing sp_commonkey, sp_primarykey, or sp_foreignkey adds the key to the syskeys system table. To display a report on the keys that have been defined, execute sp_helpkey.

Permissions

You must be the table owner to execute sp_dropkey. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_commonkey [page 191]

sp_foreignkey [page 387]

sp_helpkey [page 463]

sp_primarykey [page 677]

1.94 sp_droplanguage

Drops an alternate language from the server and removes its row from master.dbo.syslanguages.

Syntax

sp_droplanguage <language> [, dropmessages]

Parameters

<language>

is the official name of the language to be dropped.

dropmessages

drops all SAP ASE system messages in <language>. You cannot drop a language with associated system messages without also dropping its messages.

Examples

Example 1

This example drops French from the available alternate languages, if there are no associated messages:

```
sp_droplanguage french
```

Example 2

This example drops French from the available alternate languages, if there are associated messages:

```
sp_droplanguage french, dropmessages
```

Usage

Executing $sp_droplanguage$ drops a language from a list of alternate languages by deleting its entry from the master.dbo.syslanguages table.

If you try to drop a language that has system messages, the request fails unless you supply the dropmessages parameter.

Permissions

The permission checks for sp_droplanguage differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addlanguage [page 43]
sp_helplanguage [page 465]

1.95 sp_droplogin

Deprecated by SAP ASE 15.7. To drop a login account in SAP ASE, use the drop login command. See Reference Manual: Commands > Commands > drop login.

1.96 sp_dropmessage

Drops user-defined messages from sysusermessages.

Syntax

sp_dropmessage <message_num>[, <language>]

Parameters

<message num>

is the message number of the message to be dropped. Message numbers must have a value of 20000 or higher.

<language>

is the language of the message to be dropped.

When you include the optional <language> parameter, only the message with the indicated <message_num> in the indicated language is dropped. If you do not specify a <language>, all messages with the indicated <message_num> are dropped.

Examples

Example 1

Removes the French version of the message with the number 20002 from sysusermessages:

sp dropmessage 20002, french

Permissions

The permission checks for $sp_dropmessage$ differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be the user who created the message or the database owner, or a user with own database privilege on the current database.
Disabled	With granular permissions disabled, you must be the user who created the message, the database owner, or a user with sa_role.

Auditing

You can enable drop auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	drop
Event	32

Information Value

Command or access audited sp_dropmessage

Information in extrainfo

- Roles Current active roles
- Keywords or options NULL
- Previous value NULL
- Current value NULL
- Other information All input parameters
- Proxy information Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addmessage [page 47]
sp_getmessage [page 390]

1.97 sp_dropobjectdef

(Component Integration Services only) Deletes the external storage mapping provided for a local object.

Syntax

sp_dropobjectdef <tablename>

Parameters

<tablename>

has the form <dbname>.<owner>.<object>, where:

- <dbname> (optional) is the name of the database containing the object with a storage location that you are dropping. If present, it must be the current database, and the <owner> or a placeholder is required.
- <owner> is the name of the owner of the object with a storage location that you are
 dropping. <owner> is optional; it is required if <dbname> is specified.

 <object> is the name of the local table for which external storage mapping is to be dropped.

Examples

Example 1

Deletes the entry from sysattributes that provided the external storage mapping for a table known to the server as the colleges table in database personnel:

```
sp_dropobjectdef "personnel.dbo.colleges"
```

Example 2

Deletes the entry from sysattributes that provided the external storage mapping for the andrea.fishbone object, where andrea is the owner and the local table name is fishbone:

```
sp dropobjectdef "andrea.fishbone"
```

Usage

There are additional considerations when using sp dropobjectdef:

- sp_dropobjectdef deletes the external storage mapping provided for a local object. It replaces sp_droptabledef.
- Use sp dropobjectdef after dropping a remote table with drop table.
- Dropping a table does not remove the mapping information from the sysattributes table if it was added using sp_addobjectdef. It must be explicitly removed using sp_dropobjectdef.
- The <tablename> can be in any of these forms:
 - o <object>
 - o <owner>.<object>
 - o <dbname>..<object>
 - o <dbname>.<owner>.<object>

See also create existing table, create table, drop table in Reference Manual: Commands.

Permissions

The permission checks for sp dropobjectdef differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be the object owner or a user with $drop\ any\ table$ privilege.

Setting Description

Disabled With granular permissions disabled, you must be the object owner, the database owner, or a user with sa_role.

Auditing

 $For information about auditing stored procedures with the auditing options \verb|exec_procedure|, \verb|sproc_auth|, \\$ and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addobjectdef [page 50]

1.98 sp_dropremotelogin

Drops a remote user login.

Syntax

```
sp_dropremotelogin <remoteserver>[,< loginame>[, <remotename>] ]
```

Parameters

<remoteserver>

is the name of the server that has the remote login to be dropped.

<loginame>

is the local server's user name that is associated with the remote server in the sysremotelogins table.

<remotename>

is the remote user name that gets mapped to <loginame> when logging in from the remote server.

Examples

Example 1

Drops the entry for the remote server named GATEWAY:

```
sp dropremotelogin GATEWAY
```

Example 2

Drops the entry for mapping remote logins from the remote server GATEWAY to the local user named "churchy":

```
sp dropremotelogin GATEWAY, churchy
```

Example 3

Drops the login for the remote user "pogo" on the remote server GATEWAY that was mapped to the local user named "churchy":

```
sp_dropremotelogin GATEWAY, churchy, pogo
```

Usage

Executing sp_dropremotelogin drops a user login from a remote server, deleting the user's entry from master.dbo.sysremotelogins.

For a more complete discussion on remote logins, see $sp_addremotelogin$.

To add and drop local server users, use the commands create login and drop login.

Permissions

The permission checks for sp dropremotelogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any remote login

privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addserver [page 58]
sp_droplogin [page 309]
sp_helpremotelogin [page 471]
sp_helpserver [page 482]
```

1.99 sp_droprowlockpromote

Removes row lock promotion threshold values from a database or table.

Syntax

```
sp_droprowlockpromote {"database" | "table"}, <objname>
```

Parameters

database | table

specifies whether to remove the row lock promotion thresholds from a database or table.

<objname>

is the name of the database or table from which to remove the row lock promotion thresholds.

Examples

Example 1

Removes the row lock promotion values from the sales table. Lock promotion for sales now uses the database or server-wide values:

```
sp_droprowlockpromote "table", "sales"
```

Usage

There are additional considerations when using sp droprowlockpromote:

- Use sp droprowlockpromote to drop row lock promotion values set with sp setrowlockpromote.
- When you drop a database's row lock promotion thresholds, datarows-locked tables that do not have row lock promotion thresholds configured use the server-wide values. Use <code>sp_configure</code> to check the value of the row lock promotion configuration parameters.
- When a table's row lock promotion values are dropped, the SAP ASE server uses the database's row lock promotion thresholds, if they are configured, or the server-wide values, if no thresholds are set for the database.
- To change the lock promotion thresholds for a database, you must be using the master database. To change the lock promotion thresholds for a table in a database, you must be using the database where the table resides.
- You can change server-wide values with sp_setrowlockpromote. Since this changes the values in the row lock promotion configuration parameters, there is no corresponding server option for sp_droprowlockpromote.

Permissions

The permission checks for sp droprowlockpromote differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage lock promotion

threshold privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_setrowlockpromote [page 726]

1.100 sp_droprowlockpromote_ptn

Removes partition lock promotion threshold values at server, database, or table levels.

Syntax

• The syntax for dropping server-wide partition lock promotion settings is:

```
sp_droprowlockpromote_ptn "server"
```

• The syntax for dropping the partition lock promotion threshold at the database or table level is:

```
sp_droprowlockpromote_ptn {"database" | "table"}, objname
```

Parameters

server

removes server-wide values for the partition lock promotion thresholds.

"database" | "table"

specifies whether to remove the partition lock promotion thresholds for a database or table. These are Transact-SQL keywords and therefore, require quotes.

<objname>

is the name of the table or database from which to remove the partition lock promotion thresholds.

Examples

Example 1

Removes the partition lock promotion values from the sales table. Partition lock promotion for sales now uses the database or server-wide values:

```
sp_droprowlockpromote_ptn "table", "sales"
```

Usage

There are additional considerations when using sp droprowlockpromote ptn:

- Use sp_droprowlockpromote_ptn to drop partition lock promotion values set with sp setrowlockpromote ptn.
- When you drop a database's partition lock promotion thresholds, datarows-locked tables that do not have partition lock promotion thresholds configured at table level use the server-wide values. Use sp configure to check the value of the partition lock promotion configuration parameters.
- When a table's partition lock promotion values are dropped, the SAP ASE server uses the database's partition lock promotion thresholds, if they are configured, or the server-wide values, if no thresholds are set for the database.
- To change the partition lock promotion thresholds for a database, you must be using the master database. To change the partition lock promotion thresholds for a table in a database, you must be using the database where the table resides.
- When you drop server-wide partition lock promotion thresholds, partition lock promotion threshold values set at the table level will be used. Otherwise, partition lock promotion threshold values set at the database level will be used. If partition lock promotion threshold values are not set at either database or table level, then partition lock promotion is disabled. It can be enabled again using sp setrowlockpromote ptn.

Permissions

The permission checks for sp_droprowlockpromote_ptn differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage lock promotion

threshold privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.101 sp_dropsegment

Drops a segment from a database or unmaps a segment from a particular database device.

Syntax

```
sp dropsegment <segname>, <dbname> [, <device>]
```

Parameters

<segname>

is the name of the segment to be dropped.

<dbname>

is the name of the database from which the segment is to be dropped.

<device>

is the name of the database device from which the segment <segname> is to be dropped. This parameter is optional, except when the system segment system, default, or logsegment is being dropped from a database device.

Examples

Example 1

This command drops the segment indexes from the pubs2 database:

```
sp_dropsegment indexes, pubs2
```

Example 2

This command unmaps the segment indexes from the database device dev1:

```
sp_dropsegment indexes, pubs2, dev1
```

Usage

There are additional considerations when using <code>sp_dropsegment</code>:

• You can drop a segment if it is not referenced by any table, index, or partition in the specified database.

- If you:
 - Do not supply <device> the segment is dropped from the specified database.
 - Supply <device> the segment is no longer mapped to the named database device, but the segment is not dropped.
- Dropping a segment drops all thresholds associated with that segment.
- You can only execute sp dropsegment for the logsegment system segment in single-user mode.

i Note

This command may take a long time to complete in very large databases.

- When you unmap a segment from one or more devices, the SAP ASE server drops any thresholds that exceed the total space on the segment. When you unmap the logsegment from one or more devices, the SAP ASE server recalculates the last-chance threshold.
- sp_placeobject changes future space allocations for a table or index from one segment to another, and removes the references from the original segment. After using sp_placeobject, you can drop the original segment name with sp_dropsegment.
- For the system segments system, default, and logsegment, you must specify the device name from which you want the segments dropped.

Permissions

The permission checks for sp dropsegment differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addsegment [page 56]

sp_addthreshold [page 62]

sp_helpsegment [page 479]

sp_helpthreshold [page 493]

1.102 sp_dropserver

Drops a server from the list of known servers or drops remote logins and external logins in the same operation.

Syntax

sp dropserver <server>[, droplogins]

Parameters

<server>

is the name of the server to be dropped.

droplogins

indicates that any remote logins for <server> should also be dropped.

Examples

Example 1

This command drops the remote server GATEWAY:

```
sp_dropserver GATEWAY
```

Example 2

Drops the entry for the remote server RDBAM_ALPHA and drops all remote logins and external logins for that server:

```
sp_dropserver RDBAM_ALPHA, droplogins
```

Usage

There are additional considerations when using <code>sp_dropserver</code>:

• Executing sp_dropserver drops a server from the list of known servers by deleting the entry from the master.dbo.sysservers table.

- Running sp dropserver on a server that has associated entries in the master.dbo.sysremotelogins table results in an error message stating that you must drop the remote users before you can drop the server. To drop all remote logins for a server when dropping the server, use droplogins.
- Running sp dropserver without droplogins against a server that has associated entries in the sysattributes table results in an error. You must drop the remote logins and external logins before you can drop the server.
- The checks against sysattributes for external logins and for default mapping to a server apply when Component Integration Services is configured.

Permissions

The permission checks for sp. dropserver differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage server privilege.

When droplogins is specified, you must be a user with manage any remote login privilege.

SAP ASE high availability – You must be a user with manage server privilege and ha_role. When droplogins is specified, you must be a user with manage any remote login privilege.

SAP ASE shared-disk cluster - You must be a user with manage server and manage cluster privileges. When droplogins is specified, you must be a user with manage any remote login privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sso_role.} \end{tabular}$

SAP ASE high availability – You must be a user with sso_role permission and ha_role.

SAP ASE shared-disk cluster – You must be a user with sso_role and sa_role permission.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addserver [page 58] sp_dropremotelogin [page 313] sp_helpremotelogin [page 471]

sp_helpserver [page 482]

1.103 sp_dropthreshold

Removes a free-space threshold from a segment.

Syntax

sp_dropthreshold <dbname>, <segname>, <free_space>

Parameters

<dbname>

is the database from which you are dropping the threshold. This must be the name of the current database.

<segname>

is the segment with free space that is monitored by the threshold. Use quotes when specifying the "default" segment.

<free_space>

is the number of free pages at which the threshold is crossed.

Examples

Example 1

Removes a threshold from segment1 of mydb. You must specify the database, segment, and amount of free space to identify the threshold:

sp_dropthreshold mydb, segment1, 200

Usage

You cannot drop the last-chance threshold from the log segment.

You can use the no free space acctg option of sp_dboption as an alternative to sp_dropthreshold. This option disables free-space accounting on non-log segments. You cannot disable free-space accounting on log segments.

Permissions

The permission checks for $sp_dropthreshold$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addthreshold [page 62]

sp_dboption [page 228]

sp_helpthreshold [page 493]

sp_thresholdaction [page 809]

1.104 sp_droptype

Drops a user-defined datatype.

Syntax

sp droptype <typename>

Parameters

<typename>

is the name of a user-defined datatype that you own.

Examples

Example 1

Drops the user-defined datatype named birthday:

sp_droptype birthday

Usage

Executing sp droptype deletes a user-defined datatype from systypes.

You cannot drop a user-defined datatype if it is referenced by tables or another database object.

See also Reference Manual: Building Blocks > User-Defined Datatypes.

Permissions

The permission checks for sp droptype differ based on your granular permissions settings.

Setting Description

 $\textbf{Enabled} \quad \text{With granular permissions enabled, you must be the datatype owner or a user with \mathtt{manage}}$

database privilege.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be datatype owner or database owner.}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addtype [page 67]
sp_rename [page 693]

1.105 sp_dropuser

Drops a user from the current database.

Syntax

```
sp_dropuser <name_in_db>
```

Parameters

```
<name in db>
```

is the user's name in the current database's sysusers table.

Examples

Example 1

Drops the user "albert" from the current database. The user "albert" can no longer use the database:

```
sp_dropuser albert
```

Usage

There are additional considerations when using sp_dropuser:

- sp dropuser drops a user from the current database by deleting the user's row from sysusers.
- You cannot drop:
 - A user who owns objects in the database. You can use alter table modify owner to change the
 ownership of tables before dropping the user. However there is no command to transfer ownerships for
 other types of objects, you must drop these objects first before dropping the user.
 - A user who has granted permissions to other users.
 - The database owner from a database.
- If other users are aliased to the user being dropped, their aliases are also dropped. They no longer have access to the database.
- You cannot drop a user from a database if the user owns a stored procedure that is bound to an execution class in that database. See sp bindexeclass.

• sp_dropuser drops all key copies from sysencryptkeys for the specified user in the current database. sp_dropuser fails if the user owns an encryption key in any database. See the *Encrypted Columns Users Guide*.

See also grant, revoke, use in Reference Manual: Commands.

Permissions

The permission checks for sp dropuser differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any user privilege.

Disabled With granular permissions disabled, you must be the datatype owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addalias [page 26] sp_adduser [page 73] sp_bindexeclass [page 110] sp_droplogin [page 309]

1.106 sp_dump_history

Allows you to display and purge records from the dump history file.

Syntax

sp dump history

```
[ @operation = {'list' | 'purge' | 'listfiles' | 'help' | 'listpurgefiles' |
'purgefiles' | 'delete' | 'upgrade' | 'downgrade' | 'create_table'}]
        [, @until_time = '<upper_date_ limit>']
        [, @name = '[<database_name> | <config_file_name>']
        [, @dump_type = {'database' | 'tran[saction]' | 'config[uration]' |
'cum[ulative]'}]
        [, @status = {'success' | 'fail' | 'deleted'}]
        [, @file = '<dump_history_filename>']
        [, @version = '1.0']
        [, @stripe_name = '<dump_stripe_name>']
        [, @dump_date = '<dump_begin_time>']
        [, @dump_end_time = '<dump_end_time>']
        [, @format = '[raw | count]'
```

Parameters

- list displays the records from the dump history file. The list includes:
 - Dump_type dump type.
 - o Dbid database ID.
 - O Database name database name.
 - Stripes total number of dump stripes.
 - Dump_instant time the dump was made (this is the point in time up to which the database is recovered if the dump were loaded).
 - File target stripe name.
 - O Server name remote Backup Server name, if created using an at clause.
 - Compression lvl level of compression used for the dump.
 - Password specifies whether the dump file was created using the with password option.
 - Status status indicating whether the dump was a success or failure, and other information. The output shows Load, Success in records generated for load operations.
 - Label indicates if the database was marked for replication.
 - Dump begin time starting date and time of the dump.
 - Dump end time ending date and time of the dump.
 - Dump_size number of KB, MB, and GBs dumped during a dump database or written during a load database.
- purge purges records from the dump history file. The records to be purged are selected based on criteria specified using the other <code>sp_dump_history</code> parameters. If you use the <code><until_time></code> date as purge criteria, dump entries are deleted up to this date. The original dump history file is backed up as <code>original_name.<xxxxxxxxxxx></code>, where <code><xxxxxxxxxxx></code> represents an increasing numerical value from <code>000000001</code> to <code>999999999</code>. Numbering restarts once the count reaches a value of <code>9999999999</code>.
- listfiles displays the list of dump history file names using the format dumphist.*.

- help shows the syntax for sp dump history.
- listpurgefiles lists all the backup files that will be purged if you issue sp dump history with the purgefiles parameter.
- purgefiles deletes all the backup files.
- delete delete records affected by the selected criteria. A backup file is generated.
- upgrade allows you to force an upgrade of the existing file from a previous version to the current version when a release changes the format of the dump history file.
- downgrade allows you to downgrade the file to a previous version.
- create_table creates a proxy table to allow access to the dump history file. The table name is optional.

<until time>

specifies a date and time for the dump. If you are purging records, the value for <until_time> is used to purge all dump entries created before that time. By default, all dump records are purged.

<database_name>

affected records include only this database. By default, the dump records for all databases are included.

<dump type>

specifies the type of dump record to select. One of:

- 'DATABASE' database dump objects created by dump database.
- 'TRAN[SACTION]' transaction dump objects created by dump transaction.
- 'CONFIG[URATION]' server configuration objects created by dump configuration.

<status>

is one of success, fail, or deleted. By default, only successful dump records are included.

<file>

specifies the name of the dump history file to display records from. You must specify the path, or location, of the file as part of <file>. The default location of the dump history file is \$SYBASE/\$SYBASE ASE(\$SYBASE\\$SYBASE ASE% in Windows).

<version>

is used only as an extra parameter for the downgrade operation.

<stripe_name>

applies only to records that contain this stripe name.

<dump_date>

applies only to records that contain this dump date.

<dump_end_time>

applies only to records that finish by this dump date.

<format>

One of the following:

- raw returns unformatted output.
- count returns the number of records affected.

Examples

Running sp_dump_history requires that you first enable SAP ASE to create the dump history files:

```
sp_configure 'enable dump history', 1
```

Example 1

Lists all dump records from the dump history file:

```
sp_dump_history 'list'
```

Example 2

Lists dump records of a specified database created before a specified time:

```
sp_dump_history 'list', 'mar 20, 2010 10:51:43:866am', 'testdb'
```

Example 3

Lists the transaction dump objects from the model database, specifying a full path for the dump history file:

```
sp_dump_history @operation='list', @database_name = 'model',
    @dump_type='TRAN', @status = 'success',
    @file = '/john_machine/john/ASE/ASE-16_0/dumphist'
```

Example 4

Creates a table called ${\tt sysdumphist}$ in the master database:

```
sp_dump_history create_table, 'master..sysdumphist'
go
The object sysdumphist has been successfully created in database master.
(return status = 0)
```

Usage

• SAP ASE does not create the dump history files by default. Use the enable dump history configuration parameter to configure SAP ASE to create the dump history files:

```
sp_configure 'enable dump history', 1
```

Once enabled, each server instance has a dump history file (located in \$SYBASE/\$SYBASE_ASE) with information about all database dumps and server configuration dumps, successful or not.

- The default behavior for sp_dump_history with no parameters is to display the output from its list parameter.
- The output for database and transaction dumps differs from that of configuration files.

- See also:
 - o For information about dump operations, see the System Administration Guide: Volume Two.

 - o sp config dump
 - The Reference Manual: Configuration Parameters.

Permissions

The permission checks for <code>sp_dump_history</code> differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with $\tt manage \ dump \ configuration$ privilege.
Disabled	With granular permissions disabled, you must be a user with sa_role or oper_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.106.1 Creating a Proxy Table

Use the <code>sp_dump_history</code> stored procedure with the <code>create_table</code> parameter to create a proxy table, which allows access to the dump history file.

Although the proxy table is created on a file, you don't have to first enable the external file access. If you don't specify a name for the proxy table, it is assigned the default name, dumphis<random_number>, in the tempdb database. For example:

```
sp_dump_history create_table
go
The object dumphist15870 has been successfully created in database tempdb.
(return status = 0)
```

To return all DUMP DATABASE records (rec_type = 2) from the dump history file, run:

```
sp_autoformat "tempdb..dumphist15870", null, "where rec_type=2"
go
```

The proxy table is treated as a user table instead of a system table. It becomes invalid if the dump history file name is changed.

1.107 sp_dump_info

The sp_dump_info system procedure displays the size of data and log that an uncompressed cumulative dump would contain at a specific point in time.

The size is reported in units of KB, MB, or GB, as appropriate. The size reported may be slightly smaller than the actual size of the archive file (or files, if using multiple stripes), because the archive contains some additional information by way of the labels, header, trailer and runlist pages. sp_dump_info can also only assume that an uncompressed dump is done; if a compressed dump is done, the size of the archive will clearly be smaller than that reported by sp_dump_info .

You cannot use sp_dump_info:

- Unless you allow incremental dumps of your database by using the allow incremental dumps parameter of sp dboption.
- If the database has not yet been fully dumped since you enabled incremental dumps for your database.

Syntax

```
sp_dump_info <database_name>
```

Parameters

```
<database_name>
```

is the name of the database.

Examples

Data and log size

Displays the size of data and log that the cumulative dump of the test database contains

The output indicates that if a cumulative dump were taken at this point in time, it would contain approximately 4,368KB of data and a single log page, which represents 2 percent of the total database size.

Compare this with the size if you performed a cumulative dump at this time:

```
dump database test cumulative to "c:/tmp/test.dmp"
Backup Server: 4.171.1.1: The current value of 'reserved pages
threshold' is 85%.
Backup Server: 4.171.1.2: The current value of 'allocated pages
threshold' is 40%.
Backup Server session id is: 10. Use this value when executing the
'sp volchanged' system stored procedure after fulfilling any
volume change request from the Backup Server.
Backup Server: 6.28.1.1: Dumpfile name 'test122480F0EF' section
number 1 mounted on disk file 'c:/tmp/test.dmp'
Backup Server: 4.188.1.1: Database test: 4328 kilobytes (3%) DUMPED.
Backup Server: 3.43.1.1: Dump phase number 1 completed.
Backup Server: 3.43.1.1: Dump phase number 2 completed.
Backup Server: 3.43.1.1: Dump phase number 3 completed.
Backup Server: 4.188.1.1: Database test: 4370 kilobytes (3%)
DUMPED.
Backup Server: 3.42.1.1: DUMP is complete (database test).
```

The corresponding size of the archive is 4,487,168 bytes, or 2191 pages. This differs from the estimate given by sp_dump_info by 29 pages (14 KB), which is the result of 8 pages for the dump labels, 1 page for the dump header, 1 page for the dump trailer and 19 pages containing run lists. The size of the dump labels, header and trailer are independent of the numbers of pages dumped, while the number of pages used by run lists is dependent on the numbers of pages dumped.

Error message

Displays an error message when incremental dumps are not enabled on master

```
sp_dump_info mydb
go
Msg 17154, Level 16, State 1:
Procedure 'sp_dump_info', Line 32:
Incremental dumps are not enabled in database mydb.
(return status = 1)
```

Usage

sp_dump_info fails if you do not allow incremental dumps, or you have not enabled incremental dumps for your database.

Permissions

Any user can execute sp_dump_info.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.108 sp_dumpoptimize

Specifies the amount of data dumped by Backup Server during a dump database operation.

Syntax

```
sp_dumpoptimize [ 'archive_space = {maximum | minimum | default }' ]
sp_dumpoptimize [ 'reserved_threshold = {<nnn> | default }' ]
sp_dumpoptimize [ 'allocation_threshold = {<nnn> | default }' ]
```

Parameters

archive_space

specifies the amount of the database you want dumped.

maximum

dumps the whole database without determining which pages are allocated or not. The total space used by the archive image or images is equal to the size of the database. Using this option has the same effect as using the options $reserved_threshold=0$ and $allocation_threshold=0$.

minimum

dumps only the allocated pages, which results in the smallest possible archive image. This option is useful when dumping to archive devices for which the throughput is much smaller than that of the database devices such as QIC tape drives. Using this option has the same effect as using the options $reserved_threshold=100$ and allocation threshold=100.

default

specifies that default values should be used. When used with:

• archive_space - this option dumps the database with the reserved_threshold and allocation_threshold options set to their default values. Use this to reset Backup Server to the default configuration.

- reserved threshold default specifies 85 percent.
- allocation threshold default specifies 40 percent.

reserved threshold

dumps all the pages belonging to the database in a database disk if the percentage of reserved pages in the disk is equal to or greater than <nnn>. For example, if you specify <nnn> as 60 and if a database disk has a percentage of reserved pages equal to or greater than 60 percent, then the entire disk is dumped without determining which pages within that disk are allocated. The default for this option is 85 percent.

<nnn>

an integer value between 0 and 100 that represents the value of the threshold. It is used to determine how much data to dump.

When used with reserved_threshold, if the percentage of reserved pages in the disk is greater than the value specified, all the pages of the database in a database disk are dumped.

When used with allocation_threshold, if the percentage of allocated pages in an allocation unit is greater than the percentage specified for allocation_threshold, all the pages within an allocation unit are dumped.

allocation threshold

dumps all the pages in the allocation unit if the percentage of allocated pages in the unit is equal to or greater than <nnn>. For example, if <nnn> is specified as 70 and if the percentage of allocated pages in an allocation unit is equal to or greater than 70 percent, then the entire allocation unit is dumped without determining whether pages within that allocation unit are allocated or not. If the reserved_threshold setting causes the whole disk to be dumped, the allocation_threshold setting is ignored for the disk. The default for this option is 40 percent.

Examples

Example 1

Dumps the whole database:

```
sp_dumpoptimize 'archive_space=maximum'

Backup Server: 4.172.1.1: The value of 'reserved pages threshold' has been set to 0%.

Backup Server: 4.172.1.2: The value of 'allocated pages threshold' has been set to 0%.
```

Example 2

Dumps only the allocated pages, thereby resulting in the smallest archive image:

```
sp_dumpoptimize 'archive_space=minimum'

Backup Server: 4.172.1.1: The value of 'reserved pages threshold' has been set to 100%.
Backup Server: 4.172.1.2: The value of 'allocated pages threshold' has been
```

```
set to 100%.
```

Example 3

Sets the reserved threshold to 85 percent and the allocation threshold to be set to 40 percent:

```
sp_dumpoptimize 'archive_space=default'

Backup Server: 4.172.1.1: The value of 'reserved pages threshold' has been set to 85%.

Backup Server: 4.172.1.2: The value of 'allocated pages threshold' has been set to 40%.
```

Example 4

Dumps disks in the database with a percentage of reserved pages that is greater than or equal to 60 percent without reading allocation pages on this disk. For the remaining disks, the allocation pages are read, and the last set value for the allocation_threshold is used. If the allocation_threshold was not set after Backup Server was started, default allocation threshold of 40 percent is used:

```
sp_dumpoptimize 'reserved_threshold=60'

Backup Server: 4.172.1.3: The value of 'reserved pages threshold' has been set to 60%.
```

Example 5

Causes the reserved threshold to be set to 85 percent. It does not affect the allocation page threshold:

```
sp_dumpoptimize 'reserved_threshold=default'

Backup Server: 4.172.1.3: The value of 'reserved pages threshold' has been set to 85%.
```

Example 6

Reads allocation pages for those disks with a reserved page percentage that is less than the last set value for the reserved_threshold and if an allocation unit has 80 percent or more pages allocated, then the whole allocation unit is dumped:

```
sp_dumpoptimize 'allocation_threshold=80'

Backup Server: 4.172.1.4: The value of 'allocated pages threshold' has been set to 80%.
```

Example 7

This example causes the allocation page threshold to be set to the default of 40 percent. It does not affect the reserved pages threshold:

```
sp_dumpoptimize 'allocation_threshold=default'

Backup Server: 4.172.1.4: The value of 'allocated pages threshold' has been set to 40%.
```

Example 8

Dumps disks in the database with a percentage of reserved pages that is greater than or equal to 60 percent without reading allocation pages on this disk. For the remaining disks, the allocation pages are read and if an allocation unit has 30 percent or more pages allocated, then the whole allocation unit is dumped:

```
sp_dumpoptimize 'reserved_threshold=60', 'allocation_threshold=30'

Backup Server: 4.172.1.3: The value of 'reserved pages threshold' has been set to 60%.

Backup Server: 4.172.1.4: The value of 'allocated pages threshold' has been set to 30%.
```

Example 9

Displays the current value of the thresholds:

```
sp_dumpoptimize

Backup Server: 4.171.1.1: The current value of 'reserved pages threshold'
is 60%
Backup Server: 4.171.1.2: The current value of 'allocated pages threshold'
is 30%.
```

Usage

- When you set a threshold using sp_dumpoptimize, this threshold acts on each individual device that the database resides on.
- When you set values with <code>sp_dumpoptimize</code>, those values are immediately in affect without the need to restart Backup Server. However, the changes are effective only until the Backup Server is restarted. When Backup Server is restarted, the default values are used.
- If you issue <code>sp_dumpoptimize</code> multiple times, the thresholds specified by the last instance are used by later dumps. For example, if you first set the <code>reserved_threshold</code> value, and later issue <code>archive_space=maximum</code>, then that value overwrites the previous value you set for <code>reserved_threshold</code>.
- Dumps of different databases can use different thresholds by changing the sp_dumpoptimize values before each database dump.
- The optimal threshold values can vary from one database to another. Therefore, the performance of a dump depends on both the I/O configuration and the amount of used space in the database. The DBA can determine the appropriate configuration for a database by experimenting with dumps using different values and choosing the one that results in the shortest dump time.
- You can use sp_dumpoptimize for both local and remote dumps.
- sp_dumpoptimize has no effect on the performance of a transaction log dump or a load. Therefore, it need not be issued before dump transaction, load database or load transaction operations.
- If sp_dumpoptimize is issued without any parameters, the current value of the thresholds is displayed on the client.
- On configurations in which the archive device throughput is equal to or higher than the cumulative throughput of all the database disks, using archive_space=maximum may result in a faster dump. However, on configurations in which the archive device throughput is less than the cumulative throughput of all the database disks, using this option may result in a slower dump.

- The option names and the values for this procedure can be abbreviated to the unique substring that identifies them. For example, ar = ma is sufficient to uniquely identify the option archive_space=maximum.
- There can be zero or more blank space characters around the equal sign (=) in the option string.
- The option names and their values are case insensitive.

See also:

- dump database, dump transaction, load database, load transaction in *Reference Manual:* Commands
- See the System Administration Guide for information on allocation pages.

Permissions

The permission checks for sp dumpoptimize differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled vo

With granular permissions enabled, you must be a user with <code>dump database</code> privilege on the database you are dumping.

Disabled With granular permissions disabled, you must be the datatype owner, a user with sa_role, or a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.108.1 Thresholds and sp_dumpoptimize

The default values for the thresholds are: Reserved pages: 85%; allocation pages: 40%.

If the device fragment of the database has a reserved pages percentage that is:

- Greater than or equal to the reserved threshold then all the blocks on this device that pertain to this database are dumped.
- Less than the reserved threshold then Backup Server starts checking each allocation unit on this device for the allocation percentage. If the cumulative allocation percentage is:
 - Less than the allocation threshold then it would only dump those pages with data written on it
 - o Greater than the allocation threshold the entire allocation unit would be dumped.

1.109 sp_encryption

Reports encryption information.

Syntax

• To list encryption key properties:

```
sp_encryption help | helpkey
```

• To list encryption key properties for a specific key or keys matching a pattern:

```
sp_encryption help | helpkey[, <key_name> | wildcard]
   [, all_dbs | key_copy | display_cols]
```

• To report information about a master key or dual master key:

• To display objects encrypted by the service key:

```
sp_encryption 'help'[, 'servicekeyname'[, 'display_objs']]
```

• To display the encryption status of external passwords in the status column:

```
sp_encryption 'helpextpasswd'
```

• To display the column name and the key used to encrypt the column:

```
sp_encryption helpcol[, <table_name> | <column_name> ]
```

• To display the keys owned by or assigned to a user in the current database:

```
sp_encryption helpuser[, <user_name> | wildcard ][, key_copy |
login_passwd_check ]
```

• To specify credentials for SAP ASE to access the Hardware Security Module (HSM) key:

```
sp_encryption 'hsm_credential' [,'lib=<pkcs11 library name>;pin=<normal user
pin>;slot=<slot number>;']
```

• To display credentials for SAP ASE to access the Hardware Security Module (HSM) key:

```
sp_encryption 'hsm_credential'
```

• To display or set the master key startup file name and path:

```
sp_encryption 'mkey_startup_file'[, {'<new_path>' | '<default_location>' |
'null'}
   [, {sync_with_mem | sync_with_qrm}]]
```

To display or set the downgrade kek size configuration:

```
sp_encryption 'downgrade_kek_size' [, 'true'|'false']
```

• To display the encrypted keys and key copies using the system encryption password in the current database:

```
sp encryption system encr passwd, '<newpasswd>' [,'<oldpasswd>']
```

Parameters

helpkey

lists encryption key properties, including:

- Whether the database contains encryption keys.
- The following, when run by a user with sso_role, key custodian, or DBO: keyname, keyowner, key length, key algorithm, key type, pad, initialization vector, type of password used to encrypt the key, whether key recovery has been enabled and count of key copies. The output is sorted on <owner>.<key_name>. When run by a non-privileged user, this command lists <key_name>, <key_owner>, and <key_type>.

help

is identical to helpkey, and is included for backward compatibility.

<key_name>

is the name of the key you are investigating. Lists the properties defined for <key_name>. If <key_name> is omitted, lists properties for all keys.

<wildcard>

lists the properties for keys matching the wildcard pattern in the current database. See the *Reference Manual: Building Blocks* for information about using wildcards.

all dbs

lists information on encryption keys in all available databases. Only the SSO can run all_dbs.

key_copy

lists all user copies for the specified key in the current database. The output is sorted by <key_owner>.<key_name>. Includes information about:

- The base key owner.
- If the key copy is a recovery key copy.
- The user to whom a copy belongs.
- If the copy is encrypted with a user-encryption password, a login password, or the system encryption password for login association (indicated by Login Access).

login_passwd_check

indicates if the key copies assigned to the matched users are well synchronized with the user's login password. That is, the last update date of the key copy is newer than the date of the login password. The key copies are encrypted with the user's login password or login association.

display keys

is used with <system_encr_passwd> to display the encrypted keys and key copies using the system encryption password. Used with master or dual master to display the encrypted keys and key copies using the master key or the dual master key.

You must be the system security officer, key custodian, or the database owner can run sp_encryption helpkey, master | 'dual master', display_keys to display encryption keys protected by either the master or dual master key.

display cols

displays the key name, all keys (or matching wildcard keys) in the current database and the columns the key encrypts. When the SSO includes ${\tt display_cols}$, it displays columns encrypted by the keys across all available databases. When a user without the sso_role runs ${\tt display_cols}$, only those columns encrypted by the key in the current database are displayed. Data is sorted by ${\tt ckey_name}$, ${\tt ckey_owner}$,

<database name>, , , and <column name>.

master

reports information about the master key.

dual master

reports information about the dual master key.

servicekeyname

is set to syb_extpasswdkey or syb_syscommkey%. Use with display_objs to display objects encrypted by the service key.

display_objs

displays object owners.

You must be the system security officer, key custodian, or the database to run $sp_encryption\ helpkey$, $<key_name>$, $display_objs$ to $display\ objects$ in current database protected by the $syb_extpasswdkey$ or $syb_syscommkey$ service keys.

helpextpasswd

displays the encryption status of external passwords in the status column. The encryption status is one of:

- FIPS Encryption the password is protected by the syb_extpasswdkey service key using a FIPS-compliant cryptography algorithm.
- Needs Reset indicates the system removed the password, and you must reset it manually.
- Legacy Encryption the password is protected with an algorithm from a version of SAP ASE earlier than 15.7.

You must be the system security officer to run $sp_encryption\ helpextpasswd$ to check the status of external passwords.

helpcol <column_name>

displays the column name and the key used to encrypt the column. If the SSO includes helpcol, it prints the key name even if the key is not present in the current database. If a non-SSO user includes helpcol, the SAP ASE server prints the keyid of the key if it is not present in the current database, omitting the key_name . The output includes:

<owner>..<column>, <database>.<owner>.<keyname>. The information
is sorted by <owner>..<column>.

helpuser

displays the keys owned by or assigned to a user in the current database.

hsm_credential

specifies credentials for SAP ASE to access the Hardware Security Module (HSM) key.

- <pkcs11 library name> specifies the name of the PKCS#11 library to be used. The library should be located in the \$\$\text{\$\$SYBASE}/ASE-16 0/\text{lib} folder.
- <normal user pin> specifies the normal user pin on the HSM device.
- <slot number> specifies the slot number that contains the token device to be used.

mkey startup file

displays or sets the master key startup file name and path. sp_encryption sets the master key startup file to <new_path> or the default location. If you specify null or no location, sp_encryption displays the current master key startup file name and path.

sync_with_mem

(Cluster Edition only) writes the master key encryption key that exists in server memory to the master key startup file. Replaces the current master key encryption key, if it exists. If automatic master key access is set to off, sync_with_mem is also disabled.

You must be the system security officer display, set, or sync the master key startup file.

sync with qrm

updates the local master key startup file with the version in the quorum device.

You must be the system security officer display, set, or sync the master key startup file.

downgrade kek size

displays or sets the downgrade kek size configuration. true indicates that the SAP ASE server is in downgrade kek size mode; false disables this mode.

If you specify no argument, ${\tt sp_encryption}$ displays the current value for downgrade_kek_size.

You must be the system security officer or the key custodian to run this command.

system_encr_passwd

displays the encrypted keys and key copies that are using the system encryption password in the current database.

system_encr_passwd, all_dbs

displays the properties of the system encryption password in every database where it has been set. The output is sorted by database name. Only the system security officer can run this command. If the system encryption password has not been set for all databases, the SAP ASE server generates the following message:

The system encryption password has not been set for all available databases

Examples

Display Key Information for Fully Encrypted Database

This example shows a key type called "database encryption key" to indicate that the database is fully encrypted:

1> create encryption key key1 as default for database encryption

```
1> sp encryption helpkey, key1
        Key Owner Key Length Key Algorithm
                                Pad Initialization Vector
  Key Type
             Key Recovery
 Protected By
   # of Key Copies
        dbo 256 AES
  symmetric database encryption key 0
                                       0
 master key 0
1> create encryption key key2 for database encryption with master key
2> create encryption key key3 for database encryption with dual_control
1> sp_encryption helpkey, 'key%'
Key Name Key Owner Key Length Key Algorithm
 Key Type Pad Initialization Vector Protected By Key Recovery
   # of Key Copies
key1 dbo 256
                              AES
```

```
symmetric database encryption key 0 1
master key 0 0 0
key2 dbo 256 AES
symmetric database encryption key 0 1
master key 0 0 0
key3 dbo 256 AES
symmetric database encryption key 0 1
master key 0 0 1
create database encryption key 0 1
create database encryption key 0 0 1
create database encr_db1 encrypt with key1 2
create database encr_db2 encrypt with key2 3
create database encr_db3 encrypt with key3 4
create database encrypt with key3 4
create data
```

Display Key Information in Current Database

The helpkey parameter displays information in the current database on all or specific keys. The second parameter to $sp_encryption$ supplies the key name and may include SQL pattern-matching characters. If you are not the database owner and do not have sso_role or $keycustodian_role$, $sp_encryption$ displays fewer columns.

This displays properties of all base encryption keys in the current database when run by the SSO, key custodian, or the DBO:

```
sp_encryption helpkey
```

_	-	4 2	Key Algorithm Key Recovery #	1 11	Pa	d
tinnap_key t	-	128 em encryptio		symmetric key	0	0
tinnap_key1 t	innap -		AES	symmetric default key	0	3
sample_key1 o	dbo	192 n Passwd	AES	symmetric key 1	1	2

When run by user "tinnap," this displays the following properties of all base encryption keys in the current database:

If you are not the system security officer or do have keycustodian_role, the query displays all base keys you own in the current database. If you do not specify a <user_name> as the second parameter, the query displays the base keys you own.

Display Properties of Base Encryption Key When Run by SSO

Displays the properties of base encryption key sample_key1 when run by the SSO, key custodian, or DBO in the current database:

When non-privileged user "tinnap" runs this command, it displays the following properties for the base encryption key sample_key1 in the current database:

```
sp_encryption helpkey, sample_key1

Key Name Key Owner Key Type
sample_key1 dbo ymmetric key
```

Display Properties of All Base Encryption Keys in All Available Databases

Only the SSO can run this command:

```
sp_encryption helpkey, NULL, all_dbs

Db.Owner.Keyname Key Length Key Algorithm Key Type
Pad Init Vector Protected By Key Recovery #of Key Copies
```

keydb.dbo.cc_key	256	AES	symmetric	default key
1 1 system	encr passwd		0	0
keydb.dbo.sample key1	128	AES	symmetric	key
0 $\overline{0}$ system	encr passwd		1	4
keydb1.tinnap.tinnap key	128	AES	symmetric	key
0 1 $\overline{\text{system}}$	encr passwd		0	0
keydb1.tinnap.tinnap key1	128	AES	symmetric	default key
0 1 u	ser password		1	3
keydb1.dbo.sample key1	192	AES	symmetric	key
1 1	login passwd		1	2

Display Properties of All Base Encryption Keys Similar to %key in All Available Databases

all_dbs indicates that information on keys across all databases is required. You must have sso_role to use the all dbs parameter:

```
Db.Owner.Keyname Key Length Key Algorithm Key Type
Pad Init Vector Protected By Key Recovery #of Key Copies

keydb.dbo.cc_key 256 AES symmetric default key
1 1 1 system encr passwd 0 0
keydb1.tinnap.tinnap_key 128 AES symmetric key
0 1 system encr passwd 0 0
```

Display Properties of All Base Encryption Keys With Names Similar to "tinnap%" in Database Run by SSO

Displays properties of all base encryption keys with names similar to "tinnap%" in the current database when run by the SSO, key custodian, or DBO:

```
Sp_encryption helpkey, "tinnap%"

Key Name Key Owner Key Length Key Algorithm Key Type
Pad Init Vector Protected By Key Recovery # of Key Copies

tinnap_key tinnap 128 AES symmetric key
0 1 system encr passwd 0 0

tinnap_key1 tinnap 128 AES symmetric default key
0 1 user passwd 1 3
```

When run by user "tinnap," displays the following properties for the base encryption keys in the current database with names similar to "tinnap%":

```
Sp_encryption helpkey, "tinnap%"

Key Name Key Owner Key Type

tinnap_key tinnap symmetric key
tinnap_key1 tinnap symmetric default key
```

Display Information on Key Copies Using key_copy as Third Parameter

samcool

billyg

tinnap.tinnap_key1

tinnap.tinnap_key1

Displays information on key copies using key_copy as the third parameter. Enter null instead of value for < keyname> for the second parameter to see information on all key copies. You can use pattern-matching characters in < keyname> (see the previous example):

sp_encryption helpke	y, tinnap_key1	, key_copy	
Owner.Keyname	Assignee	Protected by	Key Recovery
tinnap.tinnap_key1	joesmp	user passwd	0

user passwd

user passwd

1

When run by user "joesmp," this displays all encryption key copies assigned to user "joesmp" and also all the key copies for that keyname if the user is the owner of the key in the current database:

sp_encryption helpke	y, tinnap_key1,	key_copy		
Owner.Keyname	Assignee	Protected by	Key Recovery	
tinnap.tinnap_key1	joesmp	user passwd		0

Display All Encrypted Columns in All Available Databases Encrypted by Keys from Database

Use the display_cols parameter to show all encrypted columns in all available databases encrypted by keys from the current database. If you do not have the sso_role, the query displays only the encrypted columns in the current database encrypted by keys from the current database.

You can use pattern matching characters or <code><key_name></code> for the second parameter. If you use pattern matching characters for <code><key_name></code> as sso_role, the query displays all encrypted columns in all available databases encrypted by the pattern matching <code><key_name></code>. If you use <code><key_name></code> for the second parameter and have the sso_role, displays all encrypted columns in all available databases encrypted by the specified <code><key_name></code>:

sp_encryption helpkey, null, display_cols						
Key Name	Key Owner	Database Name	Table Owner	Table Name	Column Name	
tinnap_key tinnap_key1 sample_key1 sample_key1	tinnap tinnap dbo dbo	testdb1 testdb1 coldb coldb	tinnap tinnap dbo billyg	t3 t4 t1 t2	c3 c4 c1 c2	

Display All Keys, Key Copies Encrypted With System Encryption Password in Database

Displays all keys and key copies encrypted with the system encryption password in the current database. If you do not have these privileges, the query displays the keys owned by or assigned to the user which are encrypted with the system encryption password:

Display All Base Keys Owned by Users in Database

When run by the database owner or a user with keycustodian_role or sso_role, the helpuser parameter displays all base keys owned by users in the current database:

```
Owner.Keyname Protected by

tinnap.tinnap_key system encr passwd
tinnap.tinnap_key1 user passwd
dbo.sample_key1 login passwd
```

If user "tinnap" runs this command, lists all base keys owned by this user in the current database:

```
Owner.Keyname Protected by

tinnap.tinnap_key system encr passwd
tinnap.tinnap_key1 user passwd
```

Display Key Copies Assigned to One or More Users

The database owner or a user with keycustodian_role or sso_role can use the key_copy parameter with the helpuser parameter to display key copies assigned to one or more users in the current database. You can use pattern-matching characters for the user> parameter. This shows the key copies of all users in the current database:

```
Owner.Keyname Assignee Protected by Key Recovery

dbo.sample_key1 tinnap login passwd 0
tinnap.tinnap_key1 joesmp user passwd 0
dbo.sample_key1 joesmp login passwd 1
tinnap.tinnap_key1 samcool user passwd 1
tinnap.tinnap_key1 billyg user passwd 0
```

If you are not the database owner and do not have keycustodian_role or sso_role, this query displays the copies of any keys you own and the key copies that other key owners have assigned to you. For example, when user "tinnap" runs this query:

```
sp encryption helpuser, NULL, "key copy"
                                       Protected by
Owner.Keyname
                                                          Key Recovery
                       Assignee
                        tinnap login passwd
                                           login passwd
dbo.sample key1
tinnap.tinnap_key1
tinnap.tinnap_key1
                            joesmp
samcool
                                            user passwd
                                                                   0
                                             user passwd
                                                                   1
                              billyg
                                                                   Ω
tinnap.tinnap key1
                                                user passwd
```

Display All Encrypted Columns in Database and Keys Used to Encrypt Columns

If you are the database owner or a user with keycustodian_role or sso_role, helpcol displays all encrypted columns in the current database and the keys used to encrypt the columns. If you do not have these

privileges, helpcol displays keyid instead of the <key_name> if the encryption key is in a different database:

```
Owner.Table.Column
Ob.Owner.Keyname
-----
dbo.t1.c1
billyg.t2.c2
tinnap.t3.c3

Db.Owner.Keyname
-----
keydb1.dbo.sample_key1
keydb.dbo.sample_key1
coldb.dbo.sample_key2
```

Display All Encrypted Columns or Specific Encrypted Column in a Table

Include the helpcol parameter with the <table_name> and <column_name> parameters to display all encrypted columns or a specific encrypted column in a given table. When run by a user with sso_role , the query below displays all encrypted columns in table t3 in the current database and the keys used to encrypt the columns across all available databases. When run by a user without sso_role , this query displays the key's ID instead of its name if the key is not in the current database. The second parameter can have a combination of [<database_name>.] [<table_name>.] [<column_name>]:

Display System Encryption Password Properties for Each Database

Displays the system encryption password properties for each database (you must have sso_role to run this query):

```
sp_encryption helpkey, system_encr_passwd, all_dbs

Database Type of system_encr_passwd Last modified by Date

master persistent sa Aug 26 2008 10:05AM
```

Display All Encryption Keys Encrypted With Master Key in Database

Displays all encryption keys encrypted with the master key in the current database (you must have sso_role, keycustodian_role, or be the database owner to run this query):

```
Owner.Keyname Assignee

user1.key_dual NULL
user1.key_mst NULL
user4.key_dC_pwd NULL
user4.key_dC_pwd user5
user4.key_dC_pwd user6
user4.key_dC_pwd KC_tdb1
```

Display Name and Location of Current Master Key Start-Up File

Displays the name and location of the current master key start-up file configured for the current server:

```
sp_encryption mkey_startup_file
```

```
Msg 19956, Level 16, State 1: Procedure 'sp_encryption', Line 298: The current master key startup file is:'/sybase/release/ASE-150/init/ase_encrcols_mk_l157.dat'.
```

Display Encrypted Stored Procedures

Displays three stored procedures that are encrypted with key syb_syscommkey_123456, and are owned by user1 and user2:

```
sp encryption helpkey, "syb syscommkey%", display objs
                                  Key Owner
Key Name
                                                Database Name
                            Object Name
       Object owner
                                 -----
                                                ______
syb syscommkey 1234567890ab
                                      dbo
                                                     testdb
             user1
                             sp mysproc1
syb syscommkey abcdefghijkl123456
                                     dbo
                                                    testdb
                             sp_mysproc2_
            user1
syb_syscommkey_ABCDEF123456
                                      dbo
                                                     testdb
             user2
                             sp mysproc3
```

Usage

- When a database is fully encrypted, sp_encryption reports a key type called "database encryption key".
- The privileges granted to the user who runs sp_encryption determines the output.
- If you run sp_encryption helpkey and no keys are present in the database, you see an informational message.
- Specify the <key_copy> parameter to get information about key copies. Otherwise, sp_encryption returns information only about base keys.
- If <keyname> is NULL in sp_encryption helpkey, <key_name>, key_copy, lists all the key copies in the current database for a SSO, key custodian, or DBO. If it is run by a user without privileges, it lists all the key copies assigned to the user in the current database and all key copies of the keys owned by the user in the current database.
- For sp encryption helpcol, <column name> uses the form <name>.<name>.<name>, where:
 - o <name> if sp_encryption finds no tables of this name, it looks for all columns of that name.
 - o <name>.<name> is <owner>.. If sp_encryption finds no tables of this name, it looks for a single column named <table.column>.
 - o <name>.<name> is <owner>..<name>.

For all columns identified by these rules in the current database, sp_encryption displays column name along with the key used to encrypt the column.

The output for <code>sp_encryption</code> <code>helpcol</code>, <code><column_name></code> is <code><owner>..<column></code> and <code><db>.<owner>.<keyname></code>. The <code><keyname></code> is expressed as <code><database>.<keyid></code> when run by non-SSO users, and the key is present in a different database from the encrypted column. The result set is sorted by <code><owner>..<column></code>.

The restrictions for sp encryption are:

• Only an SSO can run sp_encryption helpkey [, <keyname> | wildcard], all_dbs to get the properties of keys in all databases. If a user without the sso_role runs this command, they receive an

- "unauthorized user" error message. If no keys qualify the keyname or wildcard, the SAP ASE server returns a message stating 'There are no encryption keys (key copies) like keyname in all databases'.
- When the SSO runs sp_encryption helpkey, <keyname>, <display_cols>, it lists all columns across all available databases encrypted by <key_name>. If it is run by a user without privileges, it lists the columns in the current database encrypted by <key_name>.
 If the SSO runs sp_encryption helpkey, <key_name>, <display_cols> and the <key_name> value is NULL, it displays all encrypted columns across all available databases. When run by a user without privileges, it displays all encrypted columns in the current database.
- If an SSO, key custodian, or DBO runs sp_encryption helpuser, <user_name>, key_copy without specifying a <user_name> and <key_copy> for the helpuser parameter, it lists all the base keys owned by all users in the current database. If sp_encryption is run by a user without privileges without specifying a <user_name> or <key_copy>, it displays the base keys owned by the current user. If any user runs sp_encryption helpuser, <user_name>, it lists all the base keys owned by <owner>.<key_name>. If a user without privileges runs the command and owns no base keys, the SAP ASE server displays an informational message stating this.
 - If an SSO, key custodian, or DBO runs <code>sp_encryption</code> helpuser, <code><user_name></code>, <code><key_copy></code>, it lists the key copies assigned to <code><user_name></code>. If a user without privileges issues this command, its lists the key copies assigned to this user and all the key copies of the keys owned by the user in the current database, with these columns in the result set: <code>Owner.Keyname</code>, <code>Assignee</code>, <code>Type of Password</code>, and <code>Key Recovery</code>. The output is sorted by <code>Assignee</code>.
 - If <user_name> is NULL for sp_encryption helpuser <user_name>, <key_copy>, it lists all the key copies in the current database for a SSO, key custodian, or DBO. For users without privileges, it lists all the key copies assigned to the user in the current database and the key copies for the keys owned by this user.
- When a SSO, key custodian, or DBO runs sp_encryption helpkey, <key_name>, <key_copy>, it
 lists the key copies in the current database for <key_name>. If this is run by a user without privileges, it
 lists the key copies assigned to the user for that <key_name> and the key copies for that <key_name> if
 the user is the key owner.
- The SSO, key custodian, and DBO can run sp_encryption helpkey, <system_encr_passwd>, display_keys to receive information on all keys and key copies in the current database encrypted by system encryption password. Users without privileges receive information about the base encryption keys or key copies they own or are assigned in the current database. Key copies are encrypted with the system encryption password only when they are created for login association. The output is sorted by <owner>.<key name>.

Permissions

The permission checks for sp encryption differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled:

 downgrade_kek_size - You must be a user with manage security configuration privilege.

Setting Description

- help/help_key system_encr_passwd, display_keys You must be a user with manage column encryption key privilege. Any user can see their own key.
- help/help_key system_encr_passwd You must be a user with manage column encryption key privilege.
- help/help_key master key/dual master key, display_keys You must be a user manage master key privilege.
- help/help_key keyname/wild card, display_cols You must be a user with use any database privilege for cross database check. Any user for the current database.
- help/help_key service keyname, display_objs -You must be a user with manage service key privilege.
- help/help_key keyname/wild card, all_dbs You must be a user with the following privilege depending the key type:
 - o column encryption key manage column encryption key
 - o master key manage master key
 - o service key manage service key
- For cross-database checks, one of the above three, and use any database permission.
- help/help_key keyname wildcard You must be a user with the following privilege depending the key type:
 - o column encryption key manage column encryption key
 - o master key manage master key
 - o service key manage service key

For non-privileged users, limited encryption key information is displayed.

- help/help_key keyname wildcard, key_copy You must a user with the following privilege depending on the key type:
 - Column encryption key manage column encryption key
 - Master key manage master key
- helpcol You must be a user with use any database privilege for cross database checks.
- helpextpassword You must be a user with manage service key privilege.
- helpuser username/wildcard, [key_copy/login_passwd_check] You must be a user with manage any encryption key privilege. Non-privilege users can see their own key.
- mkey_startup_file You must be a user with manage security configuration privilege.
- system_encr_passwd You must be a user with manage column encryption key privilege.
- verify_downgrade You must be a user with manage security configuration privilege.

$\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled:} \\ \end{tabular}$

- downgrade_kek_size You must be a user with sso_role or keycustodian_role.
- help/help_key system_encr_passwd, display_keys You must be the database owner, a user with sso_role, or a user with keycustodian_role. Any user can see their own key.

Setting Description

- help/help_key system_encr_passwd You must be the database owner, a user with sso_role, or a user with keycustodian_role.
- help/help_key master key/dual master key, display_keys You must be the database owner, a user with sso_role, or a user with keycustodian_role.
- help/help_key keyname/wild card, display_cols You must be a user with sso_role for cross database check. Any user for the current database.
- help/help_key service keyname, display_objs You must be a user with sso_role or a user with keycustodian_role.
- help/help key keyname/wild card, all dbs You must be a user with sso_role.
- help/help_key keyname wildcard You must be the database owner, a user with sso_role, or a user with keycustodian_role.
- help/help_key keyname wildcard, key_copy You must be the database owner, a user with sso_role, or a user with keycustodian_role.
- For:
 - Non-privileged users displays only key copy information
 - For privileged users displays the encryption key and key_copy information for all users in the database
- helpcol You must be a user with sso_role.
- helpextpassword You must be a user with sso_role.
- helpuser username/wildcard, [key_copy/login_passwd_check] You must be the database owner, a user with sso_role, or a user with keycustodian_role. Non-privilege users can see their own keys.
- mkey startup file You must be a user with sso_role.
- system_encr_passwd You must be a user with sso_role or keycustodian_role.
- verify downgrade You must be a user with sso_role or keycustodian_role.

Auditing

You can enable <code>encryption_key</code> auditing option to audit this procedure. Values in <code>event</code> and <code>extrainfo</code> columns from the <code>sysaudits</code> table are:

Information	Value
Audit option	encryption_key
Event	106
Command or access audited	sp_encryption
Information in extrainfo	• Roles – Current active roles
	Keywords or options:

If password is set the first time:
 ENCR ADMIN system encr passwd password ********

Information

Value

- Previous value NULL
- Current value NULL
- Other information NULL
- Proxy information Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.110 sp_engine

Enables you to bring an engine online or offline. In threaded mode, use alter thread pool to bring engines online.

Syntax

```
sp_engine {"online" | [offline | can_offline][, <engine_id>] |
["shutdown", <engine_id>]}
```

Parameters

"online"

bring an engine online. The value of <code>sp_configure "max online engines"</code> must be greater than the current number of engines online. Use quotes when specifying <code>"online"</code>, as it is a reserved keyword.

In threaded mode, online increases the thread count for $syb_default_pool$ by 1.

offline

bring an engine offline. You can also use the <engine_id> parameter to specify a specific engine to bring offline.

In threaded mode, offline decreases the thread count for syb default pool by 1.

can offline

returns information on whether an engine can be brought offline. can_offline returns the SAP ASE tasks with an affinity to this engine (for example, during Omni or java.net tasks) if its state is online. If you do not specify an <engine_id>, the command describes the status of the engine in sysengines with the highest <engine id>.

In threaded mode, can_offline succeeds only if the total number of engines is less than the total number of threads in <code>syb_default_pool</code> and the total number of threads in <code>syb_default_pool</code> is greater than or equal to 2.

<engine_id>

the ID of the engine. The <engine_id> parameter is optional. If you do not specify an <engine_id>, sp_engine uses the incremented or decremented value for <engine_id> for the value of engine found within sysengines. That is, if your system uses engines 0, 1, 2, and 3, and you do not specify an engine ID, sp_engine takes engine ID 3 offline, then engine ID 2, and so on.

This parameter is ignored in threaded mode.

"shutdown"

Forces an engine offline. If there are any tasks with an affinity to this engine, they are killed after a five-minute wait. Use quotes when specifying "shutdown", as it is a reserved keyword.

Examples

Example 1

Brings engine 1 online. Messages are platform specific (this example uses Sun Solaris):

```
sp_engine "online", 1

02:00000:00000:2001/10/26 08:53:40.61 kernel Network and device connection limit is 3042.
02:00000:00000:2001/10/26 08:53:40.61 kernel SSL Plus security modules loaded successfully.
02:00000:00000:2001/10/26 08:53:40.67 kernel engine 2, os pid 8624 online 02:00000:00000:2001/10/26 08:53:40.67 kernel Enabling Sun Kernel asynchronous disk I/O strategy
00:00000:00000:2001/10/26 08:53:40.70 kernel ncheck: Network fc0330c8 online
```

Example 2

Describes the steps in taking an engine offline that is currently running tasks with an affinity for this engine:

```
engine status
-----
0 online
1 online
2 online
3 online
```

If you bring engine 1 offline:

```
sp_engine offline, 1

The following task(s) will affect the offline process:
spid: 19 has outstanding ct-lib connections.
```

And then run the same query as above, it now shows that engine 1 is in an offline state:

select engine, status from sysengines

```
engine status
-----
0 online
1 in offline
2 online
3 online
```

As soon as the task that has an affinity to engine 1 finishes, the SAP ASE server issues a message similar to the following to the error log:

```
02:00000:00000:2001/10/26 09:02:09.05 kernel engine 1, os pid 8623 offline
```

Example 3

Determines whether engine 1 can be brought offline:

```
sp_engine can_offline, 1
```

Example 4

Takes engine 1 offline:

```
sp_engine offline, 1
```

The SAP ASE server eventually returns a message similar to the following:

```
01:00000:00000:2001/11/09 16:11:11.85 kernel affinitated process(es) before going offline 01:00000:00000:2001/11/09 16:11:11.85 kernel Process 917518 is preventing engine 1 going offline 00:00000:00000:2001/11/09 16:16:01.90 kernel engine 1, os pid 21127 offline
```

Example 5

Shuts down engine 1:

```
sp_engine shutdown, 1
```

Usage

- As sp_engine works only in process mode, the SAP ASE server issues an error message if you run sp_engine in threaded mode. Use alter_thread pool in threaded mode.
- You cannot take offline or shut down engine 0.
- You can determine the status of an engine, and which engines are currently online with the following query:

```
select engine, status from sysengines
where status = "online"
```

• online and shutdown are keywords and must be enclosed in quotes.

- Engines can be brought online only if max online engines is greater than the current number of engines with an online status, and if enough CPU is available to support the additional engine.
- sp engine can run in sessions using chained transaction mode if there are no open transactions.
- An engine offline command may fail or may not immediately take effect if there are server processes with an affinity to that engine.

Permissions

The permission checks for sp engine differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.110.1 Using sp_engine "offline" Versus sp_engine "shutdown"

Sometimes when you use sp_engine "offline", the engine does not immediately go offline, and instead appears to be in "dormant" state in the engine table.

This is caused by processes that are attached to your engine that cannot be migrated to other engines. When this happens, the engine does not take new work, and consumes minimal CPU cycles. When the process preventing the completion of <code>engine offline</code> either ends or becomes available for migration, the engine moves from dormant to fully offline, and disappears from the engine table.

sp_engine "shutdown" is a more aggressive version of the offline command. sp_engine "shutdown" actively kills any processes that are preventing the engine from going offline, forcing it to shut down.

However, if you use sp_engine "shutdown" on an engine that has Client Library or Java connections, you see:

Engine has outstanding ct-lib/java connections and cannot be offlined.

When this happens, repeat the command again every few minutes until the connections are no longer there, and the engine can shut down.

1.111 sp_errorlog

Dynamically changes the path of the error log.

Syntax

```
sp_errorlog "change log", "<new_path>" [,{"jslog true" | "jslog false"}]
sp_errorlog "help", "change log"
```

Parameters

<new_path>

is the new path of the error log. Maximum length of <new path> is 255 characters.

jslog true

(default) if the Job Scheduler is running, sp_errorlog "change log" attempts to change the Job Scheduler Agent log to the directory where the new SAP ASE error log resides. Both logs indicate error messages, if any.

jslog false

specifies to not change the location of the Job Scheduler Agent log.

Examples

Example 1

Changes the SAP ASE error log to use a new location without changing the location of the Job Scheduler log:

```
sp_errorlog "change log",
"$SYBASE_$SYBASE_ASE/install/new.log", "jslog false"
```

The SAP ASE error log location is changed to \$SYBASE_ASE/install/new.log. However, the location of the Job Scheduler Agent log is not changed.

Example 2

Changes the error log location to \$SYBASE/\$SYBASE ASE/install/new.log:

```
sp_errorlog "change log",
"$SYBASE_$SYBASE_ASE/install/new.log", "jslog true"
```

If the Job Scheduler Agent is running, the agent log location is also changed to \$SYBASE_ASE/install/new.log.

If the Job Scheduler Agent is not running, SAP ASE does not change the agent log location. You see a message that the agent log location is unchanged.

Example 3

Changes the SAP ASE error log to \$SYBASE/\$SYBASE ASE/install/new.log:

```
sp_errorlog "change log",
"$SYBASE_$SYBASE_ASE/install/new.log"
```

If the Job Scheduler Agent is running, the agent log is also changed to \$SYBASE_ASE/install/new.log.

If the Job Scheduler Agent is not running, SAP ASE does not change the path of the Job Scheduler Agent log. You see a message that the agent log location is unchanged.

Usage

sp_errorlog returns 0 if the switch to the new location is successful. A non-zero return value implies an error. Use the @@errorlog global variable to view the current error log location.

i Note

To pick up the new location of the error log when the server is restarted, update the -e argument in the runserver file.

See Configuration Guide > Logging Error Messages and Events for information on the runserver file.

Permissions

The permission checks for sp errorlog differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

Information Value

Audit option errorlog

Information Value
Event 127

Command or access audited sp_errorlog

Information in extrainfo

- Roles Current active roles
- Keywords or options NULL
- Previous value NULL
- Current value NULL
- Other information -ERRORLOG ADMIN, all input parameters
- Proxy information Original login name, if set proxy in effect

Example of extrainfo after executing sp errorlog:

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.112 sp_estspace

Estimates the amount of space required for a table and its indexes, and the time needed to create the index.

Syntax

Parameters

```
<table_name>
```

is the name of the table. It must already exist in the current database.

<no_of_rows>

is the estimated number of rows that the table contains.

<fill_factor>

is the index fillfactor. The default is null, which means that the SAP ASE server uses its default fillfactor.

<cols_to_max>

is a comma-separated list of the variable-length columns for which you want to use the maximum length instead of the average. The default is the average declared length of the variable-length columns.

<textbin len>

is the length, per row, of all text and image columns. The default value is 0. You need to provide a value only if the table stores text or image data. text and image columns are stored in a separate set of data pages from the rest of the table's data. The actual table row stores a pointer to the text or image value. sp_estspace provides a separate line of information about the size of the text or image pages for a row.

<iosec>

is the number of disk I/Os per second on this machine. The default is 30 I/Os per second.

<pagesize>

allows you to estimate the space required for a given table — and all of its indexes — if you migrate the table to a server of the specified page size. You can either specify a page size (2048, 4096, 8192, 16384, or 2K, 4K, 8K, 16K) or NULL to use your current page size. If you do not use "K" as a unit specifier, the default for pagesize is bytes. Because page allocation allocates the same size page for various objects, the page size value applies to all page types (index, data, text and so on).

Examples

Example 1

Calculates the space requirements for the titles table and its indexes, and the time required to create the indexes. The number of rows is 10,000, the fillfactor is 50 percent, two variable-length columns are computed using the maximum size for the column, and the disk I/O speed is 25 I/Os per second:

sp_estspace	titles, 10000, 50,	"title, notes",	0, 25		
name	type i	dx_level Pages	Kbyt	ces	
titles titleidind titleidind titleind titleind titleind	data text/image clustered clustered nonclustered nonclustered nonclustered nonclustered	0 0 1	3364 0 21 1 1001 54 4	0 43 2	
name	type	total_pages	time_mins		
	clustered nonclustered data		13 5 2	5	

Example 2

Uses the average length of existing image data in the au_pix table to calculate the size of the table with 1000 rows. You can also provide this size as a constant:

```
declare @i int
select @i = avg(datalength(pic)) from au_pix
exec sp_estspace au_pix, 1000, null, null, 16, @i
```

au_pix has no in name	ndexes type	idx_level	Pages	Kbytes
au_pix au_pix	data text/image	0	31 21000	63 42000
Total_Mbytes41	.08			

Example 3

Calculates the size of the titles table with 50,000 rows, using defaults for all other values:

sp_estspace titles, 50000

name	type	idx_level Page	s K	bytes
titles titleidind titleidind titleind titleind titleind titleind Total_Mbytes	data clustered clustered nonclustered nonclustered nonclustered nonclustered	0 0 1 0 1 2 3	4912 31 1 1390 42 2	9824 61 2 2780 84 4
12	.46	total_pages	time_mins	
name	type			
titleidind	clustered	4943		19
titleind	noncluster	ed 1435		8

Example 4

Runs after adding a clustered index to the blurbs table:

```
declare @i int
select @i = avg(datalength(copy)) from blurbs
exec sp_estspace blurbs, 6, null, null, 16, @i, "16k"
```

name	type	idx_level Pag	es	Kbytes
blurbs blurbs_ind blurbs_ind Total_Mbytes	data text/image clustered clustered	0 0 0 1	8 6 1 1	128 96 16 16
0.25 name	type	total_pages	time_mins	:
blurbs_ind blurbs	clustered data	10 6		0

This example is run on a 2K server, and indicates that the blurbs table would require 0.25 MB after it is migrated to a 16K server. Below is the same query run on a 16K server, which verifies the .25MB space requirement:

```
declare @i int
select @i = avg(datalength(copy)) from blurbs
exec sp_estspace blurbs, 6, null, null, 16, @i, "16k"
```

name	type 	idx_level P	Pages	Kbytes
blurbs blurbs blurbs_ind blurbs_ind Total_Mbytes	data text/image clustered clustered	0 0 0 1	8 6 1 1	128 96 16 16
0.25 name	type 	total_pages	time_min	S
blurbs_ind blurbs	clustered data	10 6		0

Example 5

Estimates that, if the blurbs table had a thousand rows in it on a 2K server, it would require 1.99MB of space:

```
declare @i int
select @i = avg(datalength(copy)) from blurbs
exec sp_estspace blurbs, 1000, null, null, 16, @i, "2k"
```

name	type	idx_level	Pages	Kbytes
blurbs blurbs_ind blurbs_ind Total_Mbytes	data text/image clustered clustered	0 0 0 1	16 1000 1 1	32 2000 2 2
1.99 name	type	total_page	es time_min	s -
blurbs_ind blurbs	clustered data	100		0

Usage

To estimate the amount of space required by a table and its indexes:

- 1. Create the table.
- 2. Create all indexes on the table.
- 3. Run sp_estspace, giving the table name, the estimated number of rows for the table, and the optional arguments, as needed.

For information about tables or columns, use <code>sp_help <tablename></code>.

See also create index, create table in Reference Manual: Commands.

You do not need to insert data into the tables. sp_estspace uses information in the system tables — not the size of the data in the tables — to calculate the size of tables and indexes.

Permissions

Any user can execute $sp_{estspace}$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dboption [page 228] sp_help [page 396]

1.112.1 Estimating the Extra Space Required by a Column

If the auto identity option is set in a database, the SAP ASE server automatically defines a 10-digit IDENTITY column in each new table that is created without specifying a primary key, a unique constraint, or an IDENTITY column. To estimate how much extra space is required by this column:

Procedure

- 1. In the master database, use sp dboption to turn on the auto identity option for the database.
- 2. Create the table.
- 3. Run sp estspace on the table and record the results.
- 4. Drop the table.
- 5. Turn the auto identity option off for the database.
- 6. Re-create the table.
- 7. Re-run sp estspace on the table, and record the results.

1.113 sp_export_qpgroup

Exports all plans for a specified user and abstract plan group to a user table.

Syntax

```
sp_export_qpgroup <usr>, <group>, <tab>
```

Parameters

<usr>

is the name of the user who owns the abstract plans to be exported.

<group>

is the name of the abstract plan group that contains the plans to be exported.

<tab>

is the name of a table into which to copy the plans. It must be a table in the current database. You can specify a database name, but not an owner name, in the form <dbname>..<tablename>. With large identifiers, the total length must be no more than 255 characters.

Examples

Example 1

Creates a table called moveplans containing all the plans for the user "freidak" that are in the ap_stdout group:

```
sp export qpgroup freidak, ap stdout, "tempdb..moveplans"
```

Usage

sp_export_qpgroup copies plans from an abstract plan group to a user table. With sp_import_qpgroup, it can be used to copy abstract plans groups between servers and databases or to assign user IDs to copied plans.

The user table name that you specify cannot exist before you run $sp_export_qpgroup$. The table is created with a structure identical to that of sysqueryplans.

sp_export_qpgroup uses select...into to create the table to store the copied plans. You must use sp_dboption to enable select into/bulkcopy/pllsort in order to use sp_export_qpgroup, or create the table in tempdb.

Permissions

The permission checks for $sp_export_qpgroup$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_import_qpgroup [page 500]

1.114 sp_extendsegment

Extends the range of a segment to another database device.

Syntax

sp_extendsegment <segname>, <dbname>, <devname>

Parameters

<segname>

is the name of the existing segment previously defined with sp addsegment.

<dbname>

is the name of the database on which to extend the segment. <dbname> must be the name of the current database.

<devname>

is the name of the database device to be added to the current database device range already included in <segname>.

Examples

Example 1

Extends the range of the segment indexes for the database pubs 2 on the database device dev 2:

```
sp extendsegment indexes, pubs2, dev2
```

Usage

There are additional considerations when using sp_extendsegment:

• You cannot extend a segment on a device that already has an exclusive segment, and you cannot extend an exclusive segment on a device that has another segment.

For example, if you attempt to extend segment orders_seg on a device orders.dat, which already has an exclusive segment, you see an error message similar to:

```
A segment with a virtually hashed table exists on device orders.dat.
```

If you attempt to extend exclusive segment $orders_seg$ on device $orders_dat$, which has other segments, you see an error message similar to:

```
You cannot extend a segment with a virtually hashed table on device orders.dat, because this device has other segments.
```

- A segment can be extended over several database devices.
- $\bullet \quad \text{You can only execute $\tt sp_extendsegment for the {\tt logsegment system segment in single-user mode}.$
- If the logsegment segment is extended, any other segments on the device are dropped and the device is used for the log segment exclusively.
- When you extend the logsegment segment, the SAP ASE server recalculates its last-chance threshold.
- To associate a segment with a database device, create or alter the database with a reference to that device. A database device can have more than one segment associated with it.

• After defining a segment, you can use it in the create table and create index commands to place the table or index on the segment. If you create a table or index on a particular segment, subsequent data for the table or index is located on that segment.

See also alter database, create index, create table in Reference Manual: Commands.

Permissions

The permission checks for sp extendsegment differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.115 sp_extrapwdchecks

A custom stored procedure that can contain user-defined logic for password complexity checks. You can configure $sp_extrapwdchecks$ according to your security needs. Install $sp_extrapwdchecks$ in the master database.

Syntax

sp extrapwdchecks <caller password>, <new password>, <login name>

Parameters

<caller password>

specifies the current password.

<new_password>

specifies the new password being set.

<login_name>

specifies the login name associated with the password being changed or added.

Usage

• sp_extrapasswordchecks must use raiserror to signal a failure to the SAP ASE server. Use sp_addmessage to add error message for this failure in the SAP ASE server.

i Note

Do not use raiserror to get the expected behavior. raiserror updates the @@error global variable. @@error is also updated each time you execute a T-SQL statement, including print and if. If raiserror is followed by any T-SQL statement, @@error gets overwritten, and sp_extrapwdchecks fails to return an error for a failed password if raiserror is followed by any TSQL statement.

- sp_extrapwdchecks allows NULL values for caller_password and loginame parameters. The caller_password parameter is NULL when:
 - The system security officer creates a new login account using create login command.
 - The system security officer modifies the login account's password using alter login .. modify password command.

The loginame parameter is NULL when the system security officer creates a new login account using the create login command.

Permissions

sp_extrapwdchecks is not executed directly. It is a custom stored procedure and executed by the SAP ASE server internally as part of authentication.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.116 sp_familylock

Reports information about all the locks held by a family (coordinating process and its worker processes) executing a statement in parallel.

Syntax

sp_familylock [<fpid1>[, <fpid2>]]

Parameters

<fpid1>

is the family identifier for a family of worker processes from the master.dbo.sysprocesses table. Run sp_who or sp_lock to get the <spid> of the parent process.

<fpid2>

is the SAP ASE process ID number for another lock.

Examples

Example 1

Displays information about the locks held by all members of the family with an fid of 5:

```
sp familylock 5
                     table id partitionid page dbname
fid spid locktype
class
              context
 5 5 Sh intent
                      176003658
                                         0
                                              0 userdb Non cursor lock Sync-
pt duration request
 5 5 Sh intent-blk 208003772
                                              0 userdb Non cursor lock Sync-
pt duration request
                      208003772
                                         0 3972 userdb Non cursor lock Sync-
    6 Sh page
pt duration request
 5 7 Sh_page
                    208003772
                                         0 3973 userdb Non cursor lock Sync-
pt duration request
                      208003772
 5 8 Sh page
                                         0 3973 userdb Non cursor lock Sync-
pt duration request
```

Example 2

Displays information about partition-level locks:

sp_fa	milylock				
spid	locktype	table_id	partitionid	page	row
0	Ex_partition Sh_partition_intent	576002052 1417053053	576004423 1417053053	0	0

Table lock and fine-grained lock values for partitionid are 0. partitionid is populated only for partition-level locks.

Usage

There are additional considerations when using sp familylock:

- sp_familylock with no parameter reports information on all processes belonging to families that currently hold locks. The report is identical to the output from sp_lock; however, sp_familylock allows you to generate reports based on the family ID, rather than the process ID. It is useful for detecting family deadlocks.
- Use the object name system function to derive a table's name from its ID number.
- The "locktype" column indicates whether the lock is a shared lock ("Sh" prefix), an exclusive lock ("Ex" prefix) or an update lock, and whether the lock is held on a table ("table" or "intent") or on a page ("page"). The "blk" suffix in the "locktype" column indicates that this process is blocking another process that needs to acquire a lock. As soon as this process completes, the other process(es) moves forward. The "demand" suffix indicates that the process is attempting to acquire an exclusive lock.
- The "class" column indicates whether a lock is associated with a cursor. It displays one of the following:
 - o "Non cursor lock" indicates that the lock is not associated with a cursor.

- "Cursor Id <number>" indicates that the lock is associated with the cursor ID number< >for that SAP ASE process ID.
- A cursor name indicates that the lock is associated with the cursor <cursor_name> that is owned by the current user executing sp lock.
- The "fid" column identifies the family (including the coordinating process and its worker processes) to which a lock belongs. Values for "fid" are:
 - A zero value indicates that the task represented by the spid is executed in serial. It is not participating in parallel execution.
 - o A nonzero value indicates that the task (spid) holding the lock is a member of a family of processes (identified by "fid") executing a statement in parallel. If the value is equal to the spid, it indicates that the task is the coordinating process in a family executing a guery in parallel.
- The "context" column identifies the context of the lock. Worker processes in the same family have the same context value. Values for "context" are:
 - "NULL" means that the task holding this lock is either executing a query in serial or is a query being executed in parallel in transaction isolation level 1.
 - "FAM_DUR" means that the task holding the lock holds the lock until the query is complete.
 A lock's context may be "FAM_DUR" if the lock is a table lock held as part of a parallel query, if the lock is held by a worker process at transaction isolation level 3, or if the lock is held by a worker process in a parallel query and must be held for the duration of the transaction.

See also kill, select in Reference Manual: Commands.

Permissions

Any user can execute sp_familylock. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_lock [page 560] sp_who [page 847]

1.117 sp_file_path

Use the sp_file_path procedure to specify directory restrictions when writing output files using the transfer table ... to command.

As of version 16.0 SP02 PL04, the transfer table ... to command is no longer permitted to write an output file to any directory that is writable by the running server. Output files must be written to a specified output directory or to one of its subdirectories. Directory restrictions apply server-wide, and may be amended per-database. Path restriction takes two forms:

- The required file root of all tranfer table ... to output files may be specified using dtu path root. If it is not specified, the default is \$SYBASE/data.
- Certain paths may be noted as forbidden using the file root dtu path forbid.

Syntax

```
sp file path <database>, <attr> [, <path>] [, <option>]
```

Parameters

<database>

is the name of the database in which the procedure is being run. This helps prevent accidental changes.

<attr>

is one of dtu path root or dtu path forbid. This identifies which restriction is being affected.

<path>

is the path name that is the target of <@attr>. This path may contain the environment variables \$SYBASE, \$SYBASE_ASE, \$SYBASE_OCS, which the server will translate at runtime. (Windows note: \$SYBASE, etc., are also recognized.)

<option>

- insert inserts a new restriction.
- delete removes an existing restriction.
- select list restrictions.
- show list restrictions.
- help prints a short help message.

If no option is specified, the default is insert.

Examples

Example 1

Specify a new dtu path root in the master directory:

```
sp_file_path 'master', 'dtu path root', '$SYBASE/data'
```

Example 2

Remove the dtu path root from directory model:

```
sp_file_path 'model', 'dtu path root', NULL, 'delete'
```

Usage

- sp file path must be invoked from within the indicated database.
- Restrictions may be specified in the master database and individual databases, or both.
- A dtu path root specified in the master database applies to every database in that installation. Individual databases can override that by specifying their own dtu path root.
- The list of dtu path forbid directories is cumulative. dtu path forbid paths that are specified in the master database apply to every database in the installation. Individual databases may add to, but not subtract from, the master list.
- Running sp_file_path with @attr = "dtu path root" and @option = "insert" will replace any existing dtu path root in the indicated database.
- You can disable the dtu path root by setting it to * (a single asterisk). However, the dtu path forbid list still applies. SAP recommends disabling the dtu path root only when needed, and only for as long as is necessary. If possible, disable dtu path root for individual databases, not in the master database, so that thedtu path root restriction is still applied to other databases.
- When a transfer table ... to command specifies a relative path name as an output file, the server prefixes it with the current dtu path root. If dtu path root has never been set, or if it is set to *, the server uses \$SYBASE/data.
- Once the full path name is constructed, if it does not begin with the dtu path root, then the transfer is rejected. Similarly, if the path begins with any entry in the dtu path forbid list, the transfer is rejected. The server performs the forbid list check twice: once with the initial output path, and again after resolving any symbolic links in the path.
- The path restrictions apply only to output files using the transfer table ... to command. Any valid input file may be specified for transfer table ... from.

Permissions

The permission checks for sp_file_path differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any database privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

1.118 sp_find_qplan

Finds an abstract plan, given a pattern from the query text or plan text.

Syntax

```
sp_find_qplan <pattern>[, group ]
```

Parameters

<pattern>

is a string to find in the text of the query or abstract plan.

<group>

is the name of the abstract plan group.

Examples

Example 1

Reports on all abstract plans that have the string "from titles" in the query:

Example 2

Finds all plans that include a table scan operator:

```
sp_find_qplan "%t_scan%"
```

Example 3

Uses the range pattern matching to look for strings such as "table1", "table2", and so forth, in plans in the dev plans group:

```
sp_find_qplan "%table[0-9]%", dev_plans
```

Usage

There are additional considerations when using sp_find_qplan :

- Use sp_find_qplan to find an abstract plan that contains a particular string. You can match strings from either the query text or from the abstract plan text.
- For each matching plan, sp find qplan prints the group ID, plan ID, query text and abstract plan text.
- If you include a group name, sp_find_qplan searches for the string in the specified group. If you do not provide a group name, sp_find_plan searches all queries and plans for all groups.
- You must supply the "%" wildcard characters, as shown in the examples, unless you are searching for a string at the start or end of a query or plan. You can use any Transact-SQL pattern matching syntax, such as that shown in Example 3.
- The text of queries in sysqueryplans is broken into 255-byte column values. sp_find_qplan may miss matches that span one of these boundaries, but finds all matches that are less than 127 bytes, even if they span two rows.

Permissions

The permission checks for sp find qplan differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage abstract plans privilege or monitor qp performance privilege.

Setting Description

Any user can execute sp find qplan to find and display report plans that they own.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Any user can execute sp find qplan to find and display report plans that they own.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_help_qpgroup [page 410]
sp_help_qplan [page 412]
```

1.119 sp_fixindex

Repairs corrupt indexes on system tables. It can rebuild a specified index or all indexes on the table. sp fixindex rebuilds the data layer if the target table has a placement or clustered index (it reclaims the unused space in the data layer while working on the placement or clustered index of a system table).

