Editing	Virginia Clark
Technical Review	Evan L. Anderson, Brent Cohen, Allison Crutchfield, Paige Daniels, Gül Ege, Bruce Elsheimer, Donald J. Erdman, Kelly Fellingham, Phil Hanna, Kenneth N. Hightower, R. Bart Killam, Huiwen Lai, Michael J. Leonard, Mark R. Little, Kevin Meyer, Steve Morrison, Sunil Panikkath, Jim Seabolt, Michele A. Trovero, Jonathan Wang, Shirley Wang, Donna E. Woodward, Ozkan Zengin
Documentation Production	Kenneth N. Hightower, Michele A. Trovero, Tim Arnold

Software

The procedures in SAS/ETS software were implemented by members of the Analytical Solutions Division. Program development includes design, programming, debugging, support, documentation, and technical review. In the following list, the names of the developers currently supporting the procedure are listed first.

ARIMA	Rajesh Selukar, Michael J. Leonard, Terry Woodfield
AUTOREG	Jonathan Wang, John P. Sall
COMPUTAB	Michael J. Leonard, Alan R. Eaton, David F. Ross
DATASOURCE	Kelly Fellingham, Meltem Narter
ENTROPY	Donald J. Erdman
EXPAND	Michael J. Leonard, Mark R. Little
FORECAST	Michael J. Leonard, Mark R. Little, John P. Sall
LOAN	Gül Ege

MDC	Ozkan Zengin
MODEL	Donald J. Erdman, Mark R. Little, John P. Sall
PDLREG	Jonathan Wang, Leigh A. Ihnen
QLIM	Jonathan Wang
SIMLIN	Mark R. Little, John P. Sall
SPECTRA	Rajesh Selukar, Donald J. Erdman, John P. Sall
STATESPACE	Jonathan Wang, Michael J. Leonard
SYSLIN	Donald J. Erdman, Leigh A. Ihnen, John P. Sall
TIMESERIES	Michael Leonard,
TSCSREG	Jonathan Wang, Meltem Narter, Sunil Panikkath
UCM	Rajesh Selukar
VARMAX	Youngin Park
X11	Wilma S. Jackson, R. Bart Killam, Leigh A. Ihnen, Richard D. Langston
X12	Wilma S. Jackson
Time Series Forecasting System	Evan L. Anderson, Michael J. Leonard, Meltem Narter, Gül Ege
Investment Analysis System	Gül Ege, Scott Gray, Michael J. Leonard
Compiler and Symbolic Differentiation	Stacey Christian
SASEHAVR	Kelly Fellingham, Stephen Caudle
SASECRSP, SASEFAME, Data Interface Engines	Kelly Fellingham
Testing	Jackie Allen, Ming-Chun Chang, Evan Dean, Bruce Elsheimer, Tae Yoon Lee, Huiwen Lai, Audun Runde, Steve Morrison, Mark Traccarella, Xianghong Shirley Wang

Technical Support

Members	Paige Daniels, Kurt Jones, Kevin Meyer, Donna E. Woodward

Acknowledgments

Hundreds of people have helped the SAS System in many ways since its inception. The following individuals have been especially helpful in the development of the procedures in SAS/ETS software. Acknowledgments for the SAS System generally appear in Base SAS software documentation and SAS/ETS software documentation.

David Amick	Idaho Office of Highway Safety
David M. DeLong	Duke University
David Dickey	North Carolina State University
Douglas J. Drummond	Center for Survey Statistics
William Fortney	Boeing Computer Services
Wayne Fuller	Iowa State University
A. Ronald Gallant	The University North Carolina at Chapel Hill
Phil Hanser	Sacramento Municipal Utilities District
Marvin Jochimsen	Mississippi R&O Center
Ken Kraus	CRSP
George McCollister	San Diego Gas & Electric
Douglas Miller	Purdue University
Brian Monsell	U.S. Census Bureau
Robert Parks	Washington University
Gregory Sali	Idaho Office of Highway Safety
Bob Spatz	CRSP
Mary Young	Salt River Project

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

What’s New in SAS/ETS 9 and 9.1

Overview

New procedures in SAS/ETS include the following:

- The experimental ENTROPY procedure provides Generalized Maximum Entropy estimation for linear systems of equations.
- The QLIM procedure analyzes univariate and multivariate models where dependent variables take discrete values or values in a limited range.
- The TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format.
- The UCM procedure provides estimation for Unobserved Component Models, also referred to as Structural Models.

Several new financial and date, time, and datetime functions have been added.

The new experimental SASEHAVR interface engine is now available to SAS/ETS for Windows users for accessing economic and financial data residing in a HAVER ANALYTICS Data Link Express (DLX) database.

New features have been added to the following SAS/ETS components:

- PROC ARIMA
- PROC EXPAND
- PROC MDC
- PROC MODEL
- PROC VARMAX
- PROC X12
- Time Series Forecasting System

Financial Functions

SAS/ETS now provides new financial functions. They are described in detail in Chapter 4, “SAS Macros and Functions.”

CUMIPMT	Returns the cumulative interest paid on a loan between the start period and the end period.
CUMPRINC	Returns the cumulative principal paid on a loan between the start period and the end period.

IPMT	Returns the interest payment for a given period for an investment based on periodic, constant payments and a constant interest rate.
PMT	Returns the periodic payment for a constant payment loan or the periodic saving for a future balance.
PPMT	Returns the payment on the principal for an investment for a given period.

Date, Time, and Datetime Functions

SAS/ETS now provides the following new date, time, and datetime functions. See Chapter 3, "Date Intervals, Formats, and Functions," for more details.

INTFMT	Returns a recommended format given a date, time, or datetime interval.
INTCINDEX	Returns the cycle index given a date, time, or datetime interval and value.
INTCYCLE	Returns the date, time, or datetime interval at the next higher seasonal cycle given a date, time, or datetime interval.
INTINDEX	Returns the seasonal index given a date, time, or datetime interval and value.
INTSEA	Returns the length of the seasonal cycle given a date, time, or datetime interval.

SASEHAVR Engine

The experimental SASEHAVR interface engine gives Windows users random access to economic and financial data residing in a HAVER ANALYTICS Data Link Express (DLX) database. You can limit the range of data that is read from the time series and specify a desired conversion frequency. Start dates are recommended on the libname statement to help you save resources when processing large databases or when processing a large number of observations. You can further the subsetting of your data by using the WHERE, KEEP, or DROP statements in your DATA step. You can use the SQL procedure to create a view of your resulting SAS data set.

ARIMA Procedure

The OUTLIER statement of the ARIMA procedure has become production in SAS System 9. A new ID option that provides date labels to the discovered outliers has been added.

9.1 In the presence of embedded missing values, the new default White Noise test of residuals uses the one proposed by Stoffer and Toloi (1992), which is more appropriate.

9.1 The default forecasting algorithm when the data have embedded missing values and the model has multiple orders of differencing for the dependent series has been slightly modified. This modification usually improves the statistical properties of the forecasts.

ENTROPY Procedure

The new experimental ENTROPY procedure implements a parametric method of linear estimation based on Generalized Maximum Entropy.

Often the statistical-economic model of interest is ill-posed or underdetermined for the observed data, for example when limited data is available or acquiring data is costly. For the general linear model this can imply that high degrees of collinearity exist among explanatory variables or that there are more parameters to estimate than observations to estimate them with. These conditions lead to high variances or non-estimability for traditional GLS estimates.

The principle of maximum entropy, at the base of the ENTROPY procedure, is the foundation for an estimation methodology that is characterized by its robustness to ill-conditioned designs and its ability to fit overparameterized models.

Generalized Maximum Entropy, GME, is a means of selecting among probability distributions so as to choose the distribution that maximizes uncertainty or uniformity remaining in the distribution, subject to information already known about the distribution itself. Information takes the form of data or moment constraints in the estimation procedure. PROC ENTROPY creates a GME distribution for each parameter in the linear model, based upon support points supplied by the user. The mean of each distribution is used as the estimate of the parameter. Estimates tend to be biased, as they are a type of shrinkage estimate, but will typically portray smaller variances than OLS counterparts, making them more desirable from a mean squared error viewpoint.

PROC ENTROPY can be used to fit simultaneous systems of linear regression models, Markov models, and seemingly unrelated regression models as well as to solve pure inverse problems and unordered, multinomial choice problems. Bounds and restrictions on parameters can be specified and Wald, Likelihood ratio, and Lagrange multiplier tests can be computed. Prior information can also be supplied to enhance estimates and data. 9.1

EXPAND Procedure

The EXPAND procedure has several new transformation operators: moving product, moving rank, moving geometric mean, sequence operators, fractional differencing, Hodrick-Prescott filtering, and scaling.

The EXPAND procedure has a new option for creating time series graphics. The PLOT= option enables you to graph the input, output, and transformed time series. 9.1

MDC Procedure

The RESTRICT statement now has a new syntax and supports linear restrictions.

The new BOUNDS statement enables you to specify simple boundary constraints on the parameter estimates. You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints.

MODEL Procedure

The SMM (Simulated Method of Moments) estimation is now available as an option in the FIT statement. This method of estimation is appropriate for estimating models in which integrals appear in the objective function and these integrals can be approximated by simulation. There may be various reasons for that to happen, for example, transformation of a latent model into an observable model, missing data, random coefficients, heterogeneity, etc. A typical use of SMM is in estimating stochastic volatility models in finance, where only the stock return is observable, while the volatility process is not, and needs to be integrated out of the likelihood function. The simulation method can be used with all the estimation methods except Full Information Maximum Likelihood (FIML) in PROC MODEL. Simulated Generalized Method of Moments (SGMM) is the default estimation method.

9.1 Heteroscedastic Corrected Covariance Matrix Estimators (HCCME) have been implemented. The HCCME= option selects which correction is applied to the covariance matrix.

9.1 Instrumental variables can now be specified for specific equations rather than for all equations. This is done with expanded syntax on the INSTRUMENT statement.

QLIM Procedure

The new QLIM procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, tobit, selection, and multivariate models. The multivariate model can contain discrete choice and limited endogenous variables as well as continuous endogenous variables.

The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- tobit (censored and truncated) with heteroscedasticity
- Box-Cox regression with heteroscedasticity

- bivariate probit
- bivariate tobit
- sample selection and switching regression models
- multivariate limited dependent variables

TIMESERIES Procedure

The new TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. Once the transactional data are accumulated, time domain and frequency domain analysis can be performed on the resulting time series. The procedure produces numerous graphical results related to time series analysis.

UCM Procedure

The new UCM procedure, experimental in SAS System 9, is production in SAS 9.1. **9.1**
You can use this procedure to analyze and forecast equally spaced univariate time series data using Unobserved Components Models (UCM).

The UCMs can be regarded as regression models where, apart from the usual regression variables, the model consists of components such as trend, seasonals, and cycles. In time series literature UCMs are also referred to as Structural Models. The different components in a UCM can be modeled separately and are customized to represent salient features of a given time series. The analysis provides separate in-sample and out of sample estimates (forecasts) of these component series. In particular, model-based seasonal decomposition and seasonal adjustment of the dependent series is easily available. The distribution of errors in the model is assumed to be Gaussian and the model parameters are estimated by maximizing the Gaussian likelihood. The UCM procedure can handle missing values in the dependent series.

The domains of applicability of PROC UCM and PROC ARIMA are virtually identical; however, decomposition of a series in features such as trend, seasonals, and cycles is more convenient in PROC UCM. A seasonal decomposition of a time series can also be obtained using other procedures, for example, PROC X12. However, these seasonal decompositions generally do not take into account regression and other effects and are not model based. The seasonal decomposition in PROC UCM is based on a comprehensive model, providing all the advantages of model diagnostics.

VARMAX Procedure

The VARMAX procedure now provides the following features:

- The ECTREND option is available in the ECM=( ) option of the MODEL statement to fit the VECM(p) with a restriction on the drift. The ECTREND option is ignored when either the NSEASON or NOINT option is specified.
- You can now use the DFTEST option at multiple lags. For example, DFTEST=(DLAG=(1)(12)) provides the Dickey-Fuller regular unit root test and seasonal unit root test. If the TREND= option is specified, the seasonal unit root test is not available.
- The DYNAMIC option is added to the PRINT=( ) option. This representation displays the contemporaneous relationships among the components of the vector time series.
- The CORRX, CORRY, COVPE, COVX, COVY, DECOMPOSE, IARR, IMPULSE, IMPULSX, PARCOEF, PCANCORR, and PCORR options can be used with the number in parentheses in the PRINT=( ) option. For example, you can use CORRX or CORRX(*number*). The options print the number of lags specified by *number*. The default is the number of lags specified by the LAGMAX=*number*.
- The subset BVAR model is now available.
- The statistics for the one lagged coefficient matrix are removed in the ECM.
- The last columns of the BETA and ALPHA are removed in the COINTTEST option when the NOINT option is not specified.
- The long variable names are available in the model parameter estimation table.
- The schematic representation of the estimates that shows the significance of the parameters is now available.
- Two new ODS Tables, ParameterGraph and GARCHParameterGraph, are added.

9.1 Many ODS table names have been changed.

X12 Procedure

The X12 procedure default behavior has changed with regard to missing leading and trailing values. Previously the default was not to trim leading/trailing missing values from the series. This made it difficult to process multiple series within a data set when the series had differing spans. Now the default is to trim leading and trailing missing values. The new NOTRIMMISS option provides the old default behavior; when NOTRIMMISS is specified, PROC X12 will automatically generate missing value regressors for any missing value within the span of the series, including leading and trailing missing values.

The following statements and options are new:

- The AUTOMDL statement uses the TRAMO method based on the work of Gomez and Maravall (1997a and 1997b) to automatically select the ARIMA part of a regARIMA model for the time series.
- The OUTLIER statement automatically detects additive, level shift, and temporary change outliers in the time series. After the outliers are identified, the appropriate regression variables are incorporated into the model.
- The MAXITER and TOL options of the ESTIMATE statement provide additional control over the convergence of the nonlinear estimation.
- The ITPRINT and PRINTERR options of the ESTIMATE statement enable you to examine the iterations history of the nonlinear estimation.
- The FINAL and FORCE options of the X11 statement enable you to control the final seasonally adjusted series. The FINAL option specifies whether outlier, level shift, and temporary change effects should be removed from the final seasonally adjusted series. The FORCE option specifies whether or not the yearly totals of final seasonally adjusted series match the totals of the original series. **9.1**

Time Series Forecasting System

Enhancements to this graphical point-and-click system provide new kinds of forecasting models, better ways to customize lists of models, greater flexibility in sharing projects over a network, and support for graphical and tabular Web reports:

- The Factored ARIMA Model Specification window provides a general purpose interface for specifying ARIMA models. You can specify any number of factors and select the AR and MA lags to include in each factor. This makes it easy to model series with unusual and/or multiple seasonal cycles.
- Improvements to the Model Selection List Editor window enable you to open alternate model lists included with the software as well as user defined model lists. You can create a new model list, open an existing model list, modify it, use it to replace the current list, append it to the current list, save it in a catalog, assign it to a project, or assign it as a user default list for newly created projects. **9.1**

Several new ARIMA and dynamic regression model lists are provided. You can combine these into large sets for automatic model selection and select from them to create the best set of candidate models for your data.

9.1

- Project options are no longer stored exclusively in the SASUSER library. You can use any path to which you have write access by assigning the libname TSFSUSER. The system prompts you for this path if you do not have write access to the SASUSER library.

9.1

- The Series Viewer and Model Viewer support saving graphs and tables via the Output Delivery System (ODS). Select the "Use Output Delivery System" option in the Save As dialog to create html pages and corresponding gif files. You can access and organize these using the ODS Results window, display them automatically in your browser (depending on your results preferences settings), or publish them via the Internet or an intranet. You can also create other forms of output by providing your own ODS statements.
- The Time Series Viewer and Time Series Forecasting System can now be started from a macro submitted from the Program Editor or the Enhanced Editor. The FORECAST and TSVIEW macros accept the same arguments as the FORECAST and TSVIEW commands. You can use the FORECAST macro to generate and submit any number of independent unattended forecasting runs from a data step program.

Chapter 1
Introduction

Chapter Contents

Chapter 1
Introduction

Overview of SAS/ETS Software

SAS/ETS software, a component of the SAS System, provides SAS procedures for

- econometric analysis
- time series analysis
- time series forecasting
- systems modeling and simulation
- discrete choice analysis
- analysis of qualitative and limited dependent variable models
- seasonal adjustment of time series data
- financial analysis and reporting
- access to economic and financial databases
- time series data management

In addition to SAS procedures, SAS/ETS software also includes interactive environments for time series forecasting and investment analysis.

Uses of SAS/ETS Software

SAS/ETS software provides tools for a wide variety of applications in business, government, and academia. Major uses of SAS/ETS procedures are economic analysis, forecasting, economic and financial modeling, time series analysis, financial reporting, and manipulation of time series data.

The common theme relating the many applications of the software is time series data: SAS/ETS software is useful whenever it is necessary to analyze or predict processes that take place over time or to analyze models that involve simultaneous relationships.

Although SAS/ETS software is most closely associated with business and economics, time series data also arise in many other fields. SAS/ETS software is useful whenever time dependencies, simultaneous relationships, or dynamic processes complicate data analysis. For example, an environmental quality study might use SAS/ETS software's time series analysis tools to analyze pollution emissions data. A pharmacokinetic study might use SAS/ETS software's features for nonlinear systems to model the dynamics of drug metabolism in different tissues.

The diversity of problems for which econometrics and time series analysis tools are needed is reflected in the applications reported by SAS users. The following listed items are some applications of SAS/ETS software presented by SAS users at past annual conferences of the SAS Users Group International (SUGI).

- forecasting college enrollment (Calise and Earley 1997)
- fit a pharmacokinetic model (Morelock et al. 1995)
- testing interaction effect in reducing SIDS (Fleming, Gibson, and Fleming 1996)
- forecasting operational indices to measure productivity changes (McCarty 1994)
- spectral decomposition and reconstruction of nuclear plant signals (Hoyer and Gross 1993)
- estimating parameters for the CES-Translog model (Hisnanick 1993)
- applying econometric analysis for mass appraisal of real property (Amal and Weselowski 1993)
- forecasting telephone usage data (Fishetti, Heathcote, and Perry 1993)
- forecasting demand and utilization of inpatient hospital services (Hisnanick 1992)
- using conditional demand estimation to determine electricity demand (Keshani and Taylor 1992)
- estimating tree biomass for measurement of forestry yields (Parresol and Thomas 1991)
- evaluating the theory of input separability in the production function of U.S. manufacturing (Hisnanick 1991)
- forecasting dairy milk yields and composition (Benseman 1990)
- predicting the gloss of coated aluminum products subject to weathering (Khan 1990)
- learning curve analysis for predicting manufacturing costs of aircraft (Le Bouton 1989)
- analyzing Dow Jones stock index trends (Early, Sweeney, and Zekavat 1989)
- analyzing the usefulness of the composite index of leading economic indicators for forecasting the economy (Lin and Myers 1988)

Contents of SAS/ETS Software

Procedures

SAS/ETS software includes the following SAS procedures:

ARIMA	ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) modeling and forecasting
AUTOREG	regression analysis with autocorrelated or heteroscedastic errors and ARCH and GARCH modeling
COMPUTAB	spreadsheet calculations and financial report generation
DATASOURCE	access to financial and economic databases

ENTROPY	maximum entropy-based regression
EXPAND	time series interpolation and frequency conversion, and transformation of time series
FORECAST	automatic forecasting
LOAN	loan analysis and comparison
MDC	multinomial discrete choice analysis
MODEL	nonlinear simultaneous equations regression and nonlinear systems modeling and simulation
PDLREG	polynomial distributed lag regression (Almon lags)
QLIM	qualitative and limited dependent variable analysis
SIMLIN	linear systems simulation
SPECTRA	spectral and cross spectral analysis
STATESPACE	state space modeling and automated forecasting of multivariate time series
SYSLIN	linear simultaneous equations models
TIMESERIES	analysis of time-stamped transactional data
TSCSREG	time series cross-sectional regression analysis
UCM	unobserved components analysis of time series
VARMAX	vector autoregressive and moving-average modeling and forecasting
X11	seasonal adjustment (Census X-11 and X-11 ARIMA)
X12	seasonal adjustment (Census X-12 ARIMA)

Macros

SAS/ETS software includes the following SAS macros:

%AR	generates statements to define autoregressive error models for the MODEL procedure
%BOXCOXAR	investigates Box-Cox transformations useful for modeling and forecasting a time series
%DFPVALUE	computes probabilities for Dickey-Fuller test statistics
%DFTEST	performs Dickey-Fuller tests for unit roots in a time series process
%LOGTEST	tests to see if a log transformation is appropriate for modeling and forecasting a time series
%MA	generates statements to define moving average error models for the MODEL procedure
%PDL	generates statements to define polynomial distributed lag models for the MODEL procedure

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. Refer to *SAS Macro Language: Reference* for information about the SAS macro facility.

The Time Series Forecasting System

In addition to SAS procedures and macros, SAS/ETS software also includes an interactive forecasting user interface. This user interface was developed with SAS/AF software and uses PROC ARIMA to perform time series forecasting. The TSF system makes it easy to forecast time series and provides many features for graphical data exploration and graphical comparisons of forecasting models and forecasts. (SAS/GRAPH is required to use the graphical features of the system.)

The Investment Analysis System

The Investment Analysis system is an interactive environment for the time-value of money of a variety of investments. Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

Some of the features of SAS/ETS software are also available through menu driven interfaces provided by SAS/ASSIST software. (Both SAS/ASSIST software and SAS/ETS software must be licensed for you to use these features.)

The following components of SAS/ASSIST software enable you to use SAS/ETS procedures through a menu interface:

- loan analysis (uses PROC LOAN)
- regression with correction for autocorrelation (uses PROC AUTOREG)
- seasonal adjustment (uses PROC X11)
- convert frequency of time series data (uses PROC EXPAND)

About This Book

This book is a user's guide to SAS/ETS software. Since SAS/ETS software is a part of the SAS System, this book assumes that you are familiar with Base SAS software and have the books *SAS Language: Reference* and *SAS Procedures Guide* available for reference. It also assumes that you are familiar with SAS data sets, the SAS DATA step, and with basic SAS procedures such as PROC PRINT and PROC SORT. Chapter 2, "Working with Time Series Data," in this book summarizes the aspects of Base SAS software most relevant to the use of SAS/ETS software.

Chapter Organization

Following a brief What's New section, this book is divided into four major parts. "Part One" contains general information to aid you in working with SAS/ETS Software. "Part Two" is the "Procedure Reference" that is comprised of chapters that explain the SAS procedures that make up SAS/ETS software. "Part Three" is the reference for the Time Series Forecasting System, an interactive forecasting menu system that uses PROC ARIMA to perform time series forecasting. Finally, "Part Four" is the reference for the Investment Analysis System.

The new features added to SAS/ETS software since the publication of *SAS/ETS Software: Changes and Enhancements for Release 8.2* are summarized in “What’s New in SAS/ETS 9 and 9.1.” If you have used SAS/ETS software in the past, you may want to skim this chapter to see what’s new.

“Part One” contains the following chapters.

Chapter 1, the current chapter, provides an overview of SAS/ETS software and summarizes related SAS Institute publications, products, and services.

Chapter 2, “Working with Time Series Data,” discusses the use of SAS data management and programming features for time series data.

Chapter 3, “Date Intervals, Formats, and Functions,” summarizes the time intervals, date and datetime informats, date and datetime formats, and date and datetime functions available in the SAS System.

Chapter 4, “SAS Macros and Functions,” documents SAS macros and DATA step financial functions provided with SAS/ETS software. The macros use SAS/ETS procedures to perform Dickey-Fuller tests, test for the need for log transformations, or select optimal Box-Cox transformation parameters for time series data.

Chapter 5, “The SASECRSP Interface Engine,” documents the SASECRSP interface engine that enables SAS users to access and process time series data residing in CRSPAccess data files, and provides a seamless interface between CRSP and SAS data processing.

Chapter 6, “The SASEFAME Interface Engine,” documents the SASEFAME interface engine that enables SAS users to access and process time series data residing in a FAME database, and provides a seamless interface between FAME and SAS data processing.

Chapter 7, “The SASEHAVR Interface Engine,” documents the SASEHAVR interface engine that provides Windows users random access to economic and financial data residing in a HAVER ANALYTICS Data Link Express (DLX) database.

Chapter 8, “Using the Output Delivery System,” provides an introduction to the Output Delivery System (ODS).

Chapter 9, “Statistical Graphics Using ODS,” provides an introduction to the experimental graphics extension to the Output Delivery System.

Chapter 10, “Nonlinear Optimization Methods,” documents the NonLinear Optimization subsystem used by some ETS procedures to perform nonlinear optimization tasks.

“Part Two” contains the chapters that explain the SAS procedures that make up SAS/ETS software. These chapters appear in alphabetical order by procedure name.

The chapters documenting the SAS/ETS procedures are organized as follows:

1. Each chapter begins with an “Overview” section that gives a brief description of the procedure.

2. The “Getting Started” section provides a tutorial introduction on how to use the procedure.
3. The “Syntax” section is a reference to the SAS statements and options that control the procedure.
4. The “Details” section discusses various technical details.
5. The “Examples” section contains examples of the use of the procedure.
6. The “References” section contains technical references on methodology.

“Part Three” contains the chapters that document the features of the Time Series Forecasting System, while the features of the Investment Analysis System are documented in “Part Four.”

Typographical Conventions

This book uses several type styles for presenting information. The following list explains the meaning of the typographical conventions used in this book:

roman	is the standard type style used for most text.
UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
UPPERCASE BOLD	is used in the “Syntax” sections’ initial lists of SAS statements and options.
oblique	is used for user-supplied values for options in the syntax definitions. In the text, these values are written in *italic*.
helvetica	is used for the names of variables and data sets when they appear in the text.
bold	is used to refer to matrices and vectors, and to refer to commands (e.g **end** or **cd**.)
italic	is used for terms that are defined in the text, for emphasis, and for references to publications.
`monospace`	is used for example code. In most cases, this book uses lowercase type for SAS code.

Options Used in Examples

Output of Examples

For each example, the procedure output is numbered consecutively starting with 1, and each output is given a title. Each page of output produced by a procedure is enclosed in a box.

Most of the output shown in this book is produced with the following SAS System options:

```
options linesize=80 pagesize=200 nonumber nodate;
```

The template STATDOC.TPL is used to create the HTML output that appears in the online (CD) version. A style template controls stylistic HTML elements such as colors, fonts, and presentation attributes. The style template is specified in the ODS HTML statement as follows:

```
ODS HTML style=statdoc;
```

If you run the examples, you may get slightly different output. This is a function of the SAS System options used and the precision used by your computer for floating-point calculations.

Graphics Options

The examples that contain graphical output are created with a specific set of options and symbol statements. The code you see in the examples creates the color graphics that appear in the online (CD) version of this book. A slightly different set of options and statements is used to create the black-and-white graphics that appear in the printed version of the book.

If you run the examples, you may get slightly different results. This may occur because not all graphic options for color devices translate directly to black-and-white output formats. For complete information on SAS/GRAPH software and graphics options, refer to *SAS/GRAPH Software: Reference*.

The following GOPTIONS statement is used to create the online (color) version of the graphic output.

```
filename GSASFILE  '<file-specification>';

goptions reset=all
         gaccess=GSASFILE    gsfmode=replace
         fileonly
         transparency        dev = gif
         ftext = swiss       lfactor = 1
         htext = 4.0pct      htitle = 4.5pct
         hsize = 5.5in       vsize = 3.5in
         noborder            cback = white
         horigin = 0in       vorigin = 0in ;
```

The following GOPTIONS statement is used to create the black-and-white version of the graphic output, which appears in the printed version of the manual.

```
filename GSASFILE  '<file-specification>';

goptions reset=all
         gaccess=GSASFILE    gsfmode=replace
         fileonly
```

```
dev = pslepsf
ftext = swiss        lfactor = 1
htext = 3.0pct       htitle = 3.5pct
hsize = 5.5in        vsize = 3.5in
border               cback = white
horigin = 0in        vorigin = 0in;
```

In most of the online examples, the plot symbols are specified as follows:

```
symbol1 value=dot color=white height=3.5pct;
```

The SYMBOL*n* statements used in online examples order the symbol colors as follows: white, yellow, cyan, green, orange, blue, and black.

In the examples appearing in the printed manual, symbol statements specify COLOR=BLACK and order the plot symbols as follows: dot, square, triangle, circle, plus, x, diamond, and star.

Where to Turn for More Information

This section describes other sources of information about SAS/ETS software.

Accessing the SAS/ETS Sample Library

The SAS/ETS Sample Library includes many examples that illustrate the use of SAS/ETS software, including the examples used in this documentation. To access these sample programs, select **Help** from the menu and select **SAS Help and Documentation**. From the Contents list, choose **Learning to Use SAS** and then **Sample SAS Programs**.

Online Help System

You can access online help information about SAS/ETS software in two ways, depending on whether you are using the SAS windowing environment in the command line mode or the pull-down menu mode.

If you are using a command line, you can access the SAS/ETS help menus by typing **help** on the SAS windowing environment command line. Or you can or issue the command **help ARIMA** (or another procedure name) to bring up the help for that particular procedure.

If you are using the SAS windowing environment pull-down menus, you can pull-down the **Help** menu and make the following selections:

- SAS Help and Documentation
- Learning to Use SAS in the Contents list
- SAS Products
- SAS/ETS

The content of the Online Help System follows closely the one of this book.

Other Related SAS Institute Publications

In addition to this user's guide, SAS Institute publishes other books on using SAS/ETS software. The following books are companions to this user's guide:

- *SAS/ETS Software: Applications Guide 1, Version 6, First Edition*
- *SAS/ETS Software: Applications Guide 2, Version 6, First Edition*

The first volume, *SAS/ETS Software: Applications Guide 1*, discusses features of SAS/ETS software for time series modeling and forecasting, financial reporting, and loan analysis. The second volume, *SAS/ETS Software: Applications Guide 2*, discusses features of SAS/ETS software for econometric modeling and simulation.

Forecasting Examples for Business and Economics Using the SAS System, discusses forecasting using SAS/ETS software.

SAS Institute Short Courses

SAS Institute offers the following short course on using SAS/ETS software:

Introduction to Time Series Forecasting Using SAS/ETS Software is a Level III course is designed for statisticians, economists, business planners, inventory managers, market researchers, and others who analyze time series data and need to forecast time series data. This course uses the Time Series Forecasting System (TSFS) and the SAS/ETS procedures ARIMA, FORECAST, and EXPAND. After completing this course, you should be able to

- preprocess time series data using SAS date, time, and mathematical DATA step functions
- impute missing or invalid values in time series data using a variety of methods
- recognize and understand the basic components of time series data, including trend and seasonality
- forecast individual time series using regression, exponential smoothing, ARIMA, and composite models
- implement procedures for the automatic generation of forecasts for a large number of time series
- produce forecasts using data collected at different summary levels (for example, SKU, product group, product line, business line)
- produce effective graphics presentations of forecasts
- evaluate the accuracy of forecast models
- select from a variety of competing models

SAS Institute Technical Support Services

As with all SAS Institute products, the SAS Institute Technical Support staff is available to respond to problems and answer technical questions regarding the use of SAS/ETS software.

Major Features of SAS/ETS Software

The following sections briefly summarize major features of SAS/ETS software. See the chapters on individual procedures for more detailed information.

Discrete Choice and Qualitative and Limited Dependent Variable Analysis

The MDC procedure provides maximum likelihood (ML) or simulated maximum likelihood estimates of multinomial discrete choice models in which the choice set consists of unordered multiple alternatives. The MDC procedure supports the following models and features:

- conditional logit
- nested logit
- heteroscedastic extreme value
- multinomial probit
- mixed logit
- pseudo-random or quasi-random numbers for simulated maximum likelihood estimation
- bounds imposed on the parameter estimates
- linear restrictions imposed on the parameter estimates
- SAS data set containing predicted probabilities and linear predictor ($\mathbf{x}'\boldsymbol{\beta}$) values
- goodness-of-fit measures including
  - likelihood ratio
  - Aldrich-Nelson
  - Cragg-Uhler 1
  - Cragg-Uhler 2
  - Estrella
  - Adjusted Estrella
  - McFadden’s LRI
  - Veall-Zimmermann
  - Akaike Information Criterion (AIC)
  - Schwarz Criterion

The QLIM procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, tobit, and general simultaneous equations models. The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- tobit (censored and truncated) with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- bivariate probit
- bivariate tobit

Regression with Autocorrelated and Heteroscedastic Errors

The AUTOREG procedure provides regression analysis and forecasting of linear models with autocorrelated or heteroscedastic errors. The AUTOREG procedure includes the following features:

- estimation and prediction of linear regression models with autoregressive errors
- any order autoregressive or subset autoregressive process
- optional stepwise selection of autoregressive parameters
- choice of the following estimation methods:
  - exact maximum likelihood
  - exact nonlinear least squares
  - Yule-Walker
  - iterated Yule-Walker
- tests for any linear hypothesis involving the structural coefficients
- restrictions for any linear combination of the structural coefficients
- forecasts with confidence limits
- estimation and forecasting of ARCH (autoregressive conditional heteroscedasticity), GARCH (generalized autoregressive conditional heteroscedasticity), I-GARCH (integrated GARCH), E-GARCH (exponential GARCH), and GARCH-M (GARCH in mean) models
- ARCH and GARCH models can be combined with autoregressive models, with or without regressors
- estimation and testing of general heteroscedasticity models
- variety of model diagnostic information including
  - autocorrelation plots

  - partial autocorrelation plots
  - Durbin-Watson test statistic and generalized Durbin-Watson tests to any order
  - Durbin *h* and Durbin *t* statistics
  - Akaike information criterion
  - Schwarz information criterion
  - tests for ARCH errors
  - Ramsey's RESET test
  - Chow and PChow tests
  - Phillips-Perron stationarity test
  - CUSUM and CUMSUMSQ statistics

- exact significance levels (*p*-values) for the Durbin-Watson statistic
- embedded missing values

Simultaneous Systems Linear Regression

The SYSLIN and ENTROPY procedures provide regression analysis of a simultaneous system of linear equations. The SYSLIN procedure includes the following features:

- estimation of parameters in simultaneous systems of linear equations
- full range of estimation methods including
  - ordinary least squares (OLS)
  - two-stage least squares (2SLS)
  - three-stage least squares (3SLS)
  - iterated 3SLS
  - seemingly unrelated regression (SUR)
  - iterated SUR
  - limited-information maximum-likelihood (LIML)
  - full-information maximum-likelihood (FIML)
  - minimum-expected-loss (MELO)
  - general K-class estimators
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations
- wide range of model diagnostics and statistics including
  - usual ANOVA tables and R^2 statistics
  - Durbin-Watson statistics

  - standardized coefficients
  - test for over-identifying restrictions
  - residual plots
  - standard errors and T tests
  - covariance and correlation matrices of parameter estimates and equation errors

- predicted values, residuals, parameter estimates, and variance-covariance matrices saved in output SAS data sets

The ENTROPY procedure includes the following features:

- generalized maximum entropy (GME) estimation
- generalized cross entropy (GCE) estimation
- maximum entropy SUR (MESUR) estimation
- pure inverse estimation
- estimation of parameters in simultaneous systems of linear equations
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations

Linear Systems Simulation

The SIMLIN procedure performs simulation and multiplier analysis for simultaneous systems of linear regression models. The SIMLIN procedure includes the following features:

- reduced form coefficients
- interim multipliers
- total multipliers
- dynamic forecasts and simulations
- goodness-of-fit statistics
- processes equation system coefficients estimated by the SYSLIN procedure

Polynomial Distributed Lag Regression

The PDLREG procedure provides regression analysis for linear models with polynomial distributed (Almon) lags. The PDLREG procedure includes the following features:

- any number of regressors may enter as a polynomial lag distribution, and any number of covariates may be used
- any order lag length and degree polynomial for lag distribution may be used
- optional upper and lower endpoint restrictions
- any number of linear restrictions may be placed on covariates
- option to repeat analysis over a range of degrees for the lag distribution polynomials
- support for autoregressive errors to any lag
- forecasts with confidence limits

Nonlinear Systems Regression and Simulation

The MODEL procedure provides parameter estimation, simulation, and forecasting of dynamic nonlinear simultaneous equation models. The MODEL procedure includes the following features:

- nonlinear regression analysis for systems of simultaneous equations, including weighted nonlinear regression
- full range of parameter estimation methods including
  - nonlinear ordinary least squares (OLS)
  - nonlinear seemingly unrelated regression (SUR)
  - nonlinear two-stage least squares (2SLS)
  - nonlinear three-stage least squares (3SLS)
  - iterated SUR
  - iterated 3SLS
  - generalized method of moments (GMM)
  - nonlinear full information maximum likelihood (FIML)
  - simulated method of moments (SMM)
- supports dynamic multi-equation nonlinear models of any size or complexity
- uses the full power of the SAS programming language for model definition, including left-hand side expressions
- hypothesis tests of nonlinear functions of the parameter estimates
- linear and nonlinear restrictions of the parameter estimates
- bounds imposed on the parameter estimates
- computation of estimates and standard errors of nonlinear functions of the parameter estimates
- estimation and simulation of Ordinary Differential Equations (ODE's)
- vector autoregressive error processes and polynomial lag distributions easily specified for the nonlinear equations
- variance modeling (ARCH, GARCH, and others)

- computes goal-seeking solutions of nonlinear systems to find input values needed to produce target outputs
- dynamic, static, or *n*-period-ahead-forecast simulation modes
- simultaneous solution or single equation solution modes
- Monte Carlo simulation using parameter estimate covariance and across-equation residuals covariance matrices or user specified random functions
- a variety of diagnostic statistics including
  - model R^2 statistics
  - general Durbin-Watson statistics and exact p-values
  - asymptotic standard errors and T tests
  - first stage R^2 statistics
  - covariance estimates
  - collinearity diagnostics
  - simulation goodness-of-fit statistics
  - Theil inequality coefficient decompositions
  - Theil relative change forecast error measures
  - heteroscedasticity tests
  - Godfrey test for serial correlation
  - Chow tests
- block structure and dependency structure analysis for the nonlinear system
- listing and cross reference of fitted model
- automatic calculation of needed derivatives using exact analytic formula
- efficient sparse matrix methods used for model solution; choice of other solution methods
- model definition, parameter estimation, simulation, and forecasting may be performed interactively in a single SAS session or models can also be stored in files and reused and combined in later runs

ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) Modeling and Forecasting

The ARIMA procedure provides the identification, parameter estimation, and forecasting of autoregressive integrated moving average (Box-Jenkins) models, seasonal ARIMA models, transfer function models, and intervention models. The ARIMA procedure includes the following features:

- complete ARIMA (Box-Jenkins) modeling with no limits on the order of autoregressive or moving average processes
- model identification diagnostics, include the following:
  - autocorrelation function
  - partial autocorrelation function

  - inverse autocorrelation function
  - cross-correlation function
  - extended sample autocorrelation function
  - minimum information criterion for model identification
  - squared canonical correlations

- stationarity tests
- outlier detection
- intervention analysis
- regression with ARMA errors
- transfer function modeling with fully general rational transfer functions
- seasonal ARIMA models
- ARIMA model-based interpolation of missing values
- several parameter estimation methods including
  - exact maximum likelihood
  - conditional least squares
  - exact nonlinear unconditional least squares
- forecasts and confidence limits for all models
- forecasting tied to parameter estimation methods: finite memory forecasts for models estimated by maximum likelihood or exact nonlinear least squares methods and infinite memory forecasts for models estimated by conditional least squares
- a variety of model diagnostic statistics including
  - Akaike's information criterion (AIC)
  - Schwarz's Bayesian criterion (SBC or BIC)
  - Box-Ljung chi-square test statistics for white noise residuals
  - autocorrelation function of residuals
  - partial autocorrelation function of residuals
  - inverse autocorrelation function of residuals
  - automatic outlier detection

Vector Time Series Analysis

The VARMAX procedure enables you to model both the dynamic relationship between the dependent variables and between the dependent and independent variables. The VARMAX procedure includes the following features:

- several modeling features:
  - vector autoregressive model
  - vector autoregressive model with exogenous variables

  - vector autoregressive and moving-average model
  - Bayesian vector autoregressive model
  - vector error correction model
  - Bayesian vector error correction model
  - GARCH-type multivariate conditional heteroscedasticity models

- criteria for automatically determining AR and MA orders:
  - Akaike Information Criterion (AIC)
  - Corrected AIC (AICC)
  - Hannan-Quinn (HQ) Criterion
  - Final Prediction Error (FPE)
  - Schwarz Bayesian Criterion (SBC), also known as Bayesian Information Criterion (BIC)

- AR order identification aids:
  - partial cross-correlations
  - Yule-Walker estimates
  - partial autoregressive coefficients
  - partial canonical correlations

- testing the presence of unit roots and cointegration:
  - Dickey-Fuller tests
  - Johansen cointegration test for nonstationary vector processes of integrated order one
  - Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
  - Johansen cointegration test for nonstationary vector processes of integrated order two

- model parameter estimation methods:
  - Least Squares (LS)
  - Maximum Likelihood (ML)

- model checks and residual analysis using the following tests:
  - Durbin-Watson (DW) statistics
  - F test for autoregressive conditional heteroscedastic (ARCH) disturbance
  - F test for AR disturbance
  - Jarque-Bera normality test
  - Portmanteau test

- seasonal deterministic terms
- subset models
- multiple regression with distributed lags

- dead-start model that does not have present values of the exogenous variables
- Granger-causal relationships between two distinct groups of variables.
- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series
- forecasts

State Space Modeling and Forecasting

The STATESPACE procedure provides automatic model selection, parameter estimation, and forecasting of state space models. (*State space models* encompass an alternative general formulation of multivariate ARIMA models.) The STATESPACE procedure includes the following features:

- multivariate ARIMA modeling using the general state space representation of the stochastic process
- automatic model selection using Akaike's information criterion (AIC)
- user-specified state space models including restrictions
- transfer function models with random inputs
- any combination of simple and seasonal differencing; input series can be differenced to any order for any lag lengths
- forecasts with confidence limits
- can save selected and fitted model in a data set and reuse for forecasting
- wide range of output options; print any statistics concerning the data and their covariance structure, the model selection process, and the final model fit

Spectral Analysis

The SPECTRA procedure provides spectral analysis and cross-spectral analysis of time series. The SPECTRA procedure includes the following features:

- efficient calculation of periodogram and smoothed periodogram using fast finite Fourier transform and Chirp algorithms
- multiple spectral analysis, including raw and smoothed spectral and cross-spectral function estimates, with user-specified window weights
- choice of kernel for smoothing
- outputs the following spectral estimates to a SAS data set:
  - Fourier sine and cosine coefficients

  - periodogram
  - smoothed periodogram
  - cospectrum
  - quadrature spectrum
  - amplitude
  - phase spectrum
  - squared coherency

- Fisher's Kappa and Bartlett's Kolmogorov-Smirnov test statistic for testing a null hypothesis of white noise

Seasonal Adjustment

The X11 procedure provides seasonal adjustment of time series using the Census X-11 or X-11 ARIMA method. The X11 procedure is based on the U.S. Bureau of the Census X-11 seasonal adjustment program and also supports the X-11 ARIMA method developed by Statistics Canada. The X11 procedure includes the following features:

- decomposition of monthly or quarterly series into seasonal, trend, trading day, and irregular components
- both multiplicative and additive form of the decomposition
- includes all the features of the Census Bureau program
- supports the X-11 ARIMA method
- supports sliding spans analysis
- processes any number of variables at once with no maximum length for a series
- performs tests for stable, moving and combined seasonality
- can optionally print or store in SAS data sets the individual X11 tables showing the various components at different stages of the computation. Full control over what is printed or output
- can project seasonal component one year ahead enabling reintroduction of seasonal factors for an extrapolated series

The X12 procedure provides seasonal adjustment of time series using the X-12 ARIMA method. The X12 procedure is based on the U.S. Bureau of the Census X-12 ARIMA seasonal adjustment program (version 0.3) and also supports the X-11 ARIMA method developed by Statistics Canada and the previous X-11 method of the U.S. Census Bureau. The X12 procedure includes the following features:

- decomposition of monthly or quarterly series into seasonal, trend, trading day, and irregular components
- supports multiplicative, additive, pseudo-additive, and log additive forms of decomposition

- supports the X-12 ARIMA method
- supports regARIMA modeling
- automatically identifies outliers
- supports TRAMO-based automatic model selection
- uses regressors to process missing values within the span of the series
- processes any number of variables at once with no maximum length for a series
- performs tests for stable, moving and combined seasonality
- provides spectral analysis of original, seasonally adjusted, and irregular series
- optionally prints or stores in SAS a data set the individual X11 tables showing the various components at different stages of the decomposition. Offers full control over what is printed or output
- optionally projects seasonal component one year ahead, enabling reintroduction of seasonal factors for an extrapolated series

Structural Time Series Modeling and Forecasting

The UCM procedure provides a very flexible environment for analyzing time series data using Structural Time Series models, also called Unobserved Components Models (UCM). These models represent the observed series as a sum of suitably chosen components such as trend, seasonals, cycles, and regression effects. You can use the UCM procedure to formulate very comprehensive models that bring out all the salient features of the series under consideration. Structural models are applicable in the same situations where Box-Jenkins ARIMA models are applicable; however, the structural models tend to be more informative about the underlying stochastic structure of the series. The UCM procedure includes the following features:

- General Unobserved Components modeling where the models can include trend, multiple seasons and cycles, and regression effects
- Maximum likelihood estimation of the model parameters
- Model diagnostics that includes a variety of Goodness of Fit statistics, and extensive graphical diagnosis of the model residuals
- Forecasts and confidence limits for the series and all the model components
- Model-based seasonal decomposition
- Extensive plotting capability that includes:
  - Forecast and confidence interval plots for the series and model components such as trend, cycles, and seasons
  - Diagnostic plots such as residual plot, residual auto-correlation plots, etc.
  - Seasonal decomposition plots such as trend, trend plus cycles, trend plus cycles plus seasons, etc.
- Model-based interpolation of series missing values
- Full sample (also called smoothed) estimates of the model components

Time Series Cross-Sectional Regression Analysis

The TSCSREG procedure provides combined time series cross-sectional regression analysis. The TSCSREG procedure includes the following features:

- estimation of the regression parameters under several common error structures:
  - Fuller and Battese method (variance component model)
  - Parks method (autoregressive model)
  - Da Silva method (mixed variance component moving-average model)
  - one-way fixed effects
  - two-way fixed effects
  - one-way random effects
  - two-way random effects
- any number of model specifications
- unbalanced panel data for the fixed or random effects models
- variety of estimates and statistics including
  - underlying error components estimates
  - regression parameter estimates
  - standard errors of estimates
  - *t*-tests
  - R-squared statistic
  - correlation matrix of estimates
  - covariance matrix of estimates
  - autoregressive parameter estimate
  - cross-sectional components estimates
  - autocovariance estimates
  - F-tests of linear hypotheses about the regression parameters
  - specification tests

Automatic Time Series Forecasting

The FORECAST procedure provides forecasting of univariate time series using automatic trend extrapolation. PROC FORECAST is an easy-to-use procedure for automatic forecasting that uses simple popular methods that do not require statistical modeling of the time series, such as exponential smoothing, time trend with autoregressive errors, and the Holt-Winters method.