Syntax

```
sp_fixindex <database_name>, <table_name>[, <index_id> | null]
    [, <index_name> | null] [, force_option]
```

Parameters

<dbname>

is the database name

<tabname>

is the table name

<indiex_id>

is the ID of the index you want to fix

<index name>

indicates the index that needs to be processed. If a NULL value is used, the index associated with <index_id> is rebuilt. If <index_id> is also a NULL value, all the indexes in the system table are rebuilt

force_option

forces the SAP ASE server to rebuild the system table index in tempdb. sp_fixindex without the force_option forces the database specified by <database_name> to be in single-user mode, which is not possible for tempdb. Although the force_option allows you to rebuilt system catalogs in tempdb, it should not be used for user databases.

Examples

Example 1

Repairs the clustered index on the sysprocedures table of the pubs2 database:

```
sp_fixindex pubs2, sysprocedures, 1
```

Example 2

Rebuilds the index with an index ID of 2 on testdb..sysprocedures:

```
sp_fixindex 'testdb', 'sysprocedures', 2
```

Example 3

Rebuilds the index csysprocedures in the testdb..sysprocedures system table:

```
sp_fixindex 'testdb', 'sysprocedures', null, 'csysprocedures'
```

Example 4

Rebuilds all available indexes on the sysprocedures table in testab. If the table has clustered or placement index, sp_fixindex reclaims the unused space by removing the garbage present in data pages (that is, it rebuilds the data pages):

```
sp_fixindex 'testdb', 'sysprocedures'
```

Example 5

Rebuilds the index with an with an index ID of 2 on tempdb..sysprocedures:

```
sp_fixindex 'tempdb', 'sysprocedures', 2, null, 1
```

Example 6

Rebuilds the index csysprocedures for the table tempdb..sysprocedures:

```
sp_fixindex 'tempdb', 'sysprocedures', null,
    'sysprocedures', 1
```

Example 7

Rebuilds all indexes on sysprocedures in tempdb:

```
sp fixindex 'tempdb', 'sysprocedures', null, null, 1
```

Usage

Before you run sp_fixindex, make sure your database is in single-user mode, and is reconfigured to allow updates to system tables.

After you run sp fixindex:

- Use the dbcc checktable command to verify that the corrupted index has been fixed
- Disallow updates to system tables using sp configure
- Turn off single-user mode

Do not run sp fixindex on user tables.

You cannot use sp_fixindex against the clustered index on sysindexes. If you do, sp_fixindex returns the following error message:

Cannot re-create index on this table.

For more information on sp_fixindex, see:

- Troubleshooting and Error Message Guide > Encyclopedia of Tasks
- Performance and Tuning Guide: Basics > Indexing for Performance

Permissions

The permission checks for sp fixindex differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.120 sp_flushstats

Flushes statistics from in-memory storage to the systabstats and sysstatistics system tables.

Syntax

sp_flushstats [<objname>]

Parameters

<objname>

is the name of a table.

Examples

Example 1

Flushes statistics for the titles table:

sp_flushstats titles

Usage

There are additional considerations when using sp flushstats:

- When you do not specify a table with the <objname> parameter, sp_flushstats acts at the database level.
- Some statistics in the systabstats table are updated in in-memory storage locations and flushed to systabstats periodically, to reduce overhead and contention on systabstats.
- If you query systabstats using SQL, executing sp_flushstats guarantees that in-memory statistics are flushed to systabstats.
- The optdiag command always flushes in-memory statistics before displaying output.
- The statistics in sysstatistics are changed only by data definition language commands and do not require the use of sp flushstats.
- The in-memory datachange counters are persistently stored in sysstatistics. These are flushed to disk when sp flushstats is executed.

Permissions

The permission checks for <code>sp_flushstats</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with monitor qp performance privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.121 sp_forceonline_db

Provides access to all the pages in a database that were previously marked suspect by recovery.

Syntax

```
sp_forceonline_db <dbname>,
    {"sa_on" | "sa_off" | "all_users"}
```

Parameters

<dbname>

is the name of the database to be brought online.

sa_on

allows only users with the sa_role access to the specified page.

sa_off

revokes access privileges created by a previous invocation of ${\tt sp_forceonline_page}$ with ${\tt sa}$ on.

all users

allows all users access to the specified page.

Examples

Example 1

Allows the system administrator access to all suspect pages in the pubs2 database:

```
sp_forceonline_db pubs2, "sa_on"
```

Example 2

Revokes access to all suspect pages in the pubs2 database from the system administrator. Now, no one can access the suspect pages in pubs2:

```
sp forceonline db pubs2, "sa off"
```

Example 3

Allows all users access to all pages in the pubs2 database:

```
sp forceonline db pubs2, "all users"
```

Usage

There are additional considerations when using <code>sp_forceonline_db</code>:

- A page that is forced online is not necessarily repaired. Corrupt pages can also be forced online. The SAP ASE server does not perform any consistency checks on pages that are forced online.
- sp_forceonline_page with all users cannot be reversed. When pages have been brought online for all users, you cannot take them offline again.
- sp_forceonline_db cannot be used in a transaction.
- To bring only specific offline pages online, use sp_forceonline_page.

Permissions

The permission checks for sp forceonline db differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_forceonline_page [page 385]
sp_listsuspect_db [page 552]
sp_listsuspect_page [page 555]
sp_setsuspect_granularity [page 730]
sp_setsuspect_threshold [page 733]
```

1.122 sp_forceonline_object

Provides access to an index previously marked suspect by recovery.

Syntax

Parameters

```
is the name of the database containing the index to be brought online.

<objname>
    is the name of the table.

<indid>
    is the index ID of the suspect index being brought online.

sa_on
    allows only users with the sa_role to access the specified index.

sa_off
```

revokes access privileges created by a previous invocation of sp_forceonline_object with sa_on.

all users

allows all users to access the specified index.

no print

skips printing a list of other suspect objects after the specified object is brought online.

Examples

Example 1

Allows a system administrator to access the index with indid 3 on the titles table in the pubs2 database:

```
sp_forceonline_object pubs2, titles, 3 , sa_on
```

Example 2

Revokes access to the index from the system administrator. Now, no one has access to this index:

```
sp_forceonline_object pubs2, titles, 3, sa_off
```

Example 3

Allows all users to access the index on the titles table in the pubs2 database:

```
sp forceonline object pubs2, titles, 3, all users
```

Usage

There are additional considerations when using <code>sp_forceonline_object</code>:

- If an index on a data-only-locked table has suspect pages, the entire index is taken offline during recovery.
 Offline indexes are not considered by the query optimizer. Indexes on allpages-locked tables are not taken completely offline during recovery; only individual pages of these indexes are taken offline. Use sp forceonline page to bring these pages online.
- Use sp_listsuspect_object to see a list of databases that are offline.
- To repair a suspect index, use sp_forceonline_object with sa_on access. Then, drop and re-create the index.

i Note

If the index is on systabstats or sysstatistics (the only data-only-locked system tables) call Sybase Technical Support.

• sp_forceonline_object with all_users cannot be reversed. When an index has been brought online for all users, you cannot take it offline again.

- An index that is forced online is not necessarily repaired, as corrupt indexes can be forced online. The SAP ASE server does not perform any consistency checks on indexes that are forced online.
- sp_forceonline_object cannot be used in a transaction.
- sp_forceonline_object works only for databases in which the recovery fault isolation mode is "page." Use sp_setsuspect_granularity to display the recovery fault isolation mode for a database.
- To bring all of a database's offline pages and indexes online in a single command, use sp forceonline db.

For more information on recovery fault isolation, see the System Administration Guide.

Permissions

The permission checks for sp forceonline object differ based on your granular permissions settings.

Setting Description

 $\textbf{Enabled} \quad \text{With granular permissions enabled, you must be the database owner or a user with \verb|own|| database| \\$

privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_listsuspect_object [page 553]
sp_setsuspect_granularity [page 730]

1.123 sp_forceonline_page

Provides access to pages previously marked suspect by recovery.

Syntax

Parameters

<dbname>

is the name of the database containing the pages to be brought online.

<pgid>

is the page identifier of the page being brought online.

sa on

allows only users with the sa_role access to the specified page.

sa_off

revokes access privileges created by a previous invocation of sp_forceonline_page

 $with \; \texttt{sa_on}.$

all users

allows all users access to the specified page.

Examples

Example 1

Allows a system administrator access to page 312 in the pubs2 database:

```
sp_forceonline_page pubs2, 312, "sa_on"
```

Example 2

Revokes access to page 312 in the pubs2 database from the system administrator. Now, no one has access to this page:

```
sp_forceonline_page pubs2, 312, "sa_off"
```

Example 3

Allows all users access to page 312 in the pubs 2 database:

```
sp forceonline page pubs2, 312, "all users"
```

Usage

There are additional considerations when using sp_forceonline_page:

- sp_forceonline_page with all_users cannot be reversed. When pages have been brought online for all users, you cannot take them offline again.
- A page that is forced online is not necessarily repaired. Corrupt pages can also be forced online. The SAP ASE server does not perform any consistency checks on pages that are forced online.
- You cannot use sp forceonline page in a transaction.
- sp_forceonline_page works only for databases in which the recovery fault isolation mode is "page."

 Use sp_setsuspect_granularity to display the recovery fault isolation mode for a database.
- To bring all of a database's offline pages online in a single command, use sp_forceonline_db.

Permissions

The permission checks for sp forceonline page differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner or a user with own database privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_forceonline_db [page 380]

```
sp_listsuspect_page [page 555]
sp_setsuspect_granularity [page 730]
sp_setsuspect_threshold [page 733]
```

1.124 sp_foreignkey

Defines a foreign key on a table or view in the current database.

Syntax

```
sp_foreignkey <tabname>, <pktabname>, <col1>[, <col2>] ...
[, <col8>]
```

Parameters

<tabname>

is the name of the table or view that contains the foreign key to be defined.

<pktabname>

is the name of the table or view that has the primary key to which the foreign key applies. The primary key must already be defined.

<col1>

is the name of the first column that makes up the foreign key. The foreign key must have at least one column and can have a maximum of eight columns.

Examples

Example 1

The primary key of the publishers table is the pub_id column. The titles table also contains a pub_id column, which is a foreign key of publishers:

```
sp_foreignkey titles, publishers, pub_id
```

Example 2

The primary key of the parts table has been defined with sp_primarykey as the partnumber and subpartnumber columns. The orders table contains the columns part and subpart, which make up a foreign key of parts:

sp foreignkey orders, parts, part, subpart

Usage

There are additional considerations when using sp foreignkey:

- sp_foreignkey adds the key to the syskeys table. Keys make explicit a logical relationship that is implicit in your database design.
- sp_foreignkey does not enforce referential integrity constraints; use the foreign key clause of the create table or alter table command to enforce a foreign key relationship.
- The number and order of columns that make up the foreign key must be the same as the number and order of columns that make up the primary key. The datatypes (and lengths) of the primary and foreign keys must agree, but the null types need not agree.
- The installation process runs <code>sp_foreignkey</code> on the appropriate columns of the system tables.
- To display a report on the keys that have been defined, execute sp helpkey.
- You cannot use a Java datatype with sp foreignkey.

See also

alter table, create table, create trigger in Reference Manual: Commands.

Permissions

You must be the owner of the table or view to execute <code>sp_foreignkey</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_helpkey [page 463]
sp_primarykey [page 677]
```

1.125 sp_freedll

Unloads a dynamic link library (DLL) that was previously loaded into XP Server memory to support the execution of an extended stored procedure (ESP).

Syntax

```
sp freedll <dll name>
```

Parameters

<dll_name>

is the file name of the DLL being unloaded from XP Server memory.

Examples

Example 1

Unloads the sqlsrvdll.dll DLL:

```
sp_freedll "sqlsrvdll.dll"
```

Usage

There are additional considerations when using sp_freedll:

- You cannot execute from within a transaction.
- sp freedll cannot free the DLL of a system ESP.
- An alternative to unloading a DLL explicitly, using <code>sp_freedll</code>, is to specify that DLLs always be unloaded after the ESP request that invoked them terminates. To do this, set the <code>esp_unload_dll</code> configuration parameter to 1 or start <code>xpserver</code> with the <code>-u</code> option.

- You cannot use to update an ESP function in a DLL without shutting down XP Server or the SAP ASE server.
- If you use sp_freedll to unload a DLL that is in use, sp_freedll succeeds, causing the ESP currently using the DLL to fail.

Permissions

The permission checks for $sp_freedl1$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any ESP privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addextendedproc [page 37] sp_dropextendedproc [page 297] sp_helpextendedproc [page 448]

1.126 sp_getmessage

Retrieves stored message strings from sysmessages and sysusermessages for print and raiserror statements.

Syntax

```
sp_getmessage <message_num>, <result> output[, <language>]
```

Parameters

<message_num>

is the number of the message to be retrieved.

<result> output

is the variable that receives the returned message text, followed by a space and the keyword output. The variable must have a datatype of char, unichar, nchar, varchar, univarchar, or nvarchar.

<language>

is the language of the message to be retrieved. <language> must be a valid language name in syslanguages table. If you include <language>, the message with the indicated <message_num> and <language> is retrieved. If you do not include <language>, then the message for the default session language, as indicated by the variable @@<language>, is retrieved.

Examples

Example 1

Retrieves message number 20001 from sysusermessages:

```
declare @myvar varchar(200)
exec sp_getmessage 20001, @myvar output
```

Example 2

Retrieves the French language version of message number 20010 from sysusermessages:

```
declare @myvar varchar(200)
exec sp_getmessage 20010, @myvar output, french
```

Usage

Any application can use $sp_getmessage$, and any user can read the messages stored in sysmessages and sysusermessages.

See also

print, raiserror in Reference Manual: Commands.

Permissions

Any user can execute sp_getmessage. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addmessage [page 47]
sp_dropmessage [page 309]
```

1.127 sp_grantlogin

(Windows only) Assigns SAP ASE roles or default permissions to Windows users and groups when Integrated Security mode or Mixed mode (with Named Pipes) is active.

Syntax

```
sp_grantlogin {<login_name> | <group_name>}
    ["<role_list>" | default]
```

Parameters

```
<login_name>
```

is the network login name of the Windows user.

<group_name>

is the Windows group name.

<role_list>

is a list of the SAP ASE roles granted. The role list can include one or more of the following role names: sa_role, sso_role, oper_role. If you specify more than one role, separate the role names with spaces, not commas.

default

specifies that the <login_name> or <group_name> receive default permissions assigned with the grant statement.

Examples

Example 1

Assigns the SAP ASE oper_role to the Windows user "jeanluc":

```
sp grantlogin jeanluc, oper role
```

Example 2

Assigns the default value to the Windows user "valle". User "valle" receives any permissions that were assigned to her via the grant command:

```
sp grantlogin valle
```

Example 3

Assigns the SAP ASE sa_role and sso_role to all members of the Windows administrators group:

```
sp grantlogin Administrators, "sa role sso role"
```

Usage

There are additional considerations when using sp grantlogin:

- You must create the Windows login name or group before assigning roles with sp_grantlogin. See your Windows documentation for details.
- sp_grantlogin is active only when the SAP ASE server is running in Integrated Security mode or Mixed mode when the connection is Named Pipes. If the SAP ASE server is running under Standard mode or Mixed mode with a connection other than Named Pipes, use grant instead.
- If you do not specify a <role list> or default, the procedure automatically assigns the default value.
- The default value does not indicate an SAP ASE role. It specifies that the user or group should receive any permissions that were assigned to it via the grant command.
- Using sp_grantlogin with an existing <login_name> or <group_name> overwrites the user's or group's existing roles.

See also

grant, setuser in Reference Manual: Commands

Permissions

The permission checks for sp grantlogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage roles privilege.

Setting Description

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_revokelogin [page 704]

sp_role [page 706]

1.128 sp_ha_admin

Performs administrative tasks on SAP ASE servers configured with Failover in a high availability system. sp_ha_admin is installed with the installhavss script on UNIX platforms or the insthasv script on Windows.

Syntax

sp_ha_admin [cleansessions | help]

Parameters

cleansessions

removes old entries from syssessions. Old syssessions entries are typically left behind because either the SAP ASE server failed to clean up syssessions during a restart, or because a client failed to connect to the SAP ASE server.

help

displays the syntax for sp_ha_admin.

Examples

Example 1

Removes old entries from syssessions left by a client connection that did not exit correctly:

```
sp_ha_admin cleansessions
(return status = 0)
```

Example 2

Displays the syntax for sp ha admin:

```
sp_ha_admin "help"

sp_ha_admin Usage: sp_ha_admin command [, option1 [, option2]]
sp_ha_admin commands:
sp_ha_admin 'cleansessions'
sp_ha_admin 'help'
(return status = 0)
```

Usage

There are additional considerations when using sp ha admin:

- sp_ha_admin performs administrative tasks on the SAP ASE server that are configured for Failover in a high availability system. sp_ha_admin is not installed using the installmaster script; instead, use the installhavss script that installs and configures for Failover (insthasy on Windows).
- sp_ha_admin returns a 0 if it successfully cleaned up syssessions, and returns a 1 if it encounters an error.
- sp_ha_admin enters a message in the errorlog if it could not remove any entries from syssessions (for example, if it could not get a lock on syssessions).
- To view all the current entries in syssessions, enter:

```
select * from syssessions
```

Permissions

You must be a user with ha_role to execute sp_ha_admin. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.129 sp_help

Reports information about a database object (any object listed in sysobjects) and about system or user-defined datatypes, as well as user-defined functions, computed columns and function-based indexes. Column displays optimistic_index_lock.

Syntax

```
sp_help [<objname> [, terse]]
```

Parameters

<objname>

is the name of any object in sysobjects or any user-defined datatype or system datatype in systypes. You cannot specify database names. <objname> can include tables, views, precomputed result sets, stored procedures, logs, rules, defaults, triggers, referential constraints, encryption keys, predicates, and check constraints, but refers to tables when you enable optimistic_index_lock. Use owner names if the object owner is not the user running the command and is not the database owner.

terse

displays a shortened list of object properties in tabular format. Only valid when the object type is table.

Example 1

Displays a list of objects in sysobjects and displays each object's name, owner, and object type. Also displays a list of each user-defined datatype in systypes, indicating the datatype name, storage type, length, null type, default name, and rule name. Null type is 0 (null values not allowed) or 1 (null values allowed):

```
sp_help
```

Example 2

Displays information about a partitioned publishers table. sp_help also lists any attributes assigned to the specified table and its indexes, giving the attribute's class, name, integer value, character value, and comments:

sp_help publishers

```
Object_Type
                                                                                        Create_date
                                   Owner

1>
```

Displays information about the trigger marytrig owned by user "mary". The quotes are needed, because the period is a special character:

```
Name Owner Object_type

marytrig mary trigger
Data_located_on_segment When_created
not applicable Mar 20 2002 2:03PM
```

Displays information about the money system datatype:

```
Type_name Storage_type Length Prec Scale Nulls Defaul_name

Rule_name Access_Rule_name Identity

money money 8 NULL NULL 1 NULL

NULL 0
```

Example 7

Displays information about the user-defined datatype identype. The report indicates the base type from which the datatype was created, whether it allows nulls, the names of any rules and defaults bound to the datatype, and whether it has the IDENTITY property:

Example 8

Shows a new column, indicating whether optimistic index locking is enabled. 1 indicates that the option is enabled; 0 indicates that it is not:

```
sp_help "mytable"

-----
exp_row_size reserve pagegap fillfactor max_rows_per_page

1 0 0 0 0 0

concurrency_opt_threshold optimistic_index_lock

0 1
```

Example 9

Shows a virtual computed column:

Shows a virtual computed column to a materialized computed column:

Example 11

MATERIĀLIZED

The result set for sp_help <table_name> includes the Decrypt_Default_name column, which indicates the decrypt default name for the column. For example, run the following:

```
create table encr_table(col1 int encrypt decrypt_default 1)
```

When you then run sp help on encr table, it shows the following:

Example 12

Displays the Name, Owner, Object_type, Object_status, and Create_date of the predicate object:

```
grant select on tab1 where col1 = 5 as pred1 to robert
sp_help pred1

Name Owner Object_type Object_status Create_date
_____
pred1 dbo predicate -- none -- Feb 9 2010 12:49PM
```

Example 13

For this precomputed result set:

```
create table numtrips (source int, destination int, count_trip int)
create precomputed result set frequent_trips unique (source, destination)
as
select * from numtrips where count_trip > 100
```

 $\verb|sp_help| | \verb|numtrips| | returns the following: \\$

```
precomputed result set defined
May 11 2012 6:46AM
. . .
```

sp help frequent trips returns:

Example 14

sp help displays execute as ownerexecute as caller in the Object status field as follows:

```
create proc p1 with execute as owner asselect 1gosp_help
p1Name Owner Object_type Object_statuse Create_date

p1 dbo stored procedureexecute as ownerJun 8 2012 10:05AM
(1 row
affected) Column_name Type Length Prec Scale Nulls Not_compressed Default_nam
e
Rule _name Access_Rule_name Computed_Column_object Identity

(return status = 0) Rule_name
```

Example 15

Displays reduced output about the order number table, enabled for in-memory row storage:

```
sp help order_number, terse
Name Owner Object_type Create date
order number dbo user table Jan 13 2016 11:14AM
(1 \text{ row affected})
Column description
number int not null
title char (10) not null
Object does not have any indexes.
No defined keys for this object.
name type partition_type partitions partition_keys
order_number base table roundrobin 1 NULL
partition name partition id compression level pages row count segment
create_date
             ord num 672002394 672002394 none
                             1 0 default Jan
13 2015 11:14AM
Partition Conditions
Avg_pages Max_pages Min_pages Ratio(Max/Avg)
                                                Ratio(Min/Avg)
  1 1.000000 1.000000
```

Alter table t1 to disable row caching and then displays information about t1:

Usage

- For virtually hashed table, sp_help reports:
 - o That a table is virtually hashed with this message:

```
Object is Virtually Hashed
```

 \circ The <code>hash_key_factors</code> for the table with a message using this syntax:

```
<column_1>:<hash_factor_1>,
<column_2>:<hash_factor_2>...,
<max_hash_key>=<max_hash_value>
```

For example:

- sp help looks for an object in the current database only.
- sp help works on temporary tables if you issue it from tempdb.
- Columns with the IDENTITY property have an "Identity" value of 1; others have an "Identity" value of 0. In example 2, there are no IDENTITY columns.
- sp_help lists any indexes on a table, including indexes created by defining unique or primary key constraints in the create table or alter table statements. It also lists any attributes associated with those indexes. However, sp_help does not describe any information about the integrity constraints defined for a table. Use sp_helpconstraint for information about any integrity constraints.
- sp_help displays:
 - The locking scheme, which can be set with create table and changed with alter table
 - The expected row size, which can be set with create table and changed with sp chgattribute
 - o The reserve page gap, which can be set with create table and changed with sp chgattribute
 - The row lock promotion settings, which can be set or changed with sp_setpglockpromote and dropped with sp_droprowlockpromote
 - The recompile factor, which determines when the query plan is recompiled based on the row growth, and is changed with sp_chgattribute
 - The number of plldegree, which is the maximum number of threads the query optimizer can use and can be changed with sp_chgattribute
- sp help includes the report from:
 - sp_helpindex showing the order of the keys used to create the index and the space management properties
 - o sp helpartition showing the partition information of the table
 - o sp helpcomputedcolumn showing the computed column information of the table
- When Component Integration Services is enabled, sp_help displays information on the storage location of remote objects.
- sp_help displays information about encryption keys. When a key name is specified as the parameter to sp_help, the command lists the key's name, owner, object type, and creation date.
- For tables enabled for in-memory row storage, sp_help reports on row caching (even if it is temporarily disabled) and snapshot isolation.
- sp_help <tablename> indicates if a column is encrypted, including the name of the decrypt default on the column, if one exists.
- sp help predicate name> displays information about the predicated privilege.

See also:

- alter table, create table in Reference Manual: Commands
- Java in Adaptive Server Enterprise for more information about SQLJ routines.

Permissions

Any user can execute ${\tt sp_help}$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.129.1 Rules for Finding Objects

 sp_help follows the SAP ASE rules for finding objects:

- If you do not specify an owner name, and you own an object with the specified name, sp_help reports on that object.
- If you do not specify an owner name, and do not own an object of that name, but the database owner does, sp help reports on the database owner's object.
- If neither you nor the database owner owns an object with the specified name, sp_help reports an error condition, even if an object with that name exists in the database for a different owner. Qualify objects that are owned by database users other than yourself and the database owner with the owner's name, as shown in Example 4.
- If both you and the database owner own objects with the specified name, and you want to access the database owner's object, specify the name in the format <dbo>.<objectname>.

1.129.2 Precomputed Result Sets and sp_help

 $\verb|sp_help| \ displays \ information \ about \ precomputed \ result \ set \ objects \ in \ the \ \texttt{Object_type} \ column.$

The SAP ASE server treats precomputed result set objects internally as user tables. When you issue sp_help with a precomputed result set as the objectname, it reports all the relevant details about columns, partitions, keys, indexes, and so on, similar to when you run sp_help against a user table.

Additionally, the Object Status column returns the following for precomputed result sets:

• For user tables – returns precomputed result set defined in the Object_Status column if any precomputed result set objects are defined on the user table

- For precomputed result set objects returns the following in the Object Status column for:
 - 1. The refresh mode immediate or manual
 - 2. The precomputed result set state enabled or disabled
 - 3. The query rewrite state enable for QRW or disabled for QRW

1.130 sp_help_resource_limit

Reports on resource limits.

Syntax

Parameters

<name>

is the SAP ASE login to which the limits apply. For information about limits that govern a particular login, specify the login <name>. For information about limits without regard to login, specify null.

i Note

If you are not a system administrator, specify your own login, or a login of NULL, to display information about the resource limits that apply to you.

<appname>

is the name of the application to which the limit applies. For information about limits that govern a particular application, specify the application name that the client program passes to the SAP ASE server in the login packet. For information about limits without regard to application, specify null.

dimittime>

is the time during which the limit is enforced. For information about limits in effect at a given time, specify the time, with a value between "00:00" and "23:59", using the following form:

```
"<HH>:<MM>"
```

For information about limits without regard to time, specify null.

<limitday>

is any day on which the limit is enforced. For information about resource limits in effect on a given day of the week, specify the full weekday name for the default server language, as stored in the syslanguages system table of the master database. For information about limits without regard to the days on which they are enforced, specify null.

<scope>

is the scope of the limit. Specify one of the following:

- 1 for help on all limits that govern queries
- 2 for help on all limits that govern query batches (one or more SQL statements sent by the client to the server)
- 4 for help on all limits that govern transactions
- 6 for help on all limits that govern both query batches and transactions
- NULL for help on all limits that govern the specified <name>, <appname>, timittime>, <limitday>, and <action>, without regard to their <scope>

<action>

is the action to take when the limit is exceeded. Specify one of the following:

- 1 for help on all limits that issue a warning
- 2 for help on all limits that abort the guery batch
- 3 for help on all limits that abort the transaction
- 4 for help on all limits that kill the session
- NULL for help on all limits that govern the specified <name>, <appname>, < limittime>, limittime>, scope>, without regard to the < action> they take

verbose

when used, the output is displayed in the verbose mode, with value 1 or 0 (zero).

Examples

Example 1

Lists all resource limits stored in the sysresourcelimits system table:

```
sp help resource limit
```

Example 2

Lists all limits for the user "joe_user":

```
sp_help_resource_limit joe_user
```

Example 3

Lists all limits for the application <my app>:

```
sp help resource limit NULL, my app
```

Lists all limits enforced at 9:00 a.m.:

```
sp_help_resource_limit NULL, NULL, "09:00"
```

Example 5

An alternative way of listing the limits enforced at 9:00 a.m.:

```
sp_help_resource_limit @limittype = "09:00"
```

Example 6

Lists all limits enforced on Mondays:

```
sp_help_resource_limit NULL, NULL, NULL, Monday
```

Example 7

Lists any limit in effect for "joe_user" on Mondays at 9:00 a.m.

```
sp_help_resource_limit joe_user, NULL, "09:00", Monday
```

Example 8

To list all limits in verbose mode:

```
sp_help_resource_limit null, null, null, null, null, null, 1
```

Example 9

To list all resource limits in verbose mode:

```
sp_help_resource_limit @verbose=1
```

Usage

sp_help_resource_limit reports on all resource limits, limits for a given login or application, limits in effect at a given time or day of the week, or limits with a given scope or action.

See the System Administration Guide for more information on resource limits.

Permissions

The permission checks for sp help resource limit differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage resource limit privilege. Any user can execute sp_help_resource_limit to list their own resource limits.

Setting Description

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be a user with sa_role. Any user can execute}$ sp_help_resource_limit to list their own resource limits.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_add_resource_limit [page 18]
sp_drop_resource_limit [page 287]
sp_modify_resource_limit [page 587]
```

1.131 sp_help_qpgroup

Reports information on an abstract plan group.

Syntax

```
sp help qpgroup [ <group>[, <mode> ]]
```

Parameters

<group>

is the name of an abstract plan group.

<mode>

is the type of report to print, and is one of the following:

• full – returns the number of rows and number of plans in the group, the number of plans that use two or more rows, the number of rows and plan IDs for the longest plans, and number of hash keys and hash key collision information. This is the default report mode.

- stats returns all of the information from the "full" report, except hash key information.
- hash returns the number of rows and number of abstract plans in the group, the number of hash keys, and hash-key collision information.
- list returns the number of rows and number of abstract plans in the group, and the following information for each query/plan pair: hash key, plan ID, first few characters of the query, and the first few characters of the plan.
- queries returns the number of rows and number of abstract plans in the group, and the following information for each query: hash key, plan ID, first few characters of the query.
- plans returns the number of rows and number of abstract plans in the group, and the following information for each plan: hash key, plan ID, first few characters of the plan.
- counts returns the number of rows and number of abstract plans in the group, and the following information for each plan: number of rows, number of characters, hash key, plan ID, first few characters of the query.

Example 1

Reports summary information about all abstract plan groups in the database:

Example 2

Reports on the test plans group:

Usage

When used with an abstract plan group name, and no mode parameter, the default mode for $sp_help_qpgroup$ is full.

Hash-key collisions indicate that more than one plan for a particular user has the same hash-key value. When there are hash key collisions, the query text of each query with the matching hash key must be compared to the user's query text in order to identify the matching query, so performance is slightly degraded.

Permissions

The permission checks for sp help qpgroup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role. Any user can execute sp_help_qpgroup for their own abstract plan group.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_help_qplan [page 412]

1.132 sp_help_qplan

Reports information about an abstract plan.

Syntax

sp help qplan <id>[, <mode>]

Parameters

<id>>

is the ID of the abstract plan.

<mode>

is the type of report to print, one of the following:

- full returns the plan ID, group ID, and hash key, and the full query and plan text.
- brief returns the same as full, but only prints about 80 characters of the query and plan, rather than the full query and plan. This is the default mode.
- list returns the hash key, ID, and first 20 characters of the query and plan.

If you do not supply a value for the mode parameter, the default is brief.

Examples

Example 1

Prints the brief abstract plan report:

Example 2

Prints the full abstract plan report:

```
sp_help_qplan 784005824, full
```

Permissions

The permission checks for sp_help_qplan differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

All users can execute sp_help_qplan for their own abstract plan.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role. Any

user can execute sp help qplan for their own abstract plan.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_find_qplan [page 374]
sp_help_qpgroup [page 410]

1.133 sp_helpapptrace

Determines which sessions the SAP ASE server is tracing. Returns the server process IDs (spids) for all the sessions the SAP ASE server is tracing, the spids of the sessions tracing them, and the name of the tracefile.

Syntax

sp_helpapptrace

Examples

Example 1

Determines which sessions the SAP ASE server is tracing:

sp_helpapptrace

traced_spid tracer_spid trace_file

11 13	exited 14	<pre>/tmp/myfile1 /tpcc/sybase.15_0/myfile2</pre>

Usage

sp helpapptrace returns these columns:

- traced_spid spid of the session you are tracing.
- tracer_spid spid of the session that traced_spid is tracing. Prints "exited" if the tracer_spid session has exited.
- trace file full path to the tracefile.

If a session is tracing another session, but quits without disabling the tracing, the SAP ASE server allows a new session to rebind with the earlier trace. This means that a sa or sso is not required to finish every trace they start, but can start a trace session, quit, and then rebind to this trace session

Permissions

The permission checks for sp_helpapptrace differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage server privilege.
Disabled	With granular permissions disabled, you must be a user with sa_role or sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.134 sp_helpartition

Lists partition-related information of a table or index.

Syntax

```
sp_helpartition [ <table_name> [, { null | <indexname> | "all" }[,
<partitionname> ][, "terse" | "help" ] ] ]
```

Parameters

```
<table_name>
```

is the name of a table in the current database.

null

specifies that information about base table partitions is to be listed.

<indexname>

is the name of an index in the current table. Information about this index displays.

"all"

specifies that all index partition information is to be listed.

<partitionname>

is the name of the partition in the base table or index.

"terse"

sp_help displays a reduced output, including:

- Number of partitions
- Partition type
- Partition keys

"help"

Displays usage information for sp_helpartition.

Examples

Example 1

Returns summary and detailed information about the data partitions in the titles table.

```
sp_helpartition titles
go
```

Returns summary partition information about the titles table and detailed information about the smallsales data partition.

```
name type partition_type partitions partition_keys

titles base table range 5 total_sales
(1 row affected)
partition_name partition_id pages row_count segment create_date

smallsales 1440005130 1 5 titleseg1 Sep 26 2005 5:44PM
Partition_Conditions

VALUES <= (1000)
(return status = 0)
```

Example 3

First, creates the nonclustered index ncidx_local on the my_titles table, then returns summary partition information about my titles and detailed information on the partition ncip4 on ncidx local:

```
name type partition_type partitions partition_keys

ncidx_local local index range 5 total_sales
(1 row affected)
partition_name partition_id pages row_count segment create_date

ncip4 1584005643 1 8 default Sep 26 2005 6:06PM
Partition_Conditions

VALUES <= (10000)
```

```
(return status = 0)
```

Displays terse output for syspartition partitions:

```
partition_type : roundrobin
no_of_partitions : 1
partition_keys : NULL
(return status = 0)
```

Example 5

Displays partition information about all objects:

```
sp_helpartition null, null, "help"
```

Usage

- sp_helpartition lists partition related information at the table, index, and partition level. The table- or index-level partition information includes index type (whether it is a local or global index), partition type, number of partitions, and partition keys, if applicable. For each partition, the information include partition name, ID, number of pages, segment name, create date, and the partition condition if applicable. The summary information displays the number of pages per partition, the minimum and maximum number of pages, and the ratio between the average number of pages and the maximum or minimum number.
- If you do not supply a table name, sp_helpartition lists the owner, table name, number of partitions, and the partition type of all user tables in the current database.
- If you specify:
 - o "all" instead of an index name or null sp_helpartition lists the table- and index-level partition information for each index of the specified table and of the base table.
 - A particular index sp_helpartition lists the index-level information for that index. If the partition name is:
 - Not specified sp_helpartition displays the partition-level information for all partitions in the index, and summary information for the partitions.
 - $\circ \quad \text{Specified} \texttt{sp_helpartition} \ displays \ only \ the \ partition-level \ information \ for \ that \ partition.$
 - Only the table name sp_helpartition displays table-level index partition information for the base table and partition-level information for all partitions in the base table.
 - Null instead of an index name, and a partition name is specified sp_helpartition displays table-level partition information for the base table and partition-level information for the named partition—with no summary information.
- Partitions are created using create table, alter table, and select into. See these commands for more information about partitioning.
- Use sp_helpsegment to display the number of used and free pages on the segment on which the partition is stored.

See also alter table, create table, select into in Reference Manual: Commands.

Permissions

Any user can execute $sp_helpartition$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpsegment [page 479]
sp_statistics [page 881]

1.134.1 Determine the Accuracy of Results

The values reported in the "pages" column may differ from the actual values. To determine whether the count is inaccurate, run $sp_statistics$ and $sp_helpartition$ to compare the data page count. The count provided by $sp_statistics$ is always accurate.

Procedure

- 1. If the page count reported by sp_statistics differs from the sum of the partition pages reported by sp_helpartition by more than 5 percent, run one of these commands to update the partition statistics:
 - O dbcc checkdb
 - O dbcc checktable
 - o update all statistics
 - o update table statistics
- 2. Re-run sp helpartition for an accurate report.

Related Information

sp_statistics [page 881]

1.135 sp_helpcache

Displays information about the objects that are bound to a data cache, the amount of overhead required for a specified cache size, and total memory allocated for the in-memory row storage cache.

Syntax

Parameters

```
<cache_name>
```

is the name of an existing data cache.

<cache_size>

specifies the size of the cache, specified by $\mathbb P$ for pages, $\mathbb K$ for kilobytes, $\mathbb M$ for megabytes, or $\mathbb G$ for gigabytes. The default is $\mathbb K$.

<instance_name>

is the name of the instance with a cache that you are investigating.

Examples

Example 1

Displays information about items bound to pub cache:

```
sp helpcache pub cache
```

Example 2

Shows the amount of overhead required to create an 80MB data cache:

```
sp_helpcache "80M"
```

Example 3

Displays information about all caches and all items bound to them:

```
sp_helpcache
```

(Cluster Edition) displays the overhead for the cache C2 on instance "blade1" for size 10M:

```
sp_helpcache 'C2', '10M', 'instance blade1'
```

Example 5

Displays output for different types of caches:

```
sp helpcache
                         Config Size Run Size Overhead Cache Type
Cache Name
Cache Name Config Size Run Size Overhead Cache Type

                     imrsdb 1024.00 Mb 257.00 Mb 767.00 Mb
```

Example 6

Displays information about the IMRS cache, which is not bound to a database:

```
sp_helpcache imrs_cache1
Cache Name Config Size Run Size Overhead Cache Type
-----imrs_cache1 1024.00 Mb 1024.00 Mb 1.99 Mb Row Storage
```

Example 7

Displays information about the IMRS cache, which is bound to a data-row cache database:

Usage

There are additional considerations when using sp helpcache:

- To see the size, status, and I/O size of all data caches on the server, use sp cacheconfig.
- When you configure data caches with sp_cacheconfig, all the memory that you specify is made available
 to the data cache. Overhead for managing the cache is taken from the default data cache. The
 sp_helpcache displays the amount of memory required for a cache of the specified size.
- (Cluster Edition) If you do not specify an <instance_name>, sp_helpcache displays information for all caches
- To bind objects to a cache, use sp_bindcache. To unbind a specific object from a cache, use sp unbindcache. To unbind all objects that are bound to a specific cache, use sp unbindcache all.
- The procedure <code>sp_cacheconfig</code> configures data caches. The procedure <code>sp_poolconfig</code> configures memory pools within data caches.
- sp helpcache computes overhead accurately up to 74 GB.
- Although you can still use sp_bindcache on a system tempdb, the binding of the system tempdb is now non-dynamic. Until you restart the server, the changes do not take effect, and sp_helpcache reports a status of "P" for pending, unless you have explicitly bound the system tempdb to the default data cache, in which case the status as "V" for valid, because by default the system tempdb is already bound to the default datacache.

Permissions

Any user can execute <code>sp_helpcache</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_unbindcache_all [page 821]
```

1.136 sp_helpcomputedcolumn

Reports information on the computed columns in a specified table.

Syntax

```
sp_helpcomputedcolumn {<tabname>}
```

Parameters

<tabname>

names the table that contains computed columns.

Examples

Example 1

This example reports the computed columns in the mytitles table:

Permissions

Any user can execute <code>sp_helpcomputedcolumn</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.137 sp_helpconfig

Reports help information on configuration parameters.

Syntax

```
sp_helpconfig "<config_name>"
    [, { "<size>" | "estimate [using <argument> = <value> [, <argument> = <value> ] [, ...] ] } ]
```

Parameters

<config_name>

is the configuration parameter being queried, or a non-unique parameter fragment.

<size>

is the size of memory, specified by B (bytes), K (kilobytes), M (megabytes), G (gigabytes), or P (pages). If you do not include a size, the $\langle \text{size} \rangle$ parameter specifies the number of the entity being configured using this parameter (for example, locks, open indexes, and so on). $\langle \text{size} \rangle$ is ignored if $\langle \text{config_name} \rangle$ is not a unique parameter name.

estimate

recommends a value to which you can set the compression info pool size or HCB index memory pool size configuration parameters. This is based on the settings of other configuration parameters, or user-specified values that override those settings. The estimate parameter is only valid for the compression info pool size and HCB index memory pool size configuration parameters. See Estimating Memory Requirements for compression info pool size [page 429].

using <argument>

(Only used with the compression info pool size and HCB index memory pool size configuration parameters) provides additional arguments for the estimate parameter, allowing it to override default values:

- For the compression info pool size configuration parameter, the using parameter includes these arguments:
 - maxconcusers maximum number of concurrent users that can run statements, each requesting memory from the compression information pool.
 - numtables average number of compressed tables referenced in a statement.
 - numcolumns average number of compressed columns from each compressed table in a statement
 - numcompobjs number of compressed objects, from all databases, that can be cached in the metadata cache.
 - numcompindexes number of compressed indexes in all databases.
 - o numindexkeys average number of keys from each compressed index.
- For the HCB index memory pool size configuration parameter, the using parameter includes these arguments
 - o dbname specifies the name of the database that uses index hash caching.
 - o numdatarows average number of data rows in a table.
 - o numindexes total number of indexes to use index hash caching.
 - o numptns per idx number of index partitions per index.
 - o percentage percentage of data rows to be cached.
 - o numhashbuckets hash table bucket count used by each index.

Example 1

Returns a report on all configuration options that start with "allow":

```
sp helpconfig "allow"
Configuration option is not unique.
               config_value run_value
option name
allow sql server async i/o
                                         1
                                                    1
allow remote access
                                         1
                                                    1
allow sendmsq
allow updates to system tables
                                        0
                                                    0
 allow nested triggers
                                                    1
allow resource limits
                                                    0
                                        0
allow statement rollback
                                        0
                                                    0
allow memory grow at startup
allow procedure grouping
                                                    1
                                         1
allow backward scans
```

Example 2

Returns a report on how much memory is needed to create a metadata cache for 421 object descriptors:

```
sp_helpconfig "open objects", "421"

number of open objects sets the maximum number of database objects that are open at one time on SQL Server. The default run value is 500.
```

Minimum Value	Maximum Value	Default Value	Current Value	Memory Used
100	2147483647	500	500	243
Configuration	parameter, 'num'	ber of open obje	ects', will cons	sume 207K of
memory if conf	figured at 421.			

Returns a report on how many database descriptors would fill a 1 MB database cache:

```
number of open databases sets the maximum number of databases that can be open at one time on SQL Server. The default run value is 12.

Minimum Value Maximum Value Default Value Current Value Memory Used

5 2147483647 12 12 433

Configuration parameter, 'number of open databases', can be configured to 28 to fit in 1M of memory.
```

Example 4

Returns a report on how many locks use 512K of memory:

```
number of locks sets the number of available locks. The default run value is 5000.

Minimum Value Maximum Value Default Value Current Value Memory Used

1000 2147483647 5000 5000 528

Configuration parameter 'number of locks', can be configured to 4848 to fit in 512K of memory.
```

Example 5

Returns a report on the status of the allow updates to system tables configuration parameter:

```
sp_helpconfig "allow updates to system tables"

allow updates to system tables allows system tables to be updated directly. The default is 0 (off).

Minimum Value Maximum Value Default Value Current Value Memory Used

0 1 0 0
```

Example 8

Displays information about the enable in-memory row storage configuration parameter:

Returns a report on space usage for the HCB index memory pool size for the big_db database if it used 200000 data rows, 40 indexes, 2 indexes per partition, caches 20% of the rows, and 500000 hash buckets:

```
sp_helpconfig 'HCB index memory pool size', 'estimate USING dbname = big db,
numdatarows = 200000, numindexes = 40,
numptns_per_idx = 2, percentage = 20, numhashbuckets = 500000'
The HCB index memory pool size parameter indicates the total amount of memory
to store index hash caching information.
Minimum Value Maximum Value Default Value Current Value Memory Used
Unit
                  Type
             0
                     2147483647
                                            4096
memory pages (2k) dynamic
Suppose 200000 data rows per table, accessing 40 hash caching enabled
index(es) which have 2 index partition(s) per index
and 20 percentage(s) of data rows to cache, and each hash table has 500000
bucket(s).
Estimated memory required is 412568 KB!
Configuration parameter, 'HCB index memory pool size', can be configured to 206284 to fit in 412568 KB of memory.
(return status = 0)
```

Usage

• sp_helpconfig reports help information on configuration parameters, such as how much memory would be needed if the parameter were set to a certain value. sp_helpconfig also displays the current setting, the amount of memory used for that setting, the default value, and the minimum and maximum settings.

i Note

The "maximum value" setting refers to the largest number that the parameter's data type can accept, rather than to an actual configurable value.

In many cases, the maximum allowable values for configuration parameters are extremely high. The maximum value for your server is usually limited by available memory and other resources, rather than by configuration parameter limitations.

- Issue sp_helpconfig "cluster options" to display cluster-wide configuration parameters.
- If the set system view option is set to:
 - o cluster sp helpconfig displays configuration information for all instances in the cluster.
 - o instance sp_helpconfig displays configuration information for the current instance.
- If you use a nonunique parameter fragment for <configname>, sp_helpconfig returns a list of matching parameters with their configured values and current values. See Example 1.
- sp_helpconfig accepts static, dynamic, and read-only options.
- sp_helpconfig 'restricted decrypt permission' returns the following display:

```
sp_helpconfig 'restricted decrypt permission'

0 - restricted decrypt permission disabled (default).
1 - restricted decrypt permission enabled
```

```
Minimum Value Maximum Value Default Value Current Value

Memory Used Unit Type

------
0 1 0 0

switch dynamic
```

Permissions

Any user can execute sp helpconfig except the following, which requires sybase_ts_role:

- number of ccbs
- caps per ccb
- average cap size

Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_configure [page 203]
sp_countmetadata [page 215]
sp_monitorconfig [page 611]
```

1.137.1 Planning Metadata Cache Configuration

Use ${\tt sp_helpconfig}$ when you are planning a metadata cache configuration for a server.

For example, suppose you were planning to move a database that contained 2000 user indexes to a different server. To find how much memory you would need to configure for that server so that it would accommodate the database's user indexes, enter the following command:

```
sp_helpconfig "open indexes", "2000"

number of open indexes sets the maximum number of indexes that can be open at one time on SQL Server. The default run value is 500.

Minimum Value Maximum Value Default Value Current Value Memory Used
```

```
100 2147483647 500 500 208

Configuration parameter, 'number of open indexes', will consume 829k of memory if configured at 2000.
```

Alternatively, suppose you had 1MB of memory available for the index cache, and you needed to know how many index descriptors it would support. Run the following command:

```
number of open indexes sets the maximum number of indexes that can be open at one time on SQL Server. The default run value is 500.

Minimum Value Maximum Value Default Value Current Value Memory Used

100 2147483647 500 500 208

Configuration parameter 'number of open indexes', can be configured to 2461 to fit in 1M of memory.
```

Based on this output, if you have 1MB of memory, you can create an index descriptor cache that can contain a maximum of 2461 index descriptors. To create this cache, set the number of open indexes configuration parameter as follows:

```
sp_configure "number of open indexes", 2461
```

1.137.2 Estimating Memory Requirements for compression info pool size

Use the <code>estimate</code> parameter to determine the approximate amount of memory required for the <code>compression</code> info pool <code>size</code> configuration parameter.

The estimate parameter recommends a value to which you can set compression info pool size. This recommendation is based on the settings of other configuration parameters, or user-specified values that override those settings.

```
sp_helpcofig "config_name"
   [, { "size" | "estimate [<using_argument> = <value>[, <using_argument> = <value>] [, ...] ] } ]
```

<using_argument>= <value> provides these additional arguments for the estimate parameter to override
default values:

- maxconcusers = <value> specifies the maximum number of concurrent users, as an integer, that can access compressed tables.
 - For example, maxconcusers = 0.7 indicates 70 percent of the configured value for number of user connections. An integer value of 1 or greater specifies an absolute number of concurrent users.
- numcolumns = <value> specifies the average number of columns in a compressed table.
- numcompobjs = <value> specifies the default number of open objects as an integer, or as a percentage, that require memory for compression metadata. For example, numcompobjs = 0.2 indicates that 20 percent of the configured value for number of open objects. An integer value of 1 or greater specifies an absolute number of open objects.
- numtables = <value> determines the average number of compressed tables accessed in a statement.

Issuing sp_helpconfig without arguments generates usage information, showing the subclauses you may specify, and some examples of typical usage.

This example shows the <code>sp_helpconfig</code> ... estimate parameter run from a system database (such as <code>master</code> or <code>tempdb</code>). In this example, <code>sp_helpconfig</code> performs the estimate using default values for factors that affect the required memory:

```
sp_helpconfig 'compression info pool', 'estimate'
The compression information pool size parameter indicates the
amount of memory currently available to store table compression
information.
Minimum Value Maximum Value Default Value Current Value Memory Used
Unit.
                  Type
                 2147483647
0
                                 4096
                                                     4096
                                                                       8240
                                                                                   memory
pages(2k) dynamic
Estimated memory required for 600 concurrent users requesting
memory from this pool, accessing 500 compressed objects with
50 columns, on an average, per compressed table is 22600 KB. Configuration parameter, 'compression info pool size', can be configured to 21971 to fit in 44200K of memory.
```

This example overrides the defaults with site-specific parameters to estimate the memory and configuration value setting. sp_helpconfig is executed a second time from a system database (such as master or tempdb) to estimate the memory required for server-wide concurrent access to compressed objects, when these objects are accessed from multiple databases in the server:

```
sp_helpconfig 'compression info pool', 'estimate
using numcompobjs=0.3, numtables=2.25, numcolumns=25,
maxconcusers=0.85'
The compression information pool size parameter indicates the
amount of memory currently available to store table compression
information.
Minimum Value Maximum Value Default Value Current Value Memory Used
_____
0 2147483647 4096
                                             4096
                                                            8240
                                                                       memory
pages (2k) dynamic
Estimated memory required for 1020 concurrent users requesting
memory from this pool, accessing 150 compressed objects with 25
columns, on an average,
per compressed table is 37020 KB.
Configuration parameter, 'compression info pool size', can be
configured to 18402 to fit in 37020K of memory.
```

This example shows sp_helpconfig ... estimate run against a user database with numerous compressed tables, which are used frequently by an application. The server is configured as:

```
sp_configure 'user connections', 900
sp_configure 'worker processes', 500
sp_configure 'max parallel degree', 5
```

In this example, estimate gathers metrics from the user database from which you issue the procedure for:

- The number of compressed objects
- The average number of columns in these compressed objects

Using these input values, <code>sp_helpconfig</code> estimates the memory required for <code>compression</code> info <code>pool</code> to store table compression information:

```
sp_helpconfig 'compression info pool size', 'estimate'
The compression information pool size parameter indicates
the amount of memory currently available to store table
compression information.
Minimum Value Maximum Value Default Value Current Value Memory Used
     Unit.
Ω
            2147483647 4096
                                     15396
                                                  33384
                                                            memory
pages (2k) dynamic
Estimated memory required for 1400 concurrent users requesting
memory from this pool, accessing 78240 compressed objects
with 10 columns, on an average, per compressed table is 74850 KB.
Configuration parameter, 'compression info pool size', can be
configured to 34519 to fit in 74850K of memory.
```

This output indicates that a total of 1400 concurrent users are expected to simultaneously request memory. The database has slightly more than 78000 compressed objects, with each table having, on average, 10 columns. The estimated value for this configuration option is 34519.

However, if not all the objects are routinely accessed simultaneously, and not all the configured user connections are simultaneously active, you can refine the estimates by providing site-specific overrides with the using parameter subclause:

```
sp helpconfig 'compression info pool size', 'estimate
using numcompobjs = 50000, maxconcusers=600'
The compression information pool size parameter indicates
the amount of memory currently available to store table
compression information.
Minimum Value Maximum Value Default Value Current Value Memory Used

                                                           33384
                                                                        memorv
pages(2k) dynamic
Estimated memory required for 1100 concurrent users requesting
memory from this pool, accessing 50000 compressed objects with
10 columns, on an average, per compressed table is 55225 KB. Configuration parameter, 'compression info pool size', can be
configured to 25468 to fit in 55225K of memory.
```

In this output, maxconcusers = 600 implies that 600 concurrent client connections are accessing compressed objects requesting memory. Because of the parallel configuration settings, sp_helpconfig estimates that a total of 1100 requesters may concurrently request memory. The estimated value for this configuration option is 25468.

1.137.3 Estimating Memory Requirements for HCB index memory pool size

Use the estimate parameter to determine the approximate amount of memory required for the HCB index memory pool size configuration parameter.

The estimate parameter recommends a value to which you can set HCB index memory pool size. This recommendation is based on the settings of other configuration parameters, or user-specified values that override those settings. The syntax is:

```
sp_helpcofig "config_name"
   [, { "size" | "estimate [<using_argument> = <value>[, <using_argument> = <value> ] [, ...] ] } ]
```

The using <argument>= <value> parameter provides these additional arguments to override default values:

dbname = <value> - specifies the name of the database that uses index hash caching. For example, issuing dbname = tdb1 indicates that you are scanning database tdb1 to estimate the HCB index memory pool size.

i Note

You cannot specify system, temporary, proxy, and archive databases with the estimate parameter.

sp_helpconfig does not perform an estimate if you include dbname without the numindexes parameter if the database does not include an unique index.

- numdatarows = <value> specifies the average number of data rows in a table. The default value is 100.000.
- numindexes = <value> specifies the total number of indexes to use index hash caching. The maximum is the value of number of open indexes. If you do not specify a value, SAP ASE uses an internally generated value.

i Note

sp_helpconfig provides the most accurate estimates if you include the numdatarows and numindexes arguments.

- numptns per idx = <value> specifies the number of index partitions per index. The default value is 1.
- percentage = <value> specifies the percentage of data rows to be cached. The default value is 50, with a range from 1 100.
- numhashbuckets = <value> specifies the hash table bucket count used by each index.

Issuing $sp_helpconfig$ without arguments generates usage information, showing the subclauses you may specify, and some examples of typical usage.

In this example, <code>sp_helpconfig</code> performs an estimate using default values for factors that affect the required memory:

```
sp_helpconfig 'HCB index memory pool size', 'estimate'
The HCB index memory pool size parameter indicates the total amount of memory to store index hash caching information.

Minimum Value Maximum Value Default Value Current Value Memory Used
Unit Type
```

```
0 2147483647 4096 4096 8192

memory pages(2k) dynamic

Suppose 100000 data rows per table, accessing 1 hash caching enabled index(es) which have 1 index partition(s)
per index and 50 percentage(s) of data rows to cache, and each hash table has 150000 bucket(s).

Estimated memory required is 4298 KB!

Configuration parameter, 'HCB index memory pool size', can be configured to 2149 to fit in 4298 KB of memory.

(return status = 0)
```

This example overrides the defaults with site-specific parameters to estimate the memory and configuration value setting:

```
sp_helpconfig 'HCB index memory pool size', 'estimate USING dbname = tdb1,
numdatarows = 1000, numindexes = 20, numptns per idx = 2, percentage = 10,
numhashbuckets = 50000'
The HCB index memory pool size parameter indicates the total amount of memory to
store index hash caching information.
Minimum Value Maximum Value Default Value Current Value Memory Used
                 Type
Unit.
                 dynamic +al
              0
                                        4096
                                                       4096
                                                                  8192
                     2147483647
emory pages(2k)
Suppose 1000 data rows per table, accessing 20 hash caching enabled index(es)
which have 2 index partition(s) per index and 10 percentage(s)
of data rows to cache, and each hash table has 50000 bucket(s).
Estimated memory required is 15784 KB!
Configuration parameter, 'HCB index memory pool size', can be configured to 7892
to fit in 15784 KB of memory.
(return status = 0)
```

1.137.4 Using sp_helpconfig with sybdiagdb (SAP Product Support Only)

sp_helpconfig includes several <configname> options that are intended only for SAP Product Support to use with the sybdiagdb database:

- <number of ccbs> the number of configurable action point control blocks available to aid debugging.
- <caps per ccb> the maximum number of configurable action points that can be configured at any one time within one configurable action point.
- <average cap size> the estimated number of bytes of memory required to store the information associated with a typical configurable action point.

i Note

SAP Technical Support may create the sybdiagdb database on your system for debugging purposes. This database holds diagnostic configuration data, and is for use by SAP Technical Support only.

For example:

```
sp_helpconfig "number of ccbs"
```

	Maximum Value			
0			0	0
	"caps per ccb' Maximum Value		Current Value	Memory Used
5	500			0
sp_helpconfig	"average cap s	size"		
Minimum Value	Maximum Value	Default Value	Current Value	Memory Used
100 10	0000	200	200	0

1.138 sp_helpconstraint

Reports information about integrity constraints used in the specified tables.

Syntax

```
sp helpconstraint [<objname>][, detail]
```

Parameters

<objname>

is the name of a table that has one or more integrity constraints defined by a create table or alter table statement.

detail

returns information about the constraint's user or error messages.

Example 1

Displays the constraint information for the store_employees table in the pubs3 database. The store_employees table has a foreign key to the stores table (stor_id) and a self-reference (mgr_id references emp_id):

```
sp helpconstraint store employees
                               defn
store_empl_stor_i_272004000 store_employees FOREIGN KEY
(stor_id) REFERENCES stores(stor_id) store_empl_mgr_id_288004057 store_employees FOREIGN KEY
                               (mgr id) SELF REFERENCES
                               store_employees(emp_id)
UNIQUE INDEX(emp_id):
store empl 2560039432
                               NONCLUSTERED, FOREIGN REFERENCE
(3 rows affected)
Total Number of Referential Constraints: 2
Details:
-- Number of references made by this table: 2
-- Number of references to this table: 1
-- Number of self references to this table: 1
Formula for Calculation:
Total Number of Referential Constraints
= Number of references made by this table
+ Number of references made to this table
- Number of self references within this table
```

Example 2

Displays more detailed information about the pubs3..salesdetail constraints, including the constraint type and any constraint error messages:

```
sp helpconstraint titles, detail
                                                    defn
name
                            type
       msg
datedflt
                           default value
                                                   create default datedflt
as getdate()
typedflt
                           default value
                                                   create default typedflt
as "UNDECIDED"
titles_pub_id_96003373
                           referential constraint titles FOREIGN KEY
(pub id)
                                                    REFERENCES
publishers(pub id)
       standard system error message number : 547
roysched_title__144003544 referential constraint roysched FOREIGN KEY
(title_id)
                                                    REFERENCES
titles(title id)
       standard system error message number : 547
salesdetai title 368004342 referential constraint salesdetail FOREIGN KEY
(title id)
                                                    REFERENCES

128003487 roysched
 400004456 discounts
  448004627 au pix
                                                             1
 496004798 blurbs
                                                             1
(11 rows affected)
```

Usage

There are additional considerations when using sp helpconstraint:

- sp_helpconstraint truncates foreign keys and reference keys to 30 characters.
- sp_helpconstraint prints the name and definition of the integrity constraint, and the number of references used by the table. The detail option returns information about the constraint's user or error messages.
- sp helpconstraint displays sharable inline defaults similarly to how it displays regular inline defaults.
- Running sp_helpconstraint with no parameters lists all the tables containing references in the current database, and displays the total number of references in each table. sp_helpconstraint lists the tables in descending order, based on the number of references in each table.

- sp_helpconstraint reports only the integrity constraint information about a table (defined by a create table or alter table statement). It does not report information about rules, triggers, or indexes created using the create index statement. Use sp_help to see information about rules, triggers, and indexes for a table.
- For constraints that do not have user-defined messages, the SAP ASE server reports the system error message associated with the constraint. Query sysmessages to obtain the actual text of that error message.
- You can use sp helpconstraint only for tables in the current database.
- If a query exceeds the configured number of auxiliary scan descriptors, the SAP ASE server returns an error message. You can use sp_helpconstraint to determine the necessary number of scan descriptors. See the System Administration Guide or more information on the number of aux scan descriptors configuration parameter.
- A system security officer can prevent the source text of constraint definitions from being displayed to most users who execute <code>sp_helpconstraint</code>. To restrict <code>select</code> permission on the <code>text</code> column of the <code>syscomments</code> table to the object owner or a system administrator, use <code>sp_configure</code> to set the <code>select</code> on <code>syscomments.text</code> column parameter to 0. This restriction is required to run the SAP ASE server in the evaluated configuration. See the <code>System Administration Guide</code> for more information about the evaluated configuration.

See alsoalter table, create table in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_helpconstraint</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

1.139 sp_helpdb

Reports information about a particular database or about all databases.

Syntax

```
sp_helpdb [<dbname> [, <order>][, verbose]]
```

Parameters

<dbname>

is the name of the database on which to report information. Without this optional parameter, <code>sp_helpdb</code> reports on all databases. <dbname> can include wildcard characters to return all databases that match the specified pattern.

<order>

The default order of the output is by lstart, which is the order in which the databases were created or altered. Use device_name along with <dbname> to display the output of sp_helpdb ordered by device_name.

verbose

The ${\tt sp_helpdb}$ output displays additional detailed information about the database.

Examples

Example 1

Displays information about all the databases in the SAP ASE server:

sp_helpdb						
name	db_size	owner	bid	created		status
master model pubs2	24.0 MB 8.0 MB 8.0 MB	sa sa sa	3	Jan 07,	2004	mixed log and data mixed log and data trunc log on chkpt, mixed log and data
sybsystemdb sybsystemprocs			31513 31514	•		2
tempdb	8.0 MB	sa	2	Feb 24,	2004	7
(1 row affecte	ed)					

```
(return status = 0
```

Issued from within pubs2, displays information about the pubs2 database, and includes segment information:

```
1> use pubs2
2> go
1> sp_helpdb pubs2
2> go
```

```
name db_size owner dbid created
                                                            status
pubs2 20.0 MB sa 4 Apr 13, 2005 trunc log on chkpt, mixed log
                                                            and data
(1 row affected)
pubs2
device fragments size usage
                                                         created
                                                                                    free kbytes
master 10.0 MB data and log Apr 13 2005 10:29AM 2304 pubs_2_dev 10.0 MB data and log Apr 13 2005 10:33AM 9888 device segment
master
master
                  default
                   logsegment
master system
pubs_2_dev default
pubs_2_dev logsegment
pubs_2_dev system
pubs_2_dev titleseg1
                    system

                   titleseg2
pubs_2_dev titleseg2
pubs_2_dev titleseg3
pubs_2_dev titleseg4
pubs_2_dev titleseg5
return status = 0)
```

Example 3

Not issued from within $\verb"pubs2"$, displays information about the $\verb"pubs2"$ database:

```
sp_helpdb pubs2
```

Example 4

Specifies device_name for the <order> parameter to display the device fragments for mydb in alphabetical order, overriding the default sort order of sp_helpdb:

<pre>mydb (1 row affected)</pre>	4.5 MB	sa 5	Feb 27, 2003 no options set
device_fragments	size	usage	created free kbytes
A	1.5 MB	data only	Feb 27 2003 7:50AM 1530
В	1.0 MB	log only	Feb 27 2003 7:50AM not applicable
C	2.0 MB	data only	Feb 27 2003 7:50AM 846

Displays the row lock promotion attributes set for the pubtune database:

```
name attribute_class attribute int_value char_value comments

pubtune lock strategy row lock promotion NULL PCT = 95, LWM = 300,

HWM = 300
```

Example 6

Displays whether or not a database is a user-created temporary database under the status column:

Example 7

Reports the status of database that is being encrypted:

Example 8

Reports the status of a partially encrypted database:

```
name db_size owner dbid created durability
lobcomplvl inrowlen
status
.....
test_db 6.0 MB sa 4 Aug 07, 2013 full
onull
encrypted partly
.....
```

Reports the status of a database that is partially decrypted:

```
name db_size owner dbid created durability
lobcomplvl inrowlen
status
.....
test_db 6.0 MB sa 4 Aug 07, 2013 full
decrypted partly
.....
```

Example 10

Displays information about the durability of a user-created temporary database. For this example, if you create the database:

```
create temporary database tempdb_explicit on default = 50
with durability = no_recovery
```

sp helpdb displays this output:

```
sp_helpdb tempdb_explicit
name db_size owner dbid created durability lobcomplvl inrowlen status

tempdb_explicit 50.0 MB sa 7 Dec 05, 2012 no_recovery 0 NULL
select into/bulkcopy/pllsort, trunc log on chkpt,
mixed log and data, user-created enhanced performance
temp db, allow wide dol rows

(1 row affected)
device_fragments size usage created free kbytes

master 50.0 MB data and log Dec 5 2012 8:49PM 49216

(return status = 0)
```

Example 11

Displays detailed information about pubs2, which is enabled for data row caching and snapshot isolation:

```
sp_helpdb pubs2, lstart, verbose
name db_size owner dbid created
 pubs2 36.0 MB sa 6 Aug 11, 2016
(1 row affected)
database_property status/value
data row caching enabled
durability full
in-memory row storage enabled inrowlen NULL
 lobcomp lvl 0
mixed log and data enabled
 snapshot isolation enabled
 trunc log on chkpt enabled
                               usage created
 device_fragments size
                                                                 free kbytes
imrs_dev1 8.0 MB imrslog only Aug 11 2016 12:54AM 8144 master 28.0 MB data and log Aug 11 2016 12:53AM 9568
imrscache
```

Usage

There are additional considerations when using sp helpdb:

- When you run sp helpdb on a fully encrypted database, it reports its encryption status:
 - Encrypted
 - Encryption in progress
 - o Decryption in progress

If the database is being encrypted or decrypted, sp_helpdb reports the percentage of work that has completed.

- sp_helpdb reports on the specified database when <dbname> is given. If no value is supplied for <dbname>, sp helpdb reports on all the databases listed in master.dbo.sysdatabases.
- sp_helpdb reports all database-specific properties and settings, such as: whether a database is offline, compression type, large object compression level, in-row large object length, row lock promotion thresholds (if any are defined for the database), enabled for row storage cache, and so on.
- If you enable asynchronous log service on a database, the attribute column in the sp_helpdb output displays "async log srv".
 - For more information about asynchronous log service, see <code>sp_dboption</code>, and Advanced Optimizing Tools in Performance and Tuning: Optimizer.
- For log segment disk pieces in a dedicated log database, <code>sp_helpdb</code> issues "not applicable" for the free space field in its per-disk-piece report. <code>sp_helpdb</code> also includes a column titled <code>free pages</code>, which is the value for the number of free pages the log segment has.
- (Cluster Edition) sp_helpdb does not display device-related information if the specified database is a local temporary database owned by a remote instance.
- <dbname> can include wildcard characters to return all databases that match the specified pattern. See Expressions, Identifiers, and Wildcard Characters in Reference Manual: Building Blocks for details about using wildcard characters.
- Executing sp_helpdb <dbname> from <dbname> includes free space and segment information in the report.
- sp_helpdb displays information about a database's attributes, giving the attribute's class, name, integer value, character value, and comments, if any attributes are defined. Example 3 shows cache binding attributes for the pubs 2 database.
- A database created with the for load option has a status of "don't recover" in the output from sp helpdb.
- When Component Integration Services is enabled, sp_helpdb lists the default storage location for the specified database or all databases. If there is no default storage location, the display indicates "NULL".
- The status column of sp helpdb includes these descriptions for database durability:
 - user created temp db normal temporary database created by the user (that is, created without specifying the durability parameter).
 - user-created enhanced performance temp db user-created temporary database created explicitly with the no_durability parameter. Because a database created with no_durability depends on licensing, it may not come online if the license expires.

- sp helpdb reports this information for row storage-enabled databases:
 - Whether the database is enabled for in-memory row storage.
 - The name of the cache, if one exists.
 - Whether row caching is enabled by default for newly-created tables.
 - Whether snapshot isolation is enabled by default for newly-created tables.
 - Whether snapshot isolation uses the temporary database version storage or the row_storage cache to store the row versions.

See also:

- Performance and Tuning: Optimizer > Advanced Optimizing Tools
- Reference Manual: Building Blocks > Expressions, Identifiers, and Wildcard Characters
- Reference Manual: Commands > alter database, create database.

Permissions

Any user can execute sp helpdb. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_configure [page 203] sp_dboption [page 228] sp_rename [page 693]

1.140 sp_helpdefrag

Reports defragmentation information for either all eligible objects for reorg defrag in the database whose context it is invoked from or for the given object if it is eligible for reorg defrag.

sp_helpdefrag uses the built-in function defrag_status() on each of the required tables or on each of the required data partitions to get the information about defragmentation.

• If <table_name> is not specified, defragmentation information for all eligible tables for <reorg defrag> (that is, user tables with datarows or datapages locking scheme) is reported. Rows for tables on which

<reorg defrag> is currently executing precede those for tables where <reorg defrag> is not currently
executing. Among these two sets, rows are in ascending order of the pct defrag.

- If <table_name> is specified, and if the table is eligible for <reorg defrag>, defragmentation information of the table as well as that of each data partition is reported. Rows are in the ascending order of percentage defragmented portion. Row for the table comes first and has NULL in partition column.
- If <partition name> is specified, only that particular data partition's information is reported.

Syntax

The syntax is:

```
sp helpdefrag [][,<partition name>]
```

Parameters

<table_name>

is the name of the table.

<partition_name>

is the name of the partition.

Examples

No parameters and before defragmentation

If sp_helpdefrag is executed without parameters on database testdb with user data-only locking tables before defragmentation:

```
sp_helpdefrag
```

The output is:

table	frag_index	pct_defrag	executing	last_run
t1 forw	0.01	0	0	NULL
mymsgs	0.39	0	0	NULL
mymsgs clone	0.57	0	0	NULL
t1	0.66	0	0	NULL
myprocs	0.86	0	0	NULL
mymsgs ptnd	1.07	0	0	NULL
t1 clone	1.98	0	0	NULL
myprocs clone	2.16	0	0	NULL
t1 ptnd	2.99	0	0	NULL
myprocs ptnd	3.03	0	0	NULL
(1 row affected	d)			
(return status	= 0)			

If you execute $sp_helpdefrag$ after defragmentation, the output is:

able	frag_index	pct_defrag	executing	last_run	
1 forw	0.01	100	0	Oct 10 2012	4:15PM
_ ymsqs	0.05	100	0	Oct 10 2012	4:15PM
msgs clone	0.06	100	0	Oct 10 2012	4:15PM
1 -	0.08	100	0	Oct 10 2012	4:15PM
yprocs	0.09	100	0	Oct 10 2012	4:15PM
ymsgs ptnd	0.09	100	0	Oct 10 2012	4:15PM
clone	0.10	100	0	Oct 10 2012	4:15PM
procs clone	0.11	100	0	Oct 10 2012	4:15PM

procs ptnd	0.14	100	0	Oct 10 2012	4:15PM
row affecte	d)				
turn status	= 0)				

On a specified table

If $sp_helpdefrag$ is executed on table t1 in database testdb:

```
sp_helpdefrag t1
```

The output is:

table	partition	frag_index	pct_defrag	executing	last_run	
t1 t1	NULL p2	0.35 0.50	35 0	0	Oct 10 2012 NULL	4:33PM
t1 t1	p1 p3	0.42	20 20	0	Oct 10 2012 Oct 10 2012	4:33PM
•	p4 v affected) n status =	0.05	100	0	Oct 10 2012	4:33PM

If reorg defrag is currently processing, the output is:

table	partition	frag_index	pct_defrag	executing	last_run	
t1	NULL	0.48	13	1	Oct 10 2012	4:33PM
t1	р2	0.50	0	1	NULL	
t1	p4	0.60	0	1	Oct 10 2012	4:33PM
t1	p1	0.42	20	1	Oct 10 2012	4:33PM
t1	p3	0.42	20	1	Oct 10 2012	4:33PM
(1 row	affected)					
(return	n status = 0)				

On a specified partition

If sp_helpdefrag is executed on partition p1 in table t1:

```
sp_helpdefrag t1, p1
```

The output is:

table	partition	frag_index	pct_defrag	executing	last_run	
(1 row	p1 affected) n status = 0		20	0	Oct 10 2012	4:33PM

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.141 sp_helpdevice

Reports information about a particular device or about all SAP ASE database devices and dump devices.

Syntax

```
sp helpdevice [<devname>]
```

Parameters

<devname>

is the name of the device about which to report information. If you omit this parameter, sp helpdevice reports on all devices.

Examples

Example 1

Reports information about the dump device named diskdump:

```
sp_helpdevice diskdump
```

Example 2

Displays information about all the devices on SAP ASE:

```
cachedisk ./cachedisk.dat
file system device, NV cache device, special, dsync off, directio on, physical disk, 10.00 MB, Free: 10.00 MB 2 0 2
physical disk, 10.00 MB, Free: 10.00 MB
              /enigma_dev11/pagarwal/CRS/cachebuzz/SSBUILT/SMP/run/master.dat
 master
file system device, special, dsync on, directio off, default disk, physical
disk, 400.00 MB, Free: 176.00 MB
 mvdisk
               ./mydisk.dat
file system device, special, dsync off, directio on, physical disk, 2048.00 MB, Free: 2045.00 MB 2 0 1 0 1048575
MB, Free: 2045.00 MB
 tapedump1 /dev/nst0
unknown device type, disk, dump
device
                2
                                     20000
    16
 tapedump2 /dev/nst1
unknown device type, tape,
                                     625 MB, dump
device
                                                                           16
                 0
                      20000
```

Usage

There are additional considerations when using sp helpdevice.

• sp_helpdevice displays the amount of unallocated space per device, indicated by the placeholder Free in the description column in the output

i Note

A small amount of space can remain unused on a device, especially for servers with larger page sizes. For example, the last 2 MB of a 250 MB device in a 16K server cannot be allocated, and sp_helpdevice reports this as free. This is because the size of an allocation unit in a 16K server is 4 MB, so only multiples of allocation units can be allocated.

- sp_helpdevice displays information on the specified device, when <devname> is given, or on all devices in master.dbo.sysdevices, when no argument is given.
- The sysdevices table contains dump devices and database devices.
 - Database devices can be designated as default devices, which means that they can be used for database storage. This can occur when a user issues create database or alter database and does not specify a database device name or gives the keyword default. To make a database device a default database device, execute the system procedure sp diskdefault.
- Add database devices to the system with disk init. Add dump devices with sp addumpdevice.
- If you issue sp helpdevice against a single device, it displays a list of allocated fragments on that device.
- The description column displays information about device types:
 - o block device
 - o file system device
 - o raw device

The number in the status column corresponds to the status description in the "description" column.

The cntrltype column specifies the controller number of the device. The cntrltype is 2 for disk or file dump devices and 3 – 8 for tape dump devices. For database devices, the cntrltype is usually 0 (unless your installation has a special type of disk controller).

The vdevno column is 0 for dump devices, 0 for the master database device, and 1 or higher for other database devices.

The vpn_low and vpn_high columns represent virtual page numbers, each of which is unique among all the devices in SAP ASE.

See also disk init, dump database, dump transaction, load database, load transaction in Reference Manual: Commands.

See System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

Any user can execute $sp_helpdevice$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_dropdevice [page 292]
sp_logdevice [page 567]
```

1.142 sp_helpextendedproc

Displays extended stored procedures (ESPs) in the current database, along with their associated DLL files.

Syntax

```
sp_helpextendedproc [<esp_name>]
```

Parameters

<esp_name>

case-sensitive, this is the name of the extended stored procedure. It must be a procedure in the current database. $<esp_name>$ must match the $<esp_name>$ used to create the ESP. If you omit $<esp_name>$, $sp_helpextendedproc$ lists all the extended stored procedures in the database.

Examples

Example 1

Lists the xp cmdshell ESP and the name of the DLL file in which its function is stored:

Example 2

Lists all the ESPs in the current database, along with the names of the DLL files in which their functions are stored:

```
sp_helpextendedproc

ESP Name    DLL Name
------
xp_freedl    sybsyesp
xp_cmdshell    sybsyesp
```

Usage

See also create procedure, drop procedure in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_helpextendedproc</code>.

Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addextendedproc [page 37]
sp_dropextendedproc [page 297]
xp_cmdshell [page 889]

1.143 sp_helpexternlogin

(Component Integration Services only) Reports information about external login names.

Syntax

```
sp_helpexternlogin [<server>[, <loginame>[, <rolename>]]]
```

Parameters

<server>

is the name of the remote server that has been added to the local server with sp addserver.

<loginame>

is a login account on the local server.

<rolename>

is the SAP ASE user's assigned role.

Example 1

Displays all remote servers, local login names, role names, and external logins:

sp_helpexternlogin

Example 2

Displays local login names, role names, and external logins for the server named SSB:

sp helpexternlogin SSB

Example 3

Displays remote servers, local login names and external logins for the user named "milo":

sp_helpexternlogin NULL, milo

Example 4

Displays external logins for remote server SSB where the local user name is "trixi":

sp_helpexternlogin SSB, trixi

Example 5

Displays external logins for remote server SSB for local users with sa_role:

sp_helpexternlogin SSB, NULL, sa_role

Usage

sp_helpexternlogin displays all remote servers, the user's local login name, role name, and the user's external login name.

 $\label{local logins} \mbox{Add remote servers with $\tt sp_addserver. Add local logins with {\tt create login.} \\$

Permissions

Any user can execute $sp_helpexternlogin$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addlogin [page 47]
sp_addserver [page 58]
sp_dropexternlogin [page 299]
sp_helpserver [page 482]
```

1.144 sp_helpgroup

Reports information about a particular group or about all groups in the current database.

Syntax

```
sp_helpgroup [<grpname>]
```

Parameters

<grpname>

is the name of a group in the database created with sp_addgroup.

Examples

Example 1

Displays information about all groups in the current database:

```
sp_helpgroup
```

Displays information about the group "hackers":

sp_helpgroup h	ackers			
Group_name hackers hackers	Group_id 16384 16384	Users_in_group ann judy	Userid 4 3	

Usage

To get a report on the default group, "public," enclose the name "public" in single or double quotes ("public" is a reserved word).

If there are no members in the specified group, $sp_helpgroup$ displays the header, but lists no users, as follows:

Group_name	Group_id	Users_in_group	Userid	

See also grant, revoke in Reference Manual: Commands.

Permissions

Any user can execute $sp_helpgroup$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addgroup [page 42]

```
sp_changegroup [page 135]
sp_dropgroup [page 304]
sp_helprotect [page 472]
sp_helpuser [page 495]
```

1.145 sp_helpindex

Reports information on computed column indexes, function-based indexes, and partial indexes.

Syntax

```
sp_helpindex <objname>,[<cmdname> | "terse"]
```

Parameters

<objname>

is the name of a table in the current database.

<cmdname>

command to run for displaying index information. Supported commands are:

- help display usage information for sp_helpindex
- showpartialindex display all partial indexes in this database
- showlackindexpartition display data partitions for which partial index partitions are not built yet for table <objname>

"terse"

sp_helpindex displays a reduced output, skipping partition related information. The output for terse includes:

- Total number of indexes
- Total number of global indexes
- Total number of local indexes
- Total number of partial indexes

 $sp_helpindex$ displays index information in output that is aligned with the create index syntax.