The FORECAST procedure supplements the powerful forecasting capabilities of the econometric and time series analysis procedures described above. You can use PROC FORECAST when you have many series to forecast and want to extrapolate trends without developing a model for each series.

The FORECAST procedure includes the following features:

- choice of the following four forecasting methods:
  - exponential smoothing: single, double, triple, or Holt two-parameter smoothing
  - stepwise autoregressive models with constant, linear, or quadratic trend and autoregressive errors to any order
  - Holt-Winters forecasting method with constant, linear, or quadratic trend
  - additive variant of the Holt-Winters method
- support for up to three levels of seasonality for Holt-Winters method: time-of-year, day-of-week, or time-of-day
- ability to forecast any number of variables at once
- forecast confidence limits for all methods

Time Series Interpolation and Frequency Conversion

The EXPAND procedure provides time interval conversion and missing value interpolation for time series. The EXPAND procedure includes the following features:

- conversion of time series frequency; for example, constructing quarterly estimates from annual series or aggregating quarterly values to annual values
- conversion of irregular observations to periodic observations
- interpolation of missing values in time series
- conversion of observation types; for example, estimate stocks from flows and vice versa. All possible conversions supported between
  - beginning of period
  - end of period
  - period midpoint
  - period total
  - period average
- conversion of time series phase shift; for example, conversion between fiscal years and calendar years
- choice of four interpolation methods:
  - cubic splines
  - linear splines
  - step functions
  - simple aggregation
- ability to transform series before and after interpolation (or without interpolation) using:
  - constant shift or scale
  - sign change or absolute value

  - logarithm, exponential, square root, square, logistic, inverse logistic
  - lags, leads, differences
  - classical decomposition
  - bounds, trims, reverse series
  - centered moving, cumulative, or backward moving average
  - centered moving, cumulative, or backward moving corrected sum of squares
  - centered moving, cumulative, or backward moving sum
  - centered moving, cumulative, or backward moving median
  - centered moving, cumulative, or backward moving variance

- support for a wide range of time series frequencies:
  - YEAR
  - SEMIYEAR
  - QUARTER
  - MONTH
  - SEMIMONTH
  - TENDAY
  - WEEK
  - WEEKDAY
  - DAY
  - HOUR
  - MINUTE
  - SECOND
- The basic interval types can be repeated or shifted to define a great variety of different frequencies, such as fiscal years, biennial periods, work shifts, and so forth.

Access to Financial and Economic Databases

The DATASOURCE procedure provides a convenient way to read time series data from data files supplied by a variety of different commercial and governmental data vendors. The DATASOURCE procedure includes the following features:

- support for data files distributed by the following data vendors:
  - DRI/McGraw-Hill
  - FAME Information Services
  - Haver Analytics
  - Standard & Poors Compustat Service
  - Center for Research in Security Prices (CRSP)
  - International Monetary Fund
  - U.S. Bureau of Labor Statistics

  - U.S. Bureau of Economic Analysis
  - Organization for Economic Cooperation and Development (OECD)

- ability to select the series, time range, and cross sections of data extracted
- can create an output data set containing descriptive information on the series available in the data file
- can read EBCDIC tapes on ASCII systems and vice versa

The SASECRSP interface engine enables random access to time series data residing in CRSPAccess database files and provides a seamless interface between CRSP and SAS data processing. The SASECRSP engine uses the LIBNAME statement to enable you to specify which time series you would like to read from the CRSPAccess database, and how you would like to perform selection on the CRSP set you choose to access. The following data sets are available:

STKHEAD	header identification and summary data
NAMES	history array
SHARES	outstanding observation array
DELIST	delisting history array
PRC	Price or Bid/Ask Average Time Series
RET	Returns Time Series
BID, ASK, RETX	Returns without Dividends Time Series
SPREAD	Spread Between Bid and Ask Time Series
VOL	Volume Time Series
NUMTRD	Number of Trades Time Series
ALTPRCDT	Alternate Price Date Time Series
PORT1-PORT9	nine types of Portfolio Assignments and Portfolio Statistics.

The SASEFAME interface engine provides SAS and FAME users flexibility in accessing and processing time series data residing in either a FAME database or a SAS data set, and provides a seamless interface between FAME and SAS data processing. The SASEFAME engine uses the LIBNAME statement to enable you to specify which time series you would like to read from the FAME database, and how you would like to convert the selected time series to the same time scale. The SAS DATA step can then be used to perform further subsetting and to store the resulting time series into a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time. If you are running FAME in a client/server environment and have FAME CHLI capability on your FAME server, you can access your FAME remote data by specifying the port number of the TCP/IP service that is defined for your *frdb_m* and the node name of your FAME master server in your physical path.

The SASEHAVR interface engine is experimental for V9 and enables Windows users random access to economic and financial data residing in a HAVER ANALYTICS

Data Link Express (DLX) database. You can limit the range of data that is read from the time series and specify a desired conversion frequency. Start dates are recommended on the libname statement to help you save resources when processing large databases or when processing a large number of observations. You can further subsetting of your data by using the WHERE, KEEP, or DROP statements in your DATA step. You can use the SQL procedure to create a view of your resulting SAS data set.

Spreadsheet Calculations and Financial Report Generation

The COMPUTAB procedure generates tabular reports using a programmable data table.

The COMPUTAB procedure is especially useful when you need both the power of a programmable spreadsheet and a report generation system, and you want to set up a program to run in batch mode and generate routine reports. The COMPUTAB procedure includes the following features:

- report generation facility for creating tabular reports such as income statements, balance sheets, and other row and column reports for analyzing business or time series data
- can tailor report format to almost any desired specification
- uses the SAS programming language to provide complete control of the calculation and format of each item of the report
- reports definition in terms of a data table on which programming statements operate
- a single reference to a row or column brings the entire row or column into a calculation
- can create new rows and columns (such as totals, subtotals, and ratios) with a single programming statement
- access to individual table values is available when needed
- built-in features to provide consolidation reports over summarization variables

An alternate to the COMPUTAB procedure is the experimental SYLK procedure available in Base SAS. The documentation for the SYLK procedure can be found at http://support.sas.com/documentation/onlinedoc by selecting “Base SAS” from the Product-Specific Documentation list.

Loan Analysis, Comparison, and Amortization

The LOAN procedure provides analysis and comparison of mortgages and other installment loans. The LOAN procedure includes the following features:

- contract terms for any number of different loans may be input and various financing alternatives may be analyzed and compared
- analysis of four different types of loan contracts including

  - fixed rate
  - adjustable rate
  - buydown rate
  - balloon payment

- full control over adjustment terms for adjustable rate loans: life caps, adjustment frequency, and maximum and minimum rates
- support for a wide variety of payment and compounding intervals
- loan calculations can incorporate initialization costs, discount points, down payments, and prepayments (uniform or lump-sum)
- analysis of different rate adjustment scenarios for variable rate loans including
  - worst case
  - best case
  - fixed rate case
  - estimated case
- can make loan comparisons at different points in time
- can make loan comparisons at each analysis date on the basis of five different economic criteria
  - present worth of cost (net present value of all payments to date)
  - true interest rate (internal rate of return to date)
  - current periodic payment
  - total interest paid to date
  - outstanding balance
- can base loan comparisons on either after-tax or before-tax analysis
- reports best alternative when loans of equal amount are compared
- amortization schedules for each loan contract
- when starting date is specified, output shows payment dates rather than just payment sequence numbers
- can optionally print or output to SAS data sets the amortization schedules, loan summaries, and loan comparison information
- can specify rounding of payments to any number of decimal places

Time Series Forecasting System

SAS/ETS software includes the Time Series Forecasting System, a point-and-click application for exploring and analyzing univariate time series data. You can use the automatic model selection facility to select the best-fitting model for each time series, or you can use the system's diagnostic features and time series modeling tools interactively to develop forecasting models customized to best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The system can be invoked from the Solutions menu under Analysis, by the Forecast command, and by the Forecasting icon in the Data Analysis folder of the SAS Desktop.

The following is a brief summary of the features of the Time Series Forecasting system. With the system you can

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits. You can plot changes or transformations of series, zoom in on parts of the graphs, or plot autocorrelations.
- use hold-out samples to select the best forecasting method.
- compare goodness-of-fit measures for any two forecasting models side by side or list all models sorted by a particular fit statistic.
- view the predictions and errors for each model in a spreadsheet or view and compare the forecasts from any two models in a spreadsheet.
- examine the fitted parameters of each forecasting model and their statistical significance.
- control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models.
- customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection.
- save your work in a project catalog.
- print an audit trail of the forecasting process.
- save and print system output including spreadsheets and graphs.

Investment Analysis System

The Investment Analysis System is an interactive environment for the time-value of money of a variety of investments:

- Loans
- Savings
- Depreciations
- Bonds
- Generic cashflows

Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

These analyses can help answer a number of questions you may have about your investments:

- Which option is more profitable or less costly?
- Is it better to buy or rent?
- Are the extra fees for refinancing at a lower interest rate justified?
- What is the balance of this account after saving this amount periodically for so many years?
- How much is legally tax-deductible?
- Is this a reasonable price?

Investment Analysis can be beneficial to users in many industries for a variety of decisions:

- manufacturing: cost justification of automation or any capital investment, replacement analysis of major equipment, or economic comparison of alternative designs
- government: setting funds for services
- finance: investment analysis and portfolio management for fixed-income securities

Related SAS Software

Many features not found in SAS/ETS software are available in other parts of the SAS System. If you do not find something you need in SAS/ETS software, you may find it in one of the following SAS software products.

Base SAS Software

The features provided by SAS/ETS software are extensions to the features provided by Base SAS software. Many data management and reporting capabilities you will need are part of Base SAS software. Refer to *SAS Language: Reference* and the *SAS Procedures Guide* for documentation of Base SAS software.

The following sections summarize Base SAS software features of interest to users of SAS/ETS software. See Chapter 2 for further discussion of some of these topics as they relate to time series data and SAS/ETS software.

SAS DATA Step

The DATA step is your primary tool for reading and processing data in the SAS System. The DATA step provides a powerful general purpose programming language that enables you to perform all kinds of data processing tasks. The DATA step is documented in *SAS Language: Reference*.

Base SAS Procedures

Base SAS software includes many useful SAS procedures. Base SAS procedures are documented in the *SAS Procedures Guide*. The following is a list of Base SAS procedures you may find useful:

CATALOG	for managing SAS catalogs
CHART	for printing charts and histograms
COMPARE	for comparing SAS data sets
CONTENTS	for displaying the contents of SAS data sets
COPY	for copying SAS data sets
CORR	for computing correlations
CPORT	for moving SAS data libraries between computer systems
DATASETS	for deleting or renaming SAS data sets
FREQ	for computing frequency crosstabulations
MEANS	for computing descriptive statistics and summarizing or collapsing data over cross sections
PLOT	for printing scatter plots
PRINT	for printing SAS data sets
RANK	for computing rankings or order statistics
SORT	for sorting SAS data sets
SQL	for processing SAS data sets with Structured Query Language
STANDARD	for standardizing variables to a fixed mean and variance
SYLK	for translating spreadsheets to batch SAS programs. The SYLK procedure is experimental. The documentation can be found at http://support.sas.com/documentation/onlinedoc by selecting “Base SAS” from the Product-Specific Documentation list

TABULATE	for printing descriptive statistics in tabular format
TIMEPLOT	for plotting variables over time
TRANSPOSE	for transposing SAS data sets
UNIVARIATE	for computing descriptive statistics

Global Statements

Global statements can be specified anywhere in your SAS program, and they remain in effect until changed. Global statements are documented in *SAS Language: Reference*. You may find the following SAS global statements useful:

FILENAME	for accessing data files
FOOTNOTE	for printing footnote lines at the bottom of each page
%INCLUDE	for including files of SAS statements
LIBNAME	for accessing SAS data libraries
OPTIONS	for setting various SAS system options
RUN	for executing the preceding SAS statements
TITLE	for printing title lines at the top of each page
X	for issuing host operating system commands from within your SAS session

Some Base SAS statements can be used with any SAS procedure, including SAS/ETS procedures. These statements are not global, and they only affect the SAS procedure they are used with. These statements are documented in *SAS Language: Reference*.

The following Base SAS statements are useful with SAS/ETS procedures:

BY	for computing separate analyses for groups of observations
FORMAT	for assigning formats to variables
LABEL	for assigning descriptive labels to variables
WHERE	for subsetting data to restrict the range of data processed or to select or exclude observations from the analysis

SAS Functions

SAS functions can be used in DATA step programs and in the COMPUTAB and MODEL procedures. The following kinds of functions are available:

- character functions for manipulating character strings
- date and time functions, for performing date and calendar calculations
- financial functions, for performing financial calculations such as depreciation, net present value, periodic savings, and internal rate of return

- lagging and differencing functions, for computing lags and differences
- mathematical functions, for computing data transformations and other mathematical calculations
- probability functions, for computing quantiles of statistical distributions and the significance of test statistics
- random number functions, for simulation experiments
- sample statistics functions, for computing means, standard deviations, kurtosis, and so forth

SAS functions are documented in *SAS Language: Reference*. Chapter 2, "Working with Time Series Data," discusses the use of date and time and lagging and differencing functions. Chapter 3, "Date Intervals, Formats, and Functions," contains a reference list of date and time functions. Chapter 4, "SAS Macros and Functions," documents more financial functions that are not listed in *SAS Language: Reference*.

Formats, Informats, and Time Intervals

Base SAS software provides formats to control the printing of data values, informats to read data values, and time intervals to define the frequency of time series. See Chapter 3, "Date Intervals, Formats, and Functions," for more information.

SAS/GRAPH Software

SAS/GRAPH software includes procedures that create two- and three-dimensional high resolution color graphics plots and charts. You can generate output that graphs the relationship of data values to one another, enhance existing graphs, or simply create graphics output that is not tied to data. SAS/GRAPH software can produce

- charts
- plots
- maps
- text
- three-dimensional graphs

With SAS/GRAPH software you can produce high-resolution color graphics plots of time series data.

SAS/STAT Software

SAS/STAT software is of interest to users of SAS/ETS software because many econometric and other statistical methods not included in SAS/ETS software are provided in SAS/STAT software.

SAS/STAT software includes procedures for a wide range of statistical methodologies including

- logistic regression
- censored regression
- principal component analysis
- structural equation models using covariance structure analysis
- factor analysis
- survival analysis
- discriminant analysis
- cluster analysis
- categorical data analysis; log-linear and conditional logistic models
- general linear models
- mixed linear and nonlinear models
- generalized linear models
- response surface analysis
- kernel density estimation
- LOESS regression
- spline regression
- two-dimensional kriging
- multiple imputation for missing values

SAS/IML Software

SAS/IML software gives you access to a powerful and flexible programming language (Interactive Matrix Language) in a dynamic, interactive environment. The fundamental object of the language is a data matrix. You can use SAS/IML software interactively (at the statement level) to see results immediately, or you can store statements in a module and execute them later. The programming is dynamic because necessary activities such as memory allocation and dimensioning of matrices are done automatically.

You can access built-in operators and call routines to perform complex tasks such as matrix inversion or eigenvector generation. You can define your own functions and subroutines using SAS/IML modules. You can perform operations on an entire data matrix. You have access to a wide choice of data management commands. You can read, create, and update SAS data sets from inside SAS/IML software without ever using the DATA step.

SAS/IML software is of interest to users of SAS/ETS software because it enables you to program your own econometric and time series methods in the SAS System. It contains subroutines for time series operators and for general function optimization. If you need to perform a statistical calculation not provided as an automated feature by SAS/ETS or other SAS software, you can use SAS/IML software to program the matrix equations for the calculation.

Kalman Filtering and Time Series Analysis in SAS/IML

SAS/IML software includes a library for Kalman filtering and time series analysis which provides the following functions:

- generating univariate, multivariate, and fractional time series
- computing likelihood function of ARMA, VARMA, and ARFIMA models
- computing an autocovariance function of ARMA, VARMA, and ARFIMA models
- checking the stationarity of ARMA and VARMA models
- filtering and smoothing of time series models using Kalman method
- fitting AR, periodic AR, time-varying coefficient AR, VAR, and ARFIMA models
- handling Bayesian seasonal adjustment model

Refer to Chapter 10, "Time Series Analysis and Examples," (*SAS/IML User's Guide*) for details.

SAS/INSIGHT Software

SAS/INSIGHT software is a highly interactive tool for data analysis. You can explore data through a variety of interactive graphs including bar charts, scatter plots, box plots, and three-dimensional rotating plots. You can examine distributions and perform parametric and nonparametric regression, analyze general linear models and generalized linear models, examine correlation matrixes, and perform principal component analyses. Any changes you make to your data show immediately in all graphs and analyses. You can also configure SAS/INSIGHT software to produce graphs and analyses tailored to the way you work.

SAS/INSIGHT software is an integral part of the SAS System. You can use it to examine output from a SAS procedure, and you can use any SAS procedure to analyze results from SAS/INSIGHT software.

SAS/INSIGHT software includes features for both displaying and analyzing data interactively. A data window displays a SAS data set as a table with columns of the table displaying variables and rows displaying observations. Data windows provide data management features for editing, transforming, subsetting, and sorting data. A graph window displays different types of graphs: bar charts, scatter plots, box plots, and rotating plots. Graph windows provide interactive exploratory techniques such as data brushing and highlighting. Analysis windows display statistical analyses in the form of graphs and tables. Analysis window features include

- univariate statistics
- robust estimates
- density estimates
- cumulative distribution functions

- theoretical quantile-quantile plots
- multiple regression analysis with numerous diagnostic capabilities
- general linear models
- generalized linear models
- smoothing spline estimates
- kernel density estimates
- correlations
- principal components

SAS/INSIGHT software may be of interest to users of SAS/ETS software for interactive graphical viewing of data, editing data, exploratory data analysis, and checking distributional assumptions.

SAS/OR Software

SAS/OR software provides SAS procedures for operations research and project planning and includes a menu driven system for project management. SAS/OR software has features for

- solving transportation problems
- linear, integer, and mixed-integer programming
- nonlinear programming and optimization
- scheduling projects
- plotting Gantt charts
- drawing network diagrams
- solving optimal assignment problems
- network flow programming

SAS/OR software may be of interest to users of SAS/ETS software for its mathematical programming features. In particular, the NLP procedure in SAS/OR software solves nonlinear programming problems and can be used for constrained and unconstrained maximization of user-defined likelihood functions.

SAS/QC Software

SAS/QC software provides a variety of procedures for statistical quality control and quality improvement. SAS/QC software includes procedures for

- Shewhart control charts
- cumulative sum control charts
- moving average control charts

- process capability analysis
- Ishikawa diagrams
- Pareto charts
- experimental design

SAS/QC software also includes the SQC menu system for interactive application of statistical quality control methods and the ADX Interface for experimental design.

MLE for User-Defined Likelihood Functions

There are three SAS procedures that enable you to do maximum likelihood estimation of parameters in an arbitrary model with a likelihood function that you define: PROC MODEL, PROC NLP, and PROC IML.

The MODEL procedure in SAS/ETS software enables you to minimize general log-likelihood functions for the error term of a model.

The NLP procedure in SAS/OR software is a general nonlinear programming procedure that can maximize a general function subject to linear equality or inequality constraints. You can use PROC NLP to maximize a user-defined nonlinear likelihood function.

You can use the IML procedure in SAS/IML software for maximum likelihood problems. The optimization routines used by PROC NLP are available through IML subroutines. You can write the likelihood function in the SAS/IML matrix language and call the constrained and unconstrained nonlinear programming subroutines to maximize the likelihood function with respect to the parameter vector.

Other Statistical Tools

Many other statistical tools are available in Base SAS, SAS/STAT, SAS/OR, SAS/QC, SAS/INSIGHT, and SAS/IML software. If you don't find something you need in SAS/ETS software, you may find it in SAS/STAT software and in Base SAS software. If you still don't find it, look in other SAS software products or contact the SAS Institute Technical Support staff.

Chapter 2
Working with Time Series Data

Chapter Contents

Chapter 2
Working with Time Series Data

Overview

This chapter discusses working with time series data in the SAS System. The following topics are included:

- dating time series and working with SAS date and datetime values
- subsetting data and selecting observations
- storing time series data in SAS data sets
- specifying time series periodicity and time intervals
- plotting time series
- using calendar and time interval functions
- computing lags and other functions across time
- transforming time series
- transposing time series data sets
- interpolating time series
- reading time series data recorded in different ways

In general, this chapter focuses on using features of the SAS programming language and not on features of SAS/ETS software. However, since SAS/ETS procedures are used to analyze time series, understanding how to use the SAS programming language to work with time series data is important for the effective use of SAS/ETS software.

You do not need to read this chapter to use SAS/ETS procedures. If you are already familiar with SAS programming you may want to skip this chapter, or you may refer to sections of this chapter for help on specific time series data processing questions.

Time Series and SAS Data Sets

Introduction

To analyze data with the SAS System, data values must be stored in a SAS data set. A SAS data set is a matrix or table of data values organized into variables and observations.

The *variables* in a SAS data set label the columns of the data matrix and the observations in a SAS data set are the rows of the data matrix. You can also think of a SAS data set as a kind of file, with the observations representing records in the file and the variables representing fields in the records. (Refer to *SAS Language: Reference, Version 6* for more information about SAS data sets.)

Usually, each observation represents the measurement of one or more variables for the individual subject or item observed. Often, the values of some of the variables in the data set are used to identify the individual subjects or items that the observations measure. These identifying variables are referred to as *ID variables*.

For many kinds of statistical analysis, only relationships among the variables are of interest, and the identity of the observations does not matter. ID variables may not be relevant in such a case.

However, for time series data the identity and order of the observations are crucial. A time series is a set of observations made at a succession of equally spaced points in time.

For example, if the data are monthly sales of a company's product, the variable measured is sales of the product and the thing observed is the operation of the company during each month. These observations can be identified by year and month. If the data are quarterly gross national product, the variable measured is final goods production and the thing observed is the economy during each quarter. These observations can be identified by year and quarter.

For time series data, the observations are identified and related to each other by their position in time. Since the SAS system does not assume any particular structure to the observations in a SAS data set, there are some special considerations needed when storing time series in a SAS data set.

The main considerations are how to associate dates with the observations and how to structure the data set so that SAS/ETS procedures and other SAS procedures will recognize the observations of the data set as constituting time series. These issues are discussed in following sections.

Reading a Simple Time Series

Time series data can be recorded in many different ways. The section "Reading Time Series Data" later in this chapter discusses some of the possibilities. The example below shows a simple case.

The following SAS statements read monthly values of the U.S. Consumer Price Index for June 1990 through July 1991. The data set USCPI is shown in Figure 2.1.

```
data uscpi;
   input year month cpi;
datalines;
1990  6 129.9
1990  7 130.4
1990  8 131.6
1990  9 132.7
1990 10 133.5
1990 11 133.8
1990 12 133.8
```

```
1991  1 134.6
1991  2 134.8
1991  3 135.0
1991  4 135.2
1991  5 135.6
1991  6 136.0
1991  7 136.2
;

proc print data=uscpi;
run;
```

```
                     Obs    year    month     cpi

                       1    1990       6     129.9
                       2    1990       7     130.4
                       3    1990       8     131.6
                       4    1990       9     132.7
                       5    1990      10     133.5
                       6    1990      11     133.8
                       7    1990      12     133.8
                       8    1991       1     134.6
                       9    1991       2     134.8
                      10    1991       3     135.0
                      11    1991       4     135.2
                      12    1991       5     135.6
                      13    1991       6     136.0
                      14    1991       7     136.2
```

Figure 2.1. Time Series Data

When a time series is stored in the manner shown by this example, the terms *series* and *variable* can be used interchangeably. There is one observation per row, and one series/variable per column.

Dating Observations

The SAS System supports special date, datetime, and time values, which make it easy to represent dates, perform calendar calculations, and identify the time period of observations in a data set.

The preceding example used the ID variables YEAR and MONTH to identify the time periods of the observations. For a quarterly data set, you might use YEAR and QTR as ID variables. A daily data set might have the ID variables YEAR, MONTH, and DAY. Clearly, it would be more convenient to have a single ID variable that could be used to identify the time period of observations, regardless of their frequency.

The following section, "SAS Date, Datetime, and Time Values," discusses how the SAS System represents dates and times internally and how to specify date, datetime, and time values in a SAS program. The section "Reading Date and Datetime Values with Informats" discusses how to control the display of date and datetime values in SAS output and how to read in date and time values from data records. Later sections discuss other issues concerning date and datetime values, specifying time intervals, data periodicity, and calendar calculations.

SAS date and datetime values and the other features discussed in the following sections are also described in *SAS Language: Reference*. Reference documentation on these features is also provided in Chapter 3, "Date Intervals, Formats, and Functions."

SAS Date, Datetime, and Time Values

Year 2000 Compliance

SAS software correctly represents dates from 1582 AD to the year 20,000 AD. If dates in an external data source are represented with four-digit-year values SAS can read, write and compute these dates. If the dates in an external data source are two-digit years, SAS software provides informats, functions, and formats to read, manipulate, and output dates that are Year 2000 compliant. The YEARCUTOFF= system option can also be used to interpret dates with two-digit years by specifying the first year of a 100-year span that will be used in informats and functions. The default value for the YEARCUTOFF= option is 1920.

SAS Date Values

The SAS System represents dates as the number of days since a reference date. The reference date, or date zero, used for SAS date values is 1 January 1960. Thus, for example, 3 February 1960 is represented by the SAS System as 33. The SAS date for 17 October 1991 is 11612.

Dates represented in this way are called SAS *date values*. Any numeric variable in a SAS data set whose values represent dates in this way is called a SAS *date variable*.

Representing dates as the number of days from a reference date makes it easy for the computer to store them and perform calendar calculations, but these numbers are not meaningful to users. However, you never have to use SAS date values directly, since SAS automatically converts between this internal representation and ordinary ways of expressing dates, provided that you indicate the format with which you want the date values to be displayed. (Formatting of date values is explained in a following section.)

SAS Date Constants

SAS date values are written in a SAS program by placing the dates in single quotes followed by a D. The date is represented by the day of the month, the three letter abbreviation of the month name, and the year.

For example, SAS reads the value '17OCT1991'D the same as 11612, the SAS date value for 17 October 1991. Thus, the following SAS statements print DATE=11612.

```
data _null_;
  date = '17oct1991'd;
  put date=;
run;
```

The year value can be given with two or four digits, so '17OCT91'D is the same as '17OCT1991'D. (The century assumed for a two-digit year value can be controlled with the YEARCUTOFF= option in the OPTIONS statement. Refer to the *SAS Language: Reference* for information on YEARCUTOFF=.)

SAS Datetime Values and Datetime Constants

To represent both the time of day and the date, the SAS System uses *datetime values*. SAS datetime values represent the date and time as the number of seconds the time is from a reference time. The reference time, or time zero, used for SAS datetime values is midnight, 1 January 1960. Thus, for example, the SAS datetime value for 17 October 1991 at 2:45 in the afternoon is 1003329900.

To specify datetime constants in a SAS program, write the date and time in single quotes followed by DT. To write the date and time in a SAS datetime constant, write the date part using the same syntax as for date constants, and follow the date part with the hours, the minutes, and the seconds, separating the parts with colons. The seconds are optional.

For example, in a SAS program you would write 17 October 1991 at 2:45 in the afternoon as '17OCT91:14:45'DT. SAS reads this as 1003329900. Table 2.1 shows some other examples of datetime constants.

Table 2.1. Examples of Datetime Constants

Datetime Constant	Time
'17OCT1991:14:45:32'DT	32 seconds past 2:45 p.m., 17 October 1991
'17OCT1991:12:5'DT	12:05 p.m., 17 October 1991
'17OCT1991:2:0'DT	2 AM, 17 October 1991
'17OCT1991:0:0'DT	midnight, 17 October 1991

SAS Time Values

The SAS System also supports *time values*. SAS time values are just like datetime values, except that the date part is not given. To write a time value in a SAS program, write the time the same as for a datetime constant but use T instead of DT. For example, 2:45:32 p.m. is written '14:45:32'T. Time values are represented by a number of seconds since midnight, so SAS reads '14:45:32'T as 53132.

SAS time values are not very useful for identifying time series, since usually both the date and the time of day are needed. Time values are not discussed further in this book.

Reading Date and Datetime Values with Informats

The SAS System provides a selection of *informats* for reading SAS date and datetime values from date and time values recorded in ordinary notations.

A SAS informat is an instruction that converts the values from a character string representation into the internal numerical value of a SAS variable. Date informats convert dates from ordinary notations used to enter them to SAS date values; datetime informats convert date and time from ordinary notation to SAS datetime values.

For example, the following SAS statements read monthly values of the U.S. Consumer Price Index. Since the data are monthly, you could identify the date with the variables YEAR and MONTH, as in the previous example. Instead, in this example the time periods are coded as a three-letter month abbreviation followed by the year. The informat MONYY. is used to read month-year dates coded this way and to express them as SAS date values for the first day of the month, as follows.

```
data uscpi;
   input date: monyy7. cpi;
datalines;
jun1990 129.9
jul1990 130.4
aug1990 131.6
sep1990 132.7
oct1990 133.5
nov1990 133.8
dec1990 133.8
jan1991 134.6
feb1991 134.8
mar1991 135.0
apr1991 135.2
may1991 135.6
jun1991 136.0
jul1991 136.2
;
```

The SAS System provides informats for most common notations for dates and times. See Chapter 3 for more information on the date and datetime informats available.

Formatting Date and Datetime Values

The SAS System provides *formats* to convert the internal representation of date and datetime values used by SAS to ordinary notations for dates and times. Several different formats are available for displaying dates and datetime values in most of the commonly used notations.

A SAS format is an instruction that converts the internal numerical value of a SAS variable to a character string that can be printed or displayed. Date formats convert SAS date values to a readable form; datetime formats convert SAS datetime values to a readable form.

In the preceding example, the variable DATE was set to the SAS date value for the first day of the month for each observation. If the data set USCPI were printed or otherwise displayed, the values shown for DATE would be the number of days since 1 January 1960. (See the "DATE with no format" column in Figure 2.2.) To display date values appropriately, use the FORMAT statement.

The following example processes the data set USCPI to make several copies of the variable DATE and uses a FORMAT statement to give different formats to these copies. The format cases shown are the MONYY7. format (for the DATE variable), the DATE9. format (for the DATE1 variable), and no format (for the DATE0 variable). The PROC PRINT output in Figure 2.2 shows the effect of the different formats on how the date values are printed.

```
data fmttest;
   set uscpi;
   date0 = date;
   date1 = date;
   label date  = "DATE with MONYY7. format"
         date1 = "DATE with DATE9. format"
         date0 = "DATE with no format";
   format date monyy7. date1 date9.;
run;

proc print data=fmttest label;
run;
```

```
                 DATE with                                DATE with
                  MONYY.                     DATE with      DATE.
          Obs     format         cpi         no format     format

            1     JUN1990       129.9          11109      01JUN1990
            2     JUL1990       130.4          11139      01JUL1990
            3     AUG1990       131.6          11170      01AUG1990
            4     SEP1990       132.7          11201      01SEP1990
            5     OCT1990       133.5          11231      01OCT1990
            6     NOV1990       133.8          11262      01NOV1990
            7     DEC1990       133.8          11292      01DEC1990
            8     JAN1991       134.6          11323      01JAN1991
            9     FEB1991       134.8          11354      01FEB1991
           10     MAR1991       135.0          11382      01MAR1991
```

Figure 2.2. SAS Date Values Printed with Different Formats

The appropriate format to use for SAS date or datetime valued ID variables depends on the sampling frequency or periodicity of the time series. Table 2.2 shows recommended formats for common data sampling frequencies and shows how the date ’17OCT1991’D or the datetime value ’17OCT1991:14:45:32’DT is displayed by these formats.

Table 2.2. Formats for Different Sampling Frequencies

ID values	Periodicity	FORMAT	Example
SAS Date	Annual	YEAR4.	1991
	Quarterly	YYQC6.	1991:4
	Monthly	MONYY7.	OCT1991
	Weekly	WEEKDATX23.	Thursday, 17 Oct 1991
		DATE9.	17OCT1991
	Daily	DATE9.	17OCT1991
SAS Datetime	Hourly	DATETIME10.	17OCT91:14
	Minutes	DATETIME13.	17OCT91:14:45
	Seconds	DATETIME16.	17OCT91:14:45:32

See Chapter 3 for more information on the date and datetime formats available.

The Variables DATE and DATETIME

SAS/ETS procedures enable you to identify time series observations in many different ways to suit your needs. As discussed in preceding sections, you can use a combination of several ID variables, such as YEAR and MONTH for monthly data.

However, using a single SAS date or datetime ID variable is more convenient and enables you to take advantage of some features SAS/ETS procedures provide for processing ID variables. One such feature is automatic extrapolation of the ID variable to identify forecast observations. These features are discussed in following sections.

Thus, it is a good practice to include a SAS date or datetime ID variable in all the time series SAS data sets you create. It is also a good practice to always give the date or datetime ID variable a format appropriate for the data periodicity.

You can name a SAS date or datetime valued ID variable any name conforming to SAS variable name requirements. However, you may find working with time series data in SAS easier and less confusing if you adopt the practice of always using the same name for the SAS date or datetime ID variable.

This book always names the dating ID variable "DATE" if it contains SAS date values or "DATETIME" if it contains SAS datetime values. This makes it easy to recognize the ID variable and also makes it easy to recognize whether this ID variable uses SAS date or datetime values.

Sorting by Time

Many SAS/ETS procedures assume the data are in chronological order. If the data are not in time order, you can use the SORT procedure to sort the data set. For example

```
proc sort data=a;
   by date;
run;
```

There are many ways of coding the time ID variable or variables, and some ways do not sort correctly. If you use SAS date or datetime ID values as suggested in the preceding section, you do not need to be concerned with this issue. But if you encode date values in nonstandard ways, you need to consider whether your ID variables will sort.

SAS date and datetime values always sort correctly, as do combinations of numeric variables like YEAR, MONTH, and DAY used together. Julian dates also sort correctly. (Julian dates are numbers of the form *yyddd*, where *yy* is the year and *ddd* is the day of the year. For example 17 October 1991 has the Julian date value 91290.)

Calendar dates such as numeric values coded as *mmddyy* or *ddmmyy* do not sort correctly. Character variables containing display values of dates, such as dates in the notation produced by SAS date formats, generally do not sort correctly.

Subsetting Data and Selecting Observations

It is often necessary to subset data for analysis. You may need to subset data to

- restrict the time range. For example, you want to perform a time series analysis using only recent data and ignoring observations from the distant past.
- select cross sections of the data. (See the section "Cross-sectional Dimensions and BY Groups" later in this chapter.) For example, you have a data set with observations over time for each of several states, and you want to analyze the data for a single state.
- select particular kinds of time series from an interleaved form data set. (See the section "Interleaved Time Series and the _TYPE_ Variable" later in this chapter.) For example, you have an output data set produced by the FORECAST procedure that contains both forecast and confidence limits observations, and you want to extract only the forecast observations.
- exclude particular observations. For example, you have an outlier in your time series, and you want to exclude this observation from the analysis.

You can subset data either by using the DATA step to create a subset data set or by using a WHERE statement with the SAS procedure that analyzes the data.

A typical WHERE statement used in a procedure has the form

```
proc arima data=full;
   where '31dec1993'd < day < '26mar1994'd;
   identify var=close;
run;
```

For complete reference documentation on the WHERE statement refer to *SAS Language: Reference*.

Subsetting SAS Data Sets

To create a subset data set, specify the name of the subset data set on the DATA statement, bring in the full data set with a SET statement, and specify the subsetting criteria with either subsetting IF statements or WHERE statements.

For example, suppose you have a data set containing time series observations for each of several states. The following DATA step uses a WHERE statement to exclude observations with dates before 1970 and uses a subsetting IF statement to select observations for the state NC:

```
data subset;
   set full;
   where date >= '1jan1970'd;
   if state = 'NC';
run;
```

In this case, it makes no difference logically whether the WHERE statement or the IF statement is used, and you can combine several conditions on one subsetting statement. The following statements produce the same results as the previous example:

```
data subset;
   set full;
   if date >= '1jan1970'd & state = 'NC';
run;
```

The WHERE statement acts on the input data sets specified in the SET statement before observations are processed by the DATA step program, whereas the IF statement is executed as part of the DATA step program. If the input data set is indexed, using the WHERE statement can be more efficient than using the IF statement. However, the WHERE statement can only refer to variables in the input data set, not to variables computed by the DATA step program.

To subset the variables of a data set, use KEEP or DROP statements or use KEEP= or DROP= data set options. Refer to *SAS Language: Reference* for information on KEEP and DROP statements and SAS data set options.