Example 1

Displays the types of indexes on the sysobjects table:

```
index_name index_keys index_description
index_max_rows_per_page index_fillfactor index_reservepagegap index_created
   index_local plldegree

sysobjects id clustered, unique 0
0 Apr 12 2005 2:38PM Global Index 0
ncsysobjects name, uid nonclustered, unique
0 Apr 12 2005 2:38PM Global Index 0
(2 rows affected)
index_pt_name index_ptn_seg
sysobjects_1 system
rcsysobjects_1 system
```

Example 2

Displays information about the index on the titles table in the pubs2 database. The titles table is partitioned, but the index titleind is not titleind is a nonclustered (single-partitioned), global index:

Example 3

Displays index information about the mysalesdetail table. mysalesdetail is partitioned by hash on the ord_num column. A clustered, local index, with three partitions has also been created on ord_num with plldegree set to 1:

Displays information about the indexes created on table big table:

```
sp_helpindex big_table
```

Example 5

Displays usage information for sp helpindex:

```
sp_helpindex null, help
```

Example 6

Displays all partial indexes in the current database:

```
sp_helpindex null, showpartialindex
```

Example 7

Display all partial indexes on table big table:

```
sp_helpindex big_table, showpartialindex
```

Example 8

Displays all data partitions that do not include partial index partitions on table big table:

```
sp_helpindex big_table, showlackindexpartition
```

Example 9

Displays a function-based index:

```
create index sum_sales on mytitles (price * total_sales)
sp helpindex mytitles
Object has the following indexes
index_name index_keys index_description
index_max_rows_per_page index_fillfactor index_reservepagegap index_created
  index_local plldegree
                              _____
sum sales sybfi2 1 nonclustered
                                  Oct 12 2005 3:34PM Global Index 0
(1 row affected)
                  index_ptn_seg
index_ptn_name
sum_sales_1724867646 default
(1 row affected)
Object has the following functional index keys
Internal Index Key Name
sybfi2 1
(1 row affected)
Expression
```

```
price * total_sales
(return status = 0)
```

Displays an abbreviated information set for the syspartitions indexes:

Usage

There are additional considerations when using sp helpindex:

- sp_helpindex lists any indexes on a table, including indexes created by defining unique or primary key constraints defined by a create table or alter table statement.
- sp_helpindex displays any attributes (for example, cache bindings) assigned to the indexes on a table.
- sp helpindex displays:
 - o Partition information for each index.
 - Whether the index is local or global, clustered or nonclustered.
 - The max_rows_per_page setting of the indexes.
 - Information about clustered indexes on data-only locked tables.
 The index ID (indid) of a clustered index in data-only locked tables is not equal to 1.
 - The column order of the keys, to indicate whether they are in ascending or descending order.
 - Space manage property values.
 - The key column name followed by the order. Only descending order is displayed. For example, if there is an index on column a ASC, b DESC, c ASC, "index_keys" shows "a, b DESC, c".
 - The number of plldegree which is the maximum number of threads the query optimizer can use.

See also create index, drop index, update statistics in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_helpindex</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_help [page 396]
sp_helpkey [page 463]
sp_helpartition [page 416]
```

1.146 sp_helpjava

Displays information about Java classes and associated JARs that are installed in the database.

Syntax

```
sp_helpjava ["class"[, <java_class_name>[, "detail" | "depends"]] |
   "jar", <jar_name>[, "depends"]]]
```

Parameters

```
"class" | "jar"
```

specifies whether to display information about a class or a JAR. Both "class" and "jar" are keywords, so the quotes are required.

```
<java class name>
```

the name of the class about which you want information. The class must be a system class or a user-defined class that is installed in the database.

detail

specifies that you want to see detailed information about the class.

depends

lists all the database objects that depend on the specified class or classes in the JAR, including SQLJ functions, SQLJ stored procedures, views, Transact-SQL stored procedures, and tables.

<jar_name>

the name of the JAR for which you want to see information. The JAR must be installed in the database using installjava.

Examples

Example 1

Displays the names of all classes and associated JAR files installed in the database:

```
sp_helpjava
```

Example 2

Displays the name of all classes:

```
sp_helpjava "class"
```

Example 3

Displays detailed information about the Address class:

```
sp_helpjava "class", Address, detail
```

```
Class
Address
(1 row affected)
Class Modifiers
public synchronized
 Implemented Interfaces
 java.io.Serializable
 Extended Superclass
 java.lang.Object
 Constructors
 public Address()
 public Address(java.lang.String,java.lang.String)
Methods
public final native java.lang.Class java.lang.Object.getClass()
public native int java.lang.Object.hashCode()
public boolean java.lang.Object.equals(java.lang.Object)
public java.lang.String java.lang.Object.toString()
```

```
public final native void java.lang.Object.notify()
public final native void java.lang.Object.notifyAll()
public final native void java.lang.Object.wait(long) throws
java.lang.InterruptedException
public final void java.lang.Object.wait(long,int) throws
java.lang.InterruptedException
public final void java.lang.Object.wait() throws
java.lang.InterruptedException
public java.lang.String Address.display()
public void Address.removeLeadingBlanks()

Fields
_______
public java.lang.String Address.street
public java.lang.String Address.zip
```

Usage

The depends parameter lists dependencies of a class or classes if the class is listed in the external name clause of a create statement for a SQLJ routine or is used as a datatype of a column in the database.

See also:

- remove java in Reference Manual: Commands
- See Java in Adaptive Server Enterprise for more information about Java in the database.
- extractjava, installjava in the Utility Guide

Permissions

Any user can execute sp_helpjava. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.147 sp_helpjoins

Lists the columns in two tables or views that are likely join candidates.

Syntax

```
sp helpjoins <lefttab>, <righttab>
```

Parameters

<lefttab>

is the first table or view.

<righttab>

is the second table or view. The order of the parameters does not matter.

Examples

Example 1

Displays a list of columns that are likely join candidates in the sales and salesdetailtables:

Example 2

Displays a list of columns that are likely join candidates in the sysobjects and syscolumns system tables:

```
sp_helpjoins sysobjects, syscolumns

al a2 bl b2 cl c2 dl d2 el e2
fl f2 gl g2 hl h2
---- --- --- --- ---
id id NULL NULL NULL NULL NULL NULL NULL
```

Usage

The column pairs that <code>sp_helpjoins</code> displays come from either of two sources. <code>sp_helpjoins</code> checks the <code>syskeys</code> table in the current database to see if any foreign keys have been defined with <code>sp_foreignkey</code> on the two tables, then checks to see if any common keys have been defined with <code>sp_commonkey</code> on the two tables. If <code>sp_helpjoins</code> does not find any foreign keys or common keys there, it checks for keys with the same user-defined datatypes. If that fails, it checks for columns with the same name and datatype.

sp helpjoins does not create any joins.

Permissions

Any user can execute <code>sp_helpjoins</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_commonkey [page 191]

sp_foreignkey [page 387] sp_helpkey [page 463]

sp_primarykey [page 677]

1.148 sp_helpkey

Reports information about a primary, foreign, or common key of a particular table or view, or about all keys in the current database.

Syntax

```
sp_helpkey [<tabname>]
```

Parameters

<tabname>

is the name of a table or view in the current database. If you do not specify a name, the procedure reports on all keys defined in the current database.

Examples

Example 1

Displays information about the keys defined in the current database. The "object_keys" and "related_keys" columns refer to the names of the columns that make up the key:

Usage

There are additional considerations when using sp helpkey:

- sp_helpkey lists information about all primary, foreign, and common key definitions that reference the table <tabname> or, if <tabname> is omitted, about all the keys in the database. Define these keys with the sp primarykey, sp foreignkey, and sp commonkey system procedures.
- sp_helpkey does not provide information about the unique or primary key integrity constraints defined by a create table statement. Use sp_helpconstraint to determine what constraints are defined for a table.

- Create keys to make explicit a logical relationship that is implicit in your database design so that applications can use the information.
- If you specify an object name, sp_helpkey follows the SAP ASE rules for finding objects:
 - If you do not specify an owner name, and you own an object with the specified name, sp_helpkey reports on that object.
 - o If you do not specify an owner name, and you do not own an object of that name, but the database owner does, sp helpkey reports on the database owner's object.
 - o If neither you nor the database owner owns an object with the specified name, sp_helpkey reports an error condition, even if an object with that name exists in the database for a different owner.
 - o If both you and the database owner own objects with the specified name, and you want to access the database owner's object, specify the name in the form <dbo>.<objectname>.
- Qualify objects that are owned by database users other than yourself and the database owner with the owner's name, as in "mary.myproc".

See also create trigger in Reference Manual: Commands.

Permissions

Any user can execute $sp_helpkey$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_commonkey [page 191] sp_foreignkey [page 387] sp_primarykey [page 677]

1.149 sp_helplanguage

Reports information about a particular alternate language or about all languages.

Syntax

```
sp_helplanguage [<language>]
```

Parameters

<language>

is the name of the alternate language for which to display information about.

Examples

Example 1

Displays information about the alternate language, "french":

Example 2

Displays information about all installed alternate languages:

```
sp_helplanguage
```

Usage

sp_helplanguage reports on a specified language, when the language is given, or on all languages in master.dbo.syslanguages, when no language is supplied.

Permissions

Any user can execute $sp_helplanguage$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addlanguage [page 43] sp_droplanguage [page 308] sp_setlangalias [page 718]

1.150 sp_helplog

Reports the name of the device that contains the first page of the transaction log.

Syntax

sp_helplog

Example 1

Reports "master" as the name of the device:

```
sp_helplog
```

In database 'master', the log starts on device 'master'.

Usage

See also alter database, create database in Reference Manual: Commands.

Permissions

Any user can execute $sp_helplog$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpdevice [page 446]
sp_logdevice [page 567]

1.151 sp_helpmaplogin

Displays mapping information.

Syntax

```
sp_helpmaplogin [ (<authentication_mech> | null), (<client_username> | null) ]
```

Parameters

<authentication mech>

is one of the valid values specified for the authenticate with option in create login and alter login.

<cli>client_username>

is an external username.

Examples

Example 1

Displays information about all logins:

Usage

If you do not include any parameters, $sp_helpmaplogin$ displays login information about all users currently logged in to the SAP ASE server. Restrict the output to specific sets of client user names or authentication mechanisms by using the parameters.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_maplogin [page 580]

1.152 sp_helpobjectdef

(Component Integration Services only) Reports owners, objects, and type information for remote object definitions.

Syntax

sp_helpobjectdef [<objname>]

Parameters

<objname>

is the name of the object as it is defined in the sysattributes table. The <objname> can be in any of the following forms:

- <dbname>.<owner>.<object>
- <dbname>..<object>
- <owner>.<object>
- <object>

<dbname> and <owner> are optional. <object> is required. If <owner> is not
supplied, the <owner> defaults to the current user name. If <dbname> is supplied, it
must be the current database, and <owner> must be supplied or marked with the
placeholder <dbname>..<object>. Enclose a multipart <object> in quotes.

Examples

Example 1

Displays all remote object definitions in the current database:

sp_helpobjectdef

Displays remote object definitions for the tb1 table owned by the database owner:

```
sp helpobjectdef "dbo.tb1"
```

Usage

If no ${\tt objname}{\tt is}$ supplied, ${\tt sp_helpobjectdef}$ displays all remote object definitions.

A server name is not permitted in the <objname> parameter.

See also create table, create existing table, drop table in Reference Manual: Commands.

Permissions

Any user can execute $sp_helpobjectdef$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addobjectdef [page 50]
sp_dropobjectdef [page 311]
sp_helpserver [page 482]

1.153 sp_helpremotelogin

Reports information about a particular remote server's logins or about all remote server logins.

Syntax

sp_helpremotelogin [<remoteserver>[, <remotename>]]

Parameters

<remoteserver>

is the name of the server about which to report remote login information.

<remotename>

is the name of a particular remote user on the remote server.

Examples

Example 1

Displays information about all the remote users of the remote server GATEWAY:

 ${\tt sp_helpremotelogin~GATEWAY}$

Example 2

Displays information about all the remote users of all the remote servers known to the local server:

sp_helpremotelogin

Usage

sp_helpremotelogin reports on the remote logins for the specified server, when <remoteserver> is given, or on all servers, when no parameter is supplied.

Permissions

Any user can execute $sp_helpremotelogin$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addremotelogin [page 53]
sp_dropremotelogin [page 313]
sp_helpserver [page 482]
```

1.154 sp_helprotect

Reports on permissions for database objects, users, groups, or roles.

Syntax

Parameters

<name>

is either the name of the table, view, stored procedure, SQLJ stored procedure, SQLJ function, user-defined function, name of a user, role, or group in the current database. If you do not provide a name, $sp_helprotect$ reports on all permissions in the database.

<username>

is the name of the user, group, or role in the current database.

grant

displays the privileges granted on <name> to <username> with grant option. If <username> is null, sp_helprotect lists all privileges granted with grant option on <name>.

deny

displays the denied privileges for a table, table owner, all tables, all owners, or the status (denied or not) for the specified permission name.

none

ignores roles granted to the user when determining permissions granted.

granted

includes information on all roles granted to the user when determining permissions granted.

enabled

includes information on all roles activated by the user when determining permissions granted.

<role name>

lists privileges granted through <role name>.

<permission_name>

allows sp_helprotect to provide information (grantor name, grantee name, table/column name, grantability) for any specific permission granted in a given database.

The value of this parameter can be any value from the sysprotects.action column.

Examples

Example 1

This series of grant and revoke statements, executing sp_helprotect titles results in this display:

```
grant select on titles to judy
grant update on titles to judy
revoke update on titles(price) from judy
grant select on publishers to judy
with grant option
go
sp_helprotect titles
```

grantor	grantee	type	action	object	column	predicate	grantable
dbo	judy	Grant	Select	titles	All	0	FALSE
dbo	judy	Grant	Update	titles	advance	0	FALSE
dbo	judy	Grant	Update	titles	notes	0	FALSE
dbo	judy	Grant	Update	titles	pub id	0	FALSE
dbo	judy	Grant	Update	titles	pubdate	0	FALSE
dbo	judy	Grant	Update	titles	title	0	FALSE
dbo	judy	Grant	Update	titles	title id	0	FALSE
dbo	judy	Grant	Update	titles	total sales	0	FALSE
dbo	judy	Grant	Update	titles	type -	0	FALSE

dbo	judy	Grant	Select	titles	all	0	TRUE	

Issuing the following grant statement results in sp helprotect displaying the following:

```
grant select, update on titles(price, advance)
   to marv
    with grant option
go
sp helprotect titles
grantor grantee type
                            action object column predicate grantable
         mary Grant Select titles advance 0
mary Grant Select titles price 0
mary Grant Hudate titles advance 0
                                                                     TRUE
dbo
                                                                    TRUE
                   Grant Update titles advance 0
                                                                    TRUE
dbo
          mary
dbo
          mary
                    Grant Update titles price
```

Example 3

Displays all the permissions that "judy" has in the database:

```
sp_helprotect judy
```

Example 4

Displays any permissions that "csmith" has on the sysusers table, as well as whether "csmith" has with grant option which allows "csmith" to grant permissions to other users:

```
sp_helprotect sysusers, csmith, "grant"

grantor grantee type action object column predicate grantable

dbo doctor Grant Delete sysusers All 0 FALSE
dbo doctor Grant Insert sysusers All 0 FALSE
dbo doctor Grant References sysusers All 0 FALSE
```

Example 5

Displays information about the permissions that the doctor role has in the database:

```
grantor grantee type action object column predicate grantable doctor Grant Delete sysusers All 0 FALSE dbo doctor Grant References sysusers All 0 FALSE
```

Example 6

Displays information on all roles granted to "csmith":

```
grantor grantee type action object column predicate grantable

dbo csmith Grant Update sysusers All 0 FALSE
dbo doctor Grant Delete sysusers All 0 FALSE
dbo doctor Grant Insert sysusers All 0 FALSE
dbo doctor Grant References sysusers All 0 FALSE
```

```
(1 row affected)
(return status = 0)
```

Displays information on all active roles granted to "rpillai":

```
grantor grantee type action object column predicate grantable
dbo public Grant Select sysattributes All 0 FALSE
(1 row affected)
(return status = 0)
```

Example 8

Advises that SQLJ function access is public:

```
sp_helprotect function_sqlj
Implicit grant to public for SQLJ functions.
```

Example 9

Uses the action "Decrypt" from sysprotects.action:

Example 10

Displays the name of the predicated privilege in the output:

```
grant select, update, on tabl where col1 = 8 as pred1 to robert grant select, delete on tabl where col1 = 9 to robert, joffrey grant select, delete, update on tabl where col2 = 10 as pred2 to role1, group1
```

```
sp helprotect tab1
```

grantor	grantee	type	action	object	column	predicate	grantable
dbo	joffrey joffrey groupl groupl rolel rolel roler robert robert robert	Grant Grant Grant Grant Grant Grant Grant Grant Grant Grant Grant	Select Delete Select Update Delete	tab1 tab1 tab1 tab1 tab1 tab1 tab1 tab1	All	tab1_fdoIidqcSKLm tab1_fdoIidqcSKLm pred2 pred2 pred2 pred2 pred2 pred2 tab1_fdoIidqcSKLm pred1 tab1_fdoIidqcSKLm pred1	FALSE

Example 11 Display all permissions of table ± 1 including denied permissions:

sp_helprotect t1

	grantee ce grantable	type	action	object	column
		Deny	Delete	All tables	All
	All owners FALSE	Deny	Delete Statistics	All tables	All
dbo	All owners FALSE	Deny	Insert	All tables	All
dbo		Deny	References	All tables	All
dbo		Deny	Select	All tables	All
dbo		Deny	Transfer Table	All tables	All
dbo		Deny	Truncate Table	All tables	All
		Deny	Update	All tables	All
dbo		Deny	Update Statistics	All tables	All
dbo	user1 FALSE	Grant	Select	t1	All
dbo		Grant	Truncate Table	t1	All

Example 12

Use allow to allow some denied permissions and display remaining denied permissions:

allow update, insert, references on all tables to all owners

sp_helprotect "deny"

grantee te grantable	type	action	object	column
	Deny	Delete	All tables	All
All owners	Deny	Delete Statistics	All tables	All
All owners	Deny	Select	All tables	All
All owners	Deny	Transfer Table	All tables	All
All owners	Deny	Truncate Table	All tables	All
	Deny	Update Statistics	All tables	All
	All owners FALSE All owners	All owners Deny FALSE All owners Deny	All owners Deny Delete FALSE All owners Deny Delete Statistics FALSE All owners Deny Select FALSE All owners Deny Transfer Table FALSE All owners Deny Truncate Table FALSE All owners Deny Update Statistics	All owners Deny Delete All tables FALSE All owners Deny Delete Statistics All tables FALSE All owners Deny Select All tables FALSE All owners Deny Transfer Table All tables FALSE All owners Deny Truncate Table All tables FALSE All owners Deny Update Statistics All tables

Display permissions on a specified table and user when dbo is the owner of t1:

sp_helprotect, dbo

	grantee te grantable	type	action	object	column
dbo NULL	All owners FALSE	Deny	Delete	All tables	All
dbo NULL	All owners FALSE	Deny	Delete Statistics	All tables	All
dbo NULL	All owners FALSE	Deny	Select	All tables	All
dbo NULL	All owners FALSE	Deny	Transfer Table	All tables	All
dbo NULL	All owners FALSE	Deny	Truncate Table	All tables	All
dbo NULL	All owners FALSE	Deny	Update Statistics	All tables	All

Example 15

Display denied permissions of specific user:

sp_helprotect user1, 'deny'

_	grantee te grantable	type	action	object	column
dbo NULL	All Owners FALSE	Deny	Delete	All Tables	All
dbo NULL	All Owners FALSE	Deny	Delete Statistics	All Tables	All
dbo NULL	All Owners FALSE	Deny	Select	All Tables	All
dbo NULL	All Owners FALSE	Deny	Transfer Table	All Tables	All
dbo NULL	All Owners FALSE	Deny	Truncate Table	All Tables	All
dbo NULL	All Owners FALSE	Deny	Update Statistics	All Tables	All

Example 16

Display the status of specific permission:

sp_helprotect 'deny', @permission_name= 'update'

	grantee te grantable	type	action	object	column
dbo NULL	All Owners FALSE	Deny	Update	All Tables	All

Usage

- sp_helprotect reports permissions on a database object. If you supply the <username> parameter, only that user's permissions on the database object are reported. If <name> is not an object, sp_helprotect checks to see if it is a user, a group, a role, or a permission name. If it is, sp_helprotect lists the permissions for the user, group, or role.
- sp helprotect looks for objects and users in the current database only.
- If you do not specify an optional value such as granted, enabled, none, or <role_name>, the SAP ASE server returns information on all roles activated by the current specified user.
- If the specified user is not the current user, the SAP ASE server returns information on all roles granted to the specified user.
- Displayed information always includes permissions granted to the group in which the specified user is a member
- In granting permissions, a system administrator is treated as the object owner. If a system administrator grants permission on another user's object, the owner's name appears as the grantor in sp_helprotect output.

sp helprotect reports information on encrypted columns, encryption keys, and users as follows:

- Tables and columns reports who has been granted decrypt permission and on which columns.
- Encryption keys reports who has been granted select permission.
- Users indicates users who have been granted create encryption key permission.

sp_helprotect reports information on predicated privileges by listing the name of the predicated privilege, if any, as an extra column in the output.

See also grant, revoke in Reference Manual: Commands.

Permissions

Any user can execute $sp_helprotect$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_activeroles [page 15]

1.155 sp_helpsegment

Reports information about a particular segment or about all segments in the current database.

Syntax

```
sp_helpsegment [<segname>]
```

Parameters

<segname>

is the name of the segment about which you want information. If you omit this parameter, information about all segments in the current database appears.

Examples

Example 1

Reports information about all segments in the current database:

```
      sp_helpsegment

      segment name
      status

      0 system
      0

      1 default
      1

      2 logsegment
      0

      3 seg1
      0

      4 seg2
      0

      5 seg3
      0

      6 seg4
      0
```

Example 2

Reports information about the segment named order_seg. This includes database tables and indexes that bond to this segment — the tables/indexes currently having this segment specified at the table/index level — as well as the objects currently on this segment (partitions that are actually located on this segment). In addition, this example reports the total number of pages, free pages, used pages, and reserved pages on this segment:

```
sp_helpsegment seg1
```

```
table_name index_name indid

new_titles new_titles 0

total_size total_pages free-pages used_pages reserved pages

2.0MB 256 240 16 0
```

Reports information about the default segment. The keyword default must be enclosed in quotes. The output has been abridged due to length:

```
sp_helpsegment "default"
```

```
segment name status

1 default 1
device size free_pages

-----
master 14.0MB 303
pubs_dev1 2.0MB 240
pubs_dev2 2.0MB 232
pubs_dev3 2.0MB 232
pubs_dev3 2.0MB 232
pubs_dev4 2.0MB 240
Objects on segment 'default':
```

Reports information about the segment on which the transaction log is stored:

```
1> sp_helpsegment "logsegment" 2> go
```

```
status
 segment name
  2 logsegment 0
 device device size
master
           14.0MB
pubs_dev1 2.0MB
pubs_dev2 2.0MB
pubs_dev3 2.0MB
pubs_dev4 2.0MB
free_pages
      1239
Objects on segment 'logsegment':
table_name index_name indid partition_name
syslogs syslogs 0 syslogs 8
Objects currently bound to segment 'logsegment':
table name index name indid
syslogs syslogs 0
total_size total_pages free_pages used_pages reserved_pages
22.0MB 2816 1239 13
                                                     Ω
(return status = 0)
```

Usage

There are additional considerations when using sp helpsegment:

- sp_helpsegment displays information about the specified segment, when <segname> is given, or about all segments in the current database, when no argument is given.
- When you first create a database, the SAP ASE server automatically creates the system, default, and logsegment segments. Use sp addsegment to add segments to the current database.
- If you specify a log segment from a dedicated log database for the <segname> parameter, sp_helpsegment reports the number of free pages in the log segment.
- The system, default, and logsegment segments are numbered 0, 1, and 2, respectively.
- The "status" column indicates which segment is the default pool of space. Use sp_placeobject or the on <segment_name> clause of the create table or create index command to place objects on specific segments.
- The "indid" column is 0 if the table does not have a clustered index and is 1 if the table has a clustered index.

See also create index, create table in *Reference Manual: Commands*.

Permissions

Any user can execute <code>sp_helpsegment</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_dropsegment [page 319]
sp_extendsegment [page 365]
sp_helpdb [page 438]
sp_helpdevice [page 446]
sp_placeobject [page 665]
```

1.156 sp_helpserver

Reports information about a particular remote server or about all remote servers.

Syntax

```
sp_helpserver [<server>]
```

Parameters

<server>

is the name of the remote server about which you want information.

Example 1

Displays information about the remote server GATEWAY:

```
sp_helpserver GATEWAY
```

Example 2

Displays information about the local Backup Server:

```
name network_name security_mechanism server_principal class
status
id cost
-----

SYB_BACKUP SYB_BACKUP NULL NULL
timeouts, no net password encryption, writable, enable login redirection 1
```

Example 3

Displays information about all the remote servers known to the local server:

```
sp_helpserver
```

Usage

sp_helpserver reports information about all servers in master.dbo.sysservers or about a particular remote server, when <server> is specified.

When Component Integration Services (CIS) is installed, sp_helpserver lists the security mechanism, server principal name, and server class for each server.

Permissions

Any user can execute $sp_helpserver$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addserver [page 58]
sp_dropserver [page 321]
sp_helpremotelogin [page 471]
sp_serveroption [page 711]
```

1.157 sp_helpsort

Displays the SAP ASE server's default sort order and character set.

Syntax

```
sp_helpsort
```

Examples

Example 1

For Class 1 (single-byte) character sets, $sp_helpsort$ displays the name of the server's default sort order, its character set, and a table of its primary sort values. On a 7-bit terminal, it appears as follows:

```
Sort Order Description

Character Set = 1, iso_1
    ISO 8859-1 (Latin-1) - Western European 8-bit character set.
Sort Order = 50, bin_iso_1
    Binary sort order for the ISO 8859/1 character set (iso_1).
Characters, in Order

! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ?
@ A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [ \ ] ^ _
    a b c d e f g h i j k l m n o p q r s t u v w x y z { | } ~
```

```
! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ?
@ A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [ \ ] ^ -
` a b c d e f g h i j k l m n o p q r s t u v w x y z { | } ~
```

On an 8-bit terminal, it appears as follows:

```
Character Set = 1, iso_1
    ISO 8859-1 (Latin-1) - Western European 8-bit character set.

Sort Order = 50, bin_iso_1
    Binary sort order for the ISO 8859/1 character set (iso_1).

Characters, in Order

! " # $ % & ' ( ) * + , - . / 0 1 2 3 4 5 6 7 8 9 : ; < = > ?

@ A B C D E F G H I J K L M N O P Q R S T U V W X Y Z [ \ ] ^ _
    `a b c d e f g h i j k l m n o p q r s t u v w x y z { | } ~

    ; ¢ f x Y | § " © a ¬ - ® - ° 2 3 ′ µ ¶ · . 1 ° 1/4 1/2 3/4 ¿ À
    Á Â Ã Ä Å Æ Ç È É Ê Ë Ì Í Î Ï D Ñ Ò Ó Ô Ö × Ø Ù Ú Û Ü Y P ß à
    á â ä å æ ç è é ê ë ì í î ï ñ ò ó ô õ ö ÷ Ø ù ú û ü y p ÿ
```

Example 3

For a Class 2 (multibyte) character set, the characters are not listed, but a description of the character set is included. For example:

```
Sort Order Description

Character Set = 140, euc_jis
    Japanese. Extended Unix Code mapping for JIS-X0201
    (hankaku katakana) and JIS-X0208 (double byte) roman,
    kana, and kanji.
    Class 2 character set

Sort Order = 50, bin_eucjis
    Binary sort order for Japanese using the EUC JIS
    character set as a basis.
```

Example 4

For case-insensitive character sets, the name and sort order ID of available case-insensitive sort orders is listed:

Usage

Binary sort order is the default.

Permissions

Any user can execute $sp_helpsort$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.158 sp_helptext

Displays the source text of a compiled object, as well as the text for user-defined functions, computed columns, or function-based index definitions.

Syntax

sp helptext <objname>[, <grouping num>][, <numlines>[, <printopts>]]]

Parameters

<objname>

is the name of the compiled object for which the source text is to be displayed. The compiled object must be in the current database.

<grouping_num>

is an integer identifying an individual procedure, when <code><objname></code> represents a group of procedures. This parameter tells $sp_helptext$ to display the source text for a specified procedure in the group.

This parameter also specifies the start line number from which to generate the SQL text, when the <pri>text, when the <pri>text, argument is used.

i Note

Views, defaults, and other non-procedural objects are never grouped; use <number> only for groups of procedures.

<numlines>

specifies the numbers of lines for which to generate SQL text. If the argument <printopts> is also used with showsql, <numlines> specifies the number of lines of SQL text to display; if <printopts> is used with context, <numlines> is treated as the context block width surrounding the starting line number.

printopts>

supports various comma-separated properties of the output format. One or more of these print options can be specified, in any order, as a comma-separated string:

- showsql generates formatted SQL output for the compiled object. If showsql does not appear in the <pri>cprintopts> list, this property is not invoked.
- linenumbers produces line numbers for each line of SQL output.
- comments produces the line numbers as a comment field (/*<nnn>*/), so that
 the generated SQL can still recreate the compiled object, without further edits, if
 necessary.
- context produces a context block of output around a specified starting line number. If no, or null, <numlines >parameter is called, a default context block of five lines, generated before and after the line number of interest, is supplied.
- noparams suppresses the automatically generated parameter information. Use this print option to produce only the relevant portion of SQL output for the compiled object.
- ddlgen generates the SQL text as a DDL script, prefacing the output with a use <database> command and a drop <object> command. This allows you to reproduce almost exactly the SQL required to recreate most compiled objects, such as procedures, triggers, views, defaults, and rules.

The print options ddlgen and context are mutually exclusive specifiers. Used together, they raise an error. To get line numbers when you are displaying a context block of SQL text, use the context and linenumbers specifiers.

Examples

Example 1

Displays the source text of pub_idrule. Since this rule is in the pubs2 database, execute this command from pubs2:

Displays the source text of $sp_helptext$. Since system procedures are stored in sybsystemprocs, execute this command from sybsystemprocs:

```
sp_helptext sp_helptext
```

Example 3

Displays the source text of the myproc group behavior where you specify no <number> argument. The number of the procedure displays beside the text:

```
sp_helptext myproc
```

Example 4

Displays the source text of myproc, specifying a procedure in the <myproc> group but displaying no grouping number.

```
sp_helptext myproc, 2
# Lines of Text
```

```
1
text
create procedure myproc;2 as select 2
```

Example 5

Generates text for sp_help:

```
sp_helptext sp_help, NULL, NULLM 'showsql'
```

Example 6

To generate text for sp help, producing line numbers:

```
sp_helptext sp_help, NULL, NULL, 'showsql, linenumbers'
```

Example 7

To generate the text for <code>sp_help</code>, in a context block of seven lines starting at line 25, with output generated in a comment block:

```
sp_helptext sp_help,25,7,'showsql,comments,context'
```

Generates the text for <code>sp_droptabledef</code>, producing the output as a stand-alone DDL script that you can use to recreate the procedure:

```
sp_helptext sp_droptabledef,NULL,NULL,'showsql,ddlgen'
use sybsystemprocs
```

Example 9

Uses sp_helptext on a view created with delimited identifiers. You need not use set quoted_identifier on to extract the SQL defining the view. You do, however, need it to create objects using delimited identifiers:

Example 10

The SAP ASE server displays the text for predicates. sp_helptext can be supplied the predicate's user-defined name, if there is one, or its internal name. For example:

```
sp_helptext pred1
# Lines of Text
------
```

```
text -----
grant select on tab1 where col1 = 5 as pred1 to robert
```

Usage

There are additional considerations when using sp helptext:

- sp helptext truncates trailing spaces when displaying the source text from syscomments
- sp_helptext prints out the number of rows in syscomments (255 characters long each) that are occupied by the compiled object, followed by the source text of the compiled object.
- The source-text is displayed using char (255), so trailing spaces are present in the displayed text. The text stored in syscomments may not include these trailing spaces. syscomments stores the text "as supplied," so another application or tool may not have included these trailing spaces. Because of this, you should not use sp helptext to get a copy of the text stored. Instead, use other tools like defncopy.
- sp helptext looks for the source text in the syscomments table in the current database.
- You can encrypt the source text with sp hidetext.
- When sp_helptext operates on a group of procedures, it prints the number column from syscomments in addition to the source text.
- A system security officer can prevent the source text of compiled objects from being displayed to most users who execute <code>sp_helptext</code>. To restrict <code>select</code> permission on the <code>text</code> column of the <code>syscomments</code> table to the object owner or a system administrator, use <code>sp_configure</code> to set the <code>select</code> on <code>syscomments.text</code> column parameter to 0. This restriction is required to run SAP ASE in the evaluated configuration. See the <code>System Administration Guide</code> for more information about the evaluated configuration.
- Even when you use sp helptext in ddlgen mode, the showsql print option is required.
- The object with text that you want to retrieve must reside in the database where the procedure is executed.
- If the text is either hidden or not in syscomments, an error message is raised. If, however, you request a context block output, and the text is missing or hidden, a message reporting the missing text is printed, but no error is raised.
- Text generated using the ddlgen print option may still fail to create a compiled object correctly if it contains references to other objects, such as temporary tables, that do not already exist when the generated script is executed.
- If the compiled object contains a select * statement, it usually reflects the entire column list of the table this statement references.
- You can generate SQL text for compiled objects created with quoted identifiers, but if the compiled object contains a select * statement, the expanded column list appears with bracketed identifiers after the SAP ASE server writes the text to syscomments. For example:

```
[this column], [column name with space]
```

It is not necessary to set <code>quoted_identifier</code> ON when generating text for compiled objects that are themselves, or use, delimited identifiers.

Permissions

The permission checks for ${\tt sp_helptext}$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the object owner, the database owner, or a user

with own database privilege.

Disabled With granular permissions disabled, you must be the object owner, database owner, or a user with

sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_checksource [page 150]
sp_configure [page 203]
sp_hidetext [page 497]
System Procedure Tables [page 14]

1.159 sp_helpthread

Displays the current thread pool configuration.

Syntax

sp helpthread [<pool name>]

Parameters

<pool name>

name of the pool to show. If pool_name> is null, sp_helpthread displays configuration information about all pools.

Examples

Example 1

Displays information about all pools:

```
name type size idle_timeout

description

pubs_pool Engine 2 100

syb_blocking_pool RTC 4 0

A pool dedicated to executing blocking calls
syb_default_pool Engine 1 100

The default pool to run query sessions
syb_system_pool RTC 4 0

The I/O and system task pool
```

Example 2

Displays information about the pubs pool:

```
name type size idle_timeout description

pubs_pool Engine 2 100 NULL
thread_id osthread_id state affinity instance_id

12 1248065856 IDLE NULL 0
13 1237576000 IDLE NULL 0
```

Usage

 $\verb|sp_helpthread| gathers| information| for its reports| from the \verb|monThread| monitoring| table.$

 $\verb"sp_helpthread" produces output only in threaded mode.$

Permissions

Any user can issue $sp_helpthread$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.160 sp_helpthreshold

Reports the segment, free-space value, status, and stored procedure associated with all thresholds in the current database or all thresholds for a particular segment.

Syntax

sp helpthreshold [<segname>]

Parameters

<segname>

is the name of a segment in the current database.

Examples

Example 1

Shows all thresholds on the log segment:

sp helpthreshold logsegment

Example 2

Shows all thresholds on all segments in the current database:

sp helpthreshold

Example 3

Shows all thresholds on the default segment. Note the use of quotes around the reserved word "default":

sp_helpthreshold "default"

Usage

 $sp_helpthreshold$ displays threshold information for all segments in the current database. If you provide the name of a segment, $sp_helpthreshold$ lists all thresholds in that segment.

The status column is 1 for the last-chance threshold and 0 for all other thresholds. Databases that do not store their transaction logs on a separate segment have no last-chance threshold.

Permissions

Any user can execute $sp_helpthreshold$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addthreshold [page 62] sp_dropthreshold [page 323] sp_helpsegment [page 479] sp_modifythreshold [page 598] sp_thresholdaction [page 809]

1.161 sp_helptrigger

 $sp_helptrigger$ lists all triggers created on the table specified by <tablename>; which command (insert, update, or delete) fires the trigger, and the trigger's order number.

Syntax

sp helptrigger <tablename>

Parameters

<tablename>

is the name of the table.

Permissions

Any user can execute sp_helptrigger.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.162 sp_helpuser

Reports information about a particular user, group, or alias, or about all users, in the current database. Also identifies objects and user-defined datatypes owned by a user.

Syntax

```
sp_helpuser [<name_in_db> [, <display_object>]]
```

Parameters

<name in db>

is null or name of a valid user in the current database.

<display_object>

lists all objects and user-defined datatypes owned by <name_in_db> in the current database. If <name_in_db> is null, the objects and user-defined datatypes owned by the caller are listed. The output for objects includes object_name, object_type, and create_date, sorted by object_type and object_name. The output for user-defined datatype includes user type name.

Example 1

Displays information about all users in the current database:

Example 2

Displays information about the database owner (user name "dbo"):

```
Users_name ID_in_db Group_name Login_name

dbo 1 public sa
Users aliased to user.
Login_name

andy
christa
howard
linda
```

Example 3

Displays objects owned by the user bill:

```
Object_name Object_type Create_date

proc_update_titles stored procedures author user table Apr 27 2007 04:47PM
publisher user table Apr 27 2007 05:47PM
titles user table Apr 27 2007 06:47PM
vw_author_in_ca view Apr 27 2007 05:47PM
```

Example 4

Displays objects owned by the database owner (DBO):

```
Object_name Object_type Create_date
enter_key encryption key Sep 7 2007 03:37PM
sysalternatives system table Jul 17 2007 09:25AM
syscolumns system table Jul 17 2007 09:25AM
syscolumns system table Jul 17 2007 09:25AM
....
sysquerymetrics view Jul 17 2007 09:25AM
```

Usage

sp_helpuser reports information about all users of the current database. If you specify a <name_in_db>,
sp_helpuser reports information only on the specified user.

If the specified user is not listed in the current database's sysusers table, sp_helpuser checks to see if the user is aliased to another user or is a group name.

Permissions

Any user can execute $sp_helpuser$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_adduser [page 73]
sp_dropuser [page 326]
sp_helpgroup [page 452]
```

1.163 sp_hidetext

Hides the source text for the specified compiled object, as well as the text of computed columns, predicates, and function-based index keys. $sp_hidetext$ also encrypts the text for user-defined functions.

Syntax

```
sp_hidetext [<objname>[, <tabname>[, <username>]]]
```

Parameters

<objname>

specifies the compiled object for which to hide the source text.

<tabname>

specifies the name of the table or view for which to hide the source text.

<username>

specifies the name of the user who owns the compiled object for which to hide the source text.

Examples

Example 1

Hides the source text of all compiled objects in the current database:

```
sp_hidetext
```

Example 2

Hides the source text of the user-defined stored procedure, sp sort table, that is owned by Mary:

```
sp_hidetext @objname = "sp_sort_table",
    @username = "Mary"
```

Example 3

Hides the source text of the stored procedure pr phone list:

```
sp_hidetext "pr_phone_list"
```

Example 4

Hides the source text of all check constraints, defaults, and triggers defined on the table my_tab:

```
sp_hidetext @tabname = "my_tab"
```

Example 5

Hides the source text of the view my_vu and all check constraints, defaults, and triggers defined on the table my_tab :

```
sp_hidetext "my_vu", "my_tab"
```

Example 6

Hides the source text of all compiled objects that are owned by Tom:

```
sp hidetext @username = "Tom"
```

Usage

There are additional considerations when using sp_hidetext:

• sp_hidetext hides the source text for the specified compiled object.

Before executing $sp_hidetext$, make sure you have a backup of the source text. The results of executing $sp_hidetext$ are not reversible.

- If you do not provide any parameters, sp_hidetext hides the source text for all compiled objects in the current database.
- sp_helprotect .. expand_predicate prints a null predicate if text has been hidden.
- Hidden syscomments.text is not available for use by sp_helprotect.
- The SAP ASE server allows the predicate owner or the SSO to hide the text of a predicate. Hidden syscomments.text is not available for use by sp_helprotect. Users must be warned that the expand predicate option of sp helprotect prints a null predicate if text has been hidden.
- If you use sp_hidetext followed by a cross-platform dump and load, you must manually drop and recreate all hidden objects.

See also:

- dump database, dump transaction, load database, load transaction in *Reference Manual:*Commands
- Transact-SQL Users Guide for more information about hiding source text.

Permissions

The permission checks for $sp_hidetext$ differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage database privilege.
	Any user can execute sp_hidetext to hide the source text of their own compiled objects.
Disabled	With granular permissions disabled, you must be the datatype owner or a user with sa_role.
	Any user can execute $\mathtt{sp_hidetext}$ to hide the source text of their own compiled objects.

Auditing

You can enable security auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information Value

Audit option security

Event 145

Command or access

audited

sp hidetext

Information in extrainfo

- Roles Current active roles
- Keywords or options NULL
- Previous value NULL
- Current value NULL
- Other information Total number of objects for which sp_hidetext was executed, and object ids from syscomments table.
- **Proxy information** Original login name, if set proxy in effect

This is an example of extrainfo column:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; Total 1
    object(82096302); ; sa/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_checksource [page 150]

1.164 sp_import_qpgroup

Imports abstract plans from a user table into an abstract plan group.

Syntax

```
sp_import_qpgroup <tab>, <usr>, <group>
```

Parameters

<tab>

is the name of a table from which to copy the plans. You can specify a database name, but not an owner name, in the form <dbname>..<tablename>. The total length can be up to 255 characters long.

<usr>

is the name of the user whose ID should be assigned to the abstract plans when they are imported.

<group>

is the name of the abstract plan group that contains the plans to be imported.

Examples

Example 1

Copies plans from the table moveplans to the new_plans group, giving them the user ID for the database owner:

```
sp import qpgroup moveplans, dbo, new plans
```

Usage

There are additional considerations when using <code>sp_import_qpgroup</code>:

- sp_import_qpgroup copies plans from a user table to an abstract plan group in sysqueryplans. With sp_export_qpgroup, it can be used to copy abstract plan groups between servers and databases, or to copy plans belonging to one user and assign them the ID of another user.
- sp_import_qpgroup creates the abstract plan group if it does not exist when the procedure is executed.
- If an abstract plan group exists when <code>sp_import_qpgroup</code> is executed, it cannot contain any plans for the specified user. <code>sp_import_qpgroup</code> does not check the query text to determine whether queries already exist in the group. If you need to import plans for a user into a group where some plans for the user already exist:
 - Use sp import approup to import the plans into a new plan group.
 - Use sp_copy_all_qplans to copy the plans from the newly-created group to the destination group. sp_copy_all_qplans does check queries to be sure that no duplicate plans are created.
 - o If you no longer need the group you created for the import, drop the plans in the group with sp copy all qplans, then drop the group with sp drop qpgroup.
- To create an empty table in order to bulk copy abstract plans, use:

```
select * into load_table
from sysqueryplans
where 1 = 2
```

See also create plan in Reference Manual: Commands.

Permissions

The permission checks for <code>sp_import_qpgroup</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Disabled With granular permissions disabled, you must be the datatype owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_export_qpgroup [page 364]
sp_help_qpgroup [page 410]
```

1.165 sp_imrs

Manages and monitors an in-memory row storage cache, and synthesizes component-specific reports from IMRS-specific monitoring tables and other internal data sources.

Syntax

```
sp_imrs <action> [, <object> [, <filter> [, <secondary_filter> ] ]
```

Parameters

i Note

Most <action> parameters displayed by help are mostly for internal use (for troubleshooting the IMRS system), and are used by technical support. Only the help, show, and pack_rows <action> parameters are available for users. Avoid the using other <action> parameters unless instructed by SAP product support to do so.

<action>

specifies one of the following actions performed by sp imrs:

- help displays usage information with examples.
- show displays in-memory row storage usage metrics such as row counts, memory usage, and so on.
- clear removes SPIDs from the queue that are preventing other processes from running.
- pack_rows forces a pack of the rows from the IMRS, freeing the specified percentage of pages or number or allocation units from sysimrslogs. The syntax to pack rows from the IMRS is:

```
[ 'aus', '<number_of_allocation_units_to_pack>' | 'pct',
<'percentage_of_allocation_units_to_pack>' ]
```

The pack rows subcommand includes the following:

- aus indicates you are freeing this number of allocation units from sysimrslogs.
- o <number_of_allocation_units> is the number of allocation units you are packing.
- pct indicates you are freeing this percentage of the rows from the sysimrslogs.
- o <percentage_of_allocation_unit_to_pack> the percentage of IMRS
 rows you are packing.

<object>

specifies one of the following objects:

- all metrics displays output of all sp_imrs 'show' subcommands.
- blocking_spid displays a list of SPIDs that are blocking other processes.
- cacheinfo displays a summary of IMRS cache usage metrics.
- effectiveness displays the effectiveness of IMRS data for insert, select, update, and delete operations for all row types. For example, the UpdOfMig column indicates how many times a migrated row in IMRS was updated in IMRS.
- gcinfo displays general information about garbage collection threads, such as status, last wakeup, and the number of transactions pending that need to be attended to by the garbage collector.
- gcstats displays statistical information about garbage collector threads, such as total memory freed by the garbage collector, and the number of versions freed by the garbage collector.

- ilm_metrics displays output of all ILM-related subcommands, including metrics for ilmstats, ilmpcts, and effectiveness.
- ilmstats displays the row count-related statistics used by ILM.
- ilmpcts displays counts and percentages of DML events affected by ILM.
- memusage displays memory usage metrics for different types of rows, and for metadata in the IMRS.
- metrics displays memory and row count-related metrics.
- pack_efficiency displays metrics indicating the efficiency of pack operation on various tables, and the overall efficiency of a cache.
- pack memstats displays metrics on pack thread and subsystem memory usage.
- pack metrics displays details for all pack-related subcommands.
- pack_rowstats displays metrics related to pack subsystem row-count. For example, the total percentage of inserted rows that are packed.
- rowcounts displays counts for rows in the IMRS.
- sysimrslogs displays details about sysimrslogs (for example, the number of pages, first page, last page, and so on).
- tables displays a summary of row counts for tables with IMRS-resident data, and the percentage of rows in the IMRS for each table.
- versionstats displays statistical information about the data row versions, such as the number of versions, size of the older versions, and the size of the latest versions.

<filter>

specifies a filter on the cache or database name.

<secondary_filter>

specifies a filter on the table name, partition name, or SPID.

Examples

Example 1

Describes the full syntax and usage for sp imrs.

```
sp imrs <action> [,<object> [, <filter> [, <secondary filter> ] ] ]
  where:
  <action> is one of:
   - 'help'
   - 'show'
   - 'clear'
   - 'pack_rows'
  <object > is one of:
   - 'all metrics'
  - 'aus'
   'blocking_spid'
   - 'cacheinfo'
   - 'effectiveness'
  - 'ilm_metrics'
   - 'ilmstats'
   - 'ilmpcts'
   - 'versionstats'
```

```
- 'gcinfo'
   - 'qcstats'
   - 'memusage'
   - 'metrics'
   - 'pack efficiency'
   - 'pack memstats'
   - 'pack_metrics'
   - 'pack_rowstats'
   - 'pct'
   - 'rowcounts'
   - 'sysimrslogs'
   - 'tables'
   <filter> is the cache name or database name.
   <secondary filter> is the name of the table, partition, or the SP ID.
Examples:
 -- Show list of IMRS-enabled tables in a database
  sp imrs show, tables, perf test db
  -- Show top-level cache information for all IMRS caches:
  sp imrs show, cacheinfo
  -- Show cache information or memory usage for specific IMRS cache:
  sp_imrs show, cacheinfo, imrs_cache
sp_imrs show, memusage, 'imrs_cache%'
  -- Show row counts:
  sp imrs show, 'rowcounts', 'my imrs'
  -- Show version stats:
 sp_imrs show, 'versionstats'
sp_imrs show, 'versionstats', 'my_imrs'
sp_imrs show, 'versionstats', 'my_imrs', '<tablename>'
-- Show GC statistics or information:
  sp_imrs show, gcstats
  sp_imrs show, gcinfo
  sp_imrs show, gcstats, 'imrs_cache%'
sp_imrs show, gcinfo, 'imrs_cache%'
      Show top-level information for pack subsystem:
  sp_imrs show, pack_metrics
     Show information about SPIDS blocking GC threads:
  sp_imrs show, blocking_spid
  sp_imrs show, blocking_spid, 'imrsdb'
     Clear a SPID off the system which may be blocking GC threads:
 sp_imrs clear, blocking_spid, 'imrsdb'
sp_imrs clear, blocking_spid, 'imrsdb', '<spid>'
  NOTE: This command requires an additional 'sa role' to execute
  -- Show sysimrslogs details for an IMRS-enabled database
  -- Execute this command from an IMRS-enabled database:
  sp imrs show, sysimrslogs
```

displays information about the IMRS-enabled tables in the tpcc database:

816002907 dbo	item	1	0	100000	98992	98.99
720002565 dbo	new order	1	0	2742647	2682071	97.79
784002793 dbo	order line	1	0	136237347	69654012	51.12
752002679 dbo	orders	1	0	13644204	7400261	54.23
848003021 dbo	stock	1	0	24000000	10596743	44.15
592002109 dbo	warehouse	1	0	240	240	100.00

The database name argument is optional. When not provided, the current database is examined for IMRS-enabled tables.

Example 3

displays information about the imrs cache:

```
sp_imrs 'show', 'cacheinfo', 'imrs_cache'
CacheName DBName TotalSizeMB UsedSizeMB FreeSizeMB PctUtil UsedSizeHWM
PctUtilHWM NumTables NumRows NumRowsHWM NumVersions NumVersionsHWM

imrs_cache tpcc 153600.21 42884.98 110715.23 27.91 45516.02
29.63 9 98201102 98201102 0 586282
```

Example 4

displays information lifecycle management (ILM) metrics for the imrs cache:

The score column represents the amount of benefit to this table if you include it in the IMRS, and how suitable this table is for the IMRS. Typically, higher values for score indicates columns that are more suitable for the IMRS. In this example, the warehouse table is suited to be IMRS-enabled, and the history table does not use DMLs on these tables.

displays ILM metrics for imrs_cache:

displays memory usage information about the imrs_cache (sp_imrs internally issues sp_imrs show, rowcounts, imrs cache and sp imrs show, sysimrslogs, imrs cache):

Example 14

displays row counts for the imrs cache:

DBName Owne	n, rowcounts, : erName ObjectNa chedRows NIns	ame $\overline{N}R$	ows 1			s 1	NVersHWM	NInsRows	
	7] [Totals] 974637	_	201102	98202326	0	0	715406	76403190	
tpcc dbo	order_l:	lne 69	654448	69654471	-	0	214648	61546676	
-	426602 stock			10596745	0	0	322917	0	
10586259 tpcc dbo		0 7	-	7400262	0	0	21409	6153641	
	430798	0	0	6000000	0	0	•		
tpcc dbo 6020729	history 0	0	020729	6020729		0 (0

0 2400	0	0	0	0	0		
0 240	warenouse 0	0	0	0	0	28/42	
(10 rows affective Total number of	*						
(10 rows affect	*	240	240	0	0	28742	

displays sysimrslogs information for the imrs cache:

<pre>sp_imrs show, sysimrslogs, imrs_cache **** Description</pre>	Value	Comment
Total number of pages in imrslogsegment 250000.00 MB	16000000	
Total number of pages in use 56212.30 MB (22.48 %)	3597587	
Number of non-truncatable pages	3597587	
56212.30 MB (22.48 %) Number of truncatable pages 0.00 MB (0.00 %)	0	
Total number of free pages of imrslogsegment 192811.13 MB (77.12 %)	12339912	
First page ID of sysimrslogs Last page ID of sysimrslogs	9600001 13211696	
Page ID of oldest non-truncatable page	9600001	
Percentage of active space that can be freed by DUMP TRAN Number of pages reserved for Last-Chance Threshold (LCT) 12500.00 MB (5.00 %)		

Example 16

displays the SPIDs that are currently blocking processes:

```
sp imrs show, 'blocking spid'
SPID UserName HostName OSPID StartTime NTransBlocked DBName
Status
            big_machine 32441 Mar 29 2017 2:24AM
 36 dbo
                                                              0 imrsdb
recv sleep
            bigger_machine 6381 Mar 29 2017 2:27AM
                                                              0 imrsdb2
 37 dbo
recv sleep
Above SPID(s) are active in the server.
GC threads will be unblocked when the transaction completes (commit / abort)
If the SPID has become unresponsive, you may disconnect it and run the
following -
sp_imrs 'clear', 'blocking_spid', '<dbname>', '<spid>'
Running the above command on an active connection may result in data
corruption.
Please exercise due caution!
```

Remove blocking SPID number 36 with this command:

```
sp_imrs clear, 'blocking_spid', 'imrsdb', '36'
SPID 36 is active in the system.
Cleaning up an active process may result in data corruption. Action aborted!
(return status = 0)
```

displays all metrics for imrs_cache:

```
sp imrs 'show', 'all metrics', 'imrs cache'
  *** Execute: sp_imrs show, tables, tpcc ****

Example 21

displays the SPIDs that are currently blocking the IMRS garbage collector:

sp_imrs show, 'b SPID UserName Ho DBName Status		OSPID St	tartTin	ne 	NTran	sBlocked
36 dbo b	oig machine	66666 N	Mar 29	2017	2:24AM	0
imrsdb recv sle	ep					
37 dbo b	-	99999 N	Mar 29	2017	2:27AM	0
imrsdb2 recv sle		33333 1	102 23		_ , _ , ,	· ·
	-					
To unblock GC of	f database imrsc	db, execı	ute the	e follo	owing -	

```
sp_imrs clear, 'blocking_spid', 'imrsdb','36'
```

displays the SPIDs that are currently blocking the IMRS garbage collector, and filters the result on the database name:

```
sp_imrs show, blocking_spid, 'imrsdb'
SPID UserName HostName OSPID StartTime NTransBlocked DBName
Status

36 dbo big_machine 66666 Mar 29 2017 2:24AM 0 imrsdb
recv sleep
To unblock GC of database imrsdb, execute the following -
sp_imrs clear, 'blocking_spid', 'imrsdb','36'
```

Example 23

removes a specific SPID (SPID 36) blocking the garbage collector threads:

```
sp_imrs clear, 'blocking_spid', 'imrsdb', '36'
Successfully cleared Blocking SPID 36 from the system.
```

Example 24

Checks for SPIDs that are blocking a specific database, and clears any blocks it finds. In this example, the database imrsdb2 contains a blocking SPID 38:

```
sp_imrs clear, 'blocking_spid', 'imrsdb2'
Successfully cleared Blocking SPID 38 from the system.
```

sp imrs returns silently if there are no blocking SPIDs in the system.

Example 25

Pack four allocation units of rows from the IMRS, freeing this space from sysimrslogs:

```
sp_imrs 'pack_rows', 'aus', '4'
```

Example 26

Packs the number of rows needed to free 30% of sysimrslogs pages:

```
sp_imrs 'pack_rows', 'pct', '30'
```

Usage

- The 'aus', <'number_of_allocation_units_to_pack'> parameter packs the specified number of allocation units of sysimrslogs from the IMRS to the pagestore, freeing this amount of space in sysimrslogs. SAP ASE issues an error message if the number specified by <number_of_allocation_units_to_pack> is greater than the total number of allocation units present in the IMRS log, and suggests that you decrease the number of allocation units.
- The 'pct', <'percentage_of_allocation_units_to_pack'> packs the specified percentage of IMRS log pages of sysimrslogs from the IMRS to the pagestore, freeing this amount of space in sysimrslogs. SAP ASE issues an error message if the percentage of allocation units is greater than the total number of allocation units available in the IMRS log.

Permissions

Most sp_imrs commands require the mon_role for successful execution. The command sp_imrs clear, blocking spid requires the sa role.

1.166 sp_imrslog_thresholdaction

Creates a threshold for the minimum number of free pages in a database.

When the number of free pages falls below this threshold, the server moves a number of pages, starting with the oldest inserted transaction, until the total number of inactive pages (those that can be released by executing dump transaction) plus the number of free imrslog pages is larger than the threshold level plus the 10% of the total used space when the threshold was triggered. That is:

```
[(total number of inactive pages) + (number of free imrslog pages)] > [(threshold level) + (10% of total used space)]
```

However, $sp_imrslog_thresholdaction$ does not run if the threshold is explicitly associated with a different procedure. If the $sp_thresholdaction$ system procedure has been created, it is called after the oldest inserted transaction is moved.

Syntax

```
sp_imrslog_thresholdaction <database_name>, <segment_name>, <space_left>,
<status>
```

Parameters

Example 1

This example creates

1. Create the test database:

```
create database test on testdat=100 log on testlog=100 imrslog on testimrslog=100 row storage on imrs_cache

CREATE DATABASE: allocating 51200 logical pages (100.0 megabytes) on disk 'testdat' (51200 logical pages requested).

CREATE DATABASE: allocating 51200 logical pages (100.0 megabytes) on disk 'testlog' (51200 logical pages requested).

CREATE DATABASE: allocating 51200 logical pages (100.0 megabytes) on disk 'testimrslog' (51200 logical pages requested).

Warning: The database 'test' is using an unsafe virtual device 'testdat'.

The recovery of this database can not be guaranteed.

Database 'test' is now online.

(return status = 0)
```

2. Determine the thresholds for the test database:

```
use test
go
sp helpthreshold
qo
segment name free pages last chance threshold procedure
                    25600
                               0 sp_imrslog_thresholdaction
imrslogsegment
imrslogsegment
                    2560
                                    1 sp imrslog thresholdaction
                     3656
                                     1 sp thresholdaction
logsegment
(3 rows affected)
(return status = 0)
```

When the imrslog fills, the server writes a message similar to this to the error log:

```
The procedure sp_imrslog_thresholdaction has triggered in database 'test' for segment 'imrslogsegment' with 25600 pages left.

It will run until 28160 pages are free or inactive. Database 'test' (retcode = 2, 11 pack ops) Required to pack 2560 pages:

The number of inactive pages has changed from 0 to 2805 (delta 2805). The number of free pages has changed from 25600 to 25507 (delta -93). 2805 rows have been packed. Elapsed time 0 h, 0 m, 0 s
```

In this scenario, the number of imrslog free pages decreased because moving rows from the row storage cache to the page store requires logging to the imrslog, and the number of pages that could be freed by executing dump tran changed from 0 to 2805.

The threshold procedure ended the execution because the total number of inactive pages (25507) plus the number of free imrslog pages (2805) equals 28312, which is greater than the threshold level (25600) plus 10% of the total used space (25600 X .1), which equals 28160. That is:

```
[25507 + 2805] > [25600 + (25600)(.1)]
```

3. However, if you create a procedure to truncate the logs similar to this:

```
create or replace procedure sp_thresholdaction

@dbname sysname,

@segmentname sysname,

@space_left int,

@status int

as
```

```
print "sp_thresholdaction %1!,%2!,%3!,
%4!",@dbname,@segmentname,@space_left, @status
   dump tran @dbname with truncate_only
```

sp_imrslog_thresholdaction clears the pages from the log, moving pages to the page store, and moving the oldest insert transaction forward:

```
The procedure sp_imrslog_thresholdaction has triggered in database 'test' for segment 'imrslogsegment' with 25600 pages left.

It will run until 28160 pages are free or inactive.

sp_thresholdaction test, imrslogsegment, 25600, 0 Database 'test' (retcode = 2, 11 pack ops) Required to pack 2560 pages: The number of inactive pages has changed from 0 to 2805 (delta 2805). The number of free pages has changed from 25600 to 28312 (delta 2712). 2805 rows have been packed. Elapsed time 0 h, 0 m, 0 s
```

sp_thresholdaction truncates the log so all the pages from the first imrslog page to the new oldest inserted transaction are freed, creating a positive delta value.

Usage

- sp_imrslog_thresholdaction returns without executing any code if the <segment_name> is any segment other than imrslogsegment.
- sp imrslog thresholdaction is installed in sybsystemprocs.

1.167 sp_indsuspect

Checks user tables for indexes marked as suspect during recovery following a sort order change.

Syntax

```
sp_indsuspect [<tab_name>]
```

Parameters

<tab name>

is the name of the user table to be checked.

Example 1

Checks the table newaccts for indexes marked as suspect:

sp_indsuspect newaccts

Usage

sp_indsuspect with no parameter creates a list of all tables in the current database that have indexes that need to be rebuilt as a result of a sort order change. With a <tab_name> parameter, sp_indsuspect checks the specified table for indexes marked as suspect during recovery following a sort order change.

Use sp_indsuspect to list all suspect indexes. The table owner or a system administrator can use dbcc reindex to check the integrity of the listed indexes and to rebuild them if necessary.

See also dbcc in Reference Manual: Commands.

Permissions

Any user can execute $sp_indsuspect$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.168 sp_jreconfig

Manages the Java PCA/JVM. Enables or disables arguments and directives, changes configuration values, and reports configuration values.

Syntax

i Note

You can safely change the pca_jvm_module_path, pca_jvm_work_dir, pca_jvm_dbg_agent_port, pca_jvm_java_dbg_agent_suspend, pca_jvm_java_options, and pca_jvm_netio arguments. Do not use $sp_jreconfig$ to change other arguments or directives unless instructed to do so by Sybase Technical Support.

Parameters

disables, but does not delete, all elements in an argument array. Sets each element to disabled.

delete

removes an existing element from an argument array. Use delete only with arguments where <units type> is array.

disable

disables the specified directive or argument.

<string value>

identifies an array element in the named argument array that is to be deleted, enabled, or disabled.

directive

is the name of a valid directive.

argument

is the name of a valid argument.

enable

enables a directive or an argument.

list

lists groups of related arguments as, for example, <code>sp_jreconfig list</code>, <code>directives or sp_jreconfig list</code>, <code>enabled</code>. Also, lists all arguments of a specific type as, for example, <code>sp_jreconfig list</code>, <code>units</code>, <code>string</code>. To see all <code>current < units types > values</code>, use <code>sp jreconfig list</code>, <code>units</code>.

formatted

formats the displayed list for readability; longer values may be truncated.

i Note

In formatted reports, the process of improving readability may truncate wide columns. In addition, column headings may be overridden and may not match the actual table name. Do not format reports if the output is to be parsed or potential data truncation is not acceptable.

type>

specifies a type of list. Values are:

- directives list of directives
- enabled list of enabled arguments
- disabled list of disabled arguments
- argnames list of argument names, each argument's <units_type>, and the
 directive to which each belongs

units

when used with list, generates a list of <units type> currently in use.

<units_type>

is a type of argument. Every argument has a <units_type> that identifies its type. Values are:

- switch
- string
- number
- array

reload config

reloads the configuration from the sybpcidb tables into memory. See *Java in Adaptive Server Enterprise > Restoring Default Configuration Values to sybpcidb*.

report

creates a report based on arguments supplied. Usually used to generate a report for an argument to see its current value and whether or not it is enabled. Can also be used to generate a report for a directive or its arguments.

<directive>

is any valid directive.

args

is a keyword used with report to generate a list of argument names for the named directive. For example:

```
sp_jreconfig report, "PCA_JVM", "args"
```

update

modifies a string or numeric value for an argument where <units_type> is string, number, or array. You cannot modify an argument when <units_type> is switch.

<old value>

is a string or numeric value that identifies the existing argument or array element being updated.

<new_value>

is a string or numeric value that defines the new argument or array element.

Examples

Generating Formatted Report

Generates a formatted report for the PCA JVM OPT directive:

```
sp_jreconfig "report", "PCA_JVM_OPT", "formatted"
```

Generating Report of Arguments

Generates a report of the arguments of the PCA_JVM_OPT directive:

```
sp_jreconfig "report", "PCA_JVM_OPT", "args"
```

Generating Report of Argument

Generates a report for the argument pca_jvm_netio:

```
sp_jreconfig "report", "pca_jvm_netio"
```

Generating Report of All Arguments

Generates a report for all arguments that match "pca_jvm". A partial argument name generates a report for all matching arguments:

```
sp_jreconfig "report", "pca_jvm"
```

Generating Lists

Displays a list of all directives and their state (enabled or disabled):

```
sp_jreconfig "list", "directives"
```

Generating Lists

Displays a list of all arguments, their units types, and directives:

```
sp_jreconfig "list", "argnames", "formatted"
```

Generating Lists

Displays a list of all currently enabled arguments:

```
sp_jreconfig "list", "enabled"
```

Generating Lists

Displays a formatted list of all array arguments:

```
sp_jreconfig "list", "units", "array", "formatted"
```

Generating Lists

Display a list of argument unit types:

```
sp_jreconfig "list", "units"
```

The report for this command is formatted by default. Using the "-formatted" option generates an error.

Enabling Directives and Arguments

Enables the PCA JVM WORK DIR directive:

```
sp_jreconfig "enable", "PCA_JVM_WORK_DIR"
sp_jreconfig "enable", "WORK_DIR"
```

You can use a partial directive name as long as it includes sufficient information to uniquely identify the

Enabling Directives and Arguments

Enables the pca jvm netio argument:

```
sp_jreconfig "enable", "pca_jvm_netio"
```

Disabling Directives and Arguments

Disables the WORK_DIR directive. This example uses a partial directive name, which must include sufficient information to uniquely identify the directive:

```
sp_jreconfig "disable", "WORK_DIR"
```

i Note

Disabling a directives causes its arguments to behave as disabled, but does not change their base states

Disabling Directives and Arguments

Disables the pca jvm netio argument:

```
sp_jreconfig "disable", "pca_jvm_netio"
```

Disabling Directives and Arguments

Disables array elements in PCA JVM WORK DIR:

```
sp_jreconfig "disable", "pca_jvm_work_dir", "/some/path"
```

The path, but not the permissions mask, is required. See *Java in Adaptive Server Enterprise > File and Network Access Using Java*.

Updating String, Number, and Array Arguments

Updates a string argument:

This example updates the file location of the pca jvm log filename argument.

i Note

You cannot use update with directives or switch argument, as these items can not be modified.

Updating String, Number, and Array Arguments

Updates a number argument:

```
sp_jreconfig "update", "pca_jvm_min_port", "1026", "2056"
```

Numeric values must be enclosed in quotes (as strings) for the stored procedure. The SAP ASE server stores them as numeric values.

Updating String, Number, and Array Arguments

For the PCA_JVM_WORK_DIR directive, work_dir values consist of a path and an optional permission mask. Although the permission mask is optional, you must include the original string path to identify the work_dir. A permission mask is optional. If it is not supplied, the system uses a default mask with an octal equivalent of 0666. Example a does not set a permission mask; it uses the default mask. Examples b and c each set a permission mask of 0644:

```
[a] sp_jreconfig "update", "pca_jvm_work_dir",
   "/old/path", "/new/working/directory"

[b] sp_jreconfig "update", "pca_jvm_work_dir",
   "/old/path", "/new/working/directory(u=rw,go=r)"

[c] sp_jreconfig "update", "pca_jvm_work_dir",
   "/old/path", "/new/working/directory(u+w,ugo+r)"
```

Adding Array Elements

Adds new elements to the $pca_jvm_work_dir$ argument array in the $PCA_JVM_work_dir$ directive. Example a uses the default mask. Examples b and c each set a permissions mask of 0644 (the mask is evaluated from left to right):

```
[a] sp_jreconfig "add", "pca_jvm_work_dir", "/new/working/directory"

[b] sp_jreconfig "add", "pca_jvm_work_dir", "/new/working/directory(u=rw,go=r)"

[c] sp_jreconfig "add", "pca_jvm_work_dir", "/new/working/directory(u+w,ugo+r)"
```

Deleting Array Elements

Deletes an array element in pca jvm work dir:

```
sp_jreconfig "delete", "pca_jvm_work_dir", "/new/working/directory"
```

i Note

To delete a an element in $pca_jvm_work_dir$ in the $PCA_JVM_WORK_DIR$ directive, you can specify a partial string if the string supplied identifies a unique record. The permission mask is not required; you only need to supply the path even if the $work_dir$ element was originally defined with a specific permission mask.

Enabling or Disabling All Elements in an Array

Disables all elements in the pca jvm work dir array:

```
sp_jreconfig "array_enable", "pca_jvm_work_dir"
```

Enabling or Disabling All Elements in an Array

Disables all elements in the pca_jvm_work_dir array:

```
sp_jreconfig "array_disable", "pca_jvm_work_dir"
```

Clearing All Records in an Array

Deletes all records in the pca_jvm_work_dir array and creates an empty array:

```
sp_jreconfig "array_clear", "pca_jvm_work_dir"
```

Reloading Default Configuration Values

Loads the configuration values stored in sybpcidb into memory:

```
sp_jreconfig "reload_config"
```

Usage

There are additional considerations when using sp jreconfig.

Enabling and disabling a directive works like a toggle. When a directive is:

- Enabled the SAP ASE server uses the configured value (enabled or disabled) of each argument. This is the value stored in sybpcidb.
- Disabled the SAP ASE server disregards the configured value (enabled or disabled) of each argument and treats all arguments of the directive as disabled, although the base value of each argument is retained in sybpcidb.

Arguments can be individually enabled or disabled. The types of arguments are:

- Switch these arguments turn a feature on or off. For example, if the argument for logging is enabled, a log file is generated; if the argument for logging is disabled, no log file is generated.
- String these arguments are for string and number values. Enabling a string or number argument ensures that the SAP ASE server uses the configured value. Disabling a string or number argument means that the SAP ASE server ignores the configured value and uses the default value. The configured and default values may or may not be the same.
- Array an array argument is a collection of related string arguments, each of which can be individually enabled or disabled. When an individual string argument (or element) is disabled, its value is ignored and the behavior is the same as if the element had been deleted. When enabled, the argument value is included in the collection and is active.
 - Array arguments can be enabled or disabled at will; you do not have to delete a value and then re-enter it later on.

Table 5: pca_jvm_module_path

pca_jvm_module_path configures the path to the JVM shared-object library. If you use a JRE other than that supplied by SAP, you must configure this argument to point to a location accessible to the PCA/JVM. This can be an absolute path or a relative path that extends \$SYBASE. If an absolute path, start the path with "/" on UNIX or "\" on Windows. Otherwise, the SAP ASE server assumes a relative path and looks under \$SYBASE.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_module_path	string	Platform- specific	Enabled	The location of the JVM shared library using a relative path located under \$SYBASE, or a fully qualified filename.

Table 6: pva_jvm_opt

This table describes pva_jvm_opt.

i Note

Do not change default values unless instructed to do so by SAP Technical Support.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_abort	switch	On	Enabled	Abort abort(2) all on any failure (dangerous).
<pre>pca_jvm_allow_unchecked_so ckops</pre>	switch	N/A	Disabled	Allow unchecked socket operations.
pca_jvm_debug	switch	N/A	Disabled	Report PCA_DEBUG requests.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_except	switch	N/A	Enabled	Report excepting PCA/VM JNI/JVM invocations.
pca_jvm_heap_ratio	string	0.3	Enabled	VM Heap / PCI memory ratio.
pca_jvm_jvmti	switch	N/A	Disabled	Java VM Tools Interface.
pca_jvm_min_port	number	1026	Enabled	Allow VM network support.
pca_jvm_netio	switch	N/A	Disabled	Allow VM network support.
pca_jvm_report	switch	N/A	Disabled	Report PCA/VM JNI/JVM invocations.
<pre>pca_jvm_security_manager_e nabled</pre>	switch	N/A	Disabled	Enable the SecurityManager in the PCA/JVM.
pca_jvm_sigcache_density	number	100	Enabled	PCA/VM signature cache target density.
pca_jvm_sigcache_enabled	switch	N/A	Enabled	Enable PCA/VM signature cache.
<pre>pca_jvm_sigcache_fixed_rat io</pre>	number	50	Enabled	PCA/VM signature cache size percentage fixed.
pca_jvm_sigcache_freeboard	number	30	Enabled	PCA/VM signature cache space recovery percentage on cache sweeps.
pca_jvm_sigcache_size	number	512	Enabled	PCA/VM signature cache size in KBytes.
pca_jvm_sigcache_size_type	number	1	Enabled	PCA/VM signature cache size_type 0:AS_PCT 1:Kbyte 2:Mbyte.
pca_jvm_sigcache_washcycle	number	1000	Enabled	PCA/VM signature cache wash daemon cycle time (ms).
pca_jvm_sigcache_washdaemo	switch	N/A	Disabled	Enable PCA/VM signature cache wash daemon.
pca_jvm_strace	switch	N/A	Enabled	Produce stack traces on none emulated VM handles.

Table 7: pca_jvm_dir_options

pca_jvm_dir_options configures the directory definitions used by the JVM for the ROOT and TEMP directories. Do not change these values unless you are a knowledgeable user or you have been directed to do so by SAP Technical Support.

⚠ Caution

Use this directive with care. The $pca_jvm_tmp_dir$ in the $pcA_JvM_DIR_OPTIONS$ directive should always point to the system temporary directory. Changing this location can be a serious security risk. The JVM allows files to be opened for reading and writing, and allows file creation in this directory.

Argument	Units type	Default value	Default state	Description
<pre>pca_jvm_root_d ir</pre>	string	Platform-specific	Enabled	Absolute path to the system root directory. Required for file I/O.

Argument	Units type	Default value	Default state	Description
pca_jvm_tmp_dir	string	Platform-specific	Enabled	Absolute path to the system temporary directory. Required for file I/O.

Table 8: pca_jvm_work_dir

pca_jvm_work_dir configures the JVM trusted directories. This argument consists of a collection of specific locations in your file system where your Java program classes can perform certain file I/O operations. Each directory can have an optional permission mask that defines which file I/O operations are allowed in each directory.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_work_ dir	array	Platform-specific	Disabled	The absolute path (and optional permission mask) where the JVM is allowed to do file I/O. See <i>File and Network Access Using Java</i> in <i>Java in Adaptive Server Enterprise</i> .

Table 9: pca_jvm_min_jni_version

pca jvm min jni version configures minimum backward compatible JNI version.

Argument	Units Type	Default Value	Default State	Description
<pre>pca_jvm_min_jni_ver sion</pre>	string	'JNI_VERSION_1_2'	Enabled	Minimum backward compatible JNI version.

Table 10: pva_jvm_logging

pva_jvm_logging configures JRE/VM logging options.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_ase_logging	switch	N/A	Enabled	Configure SAP ASE logging.
pca_jvm_log_filename	string	'/tmp/Java_vm.log1'	Disabled	A fully qualified filen ame that the VM uses for logging.

Table 11: pca_jvm_ext_class_loader

 $\verb"pca_jvm_ext_class_loader" configures global and database extension class loaders.$

Argument	Units Type	Default Value	Default State	Description
<pre>pca_jvm_ext_class_loader_ global</pre>	array	none	Disabled	Global Extension Class Loader.
<pre>pca_jvm_ext_class_loader_ dbase</pre>	array	none	Disabled	Database Extension Class Loader.

Table 12: pva_jvm_java_options

pva_jvm_java_options configures Java start-up options, both normal and extended.

Argument	Units Type	Default Value	Default State	Description
pca_jvm_java_opt ions	array	"- Djava.awt.headless=t rue"	Enabled	Run Java in headless mode.
pca_jvm_java_opt	array	"- Djava.compiler=JIT"	Enabled	Force JIT compilation and optimization.
<pre>pca_jvm_java_opt ions</pre>	array	"-XX:+CITune:"	Disabled	Time spent in JIT Compiler (1.4 only).
<pre>pca_jvm_java_opt ions</pre>	array	"-XX:+Use AltSigs"	Disabled	This option seems to crash the J2SE.
<pre>pca_jvm_java_opt ions</pre>	array	"- XX:CodeCacheExpansio nSize=512000"	Enabled	Code Cache extension size.
pca_jvm_java_opt	array	"-Xbatch"	Disabled	Disabled background compilation.
pca_jvm_java_opt	array	"-Xcheck:jni"	Enabled	Perform additional checks for JNI functions.
<pre>pca_jvm_java_opt ions</pre>	array	"-Xfuture"	Disabled	Perform strict checks, anticipating future default.
pca_jvm_java_opt	array	"-Xincgc"	Disabled	Enable incremental garbage collection.
pca_jvm_java_opt	array	"-Xint"	Disabled	Interpreted mode execution only.
pca_jvm_java_opt	array	"-Xloggc:./myGClog"	Disabled	Log GC status to a file with time stamps.
pca_jvm_java_opt	array	"-Xmixed"	Disabled	Mixed mode execution (default).
pca_jvm_java_opt	array	"-Xms64m"	Disabled	Set initial Java heap size.
pca_jvm_java_opt	array	"-Xmx64m"	Disabled	Set maximum Java heap size.
<pre>pca_jvm_java_opt ions</pre>	array	"-XnoClassgc"	Disabled	Disable class garbage collection.
<pre>pca_jvm_java_opt ions</pre>	array	"-Xprof"	Disabled	Output cpu profiling data.
<pre>pca_jvm_java_opt ions</pre>	array	"-Xrs"	Disabled	Reduce use of OS signals by Java/VM.
pca_jvm_java_opt	array	"-Xshare:auto"	Disabled	Configure shared class data (set to auto, off or on).

Argument	Units Type	Default Value	Default State	Description
<pre>pca_jvm_java_opt ions</pre>	array	"-Xss64m"	Disabled	Set Java thread stack size.
pca_jvm_java_opt ions	array	"-XX:MaxPermSize"	Disabled	Sets the maximum size of the permanent heap
pca_jvm_java_opt ions	array	"- enablesystemassertio ns"	Enabled	Enable Java/VM System Assertions - applies only to platforms using the Sun HotSpot (TM) JavaVM.
pca_jvm_java_opt ions	array	"-esa"	Enabled	Enable All System Assertions - only applies to platforms using the Sun Hot-Spot (TM) JavaVM.
<pre>pca_jvm_java_opt ions</pre>	array	"-verbose:class"	Disabled	Class loading within the JRE/VM.
pca_jvm_java_opt ions	array	"-verbose:gc"	Disabled	Garbage Collection statistics.
pca_jvm_java_opt ions	array	"-verbose:jni"	Disabled	Java Native Interface (JNI) invocations.

Table 13: pva_jvm_java_dbg_agent_port

pva_jvm_java_dbg_agent_port configures the Java VM debug agent port number (used for debugging Java applications with a Java debugger). See Java in Adaptive Server Enterprise for more information.

Argument	Units Type	Default Value	Default State	Description
<pre>pca_jvm_java_dbg_agent_por t</pre>	number	8000	Disabled	Configure the port number and the Java VM Debug Agent.
<pre>pca_jvm_java_dbg_agent_sus pend</pre>	switch	N/A	Disabled	Java VM Debug Agent starts suspended when enabled.

Table 14: pca_jvm_sys_device_path

pca jvm sys device path configures platform-specific system device directories (required for Solaris).

Argument	Unit Type	Default Value	Default State	Description
<pre>pca_jvm_sys_device_p ath</pre>	array	Platform-specific	Platform- specific	Internal system option for Sun OS. Do not change.

Permissions

The permission checks for sp jreconfig differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server configuration

orivilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_pciconfig [page 661]

1.169 sp_ldapadmin

Creates or lists an LDAP URL search string, verifies an LDAP URL search string or login, or specifies the access accounts and tunable LDAPUA-related parameters.

Syntax

```
sp_ldapadmin '<command>'[, <option1>[, <option2>]]
```

Valid <command>[, <option1>[, <option2>]] options are listed in the following Parameters section.

Parameters

```
'set primary url', '<ldapurl>'
```

creates the specified search string <ldapurl>. Exactly one primary search string can be created.

The syntax for <ldapurl> is:

ldapurl::=ldap://<host>:<port>/<node>?<attributes>?base | one | sub?<filter>

where:

- <host> is the host name of the LDAP server.
- <port> is the port number of the LDAP server.
- <node> specifies the node in the object hierarchy at which to start the search.
- <attributes> is a list of attributes to return in the result set. Each LDAP server
 may support a different list of attributes.
- base qualifies the search criteria, specifying a search of the base node.
- one qualifies the search criteria. base specifies a search of the base node; one specifies a search of node and one sublevel below node; and sub specifies a search of node and all node sublevels.
- sub specifies a search of node and all node sublevels.
- <filter> specifies the attribute or attributes to be authenticated. The filter can
 be simple, such as "uid=*," or compound, such as "(uid=*) (ou=<group>)." The
 syntax is LDAP server dependent and uses a wildcard (*) to describe the login
 name.

'set_secondary_url', {'<ldapurl>' | null}

creates the specified secondary search string <ldapurl> or no secondary search
string. Exactly one secondary search string can be created.

'set_dn_lookup_url', '<distinguished_name_url>'

uses the searched distinguished name algorithm to authenticate the login with an LDAP directory server when you set set dn lookup url to a non-NULL value.

<distinguished_name_url> has a maximum length of 255 characters and is used
to search for a distinguished name associated with the login name.

'set secondary dn lookup url', '<distinguished name url>'

creates the specified secondary distinguished name algorithm to authenticate the login with an LDAP directory server when you set <code>set_secondary_dn_lookup_url</code> to a non-NULL value.

<distinguished_name_url> has a maximum length of 255 characters and is used
to search for a distinguished name associated with the login name.

'set_access_acct', '<account_distinguished_name>', '<account_password>'

specifies the identity and password that the SAP ASE server uses to conduct searches and other read-only administrative actions. The identity is in the form of a distinguished name. Use <account_distinguished_name> to authenticate this user with the LDAP server. Both <account_distinguished_name> and <account_password> are limited to 255 characters each.

```
'set_secondary_access_acct', '<account_distinguished_name>',
```

creates the secondary identity and password that the SAP ASE server uses to conduct searches and other read-only administrative actions. The identity is in the form of a distinguished name. Use <account distinguished name> to authenticate this user

^{&#}x27;<account password>'

with the LDAP server. Both <account_distinguished_name> and <account password> are limited to 255 characters each.

'set failback interval', '<time in minutes>'

sets the interval at which the SAP ASE housekeeper utility checks for failed LDAP servers

'suspend', {'primary' | 'secondary'}

suspends the use of a primary or secondary URL for authentication.

'activate', {'primary' | 'secondary'}

enables using the set of primary or secondary URLs for authentication.

'list'

displays LDAP search strings.

'list_urls'

displays LDAP URL search strings.

'list_urls'

displays LDAP URL search strings.

'list_access_acct'

displays the LDAP access account distinguished name set.

'check url', '<ldapurl>'

verifies an LDAP URL search string. Can also verify the existence of a user account, but it does not authenticate the user.

reinit_descriptors

Unbinds all established LDAP server descriptors, and reinitializes the LDAP user-authentication subsystem. The syntax is:

```
sp_ldapadmin 'reinit_descriptors'
```

Whenever a certification authority trusted root file is modified, the system security officer must use reinit_descriptors to reinitialize LDAP user authentication. For complete documentation, see sp_ldapadmin in the *Reference Manual: Procedures*.

'check login', '<login name>'

verifies a user account for the existing LDAP URL search strings. It does not authenticate the user.

'set timeout' <timeout in milli seconds>

sets the time in milliseconds that the SAP ASE server waits for a response from the LDAP server before abandoning the authentication request.

The default value for $set_timeout$ is 10,000 milliseconds (10 seconds). Valid values are between 1 and 3,600,000 (one hour).

'set_log_interval', <log_interval>

sets the log interval, specified in minutes, from 0 to 480 minutes. The default value is 3 minutes. 0 implies that all messages are printed.

'set_num_retries', <num_retries>

sets the number of retries attempted after transient errors. The valid range for set $num\ retries\ is\ 1-60$, and the default is 3.

'set_max_ldapua_naptive_threads', <max_ldapua_native_threads>

sets the maximum number of native threads that can be running concurrently in an engine processing an LDAP authentication request.

The minimum value of set_max_ldapua_native_threads is 1. The maximum value is max native threads minus number of dump threads as specified using sp configure. The default value is the same as the maximum value.

sp_configure ensures that max native threads is sufficient for
set_max_ldapua_native_threads and the value of the configuration parameter
number of dump threads.

'set_max_ldapua_desc', <max_ldapua_desc>

sets the maximum number of LDAP descriptors per engine. The valid range for $set_{max_ldapua_desc}$ is 1-20, and the default is 20.

'set abandon ldapua when full', {true | false}

allows you to seek alternative means of LDAP user authentication when the native threads per engine capacity is exceeded.

When no more threads are available, the request is abandoned if set_abandon_ldapua_when_full is set to true. If enable ldap user auth is set to 1, the client is authenticated using SAP ASE syslogins. If enable ldap user auth is set to 2, the client login fails.

If set_abandon_ldapua_when_full is set to false, the authentication request is blocked until the LDAP descriptor can accept new authentication requests.

'help'

displays usage information for sp_ldapadmin.

Examples

Example 1

Creates an LDAP URL search string for the LDAP SunONE Directory Server:

```
sp_ldapadmin set_primary_url,'ldap://voyager:389/
   ou=People,dc=MyCompany,dc=com??sub?uid=*'
```

The search string identifies a directory server listening on host name "voyager," port number 389 (the default LDAP protocol port), the base node to begin the search is within organizational unit (ou) "People," and the domain is "MyCompany.com." It returns all attributes that match the filter uid=*. The SAP ASE server replaces the wildcard with the SAP ASE login name that is to be authenticated.

Example 2

Creates an LDAP URL search string defined in OpenLDAP 2.0.25 using the criteria described in the previous example:

```
sp_ldapadmin set_primary_url,'ldap://voyager:389/
```

```
dc=MyCompany, dc=com??sub?cn=*'
```

Example 3

Sets the secondary LDAP URL search string to null, indicating no failover and no secondary LDAP server:

```
sp_ldapadmin set_secondary_url, null
```

Example 4

Creates an LDAP URL search string with a compound filter:

```
sp_ldapadmin set_primary_url, 'ldap://voyager:389/
   ou=people,dc=siroe,dc=com??sub?(&(uid=*) (ou=accounting))
```

Example 5

Uses the default Microsoft Active Directory schema found on Windows 2000 controllers:

The "aseadmin" username is added to the Active Directory server and granted read access to the trees and objects where users are found. The LDAP attribute specified by distinguishedName is obtained and used to authenticate the user. The filter specifies a search on attribute samaccountname=*; the * wildcard is replaced with the name from the SAP ASE login record.

For example, "samaccountname=jqpublic" returns DN attribute "distinguishedName" with value "cn=John Q. Public, cn=Users,dc=mycompany, dc=com" to the SAP ASE server. The SAP ASE server uses this string to bind to ldap://mydomainhostname:389. If the bind is successful, authentication succeeds.

Example 6

Sets the maximum number of native threads to 12:

```
sp_ldapadmin 'set_max_ldapua_native_threads', '12'
```

Example 7

sets the time that the SAP ASE server waits for a response from the LDAP server before abandoning the authentication request to 25,000 milliseconds:

```
sp_ldapadmin, 'set_timeout', '25000'
```

Example 8

Disables the authentications requests until the LDAP descriptor can accept new authentication requests:

```
sp_ldapadmin 'set_abandon_ldapua_when_full', 'false'
```

Example 9

Displays the current LDAP values:

```
sp ldapadminPrimary:
URL:
                       'ldap://linuxpuneeng1:50917/'
DN Lookup URL:
'ldap://linuxpuneeng1:50917/dc=sybase,dc=com??sub?uid=*'
Access Account:
                     'cn=Directory Manager'
                      'TRUE'
Active:
                      'READY'
Status:
Secondary:
URL:
DN Lookup URL:
                      1 1
                      1.1
Access Account:
Active:
                     'FALSE'
                      'NOT SET'
Status:
                     '5000' milliseconds
Timeout value:
                     '1' minutes
Log interval:
                     131
Number of retries:
Maximum LDAPUA native threads per Engine: '400'
Maximum LDAPUA descriptors per Engine: '3'
Abandon LDAP user authentication when full: 'false'(return status = 0)
```

Usage

There are additional considerations when using sp ldapadmin:

- The LDAP vendor determines the syntax of the search string. In all cases, the search string specifies the attribute name that uniquely identifies the user in the form "<attribute>=<wildcard>" as in "cn=*".
- The first attribute in a compound filter must define the Relative Distinguished Name (RDN). For example, "...sub? (uid=*) (ou=group) ". Otherwise, the authentication fails.
- When a search string is added, the SAP ASE server verifies that it uses valid LDAP URL syntax and that it references an existing node. To ensure that the valid string returns expected values, carefully choose and verify the search string when configuring the SAP ASE server.
- The secondary URL search string enables failover to another LDAP server. The SAP ASE server uses the primary URL search string unless the LDAP Server is not active or the search string is invalid. In this event, the SAP ASE server uses the secondary URL search string for authentication.
- The login sequence of searched DN algorithm requires the SAP ASE server to bind to the LDAP server using the access account before it can perform searches. The SAP ASE server obtains an LDAP descriptor (handle) as a result of the bind. This descriptor is used for searching the DN of the login on the LDAP server.
- In order to access the server, users who are being authenticated with the LDAP server should either exist as a valid user in SAP ASE, or have a mapping defined.

See System Administration Guide > Creating and Managing ASE Logins Using LDAP and sp maplogin.

Permissions

The permission checks for sp ldapadmin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage security configuration

privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sso_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_maplogin [page 580]

1.170 sp_listener

Dynamically starts and stops SAP ASE listeners on any given port on a per-server basis.

Considerations for Process Mode

When executed in process mode, <code>sp_listener</code> dynamically starts and stops SAP ASE listeners on any given port on a per-engine basis.

Syntax

• For threaded mode, the syntax is either of the following:

```
sp_listener "<command>", "<server_name> | <network>"
sp_listener "<command>", '[<protocol>:]<machine>:<port>:"CN=<common_name>"'
```

• For process mode, the syntax is either of the following:

```
sp_listener "<command>", "<server_name> | <network>", <engine> | <remaining>
```

```
sp_listener "<command>", '[<protocol>:]<machine>:<port>:"CN=<common_name>"',
<engine>
```

Parameters

<command>

can be any of:

start Starts a listener on the specified ports on each of the specified servers.

Terminates the specified listeners. You must include a specific listener address in the syntax, not just a server name. The command fails if you attempt to stop the last listener.

suspend Prevents the listener from accepting any more connections.

resume Instructs suspended listeners to resume listening.

Report on the state of the listeners specified by the parameters. The state is one of: active, stopped, or suspended. If your system is enabled for IPV6, the SAP ASE server encloses the listener name in brackets in the output.

help Displays the sp listener syntax.

<server_name> | <network>

is the name of the SAP ASE server, as specified in the interfaces file, or the name of the network.

<engine>

(Used only in process mode) specifies the number of the engine affected by this command. $\langle engine \rangle$ can be a single-engine number in quotes ("2"), a list ("3,5,6"), a range ("2 – 5"), or mix of all ("2,3 – 5,7").

i Note

Windows ignores the <engine> parameter.

remaining

specifies that the command is to take effect on all engines on which it can be meaningfully applied (that is, where the listener is in a state in which the command is can take effect).

col>

the type of protocol; one of: afunix, tcp, tli, ssltcp, ssltli, winsock, sslnlwnsck, sslwinsock.

<machine:port>

the machine name and port number (as specified in the interfaces file) to which the listener connects.

CN=<common_name>

specifies a common name for the SSL certificate.

Use CN=<common_name> only if you specify ssltcp as the protocol. The SAP ASE server validates the common_name you specify against the common_name in the SSL certificate. If you do not include CN=<common_name>, the SAP ASE server uses <server_name> to validate against the common name in the SSL certificate. If you include a fully qualified domain name in the certificate, it must match CN=<common_name>.

Examples

Example 1

Start listeners for each master entry in the interfaces file corresponding to server orion:

```
sp_listener "start", "orion"
```

Example 2

Create TCP listeners for port number 4226:

```
sp_listener "start", "goldie:4226"
```

Example 3

Create listeners for all master entries in the interfaces file for server orion:

```
sp_listener "start", "orion", "remaining"
```

Example 4

Start TCP listeners on port 4226 on machine goldie for all engines not already listening to this port:

```
sp_listener "start", "goldie:4226", "remaining"
```

Example 5

Specify the common name ase1.big server 1.com:

Example 6

Stop the listener on port number 4226:

```
sp_listener "stop", "tcp:goldie:4226"
```

Example 7

Stop all listeners on port number 4226. Because this command includes the remaining parameter, it does not fail if some engines are not listening to the port:

```
sp_listener "stop", "tcp:goldie:4226", "remaining"
```

Example 8

Suspend Winsock listener on port 4226:

```
sp_listener "suspend", "winsock:clouds:4226"
```

Example 9

Resume all active listeners on port number 4226:

```
sp_listener "resume", "tcp:goldie:4226", "remaining"
```

Example 10

Start a named pipe listener using AF_UNIX communication.

```
sp listener "start", "afunix:big server:/tmp/big pipe"
```

Usage

There are additional considerations when using sp listener:

- sp_listener uses either of two syntaxes, described in the syntax section, above. The first syntax affects all SAP ASE master ports listed in the interfaces file. The second allows you to manage listeners not listed in the interfaces file.
- The attribute name "CN" is case-insensitive (it can be "CN", "cn" or "Cn"), but the attribute value for the common name is case-sensitive.
- sp listener ignores the <engine> parameter if you include it while running in threaded mode.
- The semantics for sp_listener is atomic; if a command cannot be completed successfully, it is aborted.
- When the host component of a sp_listener command is an IPv6 address, it should be enclosed in brackets. For example, tcp: [2001:ec8:4008:1::123]:80
- You can issue the status parameter by itself. The status parameter displays the state of all the listeners in the interfaces file.
- A listener can be in one of the following states: stopped, suspended, or active. sp_listener allows you to move listeners between these states. A request to move to a nonpermissible state results in failure (For example, requesting to stop a non existent listener). Use sp_listener "status" to determine the state of a listener.
- The remaining parameter specifies that, for the command you are running (start, stop, resume, and so on), the command runs successfully for all listeners that are in a state that allow the change (for example, moving states from start to stop). For example, if you attempt to start listeners on engines one through six, but engines one, four, and five are unavailable, sp_listener... "remaining" starts listeners on engines two, three, and six, disregarding the offline engines. You cannot specify an engine number if you include the remaining parameter.
- The maximum number of listeners is 32. If you create an SAP ASE server with two master ports in the interfaces file, you can start at most 30 more listeners on other ports.

For limitations related to IPV6 in sp_listener, see Security Administration Guide Specifying a Common Name.

Permissions

The permission checks for sp listener differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.171 sp_listsuspect_db

Lists all databases that currently have offline pages because of corruption detected on recovery, including the database name, number of suspect pages, and number of objects containing suspect pages.

Syntax

sp listsuspect db

Examples

Example 1

Lists the databases that have suspect pages:

sp_listsuspect_db

Usage

To identify suspect pages, use sp listsuspect page.

Permissions

Any user can execute <code>sp_listsuspect_db</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_listsuspect_page [page 555]
sp_setsuspect_granularity [page 730]
sp_setsuspect_threshold [page 733]
```

1.172 sp_listsuspect_object

Lists all indexes in a database that are currently offline because of corruption detected on recovery.

Syntax

```
sp_listsuspect_object [<dbname>]
```

Parameters

<dbname>

is the name of the database.

Examples

Example 1

Lists the suspect indexes in the current database:

```
sp listsuspect object
```

Example 2

Lists the suspect indexes in the pubs 2 database:

```
sp listsuspect object pubs2
```

Usage

There are additional considerations when using sp listsuspect object:

- If an index on a data-only-locked table has suspect pages, the entire index is taken offline during recovery.

 Offline indexes are not considered by the query optimizer.
- Use the system procedure sp forceonline object to bring an offline index online for repair.
- Indexes on allpages-locked tables are not taken completely offline during recovery; only individual pages of these indexes are taken offline. These pages can be brought online with sp forceonline object.
- sp_listsuspect_object lists the database name, object ID, object name, index ID, and access status for every suspect index in the specified database or, if <dbname> is omitted, in the current user database.
- A value of SA_ONLY in the access column means that the index has been forced online for system administrator use only. A value of BLOCK_ALL means that the index is offline for everyone.

See the System Administration Guide for more information on recovery fault isolation.

Permissions

Any user can execute <code>sp_listsuspect_object</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_forceonline_object [page 382]

1.173 sp_listsuspect_page

Lists all pages in a database that are currently offline because of corruption detected on recovery, including the database name, page ID, object, index ID, and access status for every suspect page in the specified database or, if <dbname> is omitted, in the current user database.

Syntax

sp_listsuspect_page [<dbname>]

Parameters

<dbname>

is the name of the database.

Examples

Example 1

Lists the suspect pages in the current database:

```
sp listsuspect page
```

Example 2

Lists the suspect pages in the pubs2 database:

```
sp_listsuspect_page pubs2
```

Usage

A value of SA_ONLY in the "access" column indicates that the page has been forced online for system administrator use only. A value of BLOCK_ALL indicates that the page is offline for everyone.

Permissions

Any user can execute <code>sp_listsuspect_page</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_listsuspect_db [page 552]
sp_setsuspect_granularity [page 730]
sp_setsuspect_threshold [page 733]
```

1.174 sp_Imconfig

Configures license management-related information on SAP ASE.

Syntax

Parameters

```
sp_lmconfig
```

without parameters displays the following license status information:

- Server Name
- License Name
- Version
- Quantity Status
- Expiration Date

edition

is a static configuration parameter to specify the license edition.

<edition type>

specifies the edition type, and has the following possible values:

- null is the default value. When a null value is specified, no product edition is configured, and the SAP ASE server starts with a license for any edition.
- EE indicates the Enterprise edition.
- SE indicates the Small Business edition.
- XE indicates the Express edition.

i Note

The SAP ASE Developer Edition is no longer supported. As an alternative, you can download and evaluate a non-production environment edition of SAP ASE Enterprise Edition.

license type

is a static configuration parameter that specifies the license type for the installation of SAP ASE, and is valid only when you specify a non-null edition.

<license type name>

specifies the license type of a particular installation of SAP ASE. You need not specifylicense type if you are using the Express (XE) edition. The valid, most typical values are:

- SRST server license with network seats
- SVST standby server license with network seats
- SRCU server license with concurrent user seats
- SVCU standby server license with concurrent user seats
- SRIA server license with Internet access license
- SVIA standby server license with Internet access license
- CP CPU license
- SF standby CPU license
- null default

i Note

In addition to this list, $sp_lmconfig$ also accepts two-letter abbreviations for specialized and legacy license types. If the license type is not accepted, set the type to null and use the network license server options file to control the license used by this SAP ASE server.

smtp host, <smtp host name>

designates the SMTP host used to send e-mail for license event notifications.

smtp port, <smtp port number>

designates the SMTP port used to send e-mail for license event notifications.

email sender, <sender email address>

specifies the e-mail address used as the senders address on license event E-mail notifications.

email recipients, <email recipients>

is a comma separated list of e-mail recipients who receive license event E-mail notifications.

email severity, <email severity>

is the minimum severity of an error that causes an E-mail notification to be sent. The default is error, and the other possibilities are warning and informational.

Examples

Example 1

Displays basic license configuration information for a system:

```
1> sp_lmconfig
2> go
```

Parameter Name Co	onfig Value				
edition Ellicense type Cleanse type Cleanse type consider in the constant of t	 E :: :11 :11 :11				
License Name	Version	Quantity	Status	Expiry	
Date Server 1	Name				
ASE_HA 12:00AM cuprum	2010.03314	2	expirable	Apr 1 2010	
	null	0	not used	null	null
	null		not used	null	null
ASE DIRS	null	0	not used	null	null
ASE XRAY			not used	null	null
ASE ENCRYPTION			not used	null	null
ASE CORE	2010.03314	2	expirable	Apr 1 2010	
12:00AM cuprum			-	-	
ASE PARTITIONS	null	0	not used	null	null

Property Name Prope: PE EE LT CP ME null	rty Value				

```
MC null
MS null
MM null
CP 0
AS A

(return status = 0)
```

Usage

There are additional considerations when using sp lmconfig:

- When you do not specify any parameters, sp_lmconfig also displays the server name from the location where the license is checked out.
- If you do not specify an edition or use "null," the SAP ASE server looks for and uses whatever license edition it finds when it starts.
- The configuration options set by sp lmconfig are stored in the sylapi properties file.

See also:

• The SAP ASE installation guide for your platform.

Permissions

The permission checks for sp lmconfig differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server configuration

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.175 sp_lock

Reports the object names and IDs of processes that currently hold locks.

Syntax

```
sp_lock [<spid1>[, <spid2>]] | [@verbose = <int>]
```

Parameters

<spid1>

is the SAP ASE process ID number from the master.dbo.sysprocesses table. Run sp who to get the <spid> of the locking process.

<spid2>

is another SAP ASE process ID number to check for locks.

@verbose = <int>

displays a concatenated name of the table names instead of a <spid>, such as test..testa, following by the <spid>.

i Note

<int> can be any number, as sp_{lock} only check to see whether the value of @verbose is null or not.

Examples

Example 1

Shows the lock status of serial processes with spids 7, 18, and 23 and two families of processes. The family with fid1 has the coordinating processes with spid1 and worker processes with spids 8, 9, and 10. The family with fid1 has the coordinating processes with spid11 and worker processes with spids 12, 13, and 14:

```
The class column will display the cursor name for locks associated with a cursor for the current user and the cursor id for other users.

fid spid locktype table_id page dbname class context

0 7 Sh_intent 480004741 0 master Non Cursor Lock NULL
0 18 Ex_intent 16003088 0 pubtune Non Cursor Lock NULL
```

```
        0 18 Ex_page
        16003088

        0 18 Update_page=blk
        16003088
        634 pubtune
        Non Cursor Lock NULL

        0 18 Update_page=blk
        16003088
        0 pubtune
        Non Cursor Lock NULL

        0 23 Sh_intent
        16003088
        0 pubtune
        Non Cursor Lock NULL

        0 23 Ex_intent
        176003658
        0 tpcd
        Non Cursor Lock Sync-pt

        duratio
```

Example 2

Displays information about the locks currently held by spid 7:

```
The class column will display the cursor name for locks associated with a cursor for the current user and the cursor id for other users.

fid spid locktype table_id page dbname class context

0 7 Sh_intent 480004741 0 master Non Cursor Lock NULL
```

Example 3

First, queries the pubs2 database about the ID of its running processes that currently hold locks (1056003762), then queries the pubs2 database using the @verbose option, which returns the object name (master..spt values) in addition to the process ID:

```
0 15 30 Sh_intent 0 0 master..spt_values 1056003762 Non Cursor Lock (1 row affected) (return status = 0)
```

Example 4

This example shows all locks, including partition locks, currently held by SAP ASE.

sp_lock go fid spid loid locktype class context	table_id	partitionid	page	row	dbname	
0 13 26 Ex intent	420193516	0	0	0	master	Non
Cursor Lock						
0 13 26 Ex_intent_partition	420193516	452193630	0	0	master	Non
Cursor Lock						
0 13 26 Ex_page	420193516	452193630	4993	0	master	Non
Cursor Lock						
0 14 28 Ex_intent	420193516	0	0	0	master	Non
Cursor Lock						
0 14 28 Ex_intent_partition	420193516	468193687	0	0	master	Non
Cursor Lock						
0 14 28 Ex_page	420193516	468193687	5001	0	master	Non
Cursor Lock						
0 16 32 Sh_intent	1006623598	0	0	0	master	Non
Cursor Lock						

Table lock and fine-grained lock values for partitionid are 0. partitionid is populated only for partition-level locks.

Usage

There are additional considerations when using sp_lock:

- sp lock with no parameters reports information on all processes that currently hold locks.
- The only user control over locking is through the use of the holdlock keyword in the select statement.
- Use the object name system function to derive a table's name from its ID number.
- sp_lock in versions of the Cluster Edition earlier than 15.0.3 displayed information about only the locks associated with the instance on which you issued the stored procedure. sp_lock on Cluster Edition version 15.0.3 and later displays information about all locks in the cluster.
- sp lock output is ordered by fid and then spid.
- sp lock output also displays the following lock types:
 - o "Sh_row" indicates shared row locks
 - "Update_row" indicates update row locks
 - o "Ex_row" indicates exclusive row locks

The sp lock columns are:

loid

The column identifies unique lock owner ID of the blocking transaction. Even loid values indicate that a local transaction owns the lock. Odd values indicate that an external transaction owns the lock.

locktype The column indicates whether the lock is a shared lock ("Sh" prefix), an exclusive lock ("Ex" prefix) or an update lock, and whether the lock is held on a table ("table" or "intent") or on a page ("page").

> A "blk" suffix in the "locktype" column indicates that this process is blocking another process that needs to acquire a lock. As soon as this process completes, the other process(es) moves forward. A "demand" suffix in the "locktype" column indicates that the process is attempting to acquire an exclusive lock. See the Performance and Tuning Guide for more information about lock types.

class

The column indicates whether a lock is associated with a cursor. It displays one of the following:

- "Non Cursor Lock" indicates that the lock is not associated with a cursor.
- "Cursor Id <number>" indicates that the lock is associated with the cursor ID number that SAP ASE process ID.
- A cursor name indicates that the lock is associated with the cursor cursor</pr>
 name that is owned by the current user executing sp lock.

fid

The column identifies the family (including the coordinating process and its worker processes) to which a lock belongs. Values for fid are:

- A zero value indicates that the task represented by the spid is executed serially. It is not participating in parallel execution.
- A nonzero value indicates that the task (spid) holding the lock is a member of a family of processes (identified by fid) executing a statement in parallel. If the value is equal to the spid, it indicates that the task is the coordinating process in a family executing a query in parallel.

context

The column identifies the context of the lock. Worker processes in the same family have the same context value. Legal values for "context" are as follows:

- "NULL" the task holding this lock is either a query executing serially, or is a query executing in parallel in transaction isolation level 1.
- "Sync-pt duration request" the task holding the lock holds the lock until the query is complete.

A lock's context may be "Sync-pt duration request" if the lock is a table lock held as part of a parallel query, if the lock is held by a worker process at transaction isolation level 3, or if the lock is held by a worker process in a parallel query and must be held for the duration of the transaction.

- "Ind pg" indicates locks on index pages (allpages-locked tables only)
- "Inf key" indicates an infinity key lock (for certain range queries at transaction isolation level 3 on data-only-locked tables)
- "Range" indicates a range lock (for range queries at transaction isolation level 3 on dataonly-locked tables)

These new values may appear in combination with "Fam dur" (which replaces "Sync pt duration") and with each other, as applicable.

row

The column displays the row number for row-level locks.

See also kill, select in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_lock</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_familylock [page 369]
sp_who [page 847]
```

1.176 sp_locklogin

Locks an SAP ASE account so that the user cannot log in, or displays a list of all locked accounts.

Syntax

Or:

```
sp_locklogin
```

Parameters

is any string with wildcards that identifies a set of logins.

NULL

all logins, including the sa_role, are locked.

lock | unlock

specifies whether to lock or unlock the account.

<except_login_name>

is the name of login that is exempted from being locked.

<except_role_name>

is the name of role that is exempted from being locked. For example, all logins in a role that are to be exempted.

<number_of_inactive_days>

is the number of days, from 1 to 32,767, that an account has been inactive.

Examples

Example 1

Locks the login account for the user "charles":

```
sp locklogin charles, "lock"
```

Example 2

Locks all logins except those with the sa_role:

```
sp locklogin NULL, "lock", sa role
```

Example 3

Displays a list of all locked accounts:

sp_locklogin

Example 4

Locks all login accounts that have not authenticated within the past 60 days:

```
sp_locklogin NULL, 'lock', NULL, 60
```

i Note

This command has no effect if the sp_passwordpolicy option "enable last login updates" is set to "0".

Usage

There are additional considerations when using sp locklogin:

- Without any parameters, sp locklogin displays all locked logins.
- The syslogins columns lockdate, locksuid and lockreason are updated at time of locking/ unlocking a login.
- Conditions for using sp locklogin are:
 - No wild cards are allowed for exceptions.
 - Existing functionality is undisturbed.
 - The exception specified is first matched against logins. If such a login does not exist, then the exception is checked against roles.
 - o A value of NULL for a login means "all" logins.
 - You see an error if the login name or exception you specify does not exist.
 - Nothing happens if the specified "effective set" of logins to be locked is empty.
 - o If the exception is NULL, the set of logins specified (through the login parameter) is locked.
 - High-availability Failover only in versions of SAP ASE earlier than 15.0, sp_locklogin checked to see if the login to be locked or unlocked existed on a remote high-availability server by verifying that the suid (server user ID) of that login existed on the server.
 - In SAP ASE version 15.0, sp locklogin checks both the suid as well as the login name.
 - You see an error if you specify any word other than lock or unlock.

See also create login, alter login in Reference Manual: Commands.

Permissions

The permission checks for sp locklogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any login privilege. To unlock login account which was locked because of maxfailedlogin, you must be a user with change password privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.177 sp_logdevice

Moves the transaction log of a database with log and data on the same device to a separate database device.

Syntax

```
sp_logdevice <dbname>, <devname>
```

Parameters

<dbname>

is the name of the database with the syslogs table, which contains the transaction log, to put on a specific logical device.

<devname>

is the logical name of the device on which to put the syslogs table. This device must be a database device associated with the database (named in create database or alter database). Run sp helpdb for a report on the database's devices.

Examples

Example 1

Creates the database products and puts the table products.syslogs on the database device logs:

```
create database products on default = "10M", logs = "2M"
go
sp_logdevice products, logs
go
```

Example 2

For the database test with log and data on the same device, places the log for test on the log device logdev:

```
alter database test log on logdev
go
sp_logdevice test, logdev
go
```

Usage

There are additional considerations when using sp logdevice:

- You can only execute sp logdevice in single-user mode.
- The sp_logdevice procedure affects only future allocations of space for syslogs. This creates a window of vulnerability during which the first pages of your log remain on the same device as your data. Therefore, the preferred method of placing a transaction log on a separate device is the use of the log on option to create database, which immediately places the entire transaction log on a separate device.
- Place transaction logs on separate database devices, for both recovery and performance reasons.

 A very small, noncritical database could keep its log together with the rest of the database. Such databases use dump database to back up the database and log and dump transaction with truncate_only to truncate the log.
- dbcc checkalloc and sp_helplog show some pages for syslogs still allocated on the database device until after the next dump transaction. After that, the transaction log is completely transferred to the device named when you executed sp logdevice.
- The size of the device required for the transaction log varies, depending on the amount of update activity and the frequency of transaction log dumps. As a rule, allocate to the log device 10 percent to 25 percent of the space you allocate to the database itself.
- Use sp_logdevice only for a database with log and data on the same device. Do not use sp_logdevice for a database with log and data on separate devices.
- To increase the amount of storage allocated to the transaction log use alter database. If you used the log on option to create database to place a transaction log on a separate device, use this to increase the size of the log segment. If you did not use log on, execute sp logdevice:

```
sp extendsegment <segname>, <devname>
```

The device or segment on which you put syslogs is used **only** for syslogs. To increase the amount of storage space allocated for the rest of the database, specify any device other than the log device when you issue alter database.

• Use disk init to format a new database device for databases or transaction logs.

See also:

- System Administration Guide
- alter database, create database, dbcc, disk init, dump database, dump transaction, select in *Reference Manual: Commands*

Permissions

The permission checks for sp logdevice differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be the database owner or a user with own database privilege.

Setting Description

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be the database owner or a user with sa_role.}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_extendsegment [page 365]
sp_helpdevice [page 446]
sp_helplog [page 466]
```

1.178 sp_logging_rate

Calculates the transaction log growth rate for the specified time period.

Syntax

```
sp_logging_rate {'full'|'sum', '[day,]hh:mm:ss'}[, interval='hh:mm:ss' |
clear_option='y'|'n']
```

Parameters

```
full
```

 $\verb"sp_logging_rate" provides a detailed report for each collection.$

sum

sp_logging_rate provides summary information, including values for the average, minimum, maximum, and the maximum rate. If you do not specify a time, sp_logging_rate collects information every 10 seconds.

day, <hh:mm:ss>

Specifies the duration of time sp_logging_rate runs, using the form <date, hour:minute:second>.

```
interval = '<hh:mm:ss>'
```

Period of time during which the interval runs, using the form <hour:minute:second>

```
clear option = 'y' | 'n'
```

Determines whether to clear the monitor counters during data collection.

Examples

Example using sum parameter

This example collects information for 1 day and 8 hours, takes a sample every 10 minutes, and prints summary information at the end of the interval:

Example using full parameter

This example collects information for 3 minutes, takes samples every 10 seconds (the default), and prints summary information at the end of the interval:

	rate 'full', '00:03		og Growth Rate G	3/h		
Oct 22 2013	6:00:32:480AM	0.	406779			
Oct 22 2013	6:00:42:483AM	0.	00000			
Oct 22 2013	6:00:52:483AM	0.	00000			
Oct 22 2013	6:01:02:483AM	0.	00000			
Oct 22 2013	6:01:12:490AM	0.	00000			
Oct 22 2013	6:01:22:500AM	0.	00000			
Oct 22 2013	6:01:32:476AM	2.	341870			
	6:01:42:483AM	2.				
Oct 22 2013	6:01:52:480AM	2.				
Oct 22 2013	6:02:02:483AM	2.	782750			
	6:02:12:483AM	2.853574				
	6:02:22:480AM	2.002917				
		2.848995				
	6:02:42:483AM	2.754143				
	6:02:52:483AM	2.854949				
	6:03:02:480AM	2.722928				
	6:03:12:476AM	2.870076				
	6:03:22:480AM	2.	697094			
	ry Information					
	Log Growth Rate	Min GB/h	Max GB/h	Avg GB/h		
		0.00000	2.870076	1.823028		

Usage

- You cannot run scripts or procedures that collect monitoring data (for example, sp_sysmon) while sp_logging_rate runs. Because sp_logging_rate collects and clears monitor counter as it runs, the monitoring counter information these scripts or procedures collect will not be accurate.
- sp_logging_rate produces unreliable results if you specify an amount of time for interval = '<hh:mm:ss>' that is greater than the amount of time you specify for 'day, <hh:mm:ss>'.
- When you specify values for interval = '<hh:mm:ss>' and 'day, <hh:mm:ss>', keep in mind:
 - o If the value you specify for interval = '<hh:mm:ss>' is greater than the value you specify for
 'day, <hh:mm:ss'>, SAP ASE issues an error message and sp_logging_rate produces no result
 set
 - o sp_logging_rate may produce an unreliable result if that ratio for 'day, <hh:mm:ss>' to interval = '<hh:mm:ss>' is too small. For example, if you specify day, 00:10:00, and interval='00:04:00', sp_logging_rate collects only two values, prints an average value, with the first value as the maximum, and the second value as the minimum. A better ratio produces a more reliable result set.

Permissions

You must have system administrator privileges to execute <code>sp_logging_rate</code>.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.179 sp_loginconfig

(Windows only) Displays the value of one or all integrated security parameters.

Syntax

```
sp_loginconfig ["<parameter_name>"]
```

Parameters

<parameter name>

is the name of the integrated security parameter you want to examine. Values are:

- login mode
- default account
- default domain
- set host
- key _
- key \$
- key @
- key #

Examples

Example 1

Displays the values of all integrated security parameters:

```
sp_loginconfig
                   config_item
name
                   standard
login mode
default account
                   NULL
default domain
                  NULL
set host
                   false
key
                   domain separator
key $
                   space
key @
                   space
key #
```

Example 2

Displays the value of the login mode security parameter:

Usage

There are additional considerations when using sp loginconfig:

• The values of integrated security parameters are stored in the Windows Registry. See the chapter on login security in *Configuration Guide for Windows* for instructions on changing the parameters.

• sp_loginconfig displays the <config_item> values that were in effect when you started the SAP ASE server. If you changed the Registry values after starting the SAP ASE server, those values are not reflected in the sp_loginconfig output.

See also Configuration Guide for Windows.

Permissions

The permission checks for sp loginconfig differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any login privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_revokelogin [page 704]

1.180 sp_logininfo

 $(Windows\ only)\ Displays\ all\ roles\ granted\ to\ Windows\ users\ and\ groups\ with\ \verb"sp_grantlogin".$

Syntax

```
sp_logininfo ["<login_name>" | "<group_name>"]
```

Parameters

```
<login_name>
```

is the network login name of the Windows user.

```
<group name>
```

is the Windows group name.

Examples

Example 1

Displays the permissions granted to the Windows user "regularjoe":

```
sp_logininfo regularjoe

account name mapped login name type privilege

HAZE\regularjoe HAZE_regularjoe user 'oper_role'
```

Example 2

Displays all permissions that were granted to Windows users and groups with sp grantlogin:

```
account name mapped login name type privilege

BUILTIN\Administrators BUILTIN\Administrators group

'sa_role sso_role oper_role sybase_ts_role navigator_role

replication_role'

HAZE\regularjoe HAZE_regularjoe user 'oper_role'
PCSRE\randy PCSRE_alexander user 'default'
```

Usage

There are additional considerations when using sp_logininfo:

- sp_logininfo displays all roles granted to Windows users and groups with sp_grantlogin.
- You can omit the domain name and domain separator (\) when specifying the Windows user name or group name.

See also grant, setuser in Reference Manual: Commands.

Permissions

The permission checks for sp logininfo differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage roles privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_displaylogin [page 270]
sp_grantlogin [page 392]
sp_revokelogin [page 704]
sp_role [page 706]
sp_who [page 847]
```

1.181 sp_logiosize

Changes the log I/O size used by the SAP ASE server to a different memory pool when doing I/O for the transaction log of the current database.

Syntax

```
sp_logiosize ["syslogs" | "sysimrslogs"]["default" | "<size>" | "all"]
```

Parameters

```
"syslogs" | "sysimrslogs" indicates that you are updating the log I/O size for syslogs or sysimrslogs. If you do not specify the log type, (syslogs or sysimrslogs), sp logiosize uses syslogs
```

by default. That is, issuing sp_logiosize and sp_logiosize "syslogs" both result in the server updating syslogs.

default

sets the log I/O size for the current database to the SAP ASE server's default value (two logical pages), if a memory pool that is two logical pages is available in the cache. Otherwise, the SAP ASE server sets the log I/O size to one logical page. Since default is a keyword, the quotes are required when specifying this parameter.

<size>

is the size to set the log I/O for the current database. Values are multiples of the logical page size, up to four times the amount. You must enclose the value in quotes.

all

displays the log I/O size configured for all databases grouped by the cache name.

Examples

Example 1

Displays the log I/O size configured for the current database:

```
sp_logiosize
The transaction log for database 'master' will use I/O size of 2 Kbytes.
```

Example 2

Changes the log I/O size of the current database to use the 8K memory pool. If the database's transaction log is bound to a cache that does not have an 8K memory pool, the SAP ASE server returns an error message indicating that such a pool does not exist, and the current log I/O size does not change:

```
sp_logiosize "8"
```

Example 3

Changes the log I/O size of the current database to the SAP ASE server's default value (one logical page size). If a memory pool the size of the logical page size does not exist in the cache used by the transaction log, the SAP ASE server uses the 2K memory pool:

```
sp_logiosize "default"
```

Example 4

Displays the log I/O size configured for all databases:

pubs3	2 Kb	
pubtune	2 Kb	
dbccdb	2 Kb	
sybsyntax	2 Kb	

Example 5

Changes the log I/O size for sysimrslogs:

```
sp_logiosize "sysimrslogs" "32"
```

Usage

There are additional considerations when using sp logiosize:

- sp_logiosize displays or changes the log I/O size for the current database. Any user can execute sp_logiosize to display the configured log I/O size. Only a system administrator can change the log I/O size
- If you specify sp_logiosize with no parameters, the SAP ASE server displays the log I/O size of the current database.
- When you change the log I/O size, it takes effect immediately. The SAP ASE server records the new I/O size for the database in the sysattributes table.
- Any value you specify for sp_logiosize must correspond to an existing memory pool configured for the cache used by the database's transaction log. Specify these pools using the sp_poolconfig system procedure.
 - The SAP ASE server defines the default log I/O size of a database as two logical pages, if a memory pool the size of two logical pages is available in the cache. Otherwise, the SAP ASE server sets the log I/O size to one logical page (a memory pool of one logical page is always present in any cache). For most work loads, a log I/O size of two logical pages performs much better than one of one logical page, so each cache used by a transaction log should have a memory pool the size of a logical page. See the *System Administration Guide* and the *Performance and Tuning Guide* for more information about configuring caches and memory pools.
- If the transaction logs for one or more databases are bound to a cache of type <code>logonly</code>, any memory pools in that cache that have I/O sizes larger than the log I/O size defined for those databases is not used. For example, on a 2K server, assume that only two databases have their transaction logs bound to a "log onlyF cache containing 2K, 4K, and 8K memory pools. By default, <code>sp_logiosize</code> sets the log I/O size for these parameters at 4K, and the 8K pool is not used. Therefore, to avoid wasting cache space, be cautious when configuring the log I/O size.
- During recovery, only the logical page size memory pool of the default cache is active, regardless of the log I/O size configured for a database. Transactions logs are read into this pool of the default cache, and all transactions that must be rolled back, or rolled forward, read data pages into the default data cache.

Permissions

Any user can execute sp logiosize to display the log I/O size values.

The following permission checks for sp logiosize differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage data cache privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_cacheconfig [page 118]
sp_poolconfig [page 670]

1.182 sp_logintrigger

Sets and displays the global login trigger. This global login trigger has the same characteristics as a personal login script. It is executed before any personal login script for every user that tries to log in, including system administrators and security officers.

Syntax

sp_logintrigger '<global login trigger name>'

Parameters

<global login trigger name>

is the name of the global login trigger. Login triggers must be created in the master database.

If you include no parameter, sp_logintrigger displays the current login trigger status and name if it exists, and no rows if there is no global login trigger defined.

Examples

Example 1

Sets a global login trigger using sp_logintrigger:

```
sp_logintrigger 'master.dbo.myproc'
```

Example 2

Returns an updated global login trigger:

```
1> sp_logintrigger
2> go
Global login trigger Status
------sybsystemprocs.dbo.myproc Enabled
(1 row affected)
(return status = 0
```

Example 3

When a global login trigger does not exist:

```
1> sp_logintrigger
2> go
Global login trigger Status
-----(0 rows affected)
```

Example 4

Deletes a global login trigger specified earlier with sp logintrigger:

```
sp_logintrigger 'drop'
```

Usage

To find out if a global login trigger is defined and enabled, use the <code>@@logintrigger</code> global variable.

There is a difference between this global login and the private login script. This global login trigger is stored by name in sysattributes, while the private login script is stored only by object ID.

Permissions

The permission checks for sp logintrigger differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage security configuration privilege to set a new login trigger.

Setting Description

Any user can execute sp logintrigger to display the current global login trigger.

Disabled With granular permissions disabled, you must be a user with sso_role to set a new login trigger.

Any user can execute sp logintrigger to display the current global login trigger.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.183 sp_maplogin

Maps external users to SAP ASE logins.

Syntax

```
sp maplogin (<authentication mech> | null), (<client username> | null),
    (<action> | <login name> | null)
```

Parameters

<authentication_mech>

specifies the mechanism used for authenticating the login account.

<cli>client_username>

is an external user name. This user name can be an operating system name, a user name for an LDAP server, or anything else that the PAM library can understand. A null value indicates that any login name is valid.

<action>

indicates create login or drop. When \create login is used, the login is created as soon as the login is authenticated. drop is used to remove logins.

<login_name>

is an SAP ASE login that already exists in syslogins

Examples

Example 1

Maps external user "jsmith" to SAP ASE user "guest". Once authenticated, "jsmith" gets the privileges of "guest". The audit login record shows both the <cli>client username> and the SAP ASE user name:

```
sp_maplogin NULL, "jsmith", "guest"
```

Example 2

Tells the SAP ASE server to create a new login for all external users authenticated with PAM, in case a login does not already exist:

```
sp_maplogin PAM, NULL, "create login"
```

Usage

Use $sp_{maplogin}$ to map an external name or client name, such as "ase.open.user," defined in an LDAP directory to the SAP ASE login name of "aseopenuser." That is, the <client_username> follows the rules of a name in an LDAP server, and the <login_name> follows the SAP ASE rules for identifiers.

If you are using LDAP User Authentication and the name in the LDAP server differs from the SAP ASE login name, use $sp_maplogin$ so the LDAP server uses the <client_username> for authentication, and the SAP ASE <login_name> for identity within the SAP ASE server. That is, "isql -U <client_username>..." has the identity of <login_name> within the SAP ASE server.

Use sp helpmaplogin to determine the <client username> and <login name>, such as:

Permissions

The permission checks for sp maplogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any login privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_helpmaplogin [page 467]

1.184 sp_merge_dup_inline_default

Removes existing duplicate inline default objects, converting the unique inline defaults to sharable inline default objects.

Syntax

Parameters

@report_only

reports the number of unique inline defaults in the current database but performs no changes if you specify yes. If you specify no:

- sp_merge_dup_inline_default removes duplicate inline defaults, and all unique inline defaults are changed to sharable inline defaults
- Existing column definitions referencing the duplicate inline defaults are updated to reference the sharable inline defaults

The default value for @report only is yes.

@show_progress

if set to yes, sp_merge_dup_inline_default displays hash marks to show progress when @report only is set to no.

The default value for @show progress is no.

Examples

Example 1

Runs sp_merge_dup_inline_default against the pubs2 database without any options. sp_merge_dup_inline_default makes no changes, but displays an informational message indicating the approximate number of unique inline defaults:

```
sp merge dup inline default
_____
sp merge dup inline default is used to identify duplicate inline default
objects,
subsequently to convert one of them into sharable inline default object and
remove the
rest. As the result, it will remove entries from sysobjects, syscomments and
sysprocedures. It will also update entries in syscolumns, syscomments and
sysprocedures.
Following is the current state of your inline default objects found out by
sp merge dup inline default and what it could potentially do to them. By
sp_merge_dup_inline_default only reports the current state and this warning
message. If
you really intend to carry out the changes, please rerun this stored
procedure using
sp_merge_dup_inline_default @report only = "NO"
Database pubs2 has about 0 unique inline defaults If you convert them into
sharable inline
defaults, the rest of total 0 duplicate defaults can be removed from the
system catalogs.
              -----
```

Example 2

Converts the unique inline default to shareable inline defaults:

```
sp_merge_dup_inline_default @report_only = 'NO'

Total 2 duplicate defaults are removed and 7 defaults are converted to sharable inline defaults. Database is modified and in single-user mode. System Administrator (SA) must reset it to multi-user mode with sp dboption.
```

Example 3

Produces the following output if there are no duplicate inline defaults:

```
sp_merge_dup_inline_default @report_only = 'NO'
```

Database is not modified. Please try it later if duplicate inline defaults do exist and the current resource limitation is preventing this conversion process.

sp merge dup inline default @report only = 'NO', @show progress = "YES"

Example 4

Includes the show progress parameter to indicate progress:

Database is modified and in single-user mode.

System Administrator (SA) must reset it to multi-user mode with sp dboption

Usage

There are additional considerations when using sp merge dup inline default:

- You cannot run sp merge dup inline default on system databases.
- User databases must be in single-user mode before you run sp merge dup inline default.
- You may re-run sp merge dup inline default if the system procedure aborts.
- If sp_merge_dup_inline_default issues an error message stating that the SAP ASE server is out of locks:
 - o Increase the value for number of locks, or
 - Reduce the lock promotion threshold with sp setpglockpromote or sp setrowlockpromote.

Re-run $sp_merge_dup_inline_default$, and reset the values after $sp_merge_dup_inline_default$ finishes.

- sp_merge_dup_inline_default changes only inline default objects for which the default value is a literal string constant or simple numbers (the literal string constant cannot include escaped string delimiters).
- sp_merge_dup_inline_default does not remove any duplicate inline default objects if their source text in syscomments is "encrypted."

Permissions

The permission checks for sp_merge_dup_inline_default differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.185 sp_metrics

Backs up, drops, and flushes QP metrics—always captured in the default running group, which is group 1 in each respective database—and their statistics on queries.

Syntax

Parameters

backup

moves saved QP metrics from the default running group to a backup group, backs up the QP metrics from the old server into a backup group, and moves saved QP metrics from the default running group to a backup group.

<backup group ID>

is the ID of the group the QP metrics from the old server into a backup group. To move saved QP metrics from the default running group to a backup group.

drop

removes QP metrics from the system catalog. If you do not provide '<id>', sp metrics drops the whole group you specified with '<gid>'.

<gid>

is the group ID of the QP metrics from the system catalog.

<id>

is the ID of the QP metrics from the system catalog.

flush

flushes all aggregated metrics in memory to the system catalog. The aggregated metrics for all statements in memory are zeroed out.

```
'help', '<command>'
```

provides usage information on sp metrics commands.

Examples

Example 1

Move the QP metrics from a default group to a backup group:

```
sp_metrics 'backup', '3'
```

Example 2

Provides information about sp metrics flush:

```
sp_metrics 'help', 'flush'
```

Usage

Access metric information using a select statement with order by against the sysquerymetrics view.

Use to back up the QP metrics from the old server into a backup group. To move saved QP metrics from the default running group to a backup group, to remove QP metrics from the system catalog. Flush all aggregated metrics in memory to the system catalog.

See also select, set in Reference Manual: Commands.

Permissions

The permission checks for <code>sp_metrics</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege or with monitor qp performance privilege (for filter, show, help).

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_configure [page 203]

1.186 sp_modify_resource_limit

Changes a resource limit by specifying a new limit value, or the action to take when the limit is exceeded, or both.

Syntax

Parameters

<name>

is the SAP ASE login to which the limit applies. To modify a limit that applies to all users:

- Of a particular application, specify NULL for <name>.
- Using any application, specify NULL for both <name> and <appname>.

<appname>

is the name of the application to which the limit applies. To modify a limit that applies to:

- All applications used by <name>, specify NULL for <appname>.
- A particular application, specify the application name that the client program passes to the SAP ASE server in the login packet.
- All users using any application, specify NULL for both <name> and <appname>.

<rangename>

is the time range during which the limit is enforced. You cannot modify this value, but you must specify a non-null value to uniquely identify the resource limit.

<limittype>

is the type of resource to which the limit applies. You cannot modify this value, but you must specify a non-null value to uniquely identify the resource limit. The value must be one of the following:

- row count limits the number of rows a query can return
- elapsed_time limits the number of seconds in wall-clock time that a query batch or transaction can run
- io_cost limits either the actual cost, or the optimizer's cost estimate, for processing a query
- tempdb_space limits the number of pages from a tempdb database that a single session can have

<limit_value>

is the maximum amount of the server resource that the login or application can use before the SAP ASE server enforces the limit. This must be a positive integer less than or equal to 2^{31} or null to retain the existing value. The following table indicates what value to specify for each limit type:

- row_count the maximum number of rows a query can return before the limit is enforced
- elapsed_time the maximum number of seconds in wall-clock time that a query batch or transaction can run before the limit is enforced
- io cost a unitless measure derived from optimizer's costing formula
- tempdb_space limits the number of pages from a temporary database that a single session can have.

<enforced>

determines whether the limit is enforced prior to or during query execution. You cannot modify this value. Use null as a placeholder.

<action>

is the action to take when the limit is exceeded. The following codes apply to all limit types:

- 1 issues a warning
- 2 aborts the query batch
- 3 aborts the transaction
- 4 kills the session
- null retains the existing value

<scope>

is the scope of the limit. You cannot modify this value. You can use null as a placeholder.

Examples

Example 1

Modifies a resource limit that applies to all applications used by "robin" during the <weekends> time range:

The limit issues a warning when a query is expected to return more than 3000 rows.

Example 2

Modifies a resource limit that applies to the <acctg> application on all days of the week and at all times of the day:

The limit aborts the query batch when estimated query processing time exceeds 45 seconds.

Example 3

This example changes the value of the resource limit that restricts elapsed time to all users using any application during the tu wed 7 10 time range:

```
sp_modify_resource_limit NULL, NULL, tu_wed_7_10, elapsed_time, 90, null,
null, 2
```

The limit value for elapsed time decreases to 90 seconds (from 120 seconds). The values for time of execution, action taken, and scope remain unchanged.

Example 4

This example changes the action taken by the resource limit that restricts the row count of all ad hoc queries and applications run by "joe_user" during the <code>saturday_night</code> time range. The previous value for action was 3, which aborts the transaction when a query exceeds the specified row count. The new value is to 2, which aborts the query batch. The values for limit type, time of execution, and scope remain unchanged:

```
sp_modify_resource_limit joe_user, NULL,
saturday_night, row_count, NULL, NULL, 2, NULL
```

Usage

There are additional considerations when using sp_modify_resource_limit:

- You cannot change the login or application to which a limit applies or specify a new time range, limit type, enforcement time, or scope.
- The modification of a resource limit causes the limits for each session for that login and/or application to be rebound at the beginning of the next query batch for that session.
- SAP ASE provides resource limits to help system administrators prevent queries and transactions from monopolizing server resources. Resource limits, however, are not fully specified until they are bound to a time range.

For more information, see the System Administration Guide.

Permissions

The permission checks for <code>sp_modify_resource_limit</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_add_resource_limit [page 18]
sp_drop_resource_limit [page 287]
sp_help_resource_limit [page 407]

1.187 sp_modify_time_range

Changes the start day, start time, end day, and end time associated with a named time range.

Syntax

```
sp_modify_time_range <name>, <startday>, <endday>, <starttime>, <endtime>
```

Parameters

<name>

is the name of the time range. This must be the name of a time range stored in the systimeranges system table of the master database.

<startday>

is the day of the week on which the time range begins. This must be the full weekday name for the default server language, as stored in the syslanguages system table of the master database, or null to keep the existing <startday>.

<endday>

is the day of the week on which the time range ends. This must be the full weekday name for the default server language, as stored in the syslanguages system table of the master database, or null to keep the existing end day. The <endday> can fall either earlier or later in the week than the <startday>, or it can be the same day as the <startday>.

<starttime>

is time of day at which the time range begins. Specify the <starttime> in terms of a twenty-four hour clock, with a value between 00:00 and 23:59. Use the following form, or null to keep the existing <starttime>:

"<HH>:<MM>"

<endtime>

is the time of day at which the time range ends. Specify the <endtime> in terms of a twenty-four hour clock, with a value between 00:00 (midnight) and 23:59. Use the following form, or null to keep the existing <endtime>:

"<HH>:<MM>"

The <endtime> must occur later in the day than the < starttime>, unless <endtime> is 00:00.

i Note

For time ranges that span the entire day, specify a start time of "00:00" and an end time of "23:59".

Examples

Example 1

Changes the end day of the "business_hours" time range from Friday to Saturday. Retains the existing start day, start time, and end time:

sp_modify_time_range business_hours, NULL, Saturday, NULL, NULL

Example 2

Specifies a new end day and end time for the "before_hours" time range:

```
sp modify time range before hours, Monday, Saturday, NULL, "08:00"
```

Usage

There are additional considerations when using sp_modify_time_range:

- You cannot modify the "at all times" time range.
- It is possible to modify a time range so that it overlaps with one or more other time ranges.
- The modification of time ranges through the system stored procedures does not affect the active time ranges for sessions currently in progress.
- Changes to a resource limit that has a transaction as its scope does not affect any transactions currently in progress.

For more information, see the System Administration Guide.

Permissions

The permission checks for sp modify time range differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage resource limit privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_add_resource_limit [page 18]
sp_add_time_range [page 23]
sp_drop_time_range [page 290]
```

1.188 sp_modifylogin

Deprecated by SAP ASE version 15.7. To modify a login account in SAP ASE, use the alter login command. See Reference Manual: Commands > Commands > alter login.

1.189 sp_modifystats

Allows the system administrator, or any user with permission to execute the procedure and update statistics on the target table, to modify the density values of columns in sysstatistics.

Syntax

```
sp_modifystats [<database>].[<owner>].<table_name>, {"<column_group>" | "all"},
   modify_density, {range | total}, {absolute | factor}, "<value>"
   modify_default_selectivity, {inequality | inbetween}, {absolute | factor},
"<value>"
   modify_unique {range | total}, {absolute | factor}, "<value>"
```

Or:

Parameters

is the name of the table to change. Specify the database name if the table is in another database, and specify the owner's name if more than one table of that name exists in the database. The default value for <owner> is the current user, and the default value for <database> is the current database.

<column_group>

an ordered list of column names. To change a statistic for multiple columns (such as a density value), list the columns in the order used to create the statistic. Separate the column names with commas. For example, if your table has a density statistic on columns a1, a2, a3, a4:

- "a1" modifies column a1.
- "a1, a2, a3" modifies the column group a1, a2, a3,

• You can also use a wildcard character, %, with the column_group parameter to represent a range of characters. For example, "a1, %, a3" modifies the groups a1,a2,a3 and a1, a4, a3, and so on; "a1, %" modifies the groups a1,a2 and a1,a2,a3, and so on, but not a1; "a1%" modifies the groups a1,a2 and a1,a2,a3, and so on, as well as a1.

all

modifies all column group for this table. Because "all" is a keyword, it requires quotes.

modify density

allows you to modify either the range or total density of a column or column group to the granularity specified in the <value> parameter. Range cell density represents the average number of duplicates of all values that are represented by range cells in a histogram. <value> is either the specified density value or a multiple for the current density. Must be between zero and one, inclusive, if absolute is specified. See the *Performance and Tuning Guide* for more information. Where:

- range modifies the range cell density.
- total modifies the total cell density.
- absolute ignore the current value and use the number specified by the
 <value> parameter.
- factor multiply the current statistical value by the <value> parameter.

modify default selectivity

specifies the default selectivity value. Must be between zero and one, inclusive. Where:

- inequality indicates columns in which the predicate has an upper bound or a lower bound, but not both, and includes these range operators: > =, <=, >, <. The default value for inequality is .33
- inbetween indicates columns in which the predicate includes the upper bound and lower bound, and includes these range operators: > =, <=, >, <. The default value for inbetween is .25
- absolute ignore the current value and use the number specified by the value parameter.
- factor multiply the current statistical value by the value parameter.

modify_unique

allows you to modify the range unique or total unique values of a column or column group to the granularity specified in the value parameter.

 range – modifies the estimate for the number of unique values found in the range cells of the histogram. range does not include the frequency cells (that is, singlevalued histogram cells). The estimate is represented as a fraction between 0.0 and 1.0, equal to:

```
unique_range_values / (range_cell_rows * total
rows_in_table)
```

 total – modifies the estimate of the number of unique values for the column or column group (including the NULL value). The optimizer uses this value to estimate group by and distinct cardinality. It is represented as a fraction between 0.0 and 1.0 where the 1.0/<unique count> is stored in the catalogs.

- absolute ignore the current value and use the number specified by the value parameter.
- factor multiply the current statistical value by the value parameter.

REMOVE STICKINESS

removes the stickiness associated with the specified column. Specify null to remove the stickiness from all columns in the table.

"Stickiness" occurs when the SAP ASE server retains the memory for these update statistics parameters:

- using step values
- sampling
- histogram_tuning_factor
- hashing
- no hashing
- partial hashing

Once a phrase is "sticky," the SAP ASE server retains its behavior for that column on subsequent update statistics commands, even if you do not explicitly specify the parameters.

<column name >

is the name of a column in that table.

REMOVE SKEW FROM DENSITY

allows the system administrator to change the total density of a column to be equal to the range density, which is useful when data skew is present. Total density represents the average number of duplicates for all values, those in both frequency and range cells. Total density is used to estimate the number of matching rows for joins and for search arguments with a value that is unknown when the query is optimized. See the *Performance and Tuning Guide* for more information.

REMOVE_SKEW_FROM_DENSITY also updates the total density of any composite column statistics for which this column is the leading attribute. Most commonly, a composite index for which this column is the leading attribute would produce these composite column statistics, but they can also be produced when you issue a composite update statistics command.

Examples

Example 1

Changes the range density for column group c00, c01 in table tab 1 to 0.50000000:

```
sp_modifystats "tab_1", "c00, c01", MODIFY_DENSITY, range, absolute, "0.5"
```

Example 2

The total density for column group c00, c01 in tab_1 is multiplied by 0.5; that is, divided in half:

```
sp_modifystats "tab_1", "c00,c01", MODIFY_DENSITY, total, factor, "0.5"
```

Example 3

The total density for all the columns in table tab 1 is multiplied by 0.5:

```
sp_modifystats "tab_1", "all", MODIFY_DENSITY, total, factor, "0.5"
```

Example 4

Total density for all column groups starting with c12 is changed to equal the range density:

```
sp_modifystats "tab_1", "c12" REMOVE_SKEW_FROM_DENSITY
```

Example 5

Sets the default selectivity of inequality predicates with unknown constants (for example, a1>@v1) to 0.09:

```
sp_modifystats t10, a1, MODIFY_DEFAULT_SELECTIVITY, inequality, absolute,
"0.09"
```

Example 6

Sets the default selectivity for column a2 to use a value of 0.11 if you specify upper bound and a lower bound predicates with unknown constants (for example, a2>@v1 and a2<@v2):

```
sp_modifystats t10, a2, MODIFY_DEFAULT_SELECTIVITY, inbetween, absolute,
"0.11"
```

Example 7

Modifies the range value for all columns for table t10 by a factor of 0.13:

```
sp_modifystats t10, "all", MODIFY_UNIQUE, range, factor, "0.13"
```

Example 8

Modifies the total unique value for all columns for table t10 to an absolute value of 0.14, which indicates there are (1.0 / 0.14) = 7.1428 unique values for each column in the table:

```
sp modifystats t10, "all", MODIFY UNIQUE, total, absolute, "0.14"
```

Usage

There are additional considerations when using <code>sp_modifystats</code>:

- Allows the system administrator to modify the density values of a column—or columns—in sysstatistics.
 - Use optdiag to view a table's statistics. See the Performance and Tuning Guide for more information about table density and using optdiag.
 - Any modification you make to the statistics with sp_modifystats is overwritten when you run
 update statistics. To make sure you are using the most recent statistical modifications, you
 should run sp_modifystats after you run update statistics.
 - Because sp_modifystats modifies information stored in the sysstatistics table, you should make a backup of statistics before execute running sp_modifystats in a production system.
 - You can use modify default selectivity only on an individual column, not a column group.

o SAP ASE uses the default selectivity for modify_default_selectivity when an unknown constant prevents it from using a histogram to estimate selectivity of the respective predicate. The default selectivity for a search argument using inequality is 33%. inequality search arguments include columns for which there is an upper bound predicate or a lower bound predicate, but not both, and use the >=, <=, >, < range operators. The default selectivity for search arguments that include an inbetween search arguments is 25%. inbetween search arguments include columns that have both an upper bound predicate and a lower bound predicate, or use the between operator.

See also update statistics in Reference Manual: Commands.

Permissions

The permission checks for sp modifystats differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with update statistics on the object or with manage any statistics privilege. You must have execute permission on the procedure.

Disabled With granular permissions disabled, you must be a user with update statistics on the object or sa_role. You must have execute permission on the procedure.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Tables used

sysstatistics

1.190 sp_modifythreshold

Modifies a threshold by associating it with a different threshold procedure, free-space level, or segment name.

Syntax

```
sp_modifythreshold <dbname>, <segname>, <free_space>
   [,< new_proc_name>][, <new_free_space>][, <new_segname>]
```

Parameters

<dbname>

is the database for which to change the threshold. This must be the name of the current database.

<segname>

is the segment for which to monitor free space. Use quotes when specifying the "default" segment.

<free_space>

is the number of free pages at which the threshold is crossed. When free space in the segment falls below this level, the SAP ASE server executes the associated stored procedure.

<new_proc_name>

is the new stored procedure to execute when the threshold is crossed. The procedure can be located in any database on the current SAP ASE server or on an Open Server. Thresholds cannot execute procedures on remote SAP ASE servers.

<new_free_space>

is the new number of free pages to associate with the threshold. When free space in the segment falls below this level, the SAP ASE server executes the associated stored procedure.

<new_segname>

is the new segment for which to monitor free space. Use quotes when specifying the "default" segment.

Examples

Example 1

Modifies a threshold on the "default" segment of the mydb database to execute when free space on the segment falls below 175 pages instead of 200 pages. NULL is a placeholder indicating that the procedure name is not being changed:

```
sp modifythreshold mydb, "default", 200, NULL, 175
```

Example 2

Modifies a threshold on the data seg segment of mydb so that it executes the new proc procedure:

```
sp modifythreshold mydb, data seg, 250, new proc
```

Usage

- You cannot use sp_modifythreshold to change the amount of free space or the segment name for the last-chance threshold.
- Use sp_helpthreshold for information about existing thresholds.
- Use sp dropthreshold to drop a threshold from a segment.
- Each database can have up to 256 thresholds, including the last-chance threshold.
- Each threshold must be at least 2 times @@thresh hysteresis pages from the next closest threshold.

See also:

- create procedure, dump transaction in Reference Manual: Commands
- System Administration Guide.

Permissions

The permission checks for sp modifythreshold differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addthreshold [page 62] sp_dboption [page 228] sp_dropthreshold [page 323] sp_helpthreshold [page 493] sp_thresholdaction [page 809]

1.190.1 Crossing a Threshold

When a threshold is crossed, the SAP ASE server executes the associated stored procedure. The SAP ASE server uses the following search path for the threshold procedure:

- If the procedure name does not specify a database, the SAP ASE server looks in the database in which the threshold was crossed.
- If the procedure is not found in this database and the procedure name begins with "sp_", the SAP ASE server looks in the sybsystemprocs database.
- If the procedure is not found in either database, the SAP ASE server sends an error message to the error log.

The SAP ASE server uses a hysteresis value, the global variable <code>@@thresh_hysteresis</code>, to determine how sensitive thresholds are to variations in free space. Once a threshold executes its procedure, it is deactivated. The threshold remains inactive until the amount of free space in the segment rises to <code>@@thresh_hysteresis</code> pages above the threshold. This prevents thresholds from executing their procedures repeatedly in response to minor fluctuations in free space.

1.190.2 The Last-Chance Threshold

By default, the SAP ASE server monitors the free space on the segment where the log resides and executes $sp_thresholdaction$ when the amount of free space is less than that required to permit a successful dump of the transaction log. This amount of free space, the last-chance threshold, is calculated by the SAP ASE server and cannot be changed by users.

If the last-chance threshold is crossed before a transaction is logged, the SAP ASE server suspends the transaction until log space is freed. Use $sp_dboption$ to change this behavior for a particular database. Setting the abort tran on log full option to true causes the SAP ASE server to roll back all transactions that have not yet been logged when the last-chance threshold is crossed.

You cannot use $sp_{modifythreshold}$ to change the free-space value or segment name associated with the last-chance threshold.

Only databases that store their logs on a separate segment can have a last-chance threshold. Use sp logdevice to move the transaction log to a separate device.

Related Information

sp_logdevice [page 567]

1.190.3 Creating Threshold Procedures

Any user with create procedure permission can create a threshold procedure in a database. Usually, a system administrator creates $sp_thresholdaction$ in the master database, and database owners create threshold procedures in user databases.

sp_modifythreshold does not verify that the specified procedure exists. It is possible to associate a threshold with a procedure that does not yet exist.

sp_modifythreshold checks to ensure that the user modifying the threshold procedure has been granted the "sa_role". All system roles active when the threshold procedure is created are modified in systhresholds as valid roles for the user writing the procedure.

The SAP ASE server passes four parameters to a threshold procedure:

- @dbname, varchar (30), which identifies the database
- @segment name, varchar (30), which identifies the segment
- @space left, int, which indicates the number of free pages associated with the threshold
- @status, int, which has a value of 1 for last-chance thresholds and 0 for other thresholds

These parameters are passed by position rather than by name; your threshold procedure can use other names for them, but the procedure must declare them in the order shown and with the correct datatypes.

It is not necessary to create a different procedure for each threshold. To minimize maintenance, create a single threshold procedure in the sybsystemprocs database that can be executed by all thresholds.

Include print and raiserror statements in the threshold procedure to send output to the error log.

1.190.4 Executing Threshold Procedures

Tasks that are initiated when a threshold is crossed execute as background tasks. These tasks do not have an associated terminal or user session. If you execute sp_who while these tasks are running, the status column shows "background".

The SAP ASE server executes the threshold procedure with the permissions of the user who modified the threshold, at the time he or she executed $sp_modifythreshold$, minus any permissions that have since been revoked.

Each threshold procedure uses one user connection, for as long as it takes to execute the procedure.

1.190.5 Disabling Free-Space Accounting

Use the no free space acctg option of $sp_dboption$ to disable free-space accounting on non-log segments.

You cannot disable free-space accounting on log segments.

System procedures cannot provide accurate information about space allocation when free-space accounting is disabled.

Related Information

sp_dboption [page 228]

1.191 sp_modifyuser

Allows you to grant users read only access to objects owned by other users on standby servers.

Syntax

```
sp_modifyuser "<user_name1>", "resolve as", "<user_name2>"
```

Parameters

<user_name1>

is the name of a database user whose object references are resolved on behalf of <user_name2>.

<user_name2>

is the name of the database user whose privileges you are mapping.

Examples

Example 1

Grants user joe read-only privileges for objects owned by user bob on the standby server:

```
sp_modifyuser "joe", "resolve as", "bob"
```

Example 2

Removes the mappings:

```
sp_modifyuser "userA", "resolve as",""
```

Usage

- The user accessing another user's object must have select permission on the object being accessed.
- The user granted read only permission (that is, <user_name1>) may run only select and cursor fetch statements on the data.
- The object resolution does not take effect if the user granted the read-only privileges runs set user, set proxy, or the set role commands after issuing sp_modifyuser ... resolve as.

Permissions

You must be the database owner to issue sp modifyuser ... resolve as.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.192 sp_monitor

Displays statistics about the SAP ASE server.

Syntax

The syntax is divided by command type for clarity, since many of the types have parameters of their own. The following code paragraph shows the syntax of the stored procedure as a whole, followed by the syntax of each command type interface.

```
sp_monitor [[connection | statement], [cpu | diskio | elapsed time]]
   [event, [<spid> ]]
   [<procedure>, [<dbname>, [<procname>[, summary | detail]]]]
   [enable] [disable]
   [help],
   [deadlock][procstack]
```

Parameters

connection

displays information on each connection. connection uses the following monitoring tables:

- monProcessSQLText
- monProcessActivity

statement

displays information on each statement. statement uses the following monitoring tables:

- monProcessSQLText
- monProcessStatement

cpu | diskio | elapsed time

these parameters order the output of <code>sp_monitor</code> connection <code>or sp_monitor</code> statement.

- cpu indicates the amount of CPU time consumed by each different connection or statement
- diskio indicates the number of physical reads performed by each connection or statement.
- elapsed time indicates the sum of the CPU time and the wait times for each connection or statement.

event

displays three possibilities. When you specify:

- No option only user tasks are displayed.
- sp_monitor, event, "-1" wait information about all tasks, both user and system, is displayed.
- sp_monitor, event, "spid" wait information pertaining to only the specified server process ID is displayed.

<spid>

allows you to obtain event information for a specific task by entering its <spid>. You must specify the numeric value of <spid> within quotation marks.

displays statistics about stored procedures:

ProcName	The stored procedure being monitored.
----------	---------------------------------------

DBNAME The database in which the stored procedure is located.

NumExecs The approximate number of executions of this specific stored

procedure.

AvgCPUTime The average CPU time that it takes for the stored procedure to

execute.

AvgPhysicalReads The average number of disk reads performed by the stored

procedure.

AvgLogicalReads The average number of logical reads performed by the stored

procedure.

AvgMemUsed_KB The average amount of memory in KB used by the stored

procedure.

<dbname>

displays information on procedures for the specified database.

cname>

displays information on the specified procedure.

summary | detail

displays either summary information, which provides an average of all instances of the procedure, or detailed information, which provides information on every instance of the stored procedure.

enable

enables the new options for sp_monitor. It turns on the configuration parameter required to begin monitoring.

disable

disables monitoring.

help

displays the syntax and examples for sp_monitor, and also reports extensive information on using this procedure for deadlock analysis:

sp monitor 'help', 'deadlock'

The help option also provides command-specific examples.

deadlock

tells $sp_monitor$ to process historical data from the monDeadlock table, and prints out a block of output for each instance of deadlock.

procstack

examines the execution context of a task, including that of a deeply nested stored procedure. The stack of procedures executed is extracted from the monProcessProcedures monitoring table.

Examples

Example 1

Reports information about how busy the SAP ASE server has been:

Example 2

Shows how to display information about connections:

By default, the output by default is sorted in the descending order of the ElapsedTime.

Example 3

Identifies the connections performing the most physical reads:

```
1> sp_monitor "connection", "diskio"
2> go

spid LoginName Physical_Reads LocksHeld SQLText

12 sa 117 2 exec get_employee_salaries
27 sa 1 0 exec get_employee_perks
```

Example 4

Displays information about each statement:

```
1> sp_monitor "statement"
2> go
```

spid	LoginName	ElapsedTime	SQLText
12	sa	100	<pre>exec get_employee_salaries</pre>

Example 5

Displays the events each task spent time waiting for and the duration of the wait, reported in descending order of wait times:

```
1> sp_monitor "event"
2> go
```

hk: pause for some time 10 108200 waiting for incoming network data 10 107800 waiting while allocating new client socket 15 17100 waiting for network send to complete 14 5900 waiting for CTLIB event to complete 14 400 waiting for disk write to complete 17 200 hk: pause for some time 18 100 waiting on run queue after yield 19 100 waiting for network send to complete
12 100 waiting for network send to complete

Example 6

Displays event data for spid 14:

```
1> sp_monitor "event","14"
2> go
```

```
WaitTime Description

9000 waiting for CTLIB event to complete
600 waiting for disk write to complete
200 waiting for disk write to complete
100 waiting on run queue after yield
100 wait for buffer write to complete
```

Example 7

Provides a summary of most recently run procedures, sorted in descending order of average elapsed time. This example provides historical monitoring information rather than the current state:

```
1> sp_monitor "procedure"
2> go
```

```

```

delivery tpcc 1000 0 800 23 49 0 2

Usage

i Note

Before using the new parameters associated with $sp_monitor$, you must set up monitoring tables and the related stored procedures needed to enable. See Performance and Tuning: Monitoring and Analyzing > Installing Monitoring Tables.

- The SAP ASE server keeps track of how much work it has done in a series of global variables. sp_monitor
 displays the current values of these global variables and how much they have changed since the last time
 the procedure executed.
- For each column, the statistic appears in the form <number> (<number>) -<number>% or <number> (<number>).
 - The first number refers to the number of seconds (for cpu_busy, io_busy, and idle) or the total number (for the other columns) since the SAP ASE server restarted.
 - The number in parentheses refers to the number of seconds or the total number since the last time sp_monitor was run. The percent sign indicates the percentage of time since sp_monitor was last run.

For example, if the report shows cpu_busy as "4250 (215) -68%", it means that the CPU has been busy for 4250 seconds since the SAP ASE server was last started, 215 seconds since $sp_monitor$ last ran, and 68 percent of the total time since $sp_monitor$ was last run.

For the total_read column, the value 394 (67) means there have been 394 disk reads since the SAP ASE server was last started, 67 of them since the last time $sp_{monitor}$ was run.

• This list shows the monitoring tables accessed by monitoring type, as well as the configuration option and its type for each table:

connection	0	monProcessSQLext
		o max SQL text monitored - Value
		O SQL batch capture - Boolean
	0	monProcessActivity
		wait event timing - Boolean
		o per object statistics active - Boolean
procstack	0	monProcessProcedures
		○ None – N/A
statement	0	monProcessSQLText
		o max SQL text monitored — Value
		O SQL batch capture - Boolean
	0	monProcessStatement
		o statement statistics active - Boolean
		o per object statistics active - Boolean
		wait event timing - Boolean

wait event timing - Value

o process event waits - Boolean

statement statistics active - Boolean
 per object statistics active - Boolean
 statement pipe max messages - Value
 statement pipe active - Boolean

deadlock pipe max messages - Valuedeadlock pipe active - Boolean

- sp_monitor connection monitors connections actively executing T-SQL only, and does not report on all connections.
- You must run sp_monitor from the master database. However, if you are analyzing deadlock data archived in another database, you can run sp_monitor_deadlock from that database.
- sp_monitor event no longer displays all tasks (including system tasks), when called with no options. In SAP ASE version 15.0.2 and above, the event option provides three possibilities. When:
 - No option is provided only user tasks are displayed.
 - You specify sp_monitor, event, "-1", wait information about all tasks, both user and system, is displayed.
 - You specify sp_monitor, event, "spid", wait information pertaining to only the specified server process ID is displayed.
- The following describes the columns in the sp_monitor report, the equivalent global variables, if any, and their meanings. With the exception of last_run, current_run and seconds, these column headings are also the names of global variables except that all global variables are preceded by @@. There is also a difference in the units of the numbers reported by the global variables the numbers reported by the global variables are not milliseconds of CPU time. but machine ticks:

Column Heading	Equivalent Variable and Description
last_run	Clock time at which the sp_monitor procedure last ran.
current_run	Current clock time.
seconds	Number of seconds since sp_monitor last ran.
cpu_busy	${\tt @@cpu_busy.}$ Number of seconds in CPU time that the SAP ASE server's CPU was doing SAP ASE work.
io_busy	@@io_busy. Number of seconds in CPU time that the SAP ASE server has spent doing input and output operations.
idle	@@idle. Number of seconds in CPU time that the SAP ASE server has been idle.
packets_received	${\tt @@pack_received.}\ {\tt Number\ of\ input\ packets\ read\ by\ the\ SAP\ ASE\ server.}$
packets_sent	@@pack_sent. Number of output packets written by the SAP ASE server.

Column Heading	Equivalent Variable and Description
packet_errors	${\tt @@packet_errors.} Number of errors \ detected \ by \ the \ SAP \ ASE \ server \ while \\ reading \ and \ writing \ packets.$
total_read	@@total_read. Number of disk reads by the SAP ASE server.
total_write	@@total_write. Number of disk writes by the SAP ASE server.
total_errors	<pre>@@total_errors. Number of errors detected by the SAP ASE server while reading and writing.</pre>
connections	@@connections. Number of logins or attempted logins to the SAP ASE server.

- The first time sp monitor runs after SAP ASE start-up, the number in parentheses is meaningless.
- The SAP ASE server's housekeeper task uses the server's idle cycles to write changed pages from cache to disk. This process affects the values of the cpu_busy, io_busy, and idle columns reported by sp_monitor. To disable the housekeeper task and eliminate these effects, set the housekeeper free write percent configuration parameter to 0:

```
sp_configure "housekeeper free write percent", 0
```

- You must run sp monitor when a representative workload is running on the system.
- Typically, run procedures in this sequence:
 - Run sp monitor enable
 - Invoke sp_monitor options
 - Run sp monitor disable when you have completed the monitoring
- When you are using sp_monitor procedure, the number of rows returned can be very large; you may want to use the summary option instead of the detail option. It may also take a while for this command to complete on an active system.

Permissions

The permission checks for $sp_monitor$ are the same whether or not granular permissions is enabled:

- The database owner of sybsystemprocs can execute sp_monitor and can grant execute permission to other users
- The stored procedure is created with execute as owner. The owner is sa. The owner requires mon_role, which user sa has by default.

For more information see Monitoring Tables in Performance and Tuning: Monitoring and Analyzing.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_who [page 847]

1.193 sp_monitorconfig

Displays cache usage statistics regarding metadata descriptors for indexes, objects, databases, and the kernel resource memory pool. sp_monitorconfig also reports statistics on auxiliary scan descriptors used for referential integrity queries, and usage statistics for transaction descriptors and DTX participants.

Syntax

```
sp monitorconfig "<configname>"[, "<result tbl name>"][, "full"]
```

Parameters

<configname>

is either all, or part of the configuration parameter name with the monitoring information that is being queried. Valid configuration parameters are listed in the "Usage" section. Specifying all displays descriptor help information for all indexes, objects, databases, and auxiliary scan descriptors in the server.

"<result tbl name>"

(optional) is the name of the table you create to save the stored procedure results. If you pass a table name for <result_tabl_name> that does not already exist, sp_monitorconfig creates a table to hold the result set.

"full"

returns a set of values for the configname that you specify. The values are:

- config_val reports the configured value
- system val reports the systems default value when there's novalue configured
- total val reports the actual value used

Examples

Example 1

Shows all items that are open:

```
sp_monitorconfig "open"
```

Configuration option is not un option_name	ique. config_value	run_value
number of open databases	12	12
number of open objects	500	500
curread change w/ open cursors	1	1
open index hash spinlock ratio	100	100
number of open indexes	500	500
open index spinlock ratio	100	100
open object spinlock ratio	100	100
number of open partitions	500	500

Example 2

Shows the status for all configurations:

```
sp_monitorconfig "all"
```

```
Usage information at date and time: May 6 2010 4:32PM.

ratio 400 0 0.00 0 0
                                          NULL
```

Example 3

Shows 61 active object metadata descriptors, with 439 free. The maximum used at a peak period since the SAP ASE server was last started is 61:

```
Usage information at date and time: Apr 22 2002 2:49PM.

Name

Num_free Num_active Pct_act Max_Used Reuse_cnt Instance
Name
```

```
number of open objects 439 61 12.20 61 0 NULL
```

You can then reset the size to 550, for example, to accommodate the 439 maximum used metadata descriptors, plus space for 10 percent more:

```
sp_configure "number of open objects", 330
```

Example 4

Shows the maximum number of index metadata descriptors, which is 44:

```
Usage information at date and time: Apr 22 2002 2:49PM.

Name

Num_free Num_active Pct_act Max_Used Reuse_cnt Instance

Name

number of open
indexes 556 44 7.33 44 0 NULL
```

You can reset the size to 100, the minimum acceptable value:

```
sp_configure "number of open indexes", 100
```

Example 5

Shows the number of active scan descriptors as 30, though the SAP ASE server is configured to use 200. Use the number of aux scan descriptors configuration parameter to reset the value to at least 32. A safe setting is 36, to accommodate the 32 scan descriptors, plus space for 10 percent more:

```
Sp_monitorconfig "aux scan descriptors"

Usage information at date and time: Apr 22 2002 2:49PM.

Name

Num_free Num_active Pct_act Max_Used Reuse_cnt Instance
Name

number of aux scan
descri 170 30 15.00 32 0 NULL
```

Example 6

The SAP ASE server is configured for five open databases, all of which have been used in the current session:

```
Name
Num_free Num_active Pct_act Max_Used Reuse_cnt Instance
Name
number of open
databases

0 5 100.00 5 Yes NULL
```

However, as indicated by the Reuse_cnt column, an additional database needs to be opened. If all 5 databases are in use, an error may result, unless the descriptor for a database that is not in use can be reused. To prevent an error, reset number of open databases to a higher value.

Only 10.2 percent of the transaction descriptors are currently being used. However, the maximum number of transaction descriptors used at a peak period since the SAP ASE server was last started is 523:

```
Usage information at date and time: Apr 22 2002 2:49PM.