For example, suppose you want to subset the data set as in the preceding example, but you want to include in the subset data set only the variables DATE, X, and Y. You could use the following statements:

```
data subset;
   set full;
   if date >= '1jan1970'd & state = 'NC';
   keep date x y;
run;
```

Using the WHERE Statement with SAS Procedures

Use the WHERE statement with SAS procedures to process only a subset of the input data set. For example, suppose you have a data set containing monthly observations for each of several states, and you want to use the AUTOREG procedure to analyze data since 1970 for the state NC. You could use the following:

```
proc autoreg data=full;
   where date >= '1jan1970'd & state = 'NC';
  ... additional statements ...
run;
```

You can specify any number of conditions on the WHERE statement. For example, suppose that a strike created an outlier in May 1975, and you want to exclude that observation. You could use the following:

```
proc autoreg data=full;
   where date >= '1jan1970'd & state = 'NC'
       & date ^= '1may1975'd;
  ... additional statements ...
run;
```

Using SAS Data Set Options

You can use the OBS= and FIRSTOBS= data set options to subset the input data set. These options cannot be used in conjunction with the WHERE statement.

For example, the following statements print observations 20 through 25 of the data set FULL.

```
proc print data=full(firstobs=20 obs=25);
run;
```

You can use KEEP= and DROP= data set options to exclude variables from the input data set. Refer to *SAS Language: Reference* for information on SAS data set options.

Storing Time Series in a SAS Data Set

This section discusses aspects of storing time series in SAS data sets. The topics discussed are the standard form of a time series data set, storing several series with different time ranges in the same data set, omitted observations, cross-sectional dimensions and BY groups, and interleaved time series.

Any number of time series can be stored in a SAS data set. Normally, each time series is stored in a separate variable. For example, the following statements augment the USCPI data set read in the previous example with values for the producer price index.

```
data usprice;
   input date monyy7. cpi ppi;
   format date monyy7.;
   label cpi = "Consumer Price Index"
         ppi = "Producer Price Index";
datalines;
jun1990 129.9 114.3
jul1990 130.4 114.5

```

Figure 2.3. Time Series Data Set Containing Two Series

Standard Form of a Time Series Data Set

The simple way the CPI and PPI time series are stored in the USPRICE data set in the preceding example is termed the *standard form* of a time series data set. A time series data set in standard form has the following characteristics:

- The data set contains one variable for each time series.
- The data set contains exactly one observation for each time period.
- The data set contains an ID variable or variables that identify the time period of each observation.
- The data set is sorted by the ID variables associated with date time values, so the observations are in time sequence.
- The data are equally spaced in time. That is, successive observations are a fixed time interval apart, so the data set can be described by a single sampling interval such as hourly, daily, monthly, quarterly, yearly, and so forth. This means that time series with different sampling frequencies are not mixed in the same SAS data set.

Most SAS/ETS procedures that process time series expect the input data set to contain time series in this standard form, and this is the simplest way to store time series in SAS data sets. There are more complex ways to represent time series in SAS data sets.

You can incorporate cross-sectional dimensions with BY groups, so that each BY group is like a standard form time series data set. This method is discussed in the section "Cross-sectional Dimensions and BY Groups."

You can interleave time series, with several observations for each time period identified by another ID variable. Interleaved time series data sets are used to store several series in the same SAS variable. Interleaved time series data sets are often used to store series of actual values, predicted values, and residuals, or series of forecast values and confidence limits for the forecasts. This is discussed in the section "Interleaved Time Series and the _TYPE_ Variable" later in this chapter.

Several Series with Different Ranges

Different time series can have values recorded over different time ranges. Since a SAS data set must have the same observations for all variables, when time series with different ranges are stored in the same data set, missing values must be used for the periods in which a series is not available.

Suppose that in the previous example you did not record values for CPI before August 1990 and did not record values for PPI after June 1991. The USPRICE data set could be read with the following statements:

```
data usprice;
   input date monyy7. cpi ppi;
   format date monyy7.;
datalines;
jun1990     . 114.3
jul1990     . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990 133.8 120.1
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0 116.2
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2     .
;
```

The decimal points with no digits in the data records represent missing data and are read by the SAS System as missing value codes.

In this example, the time range of the USPRICE data set is June 1990 through July 1991, but the time range of the CPI variable is August 1990 through July 1991, and the time range of the PPI variable is June 1990 through June 1991.

SAS/ETS procedures ignore missing values at the beginning or end of a series. That is, the series is considered to begin with the first nonmissing value and end with the last nonmissing value.

Missing Values and Omitted Observations

Missing data can also occur within a series. Missing values that appear after the beginning of a time series and before the end of the time series are called *embedded missing values*.

Suppose that in the preceding example you did not record values for CPI for November 1990 and did not record values for PPI for both November 1990 and March 1991. The USPRICE data set could be read with the following statements.

```
data usprice;
   input date monyy. cpi ppi;
   format date monyy.;
datalines;
jun1990     . 114.3
jul1990     . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990     .     .
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0     .
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2     .
;
```

In this example, the series CPI has one embedded missing value, and the series PPI has two embedded missing values. The ranges of the two series are the same as before.

Note that the observation for November 1990 has missing values for both CPI and PPI; there is no data for this period. This is an example of a *missing observation*.

You might ask why the data record for this period is included in the example at all, since the data record contains no data. However, if the data record for November 1990 were deleted from the example, this would cause an *omitted observation* in the USPRICE data set. SAS/ETS procedures expect input data sets to contain observations for a contiguous time sequence. If you omit observations from a time series data set and then try to analyze the data set with SAS/ETS procedures, the omitted observations will cause errors. When all data are missing for a period, a missing observation should be included in the data set to preserve the time sequence of the series.

Cross-sectional Dimensions and BY Groups

Often, a collection of time series are related by a cross-sectional dimension. For example, the national average U.S. consumer price index data shown in the previous example can be disaggregated to show price indexes for major cities. In this case there are several related time series: CPI for New York, CPI for Chicago, CPI for Los Angeles, and so forth. When these time series are considered one data set, the city whose price level is measured is a cross-sectional dimension of the data.

There are two basic ways to store such related time series in a SAS data set. The first way is to use a standard form time series data set with a different variable for each series.

For example, the following statements read CPI series for three major U.S. cities:

```
data citycpi;
   input date monyy7. cpiny cpichi cpila;
   format date monyy7.;
datalines;
nov1989  133.200  126.700  130.000
dec1989  133.300  126.500  130.600
jan1990  135.100  128.100  132.100
feb1990  135.300  129.200  133.600
mar1990  136.600  129.500  134.500
apr1990  137.300  130.400  134.200
may1990  137.200  130.400  134.600
jun1990  137.100  131.700  135.000
jul1990  138.400  132.000  135.600
;
```

The second way is to store the data in a time series cross-sectional form. In this form, the series for all cross sections are stored in one variable and a cross-section ID variable is used to identify observations for the different series. The observations are sorted by the cross-section ID variable and by time within each cross section.

The following statements indicate how to read the CPI series for U.S. cities in time series cross-sectional form:

```
data cpicity;
   input city $11. date monyy7. cpi;
   format date monyy7.;
datalines;
Chicago     nov1989  126.700
Chicago     dec1989  126.500
Chicago     jan1990  128.100
Chicago     feb1990  129.200
Chicago     mar1990  129.500
Chicago     apr1990  130.400
Chicago     may1990  130.400
Chicago     jun1990  131.700
Chicago     jul1990  132.000
Los Angeles nov1989  130.000
Los Angeles  dec1989  130.600
Los Angeles  jan1990  132.100
 ... etc. ...
New York     may1990  137.200
New York     jun1990  137.100
New York     jul1990  138.400
;

proc sort data=cpicity;
   by city date;
run;
```

When processing a time series cross-section-form data set with most SAS/ETS procedures, use the cross-section ID variable in a BY statement to process the time series separately. The data set must be sorted by the cross-section ID variable and sorted by date within each cross section. The PROC SORT step in the preceding example ensures that the CPICITY data set is correctly sorted.

When the cross-section ID variable is used in a BY statement, each BY group in the data set is like a standard form time series data set. Thus, SAS/ETS procedures that expect a standard form time series data set can process time series cross-sectional data sets when a BY statement is used, producing an independent analysis for each cross section.

It is also possible to analyze time series cross-sectional data jointly. The TSCSREG procedure expects the input data to be in the time series cross-sectional form described here. See Chapter 27 for more information.

Interleaved Time Series

Normally, a time series data set has only one observation for each time period, or one observation for each time period within a cross section for a time series cross-sectional form data set. However, it is sometimes useful to store several related time series in the same variable when the different series do not correspond to levels of a cross-sectional dimension of the data.

In this case, the different time series can be interleaved. An interleaved time series data set is similar to a time series cross-sectional data set, except that the observations are sorted differently, and the ID variable that distinguishes the different time series does not represent a cross-sectional dimension.

Some SAS/ETS procedures produce interleaved output data sets. The interleaved time series form is a convenient way to store procedure output when the results consist of several different kinds of series for each of several input series. (Interleaved time series are also easy to process with plotting procedures. See the section "Plotting Time Series" later in this chapter.)

For example, the FORECAST procedure fits a model to each input time series and computes predicted values and residuals from the model. The FORECAST procedure then uses the model to compute forecast values beyond the range of the input data and also to compute upper and lower confidence limits for the forecast values.

Thus, the output from PROC FORECAST consists of five related time series for each variable forecast. The five resulting time series for each input series are stored in a single output variable with the same name as the input series being forecast. The observations for the five resulting series are identified by values of the ID variable _TYPE_. These observations are interleaved in the output data set with observations for the same date grouped together.

The following statements show the use of PROC FORECAST to forecast the variable CPI in the USCPI data set. Figure 2.4 shows part of the output data set produced by PROC FORECAST and illustrates the interleaved structure of this data set.

```
proc forecast data=uscpi interval=month lead=12
              out=foreout outfull outresid;
   var cpi;
   id date;
run;

proc print data=foreout;
run;
```

```
Obs       date     _TYPE_      _LEAD_         cpi

 37    JUN1991    ACTUAL         0       136.000
 38    JUN1991    FORECAST       0       136.146
 39    JUN1991    RESIDUAL       0        -0.146
 40    JUL1991    ACTUAL         0       136.200
 41    JUL1991    FORECAST       0       136.566
 42    JUL1991    RESIDUAL       0        -0.366
 43    AUG1991    FORECAST       1       136.856
 44    AUG1991    L95            1       135.723
 45    AUG1991    U95            1       137.990

```

Figure 2.4. Partial Listing of Output Data Set Produced by PROC FORECAST

Observations with _TYPE_=ACTUAL contain the values of CPI read from the input data set. Observations with _TYPE_=FORECAST contain one-step-ahead predicted values for observations with dates in the range of the input series, and contain forecast values for observations for dates beyond the range of the input series. Observations with _TYPE_=RESIDUAL contain the difference between the actual and one-step-ahead predicted values. Observations with _TYPE_=U95 and _TYPE_=L95 contain the upper and lower bounds of the 95% confidence interval for the forecasts.

Using Interleaved Data Sets as Input to SAS/ETS Procedures

Interleaved time series data sets are not directly accepted as input by SAS/ETS procedures. However, it is easy to use a WHERE statement with any procedure to subset the input data and select one of the interleaved time series as the input.

For example, to analyze the residual series contained in the PROC FORECAST output data set with another SAS/ETS procedure, include a WHERE

TYPE='RESIDUAL'; statement. The following statements perform a spectral analysis of the residuals produced by PROC FORECAST in the preceding example:

```
proc spectra data=foreout out=spectout;
   var cpi;
   where _type_='RESIDUAL';
run;
```

Combined Cross Sections and Interleaved Time Series Data Sets

Interleaved time series output data sets produced from BY-group processing of time series cross-sectional input data sets have a complex structure combining a cross-sectional dimension, a time dimension, and the values of the _TYPE_ variable. For example, consider the PROC FORECAST output data set produced by the following.

```
data cpicity;
   input city $11. date monyy7. cpi;
   format date monyy7.;
datalines;
Chicago      nov1989  126.700
Chicago      dec1989  126.500
Chicago      jan1990  128.100
 ... etc. ...
New York     may1990  137.200
New York     jun1990  137.100
New York     jul1990  138.400
;

proc sort data=cpicity;
   by city date;
run;

proc forecast data=cpicity interval=month lead=2
              out=foreout outfull outresid;
   var cpi;
   id date;
   by city;
run;
```

The output data set FOREOUT contains many different time series in the single variable CPI. BY groups identified by the variable CITY contain the result series for the different cities. Within each value of CITY, the actual, forecast, residual, and confidence limits series are stored in interleaved form, with the observations for the different series identified by the values of _TYPE_.

Output Data Sets of SAS/ETS Procedures

Some SAS/ETS procedures produce interleaved output data sets (like PROC FORECAST), while other SAS/ETS procedures produce standard form time series data sets. The form a procedure uses depends on whether the procedure is normally used to produce multiple result series for each of many input series in one step (as PROC FORECAST does).

The way different SAS/ETS procedures store result series in output data sets is summarized in Table 2.3.

Table 2.3. Form of Output Data Set for SAS/ETS Procedures

Procedures producing standard form output data sets with fixed names for result series: • ARIMA • SPECTRA • STATESPACE
Procedures producing standard form output data sets with result series named by an OUTPUT statement: • AUTOREG • PDLREG • SIMLIN • SYSLIN • X11
Procedures producing interleaved form output data sets: • FORECAST • MODEL

See the chapters for these procedures for details on the output data sets they create.

For example, the ARIMA procedure can output actual series, forecast series, residual series, and confidence limit series just as the FORECAST procedure does. The PROC ARIMA output data set uses the standard form because PROC ARIMA is designed for the detailed analysis of one series at a time and so only forecasts one series at a time.

The following statements show the use of the ARIMA procedure to produce a forecast of the USCPI data set. Figure 2.5 shows part of the output data set produced by the ARIMA procedure's FORECAST statement. (The printed output from PROC ARIMA is not shown.) Compare the PROC ARIMA output data set shown in Figure 2.5 with the PROC FORECAST output data set shown in Figure 2.4.

```
proc arima data=uscpi;
   identify var=cpi(1);
   estimate q=1;
   forecast id=date interval=month lead=12 out=arimaout;
run;
```

```
proc print data=arimaout;
run;
```

```
Obs       date     cpi     FORECAST      STD        L95        U95      RESIDUAL

 13     JUN1991   136.0    136.078    0.36160    135.369    136.787    -0.07816

 15     AUG1991     .      136.574    0.36160    135.865    137.283      .
 16     SEP1991     .      137.042    0.62138    135.824    138.260      .
```

Figure 2.5. Partial Listing of Output Data Set Produced by PROC ARIMA

The output data set produced by the ARIMA procedure's FORECAST statement stores the actual values in a variable with the same name as the input series, stores the forecast series in a variable named FORECAST, stores the residuals in a variable named RESIDUAL, stores the 95% confidence limits in variables named L95 and U95, and stores the standard error of the forecast in the variable STD.

This method of storing several different result series as a standard form time series data set is simple and convenient. However, it only works well for a single input series. The forecast of a single series can be stored in the variable FORECAST, but if two series are forecast, two different FORECAST variables are needed.

The STATESPACE procedure handles this problem by generating forecast variable names FOR1, FOR2, and so forth. The SPECTRA procedure uses a similar method. Names like FOR1, FOR2, RES1, RES2, and so forth require you to remember the order in which the input series are listed. This is why PROC FORECAST, which is designed to forecast a whole list of input series at once, stores its results in interleaved form.

Other SAS/ETS procedures are often used for a single input series but can also be used to process several series in a single step. Thus, they are not clearly like PROC FORECAST nor clearly like PROC ARIMA in the number of input series they are designed to work with. These procedures use a third method for storing multiple result series in an output data set. These procedures store output time series in standard form (like PROC ARIMA does) but require an OUTPUT statement to give names to the result series.

Time Series Periodicity and Time Intervals

A fundamental characteristic of time series data is how frequently the observations are spaced in time. How often the observations of a time series occur is called the *sampling frequency* or the *periodicity* of the series. For example, a time series with one observation each month has a monthly sampling frequency or monthly periodicity and so is called a monthly time series.

In the SAS System, data periodicity is described by specifying periodic *time intervals* into which the dates of the observations fall. For example, the SAS time interval MONTH divides time into calendar months.

Several SAS/ETS procedures enable you to specify the periodicity of the input data set with the INTERVAL= option. For example, specifying INTERVAL=MONTH indicates that the procedure should expect the ID variable to contain SAS date values, and that the date value for each observation should fall in a separate calendar month. The EXPAND procedure uses interval name values with the FROM= and TO= options to control the interpolation of time series from one periodicity to another.

The SAS System also uses time intervals in several other ways. In addition to indicating the periodicity of time series data sets, time intervals are used with the interval functions INTNX and INTCK, and for controlling the plot axis and reference lines for plots of data over time.

Specifying Time Intervals

Time intervals are specified in SAS Software using *interval names* like YEAR, QTR, MONTH, DAY, and so forth. Table 2.4 summarizes the basic types of intervals.

Table 2.4. Basic Interval Types

Name	**Periodicity**
YEAR	Yearly
SEMIYEAR	Semiannual
QTR	Quarterly
MONTH	Monthly
SEMIMONTH	1st and 16th of each month
TENDAY	1st, 11th, and 21st of each month
WEEK	Weekly
WEEKDAY	Daily ignoring weekend days
DAY	Daily
HOUR	Hourly
MINUTE	Every Minute
SECOND	Every Second

Interval names can be abbreviated in various ways. For example, you could specify monthly intervals as MONTH, MONTHS, MONTHLY, or just MON. The SAS System accepts all these forms as equivalent.

Interval names can also be qualified with a multiplier to indicate multiperiod intervals. For example, biennial intervals are specified as YEAR2.

Interval names can also be qualified with a shift index to indicate intervals with different starting points. For example, fiscal years starting in July are specified as YEAR.7.

Time intervals are classified as either date intervals or datetime intervals. Date intervals are used with SAS date values, while datetime intervals are used with SAS datetime values. The interval types YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, and DAY are date intervals. HOUR, MINUTE, and SECOND are datetime intervals. Date intervals can be turned into datetime intervals for use with datetime values by prefixing the interval name with 'DT'. Thus DTMONTH intervals are like MONTH intervals but are used with datetime ID values instead of date ID values.

See Chapter 3 for more information about specifying time intervals and for a detailed reference to the different kinds of intervals available.

Using Time Intervals with SAS/ETS Procedures

The ARIMA, FORECAST, and STATESPACE procedures use time intervals with the INTERVAL= option to specify the periodicity of the input data set. The EXPAND procedure uses time intervals with the FROM= and TO= options to specify the periodicity of the input and the output data sets. The DATASOURCE and CITIBASE procedures use the INTERVAL= option to control the periodicity of time series extracted from time series databases.

The INTERVAL= option (FROM= option for PROC EXPAND) is used with the ID statement to fully describe the observations that make up the time series. SAS/ETS procedures use the time interval specified by the INTERVAL= option and the ID variable in the following ways:

- to validate the data periodicity. The ID variable is used to check the data and verify that successive observations have valid ID values corresponding to successive time intervals.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for January 1990 is followed by an observation for April 1990, there is a gap in the input data with two omitted observations.
- to label forecast observations in the output data set. The values of the ID variable for the forecast observations after the end of the input data set are extrapolated according to the frequency specifications of the INTERVAL= option.

Time Intervals, the Time Series Forecasting System and the Time Series Viewer

Time intervals are used in the Time Series Forecasting System and Time Series Viewer to identify the number of seasonal cycles or seasonality associated with a DATE, DATETIME or TIME ID variable. For example, monthly time series have a seasonality of 12 because there are 12 months in a year; quarterly time series have a seasonality of 4 because there are 4 quarters in a year. The seasonality is used to analyze seasonal properties of time series data and to estimate seasonal forecasting methods.

Plotting Time Series

This section discusses SAS procedures available for plotting time series data. This section assumes you are generally familiar with SAS plotting procedures and only discusses certain aspects of the use of these procedures with time series data.

The Time Series Viewers displays and analyzes time series plots for time series data sets which do not contain cross-sections. Refer to the Chapter 34, "Getting Started with Time Series Forecasting," later in this book.

The GPLOT procedure produces high resolution color graphics plots. Refer to *SAS/GRAPH Software: Reference, Volume 1 and Volume 2* for information about the GPLOT procedure, SYMBOL statements, and other SAS/GRAPH features.

The PLOT procedure and the TIMEPLOT procedure produce low resolution line printer type plots. Refer to the *SAS Procedures Guide* for information about these procedures.

Using the Time Series Viewer

The following command starts the Time Series Viewer to display the plot of CPI in the USCPI data set against DATE. (The USCPI data set was shown in the previous example; the time series used in the following example contains more observations than previously shown.)

```
tsview data=uscpi var=cpi timeid=date
```

The TSVIEW DATA=option specifies the data set to be viewed; the VAR=option specifies the variable which contains the time series observations; the TIMEID=option specifies the time series ID variable.

Using PROC GPLOT

The following statements use the GPLOT procedure to plot CPI in the USCPI data set against DATE. (The USCPI data set was shown in a previous example; the data set plotted in the following example contains more observations than shown previously.) The SYMBOL statement is used to draw a smooth line between the plotted points and to specify the plotting character.

```
proc gplot data=uscpi;
   symbol i=spline v=circle h=2;
   plot cpi * date;
run;
```

The plot is shown in Figure 2.6.

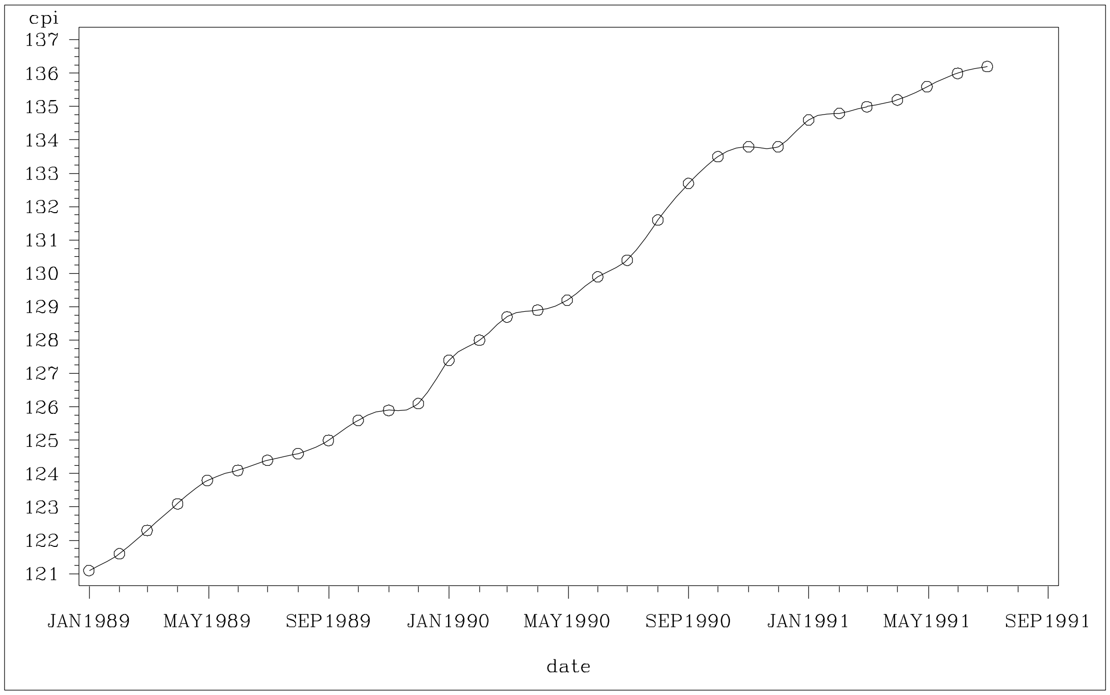

Figure 2.6. Plot of Monthly CPI Over Time

Controlling the Time Axis: Tick Marks and Reference Lines

It is possible to control the spacing of the tick marks on the time axis. The following statements use the HAXIS= option to tell PROC GPLOT to mark the axis at the start of each quarter. (The GPLOT procedure prints a warning message indicating that the intervals on the axis are not evenly spaced. This message simply reflects the fact that there is a different number of days in each quarter. This warning message can be ignored.)

```
proc gplot data=uscpi;
   symbol i=spline v=circle h=2;
   format date yyqc.;
   plot cpi * date /
        haxis= '1jan89'd to '1jul91'd by qtr;
run;
```

The plot is shown in Figure 2.7.

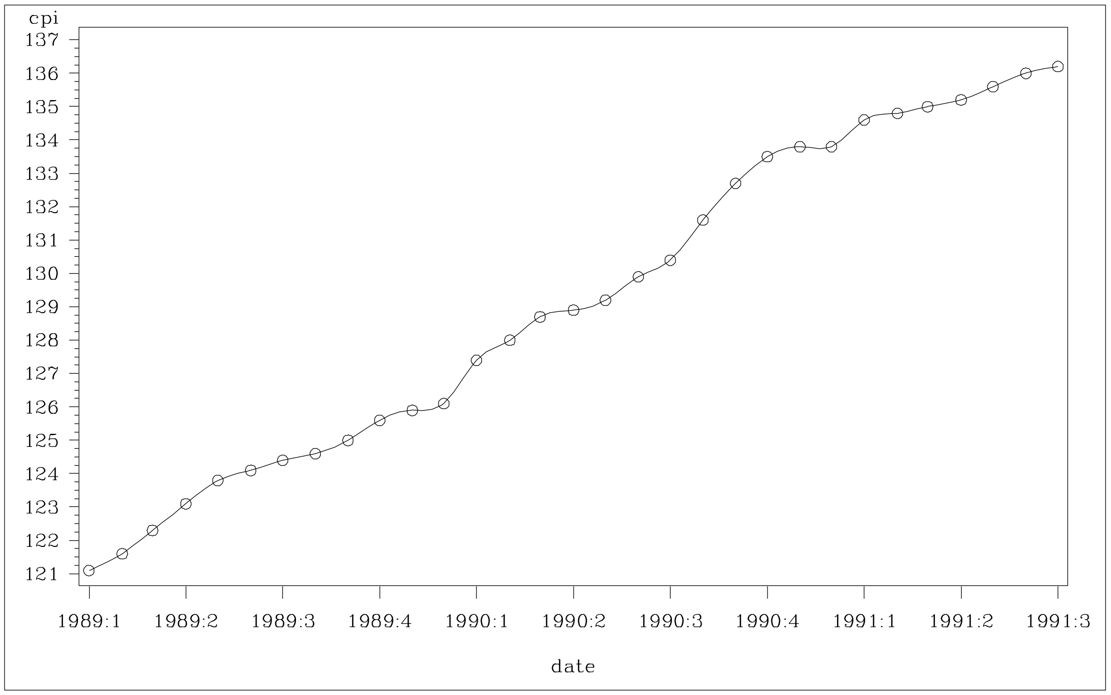

Figure 2.7. Plot of Monthly CPI Over Time

The following example changes the plot by using year and quarter value to label the tick marks. The FORMAT statement causes PROC GPLOT to use the YYQC format to print the date values. This example also shows how to place reference lines on the plot with the HREF= option. Reference lines are drawn to mark the boundary between years.

```
proc gplot data=uscpi;
   symbol i=spline v=circle h=2;
   plot cpi * date /
        haxis= '1jan89'd to '1jul91'd by qtr
        href= '1jan90'd to '1jan91'd by year;
   format date yyqc6.;
run;
```

The plot is shown in Figure 2.8.

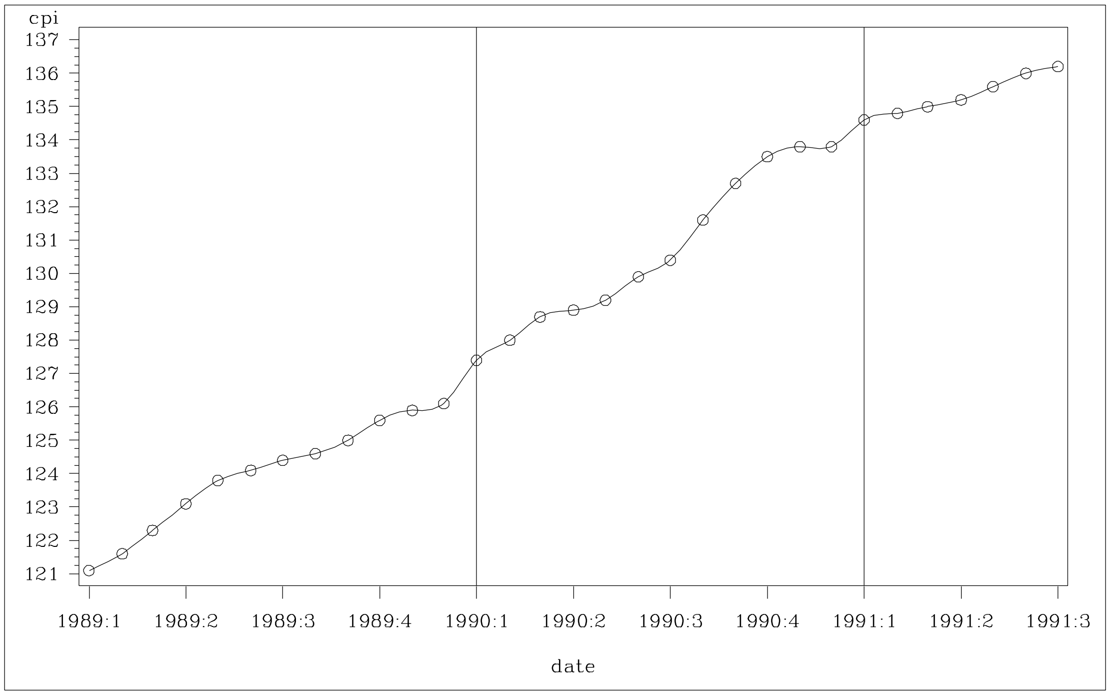

Figure 2.8. Plot of Monthly CPI Over Time

Overlay Plots of Different Variables

You can plot two or more series on the same graph. Plot series stored in different variables by specifying multiple plot requests on one PLOT statement, and use the OVERLAY option. Specify a different SYMBOL statement for each plot.

For example, the following statements plot the CPI, FORECAST, L95, and U95 variables produced by PROC ARIMA in a previous example. The SYMBOL1 statement is used for the actual series. Values of the actual series are labeled with a star, and the points are not connected. The SYMBOL2 statement is used for the forecast series. Values of the forecast series are labeled with an open circle, and the points are connected with a smooth curve. The SYMBOL3 statement is used for the upper and lower confidence limits series. Values of the upper and lower confidence limits points are not plotted, but a broken line is drawn between the points. A reference line is drawn to mark the start of the forecast period. Quarterly tick marks with YYQC format date values are used.

```
proc arima data=uscpi;
   identify var=cpi(1);
   estimate q=1;
   forecast id=date interval=month lead=12 out=arimaout;
run;

proc gplot data=arimaout;
   symbol1 i=none   v=star h=2;
   symbol2 i=spline v=circle h=2;
```

```
      symbol3 i=spline l=5;
      format date yyqc4.;
      plot cpi * date = 1
           forecast * date = 2
           ( l95 u95 ) * date = 3 /
           overlay
           haxis= '1jan89'd to '1jul92'd by qtr
           href= '15jul91'd ;
   run;
```

The plot is shown in Figure 2.9.

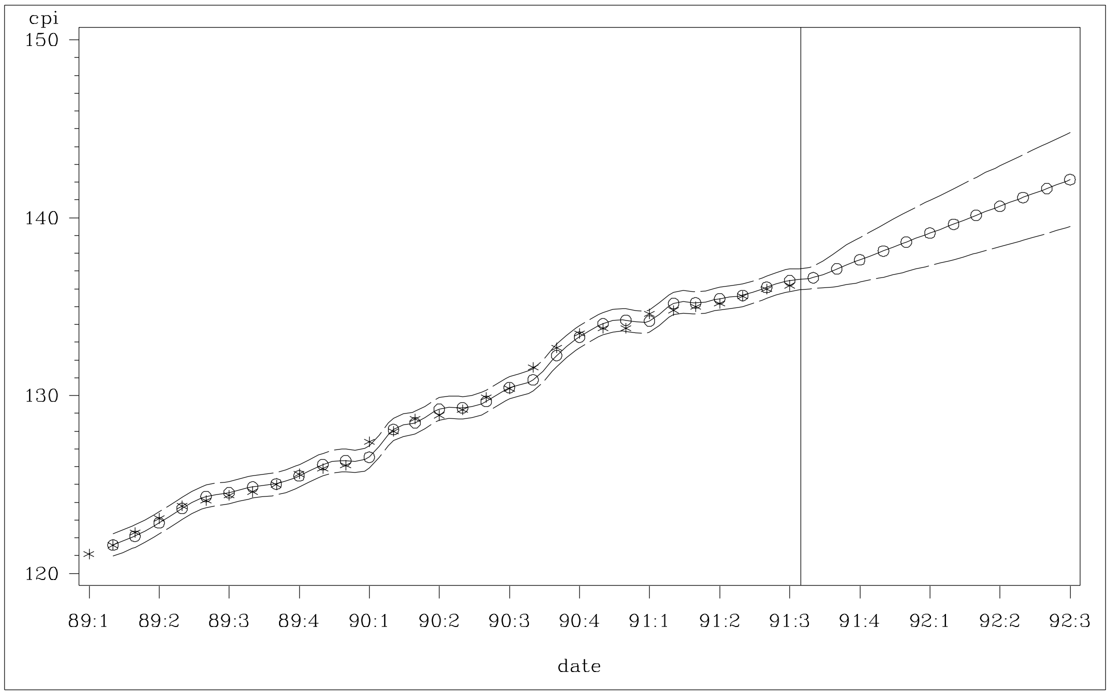

Figure 2.9. Plot of ARIMA Forecast

Overlay Plots of Interleaved Series

You can also plot several series on the same graph when the different series are stored in the same variable in interleaved form. Plot interleaved time series by using the values of the ID variable to distinguish the different series and by selecting different SYMBOL statements for each plot.

The following example plots the output data set produced by PROC FORECAST in a previous example. Since the residual series has a different scale than the other series, it is excluded from the plot with a WHERE statement.

The _TYPE_ variable is used on the PLOT statement to identify the different series and to select the SYMBOL statements to use for each plot. The first SYMBOL statement is used for the first sorted value of _TYPE_, which is _TYPE_=ACTUAL. The second SYMBOL statement is used for the second sorted value of the _TYPE_ variable (_TYPE_=FORECAST), and so forth.

```
proc forecast data=uscpi interval=month lead=12
              out=foreout outfull outresid;
   var cpi;
   id date;
run;

proc gplot data=foreout;
   symbol1 i=none   v=star h=2;
   symbol2 i=spline v=circle h=2;
   symbol3 i=spline l=20;
   symbol4 i=spline l=20;
   format date yyqc4.;
   plot cpi * date = _type_ /
        haxis= '1jan89'd to '1jul92'd by qtr
        href= '15jul91'd ;
   where _type_ ^= 'RESIDUAL';
run;
```

The plot is shown in Figure 2.10.

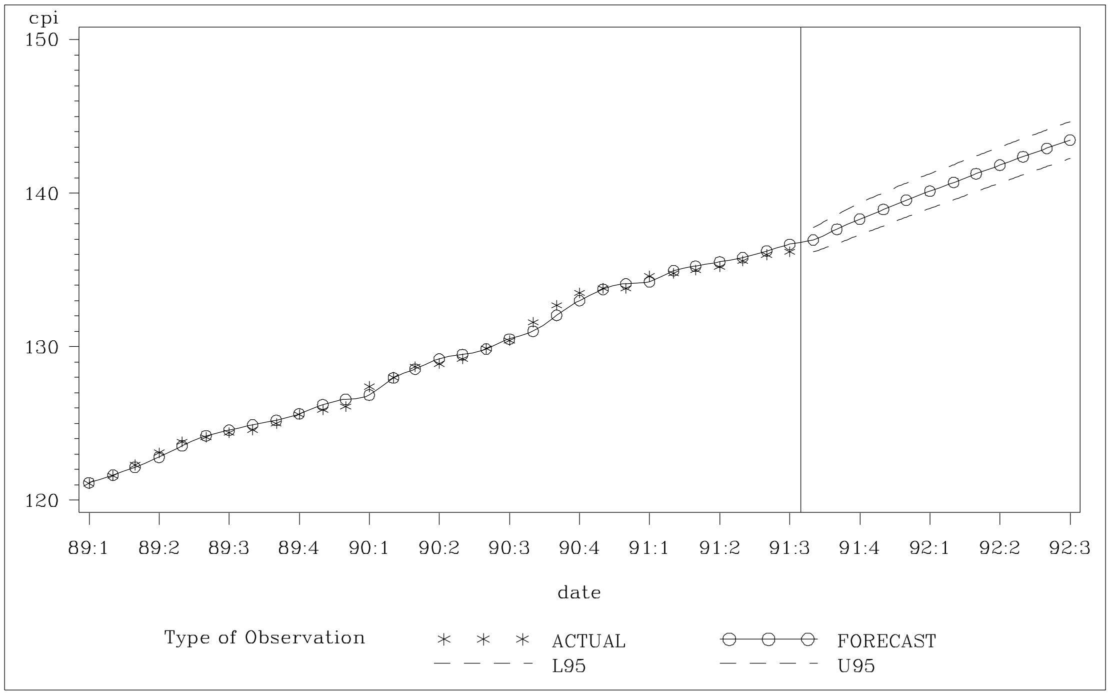

Figure 2.10. Plot of Forecast

Residual Plots

The following example plots the residuals series that was excluded from the plot in the previous example. The SYMBOL statement specifies a needle plot, so that each residual point is plotted as a vertical line showing deviation from zero.

```
proc gplot data=foreout;
   symbol1 i=needle v=circle width=6;
```

```
      format date yyqc4.;
      plot cpi * date /
           haxis= '1jan89'd to '1jul91'd by qtr ;
      where _type_ = 'RESIDUAL';
   run;
```

The plot is shown in Figure 2.11.

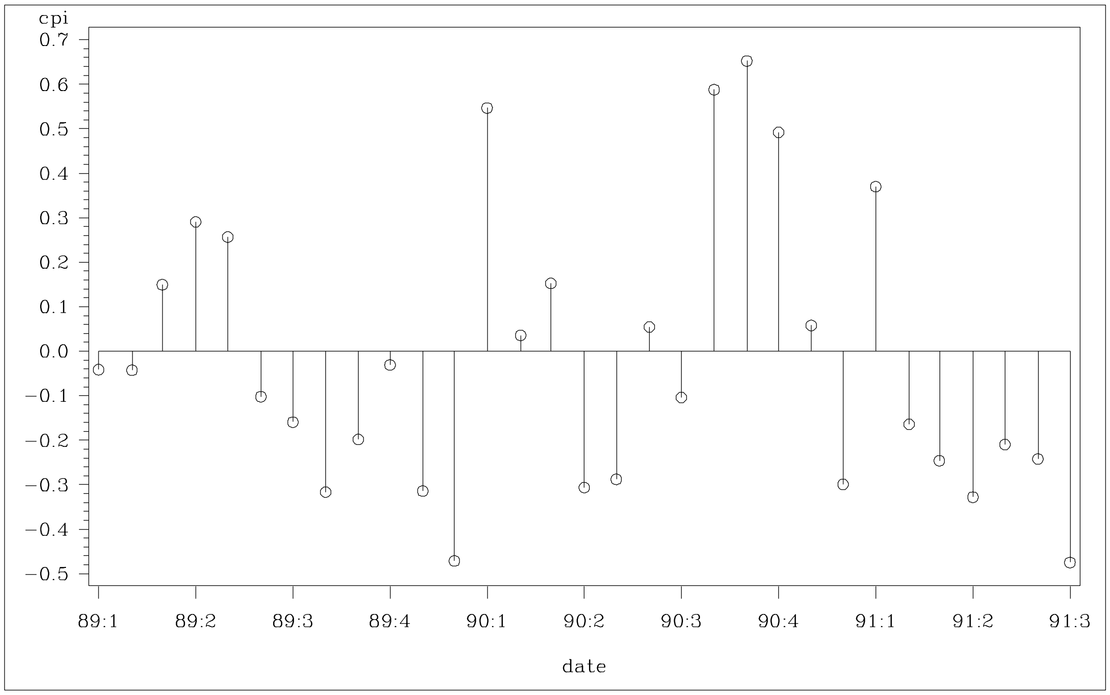

Figure 2.11. Plot of Residuals

Using PROC PLOT

The following statements use the PLOT procedure to plot CPI in the USCPI data set against DATE. (The data set plotted contains more observations than shown in the previous examples.) The plotting character used is a plus sign (+).

```
   proc plot data=uscpi;
      plot cpi * date = '+';
   run;
```

The plot is shown in Figure 2.12.

```
                     Plot of cpi*date.  Symbol used is '+'.

Figure 2.12. Plot of Monthly CPI Over Time

Controlling the Time Axis: Tick Marks and Reference Lines

In the preceding example, the spacing of values on the time axis looks a bit odd in that the dates do not match for each year. Because DATE is a SAS date variable, the PLOT procedure needs additional instruction on how to place the time axis tick marks. The following statements use the HAXIS= option to tell PROC PLOT to mark the axis at the start of each quarter.

```
proc plot data=uscpi;
   plot cpi * date = '+' /
        haxis= '1jan89'd to '1jul91'd by qtr;
run;
```

The plot is shown in Figure 2.13.

```
                     Plot of cpi*date.  Symbol used is '+'.

Figure 2.14. Plot of Monthly CPI Over Time

Marking the Subperiod of Points

In the preceding example, it is a little hard to tell which month each point is, although the quarterly reference lines help some. The following example shows how to set the plotting symbol to the first letter of the month name. A DATA step first makes a copy of DATE and gives this variable PCHAR a MONNAME1. format. The variable PCHAR is used in the PLOT statement to supply the plotting character.