Name

Num_free Num_active Pct_act Max_Used Reuse_cnt Instance
Name

txn to pss
ratio

784 80 10.20 523 0 NULL
```

Example 8

Using the optional parameter <result_tbl_name> to create a user table saves the sp_monitorconfig result to this table:

```
create table sample_table
(Name varchar(35),
Config_val int,
System_val int,
Total_val int,
Num_free int,
Num_active int,
Pct_act char(6),
Max_Used int,
Reuse_cnt int,
Date varchar(30),
Instance_Name varchar(35))
```

The name of the table created becomes the second parameter of sp_monitorconfig. Capture the values for number of locks and number of alarms in sample table:

```
sp_monitorconfig "locks", sample_table
sp_monitorconfig "number of alarms", sample_table
```

Display the values captured in sample table:

```
      Select * from sample_table

      Name
      Config_val System_val Total_val Num_free Num_active

      Pct_act Max_used Reuse_cnt Date
      Instance_Name

      number of locks
      5000
      684
      5000
      4915
      85

      1.70
      117
      0
      Aug 23 2006
      6:53AM

      number of alarms
      40
      0
      40
      28
      12

      30.00
      13
      0
      Aug 23 2006
      6:53AM
```

The result set saved to the table accumulates until you delete or truncate the table.

i Note

If sample table is in another database, you must provide its fully qualified name in quotes.

Displays the configure value, system value, and run value columns of all the configurations:

```
sp_monitorconfig "all", null, "full"
go
```

Usage information at Name Num_free Num_activ	Configu	ire Value Sy	stem Value Ru

txn to pss ratio	• • • • • • • • • • • • • • • • • • • •	16	0	16	
400	0 0.00	0	0		NULL

Usage

There are additional considerations when using sp monitorconfig:

- The output for additional network memory reports the utilization statistics for the global network memory pool regardless of whether or not memory has been added to this pool by setting additional network memory to a positive value.
- If the max cis remote connections configuration parameter has a config_value, the system_val reports a value of zero (0).
- The Max_Used value reported by sp_monitorconfig for the number of locks configuration parameter can report a value larger than the highest number of locks used. Use these values when monitoring locks:
 - Num active indicates the number of active locks being used
 - Num free indicates the number of free locks
 - Pct act indicates the percentage of active locks

The Max_Used field displayed indicates the number of locks currently available in cache, and not the maximum number used. sp_monitorconfig uses this interpretation only for locks, and not for reporting on any other values.

• If you reconfigure a resource using a value that is smaller than the original value it was given, the resource does not shrink, and the Num_active configuration parameter can report a number that is larger than Total_val. The resource shrinks and the numbers report correctly when the SAP ASE server restarts.

- sp_monitorconfig displays cache usage statistics regarding metadata descriptors for indexes, objects, and databases, such as the number of metadata descriptors currently in use by the server.
- sp_monitorconfig also reports the number of auxiliary scan descriptors in use. A scan descriptor manages a single scan of a table when queries are run on the table.
- sp monitorconfig monitors the following resources:
 - o additional network memory
 - o audit queue size
 - O heap memory per user
 - o max cis remote connection
 - o max memory
 - o max number network listeners
 - o memory per worker process
 - o max online engines
 - o number of alarms
 - o number of aux scan descriptors
 - o number of devices
 - o number of dtx participants
 - o number of java sockets
 - o number of large i/o buffers
 - o number of locks
 - o number of mailboxes
 - $^{\circ}$ number of messages
 - o number of open databases
 - o number of open indexes
 - o number of open objects
 - o number of open partitions
 - o number of remote connections
 - o number of remote logins
 - \circ number of remote sites
 - o number of sort buffers
 - o number of user connections
 - $^{\rm O}$ number of worker processes
 - o partition groups
 - o permission cache entries
 - $^{\circ}$ procedure cache size
 - o size of global fixed heap
 - o size of process object heap
 - o size of shared class heap
 - o size of unilib cache
 - o txn to pss ratio
- The number of sort buffers configuration parameter is not a server-wide setting; it specifies and limits the number of sort buffers per sort. However, the sp_monitorconfig counters are reported server-wide. If more than one sort operation is in progress, and each of them is using a large number of sort

buffers (up to the value of number of sort buffers), the total number of sort buffers can exceed the value of number of sort buffers.

The server uses sort buffers for sort operations like update statistics, create index, order by, sort merge join, reformatting (store_index) and so on. Each operation can use a number of sort buffers, up to value configured for number of sort buffers. If multiple connections are running with sort operations, the number of used sort buffers may be larger than the value of number of sort buffers. This is an expected result. However, issuing sp_monitorconfig "number of sort buffers" shows higher numbers than the configured value.

• SAP ASE uses the value of heap memory per user as a seed value for configuring the global heap pool. The value for global heap memory is based on this formula:

```
("number of user connections" + "number of worker processes") {\tt X} "heap memory per user"
```

When it starts, the server allocates the global heap memory pool based on the value of heap memory per user and the number of configured user connections and worker processes, and users acquire heap memory from the global heap memory pool as needed.

sp_monitorconfig "heap memory per user" displays information about the usages of the global pool per user. The Num_active and Max_Used counters displayed by sp_monitorconfig "heap memory per user" represent the total memory used from the global heap memory pool, and values greater than the configured value forheap memory per user are expected.

- The columns in the sp_monitorconfig output provide the following information:
 - Num_free specifies the number of available metadata or auxiliary scan descriptors not currently used.
 - Num_active specifies the number of metadata or auxiliary scan descriptors installed in cache (that is, active).
 - \circ Pct_active specifies the percentage of cached or active metadata or auxiliary scan descriptors.
 - Max_Used specifies the maximum number of metadata or auxiliary scan descriptors that have been in use since the server was started.
 - Reuse_cnt specifies whether a metadata descriptor was reused in order to accommodate an
 increase in indexes, objects, or databases in the server. The returned value is Yes, No or NA (for
 configuration parameters that do not support the reuse mechanism, such as the number of aux scan
 descriptors).
- Use the value in the Max_Used column as a basis for determining an appropriate number of descriptors; be sure to add about 10 percent for the final setting. For example, if the maximum number of index metadata descriptors used is 142, you might set the number of open indexes configuration parameter to 157.
- If the Reused column states Yes, reset the configuration parameter to a higher value. When descriptors need to be reused, there can be performance problems, particularly with open databases. An open database contains a substantial amount of metadata information, which means that to fill up an open database, the SAP ASE server needs to access the metadata on the disk many times; the server can also have a spinlock contention problem. To check for spinlock contention, use the system procedure sp_sysmon. See the Performance and Tuning Series: Monitoring Adaptive Server with sp_sysmon. To find the current number of indexes, objects, or databases, use sp_countmetadata.
- To get an accurate reading, run sp_monitorconfig during a normal SAP ASE peak time period. You can run sp_monitorconfig several times during the peak period to ensure that you are actually finding the maximum number of descriptors used.

<result tbl name> creates a table using the following syntax:

```
create table table_name(
   Name varchar(35), Num_free int,
   Num_active int, Pct_act char(6),
   Max_Used int, Reuse_cnt int,
   Date varchar(30))
```

All the result information is saved in this table, which returns no standard output.

- Some configuration parameters, such as <number of sort buffers> and <txn to pss ratio>, are dependent on the number of configured user connections, while other configuration parameters, such as <max number of network listeners>, are per engine.
- For the configuration value <permission cache entries>, the values of Num_free, Num_active, Pct_act, and Max_Used are averages of per connection values, however Reuse_cnt is a server-wide value.
- The output of sp_monitorconfig uses the number of user connections and online engines to calculate the values for the columns num free, num active, pct act and max used.
- The updates on the internal monitor counters are done without using synchronization methods because of performance reasons. For this reason, a multi-engine SAP ASE server under heavy load might report numbers in the sp monitorconfig output that are not a completely accurate.
- You might see the number of active locks as greater than 0 on an idle system. These "active" locks are reserved and used internally.

Permissions

The permission checks for <code>sp_monitorconfig</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with mon_role or have manage server privileges.

Disabled With granular permissions disabled, you must be a user with either mon_role or sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_configure [page 203]
sp_countmetadata [page 215]

```
sp_helpconfig [page 424]
sp_helpconstraint [page 434]
sp_sysmon [page 792]
```

1.194 sp_monitor_server

Provides server-wide monitoring information.

Syntax

```
sp_monitor_server [<server_name>]
```

Parameters

<server_name>

is the name of the server.

Examples

Example 1

Displays the current server monitoring information:

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.195 sp_nvbindcache

Binds databases to non-volatile cache.

Syntax

```
sp_nvbindcache <nv_cache_name>, <database_name>
```

Parameters

```
<nv_cache_name>
```

is the name of the named NV cache.

<database name>

is the name of the database you are binding.

Examples

Example

This example binds a database named tdb1 to an NV cache named nvcache1:

```
1> sp_nvbindcache nvcache1, tdb1
2> go

database: tdb1 found bound to NV cache: nvcache1
Binding/Unbind operations between databases and NV caches are critical operations, please be careful before initiating the process (return status = 0)
```

Usage

You can specify only a database when using sp_nvbindcache to create a binding to an NV cache. SAP ASE displays an error if you specify an object other than a database in the procedure.

See System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

A user requires sa_role to execute sp_nvbindcache.

1.196 sp_nvcacheconfig

Manages (creates, changes, drops, and adds) non-volatile cache on a non-volatile device that is already created.

Syntax

```
sp_nvcacheconfig <cachename>,'device=<device_name>'[,
'dirty_threshold=<threshold_percent>'][, selectivity=<selectivity_value>]
```

Parameters

<cachename>

is the name of the NV cache.

device=<device name>

is the non-volatile device on which the NV cache resides. Setting device=NULL deletes the NV cache.

dirty threshold=<threshold percent>

specifies the threshold of dirty buffer in NV cache, beyond which the NV cache lazy cleaner task cleans this cache. The valid values are:

- The minimum value is 10
- The maximum value is 90
- The default value is 50

If the value is low, the NV cache lazy cleaner perform frequent writes to the HDD to clean pages in NV cache.

selectivity=<selectivity_value>

determines the pages to evict from the NV cache. <selectivity value> is one of:

- 0 evicts all pages being unhashed from the main memory cache.
- 1 evicts pages accessed more than once (the default setting). A value of 1 filters out many infrequently accessed pages.
- 5 evicts pages accessed more than 5 times.

Examples

Create NV cache

Enables the memscale feature, creates an NV cache device named cachedisk, then creates a NV cache named nvc:

```
sp configure 'enable mem scale', 1
go
disk init
name = 'cachedisk',
physname = './cachedisk.dat',
type = 'nvcache',
size = '1000M'
sp nvcacheconfig nvc, 'device=cachedisk'
qo
(return status = 0)
sp nvcacheconfig
go
NV Cache Name NV Cache Size Dirty Threshold Selectivity
              1024.00 MB
                                          5.0
(1 row affected)
NV Cache Name NV Device Name NV Device Location
 ------
              cachedisk
                              ./cachedisk.dat
(return status = 0)
```

Create NV cache

Creates an NV cache named nvc on a device named cachedisk, with a dirty threshold percentage of 40:

```
sp_nvcacheconfig 'nvc', 'device=cachedisk', 'dirty_threshold=40'
go
```

Delete NV cache

Deletes an NV cache named nvCache1:

```
sp_nvcacheconfig nvCache1,'device=NULL'
NV cache = nvCache1 is being deleted
(return status = 0)
sp_nvcacheconfig
go
No NV Cache exists for this server
(return status = 1)
```

Create an NV cache with selectivity

Creates a cache with a selectivity of 5

```
sp_nvcacheconfig nvc, 'device=cachedisk', 'selectivity=5'
```

Display NV cache

Displays information about all named NV caches:

```
sp nvcacheconfig
go
 NV Cache Name NV Cache Size Dirty Threshold
                                                             Selectivity
       100.00 MB
10.00 MB
nvc1
                                                      50
                                                                         1
          10.00 MB
10.00 MB
nvc2
                                                      50
nvc3
(1 row affected)
NV Cache Name NV Device Name NV Device Location
                 cachedisk1 ./cachedisk1.dat
cachedisk2 ./cachedisk2.dat
cachedisk3 ./cachedisk3.dat
nvc1
nvc2
nvc3
(return status = 0)
```

Display a specific NV cache

This example displays information about an NV cache named "nvc1":

Usage

- This stored procedure will make sure the non-volatile device is already created and is of special type "non-volatile cache." Issuing sp helpdevice displays NV cache device on the NV cache device.
- Before you can create a named NV cache, create and activate the device on which the NV cache will reside by using the disk init utility. For example:

```
disk init name="NV_CACHE1",
   physname="/my_dev11/user1/cssdDir/bootClust/devDir/nvdev11.dat",
   size="1000M",
   type='nvcache'
```

- You can only create NV cache on devices created with type "nvcache."
- There is a one-to-one mapping ratio between NV caches and devices; that is, you cannot create two caches for a single device, and so on.
- The size of the cache is determined by the size of the device, as reported by the sysdevices table.

• Before invoking sp_nvcacheconfig, make sure the device is active.

See System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

Users must have sa_role to execute sp_nvcacheconfig.

1.197 sp_nvhelpcache

Provides information about non-volatile cache.

Syntax

```
sp_nvhelpcache [<NV_cachename>]
```

Parameters

<NV_cachename>

is an optional parameter that specifies the name of the NV cache.

Examples

Example 1

This example displays information about an NV cache named nvcache1:

Usage

See System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

Any user can use sp nvhelpcache.

1.198 sp_nvunbindcache

Drops the database binding for the named non-volatile cache.

Syntax

sp_ununbindcache <database_name>

Parameters

<database_name>

is the name of the database with the binding you are removing from the NV cache.

Examples

Unbind the NV cache

```
1> sp_ununbindcache tdb1
2> go
```

database: tdb1 found bound to NV cache: nvcache1 Binding/Unbind operations between databases and NV caches are critical operations, please be

```
careful before initiating the process (return status = 0)
```

Usage

See System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

Users must have sa_role to execute sp_unbindssdcache.

1.199 sp_object_stats

Shows lock contention, lock wait-time, and deadlock statistics for tables and indexes.

Syntax

```
sp_object_stats <interval>[, <top_n>[, <dbname>, <objname>[, <rpt_option>]]]
```

Parameters

<interval>

specifies the time period for the sample. It must be in HH:MM:SS form, for example "00:20:00".

<top_n>

is the number of objects to report, in order of contention. The default is 10.

<dbname>

is the name of the database to report on. If no database name is given, contention on objects in all databases is reported.

<objname>

is the name of a table to report on. If a table name is specified, the database name must also be specified.

<rpt_option>

specifies the report type:

- rpt_locks reports grants, waits, deadlocks and wait times for the tables with the highest contention. rpt_locks is the default.
- rpt_objlist reports only the names of the objects that had the highest level of lock activity.

Examples

Example 1

Reports lock statistics on the top 10 objects server-wide:

```
sp_object_stats "00:20:00"
```

Example 2

Reports only on tables in the pubtune database, and lists the five tables that experienced the highest contention:

```
sp_object_stats "00:20:00", 5, pubtune
```

Example 3

Shows only the names of the tables that had the highest locking activity, even if contention and deadlocking does not take place:

```
sp_object_stats "00:15:00", @rpt_option = "rpt_objlist"
```

Usage

There are additional considerations when using sp object stats:

• sp_object_stats reports on the shared, update, and exclusive locks acquired on tables during a specified sample period. The following reports shows the titles tables:

```
Object Name: pubtune..titles (dbid=7, objid=208003772,lockscheme=Datapages)
                                      UP PAGE
                                                           EX PAGE$
 Page Locks SH_PAGE
 Grants:
                94488
                                       4052
                                                            4828
                                                                 776
 Waits:
                  532
                                            500
 Deadlocks:
                       4
                                             0
                                                                  24
                                                           2831556 ms
                                      14265708 ms
                 20603764 ms
 Wait-time:
                    0.56%
                                          10.98%
                                                               13.79%
 Contention:
 *** Consider altering pubtune..titles to Datarows locking.
```

The meaning of the values are:

- Grants the number of times the lock was granted immediately.
- $\circ \ \ \mbox{\tt Waits}$ the number of times the task needing a lock had to wait.
- O Deadlocks the number of deadlocks that occurred.
- Wait-time the total number of milliseconds that all tasks spent waiting for a lock.

- o Contention the percentage of times that a task had to wait or encountered a deadlock.
- sp_object_stats recommends changing the locking scheme when total contention on a table is more than 15 percent, as follows:
 - If the table uses allpages locking, it recommends changing to datapages locking.
 - o If the table uses datapages locking, it recommends changing to datarows locking.
- Trace flag 1213 is enabled internally when you first execute <code>sp_object_stats</code> and disabled when the procedure is finished. If you cancel the system procedure before it finished, you must check if trace 1213 is still enabled and then disable it manually with dbcc traceoff:

```
dbcc traceoff (1213)
```

Issue this query to determine if trace flag 1213 is currently set:

```
select * from sysoptions where number = 1213
```

- sp_object_stats creates a table named tempdb..syslkstats. This table is not dropped when the stored procedure completes, so it can be queried by a system administrator using Transact-SQL.
- Only one user at a time should execute <code>sp_object_stats</code>. If more than one user tries to run <code>sp_object_stats</code> simultaneously, the second command may be blocked, or the results may be invalid.
- The tempdb..syslkstats table is dropped and re-created each time sp object stats is executed.
- The structure of tempdb..syslkstats is:

Column name	Datatype	Description
dbid	smallint	Database ID
objid	int	Object ID
lockscheme	smallint	Integer values 1–3: o 1 – allpages o 2 – datapages o 3 – datarows
page_type	smallint	0 – data page1 – index page
stat_name	char(30)	The statistics represented by this row The values in the stat_name column are composed of three parts: The first part is "ex" for exclusive lock, "sh" for shared lock, or "up" for update lock. The second part is "pg" for page locks, or "row" for row locks. The third part is "grants" for locks granted immediately, "waits" for locks that had to wait for other locks to be released, "deadlocks" for deadlocks, and "waittime" for the time waited to acquire the lock.
stat_value	float	The number of grants, waits or deadlocks, or the total wait time.

• If you specify a table name, sp_object_stats displays all tables by that name. If more than one user owns a table with the specified name, output for these tables displays the object ID, but not the owner name.

See also:

• alter table in Reference Manual: Commands

Permissions

The permission checks for sp object stats differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.200 sp_objectsegment

Reports the partition name, segment name, and creation date for the specified object.

Syntax

sp_objectsegment <object_name>

Parameters

<object_name>

is the name of the object. Acceptable objects are:

- System tables
- Views
- User tables
- System procedures

- Defaults
- Rules
- Triggers
- Referential constraints
- Check constraints
- Extended types
- Functions
- Computed columns
- Partitions

Example 1

Reports information about the authors table:

```
Partition_name Data_located_on_segment When_created auidind_576002052 default Feb 9 2012 11:18AM
```

Permissions

Any user may run sp objectsegment.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.201 sp_opt_querystats

Returns a performance analysis for the selected query.

Syntax

Parameters

```
"<query_text>"
```

is the text of the query you are analyzing, enclosed in quotation marks.

help

displays syntax and usage information for sp opt querystats.

<diagnostic_options>

(Optional) the diagnostic parameters based on set options. The diagnostic parameters and the set options are:

statio set statistics io on

showplan on

resource set statistics resource on

switches show switches

option_show_long set option show long

option show long and option show are mutually

exclusive.

option_show set option show on

set nodata on is not executed when you include showdata.

 Only available when you specify the exec or allexec options.

exec set noexec on

set noexec on is not executed when you include exec.

allrows_mix
set plan optgoal allrows mix

allrows mix, allrows oltp, and allrows dss are

mutually exclusive.

allrows_oltp
set plan optgoal allrows oltp

allrows_dss set plan optgoal allrows dss

diagmode Returns enhanced progress information.

Enables the first seven options.

all and allexec cannot be combined with other parameters,

and are mutually exclusive.

allexec Enables the first seven options.

The allexec option includes the all option.

null

 $sp_opt_querystats$ requires three parameters to specify the name of a database. If you do not require diagnostic options, enter a value of null for this parameter to specify a value for the <database name> parameter.

<database_name>

(optional) the name of the database in which the query is executed. Use this parameter if the query you are analyzing does not have fully qualified tables.

<user name>

(Optional) name of the user who executes the query within the database specified by the <database_name> parameter. This user must already exist in the database, and the login executing sp_opt_querystats must have permission to execute the setuser command in that database.

Examples

Example 1

Analyzes a select command on the pubs2 database:

```
sp_opt_querystats 'select * from pubs2.dbo.authors'
```

Analyzes a select command on the pubs2 database, and includes information based on enabling these set commands: set showplan, set statistics io, set option show, set statistics plancost on:

```
sp_opt_querystats 'select * from pubs2.dbo.authors',
    'showplan,statio,option_show, plancost'
```

Usage

There are additional considerations when using <code>sp_opt_querystats</code>:

- You must include the <code>exec</code> command for <code>sp_opt_querystats</code> to execute the query.
- To run sp_opt_querystats as a different user, include the setuser command with the exec immediate command or in an out query context.
- You must include the showdata command for sp query stats to return the result set.
- After you issue set quoted_identifier on, you may surround sp_opt_querystats options with quotes. For example:

```
sp_opt_querystats 'select "col" from "MYTABLE"', 'all','DB'
```

- The option list must be enclosed in quotation marks if you include more than one option, or if you specify the keyword all.
- Running sp opt querystats without any options is the same as running it with the all option.

Permissions

Any user can execute $sp_opt_querystats$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.202 sp_optgoal

Creates a user-defined optimization goal, and defines the set of active criteria included in the goal. This system procedure contains the functionality to make optimization goals that are run and saved into global optimization levels in the server using <code>sp_configure</code>. You can use this at the session level using the <code>set</code> command, or globally via <code>sp_configure</code>.

Syntax

```
sp_optgoal '<goal_name>', <action>
```

Parameters

<goal_name>

name of the goal you are creating. <goal_name> cannot be longer than 12 characters.

<action>

action for sp_optgoal to perform. One of:

- show | null | no action displays the contents of the goal.
- save creates new goal or updates and existing goal.
- delete deletes the goal.

Examples

Example 1

If you set these goals for the current session:

```
SET PLAN OPTLEVEL ase_current
SET PLAN OPTGOAL allrows_mix
SET HASH_JOIN 1
```

This command saves these settings in a goal named goal_1:

```
sp_optgoal 'goal_1', 'save'
```

Either of these allow you to use the settings for goal_1 for the current session:

• Using the set command:

```
set plan optgoal goal_1
```

• Using sp configure:

```
sp configure "optimization goal", 1, "goal 1"
```

Example 2

Deletes goal 1:

```
sp optgoal 'goal 1', 'delete'
```

Usage

sp optgoal with no parameters displays a list of all user-defined optimizer goals.

Permissions

The permission checks for sp optgoal differ based on your granular permissions settings.

Setting Description

 $\textbf{Enabled} \quad \text{With granular permissions enabled, users with sa_role and sa_server privs_role must have \texttt{manage} \\$ opt goal privilege to create or delete a goal. By default, sa_role and sa_serverprivs_role are granted the manage opt goal privilege. Once created, all users can use the goal.

Any user can run sp optgoal 'show'.

 $\textbf{Disabled} \quad \text{With granular permissions disabled, you must be a user with sa_role to create or delete a goal.}$ However, once created, all users can use the goal.

Any user can run sp_optgoal 'show'.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.203 sp_options

Shows option values.

Syntax

```
sp_options [ [show | help
      [, <option_name> | <category_name> | null
      [, dflt | non_dflt | null [, <spid>] ] ] ] ]
```

Parameters

show

lists the current and default values of all options, grouped according to their category. Issuing <code>sp_options</code> show with an option name specified gives you the current and default value for the individual option. You can also specify a session ID, and whether you want to view options with default settings or options with non-default settings.

help

indicates that you wish to show usage information. You achieve the same result when you issue $sp_options$ with no parameters.

<option_name>

is the name of the option.

<category_name>

is the category of the option.

null

indicates the option for which you want to view the settings.

dflt | non dflt | null

indicates whether to show options with default settings or to show options with non-default settings.

<spid>

specifies the session ID. Use the session ID to view other session settings.

Example 1

Shows sp_options usage:

Example 2

Shows a list of all current and default options:

```
1> sp_options show 2> go
```

```

Example 10

Shows the options that are set to a non-default setting in the Query Tuning category:

```
1> sp_options show, null, non_dflt
2> go

Category: Query Tuning
name currentsetting defaultsetting
```

```
repartition_degree 3 1
scan_parallel_degree 0 1
parallel_degree 0 1
(3 rows affected)
(return status = 0)
```

If you enter a parameter that sp options does not understand, you receive the following message:

Example 12

Shows correct usage:

Usage

Use sp_options to view settings for the following options:

```
• set plan dump / load
```

- set plan exists check
- set forceplan
- set plan optgoal
- set [optCriteria]
- set plan opttimeoutlimit
- set plan replace
- set statistics simulate
- set metrics_capture
- set prefetch
- set parallel_degree number
- set process_limit_action
- set resource granularity number

- set scan_parallel_degree number
- set repartition_degree number

Permissions

Any user can execute $sp_options$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.204 sp_p

Displays the shortened output of the query plan from the $sp_showplan$ system procedure. The shortened output consists of resource statistics output which includes rows affected, object list, and number of rows in the object list

Syntax

sp_p <spid>

Parameters

spid

is the process id for any user connection. Use ${\tt sp_who}$ to see spids.

Example 1

Displays the shortened showplan output for <spid> number of 112:

```
sp_p 112
select a.au lname, pv.title, sv.qty, sv.stor name from authors a, titleauthor
ta, pubsview pv, storesview sv where a.au_id = ta.au_id and ta.title id =
pv.title id and pv.title id =
sv.title id
(1 row affected)

Query has started at: 2018/06/13 09:50:50.72 .
Query is running for: 0 ms.
Rows affected: 2
(return status = 0)
```

Usage

- Execute the sp p system procedure to see the short plan output of any user connection.
- The Rows affected output is dynamic, and may change each time you run it because its value is based on the rows affected during the current execution.

Permissions

Any user can execute sp p.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.205 sp_passthru

(Component Integration Services only) Allows the user to pass a SQL command buffer to a remote server.

Syntax

Parameters

<server>

is the name of a remote server to which the SQL command buffer is passed. The class of this server must be a supported, non-local server class.

<command>

is the SQL command buffer. It can hold up to 255 characters.

<errcode>

is the error code returned by the remote server, if any. If no error occurred at the remote server, the value returned is 0.

<errmsg>

is the error message returned by the remote server. It can hold up to 1024 characters. This parameter is set only if <errcode> is a nonzero number; otherwise NULL is returned.

<rowcount>

is the number of rows affected by the last command in the command buffer. If the command was an insert, delete, or update, this value represents the number of

rows affected even though none were returned. If the last command was a query, this value represents the number of rows returned from the external server.

<arg1> ... <argn>

receives the results from the last row returned by the last command in the command buffer. You can specify up to 250 < arg > parameters. All must be declared as output parameters.

Examples

Example 1

Returns the date from the Oracle server in the output parameter <@oradate>. If an Oracle error occurs, the error code is placed in <@errcode> and the corresponding message is placed in <@errmsg>, and <@rowcount> is set to 1:

Usage

- sp_passthru allows the user to pass a SQL command buffer to a remote server. The syntax of the SQL statement or statements being passed is assumed to be the syntax native to the class of server receiving the buffer. No translation or interpretation is performed. Results from the remote server are optionally placed in output parameters.
 - Use sp passthru only when Component Integration Services is installed and configured.
- You can include multiple commands in the command buffer. For some server classes, the commands must be separated by semicolons. See the *Component Integration Services User's Guide* for a more complete discussion of query buffer handling in passthru mode.

Permissions

Any user can execute sp_passthru. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_autoconnect [page 97] sp_remotesql [page 690]

1.205.1 Return Parameters and sp_passthru

The output parameters $\langle arg1 \rangle ... \langle argn \rangle$ becomes set to the values of corresponding columns from the last row returned by the last command in the command buffer. The position of the parameter determines which column's value the parameter contains. $\langle arg1 \rangle$ receives values from column 1, $\langle arg2 \rangle$ receives values from column 2, and so on.

If there are fewer optional parameters than there are returned columns, the excess columns are ignored. If there are more parameters than columns, the remaining parameters are set to NULL.

An attempt is made to convert each column to the datatype of the output parameter. If the datatypes are similar enough to permit **implicit** conversion, the attempt succeeds. For information on implicit conversion, see Reference Manual: Building Blocks > Transact-SQL Functions. See the Component Integration Services Users Guide for information on which datatype represents the datatypes from each server class when in passthru mode.

1.206 sp_password

Deprecated by SAP ASE version 15.7. To add or change a password for a login account in SAP ASE, use the create login and alter login commands. See *create login* and *alter login* in *Reference Manual:*Commands > Commands.

1.207 sp_passwordpolicy

Allows a user with sso_role to configure login and password policy options.

Syntax

• To specify, remove, and list new password complexity options:

```
sp_passwordpolicy {"set" | "clear" | "list"}, <policy_option>, <option_value>
```

• To verify the password complexity options:

```
sp_passwordpolicy "validate password options"
```

• To generate asymmetric key pairs for network login password encryption:

```
sp_passwordpolicy "regenerate keypair"
```

• To set the network password encryption key size.

```
sp_passwordpolicy {"set" | "clear" | "list"}, "RSA keysize","<size>"
```

• To expire passwords:

```
sp_passwordpolicy "expire role passwords", "[<rolename> | <wildcard>]"
sp_passwordpolicy "expire login passwords", "[<login_name> | <wildcard>]"
sp_passwordpolicy "expire stale role passwords", "<datetime>"
sp_passwordpolicy "expire stale login passwords", "<datetime>"
```

• To display a brief description of all commands, options, and their values:

```
sp passwordpolicy "help"
```

Parameters

set

sets a value to an option. When using set, you must specify the <policy option>.

clear

deletes the row for the option specified in the master.dbo.sysattributes table. Because clear deletes **all** the option rows in the sysattributes table if no policy option is specified, you must specify <policy_option> when using clear.

list

lists the values of the options specified. When using list, you must specify the <policy_option>.

<policy option>, <option value>

string or (varchar). Is the option parameter for set, clear, and list, with
<option_value> being the their values:

allow password downgrade	ends the password downgrade period. During the password downgrade period, passwords are stored in syslogins in both old and new encodings to allow user passwords to retained if the server is downgraded, for example, to SAP ASE 15.0.2.
disallow simple passwords	specifying a value of 1 turns this option on; a value of 0 turns it off.
enable last login updates	enables or disables code in SAP ASE authentication that records the timestamp when each login occurs. The parameter:

- "set" sets the value of this attribute
- "list" displays the current value of the attribute
- "clear" deletes the row from sysattributes.
 Although "clear" deletes the row from sysattributes,
 the last setting is still effective until you restart the SAP ASE server, or when "set" sets the new value.

expire login

specifies that when new logins are created or when the SSO changes login passwords, the passwords for those logins are marked as expired, thus forcing those users to change their password when they first log in.

keypair regeneration period

<keypair regeneration frequency>

is the frequency of regeneration of an RSA key pair. The valid range of values (in hours) is from 1 to 8,760. The default value is NULL, in which case a key pair is regenerated every 24 hours. It specifies the duration's format specifier, using:

- 'T*M' indicates duration in minutes, replacing the asterisk (*) with a numeric value, such as "T2M" for two minutes.
- 'H' indicates duration in hours.
- 'D' indicates duration in days. This is the default if you do not specify another format.
- 'w' indicates duration in weeks.
- 'M' indicates duration in months.
- 'Y' indicates duration in years.

<datetime of first generation>

is the date and time of when the key-pair is first generated. If you specify only the time for the value of <datetime of first generation>, RSA key pair regeneration is scheduled for that time of day in the next 24-hour period. If you:

- Specify <datetime of first generation> the SAP ASE server regenerates a new RSA key pair immediately if that time has elapsed; otherwise the SAP ASE server waits until that specified time.
- Do not specify <datetime of first generation> the SAP ASE server regenerates a new RSA key pair at a time that is obtained by adding <keypair regeneration period> to the time when the most recent RSA key pair was generated, if this calculated time is not elapsed; otherwise the SAP ASE server regenerates a new RSA key pair immediately.

Subsequent generations of key pairs occur based on when the most recent key pair was generated and the value of <keypair regeneration period>.

i Note

You cannot simultaneously set the value of <keypair regeneration frequency> and <datetime of first generation> to NULL.

keypair error retry [wait | count]

specifies the various configurations you can set for regenerating a key pair after a failed attempt:

- wait specifies the amount of time to wait after a failure before regenerating the keypair.
- count specifies how many times you want the SAP ASE server to attempt to regenerate a key pair after a failure.

rsa keysize

indicates the network password encryption key size.

- set specifies the keysize. Configure the key size to 1024 and increment 512 bytes up to 4096. Default key size is 2048 bits.
- clear sets the key size to the default size.
- list shows the set key size.

maximum failed logins

indicates the maximum number of failed logins allowed in a session before the account is locked.

min alpha in password

indicates the minimum number of alphabetic characters in a password.

min digits in password

indicates the minimum number of digits to be allowed in a password.

min lower char in password

indicates the minimum number of lower case characters allowed in a password.

min special char in password

indicates the minimum number of special characters allowed in a password.

min upper char in password

indicates the minimum number of uppercase characters allowed in a password.

minimum password length

indicates the minimum length of the password.

password exp warn interval

indicates the password expiration warning interval in days.

systemwide password expiration

indicates the system-wide password expiration in days.

unique keypair per session

specifies the configurations you can set for generating a unique key pair for every user:

- 1 specifies to generate a new key pair for every user connection.
- 0 specifies that all connections share the same RSA key pair.

i Note

If sp_configure "net password encryption reqd" is configured to 3, this password policy option is ignored because a unique keypair per session is not needed to secure the password.

"expire login passwords", "[<login name> | <wildcard>]"

expires login passwords, all logins or logins matching a wild card pattern. The column status in master database catalog syslogins is updated with a status bit LOGIN_EXPIRED (0x4) to indicate the password is expired.

"expire role passwords", "[<rolename> | <wildcard>]"

expires the password of a role, all roles or roles matching a wild-card pattern. The column status in master database catalog syssrvroles is updated with a status bit ROLE_EXPIRED (0x4) to indicate the password is expired:

"expire stale login passwords", "<datetime>"

expires login passwords have not been changed after a datetime specified. The column status in master database catalog syslogins is updated with a status bit LOGIN_EXPIRED (0x0004) to indicate that the password is expired. See *Reference Manual: Building Blocks > Entering Date and Time Data* for an explanation of how datetime values are entered.

"expire stale role passwords", "<datetime>"

expires role passwords have not been changed after a datetime specified. The column status in master database catalog syssrvroles is updated with a status bit ROLE_EXPIRED (0x4) to indicate the password is expired.

"regenerate keypair"

generates the asymmetric key pairs to be used for network login password encryption. There is no catalog update for this option; the actions occur only in memory fields.

"validate password options"

reports errors or inconsistencies in the password complexity option values set, including length and expiration. The result is reported in a tabular format, with each row representing a validation step, the result of the step, and the validation test performed. The result is one of Pass, Fail, or Not Applicable (NA). If any validation test fails, the return status is set to 1.

Examples

The outputs in these examples have been reformatted for clarity, and may not resemble the output you see on your screen if you execute this procedure.

Example of Password Expiration Warning Interval

Sets a password expiration warning interval to seven days before the password expires:

```
sp_passwordpolicy 'set',
    'password exp warn interval', '7'
```

Example of List

Lists the option for minimum number of special characters:

```
sp_passwordpolicy 'list',
    'min special char in password'
```

Example to Disallow Simple Passwords

Resets disallow simple passwords to the default value:

```
sp_passwordpolicy 'clear', 'disallow simple passwords'
```

Example to Validate Password Options

These examples demonstrate using validate password options.

These password complexity options and their values are stored in the server:

```
minimum password length: 8
min alpha in password: 2
min digits in password: 2
min upper char in password: 2
min lower char in password: 2
```

To validate these options, enter:

```
sp_passwordpolicy 'validate password options'
Validation Step Pass/Fail/NA Validation Test
min alpha in password
                       Fail 'min alpha in password' > = 'min
                                    upper char in password + 'min
                                    lower char in password'
minimum password length - 1    Pass    'minimum password length' > = 'min
                                    digits in password' + 'min special
                                    char in password' + 'min alpha in
                                    password'
                                    'minimum password length' > = 'min
minimum password length - 2
                            Pass
                                    digits in password' + min special
                                    char in password' + 'min upper
                                    char in password' + 'min lower
                                    char in password'
                                   'max password length' > = 'min
maximum password length - 1
                             Pass
                                    digits in password' + 'min
                                    special char in password' + 'min
                                    alpha in password'
                                    'max password length' > = 'min
maximum password length - 2
                             Pass
                                    digits in password' + 'min special
                                    char in password' + 'min upper
                                    char in password' + 'min lower
                                    char in password'
password exp warn interval
                            NA
                                    'password exp warn interval' < =
```

```
'systemwide password expiration'
(6 rows affected)
(return status = 1)
```

There is one failure: The sum of min upper char in password + min lower char in password is greater than the value of min alpha in password, so the validation step min alpha in password fails

Example to Regenerate Key Pair

Sets the HouseKeeper task to automatically regenerate a key pair every two hours, starting on August 15, 2007 at 12:01 a.m.:

```
sp_passwordpolicy "set", "keypair regeneration period",
    "2H", "Aug 15 2007 12:01 AM"
```

Example to Wait to Regenerate Key Pair

Sets how long the SAP ASE server should wait before trying to regenerate the key pair after a failed attempt:

```
sp_passwordpolicy 'set', 'keypair error retry wait', '10'
```

Example of Retry Attempts to Regenerate Key Pair

Sets number of times the SAP ASE server should attempt to regenerate the key pair after a failure to 5:

```
sp_passwordpolicy 'set', 'keypair error retry count', '5'
```

Example to Display Brief Descriptions

Displays brief description about all commands, options and their values:

```
sp_passwordpolicy "help"
go
sp_ passwordpolicy Usage: sp_passwordpolicy 'help'
    passwordpolicy Usage: sp passwordpolicy command [, option1 [, option2 [,
option3]]]
sp_passwordpolicy commands:

sp_passwordpolicy expire fole passwords [, {folename | will sp_passwordpolicy 'expire stale login passwords', 'datetime' sp_passwordpolicy 'expire stale role passwords', 'datetime' sp_passwordpolicy 'regenerate keypair'[, 'datetime']
sp_passwordpolicy 'validate password options'
(return status = 0)
```

Example to Validate Options

Validating the following options stored in the SAP ASE server:

```
minimum password length: 8
min digits in password: 2
min special char in password: 2
min alpha in password: 6
min upper char in password: 3
min lower char in password: 3
```

```
sp_passwordpolicy 'validate password options'
```

```
Validation Step
                       Pass/Fail/NA
                                     Validation Test
                        ------
                                     'min alpha in password' > = 'min upper
min alpha in password
                            Pass
                                      char in password' + 'min lower
                                      char in password'
                                      'minimum password length' > = 'min
minimum password length-1
                           Fail
                                      digits in password' + 'min special
                                      char in password' + 'min alpha in
password'
minimum password length-2 Fail
                                     'minimum password length' > = 'min
                                      digits in password' + 'min special
                                      char in password' + 'min upper
                                      char in password' + 'min lower
                                      char in password'
maximum password length-1
                            Pass
                                      'max password length' > = 'min
                                      digits in password' + 'min special
                                      char in password' + 'min alpha in
password'
maximum password length-2
                                      'max password length' > = 'min
                            Pass
                                      digits in password' + 'min
                                      special char in password' + 'min
                                      upper char in password' + 'min
```

```
lower char in password'

password exp warn interval NA 'password exp warn interval' <=
'systemwide password expiration'

(6 rows affected)
(return status = 1)
```

There are two failures in step 2 and step 3. The sum of min digits in password, min special char in password and min alpha in password is greater than the value of minimum password length, so the validation step minimum password length -1 fails. The sum of min digits in password, min special char in password, min upper char in password, and min lower char in password is greater than the value of minimum password length, so the validation step minimum password length -2 fails.

Example to Validate Password Options

Illustrates the option 'validate password options'.

These password complexity options and their values are stored in the server:

```
minimum password length: 8
min alpha in password: 2
min digits in password: 2
min upper char in password: 2
min lower char in password: 2
```

sp passwordpolicy 'validate password options'

```
Validation Step
                            Pass/Fail/NA Validation Test
                                           'min alpha in password' > = 'min
min alpha in password
                            Fail
                                           upper char in password + 'min
                                           lower char in password'
minimum password length - 1 Pass
                                           'minimum password length' > = 'min
                                           digits in password' + 'min special
                                           char in password' + 'min alpha in
                                           password'
                                           'minimum password length' > = 'min
minimum password length - 2 Pass
                                           digits in password' + min special
                                           char in password' + 'min upper
                                           char in password' + 'min lower
                                           char in password'
maximum password length - 1 Pass
                                           'max password length' > = 'min
                                           digits in password' + 'min
                                           special char in password' + 'min
                                           alpha in password'
                                           'max password length' > = 'min
maximum password length - 2 Pass
                                           digits in password' + 'min special
                                           char in password' + 'min upper
                                           char in password' + 'min lower
                                           char in password'
                                          'password exp warn interval' < =
password exp warn interval
                                          'systemwide password expiration'
(6 rows affected)
(return status = 1)
```

There is one failure: The sum of min upper char in password + min lower char in password is greater than the value of min alpha in password, so the validation step min alpha in password fails

Validating the following options stored in the SAP ASE server:

```
minimum password length: 8
```

```
min digits in password: 2
min special char in password: 2
min alpha in password: 6
min upper char in password: 3
min lower char in password: 3
```

sp passwordpolicy 'validate password options'

password exp warn interval NA
                                            'password exp warn interval' < =
                                            'systemwide password expiration'
(6 rows affected)
(return status = 1)
```

There are two failures in step 2 and step 3.

The sum of min digits in password, min special char in password and min alpha in password is greater than the value of minimum password length, so the validation step minimum password length -1 fails. The sum of min digits in password, min special char in password, min upper char in password, and min lower char in password is greater than the value of minimum password length, so the validation step minimum password length -2 fails.

Validating the following options stored in the SAP ASE server:

```
minimum password length: 8
min digits in password: 11
min special char in password: 11
min alpha in password: 11
min upper char in password: 1
min lower char in password: 1
```

```
sp_passwordpolicy 'validate password options'
```

```
digits in password' + 'min
                                            special char in password' + 'min
                                            alpha in password'
minimum password length-2 Fail
                                           'minimum password length' > = 'min
                                           digits in password' + 'min special
                                            char in password' + 'min upper
                                            char in password' + 'min lower char in password'
maximum password length-1 Fail
                                           'max password length' > = 'min
                                           digits in password' + 'min special
                                            char in password' + 'min alpha in
                                            password'
maximum password length-2 Pass
                                           'max password length' > = 'min
                                            digits in password' + 'min special
                                            char in password' + 'min upper
                                            char in password' + 'min lower
                                            char in password'
password exp warn interval NA
                                           'password exp warn interval' < =
                                           'systemwide password expiration'
(6 rows affected)
(return status = 1)
```

There are three failures, including a serious one, a failure in a test for maximum password length, where the sum of the required password components is greater than the maximum password allowed.

Validating the following options stored in the SAP ASE server:

```
minimum password length: 8
min digits in password: 2
min special char in password: 1
min alpha in password: 4
min upper char in password: 0
min lower char in password: 0
```

sp passwordpolicy 'validate password options'

```
Validation Step

                                           digits in password' + 'min
                                           special char in password' + 'min
                                            upper char in password' + 'min
                                           lower char in password'
                                           'password exp warn interval' < =
password exp warn interval NA
                                           'systemwide password expiration'
(6 rows affected)
(return status = 0)
```

There are no failures with these settings. This reports all five rows returned, and a return status of 0.

Usage

- sp passwordpolicy information is stored in the master.dbo.sysattributes table.
- Once the SAP ASE server has regenerated a new RSA key pair, subsequent generations use a formula of the last time when RSA key pair was generated, combined with the value you specified for <keypair regeneration frequency>.
- The value of <keypair regeneration period> is stored in master..sysattributes under a new password policy class.
- A default value of NULL for the option indicates that this row does not exist in sysattributes and the key pair is generated on when the SAP ASE server is restarted, and every 24 hours thereafter.

 These two stored procedures do the same thing:

- These global variable use the information from keypair regeneration period:
 - o @@lastkpgendate reflects the datetime of when the last key pair was generated.
 - @@nextkpgendate reflects when the key pair is next generated.

Permissions

The permission checks for sp_passwordpolicy differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage security configuration privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

An audit option "password" audits these actions:

```
• sp_passwordpolicy 'set', '<option_name>', '<option_value>'
```

- sp passwordpolicy 'clear', '<option name>'
- sp_passwordpolicy 'expire login passwords'
- sp passwordpolicy 'expire stale login passwords'
- sp passwordpolicy 'regenerate keypair'

- sp passwordpolicy 'expire role passwords'
- sp_passwordpolicy 'expire stale role passwords'
- sp passwordpolicy 'validate password options'

The sp passwordpolicy parameters are recorded in extrainfo for event 115. For example:

```
sp_passwordpolicy 'validate password options'
```

The extrainfo is:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ;
    PASSWORD_ADMIN clear policy min digits in password ; ; sa/ase;
```

The execution of sp_passwordpolicy to regenerate RSA key pair within a specified period is audited and event 115 is recorded.

In addition, when ASE regenerates the RSA key pair, event 117 is recorded if security option has been enabled.

For example if you run:

```
sp_passwordpolicy 'set','keypair regeneration period','1','Apr 14 2015 12:40AM'
```

First, event 115 is recorded:

```
event extrainfo

115 sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; PASSWORD_ADMIN set policy keypair regeneration period 1 Apr 14 2015 12:40AM ; ; sa/ase;
```

Then, once the keypair is regenerated at the time that you specified in the command, event 117 is recorded:

When sp_passwordpolicy 'set', 'disallow simple passwords', 1 is set and you use create login to create a login that has a simple password, the security audit option records event 125. For example:

```
event extrainfo

125 sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; ; sa/ase;
```

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.207.1 Login Password Complexity Checks and sp_passwordpolicy

The login password complexity checks are extended to role passwords.

The complexity checks are:

- disallow simple passwords
- min digits in password
- min alpha in password
- min special char in password
- min upper char in password
- min lower char in password
- systemwide password expiration
- password exp warn interval
- minimum password length
- maximum failed logins
- expire login

1.207.2 High-Availability and Password Policy Options

The SAP ASE high-availability functionality synchronizes password policy options between primary and secondary servers.

The password policy options are:

- disallow simple passwords
- min digits in password
- ullet min alpha in password
- min special char in password
- min upper char in password
- min lower char in password
- systemwide password expiration
- password exp warn interval
- minimum password length
- maximum failed login
- expire login
- keypair regeneration period
- keypair error retry wait
- keypair error retry count

The SAP ASE server uses a "password policy" quorum attribute to check the inconsistency of any of those values on both the primary and secondary servers, except keypair regeneration period, keypair error retry wait, and keypair error retry count.

A high-availability advisory check succeeds when all those value are the same on both servers, and fail when the values differ. For example:

A value of 2 set in the advisory column of the output indicates that the user cannot proceed with the cluster operation unless the values on both the companions match.

The output of sp_companion do_advisory also indicates the inconsistency in any of the particular password policy checks on both servers.

1.208 sp_pciconfig

Manages the Java PCI Bridge. Enables or disables arguments and directives, changes configuration values, and reports configuration values.

i Note

Do not use $sp_pciconfig$ to change arguments or directives unless instructed to do so by SAP Product Support.

Syntax

```
sp_pciconfig {disable {<directive> | <argument>} |
    enable {<directive> | <argument>} |
    list {<list_type>[, formatted] | units | units, <units_type>[, formatted] } |
    report {<directive>[, formatted] |
        <directive>, args[, formatted] |
        <argument>[, formatted] } |
    update {<number_arg>, <old_value new_value>}}
```

Parameters

disable

disables the specified directive or argument.

<directive>

is the name of any valid directive.

<argument>

is the name of any valid argument.

enable

enables a specified directive or argument.

list

lists groups of related arguments as, for example, <code>sp_pciconfig "list"</code>, "directive" or <code>sp_pceiconfig "list"</code>, "enabled". Also, lists all arguments of a specific type as, for example, <code>sp pciconfig "list"</code>, "units", "switch".

<list_type>

specifies a type of list. Values are:

- directives list of directives
- enabled list of enabled arguments
- disabled list of disabled arguments
- argnames list of argument names

formatted

specifies that displayed list is to be formatted for readability.

i Note

In formatted reports, the process of improving readability may result in the truncation of wide columns. In addition, column headings may be overridden and may not match the actual table column name. Do not format reports if the output is parsed or potential data truncation is not acceptable.

units

when used with list, generates a list of $<units_type>$ currently in use.

report

creates a report based on arguments supplied. Usually used to generate a report for an argument to see its current value and whether or not it is enabled. Can also be used to generate a report for a directive or its arguments.

<directive>

specifies all arguments within a specified directive.

update

modifies the numeric value of arguments where units = number. Cannot be used with arguments where units = switch.

<number arg>

is an argument of units = number.

<old_value>

is the current value for <number_arg_name>.

<new_value>

is a new value for <number_arg_name>.

Usage

Enabling and disabling a directive works like a toggle. When a directive is:

- Enabled the SAP ASE server uses the configured value (enabled or disabled) of each argument. This is the value stored in sybpcidb.
- Disabled the SAP ASE server disregards the configured value (enabled or disabled) of each argument and treats all arguments of the directive as disabled, although the base value of each argument is retained in sybpcidb.

Arguments can be individually enabled or disabled. Arguments for sp_pciconfig directives are of these types:

- switch these arguments turn a feature on or off. For example, if the argument for logging is enabled, a log file is generated; if the argument for logging is disabled, no log file is generated.
- string these arguments are for strings and numbers, which are treated like strings. Enabling a string argument ensures that the SAP ASE server uses the configured value. Disabling a string argument means that the SAP ASE server ignores the configured value and uses the default value. The configured and default values may be the same or different.

Configuration directives for sp pciconfig are:

Directive	Description
PCI_BRIDGE_X_OPT	The PCI Bridge configuration parameters
PCI_BRIDGE_LOGOPT	The plug-in diagserver report facility
PCI_BRIDGE_INSTR	The PCI Bridge instrumentation settings

Table 15: PCI_BRIDGE_X_OPT Arguments
The PCI Bridge configuration parameters

Argument	Units Type	Default Value	Default State	Description
pci_xopt_maxthreads	number	1056	Enabled	Maximum available PCI Bridge PLB-controlled threads.
<pre>pci_xopt_event_scheduli ng</pre>	number	0	Enabled	Default PCI Bridge scheduling.
<pre>pci_xopt_failover_engin e</pre>	number	-1	Enabled	Default engine to which a slot should fail over.
<pre>pci_xopt_runtime_alloc_ escape</pre>	number	1	Enabled	Allow runtime escapes on memory allocation requests above PC Bridge maximum memory allocation unit.
pci_xopt_slotring_cycle	number	-1	Enabled	Disable PCI Bridge slotring washing.
<pre>pci_xopt_slotring_wash_ th</pre>	number	76	Enabled	Default PCI Bridge slotring washing threshold percentage.

Table 16: PCI_BRIDGE_LOGOPT Arguments
The plug-in diagserver report facility

Argument	Units Type	Default Value	Default State	Description
pci_logopt_asehi	switch	None	Disabled	PCI Bridge ASE host interface dispatch logging.
pci_logopt_jst	switch	None	Disabled	PCI Bridge Job Scheduler task dispatch logging.
pci_logopt_jvm	switch	None	Disabled	PCI Bridge JVM dispatch logging.
pci_logopt_omni	switch	None	Disabled	PCI Bridge OMNI dispatch logging.
pci_logopt_pci	switch	None	Disabled	Generic PCI Bridge logging (probe [pci/pca]).
pci_logopt_runtime	switch	None	Disabled	PCI Bridge runtime dispatch logging.
pci_logopt_xml	switch	None	Disabled	PCI Bridge XML dispatch logging.

Table 17: PCI_BRIDGE_INSTR Arguments

The PCI Bridge instrumentation settings

Argument	Units Type	Default Value	Default State	Description
BRIDGE	number	1	Disabled	Forces full instrumentation (noisy).
CELL	number	1	Disabled	Forces all CELL synchronization to Report.
JAVA	number	1	Disabled	Forces all Java-related entries to Report.
JCS	number	1	Disabled	Forces all JCS entries to Report.
JDBC	number	1	Disabled	Forces all JDBC entries to Report.
JVMHOST	number	1	Disabled	Forces all ASE JVM host API entries to Report.
JVMJNI	number	1	Disabled	Forces all JVM JNI external entries to Report.
PCIS	number	1	Disabled	Forces all PCI Service code to Report.
PLB	number	1	Disabled	Forces all PLB code to Report.
SLOTRING	number	1	Disabled	Forces all "slot-ring" code to Report.
SYNC	number	1	Disabled	Forces all SYNChronization code to Report.
TPM	number	1	Disabled	Forces all TPM code to Report.
fetch_classdata	number	1	Enabled	Forces all fetch_classdata hits to Report.
pcis_service	number	2	Disabled	Forces all pcis_service hits to Freeze.

Permissions

The permission checks for $sp_pciconfig$ differ based on your granular permissions settings.

Setting Description

 $\textbf{Enabled} \quad \textbf{With granular permissions enabled, you must be a user with \texttt{manage server configuration}}$

privilege.

Setting Description

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_jreconfig [page 531]

1.209 sp_placeobject

Puts future space allocations for a table or index on a particular segment on a particular segment, including for a specific partition.

Syntax

sp_placeobject <segname>, <objname>[, <partitionname>]

Parameters

<segname>

is the name of the segment on which to locate the table or index.

<objname>

is the name of the table or index for which to place subsequent space allocation on the segment segment <> segmane > . index names in the form " . index names "

<partitionname>

(optional) is the name of the partition, which allows you to set the segment for a specific partition.

Examples

Example 1

Places all subsequent space allocation for the table authors on the segment named "segment3":

```
sp placeobject segment3, authors
```

Example 2

Places all subsequent space allocation for the employee table's index named employee_nc on the segment named indexes:

```
sp placeobject indexes, 'employee.employee nc'
```

Example 3

Places all subsequent space allocation for the my tab table's segment called my seg2 in partition part1:

```
sp placeobject my_seg2, my_tab, part1
```

Usage

There are additional considerations when using sp placeobject:

- Using this procedure does not affect the location of existing table or index data, including existing partitions or new partitions added in the future if no segment is specified for the new partition. Changing the segment used by a table or index can spread the data among multiple segments.
- If you use sp placeobject with a clustered index, the table moves with the index.
- You can specify a segment when you create a table or an index with create table or create index. You can also specify a segment at the partition level as part of a partition definition. Partitions without segment specification uses the segment specified at the table/index level. If no segment is specified for the table/index level, the data goes on the default segment.
- When sp_placeobject splits a table or an index across more than one disk fragment, the diagnostic command dbcc displays messages about the data that resides on the fragments that were in use for storage before sp_placeobject executed. Ignore those messages.

See also alter table, dbcc in Reference Manual: Commands.

Permissions

The permission checks for sp placeobject differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be the table owner or a user with manage database privilege.

Setting Description

Disabled With granular permissions disabled, you must be the database owner, table owner, or a user with sa_role.

Auditing

 $For information about auditing stored procedures with the auditing options \verb|exec_procedure|, \verb|sproc_auth|, \\$ and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_helpsegment [page 479]
```

1.210 sp_plan_dbccdb

Recommends suitable sizes for new dbccdb and dbccalt databases, lists suitable devices for dbccdb and dbccalt, and suggests a cache size and a suitable number of worker processes for the target database.

Syntax

```
sp_plan_dbccdb [<dbname>]
```

Parameters

<dbname>

specifies the name of the target database. If <dbname> is not specified, sp_plan_dbccdb makes recommendations for all databases in master..sysdatabases.

Examples

Example 1

Returns configuration recommendations for creating a dbccdb database suitable for checking the master database. The dbccdb database already existed at the time this command was run, so the size of the existing database is provided for comparison:

```
Recommended size for dbccdb database is 50MB (data = 48MB, log = 2MB).

dbccdb database already exists with size 280MB.

Recommended values for workspace size, cache size and process count are:

dbname scan ws text ws cache comp mem process count
master 128K 48K 640K 0K 1
```

Example 2

Returns configuration recommendations for creating a dbccdb database suitable for checking all databases in the server. The output includes Compression Memory Requirement, which has a non-zero value only for archive databases using any compressed device. No dbccdb database existed at the time this command was run:

```
sp plan dbccdb
Recommended size for dbccdb database is 50MB (data = 48MB, log = 2MB).
dbccdb database already exists with size 280MB.
Recommended values for workspace size, cache size and process count are:
dbname
                          scan ws text ws cache comp mem process count
master
                          128K
                                   48K
                                              640K
                                 40K
176K
                                            1280K 0K
                          656K
                                                               2
tempdb
                         64K 48K 640K 0K
64K 48K 640K 0K
model
                                                               1
sybsystemdb
                         64K 48K 640K 0K
1488K 384K 640K 0K
272K 80K 1280K 0K
80K 64K 1920K 12M
sybsystemprocs
                                                               1
sybsecurity
                                                               2
adb
```

Example 3

Returns configuration recommendations for creating a dbccdb database suitable for checking pubs 2:

```
Recommended size for dbccdb is 4MB.
Recommended devices for dbccdb are:
Logical Device Name Device Size Physical Device Name
sprocdev 28672 /remote/sybase/devices/srv_sprocs_dat
tun_dat 8192 /remote/sybase/devices/srv_tun_dat
tun_log 4096 /remote/sybase/devices/srv_tun_log
Recommended values for workspace size, cache size and process count are:
dbname scan ws text ws cache process count
pubs2 64K 64K 640K 1
```

Usage

There are additional considerations when using sp plan dbccdb:

- sp_plan_dbccdb recommends suitable sizes for creating new dbccdb and dbccalt databases, lists suitable devices for the new database, and suggests cache size and a suitable number of worker processes for the target database.
- If you specify dbccdb, sp_plan_dbccdb recommends values for dbccalt, the alternate database. If you specify dbccalt, sp_plan_dbccdb recommends values for dbccdb.
- sp_plan_dbccdb does not report values for existing dbccdb and dbccalt databases. To gather configuration parameters for an existing dbccdb or dbccalt database, use sp_dbcc_evaluatedb.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for sp plan dbccdb differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, any user may execute the procedure.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

dbcc Stored Procedures [page 895] sp_dbcc_evaluatedb [page 907]

1.211 sp_poolconfig

Creates, drops, resizes, and provides information about memory pools within data caches.

Syntax

```
sp_poolconfig <cache_name>[, "<mem_size> [P | K | M | G]", "<config_pool>K"
    [, "<affected_pool> K"], instance <instance_name>]
```

• To change a pool's wash size:

```
sp_poolconfig <cache_name>, "<affected_poolK>", "wash=<size>[P|K|M|G]"
```

• To change a pool's asynchronous prefetch percentage:

```
sp_poolconfig <cache_name>, "<affected_poolK>",
    "local async prefetch limit=<percent> "
```

Parameters

<cache_name>

is the name of an existing data cache.

<mem size>

is the size of the memory pool to be created or the new total size for an existing pool with the specified I/O size. The minimum size of a pool is 256 logical server pages. For a 2K logical page size server, the minimum size is 256K. Specify size units with $\mathbb P$ for pages, $\mathbb K$ for kilobytes, $\mathbb M$ for megabytes, or $\mathbb G$ for gigabytes. The default is kilobytes.

<config_pool>

is the I/O size performed in the memory pool where the memory is to be allocated or removed.

Valid I/O sizes are multiples of the logical page size, up to four times the amount.

<affected_pool>

is the size of I/O performed in the memory pool where the memory is to be deallocated, or the pools attributes such as 'wash size' and 'prefetch limit' are to be modified. If <affected_pool> is not specified, the memory is taken from the lowest logical page size memory pool.

<instance name>

(Cluster Edition) is the name of the instance with the buffer pool you are adjusting.

wash=<size>

Changes the wash size (the point in the cache at which the SAP ASE server writes dirty pages to disk) for a memory pool.

local async prefetch limit=<percent>

sets the percentage of buffers in the pool that can be used to hold buffers that have been read into cache by asynchronous prefetch, but that have not yet been used. Valid values are 0-100. Setting the prefetch limit to 0 disables asynchronous prefetching in a pool.

Examples

Example 1

Creates a 16K pool in the data cache pub_cache with 10 MB of space. All space is taken from the default 2K memory pool:

```
sp_poolconfig pub_cache, "10M", "16K"
```

Example 2

Creates 16 MB of space to the 32K pool from the 64K pool of pub_cache:

```
sp_poolconfig pub_cache, "16M", "32K", "64K"
```

Example 3

Reports the current configuration of pub cache:

```
sp poolconfig "pub cache"
```

Example 4

Removes the 16K memory pool from pub_cache, placing all of the memory assigned to it in the 2K pool:

```
sp_poolconfig pub_cache, "OK", "16K"
```

Example 5

Changes the wash size of the 2K pool in pubs cache to 508K:

```
sp_poolconfig pub_cache, "2K", "wash=508K"
```

Example 6

Changes the asynchronous prefetch limit for the 2K pool to 15 percent:

```
sp_poolconfig pub_cache, "2K", "local async prefetch limit=15"
```

Example 7

(Cluster environment) Creates a a 16KB buffer pool of size 25 MB in the default data cache on instance blade1:

```
sp poolconfig 'default data cache', '25M', '16K', 'instance blade1'
```

Example 8

(Cluster environment) Displays the buffer pool configuration in the default data cache on instance blade1:

```
sp_poolconfig 'default data cache', 'instance blade1'
```

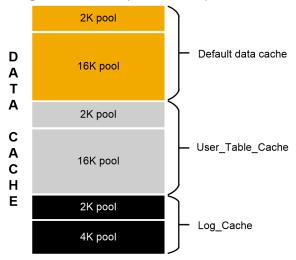

Example 9

(Cluster environment) Displays the buffer pool configuration for named cache c_log on all instances in the cluster:

sp poolconfig c log

Usage

- When you create a data cache with sp_cacheconfig, all space is allocated to the logical page size memory pool. sp_poolconfig divides the data cache into additional pools with larger I/O sizes.
- If no large I/O memory pools exist in a cache, the SAP ASE server performs I/O in logical page size units, the size of a data page, for all of the objects bound to the cache. You can often enhance performance by configuring pools that perform large I/O. A 16K memory pool reads and writes eight data pages in a single I/O for a 2K logical page size server.
- The combination of cache name and I/O size must be unique. In other words, you can specify only one pool of a given I/O size in a particular data cache in sp poolconfig commands.
- Only one sp_poolconfig command can be active on a single cache at one time. If a second sp_poolconfig command is issued before the first one completes, it sleeps until the first command completes.
- The following figure shows a data cache on a server that uses 2K logical pages with:
 - The default data cache with a 2K pool and a 16K pool
 - $\circ\quad$ A user cache with a 2K pool and a 16K pool
 - A log cache with a 2K pool and a 4K pool

- You can create pools with I/O sizes up to 16K in the default data cache for a 2K page size server.
- The minimum size of a memory pool is 256 logical pages (for example, a 2K logical page size server, the minimum size is 512K). You cannot reduce the size of any memory pool in any cache to less than 256 pages by transferring memory to another pool.
- Two circumstances can create pool less than 512K:
 - If you attempt to delete a pool by setting its size to zero, and some of the pages are in use, sp_poolconfig reduces the pool size as much as possible, and prints a warning message. The status for the pool is set to "Unavailable/deleted".

 If you attempt to move buffers to create a new pool, and enough buffers cannot be moved to the new pool, sp_poolconfig moves as many buffers as it can, and the cache status is set to "Unavailable/too small."

In both of these cases, you can retry to command at a later time. The pool is also deleted or be changed to the desired size when the server is restarted.

- You can create memory pools while the SAP ASE server is active; no restart is needed for them to take effect. However, the SAP ASE server can move only "free" buffers (buffers that are not in use or that do not contain changes that have not been written to disk). When you configure a pool or change its size, the SAP ASE server moves as much memory as possible to the pool and prints an informational message showing the requested size and the actual size of the pool. After a restart of the SAP ASE server, all pools are created at the configured size.
- Some dbcc commands and drop table perform only logical page size I/O. dbcc checkstorage can perform large I/O, and dbcc checkdb performs large I/O on tables and logical page size I/O on indexes.
- Most SAP ASE servers perform best with I/O configured for transactions logs that is twice the logical page size. The SAP ASE server uses the default I/O size of twice the logical page size if the default cache or a cache with a transaction log bound to it is configured with a memory pool twice the logical page size.
 Otherwise, it uses the logical page size memory pool.
- You can increase the default log I/O size for a database using the sp_logiosize system procedure. However, the I/O size you specify must have memory pools of the same size in the cache bound to the transaction log. If not, the SAP ASE server uses the logical page size memory pools.

Permissions

The permission checks for sp_poolconfig differ based on your granular permissions settings.

Setting Description Enabled With granular permissions enabled, you must be a user with manage data cache privilege to reconfigure memory pools. Any user can execute sp_poolconfig to retrieve information about memory pools. Disabled With granular permissions disabled, you must be a user with sa_role to reconfigure memory pools.

Any user can execute sp poolconfig to retrieve information about memory pools.

Auditing

You can enable <code>config_history</code> auditing option to audit this procedure. Values in <code>event</code> and <code>extrainfo</code> columns from the <code>sysaudits</code> table are:

Audit option	Event	Command or access audited	Information in extrainfo:		
config_history	154	sp_poolconfig	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Includes procedure name, parameter name, old value, new value, mode (static or active), and instance ID Proxy information – Original login name, if set proxy in effect 		

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.211.1 Wash Percentage and sp_poolconfig

The default value for the wash size differs depending on the pool size.

Pool Size

Less than 300 MB

The default wash size is set to 20 percent of the buffers in the pool.

Greater than 300 MB

The default wash size is 20 percent of the number of buffers in 300 MB.

The minimum setting for the wash size is 10 buffers, and the maximum setting is 80 percent of the size of the pool.

Each memory pool contains a wash area at the least recently used (LRU) end of the chain of buffers in that pool. Once dirty pages (pages that have been changed while in cache) move into the wash area, the SAP ASE server initiates asynchronous writes on these pages. The wash area must be large enough so that pages can be

written to disk before they reach the LRU end of the pool. Performance suffers when the SAP ASE server needs to wait for clean buffers.

The default percentage, placing 20 percent of the buffers in the wash area, is sufficient for most applications. If you are using an extremely large memory pool, and your applications have a very high data modification rate, you may want to increase the size to 1 or 2 percent of the pool. Run sp_sysmon to look for recommendations, or contact SAP Technical Support for more information about choosing an effective wash size.

1.211.2 Local Asynchronous Prefetch Percentage and sp_poolconfig

The default value for a pool's asynchronous prefetch percentage is set by the configuration parameter global async prefetch limit. The pool limit always overrides the global limit.

To disable prefetch in a pool (if the global limit is a nonzero number), set the pool's limit to 0.

See the *Performance and Tuning Guide* for information on the performance impact of changes to the asynchronous prefetch limit.

1.212 sp_post_xpload

Checks and rebuilds indexes after a cross-platform load database where the endian types are different.

Syntax

sp_post_xpload [force]

Parameters

force

when specified, uses reindex_opt_force for dbcc reindex in sp_post_xpload.

Examples

Example 1

Once the database is loaded from another platform, rebuilds its indexes by executing:

sp_post_xpload

Usage

- The following indexes are rebuilt on all user tables in the database:
 - Nonclustered index on an APL table
 - Clustered index on a DOL table
 - Nonclustered index on a DOL table
- Indexes on system tables are not processed with sp_post_xpload only. System table indexes are rebuilt when online database is executed.
- You can also rebuild indexes using drop index and create index.
- Run sp post xload only when the database is loaded across platforms with different endian types.
- Where the index status is suspect, reset the index by executing sp_post_xpload, drop index, or create index.
- Stored procedures are recompiled from the SQL text in syscomments at the first execution after the load database. Use dbcc upgrade_object to upgrade objects if you do not have permission to recompile from text.

See also dump database, load database in Reference Manual: Commands.

Permissions

The permission checks for sp_post_xload differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with load database privilege or own

database privilege on the database.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.212.1 Handling Suspect Partitions in Cross-Platform Dump and Load Operations

During the first online database command, after you execute load database across two platforms with different endian types, the hash partition is marked suspect.

Any global clustered index on a round-robin partition, which has an internally generated partition condition with a unichar or univarchar partition key, is marked suspect.

After the database is online, use sp post xpload to fix the suspect partitions and indexes.

1.213 sp_primarykey

Defines a primary key on a table or view.

Syntax

sp_primarykey <tabname>, <col1>[, <col2>, <col3>, ..., <col8>]

Parameters

<tabname>

is the name of the table or view on which to define the primary key.

<col1>

is the name of the first column that makes up the primary key. The primary key can consist of from one to eight columns.

Examples

Example 1

Defines the au_id field as the primary key of the table authors:

sp_primarykey authors, au_id

Example 2

Defines the combination of the fields lastname and firstname as the primary key of the table employees:

sp primarykey employees, lastname, firstname

Usage

There are additional considerations when using sp primarykey:

- Executing sp_primarykey adds the key to the syskeys table. Only the owner of a table or view can define its primary key. sp_primarykey does not enforce referential integrity constraints; use the primary key clause of the create table or alter table command to enforce a primary key relationship.
- Define keys with sp_primarykey, sp_commonkey, and sp_foreignkey to make explicit a logical relationship that is implicit in your database design. An application program can use the information.
- A table or view can have only one primary key. To display a report on the keys that have been defined, execute sp helpkey.
- The installation process runs sp primarykey on the appropriate columns of the system tables.

See also alter table, create table, create trigger in Reference Manual: Commands.

Permissions

You must be the table owner to execute $sp_primarykey$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_commonkey [page 191]
sp_dropkey [page 306]
sp_foreignkey [page 387]
sp_helpjoins [page 461]
sp_helpkey [page 463]
```

1.214 sp_procxmode

Displays or changes the execution modes associated with stored procedures.

Syntax

```
sp_procxmode [ >[,< tranmode>]]
```

Parameters

cname>

is the name of the stored procedure with the transaction mode you are examining or changing.

<tranmode>

is the execution mode for the stored procedure. Values are:

- chained
- unchained
- anymode
- Dynamic Ownership Chain
- No Dynamic Ownership Chain
- enable_dc
- disable dc

Examples

Example 1

Displays the transaction mode for all stored procedures in the current database:

sp_procxmode		
procedure name	user name	transaction mode
byroyalty discount_proc history_proc insert_sales_proc insert_detail_proc storeid_proc storename_proc title proc	dbo dbo dbo dbo dbo dbo dbo dbo dbo	Unchained

titleid_proc dbo Unchained

Example 2

Displays the transaction mode of the stored procedure byroyalty:

```
sp_procxmode byroyalty
```

```
procedure name transaction mode
-----
byroyalty Unchained
```

Example 3

Changes the transaction mode for the stored procedure byroyalty in the pubs2 database from unchained to chained:

```
sp_procxmode byroyalty, "chained"
```

Example 4

Enables deferred compilation for the storeid proc stored procedure in the pubs2 database:

```
sp_procxmode "storeid_proc", "enable_dc"
```

Disables deferred compilation for the same stored procedure:

```
sp_procxmode "storeid_proc", "disable_dc"
```

Usage

There are additional considerations when using sp procxmode:

• To change the transaction mode of a stored procedure, you must be the owner of the stored procedure, the owner of the database containing the stored procedure, or the system administrator. The database owner or system administrator can change the mode of another user's stored procedure by qualifying it with the database and user name. For example:

```
sp_procxmode "otherdb.otheruser.newproc", "chained"
```

- To use sp_procxmode, turn off chainedtransaction mode using the chained option of the set command. By default, this option is turned off.
- When you use sp_procxmode with no parameters, it reports the transaction modes of every stored procedure in the current database.
- To examine a stored procedure's transaction mode (without changing it), enter:

```
sp_procxmode <procname>
```

• To change a stored procedure's transaction mode, enter:

```
sp_procxmode
```

• When you create a stored procedure, the SAP ASE server tags it with the current session's transaction mode. This means:

- You can execute chained stored procedures only in sessions using chained transaction mode.
- You can execute unchained stored procedures only in sessions using unchained transaction mode. To execute a particular stored procedure in either chained or unchained sessions, set its transaction mode to anymode.
- If you attempt to run a stored procedure under the wrong transaction mode, the SAP ASE server returns a warning message, but the current transaction, if any, is not affected.
- Executing sp_procxmode procname, 'Dynamic Ownership Chain' makes sure that any Dynamic SQL (execute immediate) statements within the stored procedure get their permissions checked against the procedure creator.
- Executing sp_procxmode procname, 'No Dynamic Ownership Chain' (the default behavior if omitted) makes sure that any Dynamic SQL (execute immediate) statements within the stored procedure get their permissions checked against the procedure executor.
- If you enable deferred compilation for a stored procedure using the enable_dc parameter, then you must manually recompile this stored procedure.

See also:

• begin transaction, commit, save transaction, set in Reference Manual: Commands

Permissions

The permission checks for sp procxmode differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the owner of the procedure or a user with manage database privilege. Any user can execute sp procxmode to for its own procedure.

Disabled With granular permissions disabled, you must be the database owner, the owner of the procedure, or a user with sa_role. Any user can execute sp_procxmode to display the transaction mode.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.215 sp_querysmobj

(Only when the TSM is licensed at your site) Queries the Tivoli Storage Manager (TSM) for a list of the SAP ASE backup objects.

Syntax

Parameters

syb_tsm

is the keyword that invokes the libsyb_tsm.so module that enables communication with TSM.

<output file>

is the file to which Backup Server writes the list of TSM backup objects.

<server name>

is the name of the SAP ASE server associated with the TSM backup objects.

<database name>

is the name of the database associated with the TSM backup objects. An asterisk (*) indicates all databases.

<object name>

is the name of the TSM backup object as provided in the dump database or dump transaction command. If this parameter is omitted, all backup objects are queried. An asterisk (*) indicates all backup objects.

<dump type>

is the backup object type to be queried. Valid values are:

- DB database backup objects created by the dump database command.
- XACT database backup objects created by the dump transaction command.
- * all database backup objects. This is the default.

until_time

is the date timestamp. All backup objects matching the criteria entered in sp_querysmobj before the specified time are queried. If you omit this parameter, all backup objects matching the specified criteria are queried.

<bs name>

is the name of the remote Backup Server. If <bs_name> is omitted, the default, SYB_BACKUP, is used.

Examples

Example 1

Queries all TSM backup objects for the SAP ASE "demo_svr1" and writes the list to /tmp/qtsm/5 1.out:

```
sp_querysmobj "syb_tsm", "/tmp/qtsm/5_1.out", "demo_srv1"
```

Example 2

Queries all TSM backup objects for the SAP ASE "demo_svr1" and the database pubs2 and writes the list to $/tmp/qtsm/5_2.out$:

```
sp_querysmobj "syb_tsm", "/tmp/qtsm/5_2.out", "demo_srv1", "pubs2"
```

Example 3

Queries all TSM database backup objects for the SAP ASE "demo_svr1" and the database pubs2 and writes the list to $/tmp/qtsm/5_3.out$:

```
sp_querysmobj "syb_tsm", "/tmp/qtsm/5_3.out", "demo_srv1", "pubs2", "*", "DB"
```

Usage

See also Using Backup Server with IBM Tivoli Storage Manager.

Permissions

The permission checks for sp querysmobj differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must have dump any database privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_deletesmobj [page 251]

1.216 sp_recompile

Causes each stored procedure and trigger that uses the named table to be recompiled the next time it runs.

Syntax

sp recompile <objname>

Parameters

<objname>

is the name of a table in the current database.

Examples

Example 1

Recompiles each trigger and stored procedure that uses the table titles the next time the trigger or stored procedure is run:

sp recompile titles

Usage

There are additional considerations when using sp recompile:

• Compilation involves the optimizer creating a query plan that is stored in procedure cache from the normalized query tree stored in sysprocedures. This occurs whenever a procedure or trigger is executed and no free plan for it is found in procedure cache. As you add indexes or make other changes to your database that affect its statistics, these query plans may lose efficiency. By recompiling the stored procedures and triggers that act on a table, you can optimize the queries for maximum efficiency.

i Note

Do not run sp_recompile when executing create index or update statistics. These commands results in minor schema changes, which then automatically recompile stored procedures and triggers that reference the target table on next execution.

- sp_recompile looks for <objname> only in the current database. Running it causes triggers and stored procedures that reference <objname> to recompile the next time they are executed.
- You cannot use sp recompile on system tables.
- In SAP ASE versions 12.5 and earlier, sp_recompile could influence adhoc queries that you execute. The SAP ASE server would return a schema change error (error number 540), and abort the adhoc query. sp_recompile no longer affects such adhoc queries, and you no longer see error 540.

See also:

• create index, update statistics in Reference Manual: Commands

Permissions

Any user can execute <code>sp_recompile</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.217 sp_refit_admin

(Cluster environments only) Provides an interface to perform various disk refit-related actions, such as showing the current status of the disk refit process, resetting the state of the disk refit process, skipping the disk refit process for an instance, and so on.

Syntax

Parameters

help

displays information on sp refit admin syntax and usage.

status

displays the current status of the disk refit process. It lists all the instances and their private devices for which disk refit is still pending. If no such device exists, it prints a message saying so.

reset

resets the state of the disk refit process. It takes an optional parameter <instance_name>.

If <instance_name> is not supplied, this parameter resets the disk refit process back to the beginning of Phase One, so that subsequent disk refit command starts the disk refit process from Phase One and refits all the regular shareable devices, as well as private devices of the instance.

If <instance_name> is supplied, this parameter resets the disk refit process back to the beginning of Phase Two for that instance, so that a subsequent disk refit command on that instance starts the disk refit process from Phase Two for that instance, and refits only the private devices of that instance.

skiprefit

skips running Phase Two of the disk refit process for one or all instances in the cluster without dropping the device. This parameter is meaningful only after the completion of Phase One of the disk refit process. It takes <instance_name> as an optional parameter.

removedevice

removes a device from the disk refit process. This parameter requires the name of the device that is to be removed, as the input parameter <device_name> or <instance_name>.

Examples

Example 1

Resets the state of the disk refit process to the start of Phase One:

```
sp_refit_admit 'reset'
```

 $After \ executing \ {\tt reset}, \ the \ user \ must \ run \ Phase \ One \ and \ Phase \ Two \ of \ the \ disk \ refit \ process.$

Example 2

Resets the state of the disk refit process on the instance named 'cluster1_instance1' to the start of Phase Two for the instance:

```
sp_refit_admin 'reset', 'cluster1_instance1'
```

This interface removes sysdatabases entry for all the databases created on the private devices owned by 'cluster1_instance1', and the sysusages entries corresponding to the private devices owned by 'cluster1_instance1'. After executing, you must run Phase Two of disk refit on 'cluster1_instance1'.

Example 3

Skips the disk refit process of all the refit-pending private devices of instance 'cluster1 instance1':

```
sp_refit_admin 'skiprefit', 'cluster1_instance1'
```

This example removes the sysdatabases entry for all the databases that use any of the refit-pending private devices owned by 'cluster1_instance1', and removes all the entries in sysusages for all the deleted databases.

To skip the disk refit process on all the refit-pending private devices of all the instances in the cluster, enter:

```
sp_refit_admin 'skiprefit'
```

Example 4

To remove the device "device1' from the disk refit process:

```
sp_refit_admin 'removedevice', 'device1'
```

This action removes the sysdatabases entry for all databases created on 'device1', and all the sysusages entries corresponding to 'device1'. It also removes 'device1' from sysdevices.

Usage

There are additional considerations when using <code>sp_refit_admin</code>:

- You must follow the instructions in *Clusters Users Guide* > *Troubleshooting* after executing skiprefit, to ensure the consistency of the system tables before resuming normal operation.
- Use removedevice only during the disk refit process, to remove the device from the refit process. Do not use it in place of sp_dropdevice
- You can use sp_refit_admin even when the instance is started with the -m option and trace flag 3608
 ON.

For information on problems encountered with disk refit, see the Troubleshooting and Error Guide

Permissions

The permission checks for sp refit admin differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with manage disk privilege.
Disabled	With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.218 sp_remoteoption

Displays or changes remote login options.

Syntax

Parameters

<remoteserver>

is the name of the server that executes RPCs on this server.

i Note

This manual page uses the term "local server" to refer to the server that is executing the remote procedures that are run from a "remote server."

<loginame>

is the login name that identifies the local login for the <remoteserver>, <loginame>, <remotename> combination.

<remotename>

is the remote user name that identifies the remote login for the <remoteserver>, <loginame>, <remotename> combination.

<optname>

is the name of the option to change. Currently, there is only one option, trusted, which means that the local server accepts remote logins from other servers without user-access verification for the particular remote login. The default is to use password verification. The SAP ASE server understands any unique string that is part of the option name. Use quotes around the option name if it includes embedded blanks.

<optvalue>

is either true or false. true turns the option on, false turns it off.

Examples

Example 1

Displays a list of the remote login options:

```
Settable remote login options.
remotelogin_option
-----trusted
```

Example 2

Defines the remote login from the remote server GATEWAY to be trusted; that is, the password is not checked:

```
sp_remoteoption GATEWAY, churchy, pogo, trusted, true
```

Example 3

Defines the remote login "pogo" from the remote server GATEWAY as a login that is not trusted; that is, the password is checked:

```
sp_remoteoption GATEWAY, churchy, pogo, trusted, false
```

Example 4

Defines all logins from GATEWAY that map to login "albert" on the local server to be trusted:

```
sp_remoteoption GATEWAY, albert, NULL, trusted, true
```

Usage

There are additional considerations when using sp remoteoption:

- To display a list of the remote login options, execute sp_remoteoption with no parameters.
- If you have used <code>sp_addremotelogin</code> to map all users from a remote server to the same local name, specify <code>trusted</code> for those users. For example, if all users from server GOODSRV that are mapped to "albert" are trusted, specify:

```
sp_remoteoption GOODSRV, albert, NULL, trusted, true
```

If the logins are not specified as trusted, they cannot execute RPCs on the local server unless they specify local server passwords when they log into the remote server. When they use Open Client Client-Library, users can specify a password for server-to-server connections with the routine ct_remote_pwd. isql and bcp do not permit users to specify a password for RPC connections.

If users are logged into the remote server using "unified login", the logins must also be trusted on the local server, or they must specify passwords for the server when they log into the remote server.

See the *System Administration Guide* for more information about setting up servers for remote procedure calls and for using "unified login."

See also isql in the *Utility Guide*.

Permissions

The permission checks for sp remoteoption differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any remote login

privilege.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sso_role.} \end{tabular}$

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addremotelogin [page 53] sp_dropremotelogin [page 313] sp_helpremotelogin [page 471]

1.219 sp_remotesql

(Component Integration Services only) Establishes a connection to a remote server, passes a query buffer to the remote server from the client, and relays the results back to the client.

Syntax

```
sp_remotesql <server>, <query>[, <query2>, ..., <query254>]
```

Parameters

<server>

is the name of a remote server defined with sp addserver.

<query>

is a query buffer a with maximum length of 255 characters.

<query2> ... <query254>

is a query buffer with a maximum length of 255 characters. If supplied, these arguments are concatenated with the contents of <query1> into a single query buffer.

Examples

Example 1

Passes the query buffer to FREDS_SERVER, which interprets select @@version and returns the result to the client. The SAP ASE server does not interpret the result:

```
sp_remotesql FREDS_SERVER, "select @@version"
```

Example 2

Uses sp_remotesql in a stored procedure. This example and the previous example return the same information to the client:

```
create procedure freds_version
as
exec sp_remotesql FREDS_SERVER, "select @@version"
go
exec freds_version
go
```

Example 3

Concatenates two query buffers into a single buffer, and passes the complete insert statement to the server DCO_SERVER for processing. The syntax for the insert statement is a format that DCO_SERVER understands. The returned information is not interpreted by the server. This example also examines the value returned in @@error.

```
sp_remotesql DCO_SERVER,
"insert into remote_table
(numbercol,intcol, floatcol,datecol)",
"values (109.26,75, 100E5,'10-AUG-85')"
select @@error
```

Example 4

Illustrates the use of local variables as parameters to sp remotesql:

```
declare @servname varchar(30)
declare @querybuf varchar(200)
select @servname = "DCO_SERV"
select @querybuf = "select table_name
    from all_tables
    where owner = 'SYS'"
exec sp_remotesql @servname, @querybuf
```

Usage

There are additional considerations when using sp remotesql:

- sp_remotesql establishes a connection to a remote server, passes a query buffer to the remote server from the client, and relays the results back to the client. The local server does not intercept results.
- You can use sp remotesql within another stored procedure.
- The query buffer parameters must be a character expression with a maximum length of 255 characters. If you use a query buffer that is not char or varchar, you get datatype conversion errors.
- sp_remotesql sets the global variable @@error to the value of the last error message returned from the remote server if the severity of the message is greater than 10.
- If sp_remotesql is issued from within a transaction, the SAP ASE server verifies that a transaction has been started on the remote server before passing the query buffer for execution. When the transaction terminates, the remote server is directed to commit the transaction. The work performed by the contents of the query buffer is part of the unit of work defined by the transaction. If transaction control statements are part of the query buffer, it is the responsibility of the client to ensure that the transaction commit and rollback occur as expected. Mixing Transact-SQL with transaction control commands in the query buffer can cause unpredictable results.
- The local server manages the connection to the remote server. Embedding connect to or disconnect commands in the query buffer causes results that require interpretation by the remote server. This is not required or recommended. Typically, the result is a syntax error.

See also connect to...disconnect in Reference Manual: Commands.

Permissions

Any user can execute <code>sp_remotesql</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addserver [page 58]
sp_autoconnect [page 97]
sp_passthru [page 645]

1.220 sp_rename

Changes the name of a user-created object or user-defined datatype in the current database.

Syntax

```
sp_rename <objname>, <newname> [, "index" | "column" | "partition"]
```

Parameters

<objname>

is the original name of the user-created object (table, view, column, partition, stored procedure, index, trigger, default, rule, check constraint, referential constraint, or user-defined datatype). If the object to be renamed is a column in a table, <objname> must be in the form ".<column>". If the object is an index, <objname> must be in the form ".<indexname>".

<newname>

is the new name of the object or datatype. The name must conform to the rules for identifiers and must be unique to the current database.

index

specifies that the object you are renaming is an index, not a column. This argument allows you to rename an index that has the same name as a column, without dropping and re-creating the index.

column

specifies that the object you are renaming is a column, not an index. This argument is part of the same option as the index argument.

partition

specifies that the object you are renaming is a partition when the table-partition name conflicts with a column or index name.

Examples

Example 1

Renames the titles table to books:

```
sp_rename titles, books
```

Example 2

Renames the title column in the books table to bookname:

```
sp_rename "books.title", bookname
```

Example 3

Renames the titleind index in the books table to titleindex:

```
sp_rename "books.titleind", titleindex
```

Example 4

Renames the user-defined datatype tid to bookid:

```
sp_rename tid, bookid
```

Example 5

Renames the title id index in the titles table to isbn:

```
sp_rename "titles.title_id", isbn, "index"
```

Example 6

Renames the table index my tab.indl.i part1 to i part1 rename:

```
sp_rename "my_tab.ind1.i_part1", i_part1_rename
```

Example 7

Renames the index partition my_tab.ind1.ind1_928003306 to ind1_928003306_rename using "partition" to avoid conflicts between the table-partition name and index name:

```
sp rename "my tab.ind1.ind1 928003306", ind1 928003306 rename, "partition"
```

Usage

There are additional considerations when using sp_rename:

- sp_rename changes the name of a user-created object or datatype. You can change only the name of an object or datatype in the database in which you issue sp_rename.
- When you are renaming a column or index, do not specify the table name in <newname>. See Examples 2, 3, and 5.
- If a column and an index have the same name, use the [, "<index>" | "<column>"] argument, which specifies whether to rename the index or the column. In the following sample, assume that both an index and a column named idx exist:

```
sp_rename "t.idx", new_idx, "column"
Column name has been changed. (Return status = 0)
sp_rename "t.idx", new_idx, "index"
Index name has been changed. (Return status = 0)
```

• If you change the name of a an object or column name referenced by a view, you see a warning message, such as:

```
Changing an object or column name could break existing stored procedures, cached statements or other compiled objects.
```

- sp engine can run in sessions using chained transaction mode if there are no open transactions.
- You cannot change the names of system objects and system datatypes.

Permissions

You must be the object owner to execute sp_rename. Permission checks do not differ based on the granular permissions settings.

Use the setuser command to assume another database user's identity to rename objects owned by other users.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_depends [page 253]
sp_rename [page 693]

1.221 sp_rename_qpgroup

Renames an abstract plan group.

Syntax

sp rename qpgroup <old name>, <new name>

Parameters

<old name>

is the current name of the abstract plan group.

<new name>

is the new name for the group. The specified <new_name> cannot be the name of an existing abstract plan group in the database.

Examples

Example 1

Changes the name of the group from dev_plans to prod_plans:

sp_rename_qpgroup dev_plans, prod_plans

Usage

There are additional considerations when using <code>sp_rename_qpgroup</code>:

- Use sp_rename_qpgroup to rename an abstract plan group. You cannot use the name of an existing plan group for the new name.
- sp_rename_qpgroup does not affect the contents of the renamed group. IDs of existing abstract plans are not changed.
- You cannot rename the default abstract plan groups, ap_stdin and ap_stdout.
- sp_rename_qpgroup cannot be run in a transaction.

Permissions

The permission checks for <code>sp_rename_qpgroup</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_help_qpgroup [page 410]

1.222 sp_renamedb

Changes the name of a user database.

Syntax

sp renamedb <dbname>, <newname>

Parameters

<dbname>

is the original name of the database.

<newname>

is the new name of the database. Database names must conform to the rules for identifiers and must be unique.

Examples

Example 1

Renames the accounting database to financial:

sp_renamedb accounting, financial

Example 2

Renames the database named work, which is a Transact-SQL reserved word, to workdb. This example shows how $sp_dboption$ is used to place the work database in single-user mode before renaming it and restore it to multi-user mode afterward:

```
sp_dboption work, single, true
go
use work
go
checkpoint
go
sp_renamedb work, workdb
go
use master
go
sp_dboption workdb, single, false
go
use workdb
go
checkpoint
go
```

Usage

There are additional considerations when using sp renamedb:

- sp_renamedb changes the name of a database. You cannot rename system databases or databases with external referential integrity constraints.
- The system administrator must place a database in single-user mode with sp_dboption before renaming it and must restore it to multi-user mode afterward.
- sp_renamedb fails if any table in the database references, or is referenced by, a table in another database. Use the following query to determine which tables and external databases have foreign key constraints on primary key tables in the current database:

```
select object_name(tableid), db_name(frgndbid)
from sysreferences
where frgndbid is not null
```

Use the following query to determine which tables and external databases have primary key constraints for foreign key tables in the current database:

```
select object_name(reftabid), db_name(pmrydbid)
from sysreferences
where pmrydbid is not null
```

Use $\mbox{ alter table to drop the cross-database constraints in these tables. Then, rerun <math>\mbox{sp_renamedb}.$

- When you change a database name:
 - o Drop all stored procedures, triggers, and views that include the database name
 - Change the source text of the dropped objects to reflect the new database name
 - Re-create the dropped objects
 - Change all applications and SQL source scripts that reference the database, either in a use
 <database_name> command or as part of a fully qualified identifier (in the form <dbname>.
 [<owner>].<objectname>)

• If you use scripts to run dbcc commands or dump database and dump transaction commands on your databases, be sure to update those scripts.

Procedures, triggers, and views that depend on a database with a name that has been changed work until they are re-created. Change the definitions of any dependent objects when you execute <code>sp_renamedb</code>. Find dependent objects with <code>sp_depends</code>.

See also create database in Reference Manual: Commands.

Permissions

The permission checks for sp renamedb differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with own database privilege on the

database.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_changedbowner [page 133]

sp_dboption [page 228]

sp_depends [page 253]

sp_helpdb [page 438]

sp_rename [page 693]

1.223 sp_reportstats

Reports statistics on system usage.

Syntax

```
sp_reportstats [<loginame>]
```

Parameters

<loginame>

is the login name of the user to show accounting totals for.

Examples

Example 1

Displays a report of current accounting totals for all SAP ASE users:

Example 2

Displays a report of current accounting totals for user "kathy":

Usage

There are additional considerations when using sp reportstats:

- sp_reportstats prints out the current accounting totals for all logins, as well as each login's individual statistics and percentage of the overall statistics. sp_reportstats accepts one parameter, the login name of the account to report. With no parameters, sp_reportstats reports on all accounts.
- The units reported for "CPU" are SAP ASE clock ticks.
- The "probe" user exists for the two-phase commit probe process, which uses a challenge-and-response mechanism to access the SAP ASE server.

Permissions

The permission checks for sp reportstats differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_clearstats [page 163]
sp_configure [page 203]

1.224 sp_restore_system_role

Restores the system defined role or database owner to the default role privilege configuration.

Syntax

```
sp_restore_system_role [<role_name>[, all_dbs]]
```

Parameters

<role_name>

One of sa_role, sso_role, oper_role, replication_role, keycustodian_role, sa_serverprivs_role, and dbo. A usage message is displayed if no parameter is specified.

all_dbs

Restores the database owner or the role to the default role privilege configuration in all online databases. If all_dbs is not specified, only perform the change in the current database.

Examples

Example 1

Restore sso_role to the default role privilege configuration in all databases:

```
sp_restore_system_role sso_role, all_dbs
```

Example 2

Restores sa_role to the default role privilege configuration in db1 only:

```
use db1
```

```
sp_restore_system_role sa_role
```

Example 3

Restore dbo to the default privilege configuration in master:

```
use master
```

```
sp_restore_system_role dbo
```

Usage

There are additional considerations when using $sp_restore_system_role$:

- sp_restore_system_role restores a system-defined role, user-defined role sa_serverprivs_role, or database owner to the default role privilege configuration. The allowed system-defined roles include: sa_role, sso_role, oper_role, replication_role, and keycustodian_role. For the list of privileges granted to the above roles or database owner in the default role privilege configuration, see *Using Granular Permissions* in the *Security Administration Guide*.
- When you specify all_dbs, the restoration operation does not apply to sybsecurity database. You need to manually restore privileges of the role or database owner in sybsecurity if needed.

Permissions

The permission checks for <code>sp_restore_system_role</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server permissions

privileges to restore sa_role, and a user with manage security permissions to restore other roles or the database owner. To use all_dbs option, you also need to have use any database

privilege.

Disabled With granular permissions disabled, you must be a user with sa_role to restore sa_role, and a user

with sso_role to restore other roles and the database owner.

Auditing

You can enable dbcc auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

InformationValueAudit optiondbccEvent81

Information in extrainfo • Roles – Current active roles

• **Keywords or options** - upgd_grantrev_sysrole_perms

• Previous value – NULL

• Current value – NULL

• Other information – parameter list

• **Proxy information** – Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.225 sp_revokelogin

(Windows only) Revokes SAP ASE roles and default permissions from Windows users and groups when Integrated Security mode or Mixed mode (with Named Pipes) is active.

Syntax

```
sp_revokelogin {<login_name> | <group_name>}
```

Parameters

<login_name>

is the network login name of the Windows user.

<group_name>

is the Windows group name.

Examples

Example 1

Revokes all permissions from the Windows user named "jeanluc":

```
sp_revokelogin jeanluc
```

Example 2

Revokes all roles from the Windows Administrators group:

```
sp revokelogin Administrators
```

Usage

Use sp_revokelogin only when the SAP ASE server is running in Integrated Security mode or Mixed mode, when the connection is Named Pipes. If the SAP ASE server is running in Standard mode, or in Mixed mode using a connection other than Named Pipes, use the revoke command.

If you revoke a user's roles and default privileges with <code>sp_revokelogin</code>, that user can no longer log into the SAP ASE server over a trusted connection.

See also grant, revoke, setuser in Reference Manual: Commands.

Permissions

The permission checks for sp revokelogin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage roles privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

Values in event and extrainfo columns from the sysaudits table are:

 Information
 Value

 Audit option
 exec_procedure

 Event
 38

 Command or access audited
 Execution of a procedure

 Information in extrainfo
 • Roles - Current active roles

 • Keywords or options - upgd_grantrev_sysrole_perms

 • Previous value - NULL

 • Current value - NULL

 • Other information - parameter list

 • Proxy information - Original login name, if set_proxy in effect

Related Information

sp_droplogin [page 309]
sp_dropuser [page 326]

1.226 sp_role

Deprecated by SAP ASE 15.7. To grant or revoke roles, use the grant role or revoke role commands. See grant role and revoke role in Reference Manual: Commands > Commands.

Related Information

```
sp_activeroles [page 15]
sp_displayroles [page 276]
sp_displayroles [page 276]
```

1.227 sp_securityprofile

Lists the attributes or bindings associated with a login profile.

Syntax

Parameters

attributes

specifies to list attributes associated with a login profile.

login profile

specifies to obtain information about login profiles.

bindings

when login is specified, list binding of login accounts. When login profile is specified, list bindings of login profiles.

login

specifies to obtain information about login accounts.

<wildcard> | <login_profile_name> | default

specifies the login profile in which to obtain information. Options include a specific a name of a login profile, the default login profile, or wildcard characters can be used to identify login profiles.

<wildcard> | <login_name>

specifies to use a specific login account name or allows the use of wildcard characters to identify login accounts.

help

displays usage.

Examples

Example 1

Lists all attributes of the default login profile.

```
sp_securityprofile 'attributes', 'login profile', 'default'
```

```

admin_role login profile manually activated roles default

Example 3

Displays all login accounts associated with a specific login profile.

Example 4

Displays the login profile for the login account named sa.

Usage

Precedence rules are followed for attributes no set in profiles.

See also:

- create login profile, alter login profile in Reference Manual: Commands
- Applying Login Profile and Password Policy Attributes in the Security Administration Guide
- sp displaylogin

Permissions

The permission checks for sp securityprofile differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any login profile

privilege.

Disabled With granular permissions disabled, you must be a user with sso_role to see attributes and bindings of all login profiles.

For a non-privileged login account:

- You can only see the attributes of a login profile associated with the login (either directly or the default login profile).
- You cannot see the bindings of a login profile with login accounts.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.228 sp_sendmsg

(UNIX only) Sends a message to a User Datagram Protocol (UDP) port.

Syntax

```
sp_sendmsg <ip_address>, <port_number>, <message>
```

Parameters

<ip_address>

is the IP address of the machine where the UDP application is running.

<port_number>

is the port number of the UDP port.

<message>

is the message to send, up to 4096 characters in length.

Examples

Example 1

```
sp_sendmsg "120.10.20.5", 3456, "Hello World"
```

This sample C program listens on a port that you specify and echoes the messages it receives. For example, to receive the sp_sendmsg calls for this example, use:

```
updmon 3456
#include <stdlib.h>
#include <stdio.h>
#include <sys/types.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
#include <unistd.h>
#include <fcntl.h>
main(argc, argv)
int argc; char *argv[];
        struct sockaddr_in sadr;
        int portnum, sck, dummy, msglen;
        char msg[256];
        if (argc < 2) {
                 printf("Usage: udpmon <udp portnum>\n");
                 exit(1);
        if ((portnum=atoi(argv[1])) < 1) {</pre>
                 printf("Invalid udp portnum\n");
                 exit(1);
        if ((sck=socket(AF_INET,SOCK_DGRAM,IPPROTO_UDP)) < 0) {</pre>
                 printf("Couldn't create socket\n");
                 exit(1);
        sadr.sin_family = AF_INET;
sadr.sin_addr.s_addr = inet_addr("0.0.0.0");Sends the message "Hello"
World" to IP address 120.10.20.5 using port
        if (bind(sck,&sadr,sizeof(sadr)) < 0) {</pre>
                 printf("Couldn't bind requested udp port\n");
                 exit(1);
        for (;;)
                 if((msglen=recvfrom(sck,msg,sizeof(msg),0,NULL,&dummy)) < 0)</pre>
                          printf("Couldn't recvfrom() from udp port\n");
                 printf("%.*s\n", msglen, msg);
        }
```

Usage

There are additional considerations when using sp_sendmsg:

- To enable the use of UDP messaging, a system security officer must set the configuration parameter allow sendmsq to 1.
- No security checks are performed with sp_sendmsg. Be very cautious when using sp_sendmsg to send sensitive information across the network. By enabling this functionality, the user accepts any security problems that result from its use.

See also:

• syb sendmsg in Reference Manual: Building Blocks

Permissions

Any user can execute <code>sp_sendmsg</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.229 sp_serveroption

Displays or changes remote server options.

Syntax

sp serveroption [<server>, <optname>, <optvalue>]

Parameters

<server>

is the name of the remote server for which to set the option.

<optname>

is the name of the option to be set or unset. The following table lists the option names.

mutual		
authentication		

sets mutual authentication for all connections to the remote server using Kerberos authentication.

net password encryption

specifies whether to initiate connections with a remote server with the client side password encryption handshake or with the normal (unencrypted password) handshake sequence. The default is false (no network encryption).

allow password downgrade

readonly (Component Integration Services only) specifies that access

to the server named is read only.

security mechanism

specifies the security mechanism for the remote server. Enables Kerberos authentication for connections to the remote server when your login is authenticated using the Kerberos mechanism.

server cost

(Component Integration Services only) specifies the cost of a single exchange under the user's control, on a per-server basis. See *Understanding Component Integration Services* in *Understanding CIS* for more information.

server logins

(Component Integration Services only) to fully support remote logins, Client-Library provides connection properties that enable CIS to request a server connection. This connection is recognized at the receiving server as a server connection (as opposed to an ordinary client connection), allowing the remote server to validate the connection through the use of sysremotelogins as if the connection were made by a site handler.

When enabled, Omni connects to the specified server using the CS_LOGIN_TYPE connection property, with type set to LREMUSER. Also, if the remote server is an SAP ASE server, the CS_LOGIN_REMOTE_SERVER property is set to the value of the local server name, and remote passwords are set using ct remote pwd().

server principal

sets the server principal name for a remote server.

negotiated logins

(Component Integration Services only) this option is necessary if CIS connections to XP server or Backup Server are required. When enabled, Omni connects to the specified server using the CS_SEC_CHALLENGE property, and establishes a callback handler that can respond appropriately to login challenges from XP Server and Backup Server.

timeouts

when unset (false), disables the normal timeout code used by the local server, so the site connection handler does not automatically drop the physical connection after one minute with no logical connection. The default is false.

use message confidentiality

sets message confidentiality for all connections to the remote server using Kerberos authentication.

use message integrity

sets message integrity for all connections to the remote server using Kerberos authentication.

cis hafailover

(Component Integration Services only) if enabled, instructs Open Client to use automatic failover when connections fail. In this case, CIS connection failures automatically failover to the server specified in directory services (such as the interface file and Idap server) as the failover server.

The SAP ASE server accepts any unique string that is part of the option name. Use quotes around the option name if it includes embedded blanks.

<optvalue>

is true (on) or false (off) for all options except the security mechanism option.

For the security mechanism option, specify the name of the security mechanism. To see the names of the security mechanisms available on a server, execute:

select * from syssecmechs

Examples

Example 1

Displays a list of the server options:

sp serveroption

Settable server options.
-----cis hafailover
enable login redirection
external engine auto start
incompatible sort order
mutual authentication
negotiated logins
net password encryption
readonly
relocated joins

```
security mechanism
server cost
server logins
server principal
timeouts
use message confidentiality
use message integrity
```

Example 2

Tells the server not to time out inactive physical connections with the remote server GATEWAY:

```
sp_serveroption GATEWAY, "timeouts", false
```

Example 3

Specifies that when connecting to the remote server GATEWAY, GATEWAY sends back an encryption key to encrypt the password to send to it:

```
sp_serveroption GATEWAY, "net password encryption", true
```

Example 5

Specifies Kerberos authentication for connections to remote server S2.

```
sp_serveroption S2, "security mechanism", csfkrb5
```

Example 6

Specifies mutual authentication for all connections to the remote server using Kerberos authentication.

```
sp_serveroption TEST3, "mutual authentication", true
```

Usage

There are additional considerations when using sp serveroption:

- To display a list of server options that can be set by the user, use <code>sp_serveroption</code> with no parameters.
- After timeouts is set to false, the site handlers continue to run until one of the two servers is shut down.
- The net password encryption option allows clients to specify whether to send passwords in plain text or encrypted form over the network when initiating a remote procedure call. If net password encryption is true, the initial login packet is sent without passwords, and the client indicates to the remote server that encryption is desired. The remote server sends back an encryption key, which the client uses to encrypt its passwords. The client then encrypts its passwords, and the remote server uses the key to authenticate them when they arrive.
- To set network password encryption for a particular isql session, you can use a command line option for isql.
- The security mechanism, mutual authentication, use message confidentiality, and use message integrity options apply to Kerberos logins only.

See also:

- See the System Administration Guide for more information on server options.
- isql in the Utility Guide

Permissions

The permission checks for sp serveroption differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with manage server privilege. For a shared-disk cluster, you must be a user with manage server and manage cluster privileges.

Any user can execute sp serveroption with no parameters to display a list of options.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be a user with sa_role to set the \verb|timeouts| option.$

You must be a user with sso role to set:

- net password encryption
- security mechanism
- mutual authentication
- use message confidentiality
- use message integrity

Any user can execute sp serveroption with no parameters to display a list of options.

Auditing

You can enable config history auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value
Audit option	config_history
Event	154
Command or access audited	sp_serveroption
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – Includes procedure name, parameter name, old value, new value, mode (static or active), and instance ID Proxy information – Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_password [page 647]
```

1.230 sp_set_qplan

Changes the text of the abstract plan of an existing plan without changing the associated query.

Syntax

```
sp_set_qplan <id>, <plan>
```

Parameters

<id>>

is the ID of the abstract plan.

<plan>

is a new abstract plan.

Examples

Example 1

Changes the text of the abstract plan:

```
sp_set_qplan 563789159,
    "( g_join (scan t1) (scan t2))"
```

Usage

There are additional considerations when using sp_set_qplan :

• Use sp_set_qplan to change the abstract plan of an existing plan. You can specify a maximum of 255 characters for a plan. If the abstract plan is longer than 255 characters, drop the old plan with sp drop qplan, then use create plan to create a new plan for the query.

- When you change a plan with sp_set_qplan, plans are not checked for valid abstract plan syntax and the plan is not checked for compatibility with the SQL text. Immediately check all plans modified with sp_set_qplan for correctness by running the query for the specified ID.
- To find the ID of a plan, use sp_help_qpgroup, sp_help_qplan, or sp_find_qplan. Plan IDs are also returned by create plan and are included in showplan output.

See also create plan in Reference Manual: Commands.

Permissions

The permission checks for sp set qplan differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage abstract plans privilege.

Any user can execute sp_set_qplan to change the text of a plan for which they own.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Any user can execute sp set qplan to change the text of a plan for which they own.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.231 sp_setlangalias

Assigns or changes the alias for an alternate language.

Syntax

sp_setlangalias <language>, <alias>

Parameters

<language>

is the official language name of the alternate language.

<alias>

is the new local alias for the alternate language.

Examples

Example 1

Assigns the alias name "français" for the official language name "french":

sp_setlangalias french, français

Usage

<alias> replaces the current value of syslanguages.alias for the official name; the set language command can use the new <alias> in place of the official language name.

See also set in Reference Manual: Commands.

Permissions

The permission checks for sp setlangalias differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addlanguage [page 43]
sp_droplanguage [page 308]
sp_helplanguage [page 465]
```

1.232 sp_setpglockpromote

Sets or changes the lock promotion thresholds for a database, for a table, or for the SAP ASE server.

Syntax

Parameters

```
server
```

sets server-wide values for the lock promotion thresholds.

```
"database" | "table"
```

specifies whether to set the lock promotion thresholds for a database or table. "database" and "table" are Transact-SQL keywords, so the quotes are required.

<objname>

is either the name of the table or database for which you are setting the lock promotion thresholds or null, if you are setting server-wide values.

<new lwm>

specifies the value to set for the low watermark (LWM) threshold. The LWM must be less than or equal to the high watermark (HWM). The minimum value for LWM is 2. This parameter can be null.

<new_hwm>

specifies the value to set for the lock promotion HWM threshold. The HWM must be greater than or equal to the LWM. The maximum HWM is 2,147,483,647. This parameter can be null.

<new pct>

specifies the value to set for the lock promotion percentage (PCT) threshold. PCT must be between 1 and 100. This parameter can be null.

Examples

Example 1

Sets the server-wide lock promotion LWM to 200, the HWM to 300, and the PCT to 50:

```
sp setpglockpromote "server", NULL, 200, 300, 50
```

Example 2

Sets lock promotion thresholds for the master database:

```
sp setpglockpromote "database", master, 1000, 1100, 45
```

Example 3

Sets lock promotion thresholds for the titles table in the pubs2 database. This command must be issued from the pubs2 database:

```
sp setpglockpromote "table", "pubs2..titles", 500, 700, 10
```

Example 4

Changes the HWM threshold to 1600 for the master database. The thresholds were previously set with sp setpglockpromote. This command must be issued from the master database:

```
sp setpglockpromote "database", master, @new hwm=1600
```

Usage

There are additional considerations when using sp setpglockpromote:

- You can display database-level lock promotions using sp_helpdb <dbname> and table-level locks using sp helpdb <tablename>.
- sp_setpglockpromote configures the lock promotion values for a table, for a database, or for the SAP ASE server.
 - The SAP ASE server acquires page locks on a table until the number of locks exceeds the lock promotion threshold. sp_setpglockpromote changes the lock promotion thresholds for an object, a database, or the server. If the SAP ASE server is successful in acquiring a table lock, the page locks are released. When the number of locks on a table exceeds the HWM threshold, the SAP ASE server attempts to escalate to a table lock. When the number of locks on a table is below the LWM, the SAP ASE server does not attempt to escalate to a table lock. When the number of locks on a table is between the HWM and LWM and the number of locks exceeds the PCT threshold, the SAP ASE server attempts to escalate to a table lock
- Lock promotion thresholds for a table override the database or server-wide settings. Lock promotion thresholds for a database override the server-wide settings.
- Lock promotion thresholds for the SAP ASE server do not need initialization, but you must initialize database and table lock promotion thresholds by specifying LWM, HWM, and PCT with sp_setpglockpromote, which creates a row for the object in sysattributes when it is first run for a database or table. Once the thresholds have been initialized, then they can be modified individually, as in Example 4.
- For a table or a database, <code>sp_setpglockpromote</code> sets LWM, HWM, and PCT in a single transaction. If <code>sp_setpglockpromote</code> encounters an error while updating any of the values, then all changes are aborted and the transaction is rolled back. For server-wide changes, one or more thresholds may fail to be updated while others are successfully updated. The SAP ASE server returns an error message if any values fail to be updated.
- To view the server-wide settings for the lock promotion thresholds, use sp_configure "lock promotion" to see all three threshold values. To view lock promotion settings for a database, use sp helpdb. To view lock promotion settings for a table, use sp help.

Permissions

The permission checks for sp setpglockpromote differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be a user with ${\tt manage}\ {\tt lock}\ {\tt premotion}$ threshold privilege.
Disabled	With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_configure [page 203]
sp_dropglockpromote [page 301]
sp_help [page 396]
sp_helpdb [page 438]
```

1.233 sp_setpglockpromote_ptn

Sets partition-lock promotion thresholds at the server, database, and table level.

Syntax

• To set the partition lock promotion threshold at the server level:

```
sp_setpglockpromote_ptn "server", null, <new_lwm>, <new_hwm>, <new_pct>
```

To set the partition lock promotion threshold at the database or table level:

Parameters

server

sets server-wide values for the lock promotion thresholds.

"database" | "table"

specifies whether to set the lock promotion thresholds for a database or table. These are Transact-SQL keywords and therefore, require quotes.

<objname>

is either the name of the partition, table, or database for which you are setting the lock promotion thresholds, or null, if you are setting server-wide values. If you are setting

partition-wide values, use the format <table_name>.<partition_name> for the
<objname>.

<new lwm>

specifies a minimum number of page locks that must be acquired before SAP ASE acquires a partition lock.

<new hwm>

specifies a maximum number of page locks allowed on the object before SAP ASE attempts to escalate to a partition lock.

<new_pct>

specifies the percentage of locked pages (based on the table size) above which SAP ASE attempts to acquire a partition lock when the number of locks is between the <new hwm> and <new lwm> lock promotions.

Examples

Example 1

Sets the server-wide partition lock promotion threshold values LWM to 200, the HWM to 300, and the PCT to 50:

```
sp_setpglockpromote_ptn "server", NULL, 200, 300, 50
```

Example 2

Sets partition lock promotion thresholds for the master database:

```
sp_setpglockpromote_ptn "database", master, 1000, 1100, 45
```

Example 3

Sets partition lock promotion thresholds for the titles table in the pubs2 database. This command must be issued from the pubs2 database:

```
sp_setpglockpromote_ptn "table", "pubs2..titles", 500, 700, 10
```

Permissions

Any user can execute sp_setpglockpromote_ptn.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.234 sp_setpsexe

Sets custom execution attributes for a session while the session is active.

Syntax

```
sp setpsexe <spid>, <exeattr>, <value>
```

Parameters

<spid>

is the ID of the session for which to set execution variables. Use sp who to see spids.

<exeattr>

identifies the execution attribute to be set. Values are priority and enginegroup.

<value>

is the new value of exeattr. Values for each attribute are:

- If <exeattr> is priority, <value> is HIGH, MEDIUM, or LOW.
- If <exeattr> is enginegroup, <value> is the name of an existing engine group.

Examples

Example 1

This example sets the priority of the process with an ID of 1 to HIGH:

```
sp_setpsexe 1, "priority", "HIGH"
```

Usage

There are additional considerations when using sp setpsexe:

- Execution attribute values specified with sp_setpsexe are valid for the current session only and do not apply after the session terminates.
- Use sp_setpsexe with caution or it can result in degraded performance. Changing attributes "on the fly", using sp_setpsexe, can help if the process is not getting CPU time; however, if the performance problem is due to something else, such as locks, changing execution attributes could make the problem worse.

- Because you can only set execution attributes for sessions, sp_setpsexe cannot be set for a worker process spid.
- Except for the housekeeper spid, you cannot set execution attributes for system spids.
- sp setpsexe does not work if there are no online engines in the associated engine group.

Permissions

The permission checks for sp setpsexe differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class privilege.

Any user can execute sp setpsexe to lower the priority of a process owned by that user.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, you must be a user with sa_role.} \end{tabular}$

Any user can execute sp setpsexe to lower the priority of a process owned by that user.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addexeclass [page 35]

sp_bindexeclass [page 110]

sp_dropexeclass [page 296]

sp_showexeclass [page 744]

1.235 sp_setrowlockpromote

Sets or changes row-lock promotion thresholds for a datarows-locked table, for all datarows-locked tables in a database, or for all datarows-locked tables on a server.

Syntax

Parameters

server

sets server-wide values for the row lock promotion thresholds.

"database" | "table"

specifies whether to set the row-lock promotion thresholds for a database or table.

<objname>

is either the name of the table or database for which you are setting the row-lock promotion thresholds or null, if you are setting server-wide values.

<new lwm>

specifies the value to set for the low watermark (LWM) threshold. The LWM must be less than or equal to the high watermark (HWM). The minimum value for LWM is 2. This parameter can be null.

<new hwm>

specifies the value to set for the high watermark (HWM) threshold. The HWM must be greater than or equal to the LWM. The maximum HWM is 2,147,483,647. This parameter can be null.

<new_pct>

specifies the value to set for the lock promotion percentage (PCT) threshold. PCT must be between 1 and 100. This parameter can be null.

Examples

Example 1

Sets row lock promotion values for all datarows-locked tables in the engdb database:

```
sp_setrowlockpromote "database", engdb, 400, 400, 95
```

Example 2

Sets row lock promotion values for the sales table:

```
sp_setrowlockpromote "table", sales, 250, 250, 100
```

Usage

There are additional considerations when using $sp_setrowlockpromote$:

- You can display database-level lock promotions using sp_helpdb <dbname> and table-level locks using sp_helpdb <tablename>.
- sp_setrowlockpromote sets or changes row-lock promotion thresholds for a table, a database, or the SAP ASE server.

The SAP ASE server acquires row locks on a datarows-locked table until the number of locks exceeds the lock promotion threshold. If the SAP ASE server is successful in acquiring a table lock, the row locks are released.

When the number of row locks on a table exceeds the HWM, the SAP ASE server attempts to escalate to a table lock. When the number of row locks on a table is below the LWM, the SAP ASE server does not attempt to escalate to a table lock. When the number of row locks on a table is between the HWM and LWM, and the number of row locks exceeds the PCT threshold as a percentage of the number of rows in a table, the SAP ASE server attempts to escalate to a table lock.

- Lock promotion is always two-tiered, that is, row locks are promoted to table locks. The SAP ASE server does not promote from row locks to page locks.
- Lock promotion thresholds for a table override the database or server-wide settings. Lock promotion thresholds for a database override the server-wide settings.
- To change the lock promotion thresholds for a database, you must be using the master database. To change the lock promotion thresholds for a table in a database, you must be using the database where the table resides.
- Server-wide row lock promotion thresholds can also be set with sp_configure. When you use sp_setrowlockpromote to change the values server-wide, it changes the configuration parameters, and saves the configuration file. When you first install SAP ASE, the server-wide row lock promotion thresholds set by the configuration parameters are:

Parameters	Thresholds
row lock promotion HWM	200
row lock promotion LWM	200
row lock promotion PCT	100

See the System Administration Guide for more information.

- The system procedure sp sysmon reports on row lock promotions.
- Database-level row lock promotion thresholds are stored in the master..sysattributes table. If you dump a database, and load it only another server, you must set the row lock promotion thresholds on the new server. Object-level row lock promotion thresholds are stored in the sysattributes table in the user database, and are included in the dump.

Permissions

 $The permission checks for \verb|sp_setrowlockpromote| differ based on your granular permissions settings.$

Setting Description

Enabled With granular permissions enabled, you must be a user with manage lock promotion

threshold privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_configure [page 203] sp_droprowlockpromote [page 315] sp_helpdb [page 438] sp_sysmon [page 792]

1.236 sp_setrowlockpromote_ptn

Sets partition-lock promotion thresholds at the server, database, and table level.

Syntax

• To set the partition lock promotion threshold at the server level::

```
sp_setrowlockpromote_ptn "server", null, <new_lwm>, <new_hwm>, <new_pct>
```

• To set the partition lock promotion threshold at the database or table level:

Parameters

server

sets server-wide values for the lock promotion thresholds.

"database" | "table"

specifies whether to set the lock promotion thresholds for a database or table. These are Transact-SQL keywords and therefore, require quotes.

<objname>

is either the name of the partition, table, or database for which you are setting the lock promotion thresholds, or null, if you are setting server-wide values. If you are setting partition-wide values, use the format <table_name>. <partition_name> for the <objname>.

<new lwm>

specifies a minimum number of row locks that must be acquired before SAP ASE acquires a partition lock.

<new hwm>

specifies a maximum number of row locks allowed on the object before SAP ASE attempts to escalate to a partition lock.

<new pct>

specifies the percentage of locked rows (based on the table size) above which SAP ASE attempts to acquire a partition lock when the number of locks is between the <new hwm> and <new lwm> lock promotions.

Examples

Example 1

Sets the server-wide partition lock promotion threshold values LWM to 200, the HWM to 300, and the PCT to 50:

```
sp_setrowlockpromote_ptn "server", NULL, 200, 300, 50
```

Example 2

Sets partition lock promotion thresholds for the master database:

```
sp_setrowlockpromote_ptn "database", master, 1000, 1100, 45
```

Example 3

Sets partition lock promotion thresholds for the titles table in the pubs2 database. This command is issued this from the pubs2 database:

```
sp_setrowlockpromote_ptn "table", "pubs2..titles", 500, 700, 10
```

Permissions

Any user can execute sp setrowlockpromote ptn.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.237 sp_setsuspect_granularity

Displays or sets the recovery fault isolation mode for a user database, which governs how recovery behaves when it detects data corruption.

Syntax

```
sp_setsuspect_granularity [<dbname>
    [, "database" | "page" [, "read_only"]]]
```

Parameters

<dbname>

is the name of the database for which to display or set the recovery fault isolation mode. For displaying, the default is the current database. For setting, you must be in the master database and specify the target <dbname>.

database

marks the entire database suspect, which makes it inaccessible, if the recovery process detects that any of its data is suspect.

page

marks only the corrupt pages suspect, making them inaccessible, if recovery detects corrupt data in the database. The rest of the data is accessible.

read only

if specified, marks the entire database read only if recovery marks any pages suspect.

Examples

Example 1

Displays the recovery fault isolation mode for the current database:

```
sp_setsuspect_granularity

DB Name Cur. Suspect Gran. Cfg. Suspect Gran. Online mode
pubs2 database database read/write
```

Example 2

Displays the current and configured recovery fault isolation mode for the pubs2 database:

```
sp_setsuspect_granularity pubs2
```

Example 3

The next time recovery runs in the pubs 2 database, if any corrupt pages are detected, only the suspect pages are taken offline and the rest of the database is brought online:

Example 4

The next time recovery runs in the pubs 2 database, if any corrupt pages are detected, only the suspect pages are taken offline and the rest of the database is brought online in read only mode:

```
sp setsuspect granularity pubs2, "page", "read only"
```

Example 5

The next time recovery runs in the pubs2 database, if any corrupt data is detected, the entire database is marked suspect and taken offline:

```
sp_setsuspect_granularity pubs2, "database"
```

Usage

There are additional considerations when using sp setsuspect granularity:

- sp_setsuspect_granularity displays and sets the recovery fault isolation mode. This mode governs whether recovery marks an entire database or only the corrupt pages suspect when it detects that any data that it requires has been corrupted. See the *System Administration Guide* for more information.
- The default recovery fault isolation mode of a user database is "database". You can set the recovery fault isolation mode only for a user database, not for a system database.
- The Cluster Edition allows only the database option with sp setsuspect granularity.
- You must be in the master database to set the recovery fault isolation mode.
- Data marked suspect due to corruption persists across SAP ASE server start-ups. When certain pages have been marked suspect, they remain offline after you reboot the server.
- When part or all of a database is marked suspect, the suspect data is not accessible to users unless a system administrator has made the suspect data accessible with the sp_forceonline_db and sp_forceonline_page procedures.
- General database corruption, such as a corrupt database log or the unavailability of another resource not specific to a page, causes the entire database to be marked suspect, even if the recovery fault isolation mode is "page."
- If you do not specify page or database, the SAP ASE server displays the current and configured settings. The current setting is the one that was in effect the last time recovery was executed in the database. The configured setting is the one that is in effect the next time recovery is executed in the database.
- If the database comes online in read_only mode, no user can modify any of its data, including data that is unaffected by the suspect pages and is thus online. However, the system administrator can make the database writeable using the sp_dboption system procedure to set read_only to false. In this case, users could then modify the online data, but the suspect data would remain inaccessible.

See also dump database, dump transaction, load database in Reference Manual: Commands.

Permissions

The permission checks for sp_setsuspect_granularity differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with own database privilege on the

specified database to set the recovery fault isolation mode.

Any user can execute <code>sp_setsuspect_granularity</code> to display settings.

Disabled With granular permissions disabled, you must be a user with sa_role to set the recovery fault isolation mode.

Any user can execute sp setsuspect granularity to display settings.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_dboption [page 228]
sp_forceonline_db [page 380]
sp_forceonline_page [page 385]
sp_listsuspect_db [page 552]
sp_listsuspect_page [page 555]
sp_setsuspect_threshold [page 733]
```

1.238 sp_setsuspect_threshold

Displays or sets the maximum number of suspect pages that the SAP ASE server allows in a database before marking the entire database suspect.

Syntax

```
sp setsuspect threshold [<dbname> [, <threshold>]]
```

Parameters

<dbname>

is the name of the database for which you want to display or set the suspect escalation threshold. The default is the current database.

<threshold>

indicates the maximum number of suspect datapages that recovery allows before marking the entire database suspect. The default is 20 pages. The minimum is 0.

Examples

Example 1

Sets the maximum number of suspect pages to 5. If there are more than 5 suspect pages, recovery marks the entire database suspect:

```
sp_setsuspect_threshold pubs2, 5
```

Example 2

Displays the current and configured settings for the suspect escalation threshold for the pubs2 database:

```
sp_setsuspect_threshold pubs2
```

Example 3

Displays the current and configured settings for the recovery fault isolation threshold for the current user database:

```
sp setsuspect threshold
```

Usage

There are additional considerations when using sp setsuspect threshold:

- You must be in the master database to set the suspect escalation threshold with sp_setsuspect_threshold.
- If you do not specify the number of pages, the SAP ASE server displays the current and configured settings. The current setting is the one that was in effect the last time recovery was executed in the database. The configured setting is the one that is in effect the next time recovery is executed in the database.

Permissions

The permission checks for sp setsuspect threshold differ based on your granular permissions settings.

Setting Description

Enabled

With granular permissions enabled, you must be a user with own database privilege on the database to set the escalation threshold.

Any user can execute <code>sp_setsuspect_threshold</code> to display settings.

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, you must be a user with } \textbf{sa_role to set the the escalation}$ threshold.

Any user can execute sp setsuspect threshold to display settings.

Auditing

For information about auditing stored procedures with the auditing options exec procedure, sproc auth, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```

sp_forceonline_page [page 385]

sp_listsuspect_db [page 552]

sp_listsuspect_page [page 555]

sp_setsuspect_granularity [page 730]

1.239 sp_setup_table_transfer

Run once in each database containing the tables marked for incremental transfer to create the spt TableTransfer table in this database.

Syntax

sp_setup_table_transfer

Usage

Although it is optional, you should run $sp_setup_table_transfer$ before you transfer a table. If you do not run $sp_setup_table_transfer$, the SAP ASE server automatically creates $spt_TableTransfer$ when a table is marked for incremental transfer or when you perform the first transfer.

Permissions

The permission checks for $sp_setup_table_transfer$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage database privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.240 sp_shmdumpconfig

Specifies the dump condition of a shared memory dump, and displays current settings. You must enable the dump on conditions configuration parameter to perform shared memory dumps.

Syntax

Parameters

"action"

action requested. One of:

add Adds the specified shared memory dump conditions.

drop Drops the specified shared memory dump conditions.

update Changes the settings for an existing memory dump condition.

reset Resets the dump count for a shared memory dump condition.

display Displays the current shared memory dump conditions.

config One of:

- include errorlog determines if the errorlog file is included in the dump file:
 - 0 do not include the error log in the dump file.
 - 1 include the errorlog in the dump file.
- merge files determines if the dump files are merged after a parallel dump:
 - 0 do not merge dump files.
 - 1 merge the dump files.

<type>, <value>

valid values are:

- error Generates a dump file for the specified server error number (for example, error numbers 1105 or 813).
- signal Generates a dump file when the specified operating system signal occurs (for example, signals 11 or 10).
- severity Generates a dump file when an error occurs with a severity equal to or greater than the specified severity. See *Diagnosing System Problems* in the *System Administration Guide Volume 1* for more information about error severity levels.
- module Generates a dump file for a range of server error numbers. The range is delimited by multiples of 100, for example 800 or 1200.
- defaults
- timeslice Generates a dump file when a process receives a timeslice error.
- panic Generates a dump file when a server panic occurs. A server panic terminates the SAP ASE server after perfoming the shared memory dump.
- message Generates a dump file when a specified error log message occurs.
 Contact SAP Technical Support to optain specific error message numbers.
- dbcc Sets up a configuration with defaults and omissions as requested. Upon the
 next occurrence of the problem, issue dbcc memdump at the isql prompt to
 create a memory dump.

max_dumps

maximum number of dumps generated for a dump condition. The dump count is reset each time you restart the server. You can also reset the dump count with the reset <action> parameter.

<dump dir>

is the directory in which the SAP ASE server creates the dump file. The "sybase" user must have read and write permission in this directory.

You should set the <dump_dir> to a known, consistent location. Make sure there is sufficient space in this directory to hold the required number of dump files. Remove a <dump_dir> setting by performing an update action with two double quotes ("") as the <dump_dir> value:

```
sp shmdumpconfig 'update', signal, 11, null, null, ""
```

<dump file>

is the file name for the dump. If you do not supply a file name, the SAP ASE server creates a name that is guaranteed to be unique. If you provide a file name, all files for the affected conditions use this name, and existing files are overwritten.

<option1>,...,<option5>

determine whether areas of SAP ASE memory are included in the dump file (by default, the procedure cache is included). One of:

- include_page Include all pages from data caches.
- omit page Omit all pages from data caches.
- default page Use the default value when including data cache pages.
- include proc Include all pages from the procedure cache.
- omit proc Omit all pages from the procedure cache.
- default proc Use the default values for the procedure cache.
- include unused Include unused pages.
- omit unused Omit unused pages.
- default_unused Use the default value for unused pages.
- core produce a core dump if this event is triggered.
- nocore do not produce a core dump.
- csmd produce a csmd if this event is triggered.
- nocsmd do not produce a csmd.

i Note

For the core dump options (core, nocore, csmd, nocsmd), the default behavior is to produce a csmd (configured shared memory dump) but not a core, therefore the nocore option is only used to switch off a previously requested core dump using the update function.

Values for these options override the system-wide default settings. Specify default_cache, default_proc, or default_unused to inherit the appropriate value from the system-wide default settings.

Unless you are instructed otherwise by SAP Product Support, you should include the procedure cache in all shared memory dumps.

halt

determines if the SAP ASE server halts the engine while writing the dump file. One of:

no_halt - no engines halted during the dump. Use this option if you do not want
to use shared memory dumps (for example, because the downtime is unacceptable
or because the event triggering the shared memory dump is based on a
synchronization problem, and you need to see what other engines are doing).

Memory dumps made with the no_halt option may contain a "fuzzy" image and the dump file likely contains corrupted lock tables, run queues, and so on.

- default halt
- halt

Examples

Example 1

Requests a one-time memory dump on signal 11:

```
sp_shmdumpconfig "add", signal, 11, 1, "dump_dir"
```

Example 2

Requests a memory dump on the occurrence of a 605 error:

```
sp_shmdumpconfig 'add', error, 605, null, null, null,
   include_page
```

The equivalent on Windows is a STATUS ACCESS VIOLATION (0xc0000005) message:

```
declare @sig int
select @sig=hextoint("0xc0000005")
exec sp_shmdumpconfig 'add', signal, @sig,1,"dump_dir"
```

Example 3

Requests a memory dump for the 8xx range of errors:

```
sp_shmdumpconfig 'add', module, 800
```

Example 4

Removes a previously defined dump_file by performing an update action with two double quotes ("") as the <dump_file> value:

```
sp_shmdumpconfig 'update', signal, 11, null, null, null, ""
```

Example 5

Configure both a shared memory dump and core dump on Windows exception 0xc0000028 STATUS_BAD_STACK:

```
declare @sig int
select @sig=hextoint("0xc0000028")
exec sp_shmdumpconfig 'add', signal, @sig, 1, dump_dir,
dump_file,'csmd','core'
```

Usage

The sp_shmdumpconfig stored procedure uses positional parameters. When setting a parameter that falls to the right of parameters you do not want to set, specify null values for the unset parameters.

Permissions

The permission checks for sp_shmdumpconfig differ based on your granular permissions settings. If action is equal to add, update, reset:

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server configuration privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.241 sp_show_options

Prints all the server options that have been set in the current session.

Syntax

```
sp_show_options
```

Examples

Example 1

Displays the output from sp show options:

```
go
1> sp_show_options
number
            name
           7 arithabort
           8 numeric_truncation
           13 control
           40 prefetch
           41 triggers
           42 replication
           43 replication force_dll
           48 transactional_rpc
           58 remote_indexes
           62 statement cache
           64 proc return status
           65 proc_output_params
(12 rows affected)
(return status = 0)
```

Usage

@@options the array of bits corresponding to server options. For every option, "low" is the byte number in @@options, and "high" is the bit within that byte corresponding to the option. If the bit is set, print name of that option.

Permissions

Any user can execute . Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.242 sp_showcontrolinfo

Displays information about thread pool assignments, bound client applications, logins, and stored procedures.

Considerations for Process Mode

When you configure the SAP ASE server for process mode, <code>sp_showcontrolinfo</code> displays information about engine group assignments, bound client applications, logins, and stored procedures.

Syntax

```
sp_showcontrolinfo [<object_type>, <object_name>, <spid> ]
```

Parameters

<object_type>

one of:

- AP for application
- LG for login
- PR for stored procedure
- EG for thread pool (threaded mode) or engine group (process mode)
- SV for service task
- PS for process
- DF for user-defined default execution class

If you do not specify an <object_type> or specify an <object_type > of null, sp_showcontrolinfo displays information about all types.

<object name>

is the name of the application, login, stored procedure, or engine group. Do not specify an <object_name> if you specify PS or DF as the <object_type>. If you do not specify an <object_name> (or specify an <object_name> of null), sp showcontrolinfo displays information about all object names.

<spid>

is the SAP ASE process ID. Specify a spid only if you specify PS as the <object_type>. If you do not specify a spid (or specify a spid of null),
sp_showcontrolinfo displays information for all spids. Use sp_who to see spids.

Examples

Example 1

Shows all user-assigned execution class-to-object bindings:

```
sp showcontrolinfo
```

Example 2

Displays the execution class of the isql application:

```
sp showcontrolinfo 'AP', 'isql'
```

Example 3

Displays the execution class for all processes assigned to thread pools:

```
sp showcontrolinfo 'PS'
```

Example 4

Displays the execution class for spid 7:

```
sp_showcontrolinfo 'PS', null, 7
```

Usage

There are additional considerations when using $sp_showcontrolinfo$:

- When used with no parameters, <code>sp_showcontrolinfo</code> displays information about all user-assigned thread pool assignments, bound client applications, logins, and stored procedures. When used with the <code><object_type></code> parameter, <code>sp_showcontrolinfo</code> provides information on an individual basis about application, login, or stored procedure bindings to an execution class, thread pool compositions, and session-level attribute bindings. See <code>Distributing Engine Resources</code> in the <code>Performance</code> and <code>Tuning Series: Basics</code>.
- When run in process mode, sp_showcontrolinfo replaces thread_pool with the engine_group and engine columns.
- Unless object_type is PR, execute sp_showcontrolinfo from the master database. If object_type is PR, execute sp_showcontrolinfo from the database in which the procedure resides.
- If <object_type >is:
 - null sp_showcontrolinfo displays execution class information for objects that match the other parameters.
 - DF <object_name> and spid should be null, and sp_showcontrolinfo shows information about the user-defined default execution class.
- If <object_name> is null, sp_showcontrolinfo displays the binding information for all applications, logins, and stored procedures.
- If <spid> is null, sp_showcontrolinfo displays execution class information for objects that match the other parameters.

See also isql in the *Utility Guide*.

Permissions

Any user can execute <code>sp_showcontrolinfo</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_who [page 847]

1.243 sp_showexeclass

Displays the execution class attributes and the thread pool name associated with the specified execution class.

Considerations for Process Mode

In process mode, sp_showexeclass displays the execution class attributes and the engines in any engine group associated with the specified execution class.

Syntax

```
sp showexeclass [<execlassname>]
```

Parameters

<execlassname>

is the name of an execution class.

Examples

Example 1

Displays the priority and thread pool for all execution classes:

```
classname priority threadpool

EC1 HIGH syb_default_pool

EC2 MEDIUM syb_default_pool

EC3 LOW syb_default_pool
```

Example 2

Displays the attribute values of execution class EC1:

Usage

If <execlassname> is NULL or absent, sp_showexeclass displays the priority and thread pool attribute values for all execution classes, including the attribute values of the system-defined classes EC1, EC2, and EC3.

Permissions

Any user can execute $sp_showexeclass$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

```

1.244 sp_showoptstats

Similar in function to the <code>optdiag</code> standalone utility in an XML document but in a system procedure format, $sp_showoptstats$ extracts and displays statistics and histograms for various data objects from system tables such as systabstats and sysstatistics.

Syntax

```
sp_showoptstats
[[<database_name>.[<owner>].]{<table_name>|<prs_name>}]
,[<column_name>], [h]
```

Parameters

<database_name>

is the name of the database for which <code>sp_showoptstats</code> displays statistics and histograms. <dbname> has these restrictions:

- Cross-database execution is not supported
- You must currently be in the specified database to execute sp_showoptstats.
- If you do not specify a database, sp_showoptstats displays statistics and histograms about the current database

<owner>

is the name of the table owner. If owner name is not specified, the current user or dbo is used. displays statistics and histograms.

is the name of the table for which sp_showoptstats<table_name> has these restrictions:

- If you do not specify a table, sp_showoptstats displays statistics and histograms
 about all tables in the current database. However, to reduce the length of output,
 sp_showoptstats does not display column statistics and histograms are at
 database level.
- must exist in the current database.

prs_name>

displays the name of the precomputed result set for which you are displaying statistics.

- No parameter includes statistical information for all precomputed result sets in the current database.
- A precomputed result set includes statistical information for precomputed result sets.

<column name>

is the name of the column for which the SAP ASE server displays statistics and histograms. If you do not specify a column, the SAP ASE server displays the statistics for all columns and all indexes on the table you specify. If you specify a <column_name>, sp_showoptstats displays statistics and histograms for only this column

h

displays help information about the procedure.

Examples

Example 1

Displays statistics for all user tables in the pubs2 database:

```
1> use pubs2
2> go
1> sp_showoptstats 'pubs2..publishers'
2> go
```

Example 2

Displays statistics and histograms for the publishers table in the pubs2 database, in XML format:

```
1> sp_showoptstats publishers

<?xml version="1.0" encoding="UTF-8"?>
<optStats>
   <procVersion>sp_showoptstats/1.1/AnyPlatform/AnyOS/Tues April 3 14:21:21

                <value>"0736"</value>
            </steps>
            <steps>
                <step>3</step>
                <weight>0.00000000</weight>
                <equation>&lt;</equation> <value>"0877"</value>
```

```
</steps>
               <steps>
                   <step>4</step>
                   <weight>0.33333334</weight>
                   <equation>=</equation>
                   <value>"0877"</value>
               </steps>
               <steps>
                   <step>5</step>
                   <weight>0.00000000</weight>
                   <equation>&lt;</equation>
                   <value>"1389"</value>
               </steps>
               <steps>
                   <step>6</step>
                   <weight>0.33333334</weight>
                   <equation>=</equation>
                   <value>"1389"</value>
               </steps>
           </histogram>
       </colStats>
       <noStatsCol>city,pub_name,state
       </noStatsCol>
   </tables>
</optStats>
```

Example 3

Shows the syntax of the procedure:

```
1> sp_showoptstats a,b,h
2> go

Usage: sp_showoptstats [[database.[owner].]table], [column], [option]
(return status = 0)
```

Example 4

Shows output for the prs1 precomputed result set:

```
sp_showoptstats prs1
<?xml version="1.0" encoding="UTF-8"?>
<optStats>
   Tues April 3 14:21:21 2012</procVersion>
   <serverVersion>Adaptive Server Enterprise/15.7.1/EBFXXXXX SMP
    ''/P/x86_64/Enterprise Linux/asecarina/ENG/64-bit/DEBUG/Mon
    Jul 9 00:16:37 2012</serverVersion>
   <serverName></serverName>
   <specifiedDatabase>prsdb</specifiedDatabase>
   <specifiedTableOwner></specifiedTableOwner>
   <specifiedTable>prs1</specifiedTable>
   <specifiedCol></specifiedCol>
   <tables>
       <tableOwner>dbo</tableOwner>
       <tableName>prs1</tableName>
       <tableType>precomputed result set</tableType>
       <tableStats>
       </noStatsCol>
   </tables>
</optStats>
```

Usage

There are additional considerations when using sp showoptstats:

- You cannot execute sp showoptstats across databases.
- sp showoptstats does not include the system tables unless you explicitly specify them.
- Nonprintable and univarchar characters appear in hexidecimal format.
- sp showoptstats displays both global and partition-level statistics.
- When the output is larger than the value you set for <code>@@textsize</code>, the SAP ASE server returns a message to increase the <code>@@textsize</code> setting so that it can display the large output.
- Parameter values that include a period (.) require double quotation marks.
- You can issue sp showoptstats against system tables.
- sp_showoptstats does not return statistical information if you specify only the database and owner.

The DTD file for the XML output of sp showoptstats is:

```

Permissions

Any user can execute $sp_showoptstats$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.245 sp_showplan

Displays the showplan output for any user connection for the current SQL statement or for a previous statement in the same batch.

Syntax

To display the showplan output for the current SQL statement without specifying the batch_id, context_id, or stmt_num:

```
sp_showplan <spid>, null, null, null
```

Parameters

```
<spid>
```

is the process ID for any user connection. Use sp who to see spids.

<batch_id>

is a unique, nonnegative number for a batch

<context_id>

is a unique number for every procedure (or trigger) executed in a batch.

<stmt_num>

is the number of the current statement within a batch. The <stmt_num> must be a positive number.

<display level>

determines how ${\tt sp_showplan}$ displays the operator tree and resource statistics. One of

- short prints resource statistics output which includes rows affected, object list, and number of rows in the object list
- full prints the operator tree in output, including total rows
- long prints the operator tree, which includes total rows, and prints resource statistics, which includes rows affected, object list, and number of rows in the object list in output

If you do not provide a value for <display_level>, sp_showplan displays the minimal level of output.

If you set the <display_level> to short, full, or long, the output prints the datachange counters for tables. The datachange counter indicates if the statistic of a table is stale. The output also prints the datachange counters for tables when you execute the sp p or sp sp system stored procedure.

Examples

Example 1

Displays the query plan for the current statement running in the user session with a <spid> value of 99, as well as values for the <batch_id>, <context_id>, and <statement_id> parameters. These values can be used to retrieve query plans in subsequent iterations of sp_showplan for the user session with a <spid> of 99:

```
declare @batch int
declare @context int
declare @statement int
exec sp_showplan 99, @batch output, @context output, @statement output
```

Example 2

Displays the showplan output for the current statement running in the user session with a <spid>parameters. These values can be used to retrieve value of 99:

```
sp_showplan 99, null, null
```

Example 3

Displays the operator tree and the resource statistics for spid number 62:

```
sp_showplan 62, null, null, 'long'
```

Example 4

Displays the shortened showplan output for <spid> number of 112:

```
sp_showplan 112, @display_lvl="short"
```

```

Usage

There are additional considerations when using sp showplan:

- sp_showplan displays the showplan output for a currently executing SQL statement or for a previous statement in the same batch. The Rows affected output is dynamic, and may change each time you run it because its value is based on the rows affected during the current execution.
- To see the query plan for the previous statement within the same batch, execute <code>sp_showplan</code> again with the same parameter values, but subtract 1 from the statement number. Using this method, you can view all the statements in the statement batch back to query number one.
- sp_showplan can run in sessions using chained transactions after you use sp_procxmode to change the transaction mode to anymode.
- If the <context_id> is greater than 0 for a SQL batch, the current statement is embedded in a stored procedure (or trigger) called from the original SQL batch. Select the sysprocesses row with the same <spid> value to display the procedure ID and statement ID.
- To see only the long plan output for any user or connection run the sp_sp system stored procedure. For more information, see sp_sp [page 766].
- Issue thesp_p system stored procedure to see a shortened sp_showplan output consisting of resource statistics output which includes rows affected, object list, and number of rows in the object list. For more information, see sp_p [page 643].

Permissions

The permission checks for sp showplan differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with monitor <code>qp performance</code> privilege or the same user that issued the target process to issue <code>sp_showplan</code>.

Disabled With granular permissions disabled, you must be a user with sa_role or the same user that issued the target process to issue sp_showplan.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

1.246 sp_showprogress

Displays progress of an update statistics command.

Syntax

sp_showprogress <spid>[, <display_option>]

Parameters

<spid>

Process ID of the running update statistics command.

<display_option>

Determines the amount of information $sp_showprogress$ displays. One of:

- short (the default) displays general information about the running update statistics command.
- long display detailed information about the running update statistics command.

Example 1

Displays detailed information about the currently running update statistics running on spid 15:

```
sp showprogress 15, 'long'

Overall completion of this process (Based on processed row count): 1.6280%
Total running time: 30000 ms
(return status = 0)
```

Example 2

Displays general information about the currently running update statistics running on spid 15:

```
sp showprogress 15
Session 15 is running:
                                   UPDATE STATISTCIS
                                  BW.SAPSR3.E_10
Dec 9 2014 9:45:31:850PM
Table name:
Starting time:
Sampling level:
                                   50
Histogram tuning factor:
                                   20
Number of consumers:
                                   Ω
Step count:
Total row number of table: 30000091
Total number of scans: 80. Completed: 5.
                                   300000916
        Data partitions to scan: 10
                                           Completed: 0
        Global indexes to scan: 0
                                           Completed: 0
        Local indexes to scan: 70
                                           Completed: 5
Overall completion of this process(Based on processed row count): 5.4461%
Total running time: 102990 ms
(return status = 0)
```

Usage

- sp showprogress displays the progress currently executing "update statistics" commands.
- sp_showprogress reports an error if the value for <spid> is not valid. In this example, there is no spid with a value of 22 running on the server:

```
sp_showprogress 22
go
There is no active server process for the specified spid value '22'. Possibly
the user connection has terminated.
(return status = 1)
Permissions:
```

• sp_showprogress reports an error if the process is running an unsupported command:

```
sp_showprogress 33
go
Command 'select @return_value = show_progress(@spid, @display_level)' is
unsupported
(return status = 1)
```

Permissions

You must have the same user identity as the target process, or you must have the sa_role role or the monitor qp performance permission to execute $sp_showprogress$

1.247 sp_showpsexe

Displays execution class, current priority, and thread pool affinity for all client sessions running on the SAP ASE server.

Considerations for Process Mode

sp showpsexe displays engine information instead of task affinity.

Syntax

```
sp_showpsexe [<spid>]
```

Parameters

<spid>

is the SAP ASE session ID for which you want a report. The spid> must belong to the application or login executing sp_showpsexe. Use sp_who to list spids.

Examples

Example 1

Displays execution class, current priority, and affinity for all current client sessions:

sp_sho	owpsexe				
spid 5	appl_nam	e login_name NULL	exec_class 	current_priority	task_affinity syb_default_po
ol 6 ol	NULL	NULL	NULL	MEDIUM	syb_default_po
7	NULL	NULL yb default pool	NULL	LOW	
26 ol	isql	sa	EC2	MEDIUM	syb_default_po

Example 2

Displays the application name, login name, current priority, and engine affinity of the process with spid 5:

```
sp_showpsexe 5

spid appl_name login_name exec_class current_priority task_affinity

5 NULL NULL LOW syb_default_po
ol
```

Usage

There are additional considerations when using sp showpsexe:

- sp_showpsexe displays execution class, current priority, and affinity for all sessions (objects with an <spid>). See Distributing Engine Resources in Performance and Tuning Series: Basics.
- If the <spid> is NULL or absent, sp_showpsexe reports on all sessions currently running on the SAP ASE server.
- sp_showpsexe does not report information for the following system processes: deadlock, checkpoint, network, auditing, and mirror handlers. It does display information for the housekeeper <spid.>

Permissions

Any user can execute <code>sp_showpsexe</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

```

1.248 sp_sp

Displays the extended output of the query plan from the $sp_showplan$ system procedure.

Syntax

sp_sp <spid>

Parameters

spid

Example 1

Displays the extended showplan output for <spid> number of 112:

```
sp sp 112
select a.au_lname, pv.title, sv.qty, sv.stor_name from authors a, titleauthor
ta, pubsview pv, storesview sv where a.au id = ta.au id and ta.title id =
pv.title_id and pv.title_id = sv.title_id
(1 \text{ row affected})

Proccache used during compilation: 348.
Total estimated LIO: 1330.425382.
Total estimated PIO: 42.318160.
Total estimated CPU time: 22368.677267.
Query has started at: 2018/06/13 09:50:15.74.
Query is running for: 0 ms.
Rows affected: 51
(return status = 0)
```

Usage

- Execute the sp sp system procedure to see the long plan output of any user connection.
- The Rows affected output is dynamic, and may change each time you run it because its value is based on the rows affected during the current execution.

Permissions

Any user can execute sp sp.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.249 sp_shrink

Frees space on a device or database.

Syntax

• To shrink a device:

```
sp_shrink 'device', <device_name> [, {'<size>[K | M | G ]' | 'drop'} [,
```

```
'simulate' ]]
```

• To shrink a database:

```
sp_shrink 'database', <database_name>, <device_name> [, '<size>[K | M | G]'
[, 'simulate' ]]
```

Parameters

<device name>

is the name of the device from which you are freeing space.

<size>[K|M|G]

is the amount of space you are requesting to free up, followed by a unit specifier (K for kilobytes, M for megabytes, or G for gigabytes). When used for a:

- Device clears the specified space and truncates the device.
- Database moves the specified space occupied by the database off the device. If you do not include <size> when shrinking a database, SAP ASE moves the database footprint on this device to other devices on which this database exists.

drop

moves the data from this device to other eligible devices, then drops the device once the data is completely removed off this device.

simulate

performs a simulation of the commands that are run to service the request. The commands are not executed.

Examples

Example 1

Shinks or truncates free space in a device named datadev1:

```
sp_shrink 'device', 'datadev1'
```

Example 2

Shrinks or truncates a device named dev1 by 5 GB:

```
sp_shrink 'device', 'dev1', '5G'
```

Example 3

Simulates the shrinking or truncating of a device named testdat by 10 GB:

```
sp_shrink 'device', 'testdat', '10G', 'simulate'
```

Moves databases off a device named mydev and drops the device:

```
sp_shrink 'device', 'mydev', 'drop'
```

Example 5

Shrinks a database named prod db off the device named prod datadev by 5 GB:

```
sp_shrink 'database', 'prod_db', 'prod_datadev', '5G'
```

Example 6

Shrinks a database named tdb1 completely off a device named dev2:

```
sp_shrink 'database', 'tdb1', 'dev2'
```

Example 7

Simulates the shrinking of a database named tdb1 completely off the mydatadev device:

```
sp_shrink 'database', 'tdb1', 'mydatadev', NULL, 'simulate'
```

Usage

- sp shrink only works on data devices.
- sp_shrink only works on databases with segregated data and log devices.
- If you do not specify <size> or drop when shrinking a device, sp_shrink truncates the free space at the end of the specified device.

Permissions

Any user can execute sp_statistics.

1.250 sp_spaceusage

Reports the space usage for a table, index, or transaction log and estimates the amount of fragmentation for tables and indexes in a database. The estimates are computed using an average row-length for data and index rows, and the number of rows in a table. You can archive the space usage and fragmentation data for future reporting and trends analysis. $sp_spaceusagehelp, display, archive and supports a number of actions, including report, to indicate the current SAP ASE space usage.$

Syntax

The "help" action syntax:

```
sp_spaceusage 'help'[, 'all']

sp_spaceusage 'help'[, {'display' | 'display summary' | 'report' | 'report summary' | 'archive'}[, {'database' | 'table' | 'index'| 'syslogs' | 'sysimrslogs'}]]
```

The "display" action syntax:

The "archive" action syntax:

The "report" action syntax:

Parameters

help

displays the entire sp_spaceusage syntax. help <action> displays the syntax for individual actions supported.

display

displays current space usage information for the specified objects. database allows you to display information about any database while located in any other database. That is, you can be currently working in the user_db database, and display usage information for the sybsystemprocs database.

display summary

displays a summary of current space usage information for the specified objects.

archive

archives the space usage report to a table. If the archive table does not already exist, sp_spaceusage creates one. New data is appended to existing data. You can specify a prefix for the archive table name and the database in which the archive table resides with the <using> clause. archive requires that you enable the select into/bulkcopy/pllsort database option in the database in which you are running sp spaceusage.

report

reports the space usage information for the specified objects from previously archived data. The output is same as the <code>display</code> action. Include the optional using clause to specify the archive table.

report summary

reports a summary of space usage information for the specified object from previously archived data. The output is same as the display summary action. Include the optional using clause to specify the archive table.

<using_item>

specifies the unit, archive database name, and prefix string for the archive table. You can use a <unit> size of kilobytes (KB), megabytes (MB), gigabytes (GB), and pages. By default <unit> size is KB, the current database is the archive database, and no prefix string is assumed.

<name>

is the name of the entity. Depending on the entity type, you can include multipart names such as <owner_name.table_name>, or

<owner_name.table_name.index_name>. For the entity type syslogs and
sysimrslogs, the name must be syslogs, sysimrslogs, or NULL. Pattern specifiers
are allowed for each part of a multipart name to support reporting on multiple objects
in one pass.

<select_list>

is the comma-separated list of columns to select in the output columns for the display and report actions. Use * to include all columns in the output. Columns can be renamed using the alias=<name> notation.

<where clause>

is the filter to apply to the result set. Use with the display, report, or archive actions to selectively filter unnecessary data.

order_by

returns query results in the specified columns in sorted order.

<command>

command run on the entity selected (table, column, or so on) prior to gathering the space usage information for qualifying objects. The following commands are supported: update statistics, update table statistics, and update index statistics.

<from_date>

specifies beginning of the time range you are interested in.

<to_date>

specifies end of the time range you are interested in.

Examples

Example 1

Displays a brief description, syntax, and usage information for the display action:

Example 2

Displays a summary of the space usage on the titles table:

```
sp_spaceusage 'display summary', 'table', 'titles'

All the page counts in the result set are in the unit 'KB'.

OwnerName TableName Type UsedPages RsvdPages ExpRsvdPages PctBloatRsvdPages

ages

dbo titles DATA 6.0 30.0 16.0 87.50
```

dbo	titles	INDEX	8.0	64.0	32.0	50.00

Displays the space usage information for the titles table:

```
sp_spaceusage 'display', 'table', 'titles'
```

OwnerName	e counts in t TableName l ExpRsvo	IndId	NumRows	UsedPag	t 'KB'. ges RsvdPages PctBloatRsvdPages
dbo 20.00	titles 16.0	0	18.0 0.0	6.0	30.0 87.50

dbo 12.50	titles 16.0	2	NULL 0.00	4.0	32.0 100.00

Example 4

Displays index entries from the titles table with names that start with title:

```
sp_spaceusage 'display using unit=MB', 'index', 'titles.title%'
```

Example 5

Displays a summary of the space usage for all index names starting with <title> in the titles table:

```
sp_spaceusage 'display summary', 'index', 'titles.title%'
```

```
All the page counts in the result set are in the unit of 'KB'.
OwnerName TableName IndexName IndId UsedPages RsvdPages ExpRsvdPages
  PctBloatRsvdPages
             _____

	50.00						
dbo		titles	titles	0	6.0	30.0	16.0
	46.67						

Example 8

Runs update table statistics on the authors table and summarizes its space usage information in the unit <pages>:

```
sp_spaceusage 'display summary using unit=pages', 'table', 'authors', null,
null,
'update table statistics'
```

```
All the page counts in the result set are in the unit 'pages'.

OwnerName TableName Type UsedPages RsvdPages ExpRsvdPages PctBloatRsvdPages

dbo authors DATA 2.0 16.0 8.0 100.00

dbo authors INDEX 4.0 32.0 16.0 50.00
```

Example 9

Displays the space usage information for the transaction log of the current database (pubs2):

Archives the space usage information for the authors table in the current database into the default table (spaceusage object for tables and indexes):

```
sp_spaceusage 'archive', 'table', 'authors'

Data was successfully archived into table 'pubs2.dbo.spaceusage_object'.
```

Example 11

Archives the space usage information for the authors table into the default table (spaceusage_object for tables and indexes) in the pubs3 database:

```
sp_spaceusage 'archive using dbname = pubs3', 'table', 'authors'

Data was successfully archived into table 'pubs3.dbo.spaceusage_object'.
```

Example 12

Runs update table statistics on the authors table and archives its space usage information into a table in the current database with the prefix monday (for this example, monday spaceusage object):

```
sp_spaceusage 'archive using dbname = pubs2, prefix=monday_',
   'table', 'authors', null, 'update table statistics'
```

Example 13

Archives the space usage information for the transaction log of the current database into the default table (spaceusage tranlog for transaction logs) in the pubs 3 database:

```
sp_spaceusage 'archive using dbname=pubs3', 'tranlog'

Data was successfully archived into table 'pubs3.dbo.spaceusage_tranlog'.
```

Example 14

Reports in detail the last archived space usage information for the authors table from the default table (spaceusage object for table or index) in the current database:

```
sp spaceusage 'report', 'table', 'authors'
All the page counts in the result set are in the unit 'KB'
All the data in the result set are dated 'Jun 15 2013 11:50PM'.

User Tables	Data layer	.09375	.1875	.75	0.05
User Tables	Index layer	.015625	.03125	.125	0.01
User Tables	LOB layer	NULL	NULL	NULL	NULL

Displays a summary of top-level, aggregated database-wide usage information for the tpcc database:

Usage

- sp_spaceusage provides space usage information for tables, indexes, and the transaction log of the current database.
- The database in which you are archiving the space usage data must have sp_dboption ... select into enabled.
- The archive tables are created if they do not already exist at the time of archiving, otherwise the results are appended to the current table. Because of this, any user running sp_spaceusage must have create table permission in the archive database.
- While archiving or reporting data, only tables owned by the user running sp_spaceusage display the space usage information, in megabytes, for all indexes considered for the archive table. Tables with the same name but owned by another user are ignored. By default, the results are archived to or reported from the spaceusage object table for tables or indexes and spaceusage tranlog for the transaction log.
- You can use the <from_date> and <to_date> arguments only for the report action when reporting from archived data. The SAP ASE server uses only the data in the archive table that falls within the specified time-range when generating the report. If you do not include a <from_date> or a NULL, the SAP ASE server uses all archived data prior to the <to_date>. If you do not include a <to_date> or NULL, the SAP ASE server uses the current date as the value for <to_date>. If you do not include either the <from_date> or <to_date>, the SAP ASE server uses the most recent data in the archive table to generate the report.

- sp_spaceusage results are estimated based on statistical data. These estimates are only as good as the statistics provided. You can run update statistics to improve the accuracy of the results.
- The 'display', 'database' option generates aggregated, database-wide space usage metrics and a summary of space usage information from system and user tables for each level (data, index, LOB, and so on).
- For databases with a large number of objects, display may be noticeably slower since running it also involves running execution-space reporting functions for each object or index. In these situations, you can instead issue display summary to quickly retrieve database-wide aggregated space metrics.
- The 'display summary', 'database' option generates aggregated database-wide summary information, but does not investigate to the level of per-table or per-object metrics.
- sp spaceusage displays metrics for sysimrslogs for in-memory, row storage-enabled tables, .

Permissions

Any user can execute sp_spaceusage to view space usage. However, you may not be able to view certain information about tables that you do not have permissions to view.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.251 sp_spaceused

Displays estimates of the number of rows, the number of data pages, the size of indexes, and the space used by a specified table or by all tables in the current database.

Syntax

```
sp_spaceused [<objname >[,1] ]
```

Parameters

<objname>

is the name of the table on which to report. If omitted, a summary of space used in the current database appears.

1

prints separate information on the table's indexes and text/image storage.

Examples

Example 1

Reports on the amount of space allocated (reserved) for the titles table, the amount used for data, the amount used for index(es), and the available (unused) space:

sp_spaceus	ed titles				
name	rowtotal	reserved	data	index_size	unused
titles	18	46 KB	6 KB	4 KB	36 KB

Example 2

In addition to information on the titles table, prints information for each index on the table:

```
sp spaceused titles, 1
index name
                    size
                               reserved
                                          unused
 titleidind
                     2 KB
                                32 KB
                                           24 KB
titleind
                     2 KB
                                16 KB
                                           14 KB
          rowtotal reserved data index size unused
name
titles
                18
                        46 KB
                                  6 KB
                                             4 KB
                                                       36 KB
```

Example 3

Displays the space taken up by the text/image page storage separately from the space used by the table. The object name for text/image storage is "t" plus the table name:

```
sp spaceused blurbs,1
                    size
index_name
                              reserved
                                         unused
blurbs
                    0 KB
                              14 KB
                                         12 KB
tblurbs
                   14 KB
                              16 KB
                                         2 KB
         rowtotal reserved
                              data
                                     index_size unused
name
                 6
                         30 KB
                                 2 KB
                                          14 KB
                                                     14 KB
blurbs
```

Example 4

Prints a summary of space used in the current database:

```
sp_spaceused

database_name database_size
```

master reserved	5 MB data	index_size	unused
ved	data 	index_size	unuse
2176 KB	1374 KB	72 KB	730 KB

Reports on the amount of space reserved and the amount of space available for the transaction log:

```
sp_spaceused syslogs

name rowtotal reserved data index_size unused
syslogs Not avail. 32 KB 32 KB 0 KB 0 KB
```

Usage

There are additional considerations when using sp spaceused:

- sp_spaceused displays estimates of the number of data pages, space used by a specified table or by all tables in the current database, and the number of rows in the tables. sp_spaceused computes the rowtotal value using the rowcnt built-in function. This function uses a value for the average number of rows per data page based on a value in the allocation pages for the object. This method is very fast, but the results are estimates, and update and insert activity change actual values. The update statistics command, dbcc checktable, and dbcc checkdb update the rows-per-page estimate, so rowtotal is most accurate after one of these commands executes. Always use select count (*) if you need exact row counts
- sp_spaceused reports on the amount of space affected by tables, clustered indexes, and nonclustered indexes.
- The amount of space allocated (reserved) reported by sp_spaceused is a total of the data, index size, and available (unused) space.
- Space used by text and image columns, which are stored as separate database objects, is reported separately in the index_size column and is included in the summary line for a table. The object name for text/image storage in the index_size column is "t" plus the table name.
- When used on syslogs, sp spaceused reports rowtotal as "Not available". See Example 5.

See also create index, create table, drop index, drop table in Reference Manual: Commands.

Permissions

Any user can execute $sp_spaceused$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_statistics [page 881]
```

1.252 sp_ssladmin

Adds, deletes, and displays a list of server certificates for the SAP ASE server. Additionally, sets and displays cipher suite preferences and protocol versions for SAP ASE.

Syntax

Parameters

addcert

adds a certificate for the local server in the certificates file.

<certificate path>

specifies the absolute path to the certificates file on the local server.

<password>

the password that is used to encrypt the private key when adding a new server certificate to the certificates file.

refreshcert

activates the newly added certificate on the local server.

NULL

used to require an attended start-up of the SAP ASE server by requesting the password during start-up from the command line.

dropcert

deletes the certificate from the certificate file.

lscert

lists the certificates in the certificate file.

help

displays online help for sp ssladmin.

lsciphers

displays the values for any set cipher suite preferences.

setciphers

sets a specific cipher suite preference. Select one of these options:

- TLS1.2 is the set of encryption algorithms supported by TLS version 1.2.
- TLS1.0 is the set of encryption algorithms supported by TLS version 1.0.
- FIPS is the set of encryptions, hash, and key exchange algorithms that are FIPS-compliant. The algorithms included in this list are AES, 3DES, SHA1 and SHA2.
- Strong is the set of encryption algorithms using keys longer than 64 bits.
- Weak is the set of encryption algorithms from the set of all supported cipher suites that are not included in the strong set.
- All is the set of default cipher suites.
- <quoted_list_of_ciphersuites> specifies a set of cipher suites as a comma-separated list, ordered by preference. Use quotes (" ") to mark the beginning and end of the list. The quoted list can include any of the predefined sets as well as individual cipher suite names. Unknown cipher suite names cause an error to be reported, and no changes are made to preferences. See System Administration Guide > Confidentiality of Data for the list of cipher suites included in the defined sets.

setprotocol

sets the protocol version. Select one of these options:

- TLS1.2 sets the TLS protocol such that a client must use TLS 1.2 protocol version to successfully connect.
- NULL allows backward compatibility by accepting TLS 1.0 and TLS 1.2 protocol versions from clients. This is the default value.

lsprotocol

displays the protocol version. The return values are:

- When setprotocol is set to TLS1.2, lsprotocol returns TLSv1.2.
- When setprotocol is set to NULL, 1sprotocol returns 0.
- When setprotocol is not set, such as after an upgrade, then the system catalog holds no value and lsprotocol returns NULL.