This example also changes the plot by using quarterly tick marks and by using the YYQC format to print the date values. This example also changes the HREF= option to use annual reference lines. The plot is shown in Figure 2.15.

```
data temp;
   set uscpi;
   pchar = date;
   format pchar monname1.;
run;

proc plot data=temp;
   plot cpi * date = pchar /
        haxis= ’1jan89’d to ’1jul91’d by qtr
```

```
         href= '1jan90'd to '1jan91'd by year;
   format date yyqc4.;
run;
```

```
             Plot of cpi*date.  Symbol is value of pchar.

Figure 2.15. Plot of Monthly CPI Over Time

Overlay Plots of Different Variables

Plot different series in different variables by specifying the different plot requests, each with its own plotting character, on the same PLOT statement, and use the OVERLAY option.

For example, the following statements plot the CPI, FORECAST, L95, and U95 variables produced by PROC ARIMA in a previous example. The actual series CPI is labeled with the plot character plus (+). The forecast series is labeled with the plot character F. The upper and lower confidence limits are labeled with the plot character period (.). The plot is shown in Figure 2.16.

```
proc arima data=uscpi;
   identify var=cpi(1);
   estimate q=1;
   forecast id=date interval=month lead=12 out=arimaout;
run;
```

```
proc plot data=arimaout;
   plot cpi * date = '+' forecast * date = 'F'
        ( l95 u95 ) * date = '.' /
        overlay
        haxis= '1jan89'd to '1jul92'd by qtr
        href= '1jan90'd to '1jan92'd by year ;
run;
```

```
                  Plot of cpi*date.       Symbol used is '+'.
                  Plot of FORECAST*date.  Symbol used is 'F'.
                  Plot of L95*date.       Symbol used is '.'.
                  Plot of U95*date.       Symbol used is '.'.

Figure 2.16. Plot of ARIMA Forecast

Overlay Plots of Interleaved Series

Plot interleaved time series by using the first character of the ID variable to distinguish the different series as the plot character.

The following example plots the output data set produced by PROC FORECAST in a previous example. The _TYPE_ variable is used on the PLOT statement to supply plotting characters to label the different series.

The actual series is plotted with A, the forecast series is plotted with F, the lower confidence limit is plotted with L, and the upper confidence limit is plotted with U.

Since the residual series has a different scale than the other series, it is excluded from the plot with a WHERE statement. The plot is shown in Figure 2.17.

```
proc forecast data=uscpi interval=month lead=12
              out=foreout outfull outresid;
   var cpi;
   id date;
run;

proc plot data=foreout;
   plot cpi * date = _type_ /
        haxis= '1jan89'd to '1jul92'd by qtr
        href= '1jan90'd to '1jan92'd by year ;
   where _type_ ^= 'RESIDUAL';
run;
```

```
                 Plot of cpi*date.  Symbol is value of _TYPE_.

```

Figure 2.18. Plot of Residuals

Using PROC TIMEPLOT

The TIMEPLOT procedure plots time series data vertically on the page instead of horizontally across the page as the PLOT procedure does. PROC TIMEPLOT can also print the data values as well as plot them.

The following statements use the TIMEPLOT procedure to plot CPI in the USCPI data set. Only the last 14 observations are included in this example. The plot is shown in Figure 2.19.

```
proc timeplot data=uscpi;
   plot cpi;
   id date;
   where date >= ’1jun90’d;
run;
```

```
   date        cpi      min                                                  max
                        129.9                                              136.2
                       *-------------------------------------------------------*
JUN1990     129.90     |c                                                      |
JUL1990     130.40     |    c                                                  |
AUG1990     131.60     |               c                                       |
SEP1990     132.70     |                        c                              |
OCT1990     133.50     |                               c                       |
NOV1990     133.80     |                                  c                    |
DEC1990     133.80     |                                  c                    |
JAN1991     134.60     |                                         c             |

                       *-------------------------------------------------------*
```

Figure 2.19. Output Produced by PROC TIMEPLOT

The TIMEPLOT procedure has several interesting features not discussed here. Refer to "The TIMEPLOT Procedure" in the *SAS Procedures Guide* for more information.

Calendar and Time Functions

Calendar and time functions convert calendar and time variables like YEAR, MONTH, DAY, and HOUR, MINUTE, SECOND into SAS date or datetime values, and vice versa.

The SAS calendar and time functions are DATEJUL, DATEPART, DAY, DHMS, HMS, HOUR, JULDATE, MDY, MINUTE, MONTH, QTR, SECOND, TIMEPART, WEEKDAY, YEAR, and YYQ. Refer to *SAS Language Reference* for more details about these functions.

Computing Dates from Calendar Variables

The MDY function converts MONTH, DAY, and YEAR values to a SAS date value. For example, MDY(10,17,91) returns the SAS date value ’17OCT91’D.

The YYQ function computes the SAS date for the first day of a quarter. For example, YYQ(91,4) returns the SAS date value ’1OCT91’D.

The DATEJUL function computes the SAS date for a Julian date. For example, DATEJUL(91290) returns the SAS date ’17OCT91’D.

The YYQ and MDY functions are useful for creating SAS date variables when the ID values recorded in the data are year and quarter; year and month; or year, month, and day, instead of dates that can be read with a date informat.

For example, the following statements read quarterly estimates of the gross national product of the U.S. from 1990:I to 1991:II from data records on which dates are coded as separate year and quarter values. The YYQ function is used to compute the variable DATE.

```
data usecon;
   input year qtr gnp;
   date = yyq( year, qtr );
   format date yyqc.;
datalines;
1990 1 5375.4
1990 2 5443.3
1990 3 5514.6
1990 4 5527.3
1991 1 5557.7
1991 2 5615.8
;
```

The monthly USCPI data shown in a previous example contained time ID values represented in the MONYY format. If the data records instead contain separate year and month values, the data can be read in and the DATE variable computed with the following statements:

```
data uscpi;
   input month year cpi;
   date = mdy( month, 1, year );
   format date monyy.;
datalines;
6 90 129.9
7 90 130.4
8 90 131.6
 ... etc. ...
;
```

Computing Calendar Variables from Dates

The functions YEAR, MONTH, DAY, WEEKDAY, and JULDATE compute calendar variables from SAS date values.

Returning to the example of reading the USCPI data from records containing date values represented in the MONYY format, you can find the month and year of each observation from the SAS dates of the observations using the following statements.

```
data uscpi;
   input date monyy7. cpi;
   format date monyy7.;
   year  = year( date );
   month = month( date );
datalines;
jun1990 129.9
jul1990 130.4
aug1990 131.6
sep1990 132.7
 ... etc. ...
;
```

Converting between Date, Datetime, and Time Values

The DATEPART function computes the SAS date value for the date part of a SAS datetime value. The TIMEPART function computes the SAS time value for the time part of a SAS datetime value.

The HMS function computes SAS time values from HOUR, MINUTE, and SECOND time variables. The DHMS function computes a SAS datetime value from a SAS date value and HOUR, MINUTE, and SECOND time variables.

See the "Date, Time, and Datetime Functions" section on page 127 for more information on the syntax of these functions.

Computing Datetime Values

To compute datetime ID values from calendar and time variables, first compute the date and then compute the datetime with DHMS.

For example, suppose you read tri-hourly temperature data with time recorded as YEAR, MONTH, DAY, and HOUR. The following statements show how to compute the ID variable DATETIME:

```
data weather;
   input year month day hour temp;
   datetime = dhms( mdy( month, day, year ), hour, 0, 0 );
   format datetime datetime10.;
datalines;
91 10 16 21  61
91 10 17  0  56
```

```
91 10 17  3  53
91 10 17  6  54
91 10 17  9  65
91 10 17 12  72
 ... etc. ...
;
```

Computing Calendar and Time Variables

The functions HOUR, MINUTE, and SECOND compute time variables from SAS datetime values. The DATEPART function and the date-to-calendar variables functions can be combined to compute calendar variables from datetime values.

For example, suppose the date and time of the tri-hourly temperature data in the preceding example were recorded as datetime values in the datetime format. The following statements show how to compute the YEAR, MONTH, DAY, and HOUR of each observation and include these variables in the SAS data set:

```
data weather;
   input datetime datetime13. temp;
   format datetime datetime10.;
   hour = hour( datetime );
   date = datepart( datetime );
   year = year( date );
   month = month( date );
   day = day( date );
datalines;
16oct91:21:00  61
17oct91:00:00  56
17oct91:03:00  53
17oct91:06:00  54
17oct91:09:00  65
17oct91:12:00  72
 ... etc. ...
;
```

Interval Functions INTNX and INTCK

The SAS interval functions INTNX and INTCK perform calculations with date, datetime values, and time intervals. They can be used for calendar calculations with SAS date values, to count time intervals between dates, and to increment dates or datetime values by intervals.

The INTNX function increments dates by intervals. INTNX computes the date or datetime of the start of the interval a specified number of intervals from the interval containing a given date or datetime value.

The form of the INTNX function is

INTNX(*interval, from, n* <, *alignment* >)

where:

interval	is a character constant or variable containing an interval name.
from	is a SAS date value (for date intervals) or datetime value (for datetime intervals).
n	is the number of intervals to increment from the interval containing the *from* value.
alignment	controls the alignment of SAS dates, within the interval, used to identify output observations. Can take the values BEGINNING|B, MIDDLE|M, or END|E.

The number of intervals to increment, *n*, can be positive, negative, or zero.

For example, the statement NEXTMON = INTNX('MONTH',DATE,1); assigns to the variable NEXTMON the date of the first day of the month following the month containing the value of DATE.

The INTCK function counts the number of interval boundaries between two dates or between two datetime values.

The form of the INTCK function is

INTCK(*interval*, *from*, *to*)

where:

interval	is a character constant or variable containing an interval name
from	is the starting date (for date intervals) or datetime value (for datetime intervals)
to	is the ending date (for date intervals) or datetime value (for datetime intervals).

For example, the statement NEWYEARS = INTCK('YEAR',DATE1,DATE2); assigns to the variable NEWYEARS the number of New Year's Days between the two dates.

Incrementing Dates by Intervals

Use the INTNX function to increment dates by intervals. For example, suppose you want to know the date of the start of the week that is six weeks from the week of 17 October 1991. The function INTNX('WEEK','17OCT91'D,6) returns the SAS date value '24NOV1991'D.

One practical use of the INTNX function is to generate periodic date values. For example, suppose the monthly U.S. Consumer Price Index data in a previous example were recorded without any time identifier on the data records. Given that you know the first observation is for June 1990, the following statements use the INTNX function to compute the ID variable DATE for each observation:

```
data uscpi;
   input cpi;
   date = intnx( 'month', '1jun1990'd, _n_-1 );
   format date monyy7.;
datalines;
129.9
130.4
131.6
132.7
 ... etc. ...
;
```

The automatic variable _N_ counts the number of times the DATA step program has executed, and in this case _N_ contains the observation number. Thus _N_-1 is the increment needed from the first observation date. Alternatively, we could increment from the month before the first observation, in which case the INTNX function in this example would be written INTNX('MONTH','1MAY1990'D,_N_).

Alignment of SAS Dates

Any date within the time interval corresponding to an observation of a periodic time series can serve as an ID value for the observation. For example, the USCPI data in a previous example might have been recorded with dates at the 15th of each month. The person recording the data might reason that since the CPI values are monthly averages, midpoints of the months might be the appropriate ID values.

However, as far as SAS/ETS procedures are concerned, what is important about monthly data is the month of each observation, not the exact date of the ID value. If you indicate that the data are monthly (with an INTERVAL=MONTH) option, SAS/ETS procedures ignore the day of the month in processing the ID variable. The MONYY format also ignores the day of the month.

Thus, you could read in the monthly USCPI data with midmonth DATE values using the following statements:

```
data uscpi;
   input date date9. cpi;
   format date monyy7.;
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6
15sep1990 132.7
 ... etc. ...
;
```

The results of using this version of the USCPI data set for analysis with SAS/ETS procedures would be the same as with first-of-month values for DATE. Although you can use any date within the interval as an ID value for the interval, you may find working with time series in SAS less confusing if you always use date ID values normalized to the start of the interval.

For some applications it may be preferable to use end of period dates, such as 31Jan1994, 28Feb1994, 31Mar1994, ..., 31Dec1994. For other applications, such as plotting time series, it may be more convenient to use interval midpoint dates to identify the observations.

SAS/ETS procedures provide an ALIGN= option to control the alignment of dates for output time series observations. Procedures supporting the ALIGN= option are ARIMA, DATASOURCE, EXPAND, and FORECAST. In addition, the INTNX library function supports an optional argument to specify the alignment of the returned date value.

To normalize date values to the start of intervals, use the INTNX function with a 0 increment. The INTNX function with an increment of 0 computes the date of the first day of the interval (or the first second of the interval for datetime values).

For example, INTNX('MONTH','17OCT1991'D,0, BEG) returns the date '1OCT1991'D'.

The following statements show how the preceding example can be changed to normalize the mid-month DATE values to first-of-month and end-of-month values. For exposition, the first-of-month value is transformed back into a middle-of-month value.

```
data uscpi;
   input date date9. cpi;
   format date monyy7.;
   monthbeg = intnx( 'month', date, 0, beg );
   midmonth = intnx( 'month', monthbeg, 0, mid );
   monthend = intnx( 'month', date, 0, end );
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6
15sep1990 132.7
 ... etc. ...
;
```

If you want to compute the date of a particular day within an interval, you can use calendar functions, or you can increment the starting date of the interval by a number of days. The following example shows three ways to compute the 7th day of the month:

```
data test;
   set uscpi;
   mon07_1 = mdy( month(date), 7, year(date) );
   mon07_2 = intnx( 'month', date, 0, beg ) + 6;
   mon07_3 = intnx( 'day', date, 6 );
run;
```

Computing the Width of a Time Interval

To compute the width of a time interval, subtract the ID value of the start of the next interval from the ID value of the start of the current interval. If the ID values are SAS dates, the width will be in days. If the ID values are SAS datetime values, the width will be in seconds.

For example, the following statements show how to add a variable WIDTH to the USCPI data set that contains the number of days in the month for each observation:

```
data uscpi;
   input date date9. cpi;
   format date monyy7.;
   width = intnx( 'month', date, 1 ) - intnx( 'month', date, 0 );
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6
15sep1990 132.7
 ... etc. ...
;
```

Computing the Ceiling of an Interval

To shift a date to the start of the next interval if not already at the start of an interval, subtract 1 from the date and use INTNX to increment the date by 1 interval.

For example, the following statements add the variable NEWYEAR to the monthly USCPI data set. The variable NEWYEAR contains the date of the next New Year's Day. NEWYEAR contains the same value as DATE when the DATE value is the start of year and otherwise contains the date of the start of the next year.

```
data test;
   set uscpi;
   newyear = intnx( 'year', date - 1, 1 );
   format newyear date.;
run;
```

Counting Time Intervals

Use the INTCK function to count the number of interval boundaries between two dates.

Note that the INTCK function counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates.

For example, the function INTCK('MONTH','1JAN1991'D,'31JAN1991'D) returns 0, since the two dates are within the same month.

The function INTCK('MONTH','31JAN1991'D,'1FEB1991'D) returns 1, since the two dates lie in different months that are one month apart.

When the first date is later than the second date, INTCK returns a negative count. For example, the function INTCK('MONTH','1FEB1991'D,'31JAN1991'D) returns -1.

The following example shows how to use the INTCK function to count the number of Sundays, Mondays, Tuesdays, and so forth, in each month. The variables NSUNDAY, NMONDAY, NTUESDAY, and so forth, are added to the USCPI data set.

```
data uscpi;
   set uscpi;
   d0 = intnx( 'month', date, 0 ) - 1;
   d1 = intnx( 'month', date, 1 ) - 1;
   nsunday  = intck( 'week.1', d0, d1 );
   nmonday  = intck( 'week.2', d0, d1 );
   ntuesday = intck( 'week.3', d0, d1 );
   nwedday  = intck( 'week.4', d0, d1 );
   nthurday = intck( 'week.5', d0, d1 );
   nfriday  = intck( 'week.6', d0, d1 );
   nsatday  = intck( 'week.7', d0, d1 );
   drop d0 d1;
run;
```

Since the INTCK function counts the number of interval beginning dates between two dates, the number of Sundays is computed by counting the number of week boundaries between the last day of the previous month and the last day of the current month. To count Mondays, Tuesdays, and so forth, shifted week intervals are used. The interval type WEEK.2 specifies weekly intervals starting on Mondays, WEEK.3 specifies weeks starting on Tuesdays, and so forth.

Checking Data Periodicity

Suppose you have a time series data set, and you want to verify that the data periodicity is correct, the observations are dated correctly, and the data set is sorted by date. You can use the INTCK function to compare the date of the current observation with the date of the previous observation and verify that the dates fall into consecutive time intervals.

For example, the following statements verify that the data set USCPI is a correctly dated monthly data set. The RETAIN statement is used to hold the date of the previous observation, and the automatic variable _N_ is used to start the verification process with the second observation.

```
data _null_;
   set uscpi;
   retain prevdate;
   if _n_ > 1 then
      if intck( 'month', prevdate, date ) ^= 1 then
         put "Bad date sequence at observation number " _n_;
   prevdate = date;
run;
```

Filling in Omitted Observations in a Time Series Data Set

Recall that most SAS/ETS procedures expect input data to be in the standard form, with no omitted observations in the sequence of time periods. When data are missing for a time period, the data set should contain a missing observation, in which all variables except the ID variables have missing values.

You can replace omitted observations in a time series data set with missing observations by merging the data set with a data set containing a complete sequence of dates.

The following statements create a monthly data set, OMITTED, from data lines containing records for an intermittent sample of months. (Data values are not shown.) This data set is converted to a standard form time series data set in four steps.

First, the OMITTED data set is sorted to make sure it is in time order. Second, the first and last date in the data set are determined and stored in the data set RANGE. Third, the data set DATES is created containing only the variable DATE and containing monthly observations for the needed time span. Finally, the data sets OMITTED and DATES are merged to produce a standard form time series data set with missing observations inserted for the omitted records.

```
data omitted;
   input date monyy7. x y z;
   format date monyy7.;
datalines;
jan1991  ...
mar1991  ...
apr1991  ...
jun1991  ...
 ... etc. ...
;

proc sort data=omitted;
   by date;
run;

data range;
   retain from to;
   set omitted end=lastobs;
   if _n_ = 1 then from = date;
   if lastobs then do;
      to = date;
      output;
      end;
run;

data dates;
   set range;
   date = from;
   do while( date <= to );
      output;
```

```
         date = intnx( 'month', date, 1 );
         end;
      keep date;
   run;

   data standard;
      merge omitted dates;
      by date;
   run;
```

Using Interval Functions for Calendar Calculations

With a little thought, you can come up with a formula involving INTNX and INTCK functions and different interval types to perform almost any calendar calculation.

For example, suppose you want to know the date of the third Wednesday in the month of October 1991. The answer can be computed as

```
   intnx( 'week.4', '1oct91'd - 1, 3 )
```

which returns the SAS date value ’16OCT91’D.

Consider this more complex example: how many weekdays are there between 17 October 1991 and the second Friday in November 1991, inclusive? The following formula computes the number of weekdays between the date value contained in the variable DATE and the second Friday of the following month (including the ending dates of this period):

```
   n = intck( 'weekday', date - 1,
       intnx( 'week.6', intnx( 'month', date, 1 ) - 1, 2 ) + 1 );
```

Setting DATE to ’17OCT91’D and applying this formula produces the answer, N=17.

Lags, Leads, Differences, and Summations

When working with time series data, you sometimes need to refer to the values of a series in previous or future periods. For example, the usual interest in the consumer price index series shown in previous examples is how fast the index is changing, rather than the actual level of the index. To compute a percent change, you need both the current and the previous values of the series. When modeling a time series, you may want to use the previous values of other series as explanatory variables.

This section discusses how to use the DATA step to perform operations over time: lags, differences, leads, summations over time, and percent changes.

The EXPAND procedure can also be used to perform many of these operations; see Chapter 16, “The EXPAND Procedure,” for more information. See also the section "Transforming Time Series" later in this chapter.

The LAG and DIF Functions

The DATA step provides two functions, LAG and DIF, for accessing previous values of a variable or expression. These functions are useful for computing lags and differences of series.

For example, the following statements add the variables CPILAG and CPIDIF to the USCPI data set. The variable CPILAG contains lagged values of the CPI series. The variable CPIDIF contains the changes of the CPI series from the previous period; that is, CPIDIF is CPI minus CPILAG. The new data set is shown in part in Figure 2.20.

```
data uscpi;
   set uscpi;
   cpilag = lag( cpi );
   cpidif = dif( cpi );
run;

proc print data=uscpi;
run;
```

```
                  Obs    date      cpi     cpilag    cpidif

                    1    JUN90    129.9       .         .
                    2    JUL90    130.4     129.9      0.5
                    3    AUG90    131.6     130.4      1.2
                    4    SEP90    132.7     131.6      1.1
                    5    OCT90    133.5     132.7      0.8
                    6    NOV90    133.8     133.5      0.3
                    7    DEC90    133.8     133.8      0.0
                    8    JAN91    134.6     133.8      0.8
```

Figure 2.20. USCPI Data Set with Lagged and Differenced Series

Understanding the DATA Step LAG and DIF Functions

When used in this simple way, LAG and DIF act as lag and difference functions. However, it is important to keep in mind that, despite their names, the LAG and DIF functions available in the DATA step are not true lag and difference functions.

Rather, LAG and DIF are queuing functions that remember and return argument values from previous calls. The LAG function remembers the value you pass to it and returns as its result the value you passed to it on the previous call. The DIF function works the same way but returns the difference between the current argument and the remembered value. (LAG and DIF return a missing value the first time the function is called.)

A true lag function does not return the value of the argument for the "previous call," as do the DATA step LAG and DIF functions. Instead, a true lag function returns the value of its argument for the "previous observation," regardless of the sequence of previous calls to the function. Thus, for a true lag function to be possible, it must be clear what the "previous observation" is.

If the data are sorted chronologically, then LAG and DIF act as true lag and difference functions. If in doubt, use PROC SORT to sort your data prior to using the LAG and DIF functions. Beware of missing observations, which may cause LAG and DIF to return values that are not the actual lag and difference values

The DATA step is a powerful tool that can read any number of observations from any number of input files or data sets, can create any number of output data sets, and can write any number of output observations to any of the output data sets, all in the same program. Thus, in general, it is not clear what "previous observation" means in a DATA step program. In a DATA step program, the "previous observation" exists only if you write the program in a simple way that makes this concept meaningful.

Since, in general, the previous observation is not clearly defined, it is not possible to make true lag or difference functions for the DATA step. Instead, the DATA step provides queuing functions that make it easy to compute lags and differences.

Pitfalls of DATA Step LAG and DIF Functions

The LAG and DIF functions compute lags and differences provided that the sequence of calls to the function corresponds to the sequence of observations in the output data set. However, any complexity in the DATA step that breaks this correspondence causes the LAG and DIF functions to produce unexpected results.

For example, suppose you want to add the variable CPILAG to the USCPI data set, as in the previous example, and you also want to subset the series to 1991 and later years. You might use the following statements:

```
data subset;
   set uscpi;
   if date >= '1jan1991'd;
   cpilag = lag( cpi );  /* WRONG PLACEMENT! */
run;
```

If the subsetting IF statement comes before the LAG function call, the value of CPILAG will be missing for January 1991, even though a value for December 1990 is available in the USCPI data set. To avoid losing this value, you must rearrange the statements to ensure that the LAG function is actually executed for the December 1990 observation.

```
data subset;
   set uscpi;
   cpilag = lag( cpi );
   if date >= '1jan1991'd;
run;
```

In other cases, the subsetting statement should come before the LAG and DIF functions. For example, the following statements subset the FOREOUT data set shown in a previous example to select only _TYPE_=RESIDUAL observations and also to compute the variable LAGRESID.

```
data residual;
   set foreout;
   if _type_ = "RESIDUAL";
   lagresid = lag( cpi );
run;
```

Another pitfall of LAG and DIF functions arises when they are used to process time series cross-sectional data sets. For example, suppose you want to add the variable CPILAG to the CPICITY data set shown in a previous example. You might use the following statements:

```
data cpicity;
   set cpicity;
   cpilag = lag( cpi );
run;
```

However, these statements do not yield the desired result. In the data set produced by these statements, the value of CPILAG for the first observation for the first city is missing (as it should be), but in the first observation for all later cities, CPILAG contains the last value for the previous city. To correct this, set the lagged variable to missing at the start of each cross section, as follows.

```
data cpicity;
   set cpicity;
   by city date;
   cpilag = lag( cpi );
   if first.city then cpilag = .;
run;
```

Alternatives to LAG and DIF Functions

You can also calculate lags and differences in the DATA step without using LAG and DIF functions. For example, the following statements add the variables CPILAG and CPIDIF to the USCPI data set:

```
data uscpi;
   set uscpi;
   retain cpilag;
   cpidif = cpi - cpilag;
   output;
   cpilag = cpi;
run;
```

The RETAIN statement prevents the DATA step from reinitializing CPILAG to a missing value at the start of each iteration and thus allows CPILAG to retain the value of CPI assigned to it in the last statement. The OUTPUT statement causes the output observation to contain values of the variables before CPILAG is reassigned the current value of CPI in the last statement. This is the approach that must be used if you want to build a variable that is a function of its previous lags.

You can also use the EXPAND procedure to compute lags and differences. For example, the following statements compute lag and difference variables for CPI:

```
proc expand data=uscpi out=uscpi method=none;
   id date;
   convert cpi=cpilag / transform=( lag 1 );
   convert cpi=cpidif / transform=( dif 1 );
run;
```

LAG and DIF Functions in PROC MODEL

The preceding discussion of LAG and DIF functions applies to LAG and DIF functions available in the DATA step. However, LAG and DIF functions are also used in the MODEL procedure.

The MODEL procedure LAG and DIF functions do not work like the DATA step LAG and DIF functions. The LAG and DIF functions supported by PROC MODEL are true lag and difference functions, not queuing functions.

Unlike the DATA step, the MODEL procedure processes observations from a single input data set, so the "previous observation" is always clearly defined in a PROC MODEL program. Therefore, PROC MODEL is able to define LAG and DIF as true lagging functions that operate on values from the previous observation. See Chapter 20, “The MODEL Procedure,” for more information on LAG and DIF functions in the MODEL procedure.

Multiperiod Lags and Higher-Order Differencing

To compute lags at a lagging period greater than 1, add the lag length to the end of the LAG keyword to specify the lagging function needed. For example, the LAG2 function returns the value of its argument two calls ago, the LAG3 function returns the value of its argument three calls ago, and so forth.

To compute differences at a lagging period greater than 1, add the lag length to the end of the DIF keyword. For example, the DIF2 function computes the differences between the value of its argument and the value of its argument two calls ago. (The maximum lagging period is 100.)

The following statements add the variables CPILAG12 and CPIDIF12 to the USCPI data set. CPILAG12 contains the value of CPI from the same month one year ago. CPIDIF12 contains the change in CPI from the same month one year ago. (In this case, the first 12 values of CPILAG12 and CPIDIF12 will be missing.)

```
data uscpi;
   set uscpi;
   cpilag12 = lag12( cpi );
   cpidif12 = dif12( cpi );
run;
```

To compute second differences, take the difference of the difference. To compute higher-order differences, nest DIF functions to the order needed. For example, the following statements compute the second difference of CPI:

```
data uscpi;
   set uscpi;
   cpi2dif = dif( dif( cpi ) );
run;
```

Multiperiod lags and higher-order differencing can be combined. For example, the following statements compute monthly changes in the inflation rate, with inflation rate computed as percent change in CPI from the same month one year ago:

```
data uscpi;
   set uscpi;
   infchng = dif( 100 * dif12( cpi ) / lag12( cpi ) );
run;
```

Percent Change Calculations

There are several common ways to compute the percent change in a time series. This section illustrates the use of LAG and DIF functions by showing SAS statements for various kinds of percent change calculations.

Computing Period-to-Period Change

To compute percent change from the previous period, divide the difference of the series by the lagged value of the series and multiply by 100.

```
data uscpi;
   set uscpi;
   pctchng = dif( cpi ) / lag( cpi ) * 100;
   label pctchng = "Monthly Percent Change, At Monthly Rates";
run;
```

Often, changes from the previous period are expressed at annual rates. This is done by exponentiation of the current-to-previous period ratio to the number of periods in a year and expressing the result as a percent change. For example, the following statements compute the month-over-month change in CPI as a percent change at annual rates:

```
data uscpi;
   set uscpi;
   pctchng = ( ( cpi / lag( cpi ) ) ** 12 - 1 ) * 100;
   label pctchng = "Monthly Percent Change, At Annual Rates";
run;
```

Computing Year-over-Year Change

To compute percent change from the same period in the previous year, use LAG and DIF functions with a lagging period equal to the number of periods in a year. (For quarterly data, use LAG4 and DIF4. For monthly data, use LAG12 and DIF12.)

For example, the following statements compute monthly percent change in CPI from the same month one year ago:

```
data uscpi;
   set uscpi;
   pctchng = dif12( cpi ) / lag12( cpi ) * 100;
   label pctchng = "Percent Change from One Year Ago";
run;
```

To compute year-over-year percent change measured at a given period within the year, subset the series of percent changes from the same period in the previous year to form a yearly data set. Use an IF or WHERE statement to select observations for the period within each year on which the year-over-year changes are based.

For example, the following statements compute year-over-year percent change in CPI from December of the previous year to December of the current year:

```
data annual;
   set uscpi;
   pctchng = dif12( cpi ) / lag12( cpi ) * 100;
   label pctchng = "Percent Change: December to December";
   if month( date ) = 12;
   format date year4.;
run;
```

Computing Percent Change in Yearly Averages

To compute changes in yearly averages, first aggregate the series to an annual series using the EXPAND procedure, and then compute the percent change of the annual series. (See Chapter 16, “The EXPAND Procedure,” for more information on PROC EXPAND.)

For example, the following statements compute percent changes in the annual averages of CPI:

```
proc expand data=uscpi out=annual from=month to=year;
   convert cpi / observed=average method=aggregate;
run;

data annual;
   set annual;
   pctchng = dif( cpi ) / lag( cpi ) * 100;
   label pctchng = "Percent Change in Yearly Averages";
run;
```

It is also possible to compute percent change in the average over the most recent yearly span. For example, the following statements compute monthly percent change in the average of CPI over the most recent 12 months from the average over the previous 12 months:

```
data uscpi;
   retain sum12 0;
   drop sum12 ave12 cpilag12;
```

```
      set uscpi;
      sum12 = sum12 + cpi;
      cpilag12 = lag12( cpi );
      if cpilag12 ^= . then sum12 = sum12 - cpilag12;
      if lag11( cpi ) ^= . then ave12 = sum12 / 12;
      pctchng = dif12( ave12 ) / lag12( ave12 ) * 100;
      label pctchng = "Percent Change in 12 Month Moving Ave.";
   run;
```

This example is a complex use of LAG and DIF functions that requires care in handling the initialization of the moving-window averaging process. The LAG12 of CPI is checked for missing values to determine when more than 12 values have been accumulated, and older values must be removed from the moving sum. The LAG11 of CPI is checked for missing values to determine when at least 12 values have been accumulated; AVE12 will be missing when LAG11 of CPI is missing. The DROP statement prevents temporary variables from being added to the data set.

Note that the DIF and LAG functions must execute for every observation or the queues of remembered values will not operate correctly. The CPILAG12 calculation must be separate from the IF statement. The PCTCHNG calculation must not be conditional on the IF statement.

The EXPAND procedure provides an alternative way to compute moving averages.

Leading Series

Although the SAS System does not provide a function to look ahead at the "next" value of a series, there are a couple of ways to perform this task.

The most direct way to compute leads is to use the EXPAND procedure. For example

```
   proc expand data=uscpi out=uscpi method=none;
      id date;
      convert cpi=cpilead1 / transform=( lead 1 );
      convert cpi=cpilead2 / transform=( lead 2 );
   run;
```

Another way to compute lead series in SAS software is by lagging the time ID variable, renaming the series, and merging the result data set back with the original data set.

For example, the following statements add the variable CPILEAD to the USCPI data set. The variable CPILEAD contains the value of CPI in the following month. (The value of CPILEAD will be missing for the last observation, of course.)

```
   data temp;
      set uscpi;
      keep date cpi;
      rename cpi = cpilead;
      date = lag( date );
      if date ^= .;
```

```
run;

data uscpi;
   merge uscpi temp;
   by date;
run;
```

To compute leads at different lead lengths, you must create one temporary data set for each lead length. For example, the following statements compute CPILEAD1 and CPILEAD2, which contain leads of CPI for 1 and 2 periods, respectively:

```
data temp1(rename=(cpi=cpilead1)) temp2(rename=(cpi=cpilead2));
   set uscpi;
   keep date cpi;
   date = lag( date );
   if date ^= . then output temp1;
   date = lag( date );
   if date ^= . then output temp2;
run;

data uscpi;
   merge uscpi temp1 temp2;
   by date;
run;
```

Summing Series

Simple cumulative sums are easy to compute using SAS sum statements. The following statements show how to compute the running sum of variable X in data set A, adding XSUM to the data set.

```
data a;
   set a;
   xsum + x;
run;
```

The SAS sum statement automatically retains the variable XSUM and initializes it to 0, and the sum statement treats missing values as 0. The sum statement is equivalent to using a RETAIN statement and the SUM function. The previous example could also be written as follows:

```
data a;
   set a;
   retain xsum;
   xsum = sum( xsum, x );
run;
```

You can also use the EXPAND procedure to compute summations. For example

```
proc expand data=a out=a method=none;
   convert x=xsum / transform=( sum );
run;
```

Like differencing, summation can be done at different lags and can be repeated to produce higher-order sums. To compute sums over observations separated by lags greater than 1, use the LAG and SUM functions together, and use a RETAIN statement that initializes the summation variable to zero.

For example, the following statements add the variable XSUM2 to data set A. XSUM2 contains the sum of every other observation, with even-numbered observations containing a cumulative sum of values of X from even observations, and odd-numbered observations containing a cumulative sum of values of X from odd observations.

```
data a;
   set a;
   retain xsum2 0;
   xsum2 = sum( lag( xsum2 ), x );
run;
```

Assuming that A is a quarterly data set, the following statements compute running sums of X for each quarter. XSUM4 contains the cumulative sum of X for all observations for the same quarter as the current quarter. Thus, for a first-quarter observation, XSUM4 contains a cumulative sum of current and past first-quarter values.

```
data a;
   set a;
   retain xsum4 0;
   xsum4 = sum( lag3( xsum4 ), x );
run;
```

To compute higher-order sums, repeat the preceding process and sum the summation variable. For example, the following statements compute the first and second summations of X:

```
data a;
   set a;
   xsum + x;
   x2sum + xsum;
run;
```

The following statements compute the second order four-period sum of X:

```
data a;
   set a;
   retain xsum4 x2sum4 0;
   xsum4 = sum( lag3( xsum4 ), x );
   x2sum4 = sum( lag3( x2sum4 ), xsum4 );
run;
```

You can also use PROC EXPAND to compute cumulative statistics and moving window statistics. See Chapter 16, “The EXPAND Procedure,” for details.

Transforming Time Series

It is often useful to transform time series for analysis or forecasting. Many time series analysis and forecasting methods are most appropriate for time series with an unrestricted range, linear trend, and constant variance. Series that do not conform to these assumptions can often be transformed to series for which the methods are appropriate.

Transformations can be useful for the following:

- range restrictions. Many time series cannot have negative values or may be limited by a maximum possible value. You can often create a transformed series with an unbounded range.
- nonlinear trends. Many economic time series grow exponentially. Exponential growth corresponds to linear growth in the logarithms of the series.
- series variability that changes over time. Various transformations can be used to stabilize the variance.
- non-stationarity. The %DFTEST macro can be used to test a series for non-stationarity which may then be removed by differencing.

Log Transformation

The logarithmic transformation is often useful for series that must be greater than zero and that grow exponentially. For example, Figure 2.21 shows a plot of an airline passenger miles series. Notice that the series has exponential growth and the variability of the series increases over time. Airline passenger miles must also be zero or greater.

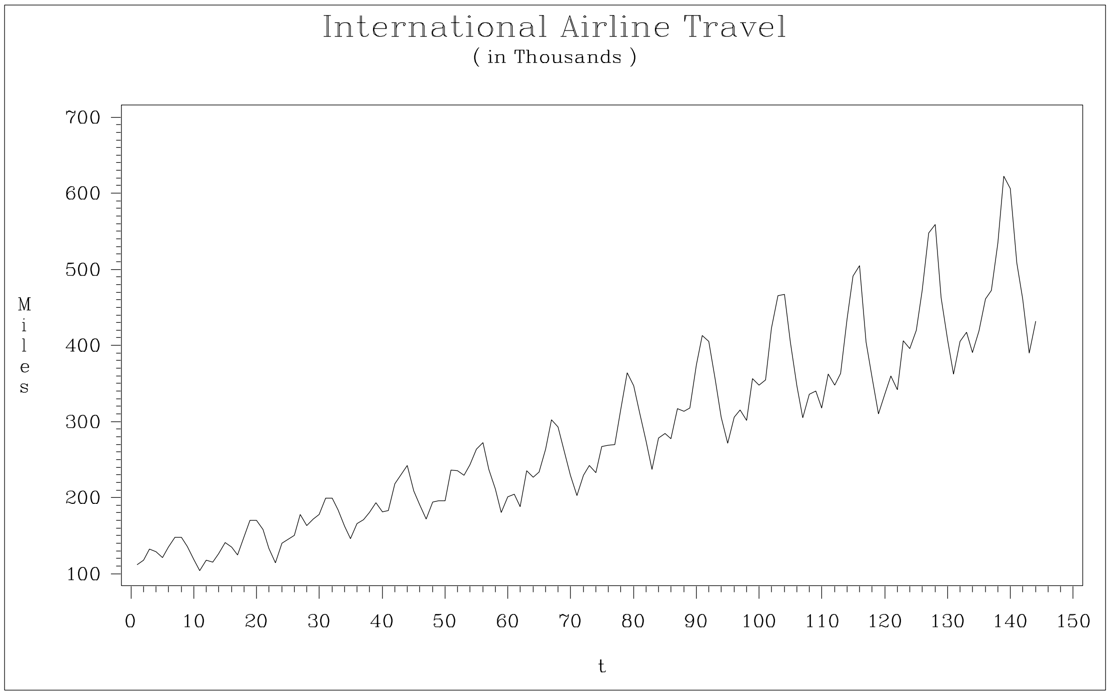

Figure 2.21. [Airline Series

The following statements compute the logarithms of the airline series:

```
data a;
   set a;
   logair = log( air );
run;
```

Figure 2.22 shows a plot of the log transformed airline series. Notice that the log series has a linear trend and constant variance.

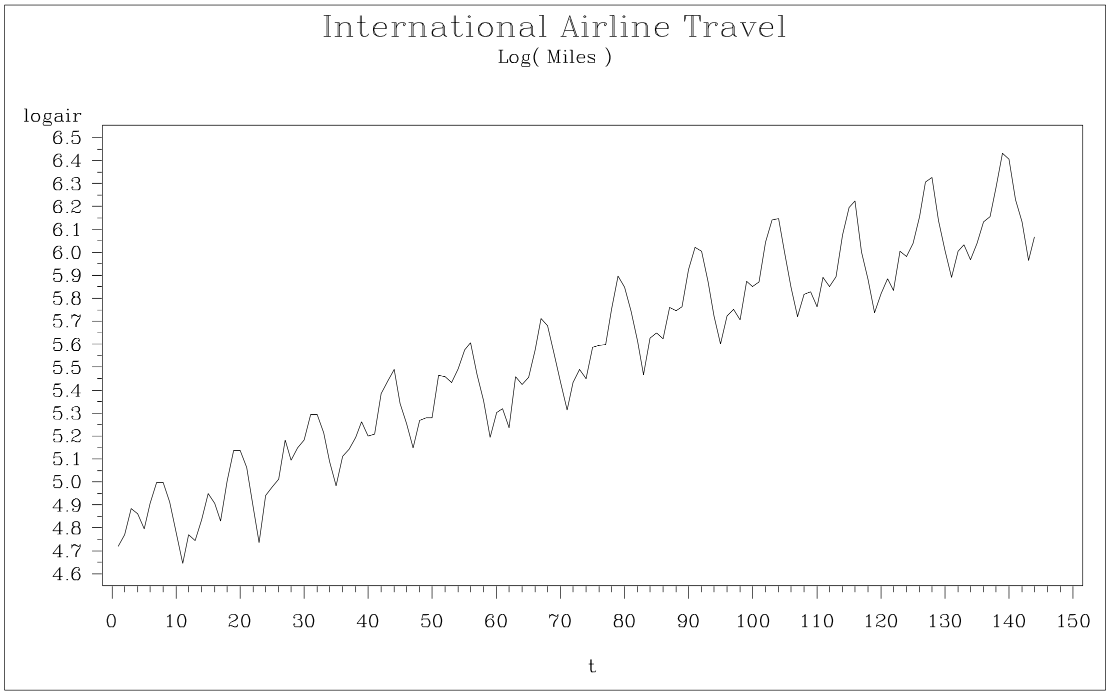

Figure 2.22. Log Airline Series

The %LOGTEST macro can help you decide if a log transformation is appropriate for a series. See Chapter 4, "SAS Macros and Functions," for more information on the %LOGTEST macro.

Other Transformations

The Box-Cox transformation is a general class of transformations that includes the logarithm as a special case. The %BOXCOXAR macro can be used to find an optimal Box-Cox transformation for a time series. See Chapter 4 for more information on the %BOXCOXAR macro.

The logistic transformation is useful for variables with both an upper and a lower bound, such as market shares. The logistic transformation is useful for proportions, percent values, relative frequencies, or probabilities. The logistic function transforms values between 0 and 1 to values that can range from $-\infty$ to $+\infty$.