Example 1

Adds an entry for the local server, Server1.crt, in the certificates file in the absolute path to $/sybase/ASE-16_0/certificates$ (x:\sybase\ASE-16_0\certificates on Windows). The private key is encrypted with the password "mypassword". The password should be the one specified when you created the private key:

Then, activate the certificate:

```
sp_ssladmin refreshcert
```

Example 2

Deletes the certificate, Server1.crt from the certificates file located in $/sybase/ASE-16_0/certificates$ (x:\sybase\ASE-16_0\certificates on Windows):

```
sp_ssladmin dropcert , "/sybase/ASE-16_0/certificates/Server1.crt"
```

Example 3

Lists of all server certificates on the local server:

Example 4

Displays the cipher suite preferences have been set:

Example 5

(1 row affected)

Uses a quoted list of cipher suites to set preferences in the SAP ASE server:

```
TLS_RSA_WITH_AES_256_CBC_SHA
```

2

Example 6

Sets the TLS protocol such that a client must use protocol version TLS 1.2 to successfully connect, and strictly enforces the use of SSL to only use version TLS 1.2:

```
1> sp_ssladmin setprotocol,'TLS1.2'
2> go
  TLS Protocol Version
  -----
TLSv1.2
(1 row affected)
(return status = 0)
```

Example 7

The cipher suite version that you specify is independent from the protocol version. For example, when the TLS 1.2 protocol version is set, a successful SSL handshake using TLS 1.2 protocol may still negotiate cipher suites defined in TLS 1.0 if cipher suite preferences include TLS 1.0 cipher suites. However, a client that sets the TLS 1.0 protocol version will fail to connect to the server and report a handshake error.

This examples shows the protocol version set to TLS 1.2 and the cipher suite set to the weak cipher suit $\tt TLS_RSA_WITH_RC4_128_SHA$. The weak cipher suit $\tt TLS_RSA_WITH_RC4_128_SHA$ is used.

```
1> sp_ssladmin lsprotocol
2> go
TLS Protocol Version
-------
TLSv1.2
(1 row affected)
(return status = 0)
1> select @@ssl_protocol
2> go
-----
TLSv1.2
(1 row affected)
1> select @@ssl_ciphersuite
2> go
------
TLS_RSA_WITH_RC4_128_SHA
(1 row affected)
```

Example 8

 $\verb|sp_ss|| admin | \verb|lsprotocol| returns | \verb|NULL| when the protocol| is not set:$

Example 9

sp ssladmin lsprotocol returns 0 when the protocol is set to NULL:

```
1> sp_ssladmin lsprotocol
2> go
TLS Protocol Version
-----
0
(1 row affected)
```

Usage

- The SAP ASE listener must present to the client a certificate. The common name in the certificate must match the common name used by the client in the interfaces file. If they do not match, the server authentication and login fail.
- When NULL is specified as the password, dataserver must be started with a -y flag. This flag prompts the administrator for the private-key password at the command line.
- The use of NULL as the password is intended to protect passwords during the initial configuration of SSL, before the SSL encrypted session begins.
 - After restarting the SAP ASE server with an SSL connection established, use <code>sp_ssladmin</code> again, this time using the actual password. The password is then encrypted and stored by the SAP ASE server. Any subsequent starts of the SAP ASE server from the command line would use the encrypted password; you do not have to specify the password on the command line during start up.
- You can specify "localhost" as the <hostname> in the interfaces file (sql.ini on Windows) to prevent clients from connecting remotely. Only a local connection can be established, and the password is never transmitted over a network connection.

See also Confidentiality of Data in the System Administration Guide.

Permissions

The permission checks for sp ssladmin differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage security configuration

privilege.

Disabled With granular permissions disabled, you must be a user with sso_role.

Auditing

You can enable security auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information Value

Audit option security

Event 99

Command or access audited security

Information

Value

Information in extrainfo

- Roles Current active roles
- **Keywords or options** SSL_ADMIN addcert if adding a certification
- Previous value NULL
- Current value NULL
- Other information Message number
- Proxy information Original login name, if set proxy in effect

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.253 sp_syntax

Displays the syntax of Transact-SQL statements, system procedures, utilities, and other routines for the SAP ASE server, depending on which products and corresponding sp_syntax scripts exist on your server.

Syntax

```
sp syntax <word>[, <mod>][, <language>]
```

Parameters

word

is the name or partial name of a command or routine; for example, "help", to list all system procedures providing help. To include spaces or Transact-SQL reserved words, enclose the word in quotes.

< mod >

is the name or partial name of one of the modules such as "Transact-SQL" or "Utility". Each sp_syntax installation script adds different modules. Use sp_syntax without any parameters to see which modules exist on your server.

<language>

is the language of the syntax description to be retrieved. <language> must be a valid language name in the syslanguages table.

Example 1

Displays all sp syntax modules available on your server:

sp syntax

Example 2

sp_syntax "disk"

Usage

The text for <code>sp_syntax</code> is in the database <code>sybsyntaxsp_syntax</code> provides syntax help for Sybase products..

Load <code>sp_syntax</code> and the <code>sybsyntax</code> database onto the SAP ASE server with the installation script described in configuration documentation for your platform. If you cannot access <code>sp_syntax</code>, see your system administrator for information about installing it on your server.

You can use wildcard characters within the command name you are searching for. However, if you are looking for a command or function that contains the literal "_", you may get unexpected results, since the underscore wildcard character represents any single character.

Permissions

Any user can execute sp syntax. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Tables used

sybsyntax..sybsyntax

Related Information

sp_helpdb [page 438]

1.254 sp_sysmon

Displays performance information.

Syntax

Parameters

begin_sample

Starts sampling. You cannot specify a section when you specify begin_sample.

end_sample

Ends sampling and prints the report.

<interval>

Specifies the time period for the sample. It must be in HH:MM:SS form, for example "00:20:00".

<section>

Is the abbreviation for one of the sections printed by <code>sp_sysmon</code>. The values and corresponding names of the report sections are:

- appmgmt Application Management
- cache wizard Cache Wizard
- dcache Data Cache Management

- diskio Disk I/O Management
- esp ESP Management
- housekeeper Housekeeper Task Activity
- indexmgmt Index Management
- kernel Kernel Utilization
- locks Lock Management
- memory Memory Management
- mdcache Metadata Cache Management
- monaccess Monitor Access to Executing SQL
- netio Network I/O Management
- parallel Parallel Query Management
- pcache Procedure Cache Management
- recovery Recovery Management
- repagent RepAgent
- nvcache NV Cache
- taskmgmt Task Management
- xactmgmt Transaction Management
- xactsum Transaction Profile
- wpm Worker Process Management

You can also obtain most of the information available through $sp_sysmon\ mdcache$ report using $sp\ monitorconfig$.

<applmon>

Specifies whether to print application detail, application and login detail, or no application detail. The default is to omit the application detail. Valid values and the information they report are:

- appl_only CPU, I/O, priority changes and resource limit violations by application name.
- appl_and_login CPU, I/O, priority changes and resource limit violations by application name and login name.
- no_appl skips the by application or by login section of the report. This is the default.

This parameter is only valid when printing the full report and when you specify appmgmt for the <section>.

noclear | clear

Specifies whether to clear or not clear monitor counters:

- clear explicitly clears the monitor counters.
- noclear sp_sysmon does not clear the monitor counters. The primarily purpose
 of the noclear parameter is to provide backward compatibility (earlier versions of
 sp_sysmon cleared monitor counters by default).

i Note

You can use the noclear parameter only when you specify a sample interval in sp_sysmon . You cannot use noclear if you specify $begin_sample$ or end sample.

By default, <code>sp_sysmon</code> does not clear the monitor counters that are used as source data for the report. If other applications or instances of the <code>sp_sysmon</code> report are running when this is done, clearing the counters may cause the data that they report to be invalid.

<filter>

Is a varchar datatype that allows you to specify a pattern for the cache(s) included in the report.

For example, if it is specified as default data cache, the report only contains information about the default data cache. If it is specified as emp%, the output includes information on all caches with a name matching this pattern. If no value is given the output contains all the caches with the default data cache appearing first, followed by the other caches in alphabetical order.

'cache wizard'

Aids in the monitoring and configuring of data caches for optimal performance.

<dumpcounters>

returns the contents of the ${\tt master..sysmonitors}$ table (which contains the names and values of all monitor counters) as a result set, after returning the requested report sections.

<option>

Allow you to specify the clear or noclear parameters if you used all the other sp_sysmon parameters to specify alternative sp_sysmon behaviors. Valid values are clear and noclear.

Examples

Monitor Information

Prints monitor information after 10 minutes:

```
sp_sysmon "00:10:00"
```

Disk Management

Prints only the "Disk Management" section of the sp sysmon report after 5 minutes:

```
sp sysmon "00:05:00", diskio
```

Data Cache

Starts the sample, executes procedures and a query, ends the sample, and prints only the "Data Cache" section of the report:

```
sp sysmon begin sample
go
execute proc1
go
execute proc2
select sum(total sales) from titles
sp_sysmon end_sample, dcache
go
```

Full Report

Prints the full report and includes application and login detail for each login:

```
sp_sysmon "00:05:00", @applmon = appl_and_login
```

Not Clearing Counters

Report usage without clearing the counters:

```
sp_sysmon "00:01:00", kernel, noclear
```

You can also use:

```
sp sysmon "00:01:00", noclear
```

Cache Wizard

Prints a report using the cache wizard:

```
sp sysmon '00:00:30', 'cache wizard'
______
Cache Wizard
______
```

```

(return status = 0)
```

Usage

There are additional considerations when using sp sysmon:

- sp_sysmon displays information about SAP ASE server performance. It sets internal counters to 0, then waits for the specified interval while activity on the server causes the counters to be incremented. When the interval ends, sp_sysmon prints information from the values in the counters. See the *Performance and Tuning Guide* for more information.
- To print only a single section of the report, use the valid values for sp sysmon <applmon>.
- If you use sp_sysmon in batch mode, with begin_sample and end_sample, the time interval between executions must be at least one second. You can use waitfor delay "00:00:01" to lengthen the execution time of a batch.
- During the sample interval, results are stored in signed integer values. Especially on systems with many CPUs and high activity, these counters can overflow. If you see negative results in your sp_sysmon output, reduce your sample time.

See also:

- Performance and Tuning Series: Monitoring Adaptive Server with sp_sysmon
- System Administration Guide Volume 2 > Configuring Data Caches > NV Cache Management for details about NV caches.

Permissions

You must be a user with execute permission to run sp_sysmon . The permission can be granted to other users by the database owner of sybsystemprocs.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.255 sp_tab_suspectptn

Lists tables with suspect partitions. A range-partitioned table on character-based partition keys can become suspect after a sort-order change, and hash-partitioned tables can become suspect after a cross-platform dump load.

Syntax

```
sp_tab_suspectptn [<table_name>]
```

Parameters

<table_name>

is the name of the table containing suspect partitions.

Usage

If you:

- Provide a table name the SAP ASE server checks only the table named by .
- Do not provide a table name the SAP ASE server checks all the tables in the current database.

Permissions

Any user can execute <code>sp_tab_suspectptn</code>. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_indsuspect [page 529]

1.256 sp_tempdb

sp tempdb allows users to:

- Create and manage temporary database groups.
- Bind users or applications to the default or other temporary database group or to a specific local temporary database.
- Manage bindings to local temporary databases and temporary database groups.

These bindings are stored in the sysattributes table in master database.

sp_tempdb provides the binding interface for maintaining bindings in sysattributes that are related to the multiple temporary database.

Syntax

```
sp_tempdb [
    [{"create" | "drop"}, "<groupname>"] |
    [{"add" | "remove"}, "<tempdbname>", "<groupname>"] |
    [{"bind", "<objtype>", "<objname>", "<bindtype>", "<bindobj>"
        [, "<scope>", "<hardness>"]} |
        {"unbind", "<objtype>", "<objname>"[, "<scope>"] "<instance_name>"}] |
    ["unbindall_db", "<tempdbname>"] |
    [show[, "all" | "gr" | "db" | "login" | "app"[, "<name>"]] |
    [who, "<dbname>"]
    [help]]
```

Parameters

create

creates the default temporary database group.

drop

drops a temporary database group.

<groupname>

is the name of the temporary database group.

add

adds temporary databases to the default temporary database group.

remove

removes temporary databases from the default temporary database group.

<tempdbname>

is the name of the temporary database you are adding or removing. For the Cluster Edition, <tempdbname> must be a local user temporary database.

bind

binds logins and applications to temporary databases or the default temporary database group.

unbind

unbinds logins and applications to temporary databases or the default temporary database group.

<objtype>

is the object type. Valid values are:

- login name (or LG)
- application_name (or AP)

Values are not case-sensitive.

<objname>

is the name of the object you bind or unbind.

<bindtype>

is the bind type. Valid values are:

- group (or GR)
- database (or DB)

Values are not case-sensitive.

<bindobj>

is the name of the object being bound, and is either a group or a database depending on the

bindtype>.

<scope>

NULL.

<instance name>

in cluster environments – is the name of the instance owning the local temporary database that is to be unbound. This option is for the Cluster Edition only.

<hardness>

hardness – is hard, soft, or NULL. The default is soft. When you set the value of <hardness> to hard, a failure to assign a temporary database according to the binding results in a failure of the login.

When you set the value to soft, such a failure results in the assignment of a temporary database from the default group or a local system temporary database.

unbindall db

removes all login and application bindings for a given temporary database. It does not remove any database to group memberships. The <tempdbname> variable is required with this option.

Existing assignments to active sessions are not affected by this operation.

show

displays information stored in the sysattributes table about the existing groups, group members, login and application bindings, and active sessions that are assigned to a given database. The values are:

- all or no argument displays the default temporary database group, all database-to-group memberships, and all login and application bindings.
- gr displays the default temporary database group. sp_tempdb show displays all temporary databases bound to the default temporary database group whether you specify "default" for the <name> option or not.
- db displays all databases and temporary databases to group memberships. If you provide <name>, then only the database to group memberships for the database <name> are printed.
- login displays all login bindings where login is not NULL. If you provide <name>, then only the bindings for the login <name> are printed.
- app displays all bindings where the application is not NULL. If you provide <name>, then the bindings for the application <name> are printed.

i Note

tempdb is always part of the default database group.

who

displays all active sessions assigned to the given temporary database. When using the ${\tt who}$ parameter, you must use:

<dbname> - is the name of a temporary database. If you provide a nontemporary
database name for <dbname>, sp_tempdb who executes, but does not report any
active sessions bound to it.

If <code>system_view</code> is set to <code>cluster</code>, all active sessions of the cluster are examined. If <code>system_view</code> is set to <code>instance</code>, sessions that are active on the current instance are examined

This command may be executed from any instance in the cluster.

help

displays usage information. Executing sp_tempdb without specifying a command is the same as executing sp_tempdb "help".

Examples

Example 1

Adds mytempdb1 to the default group:

```
sp tempdb "add", "mytempdb1", "default"
```

Removes mytempdb1 from the default group:

```
sp_tempdb "remove", "mytempdb1", "default"
```

Example 3

Binds login "sa" to the default group:

```
sp_tempdb "bind", "lg", "sa", "GR", "default"
```

The value for objtype in this example is login name. You can substitute login name with 1g or LG.

The value for bindtype in this example is group. You can substitute group with gr or GR.

Example 4

Changes the previous binding of login "sa" from the default group to mytempdb1:

```
sp_tempdb "bind", "lg", "sa", "DB", "mytempdb1"
```

The value for bindtype in this example is database. You can substitute database with db or DB.

Example 5

Binds isql to mytempdb1:

```
sp_tempdb "bind", "ap", "isql", "DB", "mytempdb1"
```

The value for objtype in this example is application_name. You can substitute application_name with ap or AP.

Example 6

Changes the previous binding of isql from mytempdb1 to the default group:

```
sp_tempdb "bind", "ap", "isql", "GR", "default"
```

Example 7

Removes the bindings of login "sa" and application "isql".

```
sp_tempdb "unbind", "lg", "sa"

sp_tempdb "unbind", "ap", "isql"
```

Example 8

Removes all login and application bindings for the mytempdb1 database:

```
sp_tempdb "unbindall_db", "mytempdb1"
```

Example 9

Demonstrates the sp_temp_show command. A selection of the different variations is chosen, and abbreviated sample output is displayed.

```
sp_tempdb show

Temporary Database Groups
```

defaul Databa	~		 GroupName	
tempdb mytemp mytemp mytemp mytemp Login	db db1 db2	Group	default default default default default Database	Hardness
NULL sa	isql NULL	default NULL	NULL mytempdb3	SOFT HARD

Displays the default temporary database group:

```
sp_tempdb show, "gr"

Temporary Database Groups
-----default
```

Example 11

Displays all the temporary database group names that are bound to the default group:

```
sp_tempdb show, "gr", "default"Member Databases
tempdb
mytempdb
mytempdb1
mytempdb2
mytempdb3
```

Example 12

Displays all the databases-to-group memberships:

```
Database Group

tempdb default
mytempdb default
mytempdb1 default
mytempdb2 default
mytempdb3 default
```

Example 13

Displays all the databases-to-group memberships for the mytempdb1 database.

```
sp_tempdb show, "db", "mytempdb1"

Database Group
mytempdb1 default
```

Displays all the login bindings where login is not NULL:

```
sp_tempdb show, "login"

Login Application Group Database Hardness
-------sa NULL NULL mytempdb3 HARD
```

Example 15

Displays all active sessions that are assigned to the system tempdb:

```
sp tempdb who, "tempdb"
spid loginame
2
      NULL
3
      NULL
4
      NULL
5
      NULL
6
      NULL
7
      NULL
8
      NULL
```

Example 16

Displays all active sessions that are assigned to the mytempdb3 user-created temporary database:

Example 17

Displays usage information:

Displays all temporary databases and the names of the groups to which the temporary databases belong:

```
create temporary database mytempdb

-------

CREATE DATABASE: allocating 1536 logical pages (3.0 megabytes) on disk

'master'.|

create temporary database mytempdb1

-------

CREATE DATABASE: allocating 1536 logical pages (3.0 megabytes) on disk

'master'.

sp_tempdb 'add', mytempdb,'default'

---------

(return status = 0

sp_tempdb show, db

-------

tempdb default

mytempdb default

mytempdb default

mytempdb1

(3 rows affected)

(return status = 0)
```

Usage

There are additional considerations when using sp tempdb:

- To display the distribution of users across all temporary databases, use both options, show and who:
 - To obtain the names of all temporary databases, execute <code>sp_tempdb 'show'</code>.
 - Pass each temporary database name to: sp tempdb 'who', <tempdbname>.

In SAP ASE versions 15.0 and above, you can obtain the same output by executing sp who.

- When using the sp tempdb create stored procedure, the <groupname> variable:
 - o Must be a valid identifier
 - Cannot already exist

The default group is the system-generated group, of which tempdb is always a member. This default group is present if you:

- Upgrade using the SAP ASE server containing this feature, or
- o Create a new master device.

If the default group is not present, you can create it by using:

```
sp_tempdb create, "default"
```

An error message displays if you attempt to create a default group that already exists.

• To add a temporary database to the default temporary database group, both the temporary database and the group name must already exist. When you use sp_tempdb add to add a <tempdbname> to a set of databases that are members of the default temporary database group, <tempdbname> becomes available for round-robin assignment from within that group.

i Note

 $\verb|sp_tempdb|| add fails if < tempdbname> is not already part of the global list of available temporary databases in the SAP ASE server.$

User-created temporary databases need not belong to the default temporary database group. The system tempdb is implicitly a member of the default group.

If you try to add a temporary database to the default temporary database group when it is already a part of that group, you get an error message, and no changes take place in sysattributes.

Permissions

The permission checks for sp tempdb differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage server privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.257 sp_tempdb_markdrop

(Cluster Edition) Places a local system temporary database in the drop state.

Syntax

```
sp_tempdb_markdrop <database_name> [, {'mark' | 'unmark'}]
```

Parameters

<database_name>

is the name of the local system temporary database you are dropping

 ${\tt mark}$

marks the specified database for dropping.

unmark

clears the mark from the database.

Examples

Example 1

Marks a local system temporary database named "old_cluster_tempdb1" to be dropped:

```
sp_tempdb_markdrop 'old_cluster_tempdb1', 'mark'
```

Example 2

Removes the mark from the local system temporary database "old_cluster_tempdb1":

```
sp_tempdb_markdrop 'old_cluster_tempdb1, 'unmark'
```

Usage

To delete the last local temporary database:

- 1. Use sp tempdb markdrop to place the local system temporary database in the drop state.
- 2. Shut down and restart the instance that owns the last local temporary database.

i Note

After you mark the local system temporary database to be dropped, the owner instance restarts if there are no other active instances. This instance does not use the marked local system temporary database when it starts.

3. Use drop database to delete the last local system temporary database.

Permissions

The permission checks for sp tempdb markup differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with the own database privilege on the specified database or the manage cluster privilege.

Disabled With granular permissions disabled, you must be the database owner or a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.258 sp_thresholdaction

Executes automatically when the number of free pages on the log segment falls below the last-chance threshold, unless the threshold is associated with a different procedure. SAP does not provide this procedure.

Syntax

When a threshold is crossed, the SAP ASE server passes the following parameters to the threshold procedure by position:

```
sp_thresholdaction @<dbname>,
    @<segment_name>,
    @<space_left>,
    @<status>
```

Parameters

@<dbname>

is the name of a database where the threshold was reached.

@<segment name>

is the name of the segment where the threshold was reached.

@<space left>

is the threshold size, in logical pages.

@<status>

is 1 for the last-chance threshold; 0 for all other thresholds.

Example 1

Creates a threshold procedure for the last-chance threshold that dumps the transaction log to a tape device:

```
create procedure sp_thresholdaction
    @dbname varchar(30),
    @segmentname varchar(30),
    @space_left int,
    @status int

as

dump transaction @dbname to tapedump1
```

Usage

There are additional considerations when using sp thresholdaction:

- sp_thresholdaction must be created by the database owner (in a user database), or a system administrator (in the sybsystemprocs database), or a user with create procedure permission.
- You can add thresholds and create threshold procedures for any segment in a database.
- When the last-chance threshold is crossed, the SAP ASE server searches for the sp_thresholdaction procedure in the database where the threshold event occurs. If it does not exist in that database, the SAP ASE server searches for it in sybsystemprocs. If it does not exist in sybsystemprocs, it searches master. If the SAP ASE server does not find the procedure, it sends an error message to the error log.
- sp_thresholdaction should contain a command to truncate the transaction log.
- By design, the last-chance threshold allows enough free space to record a dump transaction command. There may not be enough space to record additional user transactions against the database. Only commands that are not recorded in the transaction log (dump transactionselect, fast bcp, readtext, and writetext) and commands that might be necessary to free additional log space (dump transaction, dump database, and alter database) can be executed. By default, other commands are suspended and a message is sent to the error log. To abort these commands rather than suspend them, use the dumpabort tran on log full option of sp_dboption followed by the checkpoint command.

For waking suspended processes:

- Once the dump transaction command frees sufficient log space, suspended processes automatically awaken and complete.
- If fast bcp, writetext, or select into have resulted in unlogged changes to the database since the last backup, the last-chance threshold procedure cannot execute a dump transaction command. When this occurs, use dump database to make a copy of the database, then use dump transaction to truncate the transaction log.
- If this does not free enough space to awaken the suspended processes, it may be necessary to increase the size of the transaction log. Use the log on option of the alter database command to allocate additional log space.
- As a last resort, system administrators can use sp_who to determine which processes are suspended, then use the kill command to kill them.

See also create procedure, dump transaction in Reference Manual: Commands.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_dropthreshold [page 323]
sp_helpsegment [page 479]
sp_helpthreshold [page 493]
sp_modifythreshold [page 598]
sp_who [page 847]
```

1.259 sp_tran_dumpable_status

If you cannot make a transaction dump on a database, $sp_tran_dumpable_status$ displays the reasons the dump is not possible.

Syntax

```
sp_tran_dumpable_status [<database_name>]
```

Parameters

<database name>

name of the database you are researching.

Example 1

Describes the reasons you cannot currently make a transaction dump on sybsystemprocs:

```
bit description

2 Log is not on its own device
8 Trunc log on ckpt is set
32 Dump tran with truncate_only
64 Database is new or upgraded
```

Usage

This system procedure simply calls the ${\tt tran_dumpable_status}$ built-in function.

Permissions

Any user can execute $tran_dumpable_status$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.260 sp_transactions

Reports information about active transactions.

Syntax

```
sp_transactions ["xid", <xid_value>] |
```

```
["state", {"heuristic_commit" | "heuristic_abort"
| "prepared" | "indoubt"} [, "xactname"]] |
["gtrid", <gtrid_value>]
```

Parameters

<xid_value>

is a transaction name from the xactname column of master.dbo.systransactions.

<gtrid_value>

is the global transaction ID name for a transaction coordinated by the SAP ASE server.

Examples

Example 1

Displays general information about all active transactions:

```
xactkey type coordinator starttime state connection dbid spid loid failover srvname namelen xactname

0x00000b1700040000dd6821390001 Local None Jun 1 1999 3:47PM Begun Attached 1 1 2 Resident Tx NULL 17

$user_transaction
0x00000b1700040000dd6821390001 Remote ASTC Jun 1 1999 3:47PM Begun NA 0 8 0 Resident Tx caserv2 108
00000b1700040000dd6821390001-aa01f04ebb9a-00000b1700040000dd6821390001-aa0
1f04ebb9a-caserv1-caserv1-0002
```

Example 2

Displays detailed information for the specified transaction:

```
sp_transactions "xid", "00000b1700040000dd6821390001-aa01f04ebb9a-00000b1700040000dd6821390001-aa01f04ebb9a-caserv1-caserv1-0002"
```

Displays general information about transactions that are in the "prepared" state:

```
sp_transactions "state", "prepared"
```

Example 4

Displays only the transaction names of transactions that are in the "prepared" state:

```
sp_transactions "state", "prepared", "xactname"
```

Example 5

Displays status information for transactions having the specified global transaction ID:

Usage

There are additional considerations when using sp_transactions:

- sp_transactions translates data from the systransactions table to display information about active transactions. systransactions itself comprises data in the syscoordinations table, as well as inmemory information about active transactions.
- sp transactions with no keywords displays information about all active transactions.
- sp_transactions with the xid keyword displays the gtrid, commit_node, and parent_node columns only for the specified transaction.
- sp_transactions with the state keyword displays information only for the active transactions in the specified state.
 - $sp_transactions$ with both xid and xactname displays only the transaction names for transactions in the specified state.
- sp_transactions with the gtrid keyword displays information only for the transactions with the specified global transaction ID.
- sp_transactions replaces the sp_xa_scan_xact procedure provided with XA-Library and XA-Server products.

The columns for sp_transactions output are:

Column

Description

xactkey

The column shows the internal transaction key that the SAP ASE server uses to identify the transaction.

type

The column indicates the type of transaction:

- "Local" means that the transaction was explicitly started on the local SAP ASE server with a begin transaction statement.
- "Remote" indicates a transaction executing on a remote SAP ASE server.
- "External" means that the transaction has an external coordinator associated with it. For example, transactions coordinated by a remote SAP ASE server, MSDTC, or an X/Open XA transaction manager are flagged as "External."
- "Dtx_State" is a special state for distributed transactions coordinated by the SAP ASE server. It indicates that a transaction on the local server was either committed or aborted, but the SAP ASE server has been unable to resolve a branch of that transaction on a remote participant. This may happen in cases where the SAP ASE server loses contact with a server it is coordinating.

coordinator The column indicates the method or protocol used to manage a distributed transaction. The values for coordinator are:

- None transaction is not a distributed transaction and does not require a coordinating protocol.
- ASTC transaction is coordinated using the SAP ASE transaction coordination services.
- XA transaction is coordinated by the X/Open XA-compliant transaction manager via the SAP ASE XA-Library interface. Such transaction managers include Encina, CICS, and Tuxedo.
- DTC transaction is coordinated by MSDTC.
- SYB2PC transaction is coordinated using Sybase two-phase commit protocol.

starttime

The column indicates the time that the transaction started.

state

The column indicates the state of the transaction at the time sp transactions ran:

- Begun transaction has begun but no updates have been performed.
- Done Command transaction completed an update command.
- Done X/Open XA transaction has finished modifying data.
- Prepared
- Transaction has successfully prepared.
- In Command transaction is currently modifying data.
- In Abort Cmd execution of the current command in the transaction has been aborted.
- Committed transaction has successfully committed, and the commit log record has been written.
- In Post Commit transaction has successfully committed, but is currently deallocating transaction resources.
- In Abort Tran transaction is being aborted. This may happen either as a result of an explicit command, or because of a system failure.
- In Abort Savept transaction is being rolled back to a savepoint.

Column Description

- Begun-Detached transaction has begun, but there is no thread currently attached to it.
- Done Cmd-Detached transaction has finished modifying data, and no thread is currently attached to it.
- Done-Detached transaction modifies no more data, and no thread is currently attached to it
- Prepared-Detached transaction has successfully prepared, and no thread is currently attached to it.
- Heur Committed transaction has been heuristically committed using the dbcc complete xact command.
- Heur Rolledback transaction has been heuristically rolled back using the dbcc complete xact command.

connection

The column indicates whether or not the transaction is currently associated with a thread:

- "Attached" indicates that the transaction has an associated thread of control.
- "Detached" indicates that there is no thread currently associated with the transaction.
 Some external transaction managers, such as CICS and TUXEDO, use the X/Open XA
 "suspend" and "join" semantics to associate different threads with the same transaction.

dbid

The column indicates the database ID of the database in which transaction started.

spid

The column indicates the server process ID associated with the transaction. If the transaction is "Detached," the "spid" value is 0.

loid

The column indicates the unique lock owner ID from master.dbo.systransactions.

failover

The column indicates the failover state for the transaction:

- "Resident Tx" indicates that the transaction started and is executing on the same server.
 "Resident Tx" is displayed under normal operating conditions, and on systems that do not utilize SAP ASE high availability features.
- "Failed-over Tx" is displayed after there has been a failover to a secondary companion server. "Failed-over Tx" means that a transaction originally started on a primary server and reached the prepared state, but was automatically migrated to the secondary companion server (for example, as a result of a system failure on the primary server). The migration of a prepared transaction occurs transparently to an external coordinating service.
- "Tx by Failover-Conn" indicates that there was an attempt to start the transaction on a
 designated server, but the transaction was instead started on the secondary companion
 server. This occurs when the original server has experienced a failover condition.

srvname

The column indicates the name of the remote server on which the transaction is executing. This column is only meaningful for remote transactions. For local and external transactions, srvname is null.

namelen

The column indicates the total length of the xactname> value.

Column Description

<xactname> is the transaction name. For local transactions, the transaction name may be
defined as part of the begin transaction command. External transaction managers
supply unique transaction names in a variety of formats. For example, X/Open XA-compliant
transaction managers supply a transaction ID (<xid>) consisting of a global transaction
identifier and a branch qualifier, both of which are stored in <xactname>.

gtrid

For transactions coordinated by the SAP ASE server, the column displays the global transaction ID. Transaction branches that are part of the same distributed transaction share the same gtrid. You can use a specific gtrid with the sp_transactions gtrid keyword to determine the state of other transaction branches in the same distributed transaction.

sp_transactions cannot display the gtrid for transactions that have an external coordinator. For transactions coordinated by an X/Open XA-compliant transaction manager, MSDTC, or SYB2PC, the gtrid column shows the full transaction name supplied by the external coordinator.

commit node

For transactions coordinated by the SAP ASE server, the column indicates the server that executes the outermost block of the distributed transaction. This outermost block ultimately determines the commit status of all subordinate transactions.

For transactions not coordinated by the SAP ASE server, <code>commit_node</code> displays one of these values:

- <server_name> commit or parent node is an SAP ASE server with the specified
 <server_name>.
- XATM commit or parent node is an X/Open XA-compliant transaction manager.
- MSDTCTM ommit or parent node is MSDTC.
- SYB2PCTM transaction is coordinated using SYB2PC protocol.

parent_node

For transactions coordinated by the SAP ASE server, the column indicates the server that is coordinating the external transaction on the local server.

For transactions not coordinated by the SAP ASE server, parent_node displays the same values as those displayed by commit node.

i Note

The values for <code>commit_node</code> and <code>parent_node</code> can be different, depending on the levels of hierarchy in the distributed transaction.

See also Using Adaptive Server Distributed Transaction Management Features.

Permissions

Any user can execute $sp_transactions$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

```

1.261 sp_unbindcache

Unbinds a database, table, index, text object, or image object from a data cache.

Syntax

Parameters

<dbname>

is the name of database to be unbound or the name of the database containing the objects to be unbound.

<owner>

is the name of the table's owner. If the table is owned by the database owner, the owner name is optional.

<tablename>

is the name of the table to be unbound from a cache or the name of a table with an index, text object, or image object that is to be unbound from a cache.

<indexname>

is the name of an index to be unbound from a cache.

text only

unbinds text or image objects from a cache.

Example 1

Unbinds the titles bound:

```
sp unbindcache pubs2, titles
```

Example 2

Unbinds the titleidind

```
sp unbindcache pubs2, titles, titleidind
```

Example 3

Unbinds the text or image object for the au pix table from the cache to which it is bound:

```
sp unbindcache pubs2, au pix, "text only"
```

Example 4

Unbinds the transaction log, syslogs, from its cache:

```
sp unbindcache pubs2, syslogs
```

Usage

There are additional considerations when using sp_unbindcache:

- When you unbind a database or database object from a cache, all subsequent I/O for the cache is performed in the default data cache. All dirty pages in the cache being unbound are written to disk, and all clean pages are cleared from the cache.
- The SAP ASE server issues error number 857 if you attempt to use sp_unbindcache to unbind a database that is in use.
- Cache unbindings take effect immediately and do not require a restart of the server, except with the system index from the from the cache to which it is bound:tempdb.
- Although you can still use sp_unbindcache index from the from the cache to which it is on a system tempdb, the binding of the system tempdb is now non-dynamic. Until you restart the server:
 - $\circ \quad \text{The changes do not take effect} \\$
 - sp_helpcache reports a status of "P" for pending, unless you have explicitly bound the system tempdb to the default data cache, in which case the status as "V" for valid, because by default the system tempdb is already bound to the default datacache.
- When you drop a database, table, or index, its cache bindings are automatically dropped.
- To unbind a database, you must be using the master database. For tables, indexes, text objects, or image objects, you must be using the database where the objects are stored.
- To unbind any system tables in a database, you must be using the database, and the database must be in single-user mode. Use the command:

```
sp_dboption <db_name>, "single user", true
```

See $sp_dboption$ for more information.

- These procedures provide information about the bindings for their respective objects: sp_helpdb for databases, sp_help for tables, and sp_helpindex for indexes.
- sp helpcache prints the names of objects bound to caches.
- sp_unbindcache needs to acquire an exclusive table lock when you are unbinding a table or its indexes to a cache. No pages can be read while the unbinding takes place. If a user holds locks on a table, and you issue sp_unbindcache on that object, the sp_unbindcache task sleeps until the locks are released.
- When you change the cache binding for an object with sp_bindcache or sp_unbindcache, the stored procedures that reference the object are recompiled the next time they are executed. When you change the binding for a database, the stored procedures that reference objects in the database are recompiled the next time they are executed.
- To unbind all objects from a cache, use the system procedure sp unbindcache all.

See also Performance and Tuning Guide.

Permissions

The permission checks for sp unbindcache differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage data cache privilege.

Disabled With granular permissions disabled, you must be a user with sa_role

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

sp_helpindex [page 454]

sp_unbindcache_all [page 821]

1.262 sp_unbindcache_all

Unbinds all objects that are bound to a cache.

Syntax

sp_unbindcache_all <cache_name>

Parameters

<cache_name>

is the name of the data cache from which objects are to be unbound.

Examples

Example 1

Unbinds all databases, tables, indexes, text objects and image objects that are bound to pub cache:

sp_unbindcache_all pub_cache

Usage

There are additional considerations when using sp unbindcache all:

- When you unbind entities from a cache, all subsequent I/O for the cache is performed in the default cache.
- To unbind individual objects from a cache, use the system procedure <code>sp_unbindcache</code>.
- You cannot use sp_unbindcache_all if the system tempdb is bound to pub_cache. If you do, you get an
 error message, and sp_unbindcache_all rejects the unbind for all objects.
 Use sp_unbindcache to unbind the system tempdb first.
- See sp_unbindcache for more information about unbinding caches.

Permissions

The permission checks for sp unbindcache all differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage data cache privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_bindcache [page 103] sp_helpcache [page 420] sp_unbindcache [page 818]

1.263 sp_unbindefault

Unbinds a created default value from a column or from a user-defined datatype.

Syntax

sp unbindefault <objname>[, futureonly]

Parameters

<objname>

is the name of either the table and column or the user-defined datatype from which to unbind the default. If the parameter is not of the form ".<column>", then <objname> is assumed to be a user-defined datatype. When unbinding a default from a user-defined datatype, any columns of that type that have the same default as the user-defined datatype are also unbound. Columns of that type, with a default that has already been changed, are unaffected.prevents existing columns of the specified user-

defined datatype from losing their defaults. It is ignored when unbinding a default from a column.

futureonly

Examples

Example 1

Unbinds the default from the startdate prevents existing columns of the specified user-defined datatype from losing their column of the employees table:

sp unbindefault "employees.startdate"

Example 2

Unbinds the default from the user-defined datatype named ssn and all columns of that type:

sp_unbindefault ssn

Example 3

Unbinds defaults from the user-defined datatype ssn, but does not affect existing columns of that type:

sp_unbindefault ssn, futureonly

Usage

There are additional considerations when using sp_unbindefault:

- Use sp_unbindefault to remove defaults created with sp_bindefault. Use alter table to drop defaults declared using the create table or alter table statements.
- Columns of a user-defined datatype lose their current default unless the default has been changed or the value of the optional second parameter is futureonly.
- To display the text of a default, execute sp helptext with the default name as the parameter.

See also create default, drop default in Reference Manual: Commands.

Permissions

The permission checks for sp unbindefault differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the object owner or the user datatype owner.

Setting Description

Disabled With granular permissions disabled, you must be the object owner.

Auditing

You can enable unbind auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Information	Value	
Audit option	unbind	
Event	67	
Command or access audited	sp_unbindefault	
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – NULL Proxy information – Original login name, if set proxy in effect 	

Example of extrainfo after executing sp unbindefault:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; ; s
    a/ase;
```

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_bindefault [page 107]
sp_helptext [page 486]

1.264 sp_unbindexeclass

Removes the execution class attribute previously associated with an client application, login, stored procedure, or default execution class for the specified scope.

Syntax

```
sp_unbindexeclass <object_name>, <object_type>, <scope>
```

Parameters

<object name>

is the name of the application, login, or stored procedure for which you remove the association to the execution class. If the <object_type> is DF, <object_name> should be null.

<object_type>

identifies the type of <object_name> as AP, LG, PR, or DF for application, login, stored procedure, or default execution class.

<scope>

is the application name or login name for which the unbinding applies for an application or login. It is the stored procedure owner name (user name) for stored procedures. It is null for object type DF.

Examples

Example 1

Removes the association between "sa" login scoped to application <code>isql</code> and an execution class. "sa" automatically binds itself to another execution class, depending on other binding specifications, precedence, and scoping rules. If no other binding is applicable, the object binds to the default execution class, <code>EC2</code>:

```
sp_unbindexeclass 'sa', 'lg', 'isql'
```

Usage

There are additional considerations when using sp unbindexeclass:

- The parameters must match an existing entry in the sysattributes system table.
- If you specify a null value for scope, the SAP ASE server unbinds the object for which the scope is null, if there is one.
- A null value for scope does not indicate that unbinding should apply to all bound objects.
- When unbinding a stored procedure from an execution class, you must use the name of the stored procedure owner (user name) for the scope parameter.
- When unbinding a stored procedure from a user-defined default execution class, all tasks running with user-defined default execution class attributions run with attributes of system-defined default execution class EC2.
- Stored procedures can be dropped before or after unbinding.
- A user cannot be dropped from a database if the user owns a stored procedure that is bound to an execution class in that database.
- Unbind objects of type PR before dropping them from the database.
- Unbinding fails if the associated engine group has no online engines and active processes are bound to the associated execution class.
- Due to precedence and scoping rules, the execution class being unbound may or may not have been in effect for the <object_name>. The object automatically binds itself to another execution class, depending on other binding specifications and precedence and scoping rules. If no other binding is applicable, the object binds to the default execution class. If there is no use-defined default execution class, the object binds to class Ec2.

See also isql in the Utility Guide.

Permissions

The permission checks for sp unbindexeclass differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with manage any execution class privilege.

Disabled With granular permissions disabled, you must be a user with sa_role.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_addexeclass [page 35]

```
sp_bindexeclass [page 110]
sp_dropexeclass [page 296]
sp_showexeclass [page 744]
```

1.265 sp_unbindmsg

Unbinds a user-defined message from a constraint.

Syntax

sp_unbindmsg <constrname>

Parameters

<constrname>

is the name of the constraint from which a message is to be unbound.

Examples

Example 1

Unbinds a user-defined message from the constraint positive balance:

sp_unbindmsg positive_balance

Usage

You can bind only one message to a constraint. To change the message bound to a constraint, use $sp_bindmsg$; the new message number replaces any existing bound message. It is not necessary to use $sp_unbindmsg$ first.

To retrieve message text from the sysusermessages table, execute sp getmessage.

Permissions

You must be the constraint owner to execute $sp_unbindmsg$. Permission checks do not differ based on the granular permissions settings.

Auditing

You can enable ${\tt unbind}$ auditing option to audit this procedure. Values in ${\tt event}$ and ${\tt extrainfo}$ columns from the ${\tt sysaudits}$ table are:

Information	Value
Audit option	unbind
Event	69
Command or access audited	sp_unbindmsg
Information in extrainfo	 Roles – Current active roles Keywords or options – NULL Previous value – NULL Current value – NULL Other information – NULL Proxy information – Original login name, if set proxy in effect

Example of extrainfo after executing $sp_unbindmsg$:

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; ; s
    a/ase;
```

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

```
sp_addmessage [page 47]
sp_bindmsg [page 113]
sp_getmessage [page 390]
```

1.266 sp_unbindrule

Unbinds a rule from a column or from a user-defined datatype.

Syntax

```
sp unbindrule <objname>[, futureonly[, "accessrule" | "all"]]
```

Parameters

<objname>

is the name of the table and column or of the user-defined datatype from which the rule is to be unbound. If the parameter is not of the form ".<column>", then <objname> is assumed to be a user-defined datatype. Unbinding a rule from a user-defined datatype also unbinds it from columns of the same type. Columns that are already bound to a different rule are unaffected.

futureonly

prevents columns of the specified user-defined datatype from losing their rules. It is ignored when unbinding a rule from a column.

accessrule

indicates that you are unbinding the access rule bound to <objname>.

all

specifies that you are unbinding all rules bound to <objname>.

Examples

Example 1

Unbinds the rule from the startdate column of the employees table:

```
sp_unbindrule "employees.startdate"
```

Example 2

Unbinds the rule from the user-defined datatype named def_ssn and all columns of that type:

```
sp_unbindrule def_ssn
```

Example 3

The user-defined datatype ssn no longer has a rule, but existing ssn columns are unaffected:

```
sp unbindrule ssn, futureonly
```

Example 4

You can use the all parameter to unbind both accesss rules and domain rules. For example, to unbind all the access rules and domain rules on the publishers table:

```
sp_unbindrule publishers, null, "all"
```

To unbind the access rule from a user-defined datatype for subsequent uses of this datatype, issue:

```
sp_unbindrule def_ssn, futureonly, "accessrule"
```

To unbind both access rules and domain rules for subsequent uses of this datatype, issue:

```
sp_unbindrule def_ssn, futureonly, "all"
```

Example 5

This access rule is bound to the publishers table:

```
sp_bindrule empl_access, "publishers.pub_id"
```

To unbind this rule, issue:

```
sp_unbindrule "empl_access", NULL, "accessrule"
```

Usage

There are additional considerations when using sp_unbindrule:

- Executing sp_unbindrule removes a rule from a column or from a user-defined datatype in the current database. If you do not want to unbind the rule from existing objname columns, use futureonly
- You cannot use <code>sp_unbindrule</code> to unbind a check constraint. Use as the second parameter.alter table to drop the constraint.
- To unbind a rule from a table column, specify the <objname> as the argument in the form ".<column>".
- The rule is unbound from all existing columns of the user-defined datatype unless the rule has been changed or the value of the optional second parameter is futureonly.
- To display the text of a rule, execute <code>sp_helptext</code> with the rule name as the parameter.

See also create rule, drop rule in Reference Manual: Commands.

Permissions

You must be the table owner or datatype owner to execute $sp_unbindrule$. Permission checks do not differ based on the granular permissions settings.

Auditing

Information

You can enable unbind auditing option to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Audit option	unbind
Event	68
Command or access audited	sp_unbindrule
Information in extrainfo	Roles – Current active roles
	• Keywords or options – NULL
	• Previous value – NULL
	• Current value – NULL
	Other information – NULL
	• Proxy information – Original login name, if set proxy in effect

Example of extrainfo after executing sp unbindrule:

Value

```
sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; ; s
    a/ase;
```

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_bindrule [page 115]
sp_helptext [page 486]

1.267 sp_version

Returns the version information of the installation scripts (installmaster, installdbccdb, and so on) that was last run and whether it was successful.

Syntax

```
sp_version [<script_file>, [all]]
```

Parameters

<script_file>

is the name of the installation script (the default value is NULL).

all

reports details about the installation scripts, such as the date it was run and the time it took to run.

Examples

Example 1

Returns the script name, version, and status of all installation scripts that have been run:

```
sp_version

Script Version
Status
-----
```

```
installmaster     15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1/32-bit/OPT/Thu
Sep 23 22:12:12 2004
Complete
installmaster     15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1/32-bit/OPT/Thu
Sep 23 22:12:12 2004
```

Complete installmodel 15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1861/32-bit/OPT/Mon Sep 27 23:40:02 2004 Complete

Example 2

Returns information about the ${\tt installmaster}$ installation script:

```
sp_version installmaster
```

```
installmaster 15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1/32-bit/OPT/Thu Sep 23 22:12:12 2004 Complete
```

Example 3

Returns script file name, date, time, version, and status for all the installation scripts run:

```
sp version null, 'all'
Script
Version
                 Status
Start/End Date
installdbccdb
                 15.0/EBF XXXXX/B/Sun svr4/OS 5.8/asemain/1861/32-
bit/OPT/Mon Sep 27 23:40:02 2004
Complete [Started=Sep 29 2004 4:41PM]-[Completed=Sep 29 2004 4:42PM]
installmaster
15.0/EBF XXXXX/B/Sun svr4/OS 5.8/asemain/1/32-bit/OPT/Thu Sep 23 22:12:
12 2004
Complete [Started=Sep 29 2004 3:49PM]-[Completed=Sep 29 2004 3:58PM]
installmodel
15.0/EBF XXXXX/B/Sun svr4/OS 5.8/asemain/1861/32-bit/OPT/Mon Sep 27 23:
40:02 2004
```

Example 4

Returns script file name, version, and status of installation of all the install scripts having names like <install%>:

Complete [Started=Sep 29 2004 4:51PM]-[Completed=Sep 29 2004 4:51PM]

```
sp version 'install%'
Script
Version
                  Status
installdbccdb
15.0/EBF XXXXX/B/Sun svr4/OS 5.8/asemain/1861/32-bit/OPT/Mon Sep 27
23:40:02 2004
                Complete
installmaster
15.0/EBF XXXXX/B/Sun svr4/OS 5.8/asemain/1/32-bit/OPT/Thu Sep 23 22:12:
12 2004
                 Complete
installmodel
15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1861/32-bit/OPT/Mon Sep 27 23:
40:02 2004
                  Complete
```

Example 5

Returns all detailed information about installation scripts matching the wildcard "install%":

```
Script
Version Status
Start/End Date
-----
installmaster
15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1/32-bit/OPT/Thu Sep 23 22:12:
12 2004
Complete [Started=Sep 29 2004 3:49PM]-[Completed=Sep 29 2004 3:58PM]
```

Example 6

Returns all detailed information about the installmaster installation script:

```
Script
Version Status
Start/End Date
installmaster
15.0/EBF XXXXX/B/Sun_svr4/OS 5.8/asemain/1/32-bit/OPT/Thu Sep 23 22:12:
12 2004
Complete [Started=Sep 29 2004 3:49PM]-[Completed=Sep 29 2004 3:58PM]
```

Usage

 $sp_version$ allows you to determine the current version of the scripts (installmaster, installdbccdb, and so on) installed on the SAP ASE server, and whether they ran successfully or not, and the time they took to complete

Permissions

Any user can execute $sp_version$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.268 sp_volchanged

Notifies the Backup Server that the operator performed the requested volume handling during a dump or load.

Syntax

```
sp_volchanged <session_id>, <devname>, <action>
```

```
[, <fname>[, <vname>]]
```

Parameters

<session id>

identifies the Backup Server session that requested the volume change. Use the @session_id_parameter specified in the Backup Server's volume change request.

<devname>

is the device on which a new volume was mounted. Use the @devname parameter specified in the Backup Server's volume change request. If the Backup Server is not located on the same machine as the SAP ASE server, use the form:

```
<device> at <backup server name>
```

<action>

indicates whether the Backup Server should abort, proceed with, or retry the dump or load.

<fname>

is the file to be loaded. If you do not specify a file name with $sp_volchanged$, the Backup Server loads the file = <filename> parameter of the load command. If neither $sp_volchanged$ nor the load command specifies which file to load, the Backup Server loads the first file on the tape.

<vname>

is the volume name that appears in the ANSI tape label. The Backup Server writes the volume name in the ANSI tape label when overwriting an existing dump, dumping to a brand new tape, or dumping to a tape with contents that are not recognizable. If you do not specify a <vname> with sp_volchanged, the Backup Server uses the dumpvolumesp_volchanged nor the dump command specifies a volume name, the Backup Server leaves the name field of the ANSI tape label blank. value specified in the dump command. If neither

During loads, the Backup Server uses the <vname> to confirm that the correct tape has been mounted. If you do not specify a <vname> with $sp_volchanged$, the Backup Server uses the dumpvolume specified in the load command. If neither $sp_volchanged$ nor the load command specifies a volume name, the Backup Server does not check the name field of the ANSI tape label before loading the dump.

Examples

Example 1

The operator changes the tape, then issues:

```
sp_volchanged 8, "/dev/nrmt4", RETRY
```

This message from Backup Server indicates that a mounted tape's expiration date has not been reached:

Permissions

Any user can execute $sp_volchanged$. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.268.1 When Backup Server Detects a Problem

There are additional considerations when using sp volchanged.

If the Backup Server detects a problem with the currently mounted volume, it requests a volume change:

- (UNIX) The Backup Server sends messages to the client that initiated the dump or load request. Use the with notify = operator_console option of the dump or load command to route messages to the terminal where the Backup Server was started.
- After mounting another volume, the operator executes <code>sp_volchanged</code> from any SAP ASE server that can communicate with the Backup Server performing the dump or load. The operator does not have to log into the SAP ASE server on which the dump or load originated.

See also:

- dump database, dump transaction, load database, load transaction in *Reference Manual:* Commands
- isql in the Utility Guide

1.268.2 Changing Tape Volumes on UNIX

The Backup Server requests a volume change when the tape capacity has been reached. The operator mounts another tape and executes $sp_volchanged$.

The following table illustrates this process.

Table 18: Changing Tape Volumes on a UNIX System

Sequence	Operator, Using isql	SAP ASE Server	Backup Server	
1	Issues the dump database command			
2		Sends dump request to Backup Server		
3			Receives dump request message from the SAP ASE server	
			Sends message for tape mounting to operator	
			3. Waits for operator's reply	
4	Receives volume change request from Backup Server			
	2. Mounts tapes			
	3. Executes sp_volchanged			
5			1. Checks tapes	
			2. If tapes are okay, begins dump	
			When tape is full, sends volume change request to operator	
6	Receives volume change request from Backup Server			
	2. Mounts tapes			
	3. Executes sp_volchanged			
7			1. Continues dump	
			When dump is complete, sends messages to operator and the SAP ASE server	
8	Receives message that dump is complete	Receives message that dump is complete		
	2. Removes and labels tapes	2. Releases locks		
		3. Completes the dump		
		database command		

1.269 sp_w

Queries the master..sysprocesses and returns information about all current SAP Adaptive Server Enterprise (ASE) users and processes. sp_w is a simplified version of sp_w ho.

Syntax

```
sp_w
```

Examples

Example 1

Returns information about the running processes:

Usage

• The columns returned by sp_w are:

fid	Identifies the parallel family id.

spid Identifies the process id.

command Identifies the command or process currently being executed.

execution_time Identifies the duration of the current command.

physical_io Identifies the number of physical I/Os executed by the spid.

blocked Identifies the spid of the blocked connection.

- sp w does not return:
 - o The calling spid
 - spids that are in the AWAITING COMMAND
 - o spids whose execution_time is 0 (unless fid > 0)

Permissions

Any user can execute sp w.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.270 sp_webservices

Creates and manages the proxy tables used in the SAP ASE Web Services Engine.

Syntax

To create a proxy table:

```
sp_webservices 'add', '<wsdl_uri>' [, <sds_name>]
    [, '<method_name>=<proxy_table>
    [,<method_name>=<proxy_table> ]* ' ]
```

To display usage information for sp webservices:

```
sp_webservices help[, '<option>']
```

To list the proxy tables mapped to a WSDL file:

```
sp_webservices 'list'[, '<wsdl_uri>'][, <sds_name>]
```

To modify timeout setting:

```
sp_webservices 'modify', '<wsdl_uri', >'timeout=<time>'
```

To remove proxy tables mapped to a WSDL file:

```
sp_webservices 'remove', '<wsdl_uri>'[, <sds_name>]
```

Options for User-Defined Web Services:

• To create a database alias for user-defined Web services:

```
sp_webservices 'addalias' <alias_name> , <database_name>
```

• To deploy a user-defined Web service:

```
sp_webservices 'deploy', ['all' | '<service_name>']
```

• To drop a database alias in user-defined Web services:

```
sp_webservices 'dropalias' <alias_name>
```

• To list the proxy tables mapped to a WSDL file in user-defined Web services:

```
sp_webservices 'listudws' [, '<service_name>']
```

• To list a database alias or aliases for a user-defined Web service.

```
sp_webservices 'listalias'
```

• To undeploy a user-defined Web service:

```
sp_webservices 'undeploy', ['all' | '<service_name>']
```

Parameters

```
'add', '<wsdl_uri>' [, <sds_name>] [, '<method_name>=<proxy_table>[,
<method_name>=<proxy_table> ]* ']
```

is used to create a proxy table for a Web method specified by a WSDL file. When the add option is used successfully, the list option is invoked automatically to describe the schema of the new proxy table:

- <wsdl_uri> is the location for the WSDL file to be mapped to the new proxy table. If this parameter is specified, Web Services ensures that the URI exists in the syswsdl table.
- <sds_name> is the name specified for the ASE Web Services Engine in the interfaces or sql.ini file. The default value is ws. If no entry exists in the sysattributes table, an error results.
- <method_name> is the name of the Web method to be mapped to a proxy table.
 The <method_name> specified must be the name of a Web method specified in the associated WSDL file.

'addalias' <alias name> , <database name>

is used to create an alias representing a database name in user-defined Web services, where:

- <alias name> (required) is the alias for the specified database.
- <database_name> (required) is the name of the database for which the alias is specified.

An alias provides greater control in specifying the portion of the URL representing the database name. Used with the userpath option of the create service command, an alias provides complete control over the URL used to access a user-defined Web service.

'deploy', ['all' | '<service name>']

is used to deploy a user-defined Web service, making it accessible to the ASE Web Services Engine through HTTP or HTTPS, where:

- all specifies that all user-defined Web services are to be deployed for the current database.
- <service name> is the name of the user-defined Web service to be deployed.

The deploy and undeploy options are used to control when user-defined Web services are available. The system role webservices_role privilege is required for this option.

If the all parameter is specified, the ASE Web Services Engine deletes its internal cache of user-defined Web services and rereads all metadata about user-defined Web services from SAP ASE.

You cannot drop or rename a user-defined Web service that is currently deployed.

'dropalias' <alias name>

is used to drop an alias representing a database name, where <alias_name> is the alias to be dropped.

You cannot drop an alias if it is being referenced by a deployed user-defined Web service. To drop the alias, undeploy the user-defined Web service that references the alias first.

help[, '<option>']

provides instructions and examples illustrating how to use the $sp_webservices$ stored procedure. The valid values for '<option>' are add, list, remove, and modify.

If you do not specify a value for <option>, the help option prints a brief syntax description for the add, addalias, deploy, dropalias, list, listalias, listudws, modify, remove, and undeploy options.

'list' [, '<wsdl uri>'] [, <sds name>]

lists Web methods described in a WSDL file, where:

• <wsdl_uri> - is the URI for the mapped WSDL file. If you do not specify a value for <wsdl_uri>, the list option displays information about all Web methods that have been mapped to proxy tables.

• <sds_name> - is the name of the SDS server specified for the ASE Web Services Engine in the interfaces or sql.ini file. The default value is ws. If no entry exists in the sysattributes table, an error results.

If you specify neither the <wsdl_uri> nor the <sds_name> parameter, all entries in the sysattributes table are listed, ordered by wsdlid.

If the Web methods described in the WSDL file:

- Have already been mapped to proxy tables the list option prints information about each proxy table.
- Have **not** already been mapped to proxy tables the list option prints SQL that can be used to create proxy tables.

'listalias'

is used to list all aliases in user-defined Web services.

'listudws' [, '<service_name>']

is used to list user-defined Web services for the current database, where <service name> is the name of the user-defined Web service to be listed.

If you do not specify the <service_name> parameter, all user-defined Web services are listed.

'modify', '<wsdl uri', >'timeout=<time>'

is used to modify the attribute information for a WSDL file, where:

- <wsdl_uri> is the URI of the WSDL file for which attribute information is to be changed.
- <time> is the interval in seconds during which a Web method must respond before the operation is aborted.

'remove', '<wsdl_uri>' [, <sds_name>]

is used to remove a proxy table mapping for a Web method, where:

- <wsdl_uri> is the URI of the WSDL file for which the proxy table is to be removed.
- <sds_name> is the name of the SDS server specified for the ASE Web Services Engine in the interfaces or sql.ini file. The default value is ws.

i Note

An error results if no entry exists in the sysattributes table.

'undeploy', ['all' | '<service_name>']

is used to make a user-defined Web service inaccessible to the SAP ASE Web Services Engine through HTTP or HTTPS, where:

- all specifies that all user-defined Web services are to be undeployed for the current database.
- <service_name> is the name of the user-defined Web service to be undeployed.

Use the deploy and undeploy options to control when user-defined Web services are available. The system role webservices role privilege is required for this option.

Examples

Example 1

Invokes an RPC/encoded Web method to display the exchange rate between two currencies.

1. Use the add option of sp webservices to map Web methods to proxy tables:

```
1> sp_webservices 'add', 'http://www.xmethods.net/sd/2001/
CurrencyExchangeService.wsdl'
2> go
```

The getRate Web method is mapped to a proxy table of the same name.

2. Invoke the Web method by selecting from the proxy table:

```
1> select * from getRate where _country1 = 'usa' and _country2 = 'india' 2> go
```

The results returned for the previous select show the exchange rate for the specified parameters:

```
Result __country1 __country2
43.000000 usa india
(1 row affected)
```

Example 2

Invokes a Web method to display stock information within an XML document.

1. Use the add option of sp webservices to map Web methods to proxy tables:

```
1> sp_webservices "add" , "http://www.webservicex.net/stockquote.asmx?WSDL"
2> go
```

The GetQuote Web method is mapped to a proxy table of the same name.

2. Invoke the Web method by selecting the outxml column of the GetQuote proxy table:

The results for the previous select display quote information within an XML document:

```
outxml
<?xml version="1.0" encoding="UTF-8" ?><GetQuoteResponse
xmlns="http://www.webserviceX.NET/"><GetQuoteResult><StockQuotes><Stock>
<Symbol>SY</Symbol><Last>21.48</Last><Date>7/21/2005</Date><Time>4:01pm
</Time><Change>+1.72</Change><Open>20.00</Open><High>>21.60</High>
<Low>19.91</Low><Volume>2420100</Volume><MktCap>1.927B</MktCap>
<PreviousClose>19.76</PreviousClose><PercentageChange>+8.70%
</PercentageChange><AnnRange>12.75 - 20.44</AnnRange><Earns>0.706</Earns>
<P-E>27.99</P-E><Name>SYBASE INC</Name></Stock></StockQuotes>
</GetQuoteResult></GetQuoteResponse>
(1 row affected)
```

Example 3

Invokes the GetQuote Web method, mapped to a proxy table in the previous example, through a view to display stock information.

1. Create a table to hold symbols representing stocks to use this Web service:

```
1> create table stocksymbol(symbol varchar(100))
2> go
```

2. Insert data into the stocksymbol table:

```
1> insert stocksymbol values("SY")
2> insert stocksymbol values("ORCL")
3> go
```

3. Create a view that invokes the GetQuote Web method:

```
1> CREATE VIEW getstockvw as
2> select Symbol = xmlextract('//Stock/Symbol/text()',outxml returns
varchar(5)),
3> Name = xmlextract('//Stock/Name/text()',outxml returns varchar(20)),
4> Time = xmlextract('//Stock/Time/text()',outxml returns varchar(10)),
5> Date = xmlextract('//Stock/Date/text()',outxml returns date),
6> High = xmlextract('//Stock/High/text()',outxml returns decimal(15,2)),
7> Low = xmlextract('//Stock/Low/text()',outxml returns decimal(15,2)),
8> FROM GetQuote ,stocksymbol
9> WHERE _inxml = '<GetQuote xmlns="http://www.webserviceX.NET/"><symbol>'+symbol+'</symbol></GetQuote>'
10> go
```

4. Select from the getstockvw view to view output from the GetQuotes method:

```
1> select * from getstockvw
2> go
```

The results for the previous select display quote information for the parameters specified by the view definition:

```
Symbol
                        Time
                                                High
        Name
                                  Dat.e
                                                         Low
                        4:01pm
SY
                                 Jul 21 2005
                                                21.60
                                                         19.91
        SYBASE INC
ORCL
        ORACLE CORP
                        4:00pm
                                 Jul 21 2005
                                                14.05
                                                         13.54
                       4:00pm
                                 Jul 21 2005
        MICROSOFT CP
                                                26.48
                                                         26.19
(3 rows affected)
```

Example 4

Shows an audit table entry for the following command entered in the pubs2 database by the user "bob":

```
sp_webservices 'deploy', 'all'
```

The corresponding audit table entry lists 110, bob, and pubs2 as values in the event, loginname, and dbname columns, respectively. The extrainfo column contains the following:

```
webservices_role; deploy_all; ; ; ; bob/ase;
```

Example 5

Shows an audit table entry for the following command entered in the pubs 2 database by the user "bob":

```
sp_webservices 'deploy', 'rawservice'
```

The corresponding audit table entry lists 110, bob, and pubs2 as values in the event, loginname, and dbname columns, respectively. The extrainfo column contains the following:

```
webservices_role; deploy; ; ; ; bob/ase;
```

Example 6

Shows an audit table entry for the following command entered in the pubs2 database by the user "bob":

```
sp_webservices 'undeploy', 'all'
```

The corresponding audit table entry lists 111, bob, and pubs2 as values in the event, loginname, and dbname columns, respectively. The extrainfo column contains the following:

```
webservices_role; undeploy_all; ; ; ; bob/ase;
```

Example 7

Shows an audit table entry for the following command entered in the pubs 2 database by the user "bob":

```
sp_webservices 'undeploy', 'rawservice'
```

The corresponding audit table entry lists 111, bob, and pubs 2 as values in the event, loginname, and dbname columns, respectively. The extrainfo column contains the following:

```
webservices_role; deploy; ; ; ; bob/ase;
```

For a full description of sysaudits table columns, see the System Administration Guide.

Usage

If you not specify <method_name> and sproxy_table> values for a Web method, the proxy table generated for the Web method is, by default, the name of the Web method specified in the WSDL file. If there is already a proxy table with the name of this Web method, a new proxy table is generated with a name like:

```
<method_nameN>
```

Where:

- <method name> is the default proxy table name
- <N> is a digit from 1 to 9 denoting each successive mapping of the Web method. There can be as many as 99 duplicate proxy tables.

If you do specify $\mbox{\ensuremath{\texttt{mame}}}$ and $\mbox{\ensuremath{\texttt{proxy_table}}}$ values for a Web method, the name of the proxy table must be new. If there is already a proxy table with the name specified in $\mbox{\ensuremath{\texttt{proxy_table}}}$, an error results, and none of the Web methods specified in the add option are mapped to proxy tables.

The output from the add option lists the methods that have been successfully mapped to proxy tables as well as those that have not been mapped. The name of a proxy table for an unmapped Web method is indicated as NULL in the output from the add option.

i Note

The columns used for input and output vary for proxy tables generated for RPC/encoded Web methods and document/literal Web methods. A proxy table representing an RPC/encoded Web method contains a column for each input and output parameter. A proxy table representing a document/literal Web method contains two columns, _inxml and outxml.

See also:

- create service in Reference Manual: Commands
- Web Services User's Guide

Permissions

You must be a user with webservices_role (for deploy and undeploy) to execute sp_webservices. Permission checks do not differ based on the granular permissions settings.

The system role webservices_role is required to use the deploy and undeploy options for sp_webservices. To execute a user-defined Web service, a valid login and permissions to execute the corresponding stored procedure are required.

To create, drop, and execute user-defined Web services, you need the same privileges as are necessary to create, drop, and execute stored procedures in SAP ASE. See the *System Administration Guide* for details on how to set the proper privileges using the grant and revoke commands.

Auditing

User-defined Web services are modeled as stored procedures within SAP ASE. In manipulating user-defined Web services, SAP ASE generates the following events using the existing auditing coverage for stored procedures: You can enable the following auditing options to audit this procedure. Values in event and extrainfo columns from the sysaudits table are:

Audit option	Event	Command or access audited
security	110, 111	sp_webservices 'deploy' 'undeploy'
create	11	create procedure
drop	28	drop procedure

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.271 sp_who

Reports information about all current SAP ASE users and processes or about a particular user or process. Includes the thread_pool column, which describes the thread pool the SAP ASE server uses to execute a task.

Considerations for Process Mode

sp who does not include the threadpool column.

Syntax

```
sp_who [<loginame> | "<spid>"]
```

Parameters

<loginame>

is the SAP ASE login name of the user you are requesting a report on.

<spid>

is the number of the process you are requesting a report on. Enclose process numbers in quotes (the SAP ASE server expects a char type).

Examples

Example 1

Reports on the processes running on the SAP ASE server. Although no user processes other than sp_who are running, the server still shows activity. During idle cycles, the housekeeper wash task moves dirty buffers into the buffer wash region, the housekeeper chores task performs other maintenance tasks. The housekeeper garbage collection task , which cleans up data that was logically deleted and resets the rows so that tables have space again, operates at the priority level of the ordinary user.

```
fid spid status loginame origname hostname blk_spid dbname tempdbname cmd block_xloid threadpool
```

Example 2

Reports on the processes running on the SAP ASE server. Process 11 (a select into on a table) is blocked by process 8 (a begin transaction followed by an insert on the same table). For process 8, the current <loginame> is "robert", but the original <loginame> is "sa". Login "sa" executed a set proxy command to impersonate the user "robert":

sp_who				
fid sp	id status loginame pdbname cmd 	origname hostname block_xloid thread	blk_spid dpool	dbname
0	1 recv sleep bird 0 master		jazzy	
0 aster	tempdb AWAITING COMMAN 2 sleeping NULL	O 0 syb_c NULL	default_pool 0	m
0 aster	tempdb NETWORK HANDLER 3 sleeping NULL	0 syb_c	default_pool 0	m

0 aster	tempdb MIRROR HANDLER 4 sleeping NULL	0 NULL	syb_default_pool 0	m
	tempdb AUDIT PROCESS 5 sleeping NULL		syb_default_pool 0	m
0	tempdb CHECKPOINT SLEEP 6 recv sleep rose 0 master	0	<pre>syb_default_pool rose</pre>

sleep	lily lily tempdb WAITFOR	pond 0	0 master syb_default_pool	
	viola viola tempdb INSERT	cello 0	8 pubs2 syb_default_pool	

Example 3

Reports on the processes being run by the user "joe":

```
fid spid status loginame origname hostname blk_spid dbname tempdbname cmd block_xloid threadpool

------
0 28 recv
sleep joe joe tiger.sybase.com 0 pubs2 tempdb SELECT 0 syb_default_pool
```

Example 4

Reports what the SAP ASE server process number 17 is doing:

```
sp_who "17"

fid spid status loginame origname hostname blk_spid dbname tempdbname cmd block_xloid threadpool

-----
0 17 sleeping NULL NULL NULL 0 pu
bs2
tempdb NETWORK HANDLER 0 syb_default_pool
```

Example 5

Reports on a system-induced rollback, either of a transaction or a command:

```
sp_who

fid spid status loginame origname hostname blk_spid dbname tempdbname cmd block_xloid threadpool
```

0 bs2	28	running	joe	joe	tiger.sybase.	com	0	pu
DSZ		tempdb	rollback		0	syb_default	_pool	

Usage

There are additional considerations when using sp_who:

- sp_who reports information about a specified user or the SAP ASE server process.
- Without parameters, sp_who reports which users are running what processes in all databases.
- The columns returned by sp_who are:

fid	Identifies the family (including the coordinating process and its worker processes) to which a lock belongs. For more information, see <code>sp_familylock</code> .
spid	Identifies the process number. A system administrator can use this number with the Transact-SQL ${\tt kill}$ command to stop the process.
status	Indicates whether the process is running or sleeping.
loginame	The login or alias of the user who started the process. For all system processes, loginame is NULL.
origname	If the loginame is an alias, origname shows the real login name. If not, origname shows the same information as loginame.
hostname	The name of the server on which the database resides.
blk_spid	Contains the process IDs of the blocking process, if there is one. A blocking process (which may be infected or have an exclusive lock) is one that is holding resources needed by another process.
dbname	Indicates the name of the database on which the process is running.
tempdbname	Name of the temporary database assigned to the session.
cmd	Identifies the command or process currently being executed. This information is supplied from the cmd column of sysprocesses. Evaluation of a conditional statement, such as an if or while loop, returns cond.

block_xloid Identifies the unique lock owner ID of a blocking transaction.

threadpool Thread pool the task uses.

- Running sp_who on a single-engine server shows the sp_who process currently running and all other processes that are runnable or in one of the sleep states. In multiengine servers, there can be a "running" process for each engine.
- If you enable mirrored disks or remote procedure calls, the mirror handler and the site handler also appear in the report from sp_who.

• Issue the sp_w system stored procedure to view a subset of the information reported by sp_who. sp_w is a simplified version of sp_who. For more information, see sp_w [page 838].

See also kill in Reference Manual: Commands.

Permissions

Any user can execute sp who. Permission checks do not differ based on the granular permissions settings.

Auditing

For information about auditing stored procedures with the auditing options <code>exec_procedure</code>, <code>sproc_auth</code>, and <code>security</code>, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

Related Information

sp_familylock [page 369]
sp_lock [page 560]
```

1.272 sp_wlprofiler

The external interface for the SAP ASE workload profiler utility. Use this procedure to monitor transactional work loads to determine optimal sizes for IMRS components like the IMRS-cache, sysimrslogs, and so on.

See the *In-Memory Database Users Guide*.

Syntax

```
| interval = interval-specifier
| sample = sample-specifier
}
```

Parameters

drop metrics

drops all the metrics tables from the metrics databases. For example, drop all metrics tables from older profiling sessions or to gather new metrics.

finish

completes the profiling session.

<workload_ID_name>

identifies a workload by its workload ID or name. <workload_ID> is an internallygenerated unique number, and is specified by a quote-enclosed number. <name> can
be a user-specified or an internally-generated name. Internally generated workload
names use workload ID=<number> as the name format, where <number> is the
workload ID generated by the monitor parameter.

help

displays help and prints the syntax and examples.

<action_keyword>

one of:

- drop metrics
- finish
- help
- monitor
- report
- status
- uninstall

monitor {<database_name>} [, <using_clause>]

- Prepares the profiling activity of a running workload executing against a target database.
- Collects metrics by triggering a collection of baseline data from monitoring tables and metrics affecting active objects and the transaction log from the target database.
- Ends the profiling interval and triggers the collection of metrics for all the MDA tables that were included in the baseline metrics.

Issuing monitor against a new database generates a new workload ID and gathers any user-specified properties of the profiling activity that may be specified with the using parameter.

Issuing monitor against an existing profiling session collects metrics for that database with the using parameters provided in an earlier session.

<using_clause>

specifies a comma-separated list of sub-arguments. <using item> is one of:

- name = <workload_name> Name the workload being profiled.
 <workload_name> should have at least one alphabet character. If you do not specify <workload_name> with the <using_clause>, sp_wlprofiler uses the default name in the form Workload ID=.
- feature = <feature_name> specifies the SAP ASE feature being evaluated by the workload profiler. The default feature-name evaluated by the workload profiler is DRC (data row caching).
- metrics = <database_name> name of the database that stores the metrics collected by the workload profiler are stored. The default is sybdsamdb.
- interval = <interval_specifier> specifies the time interval during which the workload profiler monitors the workload, collecting metrics for the planning phase of this utility. The format is open: you can specify the time in seconds, using a positive integer (for example, 120 for 2 minutes) or you can specify in the format <hh:mm:ss>. The default monitoring profiling interval is 5 minutes. <interval specifier> allows for optional single quotes.
- sample = <interval_specifier> specifies the time interval (in seconds) at which certain metrics are periodically sampled and archived by the profiler. The format is open: you can specify the time in seconds, using a positive integer (for example, 120 for 2 minutes) or you can specify in the format <hh:mm:ss>. The default sampling interval is 120 seconds (2 minutes), which means that metrics are sampled once every 120 seconds. <interval_specifier> allows for optional single quotes.

database_name

name of the target database.

<workload id name>

Name or ID of the plan's workload.

status [<workload id name>]

prints the status of the most recent workload profiled. When the profiling is complete for a database, its states and information is stored in the control tables, including information like workload ID and name, target database, metrics database, start date, end data, and so on. This information is displayed by the status parameter. Issuing status without any parameters displays the status of the latest active workload in the system. Including the <workload_ID> or <name> displays the status of that ID or name.

report

Reports the tables qualified for IMRS, the IMRS cache size, and imrslog size. Tables that have a score above a threshold are qualified for IMRS.

uninstall

uninstalls all procedures, control tables, and other objects installed by the installwlprofiler script for the workload profiler.

Examples

Example 1

Collects metrics for the tpcc database. Collects baseline metrics first and then periodically gathers new metrics every 50 seconds. After monitoring for 10 minutes, ends the workload profiling and collects final metrics:

```
sp_wlprofiler 'monitor', 'tpcc',
"using name = DailyWorkload,
metricsdb = tempdb,
sample = '50',
interval = '00:10:00'"
```

Example 2

Collects metrics for the tpcc database. Runs the workload profiling with the parameters supplied by the previous run.