For example, the following statements transform the variable SHARE from percent values to an unbounded range:

```
data a;
   set a;
   lshare = log( share / ( 100 - share ) );
run;
```

Many other data transformation can be used. You can create virtually any desired data transformation using DATA step statements.

The EXPAND Procedure and Data Transformations

The EXPAND procedure provides a convenient way to transform series. For example, the following statements add variables for the logarithm of AIR and the logistic of SHARE to data set A:

```
proc expand data=a out=a method=none;
   convert air=logair   / transform=( log );
   convert share=lshare / transform=( / 100 logit );
run;
```

See Table 16.1 in Chapter 16 for a complete list of transformations supported by PROC EXPAND.

Manipulating Time Series Data Sets

This section discusses merging, splitting, and transposing time series data sets and interpolating time series data to a higher or lower sampling frequency.

Splitting and Merging Data Sets

In some cases, you may want to separate several time series contained in one data set into different data sets. In other cases, you may want to combine time series from different data sets into one data set.

To split a time series data set into two or more data sets containing subsets of the series, use a DATA step to create the new data sets and use the KEEP= data set option to control which series are included in each new data set. The following statements split the USPRICE data set shown in a previous example into two data sets, USCPI and USPPI:

```
data uscpi(keep=date cpi)
     usppi(keep=date ppi);
   set usprice;
run;
```

If the series have different time ranges, you can subset the time ranges of the output data sets accordingly. For example, if you know that CPI in USPRICE has the range August 1990 through the end of the data set, while PPI has the range from the beginning of the data set through June 1991, you could write the previous example as follows:

```
data uscpi(keep=date cpi)
     usppi(keep=date ppi);
   set usprice;
   if date >= '1aug1990'd then output uscpi;
   if date <= '1jun1991'd then output usppi;
run;
```

To combine time series from different data sets into one data set, list the data sets to be combined in a MERGE statement and specify the dating variable in a BY statement. The following statements show how to combine the USCPI and USPPI data sets to produce the USPRICE data set. It is important to use the BY DATE; statement so observations are matched by time before merging.

```
data usprice;
   merge uscpi usppi;
   by date;
run;
```

Transposing Data Sets

The TRANSPOSE procedure is used to transpose data sets from one form to another. The TRANSPOSE procedure can transpose variables and observations, or transpose variables and observations within BY groups. This section discusses some applications of the TRANSPOSE procedure relevant to time series data sets. Refer to the *SAS Procedures Guide* for more information on PROC TRANSPOSE.

Transposing from Interleaved to Standard Time Series Form

The following statements transpose part of the interleaved form output data set FOREOUT, produced by PROC FORECAST in a previous example, to a standard form time series data set. To reduce the volume of output produced by the example, a WHERE statement is used to subset the input data set.

Observations with _TYPE_=ACTUAL are stored in the new variable ACTUAL; observations with _TYPE_=FORECAST are stored in the new variable FORECAST; and so forth. Note that the method used in this example only works for a single variable.

```
title "Original Data Set";
proc print data=foreout;
   where date > '1may1991'd & date < '1oct1991'd;
run;

proc transpose data=foreout out=trans(drop=_name_ _label_);
   var cpi;
   id _type_;
   by date;
   where date > '1may1991'd & date < '1oct1991'd;
run;

title "Transposed Data Set";
proc print data=trans;
run;
```

The TRANSPOSE procedure adds the variables _NAME_ and _LABEL_ to the output data set. These variables contain the names and labels of the variables that were transposed. In this example, there is only one transposed variable, so _NAME_ has the value CPI for all observations. Thus, _NAME_ and _LABEL_ are of no interest and are dropped from the output data set using the DROP= data set option. (If none of the variables transposed have a label, PROC TRANSPOSE does not output the _LABEL_ variable and the DROP=_LABEL_ option produces a warning message. You can ignore this message, or you can prevent the message by omitting _LABEL_ from the DROP= list.)

The original and transposed data sets are shown in Figure 2.23. (The observation numbers shown for the original data set reflect the operation of the WHERE statement.)

```

Figure 2.23. Original and Transposed Data Sets

Transposing Cross-sectional Dimensions

The following statements transpose the variable CPI in the CPICITY data set shown in a previous example from time series cross-sectional form to a standard form time series data set. (Only a subset of the data shown in the previous example is used here.) Note that the method shown in this example only works for a single variable.

```
title "Original Data Set";
proc print data=cpicity;
run;

proc sort data=cpicity out=temp;
   by date city;
run;
```

```
proc transpose data=temp out=citycpi(drop=_name_ _label_);
   var cpi;
   id city;
   by date;
run;

title "Transposed Data Set";
proc print data=citycpi;
run;
```

The names of the variables in the transposed data sets are taken from the city names in the ID variable CITY. The original and the transposed data sets are shown in Figure 2.24.

Figure 2.24. Original and Transposed Data Sets

The following statements transpose the CITYCPI data set back to the original form of the CPICITY data set. The variable _NAME_ is added to the data set to tell PROC TRANSPOSE the name of the variable in which to store the observations in the transposed data set. (If the (DROP=_NAME_ _LABEL_) option were omitted from the first PROC TRANSPOSE step, this would not be necessary. PROC TRANSPOSE assumes ID _NAME_ by default.)

The NAME=CITY option in the PROC TRANSPOSE statement causes PROC TRANSPOSE to store the names of the transposed variables in the variable CITY. Because PROC TRANSPOSE recodes the values of the CITY variable to create valid SAS variable names in the transposed data set, the values of the variable CITY in the retransposed data set are not the same as the original. The retransposed data set is shown in Figure 2.25.

```
data temp;
   set citycpi;
   _name_ = 'CPI';
run;

proc transpose data=temp out=retrans name=city;
   by date;
run;

proc sort data=retrans;
   by city date;
run;

title "Retransposed Data Set";
proc print data=retrans;
run;
```

Figure 2.25. Data Set Transposed Back to Original Form

Time Series Interpolation

The EXPAND procedure interpolates time series. This section provides a brief summary of the use of PROC EXPAND for different kinds of time series interpolation problems. Most of the issues discussed in this section are explained in greater detail in Chapter 16.

By default, the EXPAND procedure performs interpolation by first fitting cubic spline curves to the available data and then computing needed interpolating values from the fitted spline curves. Other interpolation methods can be requested.

Note that interpolating values of a time series does not add any real information to the data as the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series containing interpolated values.

Interpolating Missing Values

To use the EXPAND procedure to interpolate missing values in a time series, specify the input and output data sets on the PROC EXPAND statement, and specify the time ID variable in an ID statement. For example, the following statements cause PROC EXPAND to interpolate values for missing values of all numeric variables in the data set USPRICE:

```
proc expand data=usprice out=interpl;
   id date;
run;
```

Interpolated values are computed only for embedded missing values in the input time series. Missing values before or after the range of a series are ignored by the EXPAND procedure.

In the preceding example, PROC EXPAND assumes that all series are measured at points in time given by the value of the ID variable. In fact, the series in the USPRICE data set are monthly averages. PROC EXPAND may produce a better interpolation if this is taken into account. The following example uses the FROM=MONTH option to tell PROC EXPAND that the series is monthly and uses the CONVERT statement with the OBSERVED=AVERAGE to specify that the series values are averages over each month:

```
proc expand data=usprice out=interpl from=month;
   id date;
   convert cpi ppi / observed=average;
run;
```

Interpolating to a Higher or Lower Frequency

You can use PROC EXPAND to interpolate values of time series at a higher or lower sampling frequency than the input time series. To change the periodicity of time series, specify the time interval of the input data set with the FROM= option, and specify the time interval for the desired output frequency with the TO= option. For example, the following statements compute interpolated weekly values of the monthly CPI and PPI series:

```
proc expand data=usprice out=interpl from=month to=week;
   id date;
   convert cpi ppi / observed=average;
run;
```

Interpolating between Stocks and Flows, Levels and Rates

A distinction is made between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series Gross National Product represents the final goods production of over the year and also the yearly average rate of that production. However, the monthly variable Inventory represents the cost of a stock of goods at the end of the month.

The EXPAND procedure can convert between point-in-time values and period average or total values. To convert observation characteristics, specify the input and output characteristics with the OBSERVED= option in the CONVERT statement. For example, the following statements use the monthly average price index values in USPRICE to compute interpolated estimates of the price index levels at the midpoint of each month.

```
proc expand data=usprice out=midpoint from=month;
   id date;
   convert cpi ppi / observed=(average,middle);
run;
```

Reading Time Series Data

Time series data can be coded in many different ways. The SAS System can read time series data recorded in almost any form. Earlier sections of this chapter show how to read time series data coded in several commonly used ways. This section shows how to read time series data from data records coded in two other commonly used ways not previously introduced.

Several time series databases distributed by major data vendors can be read into SAS data sets by the DATASOURCE procedure. See Chapter 14, “The DATASOURCE Procedure,” for more information.

The SASECRSP, SASEFAME, and SASEHAVR interface engines enables SAS users to access and process time series data in CRSPAccess data files, FAME databases, and HAVER ANALYTICS Data Link Express (DLX) data bases, respectively. See

Chapter 5, “The SASECRSP Interface Engine,” Chapter 6, “The SASEFAME Interface Engine,” and Chapter 7, “The SASEHAVR Interface Engine,” for more details.

Reading a Simple List of Values

Time series data can be coded as a simple list of values without dating information and with an arbitrary number of observations on each data record. In this case, the INPUT statement must use the trailing "@@" option to retain the current data record after reading the values for each observation, and the time ID variable must be generated with programming statements.

For example, the following statements read the USPRICE data set from data records containing pairs of values for CPI and PPI. This example assumes you know that the first pair of values is for June 1990.

```
data usprice;
   input cpi ppi @@;
   date = intnx( ’month’, ’1jun1990’d, _n_-1 );
   format date monyy7.;
datalines;
129.9 114.3  130.4 114.5  131.6 116.5
132.7 118.4  133.5 120.8  133.8 120.1 133.8 118.7
134.6 119.0  134.8 117.2  135.0 116.2 135.2 116.0
135.6 116.5  136.0 116.3  136.2 116.0
;
```

Reading Fully Described Time Series in Transposed Form

Data for several time series can be coded with separate groups of records for each time series. Data files coded this way are transposed from the form required by SAS procedures. Time series data can also be coded with descriptive information about the series included with the data records.

The following example reads time series data for the USPRICE data set coded with separate groups of records for each series. The data records for each series consist of a series description record and one or more value records. The series description record gives the series name, starting month and year of the series, number of values in the series, and a series label. The value records contain the observations of the time series.

The data are first read into a temporary data set that contains one observation for each value of each series. This data set is sorted by date and series name, and the TRANSPOSE procedure is used to transpose the data into a standard form time series data set.

```
data temp;
   length _name_ $8 _label_ $40;
   keep _name_ _label_ date value;
   format date monyy.;
```

```
      input _name_ month year nval _label_ &;
      date = mdy( month, 1, year );
      do i = 1 to nval;
         input value @;
         output;
         date = intnx( 'month', date, 1 );
      end;
   datalines;
   cpi      8 90  12  Consumer Price Index
   131.6 132.7 133.5 133.8 133.8 134.6 134.8 135.0
   135.2 135.6 136.0 136.2
   ppi      6 90  13  Producer Price Index
   114.3 114.5 116.5 118.4 120.8 120.1 118.7 119.0
   117.2 116.2 116.0 116.5 116.3
   ;

   proc sort data=temp;
      by date _name_;
   run;

   proc transpose data=temp out=usprice(drop=_name_ _label_);
      by date;
      var value;
   run;

   proc contents data=usprice;
   run;

   proc print data=usprice;
   run;
```

The final data set is shown in Figure 2.26.

Chapter 3
Date Intervals, Formats, and Functions

Chapter Contents

Chapter 3
Date Intervals, Formats, and Functions

Overview

This chapter summarizes the time intervals, date and datetime informats, date and datetime formats, and date, time and datetime functions available in the SAS System. The use of these features is explained in Chapter 2, "Working with Time Series Data." The material in this chapter is also contained in the *SAS Language: Reference*. Because these features are useful for work with time series data, documentation of these features is consolidated and repeated here for easy reference.

Time Intervals

This section provides a reference for the different kinds of time intervals supported by the SAS System. How intervals are used is not discussed here; see Chapter 2, "Working with Time Series Data," for an introduction to the use of time intervals.

Some interval names are for use with SAS date values, while other interval names are for use with SAS datetime values. The interval names used with SAS date values are YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, and DAY. The interval names used with SAS datetime or time values are HOUR, MINUTE, and SECOND. Various abbreviations of these names are also allowed, as described in the section "Summary of Interval Types."

Interval names for use with SAS date values can be prefixed with 'DT' to construct interval names for use with SAS datetime values. The interval names DTYEAR, DTSEMIYEAR, DTQTR, DTMONTH, DTSEMIMONTH, DTTENDAY, DTWEEK, DTWEEKDAY, and DTDAY are used with SAS datetime or time values.

Constructing Interval Names

Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The general form of an interval name is as follows:

NAMEn.s

The three parts of the interval name are:

NAME	the name of the basic interval type. For example, YEAR specifies yearly intervals.
n	an optional multiplier that specifies that the interval is a multiple of the period of the basic interval type. For example, the interval YEAR2 consists of two-year, or biennial, periods.
s	an optional starting subperiod index that specifies that the intervals are shifted to later starting points. For example, YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Both the multiplier *n* and the shift index *s* are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

Both the multiplier *n* and the shift index *s* are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

Shifted Intervals

Different kinds of intervals are shifted by different subperiods.

- YEAR, SEMIYEAR, QTR, and MONTH intervals are shifted by calendar months.
- WEEK, WEEKDAY, and DAY intervals are shifted by days.
- SEMIMONTH intervals are shifted by semi-monthly periods.
- TENDAY intervals are shifted by ten-day periods.
- HOUR intervals are shifted by hours.
- MINUTE intervals are shifted by minutes.
- SECOND intervals are shifted by seconds.

If a subperiod is specified, the shift index cannot be greater than the number of subperiods in the whole interval. For example, you could use YEAR2.24, but YEAR2.25 would be an error because there is no twenty-fifth month in a two-year interval. For interval types that shift by subperiods that are the same as the basic interval type, only multiperiod intervals can be shifted.

For example, MONTH type intervals shift by MONTH subintervals; thus, monthly intervals cannot be shifted since there is only one month in MONTH. However, bimonthly intervals can be shifted, since there are two MONTH intervals in each MONTH2 interval. The interval name MONTH2.2 specifies bimonthly periods starting on the first day of even-numbered months.

Alignment of Intervals

Intervals that represent divisions of a year are aligned with the start of the year (January). MONTH2 periods begin with odd-numbered months (January, March, May, and so on). Likewise, intervals that represent divisions of a day are aligned with the start of the day (midnight). Thus, HOUR8.7 intervals divide the day into the periods 06:00 to 14:00, 14:00 to 22:00, and 22:00 to 06:00.

Intervals that do not nest within years or days are aligned relative to the SAS date or datetime value 0. The arbitrary reference time of midnight on January 1, 1960, is used as the origin for nonshifted intervals, and shifted intervals are defined relative to that reference point. For example, MONTH13 defines the intervals January 1, 1960, February 1, 1961, March 1, 1962, and so forth, and the intervals December 1, 1959, November 1, 1958, and so on before the base date January 1, 1960.

Similarly, WEEK2 interval beginning days are aligned relative to the Sunday of the week of January 1, 1960. The interval specification WEEK6.13 defines six-week periods starting on second Fridays, and the convention of alignment relative to the period containing January 1, 1960, tells where to start counting to find out what dates correspond to the second Fridays of six-week intervals.

See the section “Alignment of SAS Dates” later in this chapter.

Summary of Interval Types

The interval types are summarized as follows.

YEAR
specifies yearly intervals. Abbreviations are YEAR, YEARS, YEARLY, YR, ANNUAL, ANNUALLY, ANNUALS. The starting subperiod *s* is in months.

SEMIYEAR
specifies semiannual intervals (every six months). Abbreviations are SEMIYEAR, SEMIYEARS, SEMIYEARLY, SEMIYR, SEMIANNUAL, SEMIANN.

The starting subperiod *s* is in months. For example, SEMIYEAR.3 intervals are March–August and September–February.

QTR
specifies quarterly intervals (every three months). Abbreviations are QTR, QUARTER, QUARTERS, QUARTERLY, QTRLY, QTRS. The starting subperiod *s* is in months.

MONTH
specifies monthly intervals. Abbreviations are MONTH, MONTHS, MONTHLY, MON.

The starting subperiod *s* is in months. For example, MONTH2.2 intervals are February–March, April–May, June–July, August–September, October–November, and December–January of the following year.

SEMIMONTH
specifies semimonthly intervals. SEMIMONTH breaks each month into two pe-

riods, starting on the first and sixteenth day. Abbreviations are SEMIMONTH, SEMIMONTHS, SEMIMONTHLY, SEMIMON.

The starting subperiod *s* is in SEMIMONTH periods. For example, SEMIMONTH2.2 specifies intervals from the sixteenth of one month through the fifteenth of the next month.

TENDAY

specifies 10-day intervals. TENDAY breaks the month into three periods, the first through the tenth day of the month, the eleventh through the twentieth day of the month, and the remainder of the month. (TENDAY is a special interval typically used for reporting automobile sales data.)

The starting subperiod *s* is in TENDAY periods. For example, TENDAY4.2 defines 40-day periods starting at the second TENDAY period.

WEEK

specifies weekly intervals of seven days. Abbreviations are WEEK, WEEKS, WEEKLY.

The starting subperiod *s* is in days, with the days of the week numbered as 1=Sunday, 2=Monday, 3=Tuesday, 4=Wednesday, 5=Thursday, 6=Friday, and 7=Saturday. For example, WEEK.7 means weekly with Saturday as the first day of the week.

WEEKDAY
WEEKDAY17W

specifies daily intervals with weekend days included in the preceding week day. Abbreviations are WEEKDAY, WEEKDAYS.

The WEEKDAY interval is the same as DAY except that weekend days are absorbed into the preceding weekday. Thus there are five WEEKDAY intervals in a calendar week: Monday, Tuesday, Wednesday, Thursday, and the three-day period Friday-Saturday-Sunday.

The default weekend days are Saturday and Sunday, but any one to six weekend days can be listed after the WEEKDAY string and followed by a W. Weekend days are specified as ’1’ for Sunday, ’2’ for Monday, and so forth. For example, WEEKDAY67W specifies a Friday-Saturday weekend. WEEKDAY1W specifies a six-day work week with a Sunday weekend. WEEKDAY17W is the same as WEEKDAY.

The starting subperiod *s* is in days.

DAY

specifies daily intervals. Abbreviations are DAY, DAYS, DAILY. The starting subperiod *s* is in days.

HOUR

specifies hourly intervals. Abbreviations are HOUR, HOURS, HOURLY, HR. The starting subperiod *s* is in hours.

MINUTE

specifies minute intervals. Abbreviations are MINUTE, MINUTES, MIN. The starting subperiod *s* is in minutes.

SECOND
specifies second intervals. Abbreviations are SECOND, SECONDS, SEC. The starting subperiod *s* is in seconds.

Examples of Interval Specifications

Table 3.1 shows examples of different kinds of interval specifications.

Table 3.1. Examples of Intervals

Name	Kind of Interval
YEAR	years starting in January
YEAR.10	fiscal years starting in October
YEAR2.7	biennial intervals starting in July of even years
YEAR2.19	biennial intervals starting in July of odd years
YEAR4.11	four-year intervals starting in November of leap years (frequency of U.S. presidential elections)
YEAR4.35	four-year intervals starting in November of even years between leap years (frequency of U.S. midterm elections)
WEEK	weekly intervals starting on Sundays
WEEK2	biweekly intervals starting on first Sundays
WEEK1.1	same as WEEK
WEEK.2	weekly intervals starting on Mondays
WEEK6.3	six-week intervals starting on first Tuesdays
WEEK6.11	six-week intervals starting on second Wednesdays
WEEKDAY	daily with Friday-Saturday-Sunday counted as the same day (five-day work week with a Saturday-Sunday weekend)
WEEKDAY17W	same as WEEKDAY
WEEKDAY67W	daily with Thursday-Friday-Saturday counted as the same day (five-day work week with a Friday-Saturday weekend)
WEEKDAY1W	daily with Saturday-Sunday counted as the same day (six-day work week with a Sunday weekend)
WEEKDAY3.2	three-weekday intervals (with Friday-Saturday-Sunday counted as one weekday) with the cycle three-weekday periods aligned to Monday 4 Jan 1960
HOUR8.7	eight-hour intervals starting at 6 a.m., 2 p.m., and 10 p.m. (might be used for work shifts)

Date and Datetime Informats

Table 3.2 summarizes the SAS date and datetime informats available in the SAS System. See Chapter 2, "Working with Time Series Data," for a discussion of the use of date and datetime informats. Refer to *SAS Language: Reference* for a complete description of these informats.

For each informat, Table 3.2 shows an example of a date or datetime value written in the style that the informat is designed to read. The date 17 October 1991 and the time

2:25:32 p.m. are used for the example in all cases. Table 3.2 shows the width range allowed by the informat and the default width.

Table 3.2. SAS Date and Datetime Informats

Informat **Example**	**Description**	**Width Range**	**Default Width**
DATE*w.* 17oct91	day, month abbreviation, and year: *ddMONyy*	7-32	7
DATETIME*w.d* 17oct91:14:45:32	date and time: *ddMONyy:hh:mm:ss*	13-40	18
DDMMYY*w.* 17/10/91	day, month, year: *ddmmyy*, *dd/mm/yy*, *dd-mm-yy*, or *dd mm yy*	6-32	6
JULIAN*w.* 91290	year and day of year (Julian dates): *yyddd*	5-32	5
MMDDYY*w.* 10/17/91	month, day, year: *mmddyy*, *mm/dd/yy*, *mm-dd-yy*, or *mm dd yy*	6-32	6
MONYY*w.* Oct91	month abbreviation and year	5-32	5
NENGO*w.* H.03/10/17	Japanese Nengo notation	7-32	10
TIME*w.d* 14:45:32	hours, minutes, seconds: *hh:mm:ss* or hours, minutes: *hh:mm*.	5-32	8
YYMMDD*w.* 91/10/17	year, month, day: *yymmdd*, *yy/mm/dd*, *yy-mm-dd*, or *yy mm dd*	6-32	6
YYQ*w.* 91Q4	year and quarter of year: *yyQq*	4-32	4

Date, Time, and Datetime Formats

The SAS date and datetime formats are summarized in Table 3.3 and Table 3.4. A width value can be specified with each format. The tables list the range of width values allowed and the default width value for each format.

The notation used by a format is abbreviated in different ways depending on the width option used. For example, the format MMDDYY8. writes the date 17 October 1991 as 10/17/91, while the format MMDDYY6. writes this date as 101791. In particular, formats that display the year show two- or four-digit year values depending on the width option. The examples shown in the tables are for the default width.

Refer to *SAS Language: Reference* for a complete description of these formats, including the variations of the formats produced by different width options. See Chapter 2, "Working with Time Series Data," for a discussion of the use of date and datetime formats.

Date Formats

Table 3.3 lists the date formats available in the SAS System. For each format, an example is shown of a date value in the notation produced by the format. The date '17OCT91'D is used as the example.

Table 3.3. SAS Date Formats

Format **Example**	**Description**	**Width Range**	**Default Width**
DATE*w.* 17oct91	day, month abbreviation, year: *ddMONyy*	5-9	7
DAY*w.* 17	day of month	2-32	2
DDMMYY*w.* 17/10/91	day, month, year: *dd/mm/yy*	2-8	8
DOWNAME*w.* Thursday	name of day of the week	1-32	9
JULDAY*w.* 290	day of year	3-32	3
JULIAN*w.* 91290	year and day of year: *yyddd*	5-7	5
MMDDYY*w.* 10/17/91	month, day, year: *mm/dd/yy*	2-8	8
MMYY*w.* 10M1991	month and year: *mmMyy*	5-32	7
MMYYC*w.* 10:1991	month and year: *mm:yy*	5-32	7
MMYYD*w.* 10-1991	month and year: *mm-yy*	5-32	7
MMYYP*w.*	month and year: *mm.yy*	5-32	7

Table 3.3. (continued)

Format Example	**Description**	**Width Range**	**Default Width**
10.1991			
MMYYS*w.* 10/1991	month and year: *mm/yy*	5-32	7
MMYYN*w.* 101991	month and year: *mmyy*	5-32	6
MONNAME*w.* October	name of month	1-32	9
MONTH*w.* 10	month of year	1-32	2
MONYY*w.* OCT91	month abbreviation and year: *MONyy*	5-7	5
QTR*w.* 4	quarter of year	1-32	1
QTRR*w.* IV	quarter in Roman numerals	3-32	3
NENGO*w.* H.03/10/17	Japanese Nengo notation	2-10	10
WEEKDATE*w.* Thursday, October 17, 1991	*day-of-week, month-name dd, yy*	3-37	29
WEEKDATX*w.* Thursday, 17 October 1991	*day-of-week, dd month-name yy*	3-37	29
WEEKDAY*w.* 5	day of week	1-32	1
WORDDATE*w.* October 17, 1991	*month-name dd, yy*	3-32	18
WORDDATX*w.* 17 October 1991	*dd month-name yy*	3-32	18

YYQRN*w.* 1991IV	year and quarter in Roman numerals: *yyrr*	6-32	8

Datetime and Time Formats

Table 3.4 lists the datetime and time formats available. For each format, an example is shown of a datetime value in the notation produced by the format. The datetime value ’17OCT91:14:25:32’DT is used as the example.

Table 3.4. SAS Datetime and Time Formats

Format **Example**	**Description**	**Width Range**	**Default Width**
DATETIME*w.d* 17OCT91:14:25:32	*ddMONyy:hh:mm:ss*	7-40	16
HHMM*w.d* 14:25	hour and minute: *hh:mm*	2-20	5
HOUR*w.d* 14	hour	2-20	2
MMSS*w.d* 25:32	minutes and seconds: *mm:ss*	2-20	5
TIME*w.d* 14:25:32	time of day: *hh:mm:ss*	2-20	8
TOD*w.* 14:25:32	time of day: *hh:mm:ss*	2-20	8

Alignment of SAS Dates

SAS date values used to identify time series observations produced by SAS/ETS procedures are normally aligned with the beginning of the time intervals corresponding to the observations. For example, for monthly data for 1994, the date values identifying the observations are 1Jan94, 1Feb94, 1Mar94, . . . , 1Dec94.

However, for some applications it may be preferable to use end of period dates, such as 31Jan94, 28Feb94, 31Mar94, . . . , 31Dec94. For other applications, such as plotting time series, it may be more convenient to use interval midpoint dates to identify the observations.

SAS/ETS procedures provide an ALIGN= option to control the alignment of dates for output time series observations. Procedures supporting the ALIGN= option are ARIMA, DATASOURCE, EXPAND, and FORECAST.

ALIGN=

The ALIGN= option allows the following values:

BEGINNING	Specifies that dates are aligned to the start of the interval. This is the default. BEGINNING can be abbreviated as BEGIN, BEG, or B.
MIDDLE	Specifies that dates are aligned to the interval midpoint. MIDDLE can be abbreviated as MID or M.
ENDING	Specifies that dates are aligned to the end of the interval. ENDING can be abbreviated as END or E.

The ALIGN= option can be specified on the PROC DATASOURCE statement, on the PROC EXPAND statement, on the PROC FORECAST statement, and on the FORECAST statement of the ARIMA procedure.

Date, Time, and Datetime Functions

The SAS System provides functions to perform calculations with SAS date, time, and datetime values. SAS date, time, and datetime functions are used to:

- compute date, time, and datetime values from calendar and time-of-day values.
- compute calendar and time-of-day values from date and datetime values.
- convert between date, time, and datetime values.
- perform calculations involving time intervals.

SAS date, time, and datetime functions are listed in alphabetical order in the following. Refer to *SAS Language: Reference* for a complete description of these functions.

SAS Date, Time, and Datetime Functions

DATE()
returns today's date as a SAS date value.

DATEJUL(*yyddd* **)**
returns the Julian date for a SAS date value.

DATEPART(*datetime* **)**
returns the date part of a SAS datetime value as a date value.

DATETIME()
returns the current date and time of day.

DAY(*date* **)**
returns the day of the month from a SAS date value.

DHMS(*date, hour, minute, second* **)**
returns a SAS datetime value for date, hour, minute, and second values.

HMS(*hour, minute, second* **)**
returns a SAS time value for hour, minute, and second values.

HOUR(*datetime* **)**
returns the hour from a SAS datetime or time value.

INTCINDEX(*'interval', value* **)**
returns the cycle index, given a date, time, or datetime interval and value.

INTCK(*interval, date1, date2* **)**
returns the number of boundaries of intervals of the given kind that lie between the two date or datetime values.

INTCYCLE(*'interval'* **)**
returns the date, time, or datetime interval at the next higher seasonal cycle, given a date, time, or datetime interval.

INTFMT(*'interval', 'size'* **)**
returns a recommended format, given a date, time, or datetime interval.

INTINDEX(*'interval', value* **)**
returns the seasonal index, given a date, time, or datetime interval and value.

INTNX(*interval, date, n* **<**, *'alignment'* **>)**
returns the date or datetime value of the beginning of the interval that is *n* intervals from the interval that contains the given date or datetime value. The optional alignment argument specifies that the returned date is aligned to either the beginning, middle, or end of the interval. Beginning is the default.

INTSEA(*'interval'* **)**
returns the length of the seasonal cycle, given a date, time, or datetime interval.

JULDATE(*date* **)**
returns the Julian date from a SAS date value.

MDY(*month, day, year* **)**
returns a SAS date value for month, day, and year values.

MINUTE(*datetime* **)**
returns the minute from a SAS time or datetime value.

MONTH(*date* **)**
returns the month of the year from a SAS date value.

QTR(*date* **)**
returns the quarter of the year from a SAS date value.

SECOND(*date* **)**
returns the second from a SAS time or datetime value.

TIME()
returns the current time of day.

TIMEPART(*datetime* **)**
returns the time part of a SAS datetime value.

TODAY()
returns the current date as a SAS date value. (TODAY is another name for the DATE function.)

WEEKDAY(*date* **)**
returns the day of the week from a SAS date value.

YEAR(*date* **)**
returns the year from a SAS date value.

YYQ(*year, quarter* **)**
returns a SAS date value for year and quarter values.

Chapter 4
SAS Macros and Functions

Chapter Contents

Chapter 4
SAS Macros and Functions

SAS Macros

This chapter describes several SAS macros and the SAS function PROBDF that are provided with SAS/ETS software. A SAS macro is a program that generates SAS statements. Macros make it easy to produce and execute complex SAS programs that would be time-consuming to write yourself.

SAS/ETS software includes the following macros:

%AR	generates statements to define autoregressive error models for the MODEL procedure.
%BOXCOXAR	investigates Box-Cox transformations useful for modeling and forecasting a time series.
%DFPVALUE	computes probabilities for Dickey-Fuller test statistics.
%DFTEST	performs Dickey-Fuller tests for unit roots in a time series process.
%LOGTEST	tests to see if a log transformation is appropriate for modeling and forecasting a time series.
%MA	generates statements to define moving average error models for the MODEL procedure.
%PDL	generates statements to define polynomial distributed lag models for the MODEL procedure.

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. Refer to *SAS Macro Language: Reference* for information about the SAS macro facility.

Since the %AR, %MA, and %PDL macros are used only with PROC MODEL, they are documented with the MODEL procedure. See the sections on the %AR, %MA, and %PDL macros in Chapter 20, "The MODEL Procedure," for more information about these macros. The %BOXCOXAR, %DFPVALUE, %DFTEST, and %LOGTEST macros are described in the following sections.

BOXCOXAR Macro

The %BOXCOXAR macro finds the optimal Box-Cox transformation for a time series.

Transformations of the dependent variable are a useful way of dealing with nonlinear relationships or heteroscedasticity. For example, the logarithmic transformation is often used for modeling and forecasting time series that show exponential growth or that show variability proportional to the level of the series.

The Box-Cox transformation is a general class of power transformations that include the log transformation and no-transformation as special cases. The Box-Cox transformation is

$$Y_t = \begin{cases} \frac{(X_t+c)^\lambda - 1}{\lambda} & \text{for } \lambda \neq 0 \\ \ln(X_t + c) & \text{for } \lambda = 0 \end{cases}$$

The parameter λ controls the shape of the transformation. For example, λ=0 produces a log transformation, while λ=.5 results in a square root transformation. When λ=1 the transformed series differs from the original series by $c - 1$.

The constant *c* is optional. It can be used when some X_t values are negative or 0. You choose *c* so that the series X_t is always greater than $-c$.

The %BOXCOXAR macro tries a range of λ values and reports which of the values tried produces the optimal Box-Cox transformation. To evaluate different λ values, the %BOXCOXAR macro transforms the series with each λ value and fits an autoregressive model to the transformed series. It is assumed that this autoregressive model is a reasonably good approximation to the true time series model appropriate for the transformed series. The likelihood of the data under each autoregressive model is computed, and the λ value producing the maximum likelihood over the values tried is reported as the optimal Box-Cox transformation for the series.

The %BOXCOXAR macro prints and optionally writes to a SAS data set all of the λ values tried and the corresponding log likelihood value and related statistics for the autoregressive model.

You can control the range and number of λ values tried. You can also control the order of the autoregressive models fit to the transformed series. You can difference the transformed series before the autoregressive model is fit.

Syntax

The form of the %BOXCOXAR macro is

%BOXCOXAR *(SAS-data-set, variable [, options])*

The first argument, *SAS-data-set*, specifies the name of the SAS data set containing the time series to be analyzed. The second argument, *variable*, specifies the time series variable name to be analyzed. The first two arguments are required.

The following options can be used with the %BOXCOXAR macro. Options must follow the required arguments and are separated by commas.

AR= *n*
specifies the order of the autoregressive model fit to the transformed series. The default is AR=5.

CONST= *value*
specifies a constant *c* to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The default is CONST=0.

DIF= *(differencing-list)*
specifies the degrees of differencing to apply to the transformed series before the autoregressive model is fit. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more details, see "IDENTIFY Statement" in Chapter 11, "The ARIMA Procedure."

LAMBDAHI= *value*
specifies the maximum value of lambda for the grid search. The default is LAMBDAHI=1. A large (in magnitude) LAMBDAHI= value can result in problems with floating point arithmetic.

LAMBDALO= *value*
specifies the minimum value of lambda for the grid search. The default is LAMBDALO=0. A large (in magnitude) LAMBDALO= value can result in problems with floating point arithmetic.

NLAMBDA= *value*
specifies the number of lambda values considered, including the LAMBDALO= and LAMBDAHI= option values. The default is NLAMBDA=2.

OUT= *SAS-data-set*
writes the results to an output data set. The output data set includes the lambda values tried (LAMBDA), and for each lambda value the log likelihood (LOGLIK), residual mean square error (RMSE), Akaike Information Criterion (AIC), and Schwarz's Bayesian Criterion (SBC).

PRINT= YES | NO
specifies whether results are printed. The default is PRINT=YES. The printed output contains the lambda values, log likelihoods, residual mean square errors, Akaike Information Criterion (AIC), and Schwarz's Bayesian Criterion (SBC).

Results

The value of λ producing the maximum log likelihood is returned in the macro variable &BOXCOXAR. The value of the variable &BOXCOXAR is "ERROR" if the %BOXCOXAR macro is unable to compute the best transformation due to errors. This may be the result of large lambda values. The Box-Cox transformation parameter involves exponentiation of the data, so that large lambda values may cause floating-point overflow.

Results are printed unless the PRINT=NO option is specified. Results are also stored in SAS data sets when the OUT= option is specified.

Details

Assume that the transformed series Y_t is a stationary *p*th order autoregressive process generated by independent normally distributed innovations.

$$(1 - \Theta(B))(Y_t - \mu) = \epsilon_t$$

$$\epsilon_t \sim iid\mathrm{N}(0, \sigma^2)$$

Given these assumptions, the log likelihood function of the transformed data Y_t is

$$\begin{aligned} l_Y(\cdot) = & - \frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma|) - \frac{n}{2}\ln(\sigma^2) \\ & - \frac{1}{2\sigma^2}(\mathbf{Y} - \mathbf{1}\mu)'\Sigma^{-1}(\mathbf{Y} - \mathbf{1}\mu) \end{aligned}$$

In this equation, *n* is the number of observations, μ is the mean of Y_t, **1** is the *n*-dimensional column vector of 1s, σ^2 is the innovation variance, $\mathbf{Y} = (Y_1, \cdots, Y_n)'$, and Σ is the covariance matrix of Y.

The log likelihood function of the original data $X_1, \cdots, X_n$ is

$$l_X(\cdot) = l_Y(\cdot) + (\lambda - 1)\sum_{t=1}^{n} \ln(X_t + c)$$

where *c* is the value of the CONST= option.

For each value of λ, the maximum log likelihood of the original data is obtained from the maximum log likelihood of the transformed data given the maximum likelihood estimate of the autoregressive model.

The maximum log likelihood values are used to compute the Akaike Information Criterion (AIC) and Schwarz's Bayesian Criterion (SBC) for each λ value. The residual mean square error based on the maximum likelihood estimator is also produced. To compute the mean square error, the predicted values from the model are re-transformed to the original scale (Pankratz 1983, pp. 256-258, and Taylor 1986).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You can check for stationarity of the series with the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving average terms, a large value for the AR= option may be appropriate.

DFPVALUE Macro

The %DFPVALUE macro computes the significance of the Dickey-Fuller test. The %DFPVALUE macro evaluates the *p*-value for the Dickey-Fuller test statistic τ for the test of H_0: "The time series has a unit root" vs. H_a: "The time series is stationary" using tables published by Dickey (1976) and Dickey, Hasza, and Fuller (1984).

The %DFPVALUE macro can compute *p*-values for tests of a simple unit root with lag 1 or for seasonal unit roots at lags 2, 4, or 12. The %DFPVALUE macro takes into account whether an intercept or deterministic time trend is assumed for the series.

The %DFPVALUE macro is used by the %DFTEST macro described later in this chapter.

Note that the %DFPVALUE macro has been superseded by the PROBDF function described later in this chapter. It remains for compatibility with past releases of SAS/ETS.

Syntax

The %DFPVALUE macro has the following form:

%DFPVALUE *(tau , nobs [, options])*

The first argument, *tau*, specifies the value of the Dickey-Fuller test statistic.

The second argument, *nobs*, specifies the number of observations on which the test statistic is based.

The first two arguments are required. The following options can be used with the %DFPVALUE macro. Options must follow the required arguments and are separated by commas.

DLAG= 1 | 2 | 4 | 12
specifies the lag period of the unit root to be tested. DLAG=1 specifies a 1-period unit root test. DLAG=2 specifies a test for a seasonal unit root with lag 2. DLAG=4 specifies a test for a seasonal unit root with lag 4. DLAG=12 specifies a test for a seasonal unit root with lag 12. The default is DLAG=1.

TREND= 0 | 1 | 2
specifies the degree of deterministic time trend included in the model. TREND=0 specifies no trend and assumes the series has a zero mean. TREND=1 includes an intercept term. TREND=2 specifies both an intercept and a deterministic linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed *p*-value is returned in the macro variable &DFPVALUE. If the *p*-value is less than 0.01 or larger than 0.99, the macro variable &DFPVALUE is set to 0.01 or 0.99, respectively.

Details

Minimum Observations

The minimum number of observations required by the %DFPVALUE macro depends on the value of the DLAG= option. The minimum observations are as follows:

DLAG=	Min. Obs.
1	9
2	6
4	4
12	12

DFTEST Macro

The %DFTEST macro performs the Dickey-Fuller unit root test. You can use the %DFTEST macro to decide if a time series is stationary and to determine the order of differencing required for the time series analysis of a nonstationary series.

Most time series analysis methods require that the series to be analyzed is stationary. However, many economic time series are nonstationary processes. The usual approach to this problem is to difference the series. A time series which can be made stationary by differencing is said to have a *unit root*. For more information, see the discussion of this issue in the "Getting Started" section on page 366 of Chapter 11, "The ARIMA Procedure."

The Dickey-Fuller test is a method for testing whether a time series has a unit root. The %DFTEST macro tests the hypothesis H_0: "The time series has a unit root" vs. H_a: "The time series is stationary" based on tables provided in Dickey (1976) and Dickey, Hasza, and Fuller (1984). The test can be applied for a simple unit root with lag 1, or for seasonal unit roots at lag 2, 4, or 12.

Note that the %DFTEST macro has been superseded by the PROC ARIMA stationarity tests. See Chapter 11, "The ARIMA Procedure," for details.

Syntax

The %DFTEST macro has the following form:

%DFTEST *(SAS-data-set , variable [, options])*

The first argument, *SAS-data-set*, specifies the name of the SAS data set containing the time series variable to be analyzed.

The second argument, *variable*, specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %DFTEST macro. Options must follow the required arguments and are separated by commas.

AR= *n*
specifies the order of autoregressive model fit after any differencing specified by the DIF= and DLAG= options. The default is AR=3.

DIF= *(differencing-list)*
specifies the degrees of differencing to be applied to the series. The differencing list is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the series be differenced once at lag 1 and once at lag 12. For more details, see the "IDENTIFY Statement" section on page 397 in Chapter 11, "The ARIMA Procedure."

If the option DIF=(d_1, $\cdots$, d_k) is specified, the series analyzed is $(1 - B^{d_1})\cdots(1 - B^{d_k})Y_t$, where Y_t is the variable specified,

and B is the backshift operator defined by $BY_t = Y_{t-1}$.

DLAG= 1 | 2 | 4 | 12
specifies the lag to be tested for a unit root. The default is DLAG=1.

OUT= *SAS-data-set*
writes residuals to an output data set.

OUTSTAT= *SAS-data-set*
writes the test statistic, parameter estimates, and other statistics to an output data set.

TREND= 0 | 1 | 2
specifies the degree of deterministic time trend included in the model. TREND=0 includes no deterministic term and assumes the series has a zero mean. TREND=1 includes an intercept term. TREND=2 specifies an intercept and a linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed *p*-value is returned in the macro variable &DFTEST. If the *p*-value is less than 0.01 or larger than 0.99, the macro variable &DFTEST is set to 0.01 or 0.99, respectively. (The same value is given in the macro variable &DFPVALUE returned by the %DFPVALUE macro, which is used by the %DFTEST macro to compute the *p*-value.)

Results can be stored in SAS data sets with the OUT= and OUTSTAT= options.

Details

Minimum Observations

The minimum number of observations required by the %DFTEST macro depends on the value of the DLAG= option. Let s be the sum of the differencing orders specified by the DIF= option, let t be the value of the TREND= option, and let p be the value of the AR= option. The minimum number of observations required is as follows:

DLAG=	Min. Obs.
1	$1 + p + s + \max(9, p + t + 2)$
2	$2 + p + s + \max(6, p + t + 2)$
4	$4 + p + s + \max(4, p + t + 2)$
12	$12 + p + s + \max(12, p + t + 2)$

Observations are not used if they have missing values for the series or for any lag or difference used in the autoregressive model.

LOGTEST Macro

The %LOGTEST macro tests whether a logarithmic transformation is appropriate for modeling and forecasting a time series. The logarithmic transformation is often used for time series that show exponential growth or variability proportional to the level of the series.

The %LOGTEST macro fits an autoregressive model to a series and fits the same model to the log of the series. Both models are estimated by the maximum likelihood method, and the maximum log likelihood values for both autoregressive models are computed. These log likelihood values are then expressed in terms of the original data and compared.

You can control the order of the autoregressive models. You can also difference the series and the log transformed series before the autoregressive model is fit.

You can print the log likelihood values and related statistics (AIC, SBC, and MSE) for the autoregressive models for the series and the log transformed series. You can also output these statistics to a SAS data set.

Syntax

The %LOGTEST macro has the following form:

%LOGTEST(*SAS-data-set , variable ,***[***options***])**

The first argument, *SAS-data-set*, specifies the name of the SAS data set containing the time series variable to be analyzed. The second argument, *variable*, specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %LOGTEST macro. Options must follow the required arguments and are separated by commas.

AR= *n*
specifies the order of the autoregressive model fit to the series and the log transformed series. The default is AR=5.

CONST= *value*
specifies a constant to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The series analyzed must be greater than the negative of the CONST= value. The default is CONST=0.

DIF= *(differencing-list)*
specifies the degrees of differencing applied to the original and log transformed series before fitting the autoregressive model. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more details, see the "IDENTIFY Statement" section on page 397 in Chapter 11, "The ARIMA Procedure."

OUT= *SAS-data-set*
writes the results to an output data set. The output data set includes a variable TRANS identifying the transformation (LOG or NONE), the log likelihood value (LOGLIK), residual mean square error (RMSE), Akaike Information Criterion (AIC), and Schwarz's Bayesian Criterion (SBC) for the log transformed and untransformed cases.

PRINT= YES | NO
specifies whether the results are printed. The default is PRINT=NO. The printed output shows the log likelihood value, residual mean square error, Akaike Information

Criterion (AIC), and Schwarz's Bayesian Criterion (SBC) for the log transformed and untransformed cases.

Results

The result of the test is returned in the macro variable &LOGTEST. The value of the &LOGTEST variable is 'LOG' if the model fit to the log transformed data has a larger log likelihood than the model fit to the untransformed series. The value of the &LOGTEST variable is 'NONE' if the model fit to the untransformed data has a larger log likelihood. The variable &LOGTEST is set to 'ERROR' if the %LOGTEST macro is unable to compute the test due to errors.

Results are printed when the PRINT=YES option is specified. Results are stored in SAS data sets when the OUT= option is specified.

Details

Assume that a time series X_t is a stationary *p*th order autoregressive process with normally distributed white noise innovations. That is,

$$(1 - \Theta(B))(X_t - \mu_{\mathbf{x}}) = \epsilon_t$$

where $\mu_{\mathbf{x}}$ is the mean of X_t.

The log likelihood function of X_t is

$$\begin{aligned} l_1(\cdot) = & - \frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{\mathbf{xx}}|) - \frac{n}{2}\ln(\sigma_{\mathbf{e}}^2) \\ & - \frac{1}{2\sigma_{\mathbf{e}}^2}(\mathbf{X} - \mathbf{1}\mu_{\mathbf{x}})'\Sigma_{\mathbf{xx}}^{-1}(\mathbf{X} - \mathbf{1}\mu_{\mathbf{x}}) \end{aligned}$$

where *n* is the number of observations, **1** is the *n*-dimensional column vector of 1s, $\sigma_{\mathbf{e}}^2$ is the variance of the white noise, $\mathbf{X} = (X_1, \cdots, X_n)'$, and $\Sigma_{\mathbf{xx}}$ is the covariance matrix of $\mathbf{X}$.

On the other hand, if the log transformed time series $Y_t = \ln(X_t + c)$ is a stationary *p*th order autoregressive process, the log likelihood function of X_t is

$$\begin{aligned} l_0(\cdot) = & - \frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{\mathbf{yy}}|) - \frac{n}{2}\ln(\sigma_{\mathbf{e}}^2) \\ & - \frac{1}{2\sigma_{\mathbf{e}}^2}(\mathbf{Y} - \mathbf{1}\mu_{\mathbf{y}})'\Sigma_{\mathbf{yy}}^{-1}(\mathbf{Y} - \mathbf{1}\mu_{\mathbf{y}}) - \sum_{t=1}^{n}\ln(X_t + c) \end{aligned}$$

where $\mu_{\mathbf{y}}$ is the mean of Y_t, $\mathbf{Y} = (Y_1, \cdots, Y_n)'$, and $\Sigma_{\mathbf{yy}}$ is the covariance matrix of $\mathbf{Y}$.

The %LOGTEST macro compares the maximum values of $l_1(\cdot)$ and $l_0(\cdot)$ and determines which is larger.

The %LOGTEST macro also computes the Akaike Information Criterion (AIC), Schwarz's Bayesian Criterion (SBC), and residual mean square error based on the maximum likelihood estimator for the autoregressive model. For the mean square error, retransformation of forecasts is based on Pankratz (1983, pp. 256-258).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You may wish to check for stationarity of the series using the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving average terms, a large value for the AR= option may be appropriate.

Financial Functions

This section contains the data step financial functions provided with SAS/ETS software in addition to the financial functions in Base SAS software. Refer to *SAS Language Reference: Functions and CALL Routines* for more details on data step functions in general, and for other financial functions not described in this chapter.

The PMT, CUMIPMT, CUMPPMT, PPMT, and IPMT functions are focused on calculations of loans and savings. The EFFRATE and NOMRATE functions perform conversion between effective and nominal interest rates depending on compounding intervals. TIMEVALUE and SAVINGS functions perform time value of money calculations with interest rates that vary over time.

CUMIPMT Function

The CUMIPMT function returns the cumulative interest paid on a loan between *StartPeriod* and *EndPeriod*.

Syntax

CUMIPMT(*Rate, NumberOfPeriods, PrincipalAmount, StartPeriod, EndPeriod, Type* **)**

Rate	specifies the interest rate per payment period. The argument *Rate* is required.
NumberOfPeriods	specifies the number of payment periods. The argument *NumberOfPeriods* is required. It needs to have a positive integer value.
PrincipalAmount	specifies the principal amount of the loan. The argument *PrincipalAmount* is required. Zero is assumed if a missing value is specified.
StartPeriod	specifies the start period for the calculation.
EndPeriod	specifies the end period for the calculation.

Type	specifies whether the payments are at the beginning or end of a period. 0 represents end of period payments and 1 represents beginning of period payments. 0 (end of period payments) is assumed if omitted or a missing value is specified.

Examples

The cumulative interest paid during the second year of the loan on a $125,000 30-year loan with end of period monthly payments and a nominal annual rate is 9% is specified as:

```
TotalInterest  = CUMIPMT (.09/12, 360, 125000, 13, 24, 0);
```

and returns 11,135.23.

The interest paid on the first period of the same loan is specified as:

```
first_period_interest = CUMIPMT (.09/12, 360, 125000, 1, 1, 0);
```

and returns 937.50.

CUMPRINC Function

The CUMPRINC function returns the cumulative principal paid on a loan between *StartPeriod* and *EndPeriod*.

Syntax

CUMPRINC(*Rate, NumberOfPeriods, PrincipalAmount, StartPeriod, EndPeriod, Type* **)**

Rate	specifies the interest rate per payment period. The argument *Rate* is required.
NumberOfPeriods	specifies the number of payment periods. The argument *NumberOfPeriods* is required. It needs to have a positive integer value.
PrincipalAmount	specifies the principal amount of the loan. The argument *PrincipalAmount* is required. Zero is assumed if a missing value is specified.
StartPeriod	specifies the start period for the calculation.
EndPeriod	specifies the end period for the calculation.
Type	specifies whether the payments are at the beginning or end of a period. ‘0’ represents end of period payments and ‘1’ represents beginning of period payments. ‘0’ (end of period payments) is assumed if omitted or a missing value is specified.

Examples

The cumulative principal paid during the second year of a $125,000 30-year loan with end of period monthly payments and a nominal annual rate of 9% is specified as:

```
PrincipalYear2  = CUMRINC (0.09/12, 360, 125000, 12, 24, 0);
```

and returns 934.107.

The principal paid on the second year of the same loan with beginning of period payments is specified as:

```
PrincipalYear2b = CUMPRINC (0.09/12, 360, 125000, 12, 24, 1);
```

and returns 927.153.

EFFRATE Function

The EFFRATE function returns the effective annual interest rate. EFFRATE computes the effective annual interest rate corresponding to a nominal annual interest rate.

Syntax

EFFRATE(*CompoundingInterval, Rate* **)**

CompoundingInterval	is a SAS interval. This is how often *Rate* compounds.
Rate	is a numeric. This is a nominal annual interest rate (expressed as a percentage) that is compounded each *CompoundingInterval*.

Details

- The values for rates must be at least -99.
- Consider a nominal interest *Rate* and a compounding *CompoundingInterval*. If *CompoundingInterval* is 'CONTINUOUS,' the value returned by EFFRATE(*CompoundingInterval, Rate*) equals

  $$e^{Rate/100} - 1$$

  If *CompoundingInterval* is not 'CONTINUOUS,' and *m* *CompoundingInterval*s occur in a year, the value returned by EFFRATE(*CompoundingInterval, Rate*) equals

  $$\left(1 + \frac{Rate}{100\ m}\right)^m - 1$$

- Valid values for *CompoundingInterval* are: 'CONTINUOUS,' 'DAY,' 'SEMIMONTH,' 'MONTH,' 'QUARTER,' 'SEMIYEAR,' and 'YEAR.'
- If *Interval* is 'DAY,' then $m = 365$.

Examples

Suppose a nominal rate is 10%. The corresponding effective rate when interest is compounded monthly can be expressed as

```
effective_rate1 = EFFRATE ("MONTH" 10);
```

Again, suppose a nominal rate is 10%. The corresponding effective rate when interest is compounded quarterly can be expressed as

```
effective_rate2 = EFFRATE ("QUARTER", 10);
```

IPMT Function

The IPMT function returns the interest payment for a given period for a constant payment loan or the periodic saving for a future balance.

Syntax

IPMT(*Rate, Period, NumberOfPeriods, PrincipalAmount, FutureAmount, Type* **)**

Rate	specifies the interest rate per payment period. The argument *Rate* is required.
Period	specifies the payment period for which the interest payment is computed. The argument *Period* is required. *Period* needs to have a positive integer value less than or equal to the *NumberofPeriods*.
NumberOfPeriods	specifies the number of payment periods. The argument *NumberOfPeriods* is required. It needs to have a positive integer value.
PrincipalAmount	specifies the principal amount of the loan. The argument *PrincipalAmount* is required. Zero is assumed if a missing value is specified.
FutureAmount	specifies the future amount, either outstanding balance after *NumberOfPeriods* in case of a loan or the future balance of periodic savings. Zero is assumed if omitted or a missing value is specified.
Type	specifies whether the payments are at the beginning or end of a period. ‘0’ represents end of period payments and ‘1’ represents beginning of period payments. ‘0’ (end of period payments) is assumed if omitted or a missing value is specified.

Examples

The interest payment on the first periodic payment for a $8,000 loan where the nominal annual rate is 10% and there are 36 end of period monthly payments is specified as:

```
    InterestPaid1 = IPMT(0.1/12, 1, 36, 8000);
```

and returns 66.67.

If the same loan has beginning of period payments then:

```
   InterestPaid2 =IPMT(.1/12, 1, 36, 8000, 0, 1);
```

and returns 0.0.

```
   InterestPaid3 =IPMT(.1, 3, 3, 8000);
```

returns 292.447.

```
  InterestPaid4 = IPMT(0.09/12, 359, 360,125000,0, 1);
```

returns 7.4314473.

NOMRATE Function

The NOMRATE function returns the nominal annual interest rate. NOMRATE computes the nominal annual interest rate corresponding to an effective annual interest rate.

Syntax

NOMRATE(*Interval*, *Rate* **)**

Interval	is a SAS interval. This is how often the returned value is compounded.
Rate	is a numeric. This is an effective annual interest rate (expressed as a percentage) that is compounded each *Interval*.

Details

- The values for rates must be at least -99.
- Consider an effective interest *Rate* and a compounding *Interval*. If *CompoundingInterval* is “CONTINUOUS”, the value returned by NOMRATE(*Interval, Rate*) equals

  $$\log_e\left(1+\frac{Rate}{100}\right)$$

  If *CompoundingInterval* is not “CONTINUOUS” and *m Interval*s occur in a year, the value returned by NOMRATE(*Interval, Rate*) equals

  $$m\left(\left(1+\frac{Rate}{100}\right)^{\frac{1}{m}}-1\right)$$

- Valid values for *CompoundingInterval* are: “CONTINUOUS”, “DAY”, “SEMIMONTH”, “MONTH”, “QUARTER”, “SEMIYEAR”, and “YEAR”.
- If *Interval* is “DAY”, then $m = 365$.

Examples

Suppose an effective rate is 10% when compounding monthly. The corresponding nominal rate can be expressed as

```
effective_rate1 = NOMRATE ("MONTH", 10);
```

Suppose an effective rate is 10% when compounding quarterly. The corresponding nominal rate can be expressed as

```
effective_rate2 = NOMRATE ("QUARTER", 10);
```

PMT Function

The PMT function returns the periodic payment for a constant payment loan or the periodic saving for a future balance.

Syntax

PMT(*Rate, NumberOfPeriods, PrincipalAmount, FutureAmount, Type* **)**

Rate	specifies the interest rate per payment period. The argumentRate is required.
NumberOfPeriods	specifies the number of payment periods. The *NumberOfPeriods* is required. NumerofPeriods needs to have a positive integer value.

PrincipalAmount	specifies the principal amount of the loan. The argument *PrincipalAmount* is a required argument. Zero is assumed if a missing value is specified.
FutureAmount	specifies the future amount, either outstanding balance after *NumberOfPeriods* in case of a loan or the future balance of periodic savings. Zero is assumed if omitted or a missing value is specified.
Type	specifies whether the payments are at the beginning or end of a period. ‘0’ represents end of period payments and 1 represents beginning of period payments. ‘0’ (end of period payments) is assumed if omitted or a missing value is specified.

Examples

The monthly payment for a $10,000 loan with a nominal annual rate of 8% and 10 end of month payments is specified as:

```
    Payment1 = PMT (0.08/12, 10, 10000, 0, 0);
```

or

```
   Payment1 = PMT (0.08/12, 10, 10000);
```

and returns 1037.03.

If the same loan has beginning of period payments then:

```
   Payment2 = PMT  (0.08/12, 10, 10000, 0, 1);
```

and returns 1030.16.

If you loan $5000 to be paid back to you in 5 monthly payments earning a 12% annual nominal rate, it is specified as:

```
   Payment3= PMT (.01, 5, -5000);
```

and returns -1030.20

The monthly periodic savings over 18 years earning a 6% annual nominal interest rate which would accumulate $50,000 at the end of the 18 years is specified as:

```
   payment3 = PMT (0.06/12, 216, 0, 50000, 0);
```

and returns 129.081.

PPMT Function

The PPMT function returns the principal payment for a given period for a constant payment loan or the periodic saving for a future balance.

Syntax

PPMT(*Rate, Period, NumberOfPeriods, PrincipalAmount, FutureAmount, Type* **)**

Rate	specifies the interest rate per payment period. The argument *Rate* is required.
Period	specifies the payment periods for which the principal payment is computed. The argument *Period* is required. *Period* needs to have a positive integer value less than or equal to the *NumberofPeriods*.
NumberOfPeriods	specifies the number of payment periods. The argument *NumberOfPeriods* is required. It needs to have a positive integer value.
PrincipalAmount	specifies the principal amount of the loan. The argument *PrincipalAmount* is a required argument. Zero is assumed if a missing value is specified.
FutureAmount	specifies the future amount, either outstanding balance after *NumberOfPeriods* in case of a loan or the future balance of periodic savings. '0' is assumed if omitted or a missing value is specified.
Type	specifies whether the payments are at the beginning or end of a period. '0' represents end of period payments and 1 represents beginning of period payments. '0' (end of period payments) is assumed if omitted or a missing value is specified.

Examples

The principal payment amount of the first monthly periodic payment for a 2 year $2,000 loan with a nominal annual rate of 10% is specified as:

```
PrincipalPayment = PPMT(.1/12, 1, 24, 2000);
```

and returns 75.62.

A 3-year $20,000 loan with beginning of month payments is specified as:

```
PrincipalPayment2  =PPMT(.1/12, 1, 36, 20000, 0, 1);
```

and returns $640.10 as the principal paid with the first payment.

An end-of-month payment loan with an outstanding balance of $5,000 at the end of 3 years is specified as:

```
PrincipalPayment3 =PPMT(.1/12, 1, 36, 20000, 5000, 0);
```

and returns $389.914 as the principal paid with the first payment.

SAVINGS Function

The SAVINGS function returns the balance of a periodic savings using variable interest rates.

Syntax

SAVINGS(*BaseDate, InitialDepositDate, DepositAmount, DepositNumber, DepositInterval, CompoundingInterval, Date-1, Rate-1* **[** , *Date-2, Rate-2,* ...**]** *)*

BaseDate	is a SAS date. The returned value is the balance of the savings at *BaseDate*.
InitialDepositDate	is a SAS date. This is the date of the first deposit. Subsequent deposits are at the beginning of subsequent deposit intervals.
DepositAmount	is a numeric. All deposits are assumed constant. This is the value of each deposit.
DepositNumber	is a positive integer. This is the number of deposits.
DepositInterval	is a SAS interval. This is the frequency at which you make deposits.
CompoundingInterval	is a SAS interval. This is the compounding interval.
Date-i	is a SAS date. Each date is paired with a rate. The date *Date-i* is the time that *Rate-i* takes effect.
Rate-i	is a numeric percentage. Each rate is paired with a date. The rate *Rate-i* is the interest rate that starts on *Date-i*.

Details

- The values for rates must be between -99 and 120.
- *DepositInterval* cannot be ‘CONTINUOUS’
- The list of date-rate pairs does not need to be given in chronological order.
- When multiple rate changes occur on a single date, SAS applies only the final rate listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *InitialDepositDate* and *BaseDate*.

Examples

Suppose you deposit $300 monthly for two years into an account that compounds quarterly at an annual rate of 4%. The balance of the account after five years can be expressed as

```
amount_base1 = SAVINGS ("01jan2005"d, "01jan2000"d, 300, 24,
                        "MONTH", "QUARTER", "01jan2000"d, 4.00);
```

Suppose the interest rate increases by a quarter-point each year. Then the balance of the account could be expressed as

```
amount_base2 = SAVINGS ("01jan2005"d, "01jan2000"d, 300, 24,
                        "MONTH", "QUARTER", "01jan2000"d, 4.00,
                        "01jan2001"d, 4.25, "01jan2002"d, 4.50,
                        "01jan2003"d, 4.75, "01jan2004"d, 5.00);
```

If you want to know the balance after one year of deposits, the following statement sets amount_base3 to the desired balance.

```
amount_base3 = SAVINGS ("01jan2001"d, "01jan2000"d, 300, 24,
                        "MONTH", "QUARTER", "01jan2000"d, 4);
```

Recall that SAS ignores deposits after the base date, so the deposits after the *ReferenceDate* do not affect the returned value.

TIMEVALUE Function

The TIMEVALUE function returns the equivalent of a reference amount at a base date using variable interest rates. TIMEVALUE computes the time-value equivalent of a date-amount pair at a specified date.

Syntax

TIMEVALUE(*BaseDate, ReferenceDate, ReferenceAmount, CompoundingInterval, Date-1, Rate-1* **[** *, Date-2, Rate-2, ...* **]** *)*

BaseDate	is a SAS date. The returned value is the time value of *ReferenceAmount* at *BaseDate*.
ReferenceDate	is a SAS date. This is the date of *ReferenceAmount*.
ReferenceAmount	is a numeric. This is the amount at *ReferenceDate*.
CompoundingInterval	is a SAS interval. This is the compounding interval.
Date-i	is a SAS date. Each date is paired with a rate. The date *Date-i* is the time that *Rate-i* takes effect.
Rate-i	is a numeric percentage. Each rate is paired with a date. The rate *Rate-i* is the interest rate that starts on *Date-i*.

Details

- The values for rates must be between -99 and 120.
- The list of date-rate pairs does not need to be sorted by date.
- When multiple rate changes occur on a single date, SAS applies only the final rate listed for that date.
- Simple interest is applied for partial periods.
- There must be a valid date-rate pair whose date is at or prior to both the *ReferenceDate* and *BaseDate*.

Examples

You can express the accumulated value of an investment of $1,000 at a nominal interest rate of 10% compounded monthly for one year as

```
amount_base1 = TIMEVALUE ("01jan2001"d, "01jan2000"d, 1000,
                          "MONTH", "01jan2000"d, 10);
```

If the interest rate jumps to 20% halfway through the year, the resulting calculation would be

```
amount_base2 = TIMEVALUE ("01jan2001"d, "01jan2000"d, 1000,
                          "MONTH",
                          "01jan2000"d, 10, "01jul2000"d, 20);
```

Recall that the date-rate pairs do not need to be sorted by date. This flexibility allows amount_base2 and amount_base3 to assume the same value.

```
amount_base3 = TIMEVALUE ("01jan2001"d, "01jan2000"d, 1000,
                          "MONTH",
                          "01jul2000"d, 20, "01jan2000"d, 10);
```

Other Functions

PROBDF Function for Dickey-Fuller Tests

The PROBDF function calculates significance probabilities for Dickey-Fuller tests for unit roots in time series. The PROBDF function can be used wherever SAS library functions may be used, including DATA step programs, SCL programs, and PROC MODEL programs.

Syntax

PROBDF(*x*, *n* **[** , *d* **[** , *type* **]])**

x	is the test statistic.
n	is the sample size. The minimum value of *n* allowed depends on the value specified for the second argument *d*. For *d* in the set (1,2,4,6,12), *n* must be an integer greater than or equal to $\max(2d, 5)$; for other values of *d* the minimum value of *n* is 24.
d	is an optional integer giving the degree of the unit root tested for. Specify $d = 1$ for tests of a simple unit root $(1 - \mathrm{B})$. Specify *d* equal to the seasonal cycle length for tests for a seasonal unit root $(1 - \mathrm{B}^{\mathrm{d}})$. The default value of *d* is 1; that is, a test for a simple unit root $(1 - \mathrm{B})$ is assumed if *d* is not specified. The maximum value of *d* allowed is 12.
type	is an optional character argument that specifies the type of test statistic used. The values of *type* are

SZM	studentized test statistic for the zero mean (no intercept) case
RZM	regression test statistic for the zero mean (no intercept) case
SSM	studentized test statistic for the single mean (intercept) case
RSM	regression test statistic for the single mean (intercept) case
STR	studentized test statistic for the deterministic time trend case
RTR	regression test statistic for the deterministic time trend case

The values STR and RTR are allowed only when $d = 1$. The default value of *type* is SZM.

Details

Theoretical Background

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots.

Consider the (*p*+1)th order autoregressive time series

$$Y_t = \alpha_1 Y_{t-1} + \alpha_2 Y_{t-2} + \cdots + \alpha_{p+1} Y_{t-p-1} + e_t$$

and its characteristic equation

$$m^{p+1} - \alpha_1 m^p - \alpha_2 m^{p-1} - \cdots - \alpha_{p+1} = 0$$

If all the characteristic roots are less than 1 in absolute value, Y_t is stationary. Y_t is nonstationary if there is a unit root. If there is a unit root, the sum of the autoregressive parameters is 1, and, hence, you can test for a unit root by testing whether the sum of the autoregressive parameters is 1 or not. For convenience, the model is parameterized as

$$\nabla Y_t = \delta Y_{t-1} + \theta_1 \nabla Y_{t-1} + \cdots + \theta_p \nabla Y_{t-p} + e_t$$

where $\nabla Y_t = Y_t - Y_{t-1}$ and

$$\delta = \alpha_1 + \cdots + \alpha_{p+1} - 1$$

$$\theta_k = -\alpha_{k+1} - \cdots - \alpha_{p+1}$$

The estimators are obtained by regressing ∇Y_t on $Y_{t-1}, \nabla Y_{t-1}, \cdots, \nabla Y_{t-p}$. The *t* statistic of the ordinary least squares estimator of δ is the test statistic for the unit root test.

If the TREND=1 option is used, the autoregressive model includes a mean term α_0. If TREND=2, the model also includes a time trend term and the model is as follows:

$$\nabla Y_t = \alpha_0 + \gamma t + \delta Y_{t-1} + \theta_1 \nabla Y_{t-1} + \cdots + \theta_p \nabla Y_{t-p} + e_t$$

For testing for a seasonal unit root, consider the multiplicative model

$$(1 - \alpha_d B^d)(1 - \theta_1 B - \cdots - \theta_p B^p) Y_t = e_t$$

Let $\nabla^d Y_t \equiv Y_t - Y_{t-d}$. The test statistic is calculated in the following steps:

1. Regress $\nabla^d Y_t$ on $\nabla^d Y_{t-1} \cdots \nabla^d Y_{t-p}$ to obtain the initial estimators $\hat{\theta}_i$ and compute residuals $\hat{e}_t$. Under the null hypothesis that $\alpha_d = 1$, $\hat{\theta}_i$ are consistent estimators of θ_i.
2. Regress $\hat{e}_t$ on $(1 - \hat{\theta}_1 B - \cdots - \hat{\theta}_p B^p) Y_{t-d}, \nabla^d Y_{t-1}, \cdots, \nabla^d Y_{t-p}$to obtain estimates of $\delta = \alpha_d - 1$ and $\theta_i - \hat{\theta}_i$.

The *t* ratio for the estimate of δ produced by the second step is used as a test statistic for testing for a seasonal unit root. The estimates of θ_i are obtained by adding the estimates of $\theta_i - \hat{\theta}_i$ from the second step to $\hat{\theta}_i$ from the first step. The estimates of $\alpha_d - 1$ and θ_i are saved in the OUTSTAT= data set if the OUTSTAT= option is specified.

The series $(1 - B^d) Y_t$ is assumed to be stationary, where *d* is the value of the DLAG= option.

If the OUTSTAT= option is specified, the OUTSTAT= data set contains estimates $\hat{\delta}, \hat{\theta}_1, \cdots, \hat{\theta}_p$.

If the series is an ARMA process, a large value of the AR= option may be desirable in order to obtain a reliable test statistic. To determine an appropriate value for the AR= option for an ARMA process, refer to Said and Dickey (1984).

Test Statistics

The Dickey-Fuller test is used to test the null hypothesis that the time series exhibits a lag *d* unit root against the alternative of stationarity. The PROBDF function computes the probability of observing a test statistic more extreme than *x* under the assumption that the null hypothesis is true. You should reject the unit root hypothesis when PROBDF returns a small (significant) probability value.

There are several different versions of the Dickey-Fuller test. The PROBDF function supports six versions, as selected by the *type* argument. Specify the *type* value that corresponds to the way that you calculated the test statistic *x*.

The last two characters of the *type* value specify the kind of regression model used to compute the Dickey-Fuller test statistic. The meaning of the last two characters of the *type* value are as follows.

ZM	zero mean or no intercept case. The test statistic *x* is assumed to be computed from the regression model $y_t = \alpha_d y_{t-d} + e_t$
SM	single mean or intercept case. The test statistic *x* is assumed to be computed from the regression model $y_t = \alpha_0 + \alpha_d y_{t-d} + e_t$
TR	intercept and deterministic time trend case. The test statistic *x* is assumed to be computed from the regression model $y_t = \alpha_0 + \gamma t + \alpha_1 y_{t-1} + e_t$

The first character of the *type* value specifies whether the regression test statistic or the studentized test statistic is used. Let $\hat{\alpha}_d$ be the estimated regression coefficient for the *d*th lag of the series, and let $\mathrm{se}_{\hat{\alpha}}$ be the standard error of $\hat{\alpha}_d$. The meaning of the first character of the *type* value is as follows.

R	the regression coefficient-based test statistic. The test statistic is $x = n(\hat{\alpha}_d - 1)$
S	the studentized test statistic. The test statistic is $x = \dfrac{(\hat{\alpha}_d - 1)}{\mathrm{se}_{\hat{\alpha}}}$

Refer to Dickey and Fuller (1979) and Dickey, Hasza, and Fuller (1984) for more information about the Dickey-Fuller test null distribution. The preceding formulas are for the basic Dickey-Fuller test. The PROBDF function can also be used for the augmented Dickey-Fuller test, in which the error term e_t is modeled as an autoregressive process; however, the test statistic is computed somewhat differently for the augmented Dickey-Fuller test. Refer to Dickey, Hasza, and Fuller (1984) and Hamilton (1994) for information about seasonal and nonseasonal augmented Dickey-Fuller tests.

The PROBDF function is calculated from approximating functions fit to empirical quantiles produced by Monte Carlo simulation employing 10^8 replications for each simulation. Separate simulations were performed for selected values of *n* and for $d = 1, 2, 4, 6, 12$.

The maximum error of the PROBDF function is approximately $\pm 10^{-3}$ for *d* in the set (1,2,4,6,12) and may be slightly larger for other *d* values. (Because the number of simulation replications used to produce the PROBDF function is much greater than the 60,000 replications used by Dickey and Fuller (1979) and Dickey, Hasza, and Fuller (1984), the PROBDF function can be expected to produce results that are substantially more accurate than the critical values reported in those papers.)

Examples

Suppose the data set TEST contains 104 observations of the time series variable Y, and you want to test the null hypothesis that there exists a lag 4 seasonal unit root in the Y series. The following statements illustrate how to perform the single-mean Dickey-Fuller regression coefficient test using PROC REG and PROBDF.

```
data test1;
   set test;
   y4 = lag4(y);
run;

proc reg data=test1 outest=alpha;
   model y = y4 / noprint;
run;

data _null_;
   set alpha;
   x = 100 * ( y4 - 1 );
   p = probdf( x, 100, 4, "RSM" );
   put p= pvalue5.3;
run;
```

To perform the augmented Dickey-Fuller test, regress the differences of the series on lagged differences and on the lagged value of the series, and compute the test statistic from the regression coefficient for the lagged series. The following statements illustrate how to perform the single-mean augmented Dickey-Fuller studentized test using PROC REG and PROBDF.

```
data test1;
   set test;
   yl  = lag(y);
   yd  = dif(y);
```

```
      yd1 = lag1(yd); yd2 = lag2(yd);
      yd3 = lag3(yd); yd4 = lag4(yd);
   run;

   proc reg data=test1 outest=alpha covout;
      model yd = yl yd1-yd4 / noprint;
   run;

   data _null_;
      set alpha;
      retain a;
      if _type_ = 'PARMS' then a = yl - 1;
      if _type_ = 'COV' & _NAME_ = 'YL' then do;
         x = a / sqrt(yl);
         p = probdf( x, 99, 1, "SSM" );
         put p= pvalue5.3;
         end;
   run;
```

The %DFTEST macro provides an easier way to perform Dickey-Fuller tests. The following statements perform the same tests as the preceding example.

```
   %dftest( test, y, ar=4 );
   %put p=&dftest;
```

Chapter 5
The SASECRSP Interface Engine

Chapter Contents

Chapter 5 The SASECRSP Interface Engine

Overview

The SASECRSP interface engine enables SAS users to access and process time series data residing in CRSPAccess data files and provides a seamless interface between CRSP and SAS data processing.

The SASECRSP engine uses the LIBNAME statement to enable you to specify which time series you would like to read from the CRSPAccess data files, and how you would like to perform selection on the CRSP set you choose to access. You choose the daily CRSP data by specifying SETID=10, or the monthly CRSP data by specifying SETID=20. You can select which securities you wish to access by specifying PERMNO=*number*, the primary key, or you can select which securities you wish to access by specifying a secondary key, such as PERMCO=*number*, a secondary key, a unique permanent identifier assigned by CRSP to all companies with issues on the CRSP Stock Files, or CUSIP=*number*, a secondary key, assigned to individual securities by the Standard and Poor's CUSIP Service, or HCUSIP=*number*, a secondary key, historical cusip for a security, or TICKER=*character*, a secondary key, ticker symbol for a security, or SICCD=*character*, a secondary key, standard industrial classification code, and you can specify your range of dates for the selected time series by using RANGE=‘*begdt-enddt*’, or specify an input SAS data set named *setname* as input for issues with the INSET=‘*setname*’ option. The SAS Data step can then be used to perform further subsetting and to store the resulting time series into a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time. Since CRSP and SAS use three different date representations, you can use the engine-provided CRSP date formats, informats, and functions for flexible seamless programming.

SASECRSP for Version 9 supports Windows, Solaris 8 (SUNOS5.8), LINUX and DEC/OSF Digital UNIX.

Getting Started

Structure of a SAS Data Set Containing Time Series Data

SAS requires time series data to be in a specific form that is recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASECRSP engine provides a time ID variable called CALDT.

Reading CRSP Data Files

The SASECRSP engine supports reading time series, events, and portfolios from CRSPAccess data files. Only the series specified by the CRSP *setid* is written to the SAS data set. The CRSP environment variable CRSPDB_SASCAL must be defined to allow the SASECRSP engine access to the CRSPAccess database calendars.

Using the SAS DATA Step

If desired, you can store the selected series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. Once the data is stored in a SAS data set you can use it as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure and report information concerning the contents of your data set by using the CONTENTS procedure. You can create a view of the CRSPAccess data base by using the SQL procedure to create your view using the SASECRSP engine in your *libref*, along with the USING clause.

Using CRSP Date Formats, Informats, and Functions

CRSP has historically used two different methods to represent dates, and SAS has used a third. The SASECRSP engine provides 22 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. See the section "Understanding CRSP Date Formats, Informats, and Functions" on page 170 for details.

Syntax

The SASECRSP engine uses standard engine syntax. Options used by SASECRSP are summarized in the table below.

Description	Statement	Option
specify a CRSPAccess set id where 10 is daily and 20 monthly. This is a required option.	LIBNAME *libref* SASECRSP	SETID=
specify the PERMNO of a security to be kept in the SAS data set.	LIBNAME *libref* SASECRSP	PERMNO=
specify the PERMCO of a security to be kept in the SAS data set,	LIBNAME *libref* SASECRSP	PERMCO=
specify the CUSIP of a security to be kept in the SAS data set,	LIBNAME *libref* SASECRSP	CUSIP=
specify the HCUSIP of a security to be kept in the SAS data set,	LIBNAME *libref* SASECRSP	HCUSIP=
specify the TICKER of a security to be kept in the SAS data set,	LIBNAME *libref* SASECRSP	TICKER=
specify the SICCD of a security to be kept in the SAS data set,	LIBNAME *libref* SASECRSP	SICCD=
specify the range of data in format YYYYMMDD using the *crsp_begdt* and *crsp_enddt*.	LIBNAME *libref* SASECRSP	RANGE=
use a SAS data set named *setname* as input for issues.	LIBNAME *libref* SASECRSP	INSET=

The LIBNAME *libref* SASECRSP Statement

LIBNAME *libref* **SASECRSP** **'***physical name***'** *options;*

The CRSP environment variable CRSPDB_SASCAL must be defined to allow the SASECRSP engine access to the CRSPAccess database calendars. Often your CRSPDB_SASCAL will be pointing to the same path as your *physical name*. You must use a fully qualified pathname. Your *physical name* must end with either a forward slash if you are on a UNIX system, or a backward slash if you are on WINNT.

For a more complete description of SASECRSP set names, key fields, and date fields, see Table 5.1.

The following options can be used in the LIBNAME *libref* SASECRSP statement:

SETID=*crsp_setidnumber*

specifies the CRSP set ID number where 10 is the daily data set ID and 20 is the monthly data set ID number. Two possible values for *crsp_setidnumber* are 10 or 20. The SETID limits the frequency selection of time series that are included in the SAS data set. SETID is a required option for the SASECRSP engine. Depending on your host system, both should end in either a forward slash (UNIX) or a backward slash (WINNT). For more details about the CRSPAccess *crsp_setidnumber*, refer to

“Using Multiple Products” in the *CRSPAccess Database Format Installation Guide*. As an example, to access monthly data, you would use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
   SETID=20;
```

PERMNO=*crsp_permnumber*
By default, the SASECRSP engine reads all PERMNOs in the CRSPAccess database that you name in your SASECRSP *libref*. You can limit the time series read from the CRSP database by specifying the PERMNO= option on your LIBNAME statement. From a performance standpoint, the PERMNO= option does random access and reads only the data for the PERMNOs listed. You can also subset using random access based on the secondary keys, PERMCO= option to read selected securities based on the PERMCOs listed, CUSIP= option to read selected securities based on the the CUSIPs listed, HCUSIP= option to read selected securities based on the HCUSIPs listed, SICCD= option to read selected securities based on the SICCDs listed, and TICKER= option to read selected securities based on the TICKERs listed. There is no limit to the number of *crsp_permnumber* options that you can use. As an example, to access monthly data for Microsoft Corporation and for International Business Machine Corporation, you could use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
   SETID=20
   PERMNO=10107
   PERMNO=12490;
```

In like manner, secondary keys PERMCO, CUSIP, HCUSIP, SICCD and TICKER may be used instead of PERMNO= option.

PERMCO=*crsp_permcompany*
There is no limit to the number of *crsp_permcompany* options that you can use.

CUSIP=*crsp_cusip*
There is no limit to the number of *crsp_cusip* options that you can use.

HCUSIP=*crsp_hcusip*
There is no limit to the number of *crsp_hcusip* options that you can use.

TICKER=*crsp_ticker*
There is no limit to the number of *crsp_ticker* options that you can use.

SICCD=*crsp_siccd*
There is no limit to the number of *crsp_siccd* options that you can use.

RANGE=*'crsp_begdt-crsp_enddt'*
To limit the time range of data read from the CRSPAccess database, specify the RANGE= option in your SASECRSP *libref*, where *crsp_begdt* is the beginning date in YYYYMMDD format and *crsp_enddt* is the ending date of the range in YYYYMMDD format. From a performance standpoint, the engine reads all the data for a company and then restricts the data range before passing it back.

As an example, to access monthly data for Microsoft Corporation and for International Business Machine Corporation for the first quarter of 2000, you could use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
   SETID=20
   PERMNO=10107
   PERMNO=12490
   RANGE='19990101-19990331';
```

INSET=*'setname[,keyfieldname][,keyfieldtype][,date1field][,date2field]'*

When you specify a SAS data set named *setname* as input for issues, the SASECRSP engine assumes a default PERMNO field containing selected CRSP PERMNOs is present in the data set. If optional parameters are included, the first one is the CRSPAccess supported key name, and the second is the key type. Version 9 supports the PERMNO key field on the INSET option, the PERMCO key field on the INSET option, the CUSIP key field on the INSET option, the HCUSIP key field on the INSET option, the SICCD key field on the INSET option, or the TICKER key field on the INSET option. The third optional parameter is the beginning date or event date, and the fourth is the ending date in YYYYMMDD format. For more details about the CRSPAccess keyfields and keyfieldtypes, refer to "Stock and Indices Data Structures" in the *CRSP Data Description Guide*.

The following example might be used to extract the data for a portfolio of four companies to access monthly data where the range of dates is left open:

```
data testin1;
   permno = 10107; output;
   permno = 12490; output;
   permno = 14322; output;
   permno = 25788; output;
run;

LIBNAME mstk sasecrsp 'physical-name'
   SETID=20
   INSET='testin1';

data a;
   set mstk.prc;
run;

proc print data=a;
run;
```

Suppose you want to restrict the dates for each PERMNO specifically. The example below shows how to specify the INSET= option with the *'setname[,keyfieldname][,keyfieldtype][,date1field][,date2field]'* parameters:

```
data testin2;
   permno = 10107; date1 = 19990101; date2 = 19991231; output;
   permno = 12490; date1 = 19970101; date2 = 19971231; output;
   permno = 14322; date1 = 19990901; date2 = 19991231; output;
   permno = 25788; date1 = 19950101; date2 = 19950331; output;
run;

LIBNAME mstk2 sasecrsp 'physical-name'
   SETID=20
   INSET='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
   set mstk2.prc;
run;

proc print data=b;
run;
```

Details

The SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP data to a SAS data set. This enables the user to easily analyze the data using SAS. The name of the output data set is specified by you on the DATA statement. This causes the engine supervisor to create a SAS data set using the specified name in either the SAS WORK library or, if specified, the USER library.

The contents of the SAS data set include the DATE of each observation, the series names of each series read from the CRSPAccess database, event variables, and the label or description of each series/event.

Available Data Sets

Table 5.1 shows the available data sets provided by the SASECRSP interface. Missing values are represented as '.' in the SAS data set. You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASECRSP libref in the LIBNAME window that you have previously used in your libname statement. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can view your SAS output observations by double clicking on the desired output data set libref in the libname window of the SAS windowing environment. You can use PROC SQL along with the SASECRSP engine to create a view of your SAS data set.