```
sp_wlprofiler 'monitor', 'tpcc'
```

Example 3

Show the status of the workload profiler with an ID of 10:

```
sp_wlprofiler 'status', '10'
```

Example 4

Shows the status of the latest active workload profiled:

```
sp_wlprofiler 'status'
```

Example 11

Displays the plan for the workload for a specific ID (in this example, ID number 10):

```
sp_wlprofiler 'plan', '10'
```

Example 12

Drop all the metrics tables in all metrics databases for previously completed or active profiling sessions:

```
sp_wlprofiler 'drop metrics'
```

Example 13

Finishes the latest active workload session, and finishes the active workload session with an ID of 2:

```
sp_wlprofiler 'finish'
sp_wlprofiler 'finish', '2'
```

Example 13

Reports

```
sp_wlprofiler 'report ', '1'
```

Example 14

Reports

```
sp_wlprofiler 'report config', '1'
```

Example 15

Drops all procedures, views, and control tables installed for the workload profiler:

```
sp_wlprofiler 'uninstall'
```

Example 16

Collects metrics for an estimation of IMRS cache and version storage size required to enable on-disk MVCC for the tpcc database:

```
sp_wlprofiler 'monitor', 'tpcc', "USING interval='00:02:00', feature='ODMVCC'"
```

Usage

- The drop metrics parameter drops only the metrics tables that are recreated when the monitor parameter is issued.
- The finish parameter marks a workload profiling activity as completed, so no more metrics are collected as part of that workload after finish is run.
- The metrics table must first exist if you manually add new metrics table to the control tables and displayed with the show parameter.
- You cannot run plan concurrently for the same workload.
- uninstall drops everything from the system. You must rerun the installwlprofiler script to reinstall the workload profiler.

Permissions

The permission checks for <code>sp_wlprofiler</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be a user with mon_role, manage any database, own any database, manage disk, and manage data cache privileges.

Disabled With granular permissions disabled, you must be a user with sa_role and mon_role.

1.273 sp_xact_loginfo

sp xact loginfo provides the span of oldest active transaction in terms of percentage of total log space.

Syntax

```
sp_xact_loginfo <dbid>[, <vcharparam1>][, <vcharparam2>]
    [, <intparam1>][, <intparam2>][' <span_pct>][, <startpage>]
    [, <xact_spid>][, <starttime>][, <firstlog_page>][, <stp_page>]
    [, <stp_pages>][, <stp_blocking>][, <canfree_without_abort_pct>]
    [, <dump_in_progress>][, <activexact>][, <errorcode>]
```

Parameters

dbid

is the database ID.

vcharparam1

varchar parameter indicating the mode. If oldestactive, the output parameter values are indicative of oldest active transaction. If xactspanbyspid, then output parameter values reflect values of active transaction for given spid.

vcharparam2

is reserved for future use. Provide NULL as a value.

intparam1

is integer parameter1 (SPID if <vcharparam1> = xactspanbyspid)

intparam2

is integer parameter2

span pct

is a value from 0 to 100. Indicates the span of transaction in percentage of total log space based on value of <vcharparam1>(output parameter).

startpage

is the page number that is the start of the active transaction in the log based on value of vcharparam1. This page will hold the begin transaction log record of the active transaction.

xact_spid

is the server process ID of the client having the active transaction based on <vcharparam1>.

starttime

is the start time of active transaction based on <vcharparam1>.

firstlog_page

is the server process ID of the client having active transaction based on <vcharparam1>.

stp_page

is the secondary truncation point logical page number in the log. Returns –1 if replication is not active.

stp_pages

returns the total number of log pages between the secondary truncation point and the oldest active transaction. Returns 0 if:

- Replication is not active
- There is no active transaction in the log
- There is no secondary truncation point before oldest active transaction

stp_blocking

is a value of 0 or 1:

- 1 indicates that the secondary truncation checkpoint will block some portion for truncation beyond oldest active transaction span. Meaning that secondary truncation point is in between the start of the log and the start of oldest active transaction and replication agent must catch up.
- 0 indicates that aborting the oldest active transaction will free transaction log space without the secondary checkpoint blocking the abort.

canfree without abort pct

is a value from 0 to 100. Indicates the difference between startlogpagenum and startxactpagenum in terms of percentage of total log space. This portion can be truncated with the dump transaction command without aborting the oldest active transaction.

dump in progress

returns 1 if the dump transaction command is in progress, returns 0 if no dump command is in progress. Values of output parameters firstlog_page and canfree_without_abort_pct are not reliable. (output parameter).

activexact

is a Boolean flag indicating that there are active transactions in the log.

errorcode

Values are:

- 0 there are no errors.
- 1 insufficient permission to execute.
- 2 error in opening dbtable. This could be due to various reasons including the dbid or database name given does not exist.
- 3 cannot start xls session for log scan.
- 4 there are no open transaction in the log against this database.

i Note

For a Mixed Log Data (MLD) database, this procedure returns values equivalent to 0 in output parameters. This procedure is not supported or meant to be used for MLD databases.

Auditing

For information about auditing stored procedures with the auditing options $exec_procedure$, $sproc_auth$, and security, see Auditing Stored Procedures [page 13]. For more information about auditing, see Security Administration Guide > Auditing.

1.274 sp_xmlschema

Creates and maintains the $spt_xmlcatalog$ user table in the SAP ASE database. $spt_xmlcatalog$ stores schema definitions that the xmlvalidate function uses to validate XML documents

Syntax

See XML Services for syntax, examples, and usage information for sp xmlschema.

2 Catalog Stored Procedures

Catalog stored procedures retrieve information from the system tables in tabular form. Created by installmaster at installation, they are located in the sybsystemprocs database and are owned by the system administrator.

Many of them can be run from any database. If a catalog stored procedure is executed from a database other than sybsystemprocs, it retrieves information from the system tables in the database from which it was executed.

All catalog stored procedures execute at isolation level 1.

All catalog stored procedures report a return status. For example, this means that the procedure executed successfully. The examples in this book do not include the return status:

```
return status = 0
```

2.1 Specifying Optional Parameters

Use single or double quotes around parameter values for catalog stored procedures that contain punctuation or embedded blanks, or are reserved words. If the parameter is an object name qualified by a database name or owner name, enclose the entire name in single or double quotes.

i Note

Do not use delimited identifiers as catalog stored procedure parameters. Doing so may produce unexpected results.

In many cases, it is more convenient to supply parameters to the catalog stored procedures in this form than to supply all the parameters:

```
@<parametername> = <value>
```

The parameter names in the syntax statements match the parameter names defined by the procedures.

For example, the syntax for sp columns is:

```
sp_columns <table_name>[, <table_owner>]
    [, <table_qualifier>][, <column_name>]
```

You can use sp column to find information about a particular column, such as:

```
sp_columns publishers, @column_name = "pub_id"
```

This provides the same information as the command with all of the parameters specified:

```
sp_columns publishers, "dbo", "pubs2", "pub_id"
```

You can also use "null" as a placeholder:

```
sp columns publishers, null, null, "pub id"
```

If you specify more parameters then the number of parameters expected by the system procedure, the SAP ASE server ignores the extra parameters.

2.2 Pattern Matching

SAP ASE supports wildcards $_$, \$, [], and $[^]$. For maximum interoperability, use only the \$ and $_$ wildcard characters as defined by ANSI SQL Standards.

2.3 System Procedure Tables

The catalog stored procedures <code>sp_columns</code>, <code>sp_datatype_info</code>, <code>sp_special_columns</code>, and <code>sp_sproc_columns</code> use the catalog stored procedure tables <code>spt_datatype_info</code>, <code>spt_datatype_info_ext</code>, and <code>spt_server_info</code> in the <code>sybsystemprocs</code> database to convert internal system values such as status bits into human-readable format.

The catalog stored procedures <code>sp_column_privileges</code> and <code>sp_table_privileges</code> create and then drop temporary tables.

2.4 ODBC Datatypes

These two tables list the datatype code numbers and matching datatype names returned by $sp_columns$ and $sp_column_privileges$ in the data_type column. The source for the description is the Open Database Connectivity (ODBC) Application Programming Interface (API).

Table 19: Code Numbers for ODBC Datatypes

Datatype	Code #
char	1
decimal	3
double precision	8
float	6
integer	4

Datatype	Code #
numeric	2
real	7
smallint	5
varchar	12
wchar	-8
wvarchar	-9
wlongvarchar	-10
Table 20: Code Numbers for Extended Datatypes	
Datatype	Code #
bigint	-5
binary (bit datatype)	-2
bit	-7
date	9
java.lang.Object	1111
long univarchar	-10
long varbinary	-4
long varchar	-1
time	10
timestamp	11
tinyint	-6
unichar	-8
univarchar	-9
varbinary (bit-varying datatype)	-3

2.5 sp_column_privileges

Returns permissions information for one or more columns in a table or view.

Syntax

Parameters

<table_name>

is the name of the table. The use of wildcard characters in pattern matching is not supported.

<table_owner>

is the name of the table owner. The use of wildcard characters in pattern matching is not supported. If you do not specify the table's owner, <code>sp_column_privileges</code> looks for a table owned by the current user and then for a table owned by the Database Owner.

<table_qualifier>

is the name of the database. Values are the name of the current database and null.

<column_name>

is the name of the column with permissions that you want to display. Use wildcard characters to request information for more than one column. If you do not specify a column name, permissions information for all columns in the specified table is returned.

Examples

Example 1

This example displays information about the discounts table:

```
sp_column_privileges discounts, null, null, discounttype

table_qualifier table_owner table_name column_name
    grantor grantee privilege is_grantable

pubs2 dbo discounts discounttype
    dbo dbo SELECT YES
```

pubs2	dbo	discounts	discounttype
dbo	dbo	UPDATE YES	
pubs2	dbo	discounts	discounttype
dbo	dbo	REFERENCE YES	
pubs2	dbo	discounts	discounttype
dbo	guest	SELECT NO	
pubs2	dbo	discounts	discounttype
dbo	guest	UPDATE NO	
pubs2	dbo	discounts	discounttype
dbo	guest	REFERENCE NO	

Usage

The results set for <code>sp_column_privileges</code> is:

Column	Datatype	Description
table_qual ifier	varchar(3 2)	The name of the database in which the table specified for the <table_name> parameter is stored.</table_name>
table_owne	varchar(3 2)	The table owner. If no value was specified for the <table_owner> parameter, this value is the current owner or the Database Owner.</table_owner>
table_name	varchar(3 2)	The name specified for the <table_name> parameter. This value cannot be NULL.</table_name>
column_nam	varchar(3 2)	The specified column name. If no column name was specified in the statement, the results include all columns in the specified table.
grantor	varchar(3 2)	The name of the database user who has granted permissions on column_name to grantee. This value cannot be NULL.
grantee	varchar(3 2)	The name of the database user who was granted permissions on column_name by grantor. This value cannot be NULL.
privilege	varchar(3 2)	 Identifies the column privilege. May be one of the following: SELECT – The grantee is permitted to retrieve data for the column. UPDATE – The grantee is permitted to update data in the column. REFERENCE – The grantee is permitted only for referential constraint.
is_grantab le	varchar(3	Indicates whether the grantee is permitted to grant the privilege to other users. The values are YES, NO, and NULL.

Permissions

Any user can execute ${\tt sp_column_privileges}.$

2.6 sp_columns

Returns information about the type of data that can be stored in one or more columns.

Syntax

```
sp_columns <table_name>[, <table_owner>]
    [, <table_qualifier>][, <column_name>]
```

Parameters

<table_name>

is the name of the table or view. Use wildcard characters to request information about more than one table.

<table_owner>

is the owner of the table or view. Use wildcard characters to request information about tables owned by more than one user. If you do not specify a table owner, <code>sp_columns</code> looks for tables owned by the current user and then for tables owned by the Database Owner.

<table_qualifier>

is the name of the database. This can be either the current database or NULL.

<column_name>

is the name of the column for which you want information. Use wildcard characters to request information about more than one column.

Examples

Example 1

Displays information about all columns in the publishers table that begin with "p":

```
sp_columns "publishers", null, null, "p%"

table_qualifier table_owner table_name column_name data_type type_name pr
ecision length scale radix nullable remarks ss_data_type colid

pubs2 dbo publishers pub_id 1 char
NULL 4 NULL NULL 0 NULL 47 1
pubs2 dbo publishers pub_name 12 varchar
NULL 40 NULL NULL 1 NULL 39 2
```

Example 2

Displays information about all columns beginning with "st" in tables that begin with "s":

```
sp_columns "s%", null, null, "st%"
```

Usage

The results set for sp_columns is:

Column	Datatype	Description
table_qualifi	varchar(3 2)	The name of the database in which the table specified for the <table_name> parameter is stored.</table_name>
table_owner	varchar(3 2)	The table owner. If no value was specified for the <table_owner> parameter, this value is the current owner or the Database Owner.</table_owner>
table_name	varchar(3	NOT NULL.
column_name	varchar(3	NOT NULL.
data_type	smallint	Integer code for ODBC datatype. If this is a datatype that cannot be mapped into an ODBC type, it is NULL.
type_name	varchar(3 0)	String representing a datatype. The underlying DBMS presents this datatype name.
precision	int	Number of significant digits.
length	int	Length in bytes of a datatype.
scale	smallint	Number of digits to the right of the decimal point.
radix	smallint	Base for numeric datatypes.
nullable	smallint	The value 1 means NULL is possible; 0 means NOT NULL.
remarks	varchar(2 54)	
ss_data_type	smallint	An SAP ASE datatype.
colid	tinyint	A column appended to the results set.

Column	Datatype	Description
column_def	varchar(2 55)	NULL.
sql_data_type	smallint	An SAP ASE datatype.
sql_datetime_ sub	smallint	NULL.
<pre>char_octet_le ngth</pre>	int	The value of char_octet_length is the same as the value for the precision column if the datatype for char_octet_length is:
		• binary
		• char
		• image
		• nchar
		• nvarchar
		• sysname
		• text
		• timestamp
		• varbinary
		• varchar
		Otherwise, the value of char_octet_length is 0.
ordinal_posit	int	The ordinal position of the column in the table. The first column in the table is 1 .
is_nullable	varchar(3	Describes whether the column or parameter allows NULL as a value. From syscolumns.

 ${\tt sp_columns}\ reports\ the\ {\tt type_name}\ as\ float, and\ {\tt data_type}\ as\ 6\ for\ columns\ defined\ as\ {\tt double}\ precision.$ The SAP ASE double precision datatype is a float implementation supports the range of values as specified in the ODBC specifications.

Permissions

Any user can execute ${\tt sp_columns}.$

2.7 sp_databases

Returns a list of databases in the SAP ASE server.

Syntax

sp_databases

Examples

Example 1

Returns a list of databases in the server:

sp_databases		
database_name	database_size	remarks
master	5120	NULL
model	2048	NULL
mydb	2048	NULL
pubs2	2048	NULL
sybsecurity	5120	NULL
sybsystemprocs	16384	NULL
tempdb	2048	NULL

Usage

The results set for $sp_databases$ is:

Column	Datatype	Description
database_name	char(32)	NOT NULL database name.
database_size	bigint	Size of database, in kilobytes.
remarks	varchar(254)	SAP ASE always returns NULL.

Permissions

Any user can execute sp_databases.

2.8 sp_datatype_info

Returns information about a particular ODBC datatype or about all ODBC datatypes.

Syntax

```
sp_datatype_info [<data_type>]
```

Parameters

<data_type>

is the code number for the specified ODBC datatype about which information is returned.

Usage

The results set for sp_datatype_info is:

Column	Datatype	Description
type_name	varchar(3 0)	A DBMS-dependent datatype name (the same as the type_name column in the sp_columns results set).
data_type	smallint	A code for the ODBC type to which all columns of this type are mapped.
precision	int	The maximum precision for the datatype on the data source. Zero is returned for datatypes where precision is not applicable.
literal_prefix	varchar(3 2)	Character(s) used to prefix a literal. For example, a single quotation mark (') for character types and 0x for binary.
literal_suffix	varchar(3 2)	Character(s) used to terminate a literal. For example, a single quotation mark (') for character types and nothing for binary.
create_params	varchar(3 2)	A description of the creation parameters for this datatype.
nullable	smallint	The value 1 means this datatype can be created allowing null values; 0 means it cannot.

Column	Datatype	Description
case_sensitive	smallint	The value 1 means all columns of this type are case sensitive (for collations); 0 means they are not.
searchable	smallint	The value 1 means columns of this type can be used in a where clause.
unsigned_attri bute	smallint	The value 1 means the datatype is unsigned; 0 means the datatype is signed.
money	smallint	The value 1 means it is a money datatype; 0 means it is not.
auto_increment	smallint	The value 1 means the datatype is automatically incremented; 0 means it is not.
local_type_nam e	varchar(1 28)	Localized version of the data source dependent name of the datatype.

Any user can execute sp_datatype_info.

2.9 sp_fkeys

Returns information about foreign key constraints created with the create table or alter table command in the current database.

Syntax

```
sp_fkeys <pktable_name>[, <pktable_owner>]
    [, <pktable_qualifier>][,< fktable_name>]
    [,< fktable_owner>][,< fktable_qualifier>]
```

Parameters

<pktable_name>

is the name of the primary key table. The use of wildcard characters in pattern matching is not supported. You must specify either the $\protect\operatorname{pktable_name}$ or the $\protect\operatorname{fktable_name}$, or both.

<pktable_owner>

is the name of the primary key table owner. The use of wildcard characters in pattern matching is not supported. If you do not specify the table owner, <code>sp_fkeys</code> looks for a table owned by the current user and then for a table owned by the Database Owner.

<pktable_qualifier>

is the name of the database that contains the primary key table. This can be either the current database or NULL.

<fktable name>

is the name of the foreign key table. The use of wildcard characters in pattern matching is not supported. Either the <fktable_name> or the <pktable_name>, or both, must be given.

<fktable_owner>

is the name of the foreign key table owner. The use of wildcard characters in pattern matching is not supported. If an <fktable_owner> is not specified, sp_fkeys looks for a table owned by the current user and then for a table owned by the database owner.

<fktable_qualifier>

is the name of the database that contains the foreign key table. This can be either the current database or null.

Usage

The results set for sp fkeys is:

Column	Datatype	Description
<pre>pktable_qual ifier</pre>	varchar(3 2)	The database that contains the primary key table.
pktable_owne	varchar(3 2)	The owner of the primary key table.
pktable_name	varchar(3 2)	NOT NULL.
pkcolumn_nam	varchar(3 2)	NOT NULL.
fktable_qual ifier	varchar(3 2)	The database that contains the foreign key table.
fktable_owne	varchar(3 2)	The owner of the foreign key table.

Column	Datatype	Description
fktable_name	varchar(3 2)	NOT NULL.
fkcolumn_nam	varchar(3 2)	NOT NULL.
key_seq	smallint	NOT NULL. The sequence number of the column in a multicolumn primary key.
update_rule	smallint	Action to be applied to the foreign key when the SQL operation is UPDATE. Zero is returned for this column.
delete_rule	smallint	Action to be applied to the foreign key when the SQL operation is DELETE. Zero is returned for this column.

There are additional considerations when using sp fkeys:

- sp_fkeys returns information about foreign key constraints created with the create table or alter table command in the current database. A foreign key is a key column in a table that logically depends on a primary key column in another table.
- Both the primary key and foreign key must have been declared in acreate table or alter table statement.
- If the primary key table name is supplied, but the foreign key table name is NULL, sp_fkeys returns all tables that include a foreign key to the given table. If the foreign key table name is supplied, but the primary key table name is NULL, sp_fkeys returns all tables that are related by a primary key/foreign key relationship to foreign keys in the foreign key table.
- sp_fkeys does not return information about keys declared with sp_commonkey, sp_foreignkey, or sp_primarykey.

See also alter table, create table in Reference Manual: Commands.

Permissions

Any user can execute sp fkeys.

Related Information

sp_commonkey [page 191] sp_foreignkey [page 387] sp_primarykey [page 677]

2.10 sp_pkeys

Returns information about primary key constraints created with the create table or alter table command for a single table.

Syntax

```
sp_pkeys <table_name> [, <table_owner>] [, <table_qualifier>]
```

Parameters

<table_name>

is the name of the table. The use of wildcard characters in pattern matching is not supported.

<table_owner>

is the name of the table owner. The use of wildcard characters in pattern matching is not supported. If <table_owner> is not specified, sp_pkeys looks for a table owned by the current user and then for a table owned by the Database Owner.

is the name of the database that contains the table. This can be either the current database or NULL.

Usage

The results set for sp pkeys is:

Column	Datatype	Description
table_quali fier	varchar(32)	The database name. This field can be NULL.
table_owner	varchar(32)	The table owner. If no value was specified for the <table_owner> parameter, this value is the current owner or the Database Owner.</table_owner>
table_name	varchar(32)	NOT NULL.
column_name	varchar(32)	NOT NULL.
key_seq	smallint	NOT NULL. The sequence number of the column in a multicolumn primary key.

Primary keys must have been declared with the create table or alter table statement, not with $sp_primarykey$.

The term primary key refers to a logical primary key for a table. The SAP ASE server expects that every logical primary key has a unique index defined on it and that this unique index is also returned in <code>sp_statistics</code>.

See also alter table, create table in Reference Manual: Commands.

Permissions

Any user can execute sp_pkeys.

Related Information

sp_primarykey [page 677]
sp_statistics [page 881]

2.11 sp_server_info

Returns a list of SAP ASE attribute names and current values.

Syntax

sp_server_info [<attribute_id>]

Parameters

<attribute_id>

is the integer ID of the server attribute.

Examples

Example 1

Returns a list of server attributes for attribute ID 12:

Example 2

Returns the list of server attributes, described by the mandatory rows, and their values:

```
sp_server_info
```

Usage

The results set for sp_server_info is:

Column	Datatype	Description
attribute_id	int	NOT NULL.
attribute_name	varchar(60)	NOT NULL.
attribute_value	varchar(255)	

The mandatory rows in the results set returned by sp_server_info are:

ID	Server Attribute Name	Description	Value
1	DBMS_NAME	Name of the DBMS.	SQL SERVER
2	DBMS_VER	The value used by the ODBC driver to determine version compatibility.	Actual value
		i Note Do not change the value of DBMS_VER. This is not the same as @@version, and the value must match the value used by the ODBC driver.	
6	DBE_NAME	Unused	
10	OWNER_TERM	SAP ASE server's term for a table owner (the second part of a three-part name).	owner

ID	Server Attribute Name	Description	Value
11	TABLE_TERM	SAP ASE server's term for a table (the third part of a three-part name).	table
12	MAX_OWNER_NAME_LENGTH	Maximum length of the name for a table owner (the second part of a three-part name).	30
13	TABLE_LENGTH	The maximum number of characters for a table name.	30
14	MAX_QUAL_LENGTH	Maximum length of the name for a table qualifier (the first part of a three-part table name).	30
15	COLUMN_LENGTH	The maximum number of characters for a column name.	30
16	IDENTIFIER_CASE	The case sensitivity of user-defined names (table names, column names, and stored procedure names) in the database (the case in which these objects are presented in the system catalogs).	MIXED
18	COLLATION_SEQ	The assumed ordering of the character set for this server.	
19	SAVEPOINT_SUPPORT	Does the underlying DBMS support named savepoints?	Y
20	MULTI_RESULT_SETS	Does the underlying DBMS or the gateway itself support multiple results sets (can multiple statements be sent through the gateway, with multiple results sets returned to the client)?	Υ
22	ACCESSIBLE_TABLES	In sp_tables, does the gateway return only tables, views, and so on, that are accessible by the current user (that is, the user who has at least select privileges for the table)?	Y
100	USERID_LENGTH	The maximum number of characters for a user name.	30
101	QUALIFIER_TERM	SAP ASE server's term for a table qualifier (the first part of a three-part name).	database
102	NAMED_TRANSACTIONS	Does the underlying DBMS support named transactions?	Y
103	SPROC_AS_LANGUAGE	Can stored procedures be executed as language events?	Y
103	REMOTE_SPROC	Can stored procedures be executed through the remote stored procedure APIs in DB-Library?	Y
104	ACCESSIBLE_SPROC	In sp_stored_procedures, does the gateway return only stored procedures that are executable by the current user?	Y

ID	Server Attribute Name	Description	Value
105	MAX_INDEX_COLS	Maximum number of columns in an index for the DBMS.	32
106	RENAME_TABLE	Can tables be renamed?	Y
107	RENAME_COLUMN	Can columns be renamed?	Y
108	DROP_COLUMN	Can columns be dropped?	Y
109	INCREASE_COLUMN_LENGTH	Can column size be increased?	N
110	DDL_IN_TRANSACTION	Can DDL statements appear in transactions?	Y
111	DESCENDING_INDEXES	Are descending indexes supported?	Y
112	SP_RENAME	Can a stored procedure be renamed?	Y
500	SYS_SPROC_VERSION	The version of the catalog stored procedures currently implemented.	01.01.2822

Any user can execute sp_server_info.

2.12 sp_special_columns

Returns the optimal set of columns that uniquely identify a row in a table or view; can also return a list of timestamp columns, with values that are automatically generated when any value in the row is updated by a transaction.

Syntax

```
sp_special_columns <table_name> [, <table_owner>]
    [, <table_qualifier>] [, <col_type>]
```

Parameters

<table_name>

is the name of the table or view. The use of wildcard characters in pattern matching is not supported.

<table_owner>

is the name of the table or view owner. The use of wildcard characters in pattern matching is not supported. If you do not specify the table owner, sp_special_columns looks for a table owned by the current user and then for a table owned by the Database Owner.

<table_qualifier>

is the name of the database. This can be either the current database or NULL.

<col_type>

is "R" to return information about columns with values that uniquely identify any row in the table, or "V" to return information about timestamp columns, with values that are generated by the SAP ASE server each time a row is inserted or updated.

Examples

Example 1

Returns the optimal set of columns for systypes:

```
sp_special_columns systypes

scope column_name data_type type_name precision length scale
0 name 12 varchar 30 30 NULL
```

Example 2

Returns the optimal set from the from the authors table with values that uniquely identify any row in the table:

```
sp_special_columns @table_name=authors, @col_type=R

scope column_name data_type type_name precision length scale

0 au_id 12 varchar 11 11 NULL
```

Usage

The results set for sp special columns is:

Column	Datatype	Description
scope	int	NOT NULL. Actual scope of the row ID. The SAP ASE server always returns 0.

Column	Datatype	Description
column_name	varchar(30)	NOT NULL. Column identifier.
data_type	smallint	The integer code for an ODBC datatype. If this datatype cannot be mapped to an ANSI/ISO type, the value is NULL. The native datatype name is returned in the type_name column.
type_name	varchar(13)	The string representation of the datatype. This is the datatype name as presented by the underlying DBMS.
precision	int	The number of significant digits.
length	int	The length in bytes of the datatype.
scale	smallint	The number of digits to the right of the decimal point.

Any user can execute $sp_special_columns$.

2.13 sp_sproc_columns

Returns information about a stored procedure's input and return parameters.

Syntax

```
sp_sproc_columns columns column=name[, column_name]
```

Parameters

cprocedure_name>

is the name of the stored procedure. The use of wildcard characters in pattern matching is not supported.

cprocedure_owner>

is the owner of the stored procedure. The use of wildcard characters in pattern matching is not supported. If no owner is specified, $sp_sproc_columns$ returns all columns.

cprocedure_qualifier>

is the name of the database. This can be either the current database or NULL.

<column name>

is the name of the parameter about which you want information. If you do not supply a parameter name, <code>sp_sproc_columns</code> returns information about all input and return parameters for the stored procedure.

Usage

The results set for sp sproc columns is:

Column	Datatype	Description
<pre>procedure_qual ifier</pre>	varchar(3 0)	Procedure qualifier name. Can be NULL.
procedure_owne	varchar(3	Procedure owner name. Always returns a value.
procedure_name	varchar(4 1)	Procedure name. Always returns a value.
column_name	varchar(3	Column name for each column of the <table_name> returned. Always returns a value.</table_name>
column_type	smallint	
data_type	smallint	The integer code for an ODBC datatype. If this datatype cannot be mapped to an ANSI/ISO type, the value is NULL. The native datatype name is returned in the type_name column.
type_name	char(30)	The string representation of the datatype. This is the datatype name as presented by the underlying DBMS.
precision	int	The number of significant digits.
length	int	The length in bytes of the datatype.
scale	smallint	The number of digits to the right of the decimal point.
radix	smallint	The base for numeric types.
nullable	smallint	The value 1 means this datatype can be created allowing null values; 0 means it cannot.

Column	Datatype	Description
remarks	varchar(2 54)	The description of the procedure column. NULL.
ss_data_type	tinyint	An SAP ASE datatype.
colid	tinyint	The column ID from syscolumns.
column_def	varchar(2 55)	NULL.
sql_data_type	smallint	An SAP ASE datatype.
sql_datetime_s	smallint	NULL.
char_octet_len gth	int	The value of char_octet_length is the same as the value for the precision column if the datatype for char_octet_length is: • binary • char • image • nchar • nvarchar • sysname • text • timestamp • varbinary • varchar Otherwise, the value of char_octet_length is 0.
ordinal_positi	int	The ordinal position of the parameter in the parameter list. The first parameter in the list is 1, and return values have an ordinal.
is_nullable	varchar(3	Describes whether the column or parameter allows NULL as a value. From syscolumns.
mode	varchar(2 0)	 For SQL procedures – in, out, or "return value". For SQLJ procedures (Java) – in, out, inout, or "return value".

 $sp_sproc_columns$ reports the $type_name$ as float, and $data_type$ as 6 for parameters defined as double precision. The SAP ASE double precision datatype is a float implementation supports the range of values as specified in the ODBC specifications.

Any user can execute sp sproc columns.

2.14 sp_statistics

Returns a list of indexes on a single table.

Syntax

```
sp_statistics <table_name>[, <table_owner>][, <table_qualifier>]
    [, <index_name>][, <is_unique>]
```

Parameters

<table_name>

is the name of the table. The use of wildcard character pattern matching is not supported.

<table_owner>

is the owner of the table. The use of wildcard character pattern matching is not supported. If <table_owner> is not specified, sp_statistics looks for a table owned by the current user and then for a table owned by the database owner.

<table_qualifier>

is the name of the database. This can be either the current database or NULL.

<index_name>

is the index name. The use of wildcard character pattern matching is not supported.

<is_unique>

is ${\tt Y}$ to return only unique indexes; otherwise, is ${\tt N}$ to return both unique and nonunique indexes.

Examples

Example 1

Shows the list of indexes for publishers:

```
sp statistics publishers
```

```
table_qualifier table_owner table_name non_unique index_qualifier index_name type seq_in_index column_name
                                               collation
  cardinality pages
  _____
   NULL 0 NULL NULL 3
pubs2
              dbo publishers NULL
                           NULL
  NULL
                                               NULL
                          dbo
pubs2
                              0
pubind
  publishers
   publishers
publishers
1
               1 pub_id
1
```

Usage

The results set for sp_statistics is:

Column	Datatype	Description
table_quali fier	varchar(The database name. This field can be NULL.
table_owner	varchar(
table_name	varchar(32)	NOT NULL.
non_unique	smallint	NOT NULL. The value 0 means unique, and 1 means not unique.
index_quali fier	varchar(32)	
index_name	varchar(32)	
type	smallint	NOT NULL. The value 0 means clustered, 2 means hashed, and 3 means other.
seq_in_inde	smallint	NOT NULL.
column_name	varchar(NOT NULL.
collation	char(1)	The value A means ascending; D means descending; and NULL means not applicable.

Column	Datatype	Description
cardinality	int	Number of rows in the table or unique values in the index.
pages	int	Number of pages to store the index or table.

The indexes in the results set appear in ascending order, ordered by the non-unique, type, index_name, and seq_in_index columns.

The index type hashed accepts exact match or range searches, but searches involving pattern matching do not use the index.

Permissions

Any user can execute sp statistics.

2.15 sp_stored_procedures

Returns information about one or more stored procedures.

Syntax

```
sp stored procedures [<sp name>[, <sp owner>[, <sp qualifier>]]]
```

Parameters

<sp_name>

is the name of the stored procedure. Use wildcard characters to request information about more than one stored procedure.

<sp_owner>

is the owner of the stored procedure. Use wildcard characters to request information about procedures that are owned by more than one user.

<sp_qualifier>

is the name of the database. This can be the current database or NULL.

Usage

The results set for sp_stored_procedures is:

Column	Datatype	Description
procedure_quali fier	varchar(3 0)	The name of the database.
procedure_owner	varchar(3 0)	
procedure_name	varchar(4	NOT NULL.
<pre>num_input_param s</pre>	int	NOT NULL. Always returns -1.
num_output_para ms	int	NOT NULL. The value >= 0 shows the number of parameters; -1 means the number of parameters is indeterminate.
num_result_sets	int	NOT NULL. Always returns -1.
remarks	varchar(2 54)	NULL.

sp_stored_procedures returns information about stored procedures in the current database only.

sp_stored_procedures can return the name of stored procedures for which the current user does not have
execute permission. However, if the server attribute accessible_sproc is "Y" in the results set for
sp_server_info, only stored procedures that are executable by the current user are returned.

Permissions

Any user can execute <code>sp_stored_procedures</code>.

Related Information

sp_server_info [page 873]

2.16 sp_table_privileges

Returns privilege information for all columns in a table or view.

Syntax

```
sp_table_privileges <table_name>[, <table_owner>[, <table_qualifier>]]
```

Parameters

<table_name>

is the name of the table. The use of wildcard characters in pattern matching is not supported.

<table_owner>

is the name of the table owner. The use of wildcard characters in pattern matching is not supported. If you do not specify the table owner, <code>sp_table_privileges</code> looks for a table owned by the Current user and then for a table owned by the Database Owner.

<table_qualifier>

is the name of the database. This can be either the current database or NULL.

Usage

The results set for sp_table_privileges is:

Column	Datatype	Description
table_qual ifier	varchar(32)	The name of the database. This field can be NULL.
table_owne	varchar(32)	
table_name	varchar(32)	NOT NULL.
grantor	varchar(32)	NOT NULL.

Column	Datatype	Description
grantee	varchar(32)	NOT NULL.
privilege	varchar(32)	 SELECT – The grantee is permitted to retrieve data for one or more columns of the table. INSERT – The grantee is permitted to insert rows containing data. UPDATE – The grantee is permitted to update the data in one or more columns of the table. DELETE – The grantee is permitted to delete rows of data from the table. REFERENCE – The grantee is permitted to refer to one or more columns of the table within a constraint.
is_grantab le	varchar(3)	Indicates whether the grantee is permitted to grant the privilege to other users. The values are YES, NO, and NULL.

Any user can execute <code>sp_table_privileges</code>.

2.17 sp_tables

Returns a list of objects that can appear in a from clause.

Syntax

sp_tables [<table_name>] [, <table_owner>][, <table_qualifier>][, <table_type>]

Parameters

<table_name>

is the name of the table. Use wildcard characters to request information about more than one table.

<table_owner>

is the table owner. Use wildcard characters to request information about more than one table.

<table_qualifier>

is the name of the database. Acceptable values are the name of the current database and NULL.

<table_type>

is a list of values, separated by commas, giving information about all tables of the table type(s) specified, including the following:

```
"'TABLE', 'SYSTEM TABLE', 'VIEW'"
```

i Note

Enclose each table type with single quotation marks, and enclose the entire parameter with double quotation marks. Enter table types in uppercase.

Examples

Example 1

This example returns information about all tables in the current database of the type TABLE and VIEW and excludes information about system tables:

```
sp_tables @table_type = "'TABLE', 'VIEW'"
```

Usage

The results set for sp_tables is:

Column	Datatype	Description
table_qualifi er	varchar(30	The database name. This field can be NULL.
table_owner	varchar(30	
table_name	varchar(30	NOT NULL. The table name.
table_type	varchar(32	NOT NULL. One of the following: 'TABLE', 'VIEW', 'SYSTEM TABLE'.

Column	Datatype	Description
remarks	varchar(25	NULL

- The SAP ASE server does not necessarily check the read and write permissions on <table_name>. Access to the table is not guaranteed, even if you can display information about it.
- The results set includes tables, views, and synonyms and aliases for gateways to DBMS products.
- If the server attribute accessible_tables is "Y" in the results set for sp_server_info, only tables that are accessible by the current user are returned.

Any user can execute <code>sp_tables</code>.

Tables used

master.dbo.sysattributes, master.dbo.sysloginroles, master.dbo.syssrvroles, sysroles

Related Information

sp_server_info [page 873]

3 System Extended Stored Procedures

System extended stored procedures (ESPs) are supplied by SAP.

- ESPs are created by installmaster during the installation process. They are located in the sybsystemprocs database and owned by the system administrator. They can be run from any database.
- Permissions are set in the sybsystemprocs database.
 Users with the sa_role have default execution permissions on the system ESPs. These System Administrators can grant execution permissions to other users.
- You can get the names of the DLLs associated with the system ESPs by running sp_helpextendedproc in the sybsystemprocs database.
- The system ESPs follow the same calling conventions as the regular system procedures. The only additional requirement for system ESPs is that the Open Server application, XP Server, must be running. The SAP ASE server starts XP Server the first time an ESP is invoked. XP Server continues to run until you shut down the SAP ASE server.

3.1 xp_cmdshell

Executes a native operating system command on the host system running the SAP ASE server.

Syntax

```
xp cmdshell <command>[, no output] [return status | no wait]
```

Parameters

<command>

is the operating system command string; maximum length is 8192 bytes.

no_output

if specified, suppresses any output from the command.

return_status

if specified, returns the completion status of the operating system command specified in the command parameter. If you do not use this parameter, the returned value is either 0 for success, or or 1 for failure, respectively.

no wait

if specified, the $xp_cmdshell$ operation immediately returns to the caller and the specified command executes as a background process. You see no output, and the returned result reflects only the success or failure of starting the command as a background process, not the success or failure of the process itself.

Examples

Example on Windows

Silently copies the file named log on the C drive to a file named log.0102 on the A drive:

```
xp_cmdshell 'copy C:\log A:\log.0102', no_output
```

Example on UNIX

Executes the operating system's 1s command and returns the list directory contents as a row of data:

```
xp cmdshell 'ls'
```

Usage

There are additional considerations when using xp cmdshell:

- xp_cmdshell returns any output, including operating system errors, as rows of text in a single column.
- xp cmdshell is run from the current directory of the XP Server.
- The width of the column of returned output is 80 characters. The output is not formatted.
- xp cmdshell cannot perform commands that require interaction with the user, such as "login".
- The user context in which an operating system command is executed via xp_cmdshell is controlled by the value of the xp_cmdshell context configuration parameter. If this parameter is set to 1 (the default), xp_cmdshell restricts permission to users with System Administration privileges at the operating system level. If this parameter is set to 0, xp_cmdshell uses the security context of the operating system account under which the SAP ASE server is running. Therefore, using xp_cmdshell with the xp_cmdshell context configuration parameter set to 0, any user can execute operating system commands using the permissions of the account running the SAP ASE server. This account may have fewer restrictions than the user's own account.
- Regardless of the value of xp_cmdshell context, if the user who is executing xp_cmdshell is not a system administrator (does not have the sa_role), a system administrator must have granted that user explicit permission to execute xp_cmdshell. For example, the following statement grants "joe" permission to execute xp_cmdshell:

```
grant execute on xp_cmdshell to joe
```

• To find out if xp_cmdshell was successful in spawning an external command XP Server, enter the following, where <command> is the name of the command you ran with xp_cmdshell:

```
exec @ret = xp_cmdshell <command>
```

If $xp_cmdshell$ was successful, exec @ret = $xp_cmdshell$ <command> returns a value of 0. If $xp_cmdshell$ failed, exec @ret = $xp_cmdshell$ <command> returns a value of 1.

• To find out if the command you ran using xp_cmdshell was itself successful, enter the following, where <command > is the name of the command you ran with xp_cmdshell:

```
exec @ret = xp_cmdshell <command>, return_status
```

exec @ret = xp_cmdshell <command>, return_status causes xp_cmdshell to return the actual exit status code of the command. If a failure occurs and XP Server cannot run the command, xp_cmdshell returns a value of 1. If the command runs successfully, xp_cmdshell returns a value of 0. If the command was successful, exec @ret = xp_cmdshell <command> returns a value of 0. If the command failed, exec @ret = xp cmdshell <command> returns a value of 1.

i Note

Both exec @ret = xp_cmdshell <command> and exec @ret = xp_cmdshell <command>, return_status are backward-compatible. Old stored procedures that do not use the return_status parameter treat exec @ret = xp_cmdshell <command>, return_status as if it were exec @ret = xp_cmdshell <command>.

Also, the no output parameter can still be used in combination with return status, in any order.

• You must use the <code>cmdstr</code> column name when you create a proxy table with the <code>xp_cmdshell</code> remote procedure:

```
create existing table xpoutput
(
          cmdstr varchar(255) null
)
external procedure at "THIS...xp_cmdshell"
select cmdstr from xpoutput where cmdstr = "date"
```

If you do not use cmdstr, you see an error message.

See Remote Procedures as Proxy Tables in the Component Integration Services User's Guide for more information about results returned from the proxy table.

See also System Administration Guide.

Permissions

By default, only a system administrator can execute $xp_cmdshell$. A system administrator can grant execute permission to other users.

3.2 xp_enumgroups

(Windows only) Displays groups for a specified Windows domain.

Syntax

```
xp_enumgroups [<domain_name>]
```

Parameters

<domain name>

is the Windows domain for which you are listing user groups.

Examples

Example 1

Lists all user groups on the Windows computer running XP Server:

```
xp_enumgroups
```

Example 2

Lists all user groups in the PCS domain:

```
xp_enumgroups 'PCS'
```

Usage

There are additional considerations when using xp_enumgroups:

- xp enumgroups displays all local user groups if no parameter is passed.
- A *domain* is a named collection of computers that share a common user account database and security policy.
- A return status of 0 indicates success; 1 indicates failure.

By default, only a system administrator can execute $xp_enumgroups$. A system administrator can grant this permission to other users.

3.3 xp_logevent

(Windows only) Provides for logging a user-defined event in the Windows Event Log from within the SAP ASE server.

Syntax

```
xp_logevent <error_number>, <message>[, <type>]
```

Parameters

<error_number>

is the user-assigned error number. It must be equal to or greater than 50000.

<message>

is the text of the message that is displayed in the description field of the event viewer. The maximum length of the message is 255 bytes. Enclose the message in quotes.

<type>

describes the urgency of the event. Values are informational, warning, and error. The default is informational. Enclose the value in quotes.

Examples

Example 1

An informational event, number 55555, is logged in the Windows Event Log. The text of the description in the event detail window is "Email message deleted":

```
xp_logevent 55555, 'Email message deleted.'
```

Example 2

An error event, number 66666, is logged in the Windows Event Log. The text of the description in the event detail window is "DLL not found":

```
xp_logevent 66666, 'DLL not found.', 'error'
```

Usage

The following table describes the default event details for events generated with xp_logevent:

User N/A

Computer Name of machine running XP Server

Event ID 12

Source Name of the SAP ASE server

Category User

Permissions

Only a system administrator can execute ${\tt xp_logevent}.$

4 dbcc Stored Procedures

dbcc stored procedures access the tables only in the dbccdb database or in the alternate database, dbccalt.

See the System Administration Guide for details on setting up dbccdb or dbccalt. See dbccdb Tables in Reference Manual: Tables for information on the tables used in these databases.

For details on the dbcc system procedure sp_plan_dbccdb, see sp_plan_dbccdb. See the System Administration Guide for more information on this system procedure and the dbcc stored procedures.

The permission checks for dbcc stored procedures differ based on your granular permissions settings. See the *Security Administration Guide* for more information on granular permissions.

4.1 Specifying the Object Name and Date

Several dbcc stored procedures use parameters for the object name and date. This section provides important information on specifying the object name and date.

4.1.1 Specifying the Object Name

The object name specifies only the name of the table or index for which to generate a report. When you specify an object name, you must also specify a database name (<dbname>). You cannot specify an owner for the object. If the specified object name is not unique in the target database, the system procedure generates a report on all objects with the specified name.

4.1.2 Specifying the Date

Use the following syntax to specify the date and time (optional):

mm/dd/yy[:hh:mm:ss]

A 24-hour clock is assumed.

When you specify the date, the system procedures interpret it as follows:

- If both the date and the time are specified, the dbcc operation that completed at the specified date and time is selected for the report.
- If the specified date is the current date, and no time is specified, the time is automatically set to the current time. The dbcc operation that completed within the previous 24 hours with a finish time closest to the current time is selected for the report.

• If the specified date is not the current date, and no time is specified, the time is automatically set to "23:59:59". The dbcc checkstorage operation that completed with a finish date and time closest to the specified date and system-supplied time is selected for the report.

For example, suppose the most recent dbcc checkstorage operation completed on March 4, 1997 at 10:20:45.

If you specify the date as "03/04/97", the system procedure interprets the date as 03/04/97:23:59:59. This date and time are compared to the actual finish date and time of 03/04/97:10:20:45.

If you specify the date as "03/04/97:10:00:00", the operation that completes at 10:20:45 is not selected for the report because only the operations that complete on or before the specified time meet the criteria.

If you specify the date as "03/06/97", no report is generated because the most recent operation completed more than 24 hours earlier.

4.2 sp_dbcc_alterws

Changes the size of the specified workspace to a specified value, and initializes the workspace.

Syntax

sp dbcc alterws <dbname>, <wsname>, "<wssize>[K|M]"

Parameters

<dbname>

is the name of the database in which the workspace resides. Specify either dbccdb and dbccalt.

<wsname>

specifies the name of the workspace to alter.

<wssize>

is the new size of the workspace, specified by \mathbb{K} (kilobytes) or \mathbb{M} (megabytes). If you do not specify \mathbb{K} or \mathbb{M} , <wssize> specifies the number of pages. Page size is platform-dependent. The minimum size for a workspace is 24 pages.

Examples

Example 1

Changes the size of the scan ws 000001 workspace on dbccdb to 30 MB:

```
sp_dbcc_alterws dbccdb, scan_ws_000001, "30M"
```

Workspace scan ws 000001 has been altered successfully to size 30MB

Usage

There are additional considerations when using sp dbcc alterws:

- sp_dbcc_alterws changes the size of the specified workspace to the specified value and initializes the workspace.
- To achieve maximum performance, make sure you have configured a buffer pool of at least 16K before you alter a workspace.
- Use sp plan dbccdb to determine size estimates before altering the workspace.
- The workspace must exist before it can be altered. For information on creating workspaces, see sp_dbcc_createws.
- To delete a workspace, in dbccdb issue:

```
drop table <workspace name>
```

See also:

- dbcc in Reference Manual: Commands
- See the System Administration Guide for more information on the scan and text workspaces, and the dbccalt database.

Permissions

The permission checks for sp dbcc alterws differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt).

Disabled

Related Information

sp_dbcc_createws [page 899]

```
sp_dbcc_evaluatedb [page 907]
sp_plan_dbccdb [page 667]
sp_helpdb [page 438]
```

4.3 sp_dbcc_configreport

Generates a report that describes the configuration information used by the dbcc checkstorage operation for the specified database.

Syntax

```
sp dbcc configreport [<dbname>]
```

Parameters

<dbname>

specifies the name of the database. If <dbname> is not specified, the report contains information on all databases in dbccdb..dbcc operation log.

Examples

Example 1

Generates a report on the configuration information related to dbcc for the sybsystemprocs database. The Value column lists the object name, where applicable, and the size:

```
sp dbcc configreport
Reporting configuration information of database sybsystemprocs.
Parameter Name
                            Value
                                                          Size
                            sybsystemprocs
                                                          51200K
database name
dbcc named cache
                            default data cache
                                                          1024K
                            textws 001 (id = 544004969)
                                                          128K
text workspace
                            scanws 001 (id = 512004855)
scan workspace
                                                         1024K
max worker processes
operation sequence number
```

Usage

There are additional considerations when using sp_dbcc_configreport:

- sp_dbcc_configreport generates a report that describes the configuration information used by dbcc operations for the specified database. This information is stored in the dbcc_config table.
- To evaluate the most current configuration parameters, run sp_dbcc_updateconfig before running sp_dbcc_configreport.
- To change the configuration values for a workspace, use <code>sp_dbcc_alterws</code>.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for <code>sp_dbcc_configreport</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.

Disabled With granular permissions disabled, any valid user for the database name specified can run sp_dbcc_configreport.

Related Information

```
sp_dbcc_alterws [page 896]
sp_dbcc_fullreport [page 916]
sp_dbcc_statisticsreport [page 925]
sp_dbcc_summaryreport [page 928]
sp_dbcc_updateconfig [page 931]
```

4.4 sp_dbcc_createws

Creates a workspace of the specified type and size on the specified segment and database.

Syntax

```
sp_dbcc_createws <dbname>, <segname>, [<wsname>], <wstype>, "wssize[K|M]"
```

Parameters

<dbname>

is the name of the database in which the workspace is to be created. Values are dbccdb and dbccalt.

<segname>

is the name of the segment for the workspace.

<wsname>

is the name of the workspace. If the value is null, <code>sp_dbcc_createws</code> generates the name <code>scan_wsnnnnn</code> for the <code>scan</code> workspace and <code>text_wsnnnnn</code> for the <code>text</code> workspace, where <code><nnnnnn></code> is a unique 6-digit number.

<wstype>

specifies the type of workspace to be create. Values are scan and text.

<wssize>

is the workspace size, specified with K (kilobytes) or M (megabytes). If you do not specify K or M, <wssize> specifies the number of pages. The minimum size for a workspace is 24 pages.

Examples

Example 1

Creates a 10MB scan workspace named scan wspubs2 on the scanseg segment in dbccdb:

```
sp_dbcc_createws dbccdb, scanseg, scan_wspubs2, scan, "10M"
```

Example 2

Creates a 14MB scan workspace named text ws000001 on the textseg segment in dbccdb:

```
sp dbcc createws dbccdb, textseg, text, "14M"
```

Usage

There are additional considerations when using sp dbcc createws:

- sp dbcc createws creates a workspace with the specified name and size and initializes it.
- Before you create a workspace, create the segment with <code>sp_addsegment</code>.
- Before you create a workspace, make sure you have configured a buffer pool of at least 16K, to achieve maximum performance.
- When you create a workspace, make sure to add a 5 percent overhead on the space needed on the device because of large page allocation scheme used when creating the workspace.
- Use sp plan dbccdb to determine size estimates.

- After creating a workspace, run sp_dbcc_updateconfig to record the new configuration information in dbcc config.
- Each workspace must have a unique name.
- To delete a workspace, in dbccdb issue:

```
drop table <workspace name>
```

See also:

- dbcc in Reference Manual: Commands
- See the System Administration Guide for more information on the scan and text workspaces, and the dbccalt database.

Permissions

The permission checks for sp_dbcc_createws differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt).

Disabled With granular permissions disabled, you must be the database owner of dbccdb (or dbccalt), or have sa_role to run sp_dbcc_createws.

Related Information

```
sp_addsegment [page 56]
sp_dbcc_alterws [page 896]
sp_dbcc_evaluatedb [page 907]
sp_dbcc_updateconfig [page 931]
sp_plan_dbccdb [page 667]
sp_helpsegment [page 479]
```

4.5 sp_dbcc_deletedb

Deletes from dbccdb all the information related to the specified target database.

Syntax

```
sp_dbcc_deletedb [<dbname> | <dbid>]
```

Parameters

<dbname>

specifies the name of the target database for which you want the configuration information deleted. If you do not specify a value for <dbname>, the server deletes data from all databases in dbccdb..dbcc_config. If the target database is dbccdb, and dbccalt exists, the SAP ASE server deletes the data from dbccalt.

<dbid>

specifies the database ID number of the target database for which you want the configuration information deleted.

Examples

Example 1

Deletes all information for the database named engdb from dbccdb:

```
sp_dbcc_deletedb "engdb"
```

Usage

There are additional considerations when using <code>sp_dbcc_deletedb</code>:

- sp_dbcc_deletedb deletes from dbccdb all the information related to the specified target database, including configuration information and the results of previous dbcc_checkstorage_operations.
- If the deleted database is dbccdb, and the dbccalt database exists, sp_dbcc_deletedb deletes the configuration information and results of dbccdb from dbccalt.
- To remove the results of dbcc checkstorage operations created before a specific date, use sp_dbcc_deletehistory.
- Using the <dbid> option is the only way to delete the contents of the dbccdb database for a database that has already been dropped.

See also:

- dbcc in Reference Manual: Commands
- System Administration Guide for information about the dbccalt database.

Permissions

The permission checks for sp dbcc deletedb differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or

have the , the manage checkstorage privilege on the specified database.

Disabled With granular permissions disabled, you must be the database owner of the specified database or

have sa_role to run sp dbcc deletedb.

Related Information

sp_dbcc_deletehistory [page 903] sp_dbcc_evaluatedb [page 907] sp_plan_dbccdb [page 667]

4.6 sp_dbcc_deletehistory

Deletes the results of dbcc checkstorage operations performed on the target database before the specified date and time.

i Note

 $sp_dbcc_deletehistory$ does not free any space associated with the deleted historical data, as workspaces are pre-allocated and of a fixed size.

Syntax

```
sp_dbcc_deletehistory [<cutoffdate>[, <dbname> | <dbid>]]
```

Parameters

<cutoffdate>

deletes all entries made on or before this date. This parameter is of type datetime. If a date is not specified, only the results of the last operation are retained.

<dbname>

specifies the name of the database for which the data must be deleted. If not specified, sp_dbcc_deletehistory deletes the history information for all databases in dbccdb..dbcc_config.

<dbid>

specifies the database ID number of the target database for which you want the history information deleted.

Examples

Example 1

Deletes results of all operations performed on the database pubs2 on or before March 4, 1997:

```
sp dbcc deletehistory "03/04/1997", "pubs2"
```

Usage

There are additional considerations when using <code>sp_dbcc_deletehistory</code>:

- sp_dbcc_deletehistory deletes the results of dbcc checkstorage operations performed on the target database before the specified date and time.
- If the target database is dbccdb, and the dbccalt database exists, sp_dbcc_deletehistory deletes historical data for dbccdb from dbccalt.
- The value specified for <cutoffdate> is compared to the finish time of each dbcc operation.
- Use the <dbid> option to delete the historical data of the dbccdb database for a database that has already been dropped.
- Using the <dbid> option is the only way to delete the historical data of the dbccdb database for a database that has already been dropped.
- To see the dates when dbcc checkstorage was run so that you can choose the value for <cutoffdate>, run sp_dbcc_summaryreport.

See also:

- dbcc in Reference Manual: Commands
- System Administration Guide for information on the dbccalt database.

Permissions

The permission checks for sp dbcc deletehistory differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the manage checkstorage privilege on the specified database.

Disabled With granular permissions disabled, you must be the database owner of the specified database or a user with sa_role to run sp_dbcc_deletehistory on a specific database. Only a user with sa_role can run sp_dbcc_deletehistory without specifying a database name.

Related Information

```
Specifying the Date [page 895]
sp_dbcc_deletedb [page 901]
sp_dbcc_evaluatedb [page 907]
sp_dbcc_summaryreport [page 928]
sp_plan_dbccdb [page 667]
```

4.7 sp_dbcc_differentialreport

Generates a report that highlights the changes in I/O statistics and faults that took place between two dbcc operations.

Syntax

```
sp_dbcc_differentialreport [<dbname> [, <objectname>]],
        [<db_op>] [, "<date1>" [, "<date2>"]]
```

Parameters

<dbname>

specifies the name of the database. If you do not specify a <dbname>, the report contains information on all databases in dbccdb..dbcc operation log.

<objectname>

specifies the name of the table or index for which you want the report generated. If <object_name> is not specified, statistics on all objects in the target database are reported.

<db op>

specifies the source of the data to be used for the report. The only value is checkstorage. The report is generated on the data specified by <db_op> on <date1> and <date2> for the specified object in the target database. If dates are not specified, the last two operations of the type <db op> are compared.

<date1>

specifies the first date of a dbcc checkstorage operation to be compared.

<date2>

specifies the last date of a dbcc checkstorage operation to be compared.

Examples

Example 1

Generates a report that shows the changes in I/O statistics and faults that occurred in the sysprocedures table between May 1, 1997 and May 4, 1997:

```
sp_dbcc_differentialreport master, sysprocedures,
     checkstorage, "05/01/97", "05/04/97"
```

Usage

There are additional considerations when using sp_dbcc_differentialreport:

- sp_dbcc_differentialreport generates a report that highlights the changes in I/O statistics and faults that occurred between two dbcc operations. It compares counter values reported from two instances of dbcc_checkstorage. Only the values that have been changed are reported.
- If only one date is specified, the results of the dbcc checkstorage operation selected by the specified date are compared to the results of the dbcc checkstorage operation immediately preceding the selected operation.
- If no dates are specified, the results of last two dbcc checkstorage operations are compared.
- If sp_dbcc_differentialreport returns a number for <object_name>, it means the object was dropped after the dbcc_checkstorage operation completed.
- If no changes occurred between the specified operations, <code>sp_dbcc_differentialreport</code> does not generate a report.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for $sp_dbcc_differentialreport$ differ based on your granular permissions settings.

Setting	Description
Enabled	With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.
Disabled	With granular permissions disabled, any valid user for the specified database can run sp dbcc differentialreport.

Related Information

```
sp_dbcc_fullreport [page 916]
sp_dbcc_statisticsreport [page 925]
sp_dbcc_summaryreport [page 928]
sp_dbcc_updateconfig [page 931]
```

4.8 sp_dbcc_evaluatedb

Recomputes configuration information for the target database and compares it to the current configuration information.

Syntax

```
sp_dbcc_evaluatedb [<dbname>]
```

Parameters

<dbname>

specifies the name of the target database. If you do not specify <dbname>, sp_dbcc_evaluatedb compares all databases listed in the dbcc_config table.

Examples

Example 1

Recomputes configuration information for the current database, sybsystemprocs, and suggests new values for some parameters:

```
1> sp dbcc evaluatedb
2> go
Recommended values for workspace size, cache size and process count are:
Database name : one_G
                                      current
                                                      suggested
scan workspace size :
                                         750M
                                                            16M
text workspace size :
                                           2K
                                                            48K
                                       10240K
cache size
                                                          1280K
process count
```

```
compression mem size: 2048K 12M  
Each of the reported quantities is reported in a scaled unit according to G if size > 10G M if 10M < \text{size} <=10 G K otherwise
```

Usage

There are additional considerations when using sp dbcc evaluatedb:

- When there is an archive database with a compressed data or log device, the output includes a line with the recommendation of the compression memory size.
- sp dbcc evaluatedbdbcc counters table.
- The cache size is the size of the 16K buffer pool in the cache. For a 2K buffer pool, the minimum size of this cache must be the recommended value, plus 512. recomputes configuration information for the target database and compares the data to the current configuration information. It uses counter values recorded for the target database in the
- When the size and data distribution pattern of the target database changes, run sp_dbcc_evaluatedb to optimize the configuration information.
- To gather configuration information for the target database the first time, use sp plan dbccdb.
- To make sure you are evaluating the most current configuration parameters, run sp_dbcc_updateconfig recomputes configuration before running sp_dbcc_evaluatedb.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for sp_dbcc_evaluatedb differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the manage checkstorage privilege on the specified database.

Disabled With granular permissions disabled, you must be the database owner of the specified database, a user with sa_role. Only a system administrator can run sp_dbcc_evaluatedb without specifying a database name.

Related Information

sp_dbcc_updateconfig [page 931]
sp_plan_dbccdb [page 667]

4.9 sp_dbcc_exclusions

Allows the user to create and manage persistent exclusion lists for use by checkverify and sp dbcc faultreport.

Syntax

```
sp_dbcc_exclusions <dbname>, <op>, <type>, <exclusion_list>
```

Parameters

<dbname>

is the name of the database for which the exclusions apply, or null if it applies to all databases.

<op>

is the operation you want to perform. Valid values are:

- add registers new exclusions (duplicates are ignored).
- drop drops the specified exclusions if they were previously registered
- listall lists the recorded exclusions for all databases.

<type>

is the type of item to be excluded. Accepted values are faults, tables, <combo>, or null (when <op> is either null or listall). Type, varchar.

<exclusion list>

is a comma-separated list of faults, tables, table and fault entries, or nulls. Type, varchar.

Examples

Example 1

Excludes the tables syslogs and syscomments from sp_dbcc_faultreport processing on all databases:

```
sp_dbcc_exclusions null, 'add', 'tables', 'syslogs, syscomments'
```

Example 2

Excludes fault type 100036 from processing of the database my_db :

```
sp_dbcc_exclusions my_db, 'add', 'faults', '100036'
```

Example 3

Adds the following to the exclusion list corresponding to my_db : fault type 100002 pertaining to table mytable and fault type 100035 pertaining to syslogs:

```
sp dbcc exclusions my db, 'add', 'combo', 'mytable:100002, syslogs:100035'
```

Example 4

Removes fault type 100036 from the exclusion list corresponding to my_db :

```
sp_dbcc_exclusions my_db, 'drop', 'faults', '100036'
```

Example 5

Displays the exclusion list corresponding to my_db:

```
sp_dbcc_exclusions my_db
```

Example 6

Displays the recorded exclusions for all databases:

```
sp_dbcc_exclusions null, 'listall'
```

Usage

There are additional considerations when using sp dbcc exclusions:

- <dbname> must be null when <listall> is specified. If <op> is null, sp_dbcc_exclusions lists the recorded exclusions for the specified database.
- Only a system administrator or the Database Owner can run sp_dbcc_exclusions with a <dbname> parameter that is not null.
- If the <dbname> and <op> parameters are null, the user must either be a system administrator or own at least one of the databases for which exclusions have been recorded.
- If the <dbname> parameter is null and the <op> parameter is <listall>, the user must either be a system administrator or own at least one of the databases for which exclusions have been recorded. If the user is not a system administrator, only the recorded exclusions for databases owned by the user are reported.

Permissions

The permission checks for sp dbcc exclusions differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the manage checkstorage privilege on the specified database.

Disabled With granular permissions disabled, you must be a user with sa_role.

4.10 sp_dbcc_faultreport

Generates a report covering fault statistics for the dbcc checkstorage operations performed for the specified object in the target database on the specified date. The report lists the tables and indexes in order.

Syntax

Parameters

<report type>

specifies the type of fault report. Valid values are short and long. The default is short.

<dbname>

specifies the name of the target database; for example, master..sysdatabases. If <dbname> is not specified, the report contains information on all databases in dbccdb..dbcc operation log.

<object_name>

specifies the name of the table or index for which you want the report generated. If <object_name> is not specified, statistics on all objects in the target database are reported.

<date>

specifies exact date and time that the dbcc checkstorage operation finished. You can find this value in dbcc_operation_log.finish. You can create the value by combining the date from start time and the hours and minutes from end time in the $sp_dbcc_summaryreport$ output. If you do not specify <date>, the SAP ASE server uses the date of the most recent operation.

When you specify the <date> parameter, be certain that the time you enter is later than the date of the operation. $sp_dbcc_faultreport$ cannot report faults that occur later than the time you enter in this parameter.

i Note

To focus on the <date> parameter, use "null" for all other parameters. If you omit a parameter entirely, $sp_dbc_faultreport$ cannot generate a correct report.

<hard only>

enables the reporting of hard faults when you specify 1. Valid values are 0 or 1, and the default is 0.

<display recommendations>

enables reporting the recommendations generated by sp_dbcc_recommendations,
and the parameters <exclusion_mode>, <exclusion_faults>,

<exclusion_tables>, <display_recommendations>, and <exclusion_combo>
refer to exclusion support and are optional.

<exclusion mode>

is a varchar and is on by default. To disable this, you must provide an "ignore" each time the sp dbcc faultreport is run. Use either of the following:

- ignore ignores the persistent exclusion list and uses the temporary exclusion list, if one is provided (type, varchar).
- extend applies the temporary exclusion list as well as the persistent exclusion list (type, varchar).

<exclusion faults>

is a comma-separated list of fault types to be excluded from reporting (type, varchar).

<exclusion tables>

is a comma-separated list of tables to be excluded from reporting (type is varchar).

<exclusion combo>

is a comma-separated list of fault/table combinations to be excluded from reporting (type is varchar).

<opid>

enables fault reporting for a specific—instead of latest—operation ID for a specific date. No operation ID is specified by default.

<fault_type_in>

enables fault reporting for a specific fault type. The default is NULL.

Examples

Example 1

Generates a short report of the faults found in tables in the sybsystemprocs database. The report includes the table name, the index number in which the fault occurred, the type code of the fault, a brief description of the fault, and the page number on which the fault occurred:

Example 2

Generates a long report of the faults found in tables in the sybsystemprocs database. This example shows the first part of the output of a long report. The complete report repeats the information for each object in the target database in which dbcc checkstorage found a fault. The data following the long string of numbers shown under the "page header" field ("Header for 14151, next 14216, previous 14150 ...") describes the components of the "page header" string:

```
Sp_dbcc_faultreport "long"

Generating 'Fault Report' for object sysprocedures in database sybsystemprocs.
Type Code: 100031; Soft fault, possibly spurious
Page reached by the chain is not allocated.
page id: 14151
page header:
0x00003747000037880000374600000005000648B803EF0001000103FE0080000F
Header for 14151, next 14216, previous 14150, id = 5:1
  time stamp = 0x0001000648B8, next row = 1007, level = 0
  free offset = 1022, minlen = 15, status = 128(0x0080)
.
.
.
```

Example 3

Generates a short report of faults from all tables on all databases, for an operation finished at a date and time found as an End Time, from the output of sp_dbcc_summaryreport. It is important that you use accurate end times in the <date> parameter; for instance, if you enter:

```
7/25/2000 9:58
```

instead of

```
7/25/2000 9:58:0:190
```

the report generates faults only up to 9:58, not after it. You could use 9:59 if you do not want to enter the exact time the operation ends:

In this case, the report generates faults up to 9:59.

Example 4

Generates a short form report only for hard faults reported by the latest checkstorage run for a database called mydb:

```
sp_dbcc_faultreport short, mydb, @hard_only = 1
```

Example 5

Adds recommended fixes to the fault report of database my db:

```
sp_dbcc_faultreport @dbname = my_db,
    @display_recommendations = 1
```

Example 6

Generates a fault report that does not contain fix recommendations:

```
sp_dbcc_faultreport @dbname = my_db
```

Example 7

Runs sp dbcc faultreport on database my db with the persistent exclusion list disabled:

```
sp_dbcc_faultreport @dbname = 'my_db', @exclusion_mode = 'ignore'
```

Example 8

Runs sp_dbcc_faultreport on database my_db with the persistent exclusion list enabled and extended to exclude from processing fault type 100036:

Example 9

Runs sp_dbcc_faultreport on database my_db with the persistent exclusion list enabled and extended to exclude from processing and the table tab:

Example 10

Runs $sp_dbcc_faultreport$ on database my_db with the persistent exclusion list disabled and an enabled temporary exclusion list that excludes from processing the table tab and fault type 100036:

Example 11

Runs $sp_dbcc_faultreport$ on database my_db with the persistent exclusion list disabled and an enabled temporary exclusion list that excludes from processing fault type '100002' pertaining to the table mytable and fault type 100035 pertaining to the table tab:

Example 12

Generates a long form report for the 100029 faults reported by the latest checkstorage run for the mydb database (100029 is the fault type for page header errors):

```
sp_dbcc_faultreport long, mydb, @fault_type_in = 100029
```

Example 13

Generates a short form report for faults reported by the checkstorage run with operation ID 5 for the mydb database:

```
sp_dbcc_faultreport short, mydb, @opid = 5
```

Usage

There are additional considerations when using sp dbcc faultreport:

- sp_dbcc_faultreport generates a report that shows all faults for the specified object in the target database.
- sp dbcc faultreport issues numerous error message number 10028 If you use:
 - sp_placeobject to make an object that has existing allocations put new allocations on a new segment.
 - sp_dropsegment to remove a segment from a fragment that contains allocations of an object assigned to that segment.

Error message number 100028 is an informational message rather than an indication of a serious error. If you prefer not to receive such messages, you can create your own reporting procedure that does not report this (or any other) error. One way to do this is to add the following to the very beginning of the standard sp dbcc faultreport stored procedure in the installdbccdb script:

```
print "removing 100028 errors from dbcc_faults table"
delete dbcc_faults where type_code = 100028
```

• If sp_dbcc_faultreport returns a number for <object_name>, it means the object was dropped after the dbcc_checkstorage operation completed.

See also:

- dbcc in Reference Manual: Commands
- type code in the System Administration Guide for information on the fault ID and on the fault status.

Permissions

The permission checks for sp dbcc faultreport differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.

Disabled With granular permissions disabled, any valid user for the database name specified can run sp dbcc faultreport.

Related Information

sp_dbcc_fullreport [page 916] sp_dbcc_statisticsreport [page 925] sp_dbcc_summaryreport [page 928] sp_dbcc_updateconfig [page 931]

4.11 sp_dbcc_fullreport

Runs $sp_dbcc_summaryreport, sp_dbcc_configreport, sp_dbcc_statisticsreport, and <math>sp_dbcc_faultreport short for < database>..<object_name> on or before the specified < date>..$

Syntax

```
sp dbcc fullreport [<dbname> [, <objectname> [, <date>]]]
```

Parameters

<dbname>

specifies the name of the database. For example, master..sysdatabases. If you do not specify <dbname>, the report contains information on all databases in dbccdb..dbcc operation log.

<object name>

specifies the name of the table or index for which you want the report generated. If you do not specify <object_name>, statistics on all objects in the target database are reported.

<date>

specifies the date on which the dbcc checkstorage operation was performed. If you do not specify a <date>, the date of the last operation is used.

Examples

Example 1

Runs $sp_dbcc_summaryreport$, $sp_dbcc_configreport$, $sp_dbcc_statisticsreport$, and $sp_dbcc_faultreport$ short for the most recent dbcc checkstorage operation run on the sysprocedures table in the master database:

```
sp_dbcc_fullreport master, sysprocedures
```

Usage

```
\label{lem:spdbcc_summary} $$ sp_dbcc_summary report, sp_dbcc_configreport, $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database..object_name on or before the specified date $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database..object_name on or before the specified date $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_faultreport short for database... $$ sp_dbcc_statistics report, and $$ sp_dbcc_statistics report, and $$ sp_dbcc_statistics report, and sp_dbcc_statistics report, and
```

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for sp dbcc fullreport differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.

Disabled With granular permissions disabled, any valid user for the database name specified can run sp_dbcc_fullreport.

Related Information

```
sp_dbcc_configreport [page 898]
sp_dbcc_faultreport [page 911]
sp_dbcc_statisticsreport [page 925]
sp_dbcc_summaryreport [page 928]
sp_dbcc_updateconfig [page 931]
```

4.12 sp_dbcc_help_fault

Provides a description of the specified fault type and the recommended fix.

Syntax

```
sp dbcc help fault [<fault type>]
```

Parameters

<fault_type>

is the fault type for which a description and recommended fix should be reported. This parameter is type int. If <fault_type> is not provided, $sp_dbcc_help_fault$ reports on all fault types.

Examples

Example 1

To view a description of fault type 100038, and its recommended fix, enter:

```
sp dbcc help fault 100038
```

Example 2

To view a description of all fault types and their recommended fixes, enter:

```
sp_dbcc_help_fault
```

Usage

 $sp_dbcc_help_fault$ provides a description of the specified fault type and the recommended fix.

Permissions

The permission checks for sp dbcc help fault differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt).

 $\textbf{Disabled} \quad \textbf{With granular permissions disabled, any user can run } \texttt{sp_dbcc_help_fault}.$

4.13 sp_dbcc_patch_finishtime

Facilitates reporting on aborted checkverify and checkstorage operations.

Syntax

```
sp_dbcc_patch_finishtime <dbname>, <opid> [,<optype> [,<seq> [,<finishtime>]]]
```

Parameters

<dbname>

is the name of the database checkstoragecheckverify was operating on when it aborted. This parameter's type is or varchar.

<opid>

is the operation ID corresponding to the aborted operation. This parameter's type is ${\tt smallint}.$

<optype>

oris the type of operation you are investigating. Accepted values are either 'checkstorage' or 'checkverify'. This parameter's type is varchar.

<seq>

is the checkverify sequence number (not used for checkstorage but required for checkverify). This parameter's type is smallint.

<finishtime>

is a datetime value representing the time the checkstorage or checkverify operation aborted. The default value is the current time.

Examples

Example 1

Enables reporting on checkstorage and checkverify for database my_db when the following errors occur:

```
dbcc checkstorage (my_db)

Checking my_db: Logical pagesize is 2048 bytes
00:00000:00014:2003/01/20 11:50:05.01 server Error: 9960,
Severity: 20, State: 1
A non-recoverable error has occurred in the CHECKSTORAGE operation. The
```

Example 2

Enables reporting on checkstorage and checkverify for database my_db when the following errors occur:

Execute sp dbcc patch finishtime with the information included in the error message:

```
sp_dbcc_patch_finishtime my_db, 1
```

Usage

When a checkstorage or checkverify operation aborts, it prints a message that contains the operation's ID and the name of the database that was being examined when the operation aborted. An aborted checkverify operation also provides a sequence number in the message. The message instructs the user to run sp_dbcc_patch_finishtime, and provides the <dbname>, <opid>, and if it was a checkverify operation, the sequence number, <seq>. After executing sp_dbcc_patch_finishtime, you can create fault reports on the aborted operation.

Permissions

The permission checks for sp dbcc patch finishtime differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the manage checkstorage privilege on the specified database.

Setting Description

Disabled With granular permissions disabled, you must be the database owner of the specified database or a user with sa_role.

4.14 sp_dbcc_recommendations

Analyzes faults reported by the checkstorage operation corresponding to the specified operation ID, or date, and generates a list of recommended corrective actions for the specified object in the target database.

Syntax

```
sp_dbcc_recommendations dbname [,"<date>"[, <opid>[, "<objectname>"]]]
```

Parameters

<dbname>

is the name of the database for which recommendations are generated. Type is varchar, and this parameter is required.

<date>

is a datetime value representing the date and time the dbcc checkstorage operation (for which the reported faults are analyzed) finished. If you do not specify <date> or <opid>, the SAP ASE server uses the date of the most recent operation. If you specify both <date> and <opid>, the SAP ASE server ignores the date. <date> is optional.

<opid>

is the operation ID of the <code>checkstorage</code> operation, for which the reported faults are analyzed. If an <code><opid></code> or <code><date></code> is not specified, the SAP ASE server uses the date of the most recent operation. If both <code><date></code> and <code><opid></code> are specified, the SAP ASE server ignores the <code><date></code>. The type for this parameter is <code>int</code>.

<objectname>

is the name of the object for which <code>sp_dbcc_recommendations</code> generates the recommendations. If an <code><objectname></code> is not specified, recommendations for all objects in the database are generated. The type for this parameter is <code>varchar</code>.

Examples

Example 1

Generates a list of recommended fixes for the object t1, in database my_db , based on the faults reported by the checkstorage operation corresponding to operation id 2:

```
sp_dbcc_recommendations my_db, null, 2, 't1'
```

Example 2

Generates a list of recommended fixes for all objects in database my_db, based on the faults reported by the checkstorage operation that finished on September 15, 2002 at 7:10:18:463PM:

```
sp_dbcc_recommendations my_db, 'Sep 15 2002 7:10:18:463PM'
```

Example 3

Generates a list of recommended fixes for all objects in database my_db , based on the most recent checkstorage operation:

```
sp_dbcc_recommendations my_db
```

Usage

sp_dbcc_recomendations analyzes faults reported by the checkstorage operation corresponding to the specified operation ID, or date, and generates a list of recommended corrective actions for the specified object in the target database

Permissions

The permission checks for sp dbcc recommendations differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or report checkstorage privilege on the specified database.

Disabled With granular permissions disabled, any valid user of the specified database can run sp dbcc recommendations.

4.15 sp_dbcc_runcheck

Runs dbcc checkstorage on the specified database, then runs $sp_dbcc_summaryreport$ or a report you specify.

Syntax

```
sp_dbcc_runcheck <dbname>[, <user_proc>]
```

Parameters

<dbname>

specifies the name of the database on which the check is to be performed.

<user_proc>

specifies the name of the dbccsp dbcc sunmmaryreport.

Examples

Example 1

Checks the database engdb and generates a summary report on the information found: stored procedure or a user-created stored procedure that is to be run instead of

```
sp dbcc runcheck "engdb"
```

Example 2

Checks the database pubs2 and runs the $sp_dbcc_fullreport$ stored procedure and generates a full report:

```
sp_dbcc_runcheck "pubs2", sp_dbcc_fullreport
```

Example 3

Checks the database pubs2 and runs the $sp_dbcc_recommendations$ stored procedure:

```
sp_dbcc_runcheck "pubs2", sp_dbcc_recommendations
```

Usage

There are additional considerations when using sp dbcc runcheck:

- sp dbcc runcheck runs dbcc checkstorage on the specified database.
- When you include the <code>sp_dbcc_recommendations</code> as the <code><user_proc></code>, <code>sp_dbcc_runcheck</code> also runs dbcc checkstorage and dbcc checkverify against the specified database.
- If sp_dbcc_runcheck discovers any errors while running, it then automatically runs dbcc_checkverify in order to confirm or dismiss soft faults from checkstorage before running sp_dbcc_summaryreport.
- After the dbcc_checkstorage operation is complete, <code>sp_dbcc_runcheck</code> runs <code>sp_dbcc_summaryreport</code> to generate a summary report. If you specify one of the other report-generating <code>dbcc_stored</code> procedures for <code><dbcc_report></code>, <code>sp_dbcc_runcheck</code> runs that procedure instead of <code>sp_dbcc_summaryreport</code>. See the <code>System Administration Guide</code> for a brief description and examples of all the report-generating stored procedures provided with <code>dbccdb</code>.
- You can write your own report-generating stored procedure and specify its name for user_proc. The stored procedure must be self-contained. sp_dbcc_runcheck cannot pass any parameters to the SAP ASE server.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for <code>sp_dbcc_runcheck</code> differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must have the dbcc checkstorage and dbcc checkvverify privileges on the specified database.

Disabled With granular permissions disabled, you must be the database owner of the specified database or a user with sa_role.

Related Information

sp_dbcc_summaryreport [page 928]

4.16 sp_dbcc_statisticsreport

Generates an allocation statistics report on the specified object in the target database.

Syntax

```
sp_dbcc_statisticsreport [<dbname> [, <objectname> [, <date>]]]
```

Parameters

<dbname>

specifies the target database. If <dbname> is not specified, the report contains information on all databases in dbccdb..dbcc operation log.

<objectname>

specifies the name of the table or index for which you want the report generated. If you do not specify <objectname>, the SAP ASE server reports statistics on all objects in the target database.

<date>

specifies the date on which the dbcc checkstorage operation was performed. If you do not specify <date>, the SAP ASE server uses the date of the most recent operation.

Examples

Example 1

Generates a statistics report on the sysobjects table in the sybsystemprocs database:

```
Statistics Report on object sysobjects in database
sybsystemprocs
Parameter Name
                          Index Id Value
                          0

Usage

There are additional considerations when using $sp_dbcc_statisticsreport$:

- sp_dbcc_statisticsreport generates an allocation statistics report on the specified object in the target database. It uses data from the dbcc_counters table, which stores information about page utilization and error statistics for every object in the target database.
- If sp_dbcc_statisticsreport returns a number for <object_name>, it means the object was dropped after the dbcc_checkstorage operation completed.
- sp_dbcc_statisticsreport reports values recorded in the dbcc_counters table for the datatypes 5000-5024.

For bytes data, bytes used, and overflow pages, sp_dbcc_statisticsreport reports the sum of the values reported for all partitions and devices.

For count, max size and max level, sp_dbcc_statisticsreport reports the largest of the values reported for all partitions and devices.

sp_dbcc_statisticsreport reports information for each device and partition used by objects in the target database for the following rows:

o extents used

- o io errors
- o page gaps
- o page extent crosses
- o page extent gaps
- o page format errors
- o pages reserved
- o pages overhead
- o pages misallocated
- o pages not allocated
- o pages not referenced
- o pages used

The page gaps, page extent crosses, and page extent gaps indicate how the data pages for the objects are distributed on the database devices. Large values indicate less effectiveness in using larger buffer sizes and in data prefetch.

• If multiple dbcc checkstorage operations were run on a target database on the same day, sp_dbcc_statisticsreport generates a report based on the results of the last dbcc checkstorage operation that finished before the specified time.

- dbcc in Reference Manual: Commands
- dbcc counters in Reference Manual: Tables

Permissions

The permission checks for $sp_dbcc_statisticsreport$ differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.

 $\begin{tabular}{ll} \textbf{Disabled} & \textbf{With granular permissions disabled, any valid user for the database name specified can run } & \textbf{sp_dbcc_statisticsreport} \\ \end{tabular}$

Related Information

sp_dbcc_fullreport [page 916]
sp_dbcc_summaryreport [page 928]
sp_dbcc_updateconfig [page 931]

4.17 sp_dbcc_summaryreport

Generates a summary report on the specified database.

Syntax

sp_dbcc_summaryreport [dbname[, date[, op_name[, <display_recommendations>]]]]

Parameters

<dbname>

specifies the name of the database for which you want the report generated. If you do not specify <dbname>, sp_dbcc_summaryreport generates reports on all databases in dbccdb..dbcc_operation_log for which the date is on or before the date and time specified by the <date> option.

<date>

specifies the date on which dbcc checkstorage was performed. If you do not specify a date, sp_dbcc_summaryreport uses the date of last dbcc checkstorage operation performed on the target database. This parameter is of the datatype datetime. If both the date and the time are specified for <date>, summary results of all the operations performed on or before the specified time are reported. If no date is specified, all operations are reported.

<opname>

specifies the operation. <opname> may be either checkstorage, which is the default,
or checkverify, or both. If <opname> is not specified, reports are generated for all
operations.

<display_recommendations>

enables reporting the recommendations generated by $sp_dbcc_recommendations$

Examples

Example 1

Generates a summary report on the sybsystemprocs database, providing information on all dbcc checkstorage and operations performed:dbcc checkverify

sp dbcc summaryreport

Example 2

```
      sp_dbcc_summaryreport "testdb"

      DBCC Operation : checkstorage

      Database Name Start time End Time Operation ID

      Hard Faults Soft Faults Text Columns Abort Count User Name

      testdb 05/11/1999 14:55:29 14:55:49:903 1

      0 0 0 sa

      testdb 05/11/1999 14:55:50 14:56:9:546 2

      0 0 0 sa

      testdb 05/11/1999 14:56:28 14:56:40:666 3

      0 0 0 sa
```

Example 3

Generates a summary report on the sybsystemprocs database, providing information on all dbcc checkverify operations performed. Because dbcc checkverify was the specified operation, no dbcc checkstorage information appears on the report:

Example 4

Generates a summary report on the sybsystemprocsDBCC Operation: checkstorage database, providing information on all dbcc checkstorage operations performed. Because dbcc checkstorage was the specified operation, no dbcc checkverify information appears on the report:

```
sybsystemprocs 05/11/1999 14:53:11 14:53:32:163 1 0 0 0 sa sa sybsystemprocs 05/11/1999 14:55:06 14:55:29:200 2 0 0 0 sa sybsystemprocs 05/11/1999 14:56:10 14:56:27:750 3 0 0 0 sa
```

Example 5

Adds recommended fixes to the summary report of database my db:

```
sp_dbcc_summaryreport @dbname = my_db, @display_recommendations = 1
```

Usage

There are additional considerations when using sp_dbcc_summaryreport:

- sp_dbcc_summaryreport generates a summary report of checkstorage or checkverify operations, or both, on the specified database.
- The report indicates the name of the database that was checked, the start and end time of the dbcc checkstorage run and the number of soft and hard faults found.
- The "Operation ID" column contains a number that identifies the results of each dbcc checkstorage operation on a given database at a specific time. The number provided in the report comes from the opid column of the dbcc operation log table. See the System Administration Guide for more information.
- The "Text Columns" column shows the number of non-null text columns found by dbcc checkstorage during the run.
- The "Abort Count" column shows the number of tables that contained errors, which caused dbcc checkstorage to abort the check on the table. For details on the errors, run sp dbcc faultreport.

See also dbcc in Reference Manual: Commands.

Permissions

The permission checks for sp dbcc summaryreport differ based on your granular permissions settings.

Setting Description

Enabled With granular permissions enabled, you must be the database owner of dbccdb (or dbccalt), or have the report checkstorage privilege on the specified database.

Disabled With granular permissions disabled, any valid user for the database name specified can run sp dbcc summaryreport.

4.18 sp_dbcc_updateconfig

Updates the dbcc config table in dbccdb with the configuration information of the target database.

Syntax

```
sp_dbcc_updateconfig <dbname>, <type>, "<str1>" [, "<str2>"]
```

Parameters

<dbname>

is the name of the target database for which configuration information is being updated. To configure the default values, enter a null <dbname> parameter.

<type>

specifies the type name from the dbcc types table.

<str1>

specifies the first configuration value for the specified <type> to be updated in the dbcc config table.

<str2>

specifies the second configuration value for the specified <type> that you want to update in the dbcc_config table.

Examples

Example 1

Updates $dbcc_config$ with the maximum number of worker processes for $dbcc_checkstorage$ to use when checking the pubs2 database. The new maximum number of worker processes is 4:

```
sp_dbcc_updateconfig pubs2, "max worker processes", "4"
```

Example 2

This sets the max worker processes to 2:

```
sp_dbcc_updateconfig null, 'max worker processes', '2'
```

Example 3

Updates dbcc config with the size of the dbcc named cache "pubs2_cache". The new size is 10K:

```
sp_dbcc_updateconfig pubs2, "dbcc named cache", pubs2_cache, "10K"
```

Example 4

Updates dbcc_config with the new name of the scan workspace for the pubs2 database. The new name is scan_pubs2. This update is made after using sp_dbcc_alterws to change the name of the scan workspace:

```
sp_dbcc_updateconfig pubs2, "scan workspace", scan_pubs2
```

Example 5

Updates $dbcc_config$ with the new name of the text workspace for the pubs2 database. The new name is text_pubs2. This update is made after using $sp_dbcc_alterws$ to change the name of the text workspace:

```
sp_dbcc_updateconfig pubs2, "text workspace", text_pubs2
```

Example 6

Updates dbcc config with the OAM count threshold value for the pubs2 database. The new value is 5:

```
sp_dbcc_updateconfig pubs2, "OAM count threshold", "5"
```

Example 7

Updates dbcc config with the I/O error abort value for the pubs2 database. The new value is 3:

```
sp dbcc updateconfig pubs2, "IO error abort", "3"
```

Example 8

Updates dbcc config with the linkage error abort value for the pubs2 database. The new value is 8:

```
sp dbcc updateconfig pubs2, "linkage error abort", "8"
```

Example 9

Enables automatic workspace expansion for the database my db:

```
sp_dbcc_updateconfig my_db, "enable automatic workspace expansion", "1"
```

Usage

There are additional considerations when using sp dbcc updateconfig:

• sp dbcc updateconfig updates the dbcc config table for the target database.

- If the name of the target database is dbccdb, and the database dbccalt exists, sp_dbcc_updateconfig updates the dbcc_config table in dbccalt.
- If the target database name is not found in dbcc_config, sp_dbcc_updateconfig adds it and sets the operation sequence number to 0 before updating other configuration information.
- If the expected value for the specified <type> is a number, sp_dbcc_updateconfig converts the values you provide for <strl> and <strl> to numbers.
- The OAM count threshold parameter represents the percentage by which the actual row count can vary from the row count (as reported by the OAM pages) before dbcc checkstorage raises error 100025, row count error. Generally, you can leave OAM count threshold at the default value of 2%.
- The valid type names to use for <type> and the expected value for <str1> or <str2> are:

dbcc named cache	The name of the cache, specified by $$, and the new size (in kilobytes or megabytes) or the number of 2K pages, specified by $$.
IO error abort	The new error count, specified by $$. The value must be a number greater than $0. $ is not used with this type.
linkage error abort	The new linkage error count value specified in $$. The value must be a number greater than $0. $ is not used with this type.
max worker processes	The new number of worker processes, specified by $$. The value must be a number greater than $0. < str2>$ is not used with this type.
OAM count threshold	The new threshold count, specified by $$. The value must be a number greater than 0. $$ is not used with this type.
scan workspace	The new name for the \mathtt{scan} workspace, specified by $<\mathtt{str1}>$. $<\mathtt{str2}>$ is not used with this type.
text workspace	The new name of the \texttt{text} workspace, specified by $\texttt{}$. $\texttt{}$ is not used with this type.
automatic workspace expansion	Allows checkstorage to automatically expands the workspace if adequate space is available on the respective segments. The default value of 1 enables automatic workspace expansion, and the value of 0 disables it.
enable excluded faults inserts	determines if excluded faults are inserted in the dbcc_faults and dbcc_fault_params tables during dbcc_checkstorage. Excluded faults are defined using sp_dbcc_exclusions. When set to 1 (the default), all rows are inserted in dbcc_faults and dbcc_fault_params tables. A value of 0 means they are not.
enable dbcc_counter inserts	determines if rows are inserted in the dbcc_counters table when dbcc checkstorage finishes. When set to 1, rows are inserted in dbcc_counters table. A value of 0 (the default) means they are not.