Understanding CRSP Date Formats, Informats, and Functions

CRSP has historically used two different methods to represent dates, while SAS has used a third. The three formats are SAS Dates, CRSP Dates, and Integer Dates. The SASECRSP engine provides 22 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. A SASECRSP libname assign must be active to use these date access methods. See Example 5.5, "Converting Dates Using the CRSP Date Functions."

SAS dates are internally stored as the number of days since January 1, 1960. The SAS method is an industry standard and provides a great deal of flexibility, including a wide variety of informats, formats, and functions.

CRSP dates are designed to ease time series storage and access. Internally the dates are stored as an offset into an array of trading days. Note that there are five different CRSP trading day calendars: Annual, Quarterly, Monthly, Weekly, and Daily. The CRSP method provides fewer missing values and makes trading period calculations very easy. However, there are also many valid calendar dates that are not available in the CRSP trading calendars, and care must be taken when using other dates.

Integer dates are a way to represent dates that are platform independent and maintain the correct sort order. However, the distance between dates is not maintained.

The best way to illustrate these formats is with some sample data. The table below only shows CRSP Daily and Monthly dates.

Table 5.2. Date Representations for Daily and Monthly Data

Date	SAS Date	CRSP Date (Daily)	CRSP Date (Monthly)	Integer Date
July 31, 1962	942	21	440	19620731
August 31, 1962	973	44	441	19620831
December 30, 1998	14,243	9190	NA*	19981230
December 31, 1998	14,244	9191	877	19981231

* Not available if an exact match is requested.

Having an understanding of the internal differences in representing SAS dates, CRSP dates, and CRSP integer dates will help you use the SASECRSP formats, informats, and functions effectively. Always keep in mind the frequency of the CRSP calendar that you are accessing when you specify a CRSP date.

The CRSP Date Formats

There are two types of formats for CRSP dates, and five frequencies are available for each of the two types. The two types are exact dates (CRSPDT*) and range dates (CRSPDR*), where * can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The ten formats are: CRSPDTA, CRSPDTQ, CRSPDTM, CRSPDTW, CRSPDTD, CRSPDRA, CRSPDRQ, CRSPDRM, CRSPDRW, and CRSPDRD.

Here are some samples using the monthly and daily calendar as examples. The Annual (CRSPDTA and CRSPDRA), Quarterly (CRSPDTQ and CRSPDRQ), and the Weekly (CRSPDTW and CRSPDRW) work analogously.

Table 5.3. Sample CRSPDT Formats for Daily and Monthly Data

Date	CRSP Date Daily , Monthly	CRSPDTD8. Daily Date	CRSPDRD8. Daily Range	CRSPDTM8. Monthly Date	CRSPDRM8. Monthly Range
July 31,1962	21 , 440	19620731	19620731 +	19620731	19620630-19620731
August31,1962	44 , 441	19620831	19620831 +	19620831	19620801-19620831
December30, 1998	9190 , NA *	19981230	19981230 +	NA*	NA*
December31, 1998	9191 , 877	19981231	19981231 +	19981231	19981201-19981231

+ Daily ranges will look similar to Monthly Ranges if they are Mondays or immediately following a trading holiday.
* When working with exact matches, no CRSP monthly date exists for December 30, 1998.

The @CRSP Date Informats

There are three types of informats for CRSP dates, and five frequencies are available for each of the three types. The three types are exact (@CRSPDT*), range (@CRSPDR*), and backward (@CRSPDB*) dates, where * can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The fifteen formats are: @CRSPDTA, @CRSPDTQ, @CRSPDTM, @CRSPDTW, @CRSPDTD, @CRSPDRA, @CRSPDRQ, @CRSPDRM, @CRSPDRW, @CRSPDRD, @CRSPDBA, @CRSPDBQ, @CRSPDBM, @CRSPDBW, and @CRSPDBD.

The five CRSPDT* informats find exact matches only. The five CRSPDR* informats look for an exact match, and if it is not found it goes forward, matching the CRSPDR* formats. The five CRSPDB* informats look for an exact match, and if it is not found it goes backward. Here is a sample using only the CRSP monthly calendar as an example, but the daily, weekly, quarterly, and annual frequencies work analogously.

Table 5.4. Sample @CRSP Date Informats Using Monthly Data

Input Date (Integer Date)	CRSP Date CRSPDTM	CRSP Date CRSPDRM	CRSP Date CRSPDBM	CRSPDTM8. Monthly Date	CRSPDRM8. Monthly Range
19620731	440	440	440	19620731	19620630-19620731
19620815	.(missing)	441	440	See below+	See below*
19620831	441	441	441	19620831	19620801-19620831

+ If missing, then missing. If 441, then 19620831. If 440, then 19620731.
* If missing, then missing. If 441, then 19620801-19620831. If 440, then 19620630-19620731.

The CRSP Date Functions

There are 22 date functions provided with the SASECRSP engine. These functions are used internally by the engine, but also are available to the end users. There are six groups of functions. The first four have five functions each, one for each CRSP calendar frequency.

Table 5.5. CRSP Date Functions

Function Group	Function Name	Argument One	Argument Two	Return Value
CRSP dates to Integer dates for December 31, 1998				
Annual	crspdcia	74	None	19981231

Examples

Example 5.1. Extracting a List of PERMNOs Using a RANGE

This example specifies a list of PERMNOs that are desired from the monthly set of CRSPAccess data. Suppose you want the range of data starting January 1, 1995, and ending June 30, 1996.

```
title2 'Define a range inside the data range ';
title3 'Valid trading dates (19890131--19981231)';
title4 'My range is ( 19950101-19960630 )';

libname testit1 sasecrsp '/mydata/crspeng/m_sampdata/'
   setid=20
   permno=81871
   permno=82200
   permno=82224
   permno=83435
   permno=83696
   permno=83776
   permno=84788
   range='19950101-19960630';

data a;
   set testit1.ask;
run;

proc print data=a;
run;
```

Output 5.1.1. Printout of the ASK Monthly Time Series Data with RANGE

```
                                The SAS System                                 1
                       Define a range inside the data range
                      Valid trading dates (19890131--19981231)
                         My range is ( 19950101-19960630 )

                   36       83435    19960628       21.00000
                   37       83696    19960628       19.12500
```

Example 5.2. Extracting All PERMNOs Using a RANGE

If you want all PERMNOs extracted for the ASK time series from the monthly data set, then you would not specify the PERMNO= option.

```
title2 'Define a range inside the data range ';
title3 'Valid trading dates (19890131--19981231)';
title4 'My range is ( 19950101-19950228 )';

libname testit2 sasecrsp '/mydata/crspeng/m_sampdata/'
   setid=20
   range='19950101-19950228';

data b;
   set testit2.ask;
run;

proc print data=b;
run;
```

Output 5.2.1. Printout of All PERMNOs of ASK Monthly with RANGE

```
                              The SAS System                             1
                 Define a range inside the data range
                Valid trading dates (19890131--19981231)
                   My range is ( 19950101-19950228 )

                  Obs      PERMNO    CALDT               ASK

Example 5.3. Extracting One PERMNO Using No RANGE, Wide Open

If you want the entire range of available data for one particular PERMNO extracted from the monthly data set, then you would not specify the RANGE= option.

```
title2 'Select only PERMNO = 81871';
title3 'Valid trading dates (19890131--19981231)';
title4 'No range option, leave wide open';

libname testit3 sasecrsp '/mydata/crspeng/m_sampdata/'
   setid=20
   permno=81871;

data c;
   set testit3.ask;
run;

proc print data=c;
run;
```

Output 5.3.1. Printout of PERMNO = 81871 of ASK Monthly without RANGE

```
                              The SAS System                              1
                        Select only PERMNO = 81871
                  Valid trading dates (19890131--19981231)
                      No range option, leave wide open

Example 5.4. Extracting Selected PERMNOs in Range Using INSET= Option

You can select the PERMNOs you want to extract and specify the range of data to extract by defining an INSET such as testin2.

```
title2 'INSET=testin2 uses date ranges along with PERMNOs:';
title3 '10107, 12490, 14322, 25788';
title4 'Begin dates and end dates for each permno are used in the INSET';

data testin2;
   permno = 10107; date1 = 19980731; date2 = 19981231; output;
   permno = 12490; date1 = 19970101; date2 = 19971231; output;
   permno = 14322; date1 = 19950731; date2 = 19960131; output;
   permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname mstk2 sasecrsp '/mydata/crspeng/m_sampdata/' setid=20
   inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
   set mstk2.prc;
run;

proc print data=b;
run;
```

Output 5.4.1. Printout of PRC Monthly Time Series Using INSET= Option

```
                                The SAS System                              1
          Second INSET=testin2 uses date ranges along with PERMNOs:
                          10107, 12490, 14322, 25788
       Begin dates and end dates for each permno are used in the INSET

                     19       14322    19950731        32.62500
                     20       14322    19950831        32.37500
                     21       14322    19950929        36.87500
                     22       14322    19951031        34.00000
                     23       14322    19951130        39.37500
                     24       14322    19951229        39.00000
                     25       14322    19960131        41.50000
                     26       25778    19950131        49.87500
                     27       25778    19950228        57.25000
                     28       25778    19950331        59.37500
```

If you prefer, you can use PERMCO, or CUSIP, or HCUSIP, or TICKER in your inset= option instead of PERMNO to subset if you have them defined in your inset data set.

Example 5.5. Converting Dates Using the CRSP Date Functions

This example shows how to use the CRSP date functions and formats. The CRSPDTD formats are used for all the crspdt variables, while the YYMMDD format is used for the sasdt variables.

```
title2 'OUT= Data Set';
title3 'CRSP Functions for sasecrsp';
title4 'Always assign the libname sasecrsp first';

libname mstk sasecrsp '/mydata/crspeng/m_sampdata/' setid=20;

data a (keep = crspdt crspdt2 crspdt3
               sasdt sasdt2 sasdt3
               intdt intdt2 intdt3);
   format crspdt crspdt2 crspdt3 crspdtd8.;
   format sasdt sasdt2 sasdt3 yymmdd6.;
   format intdt intdt2 intdt3 8.;
   format exact 2.;
   crspdt = 1;
   sasdt = '2jul1962'd;
   intdt = 19620702;
   exact = 0;

/* Call the CRSP date to Integer function*/
   intdt2 = crspdcid(crspdt);

/* Call the SAS date to Integer function*/
   intdt3 = crspds2i(sasdt);

/* Call the Integer to Crsp date function*/
   crspdt2 = crspdicd(intdt,exact);

/* Call the Sas date to Crsp date conversion function*/
   crspdt3 = crspdscd(sasdt,exact);

/* Call the CRSP date to SAS date conversion function*/
   sasdt2 = crspdcsd(crspdt);

/* Call the Integer to Sas date conversion function*/
   sasdt3 = crspdi2s(intdt);
   run;

proc print;
   run;

title2 'Proc CONTENTS showing formats for sasecrsp';
proc contents data=a;
   run;
```

Output 5.5.1. Printout of Date Conversions Using the CRSP Date Functions

```
                                The SAS System                                 1
                                OUT= Data Set

Acknowledgments

Many people have been instrumental in the development of the ETS Interface engine. The individuals listed here have been especially helpful.

Bob Spatz, Center for Research in Security Prices, University of Chicago Graduate School of Business.

Ken Kraus, Center for Research in Security Prices, University of Chicago Graduate School of Business.

Rick Langston, SAS Institute, Cary, NC.

Peng Zang, University of Illinois, Urbana, IL.

Stephen Caudle, Rose-Hulman Institute of Technology, Terre Haute, IN.

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Chapter 6
The SASEFAME Interface Engine

Chapter Contents

Chapter 6
The SASEFAME Interface Engine

Overview

The SASEFAME interface engine enables SAS users to access and process time series data residing in a FAME database, and provides a seamless interface between FAME and SAS data processing.

The SASEFAME engine uses the LIBNAME statement to enable you to specify which time series you would like to read from the FAME database, and how you would like to convert the selected time series to the same time scale. The SAS DATA step can then be used to perform further subsetting and to store the resulting time series into a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time.

SASEFAME for Release 8.2 supports Windows, Solaris2, AIX, and HP-UX hosts.

SASEFAME for Version 9 supports Windows, Solaris 8, AIX, LINUX and DEC/OSF Digital UNIX.

Getting Started

Structure of a SAS Data Set Containing Time Series Data

SAS requires time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEFAME engine provides a time ID variable named DATE.

Reading and Converting FAME Database Time Series

The SASEFAME engine supports reading and converting time series stored in FAME databases. The SASEFAME engine uses the FAME WORK database to temporarily store the converted time series. All series specified by the FAME wildcard are written to the FAME WORK database. For conversion of very large databases, you may want to define the FAME_TEMP environment variable to point to a location where there is ample space for FAME WORK. The FAME CHLI does not support writing more than 2 gigabytes to the FAME WORK area, and when this happens SASEFAME will terminate with a system error.

Using the SAS DATA Step

If desired, you can store the converted series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. Once your data is stored in a SAS data set you can use it as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure and report information concerning the contents of your data set by using the CONTENTS procedure, as in Example 6.1. You can create a view of the FAME database by using the SQL procedure to create your view using the SASEFAME engine in your *libref*, along with the using clause. See Example 6.5.

Using Remote FAME Data Access

There are two ways to access your remote FAME databases. The first way is to use your SAS/CONNECT capability to submit a remote SAS session to your FAME server, and then use PROC DOWNLOAD to bring your results back to your SAS client. See Example 6.6. Refer to *Communications Access Methods for SAS/CONNECT and SAS/SHARE Software*.

The second way is an experimental feature of the SASEFAME interface that uses the FAME CHLI to communicate with your remote FAME server by giving the frdb_m port number and node name of your FAME master server in your *libref*. See Example 6.7. Refer to “Starting the Master Server” in the *Guide to FAME Database Servers*.

Syntax

The SASEFAME engine uses standard engine syntax. Options used by SASEFAME are summarized in the table below.

Description	**Statement**	**Option**
specifies the FAME frequency and the FAME technique.	LIBNAME *libref* SASEFAME	CONVERT=
specifies a FAME wildcard to match data object series names within the FAME database, which limits the selection of time series that are included in the SAS data set.	LIBNAME *libref* SASEFAME	WILDCARD=

The LIBNAME *libref* SASEFAME Statement

LIBNAME *libref* **SASEFAME ’physical name’** *options;*

Since *physical name* specifies the location of the folder where your FAME database resides, it should end in a backslash if you are on a Windows platform, or a forward slash if you are on a UNIX platform.

If you are accessing a remote FAME database using FAME CHLI, you can use the following syntax for *physical name*:
’**#port number\@hostname physical path name**’

The following options can be used in the LIBNAME libref SASEFAME statement:

CONVERT=*(FREQ=fame_frequency TECH= fame_technique)*

specifies the FAME frequency and the FAME technique just as you would in the FAME CONVERT function. There are four possible values for *fame_technique*: CONSTANT (default), CUBIC, DISCRETE, or LINEAR. All FAME frequencies except PPY and YPP are supported by the SASEFAME engine. For a more complete discussion of FAME frequencies and SAS time intervals see the section “Mapping FAME Frequencies to SAS Time Intervals” on page 190. For all possible *fame_frequency* values, refer to “Understanding Frequencies” in the *User’s Guide to FAME*. As an example,

```
LIBNAME libref sasefame ’physical-name’
   CONVERT=(TECH=CONSTANT FREQ=TWICEMONTHLY);
```

WILDCARD=*"fame_wildcard"*

By default, the SASEFAME engine reads all time series in the FAME database that you name in your SASEFAME libref. You can limit the time series read from the FAME database by specifying the WILDCARD= option on your LIBNAME statement. The *fame_wildcard* is a quoted string containing the FAME wildcard you wish to use. The wildcard is used against the data object names (time series only) in the FAME database that resides in the library you are in the process of assigning. For more information about wildcarding, see “Specifying Wildcards” in the *User’s Guide to FAME*.

For example, to read all time series in the TEST library being accessed by the SASEFAME engine, you would specify

```
LIBNAME test sasefame ’physical name of test database’
   WILDCARD="?";
```

To read series with names such as A_DATA, B_DATA, C_DATA, you could specify

```
LIBNAME test sasefame ’physical name of test database’
   WILDCARD="^_DATA";
```

When you use the WILD= option, you are limiting the number of time series that are read and converted to the desired frequency. This option can help you save resources when processing large databases or when processing a large number of observations, such as daily, hourly, or minutely frequencies. Since the SASEFAME engine uses the FAME WORK database to store the converted time series, using wildcards is recommended to prevent your WORK space from getting too large.

Details

The SAS Output Data Set

You can use the SAS DATA step to write the FAME converted series to a SAS data set. This allows the user the ability to easily analyze the data using SAS. You can specify the name of the output data set on the DATA statement. This causes the engine supervisor to create a SAS data set using the specified name in either the SAS WORK library, or if specified, the USER library. For more about naming your SAS data set see the section “Characteristics of SAS Data Libraries” in *SAS Language Reference: Dictionary*.

The contents of the SAS data set include the DATE of each observation, the name of each series read from the FAME database as specified by the WILDCARD option, and the label or FAME description of each series. Missing values are represented as ’.’ in the SAS data set. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL along with the SASEFAME engine to create a view of your SAS data set.

The DATE variable in the SAS data set contains the date of the observation. For FAME weekly intervals that end on a Friday, FAME reports the date on the Friday that ends the week whereas SAS reports the date on the Saturday that begins the week. A more detailed discussion of how to map FAME frequencies to SAS Time Intervals follows.

Mapping FAME Frequencies to SAS Time Intervals

The following table summarizes the mapping of FAME frequencies to SAS time intervals. It is important to note that FAME frequencies often have a sample unit in parentheses following the keyword frequency. This sample unit is an end-of-interval unit. SAS dates are represented using begin-of-interval notation. For more on SAS time intervals, see “Date Intervals, Formats, and Functions” in *SAS/ETS User’s Guide*. For more on FAME frequencies, see the section “Understanding Frequencies” in the *User’s Guide to FAME*.

FAME FREQUENCY	SAS TIME INTERVAL

MONTHLY	MONTH

Examples

Example 6.1. Converting an Entire FAME Database

To enable conversion of all Time Series no wildcard is specified, so the default “?” wildcard is used. Always consider both the number of time series and the number of observations generated by the conversion process. The converted series are stored in the FAME WORK database during the SAS DATA step. You may further limit your resulting SAS data set by using KEEP, DROP, or WHERE statements inside your data step.

The following statements convert a FAME database and print out its contents:

```
libname famedir sasefame '.'
                convert=(freq=annual technique=constant);

libname mydir '/mine/data/europe/sas/oecdir';

data mydir.a;  /* add data set to mydir */
   set famedir.oecd1;
   /* do nothing special */
   run;

proc print data=mydir.a; run;
```

In the above example, the FAME database is called oecd1.db and it resides in the famedir directory. The DATA statement names the SAS output data set ’a’ which will reside in mydir. All time series in the FAME oecd1.db database will be converted to an annual frequency and stored in the mydir.a SAS data set. The PROC PRINT statement creates a listing of all of the observations in the mydir.a SAS data set.

Example 6.2. Reading Time Series from the FAME Database

Use the FAME wildcard option to limit the number of series converted. For example, suppose you want to read only series starting with “WSPCA”. You could use the following code:

```
libname lib1 sasefame '/mine/data/econ_fame/sampdir'
             wildcard="wspca?"
             convert=(technique=constant freq=twicemonthly );

libname lib2 '/mine/data/econ_sas/sampdir';

data lib2.twild(label='Annual Series from the FAMEECON.db');
   set lib1.subecon;
   /* keep only  */
   keep date wspca;
   run;

proc contents data=lib2.twild; run;

proc print data=lib2.twild; run;
```

The wildcard=“wspca?” option limits reading only those series whose names begin with WSPCA. The SAS KEEP statement further restricts the SAS data set to include only the series named WSPCA and the DATE variable. The time interval used for the conversion is TWICEMONTHLY.

Example 6.3. Writing Time Series to the SAS Data Set

You can use the KEEP or DROP statement to include or exclude certain series names from the SAS data set.

```
libname famedir sasefame '.'
        convert=(freq=annual technique=constant);

libname mydir '/mine/data/europe/sas/oecdir';

data mydir.a;  /* add data set to mydir */
   set famedir.oecd1;
   drop ita_dird--jpn_herd tur_dird--usa_herd;
   run;

proc print data=mydir.a; run;
```

You can rename your SAS variables by using the RENAME statement.

```
option validvarname=any;

libname famedir sasefame '.'
```

```
        convert=(freq=annual technique=constant);

libname mydir '/mine/data/europe/sas/oecdir';

data mydir.a;  /* add data set to mydir */
   set famedir.oecd1;
   /* keep and rename  */
   keep date ita_dird--jpn_herd tur_dird--usa_herd;
   rename ita_dird='Italy.dirdes'n
          jpn_dird='Japan.dirdes'n
          tur_dird='Turkey.dirdes'n
          usa_dird='UnitedStates.dirdes'n ;
   run;

proc print data=mydir.a; run;
```

Example 6.4. Limiting the Time Range of Data

You may also limit the time range of the data in the SAS data set by using the WHERE statement in the data step to process the time ID variable DATE only when it falls in the range you are interested in.

```
libname famedir SASEFAME '.'
        convert=(freq=annual technique=constant);

libname mydir '/mine/data/europe/sas/oecdir';

data mydir.a;  /* add data set to mydir */
   set famedir.oecd1;
   /* where only  */
   where date between '01jan88'd and '31dec90'd;
   run;

proc print data=mydir.a; run;
```

All data for 1988, 1989, and 1990 are included in the SAS data set. See the *SAS Language: Reference, Version 7* for more information on KEEP, DROP, RENAME and WHERE statements.

Example 6.5. Creating a View Using the SQL Procedure and SASEFAME

This example creates a view using the SQL procedure's from and using clauses. See *SQL Procedure Guide, Version 7* for details on SQL views.

```
title1 'famesql5: PROC SQL Dual Embedded Libraries w/ FAME option';

proc print data=fameview;
run;
```

Note that the SAS option VALIDVARNAME=ANY was used at the top of this example due to special characters being present in the time series names. The output from this example shows how each FAME view is the output of the SASEFAME engine's processing. Note that different engine options could have been used in the USING LIBNAME clause if desired.

Output 6.5.4. Printout of the FAME View of DRI Basic Economic Data

```
          PROC SQL Dual Embedded Librarys w/ FAME option
     DRIECON: Print of View from Embedded Library with Option

Example 6.6. Remote FAME Access, using SAS CONNECT

Suppose you are running SAS in a client/server environment and have SAS/CONNECT capability allowing you access to your FAME server. You could access your FAME remote data by signing on to your Fame server from your client session and doing a remote submit to access your Fame data. You could then use PROC DOWNLOAD to bring your remote data into the local client SAS session.

```
options validvarname=any;

%let remnode=mysunbox.unx.sas.com;
signon remnode.shr2;  /* name the sastcpd service for the connection */
rsubmit;

%let FAME=%sysget(FAME);
%put(&FAME);

options validvarname=any;
libname lib1 sasefame "/usr/local/famelib/util"
             convert=(frequency=annual technique=constant)
             wildcard="?";

data oecd1;
   set lib1.oecd1;
run;

title2 'OECD1: PRINT Procedure';
proc print data=oecd1(obs=10);
run;

title2 'OECD1: CONTENTS Procedure';
proc contents data=oecd1;
run;

proc sort data=oecd1;
   by date;
run;

title2 'OECD1: MEANS Procedure';
proc means data=oecd1 sum;
   by date;
   var 'fin.herd'n;
run;

proc download inlib=work  /* remote SASWORK */
   outlib=work;  /* local SASWORK */
run;

proc datasets lib=work;
   contents data=_ALL_;
run;
```

```
endrsubmit;
signoff;

proc datasets lib=work;  /* NOW the local work has the fame data */
   contents data=_ALL_;
run;
```

Output 6.6.1. Printout of the SAS/CONNECT Remote Access to FAME Data

```
          ***fameproc: Using FAME with a multitude of SAS Procs***

Example 6.7. Remote FAME Access, using FAME CHLI

Suppose you are running FAME in a client/server environment and have FAME CHLI capability allowing you access to your FAME server. You could access your FAME remote data by specifying the port number of the tcpip service that is defined for your frdb_m and the node name of your FAME master server in your physical path. In the example below, the FAME server node name is booker, and the port number is 5555, which was designated in the FAME master command. Refer to "Starting the Master Server" in the *Guide to FAME Database Servers* for more about starting your FAME master server.

```
 /* DRIECON Database, Using FAME with REMOTE ACCESS VIA CHLI */
 /**********************************************************/

libname test1 sasefame '#5555\@booker \$FAME/util';
data a;
   set test1.driecon;
   run;

proc contents data=a;
   run;
proc means data=a n;
   run;
```

Output 6.7.1. Printout of the FAME CHLI Remote Access to FAME Data

```

Acknowledgments

Many people have been instrumental in the development of the ETS Interface engine. The individuals listed here have been especially helpful.

Jeff Kaplan, FAME Information Services, Ann Arbor, MI.

Rick Langston, SAS Institute, Cary, NC.

The final responsibility for the SAS System lies with SAS Institute alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Chapter 7
The SASEHAVR Interface Engine (Experimental)

Chapter Contents

Chapter 7
The SASEHAVR Interface Engine (Experimental)

Overview

The SASEHAVR interface engine, experimental in Version 9, enables SAS users to read economic and financial time series data residing in a Haver Analytics Data Link Express database, and provides a seamless interface between Haver and SAS data processing.

The SASEHAVR engine uses the LIBNAME statement to enable you to specify how you would like to convert the selected time series to the same time scale. The SAS DATA step can then be used to perform further subsetting and to store the resulting time series into a SAS data set. You can perform more analysis if desired either in the same SAS session or in another session at a later time.

Getting Started

Structure of a SAS Data Set Containing Time Series Data

SAS requires time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEHAVR engine provides a time ID variable called DATE.

Reading and Converting Haver DLX Time Series

The SASEHAVR engine supports reading and converting time series stored in Haver DLX databases. The SASEHAVR engine enables you to limit the range of data with the START= and END= libname options.

Using the SAS DATA Step

If desired, you can store the converted series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. Once your data is stored in a SAS data set you can use it as you would any other SAS data set.

Syntax

The SASEHAVR engine uses standard engine syntax. Options used by SASEHAVR are summarized in the table below.

Description	**Statement**	**Option**
specifies the Haver frequency.	LIBNAME *libref* SASEHAVR	FREQ=
specifies a Haver start date to limit the selection of time series that begins with the specified date.	LIBNAME *libref* SASEHAVR	START=
specifies a Haver end date to limit the selection of time series that ends with the specified date.	LIBNAME *libref* SASEHAVR	END=
specifies a list of comma delimited Haver variables to keep in the generated SAS data set.	LIBNAME *libref* SASEHAVR	KEEP=
specifies a list of comma delimited Haver variables to drop in the generated SAS data set.	LIBNAME *libref* SASEHAVR	DROP=
specifies a list of comma delimited Haver groups to keep in the generated SAS data set.	LIBNAME *libref* SASEHAVR	GROUP=
specifies a list of comma delimited Haver groups to drop in the generated SAS data set.	LIBNAME *libref* SASEHAVR	DROPGROUP=
specifies a list of comma delimited Haver sources to keep in the generated SAS data set.	LIBNAME *libref* SASEHAVR	SOURCE=
specifies a list of comma delimited Haver sources to drop in the generated SAS data set.	LIBNAME *libref* SASEHAVR	DROPSOURCE=
specifies that all selected variables should be aggregated to the frequency specified in the FREQ= option. This option is ignored if it is specified without the FREQ= option.	LIBNAME *libref* SASEHAVR	FORCE=FREQ

The LIBNAME *libref* SASEHAVR Statement

LIBNAME *libref* **sasehavr ’physical name’** *options;*

The following options can be used in the LIBNAME libref SASEHAVR statement:

FREQ=*haver_frequency*
specifies the Haver frequency. All Haver frequencies are supported by the SASEHAVR engine.

START=*start_date*
specifies the start date for the time series in the form YYYYMMDD.

END=*end_date*
specifies the end date for the time series in the form YYYYMMDD.

KEEP=*haver_variables*
specifies the list of Haver variables to be included in the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

DROP=*haver_variables*
specifies the list of Haver variables to be excluded from the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

GROUP=*haver_variables*
specifies the list of Haver groups to be included in the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

DROPGROUP=*haver_groups*
specifies the list of Haver groups to be excluded from the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

SOURCE=*haver_sources*
specifies the list of Haver sources to be included in the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

DROPSOURCE=*haver_sources*
specifies the list of Haver sources to be excluded from the generated SAS data set. this list is comma delimited and must be surrounded by quotes “”.

FORCE=FREQ
specifies that the selected variables are to be aggregated to the frequency in the FREQ= option. This option is ignored if the FREQ= option is not set.

For a more complete discussion of Haver frequencies and SAS time intervals see the section “Mapping Haver Frequencies to SAS Time Intervals” on page 223. As an example,

```
LIBNAME libref sasehavr 'physical-name'
   FREQ=MONTHLY);
```

By default, the SASEHAVR engine reads all time series in the Haver database that you reference when using your SASEHAVR libref. The *haver_startdate* is specified in the form YYYYMMDD. The start date is used to delimit the data to a specified start date.

For example, to read the time series in the TEST library starting on July 4, 1996, you would specify

```
LIBNAME test sasehavr 'physical-name'
   STARTDATE=19960704;
```

When you use the START= option, you are limiting the range of data that is read from the time series and that are converted to the desired frequency. Start dates are recommended to help you save resources when processing large databases or when processing a large number of observations. It is also possible to select specific variables to be included or excluded from the SAS data set by using the KEEP= and DROP= options.

```
LIBNAME test sasehavr 'physical-name'
   KEEP="ABC*, XYZ??";

LIBNAME test sasehavr 'physical-name'
   DROP="*SC*, #T#";
```

When the KEEP= and DROP= options are used the SAS data set that gets generated will keep or drop the variables that you select in the options. There are three wildcards currently available: '*', '?' and '#'. The '*' wildcard corresponds to any string that includes everthing in that position. The '?' means that any single alpha-numeric character is valid. And finally, the '#' wildcard corresponds to a single numeric character. You can further delimit your data by using the GROUP= and SOURCE= options and their corresponding DROPGROUP= and DROPSOURCE= options.

```
LIBNAME test sasehavr 'physical-name'
   GROUP="CBA, *ZYX";

LIBNAME test sasehavr 'physical-name'
   DROPGROUP="TKN*, XCZ?";

LIBNAME test sasehavr 'physical-name'
   SOURCE="FRB";

LIBNAME test sasehavr 'physical-name'
   DROPSOURCE="NYSE";
```

By default, SASEHAVR selects only the variables that are of the specified frequency in the FREQ= option. If this option is ignored, SASEHAVR selects the variables that match the frequency of the first selected variable. If it is desired to have all variables to be selected to have the same frequency, the FORCE=FREQ option can be specified to force the aggregation of all variables selected to be of the given frequency specified by the FREQ= option. This option is ignored if the FREQ= option is not given.

Details

The SAS Output Data Set

You can use the SAS DATA step to write the Haver converted series to a SAS data set. This allows the user the ability to easily analyze the data using SAS. You can specify the name of the output data set on the DATA statement. This causes the engine supervisor to create a SAS data set using the specified name in either the SAS WORK library, or if specified, the USER library. For more about naming your SAS data set see the section “Characteristics of SAS Data Libraries” in *SAS Language Reference: Dictionary*.

The contents of the SAS data set include the DATE of each observation, the name of each series read from the Haver database, and the label or Haver description of each series. Missing values are represented as ’.’ in the SAS data set. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL along with the SASEHAVR engine to create a view of your SAS data set.

The DATE variable in the SAS data set contains the date of the observation. The SASEHAVR engine internally maps the Haver intervals to the appropriate corresponding SAS interval.

A more detailed discussion of how to map Haver frequencies to SAS Time Intervals follows.

Mapping Haver Frequencies to SAS Time Intervals

The following table summarizes the mapping of Haver frequencies to SAS time intervals. For more information refer to “Date Intervals, Formats, and Functions” in *SAS/ETS User’s Guide*.

HAVER FREQUENCY	**SAS TIME INTERVAL**
ANNUAL	YEAR
QUARTERLY	QTR
MONTHLY	MONTH
WEEKLY (SUNDAY)	WEEK.1
WEEKLY (MONDAY)	WEEK.2
WEEKLY (TUESDAY)	WEEK.3
WEEKLY (WEDNESDAY)	WEEK.4
WEEKLY (THURSDAY)	WEEK.5
WEEKLY (FRIDAY)	WEEK.6
WEEKLY (SATURDAY)	WEEK.7
DAILY	WEEKDAY

Examples

Example 7.1. Examining the Contents of a Haver Database

To see which time series are in your HAVER database, use PROC CONTENTS with the SASEHAVR libname statement to read the contents.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=yearly start=19860101 end=19991231 force=freq;

data hwouty;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, HAVERW.DAT';
title2 'PROC CONTENTS for Time Series converted to yearly frequency';

proc contents
   data=hwouty;
run;
```

In the above example, the Haver database is called haverw and it resides in the directory referenced in lib1. The DATA statement names the SAS output data set hwouty, which will reside in saswork. All time series in the Haver haverw database are listed alphabetically in Output 7.1.1.

Output 7.1.1. Examining the Contents of Haver Analytics Database, haverw.dat

```
                       Haver Analytics Database, HAVERW.DAT
                 PROC CONTENTS for Time Series converted to yearly frequency

                              The CONTENTS Procedure

                    Alphabetic List of Variables and Attributes

16 FXTWOTP  Num    8        Nominal Trade-Weighted Exchange
                            Value of US$ vs OITP (1/97=100)
17 FXUK     Num    8        Foreign Exchange Rate: United Kingdom (US$/Pound)
18 LICN     Num    8        Unemployment Insurance: Initial Claims,
                            State Programs (NSA, Thous)
19 LIU      Num    8        Insured Unemployment, State Programs (SA, Thous)
20 MBAMP    Num    8        MBA: Purchase Index: Mortgage Loan
                            Applications (SA, 3/16/90=100)
21 MBAMR    Num    8        MBA: Refinancing Index: Mortgage Loan
                            Applications (SA, 3/16/90=100)
```

You could use the following SAS statements to create a SAS data set named hwouty and to print its contents.

```
libname lib1 sasehavr ’path-to-haver-data’
             freq=yearly start=19860101 end=19991231 force=freq;

data hwouty;
   set lib1.haverw;
run;

title1 ’Haver Analytics Database, Frequency=yearly, infile=haverw.dat’;

proc print
   data=hwouty;
run;
```

The libref above specifies that all time series in the haverw database be converted to yearly frequency but to only select the range of data from January 1, 1986, to December 31, 1999. The resulting SAS data set hwouty is shown in Output 7.1.2.

Output 7.1.2. Defining a Range Inside the Data Range Using the START=19860101 END=19991231 Libname Options

```
          Haver Analytics Database, Frequency=yearly, infile=haverw.dat

Example 7.2. Viewing Quarterly Time Series from a Haver Database

Consider the following statements for quarterly frequency conversion of all time series for the period spanning April 1, 1996, to December 31, 1999.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=quarterly start=19960401 end=19991231 force=freq;

data hwoutq;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=quarterly, infile=haverw.dat';

proc print
   data=hwoutq;
run;
```

The resulting SAS data set hwoutq is shown in Output 7.2.1.

```

Example 7.3. Viewing Monthly Time Series from a Haver Database

Suppose you wish to convert your time series to the monthly frequency. An example of monthly conversion would look like this:

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=monthly start=19990401 end=19991231 force=freq;

data hwoutm;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=monthly, infile=haverw.dat';

proc print
   data=hwoutm;
run;
```

The result from using the range of April 1, 1999, to December 31, 1999, is shown in Output 7.3.1.

Output 7.3.1. Defining a Range Inside the Data Range Using the START=19960401 END=19991231 Libname Options

```

Example 7.4. Viewing Weekly Time Series from a Haver Database

An example of weekly data spanning September 1, 1999, to December 31, 1999, is shown in Output 7.4.1.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=weekly start=19990901 end=19991231;

data hwoutw;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=weekly, infile=haverw.dat';

proc print
   data=hwoutw;
run;
```

Output 7.4.1. Defining a Range Inside the Data Range Using the START=19960401 END=19991231 Libname Options

Example 7.5. Viewing Daily Time Series from a Haver Database

Consider viewing the Haver Analytics daily database named haverd. The contents of this database can be seen by submitting the following data step.

```
libname lib1 sasehavr 'path-to-haver-data'
             freq=daily start=19991201 end=19991231;

data hwoutd;
   set lib1.haverd;
run;

title1 'Haver Analytics Database, HAVERD.DAT';
title2 'PROC CONTENTS for Time Series converted to daily frequency';

proc contents
   data=hwoutd;
run;
```

Output 7.5.1 shows the output of PROC CONTENTS with the following time series.

Output 7.5.1. Examining the Contents of a Daily Haver Analytics Database, haverd.dat

```
                       Haver Analytics Database, HAVERD.DAT
            PROC CONTENTS for Time Series converted to daily frequency

                              The CONTENTS Procedure

                    Alphabetic List of Variables and Attributes

# Variable Type Len Format Label

1 DATE     Num    8 DATE9. Date of Observation

```

Example 7.6. Limiting the Range of Time Series from a Haver Database

Suppose we limit the range of data to the month of December:

```
libname lib1 sasehavr 'path-to-haver-data'
                freq=daily start=19991201 end=19991231;

data hwoutd;
   set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';

proc print
   data=hwoutd;
run;
```

Note that Output 7.6.1 for daily conversion shows the frequency as the SAS time interval for WEEKDAY.

Output 7.6.1. Defining a Range Inside the Data Range Using the START=19991201 END=19991231 Libname Options

```
          Haver Analytics Database, Frequency=daily, infile=haverd.dat

  23    31DEC1999    7.64    8.18   2770.01      .        .      1469.25   3214.38
```

Example 7.7. Using the WHERE Statement to Subset Time Series from a Haver Database

Using a WHERE statement in the DATA step can be useful for further subsetting.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=daily start=19991101 end=19991231;

data hwoutd;
   set lib1.haverd;
   where date  between '01nov99'd and '01dec99'd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
proc print
   data=hwoutd;
run;
```

Output 7.7.1 shows that the time slice of November 1, 1999, to December 31, 1999, is narrowed further by the DATE test on the WHERE statement to stop at December 1, 1999.

Output 7.7.1. Defining a Range Using START=19991101 END=19991231 Along with the WHERE statement

```

```

Example 7.8. Using the KEEP Option to Subset Time Series from a Haver Database

To select specific time series the KEEP or DROP option may also be used as follows.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=daily start=19991101 end=19991231 keep="SP*";

data hwoutd;
   set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
proc print
   data=hwoutd;
run;
```

Output 7.8.1 shows two series that are selected by using KEEP="SP*" on the libname statement.

Output 7.8.1. Using the KEEP option along with defining a Range Using START=19991101 END=19991231

```
           Haver Analytics Database, Frequency=daily, infile=haverd.dat

```

The DROP option can be used to drop specific variables from a Haver dataset. To specify this option, use DROP= instead of KEEP= as shown above.

Example 7.9. Using the SOURCE Option to Subset Time Series from a Haver Database

To select specific variables that belong to a certain source, the SOURCE or DROPSOURCE option may also be used much like KEEP and DROP.

```
libname lib1 sasehavr 'path-to-haver-data'
            freq=daily start=19991101 end=19991223 source="FRB";

data hwoutd;
   set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
proc print
   data=hwoutd;
run;
```

Output 7.9.1 shows two series that are selected by using SOURCE="FRB" on the libname statement.

Output 7.9.1. Using the SOURCE option along with defining a Range Using START=19991101 END=19991213

```
          Haver Analytics Database, Frequency=daily, infile=haverd.dat

                     31     13DEC1999     7.40     8.06
```

Example 7.10. Using the GROUP Option to Subset Time Series from a Haver Database

To select specific variables that belong to a certain group, the GROUP or DROPGROUP option may also be used much like KEEP and DROP.

```
libname lib1 sasehavr 'path-to-haver-date'
            freq=week.6 start=20000107 end=20001007 group="C*";

data hwoutw;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=week.6, infile=haverw.dat';
proc print
   data=hwoutw;
run;
```

Output 7.10.1 shows two series that are selected by using GROUP="C*" on the libname statement.

Output 7.10.1. Using the GROUP option along with defining a Range Using START=20000107 END=20000609

```
       Haver Analytics Database, Frequency=week.6, infile=haverw.dat

Chapter 8
Using the Output Delivery System

Chapter Contents

Chapter 8
Using the Output Delivery System

Overview

In the latest version of SAS software, all SAS/ETS procedures use the Output Delivery System (ODS) to manage their output. This includes managing the form in which the output appears as well as its organization and format. The default for SAS/ETS procedures is to produce the usual SAS listing file. However, by using the features of the Output Delivery System, you can make changes to the format and appearance of your SAS output. In particular, you can

- display your output in hypertext markup language (HTML).
- display your output in Rich-Text-Format (RTF).
- create SAS data sets directly from output tables.
- select or exclude individual output tables.
- customize the layout, format, and headers of your output.

ODS features can provide you with a powerful tool for managing your output. This chapter provides background material and illustrates typical applications of ODS with SAS/ETS software.

For complete documentation on the Output Delivery System, refer to *SAS Output Delivery System User's Guide*.

Output Objects and ODS Destinations

All SAS procedures produce *output objects* that the Output Delivery System delivers to various *ODS destinations*, according to the default specifications for the procedure or to your own specifications.

All output objects (for example, a table of parameter estimates) consist of two component parts:

- the data component, which consists of the results computed by a SAS procedure.
- the template, which contains rules for formatting and displaying the results.

When you invoke a SAS procedure, the procedure sends all output to the Output Delivery System. ODS then routes the output to all open destinations. You define the form the output should take when you specify an ODS destination. Supported destinations are as follows:

- Listing destination (the standard SAS listing), which is the default.
- HTML destination, hypertext markup language.
- Output destination, SAS data set.

Future versions of ODS will support the following additional destinations:

- the ODS Output Document for modifying and replaying output without rerunning the procedure that created it.
- Rich Text Format (RTF) for inclusion in Microsoft Word.
- postscript and PCL for high fidelity printers.

You can activate multiple ODS destinations at the same time, so that a single procedure step can route output to multiple destinations. If you do not supply any ODS statements, ODS delivers all output to the SAS listing, which is the default.

Each output object has an associated template that defines its presentation format. You can modify the presentation of the output by using the TEMPLATE procedure to alter these templates or to create new templates. You can also specify stylistic elements for ODS destinations, such as cell formats and headers, column ordering, colors, and fonts. For detailed information, refer to the chapter titled "The Template Procedure" in the *SAS Procedures Guide*.

Using the Output Delivery System

The ODS statement is a global statement that enables you to provide instructions to the Output Delivery System. You can use ODS statements to specify options for different ODS destinations, select templates to format your output, and select and exclude output. You can also display the names of individual output tables as they are generated.

In order to select, exclude, or modify a table, you must first know its name. You can obtain the table names in several ways:

- For any SAS/ETS procedure, you can obtain table names from the individual procedure chapter or from the individual procedure section of the SAS online Help system.
- For any SAS procedure, you can use the SAS Explorer window to view the names of the tables created in your SAS run (see the section "Using ODS with the SAS Explorer" on page 247 for more information).
- For any SAS procedure, you can use the ODS TRACE statement to find the names of tables created in your SAS run. The ODS TRACE statement writes identifying information to the SAS log (or, optionally, to the SAS listing) for each generated output table.

Specify the ODS TRACE ON statement prior to the procedure statements that create the output for which you want information. For example, the following statements write the trace record for the specific tables created in this AUTOREG procedure step.

```
ods trace on;
proc autoreg;
   model y1 = time;
   model y2 = time;
run;
```

By default, the trace record is written to the SAS log, as displayed in Figure 8.1. Alternatively, you can specify the LISTING option, which writes the information, interleaved with the procedure output, to the SAS listing (see Example 8.1).

```
   ods trace on;
   proc autoreg;
      model y1 = time;
      model y2 = time;
   run;

.
.
.

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   ets.autoreg.ParameterEstimates
Path:       Autoreg.Model1.OLSEst.ParameterEstimates
-------------

.
.
.

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   ets.autoreg.ParameterEstimates
Path:       Autoreg.Model2.OLSEst.ParameterEstimates
-------------
```

Figure 8.1. Partial Contents of the SAS Log: Result of the ODS TRACE Statement

Figure 8.1 displays the trace record, which contains the name of each created table and its associated label, template, and path. The label provides a description of the table. The template name displays the name of the template used to format the table. The path shows the output hierarchy to which the table belongs.

The fully qualified path is given in the trace record. A partially qualified path consists of any part of the full path that begins immediately after a period (.) and continues to the end of the full path. For example, the full path for the parameter estimates for the first model in the preceding regression analysis is

```
Autoreg.Model1.OLSEst.ParameterEstimates
```

Therefore, partially qualified paths for the table are

```
Autoreg.Model1.OLSEst.ParameterEstimates
Model1.OLSEst.ParameterEstimates
OLSEst.ParameterEstimates
ParameterEstimates
```

To refer to a table (in order to select or exclude it from display, for example), specify either the table name or use the table's fully or partially qualified path. You may want to use qualified paths when your SAS program creates several tables that have the same name, as in the preceding example. In such a case, you can use a partially qualified path to select a subset of tables, or you can use a fully qualified path to select a particular table.

You specify the tables that ODS selects or excludes with the ODS SELECT or ODS EXCLUDE statement. Suppose that you want to display only the tables of parameter estimates from the preceding regression analysis. You can give any of the following statements (before invoking the AUTOREG procedure) to display both tables of parameter estimates. For this example, these statements are equivalent:

```
ods select Autoreg.Model1.OLSEst.ParameterEstimates
           Autoreg.Model2.OLSEst.ParameterEstimates;

ods select Model1.OLSEst.ParameterEstimates
           Model2.OLSEst.ParameterEstimates;

ods select OLSEst.ParameterEstimates;

ods select ParameterEstimates;
```

The first ODS SELECT statement specifies the full path for both tables. The second statement specifies the partially qualified path for both tables. The third and fourth statements specify the partial path "OLSEst.ParameterEstimates," and single name "ParameterEstimates," which are shared by both tables.

The Output Delivery System records the specified table names in its internal selection or exclusion list. ODS then processes the output it receives. Note that ODS maintains an overall selection or exclusion list that pertains to all ODS destinations, and it maintains a separate selection or exclusion list for each ODS destination. The list for a specific destination provides the primary filtering step. Restrictions you specify in the overall list are added to the destination-specific lists.

Suppose, for example, that your listing exclusion list (that is, the list of tables you wish to exclude from the SAS listing) contains the "Summary" table, which you specify with the statement

```
ods listing exclude Summary;
```

and your overall selection list (that is, the list of tables you want to select for all destinations) contains the tables "Summary" and "ParameterEstimates," which you specify with the statement

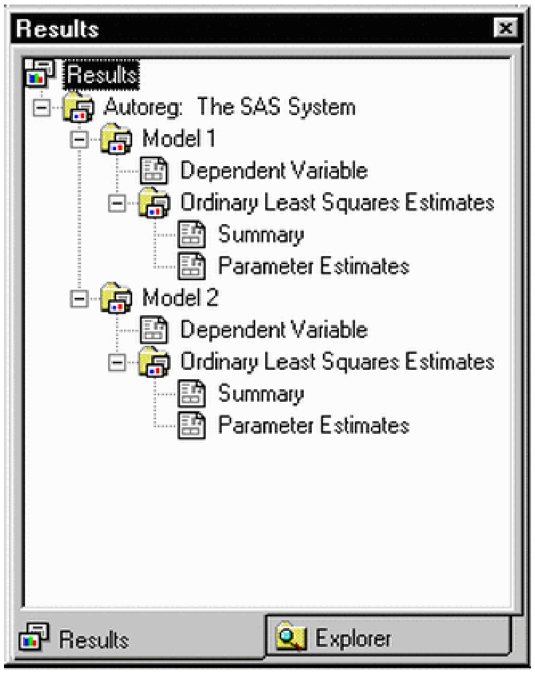
```
   ods select ParameterEstimates Summary;
```

The Output Delivery System then sends only the "ParameterEstimates" and "Summary" tables to all open destinations except the SAS listing. It sends only the "ParameterEstimates" table to the SAS listing because the table "Summary" is excluded from that destination.

Some SAS procedures, such as the ARIMA or the MODEL procedure, support run-group processing, which means that a RUN statement does not end the procedure. A QUIT statement explicitly ends such procedures; if you omit the QUIT statement, a PROC or a DATA statement implicitly ends such procedures. When you use the Output Delivery System with procedures that support run-group processing, it is good programming practice to specify a QUIT statement at the end of the procedure. This causes ODS to clear the selection or exclusion list, and you are less likely to encounter unexpected results.

Using ODS with the SAS Explorer

The SAS Explorer is a new feature that enables you to examine the various parts of the SAS System. Figure 8.2 displays the Results window from the SAS Explorer. The Results node retains a running record of your output as it is generated during your SAS session. Figure 8.2 displays the output hierarchy when the preceding statements are executed.



```
Results
Results
  Autoreg: The SAS System
    Model 1
      Dependent Variable
      Ordinary Least Squares Estimates
        Summary
        Parameter Estimates
    Model 2
      Dependent Variable
      Ordinary Least Squares Estimates
        Summary
        Parameter Estimates
```

Figure 8.2. The Results Window from the SAS Explorer

When you click on the output table names in the Results window, you link directly to the output in the output window or, if you specify the HTML destination, in an HTML browser. The items on the left-hand side of the Results node are output directories. The items on the right-hand side of the Results node are the names of the actual output objects. You can also use the Explorer to determine names of the templates associated with each output table.

Controlling Output Appearance with Templates

A template is an abstract description of how output should appear when it is formatted. Templates describe several characteristics of the output, including headers, column ordering, style information, justification, and formats. All SAS/ETS procedures have templates, which are stored in the SASHELP library.

You can create or modify a template with the TEMPLATE procedure. For example, you can specify different column headings or different orderings of columns in a table. You can find the template associated with a particular output table by using the ODS TRACE statement or the SAS Explorer.

You can display the contents of a template by executing the following statements:

```
proc template;
   source  templatename;
run;
```

where *templatename* is the name of the template.

Suppose you want to change the way all of the parameter estimates are displayed by the AUTOREG procedure. You can redefine the templates that the procedure uses with PROC TEMPLATE. For example, in order to have the ESTIMATE and STANDARD ERROR columns always displayed with more digits, you can redefine the columns used by the procedure to display them:

```
proc template;
   edit ets.autoreg.ParameterEstimates;
      edit Estimate; format=Best16.; end;
      edit StdErr; format=Best16.; end;
   end;
run;
```

The BEST*w*. format enables you to display the most information about a value, according to the available field width. The BEST16. format specifies a field width of 16. Refer to the chapter on formats in *SAS Language Reference: Dictionary* for detailed information.

When you run PROC TEMPLATE to modify or edit a template, the template is stored in your SASUSER library. You can then modify the path that ODS uses to look up templates with the ODS PATH statement in order to access these new templates in a later SAS session. This means that you can create a default set of templates to modify the presentation format for all your SAS output. (Note that you can specify the SHOW option in the ODS PATH statement to determine the current path.)

It is important to note the difference between a style template and a table template. A table template applies only to the specific tables that reference the template. The preceding statements that modify the "ets.autoreg.ParameterEstimates" template provide an example of modifying columns within a table template.

A style template applies to an entire SAS job and can be specified only in the ODS HTML statement. You can specify a style as follows:

```
ods html style=Styles.Brown;
```

A style template controls stylistic elements such as colors, fonts, and presentation attributes. When you use a style template, you ensure that all your output shares a consistent presentation style.

You can also reference style information in table templates for individual headers and data cells. You can modify either type of template with the TEMPLATE procedure. For information on creating your own styles, refer to *SAS Output Delivery System User's Guide*.

Interaction Between ODS and the NOPRINT Option

Most SAS/ETS procedures support a NOPRINT option that you can use when you want to create an output data set but do not want any displayed output. Typically, you use an OUTPUT statement in addition to the procedure's NOPRINT option to create a data set and suppress displayed output.

You can also use the Output Delivery System to create output data sets by using the ODS OUTPUT statement. However, if you specify the NOPRINT option, the procedure may not send any output to the Output Delivery System. Therefore, when you want to create output data sets through ODS (using the ODS OUTPUT statement), and you want to suppress the display of all output, specify

```
ODS SELECT NONE;
```

or close the active ODS destinations by giving the command

```
ODS  destinationname CLOSE;
```

where *destinationname* is the name of the active ODS destination (for example, ODS HTML CLOSE).

Note: The ODS statement does not instruct a procedure to generate output: instead, it specifies how the Output Delivery System should manage the table once it is created. The requested data table (output) has to be generated by the procedure before ODS can manage it. You must ensure that the proper options are in effect. For example, the following code does not create the requested data set Parms.

```
proc autoreg;
   ods output ML.ParameterEstimates=Parms;
   model y1 = time;
run;
```

When you execute these statements, the following line is displayed in the log:

```
WARNING: Output 'ML.ParameterEstimates' was not created.
```

The data set Parms is not created because the table of parameter estimates is generated only when the METHOD=ML option is specified in the MODEL statement in the AUTOREG procedure.

Compatibility Issues with Version 6 Prototypes

- The Version 6 prototype of the ODS output hierarchy is stored in a SAS catalog. The latest version of SAS software has a more flexible item-store file type used to store templates and ODS output.
- The Version 6 prototype ODS uses two macro variables (_DISK_ and _PRINT_) to regulate the saving of an output hierarchy. The latest version of SAS software uses the global ODS statement to accomplish this task.
- The Version 6 PROC TEMPLATE and PROC OUTPUT syntax is not compatible with the latest version of SAS software.

Examples

The following examples display typical uses of the Output Delivery System.

Example 8.1. Creating HTML Output with ODS

This example demonstrates how you can use the ODS HTML statement to display your output in hypertext markup language (HTML).

The following statements create the data set AR2, which contains a second-order autocorrelated time series Y. The AUTOREG procedure is then invoked to estimate the time trend of Y.

The ODS HTML statement specifies the name of the file to contain body of the HTML output.

```
data AR2;
   ul = 0; ull = 0;
   do Time = -10 to 36;
      u = + 1.3 * ul - .5 * ull + 2*rannor(12346);
      Y = 10 + .5 * time + u;
      if Time > 0 then output;
      ull = ul; ul = u;
   end;
run;

ods html body='trend.htm';

title 'Estimated Time Trend of Y';
proc autoreg;
   model Y = Time;
run;
ods html close;
```

By default, the SAS listing receives all output generated during your SAS run. In this example, the ODS HTML statement opens the HTML destination, and both destinations receive the generated output. Output 8.1.1 displays the results as they are displayed in the SAS listing.

Note that you must specify the following statement before you can view your output in a browser.

```
   ods html close;
```

If you do not close the HTML destination, your HTML file may contain no output, or you may experience other unexpected results.

Output 8.1.2 displays the file 'trend.htm', which is specified in the preceding ODS HTML statement.

Output 8.1.1. Results for PROC AUTOREG: SAS Listing Output

```
                              Estimated Time Trend of Y

                                The AUTOREG Procedure

Example 8.2. Creating HTML Output with a Table of Contents

The following example uses ODS to display the output in HTML with a table of contents.

The data are the population of the United States in millions recorded at ten year intervals starting in 1790 and ending in 1990. The MODEL procedure is used to estimate a logistic growth curve by nonlinear ordinary least squares.

```
data uspop;
   input pop :6.3 @@;
   retain year 1780;
   year=year+10;
   label pop='U.S. Population in Millions';
   datalines;
3929   5308   7239   9638   12866  17069  23191  31443
39818  50155  62947  75994  91972  105710 122775 131669
151325 179323 203211 226542 248710
;

ods html body='uspop.htm'
         contents='uspopc.htm'
         frame='uspopf.htm';

title 'Logistic Growth Curve Model of U.S. Population';
```

```
proc model data=uspop;
   label a = 'Maximum Population'
         b = 'Location Parameter'
         c = 'Initial Growth Rate';
   pop = a / ( 1 + exp( b - c * (year-1790) ) );
   fit pop start=(a 1000  b 5.5  c .02)/ out=resid outresid;
run;
ods html close;
```

The ODS HTML statement specifies three files. The BODY= option specifies the file to contain the output generated from the statements that follow. The BODY= option is the only required option.

The CONTENTS= option specifies a file to contain the table of contents. The FRAME= option specifies a file to contain both the table of contents and the output. You open the FRAME= file in your browser to view the table of contents together with the generated output (see Output 8.2.1). Note that, if you specify the ODS HTML statement with only the BODY= argument, no table of contents is created.

The MODEL procedure is invoked to fit the specified model. The resulting output is displayed in Output 8.2.1.

Output 8.2.1. HTML Output from the MODEL Procedure

Logistic Growth Curve Model of U.S. Population

The table of contents displayed in Output 8.2.1 contains the descriptive label for each output table produced in the MODEL procedure step. You can select any label in the table of contents and the corresponding output will be displayed in the right-hand side of the browser window.

Example 8.3. Determining the Names of ODS Tables

In order to select or exclude a table, or to render it as a SAS data set, you must first know its name. You can obtain the table names in several ways:

- For any SAS/ETS procedure, you can obtain table names from the individual procedure chapter or from the SAS online Help system.
- For any SAS procedure, you can use the SAS Explorer window to view the names of the tables created in your SAS run.
- For any SAS procedure, you can use the ODS TRACE statement to find the names of tables created in your SAS run. The ODS TRACE statement writes identifying information to the SAS log for each generated output table.

This example uses the ODS TRACE statement with the LISTING option to obtain the names of the created output objects. By default, the ODS TRACE statement writes its information to the SAS log. However, you can specify the LISTING option to have the information interleaved with the procedure output in the SAS listing.

The model will be the U.S. population model from the previous example.

```
ods trace on/listing;

title 'Logistic Growth Curve Model of U.S. Population';
proc model data=uspop;
   label a = 'Maximum Population'
         b = 'Location Parameter'
         c = 'Initial Growth Rate';
   pop = a / ( 1 + exp( b - c * (year-1790) ) );
   fit pop start=(a 1000  b 5.5  c .02)/ out=resid outresid;
run;

ods trace off;
```

The purpose of these statements is to obtain the names of the ODS tables produced in this PROC MODEL run. The ODS TRACE ON statement writes the trace record of ODS output tables. The LISTING option specifies that the information is interleaved with the output and written to the SAS listing.

The MODEL procedure is invoked to perform the analysis, the SAS listing receives the procedure output and the trace record, and the trace is then turned off with the OFF option.

Output 8.3.1. The ODS Trace, Interleaved with MODEL Results: Partial Results

```
                                   The MODEL Procedure

      c               0.022703      0.00107      21.22       <.0001    Initial Growth Rate
```

As displayed in Output 8.3.1, the ODS TRACE ON statement writes the name, label, template, and path name of each generated ODS table. For more information on names, labels, and qualified path names, see the discussion in the section "Using the Output Delivery System" beginning on page 244.

The information obtained with the ODS TRACE ON statement enables you to request output tables by name. The examples that follow demonstrate how you can use this information to select, exclude, or create data sets from particular output tables.

Example 8.4. Selecting ODS Tables for Display

You can use the ODS SELECT statement to deliver only certain tables to open ODS destinations. In the following example, the MODEL procedure is used to fit a model for new one-family home sales.

```
title 'Modeling One-Family Home Sales';
    data homes;
       input year q pop yn cpi @@;
          y=yn/cpi;
       label q='New One-Family Houses Sold in Thousands'
          pop='U.S. Population in Millions'
          y='Real Personal Income in Billions'
          cpi='U.S. CPI 1982-1984 = 100';
```

```
   datalines;
70 485 205.052  715.6  .388  71 656 207.661  776.8  .405
72 718 209.896  839.6  .418  73 634 211.909  949.8  .444
74 519 213.854 1038.4  .493  75 549 215.973 1142.8  .538
76 646 218.035 1252.6  .569  77 819 220.239 1379.3  .606
78 817 222.585 1551.2  .652  79 709 225.055 1729.3  .726
80 545 227.719 1918.0  .824  81 436 229.945 2127.6  .909
82 412 232.171 2261.4  .965  83 623 234.296 2428.1  .996
84 639 236.343 2668.6 1.039  85 688 238.466 2838.7 1.076
86 750 240.658 3013.3 1.096  87 671 242.820 3194.7 1.136
88 676 245.051 3479.2 1.183  89 650 247.350 3725.5 1.240
90 536 249.975 3945.8 1.307
;

ods select ResidSummary ParameterEstimates;
ods trace on;
ods show;
```

The ODS SELECT statement specifies that only the two tables “ResidSummary” and “ParameterEstimates” are to be delivered to the ODS destinations. In this example, no ODS destinations are explicitly opened. Therefore, only the SAS listing, which is open by default, receives the procedure output. The ODS SHOW statement displays the current overall selection list in the SAS log. The ODS TRACE statement writes the trace record of the ODS output objects to the SAS log. In the following statements, the MODEL procedure is invoked to produce the output.

```
proc model data=homes;
   parms a b c d;
      q = a + b*y + c*lag(y) + d*pop;
   %ar(ar_q,1,q)
   endo q;
   exo y pop;
   id year;
   fit q / dw;
run;
```

Output 8.4.1 displays the results of the ODS SHOW statement, which writes the current overall selection list to the SAS log. As specified in the preceding ODS SELECT statement, only the two ODS tables “ResidSummary” and “ParameterEstimates” are selected for output.

Output 8.4.1. Results of the ODS SHOW Statement

```
     ods select ResidSummary ParameterEstimates;
     ods trace on;
     ods show;

Current OVERALL select list is:
1. ResidSummary
2. ParameterEstimates
```

Partial results of the ODS TRACE statement, which is written to the SAS log, are displayed in Output 8.4.2.

Output 8.4.2. The ODS TRACE: Partial Contents of the SAS Log

```
      proc model data=homes;
         parms a b c d;
            q = a + b*y + c*lag(y) + d*pop;
         %ar(ar_q,1,q)
         endo q;
         exo y pop;
         id year;

         fit q / dw;
      run;

Output Added:
-------------
Name:       ResidSummary
Label:      Nonlinear OLS Summary of Residual Errors
Template:   ets.model.ResidSummary
Path:       Model.OLS.ResidSummary
-------------

Output Added:
-------------
Name:       ParameterEstimates
Label:      Nonlinear OLS Parameter Estimates
Template:   ets.model.ParameterEstimates
Path:       Model.OLS.ParameterEstimates
-------------
```

In the following statements, the ODS SHOW statement writes the current overall selection list to the SAS log. The QUIT statement ends the MODEL procedure. The second ODS SHOW statement writes the selection list to the log after PROC MODEL terminates. The ODS selection list is reset to ’ALL,’ by default, when a procedure terminates. For more information on ODS exclusion and selection lists, see the section “Using the Output Delivery System” beginning on page 244.

```
   ods show;
   quit;
   ods show;
```

The results of the statements are displayed in Output 8.4.3. Before the MODEL procedure terminates, the ODS selection list includes only the two tables, “ResidSummary” and “ParameterEstimates.”

Output 8.4.3. The ODS Selection List, Before and After PROC MODEL Terminates

```
     ods show;

Current OVERALL select list is:
1. ResidSummary
2. ParameterEstimates

     quit;

NOTE: PROCEDURE MODEL used:
      real time           0.34 seconds
      cpu time            0.19 seconds

     ods show;

Current OVERALL select list is: ALL
```

The MODEL procedure supports run-group processing. Before the QUIT statement is executed, PROC MODEL is active and the ODS selection list remains at its previous setting before PROC MODEL was invoked. After the QUIT statement, the selection list is reset to deliver all output tables.

The entire displayed output consists of the two selected tables, as displayed in Output 8.4.4.

Output 8.4.4. The Listing Output of the ResidSummary and ParameterEstimates Tables from PROC MODEL

```
                       Logistic Growth Curve Model of U.S. Population

                                   The MODEL Procedure

                                                                     parameter
```

Example 8.5. Creating an Output Data Set from an ODS Table

The ODS OUTPUT statement creates SAS data sets from ODS tables. In the following example, the AUTOREG procedure is invoked to estimate a large number of Dickey-Fuller type regressions and part of the resulting procedure output is output to a SAS data set. The Dickey-Fuller t-statistic is then calculated and PROC MEANS is used to calculate the empirical critical values.

The data set UNITROOT contains 10,000 unit root time series.

```
data unitroot;
  YLag = 0;
  do rep = 1 to 10000;
    do time = -50 to 100;
      Y = YLag + rannor(123);
      if time > 0 then output;
      YLag = Y;
    end;
  end;
run;
```

Determining the Names of the ODS Tables

The purpose of the following statements is to obtain the names of the output tables produced in this PROC AUTOREG run. Note that a smaller data set, test, is used for this trial run. The ODS TRACE statement lists the trace record.

```
data test;
  YLag = 0;
    do time = -50 to 100;
      Y = YLag + rannor(123);
      if time > 0 then output;
      YLag = Y;
    end;
run;

ods trace on;
proc autoreg data=test;
   model Y = YLag;
run;
ods trace off;
```

Output 8.5.1. The ODS TRACE: Partial Contents of the SAS Log

```
     ods trace on;
     ods listing close;
     proc autoreg data=test;
        model Y = YLag;
     run;

Output Added:
-------------
Name:       Dependent
Label:      Dependent Variable
Template:   ets.autoreg.Dependent
Path:       Autoreg.Model1.Dependent
-------------

.
.
.

Output Added:
-------------
Name:       ParameterEstimates
Label:      Parameter Estimates
Template:   ets.autoreg.ParameterEstimates
Path:       Autoreg.Model1.OLSEst.ParameterEstimates
-------------
```

By default, the trace record is written to the SAS log, as displayed in Output 8.5.1. Note that you can alternatively specify that the information be interleaved with the procedure output in the SAS listing (see Example 8.3).

Creating the Output Data Set

In the statements that follow, the ODS OUTPUT statement writes the ODS table "ParameterEstimates" to a SAS data set called myParms. All of the usual data set options, such as the KEEP= or WHERE= options, can be used in the ODS OUTPUT statement. Thus, to modify the ParameterEstimates data set so that it contains only certain variables, you can use the data set options as follows.

```
ods listing close;
proc autoreg data=unitRoot;
   ods output ParameterEstimates = myParms
           (keep=Variable Estimate StdErr
            where=(Variable='YLag')) ;
   by rep;
   model Y = YLag;
run;
ods listing;
```

The KEEP= option in the ODS OUTPUT statement specifies that only the variables Variable, Estimate, and StdErr are written to the data set. The WHERE= option selects the specific variable in which we are interested , YLag. The AUTOREG procedure is again invoked. In order to limit the amount of displayed output, the ODS exclusion list is set to ALL.

In the following statements, the output data set myParms is used to create the data set TDISTN which contains the Dickey-Fuller t-statistics. PROC MEANS is then utilized to tabulate the empirical 1, 5, and 10 percent critical values. The results are displayed in Output 8.5.2.

```
data tdistn;
  set myParms;
  tStat = (Estimate-1)/StdErr;
run;

ods select Means.Summary;
proc means data=tDistn P1 P5 P10 fw=5;
   var tStat;
   title 'Simulated Dickey-Fuller Critical Values';
run;
```

Output 8.5.2. The Empirical Critical Values, Tabulated by PROC MEANS

```
                    Simulated Dickey-Fuller Critical Values

                             The MEANS Procedure

                          Analysis Variable : tStat

                             1st      5th     10th
                            Pctl     Ptcl     Pctl
                           -----------------------
                           -3.51    -2.90    -2.59
                           -----------------------
```

Chapter 9
Statistical Graphics Using ODS (Experimental)

Chapter Contents

Chapter 9
Statistical Graphics Using ODS (Experimental)

Overview

Graphics are indispensable for modern statistical analysis. They enrich the analysis by revealing patterns, identifying differences, and expressing uncertainty that would not be readily apparent in tabular output. Effective graphics also add visual clarity to an analytical presentation, and they provoke questions that would not otherwise be raised, stimulating deeper investigation.

In SAS 9.1, a number of SAS/ETS procedures have been modified to use an experimental extension to the Output Delivery System (ODS) that enables them to create statistical graphics as automatically as tables. This facility is referred to as *ODS Statistical Graphics* (or *ODS Graphics* for short), and it is invoked when you provide the experimental ODS GRAPHICS statement prior to your procedure statements. Any procedures that use ODS Graphics then create graphics, either by default or when you specify procedure options for requesting specific graphs.

With ODS Graphics, a procedure creates the graphs that are most commonly needed for a particular analysis. In many cases, graphs are automatically enhanced with useful statistical information or metadata, such as sample sizes and p-values, which are displayed in an inset box. Using ODS Graphics eliminates the need to save numerical results in an output data set, manipulate them with a DATA step program, and display them with a graphics procedure.

The SAS/ETS procedures that use ODS Graphics in SAS 9.1 are listed on page 297. The plots produced by each procedure and any corresponding options are described in the procedure chapter. See the “ODS Graphics” subsection in the “Details” section of each procedure chapter for additional information.

In many ways, creating graphics with ODS is analogous to creating tables with ODS. You use

- procedure options and defaults to determine which graphs are created
- ODS destination statements (such as ODS HTML) to specify the output destination for graphics

Additionally, you can use

- graph names in ODS SELECT and ODS EXCLUDE statements to select or exclude graphs from your output
- ODS styles to control the general appearance and consistency of *all graphs*
- ODS templates to control the layout and details of *individual graphs*. A default template is provided by SAS for each graph.

In SAS 9.1, the ODS destinations that support ODS Graphics include HTML, LATEX, PRINTER, and RTF. These are discussed on page 274.

Both tables and graphs are saved in the ODS output file produced for a destination. However, individual graphs can also be saved in files, which are produced in a specific graphics image file type, such as GIF or PostScript. This enables you to access individual graphs for inclusion in a document. For example, you can save graphs in PostScript files to include in a paper that you are writing with LaTeX. Likewise, you can save graphs in GIF files to include in an HTML document. With the HTML destination, you can also request an image map format that supports tool tip displays, which appear when you move a mouse over certain features of the graph.

In common applications of procedures that use ODS Graphics, the default graphs should suffice. However, when modifications become necessary, you can customize a particular graph by changing its template, or you can make consistent changes to all your graphs by selecting a different ODS style or by modifying an existing ODS style definition:

- As with table definitions, you can access graph template definitions and modify them with the TEMPLATE procedure. Graph template definitions are written in an experimental graph template language, which has been added to the TEMPLATE procedure in SAS 9.1. This language includes statements for specifying plot types (such as scatter plots and histograms), plot layouts, and text elements (such as titles and insets). It also provides support for built-in computations (such as histogram binning) and evaluation of computational expressions. Options are available for specifying colors, marker symbols, and other aspects of plot features.
- ODS style definitions include a number of graph elements that correspond to general features of statistical graphics, such as titles and fitted lines. The attributes of these elements, such as fonts and colors, provide the defaults for options in graph templates provided by SAS. Consequently, you can change all of your graphs in a consistent manner by simply selecting a different style. For example, by specifying the “Journal” style, you can create gray-scale graphs and tables that are suitable for publication in professional journals.

Note: Statistical graphics created with ODS are experimental in this release, meaning that both their appearance and their syntax are subject to change in a future release.

This chapter illustrates the use of ODS Graphics, and it provides general information on managing your graphics. If you are unfamiliar with ODS, you will find it helpful to read Chapter 8, “Using the Output Delivery System.” For complete documentation on the Output Delivery System, refer to the *SAS Output Delivery System User’s Guide*.

How to Use This Chapter

If you are trying out ODS Graphics for the first time, begin by reading the section "Getting Started" on page 267, which provides the essentials. Additional examples are given in the chapters for procedures that use ODS Graphics in SAS 9.1.

To take full advantage of ODS Graphics, you will need to learn more about ODS destinations, output files, and image file types for graphics, as well as ways to access and include individual graphs in reports and presentations. This is explained in the section "Managing Your Graphics" on page 274, the section "Graphics Image Files" on page 283, and the section "Examples" beginning on page 300.

If you need to customize a graph by modifying its template, read the section "Customizing Graphics with Templates" on page 287 and the series of examples beginning on page 312.

If you need to customize a style definition read the section "Styles for Graphics" on page 293 and the series of examples beginning on page 322.

Getting Started

This section introduces the use of ODS Graphics with two simple examples, which illustrate how the ODS GRAPHICS statement and an ODS destination statement are required to produce graphics. In the first example, no procedure options are required; basic graphics are produced by default. In the second example, procedure options are used to request specific plots.

Using the ODS GRAPHICS Statement

This example is taken from the "Getting Started" section of Chapter 20, "The MODEL Procedure." It illustrates a situation in which only the ODS GRAPHICS statement and a supported ODS destination are needed to create graphical displays.

The SASHELP library contains the data set CITIMON, which, in turn, includes the variable LHUR, the monthly unemployment figures, and the variable IP, the monthly industrial production index. Assume that these variables are related by the following nonlinear equation:

$$lhur = \frac{1}{a \cdot \mathrm{ip} + b} + c + \epsilon$$

In this equation *a*, *b*, and *c* are unknown coefficients and ϵ is an unobserved random error.

The following statements illustrate how to use PROC MODEL to estimate values for *a*, *b*, and *c* from the data in SASHELP.CITIMON.

```
ods html;
ods graphics on;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;

ods graphics off;
ods html close;
```

The ODS HTML statement specifies an HTML destination for the output. Note that the LISTING destination is not supported by ODS Graphics in SAS 9.1. For a discussion of ODS destinations that are supported, see page 274.

The ODS GRAPHICS statement is specified to request ODS Graphics in addition to the usual tabular output. Here, the graphical output consists of a studentized residual plot, a Cook's D plot, a plot of actual and predicted values, plots of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation function of residuals, a QQ plot and a histogram of residuals; these are shown in Figure 9.1 through Figure 9.8, respectively.

The ODS GRAPHICS OFF statement disables ODS Graphics, and the ODS HTML CLOSE statement closes the HTML destination.

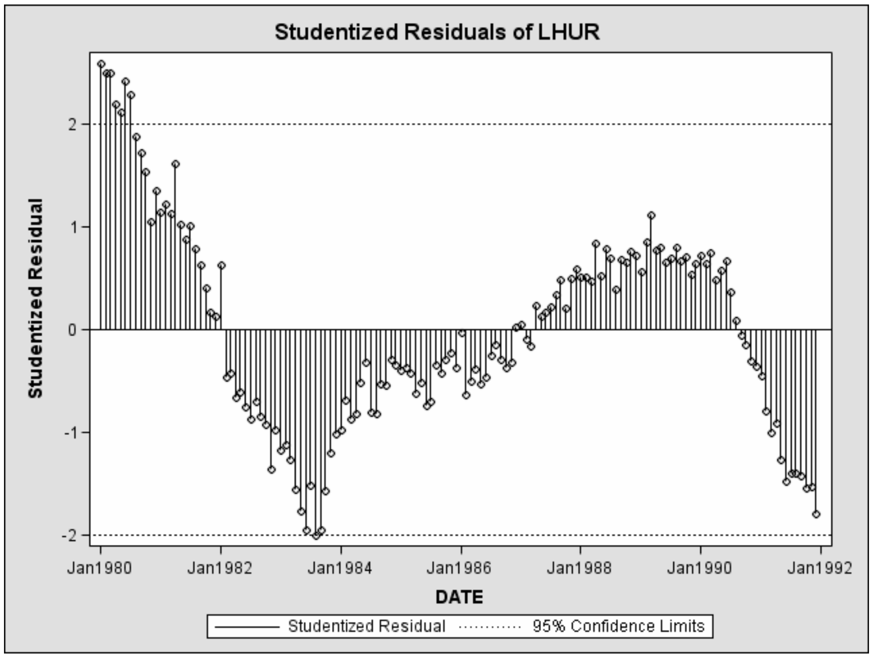

Figure 9.1. Studentized Residuals

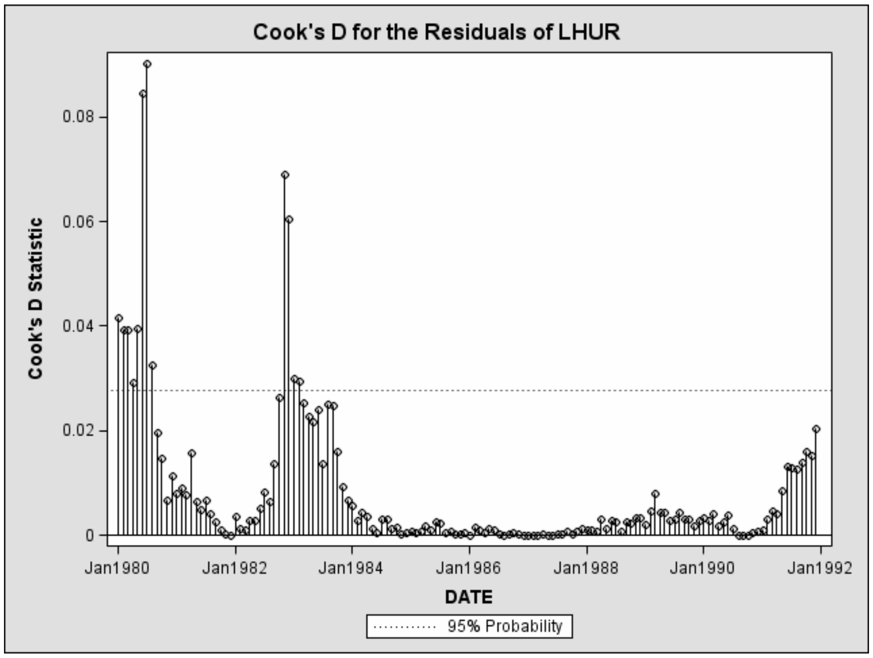

Figure 9.2. Cook's D for Residuals

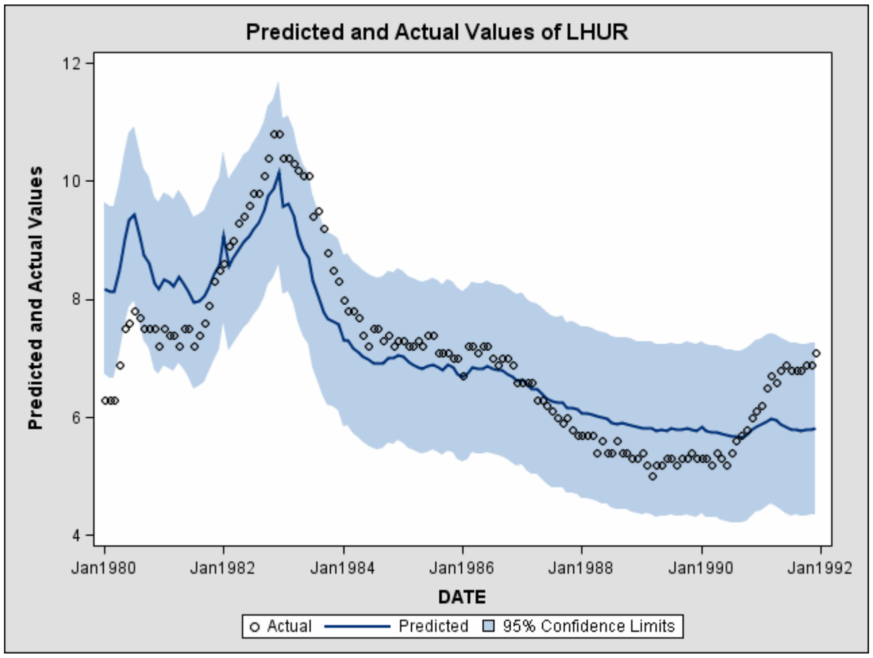

Figure 9.3. Predicted and Actual Values

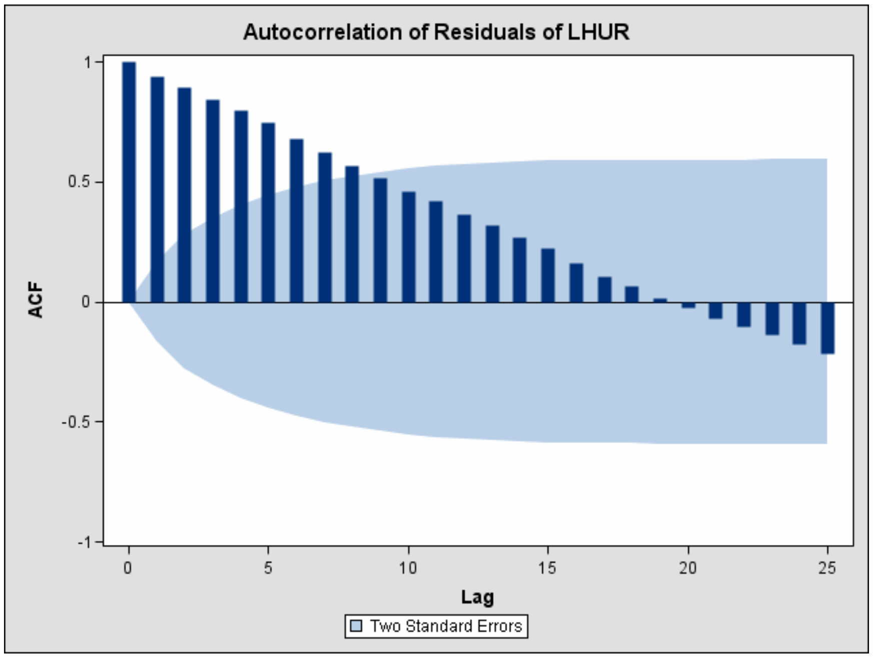

Figure 9.4. Autocorrelation of Residuals

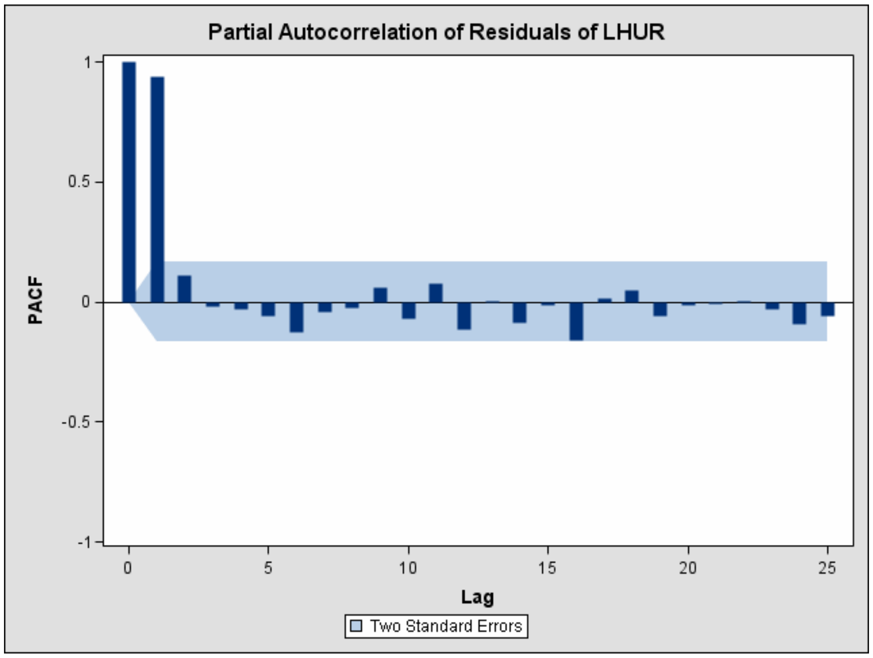

Figure 9.5. Partial Autocorrelation of Residuals

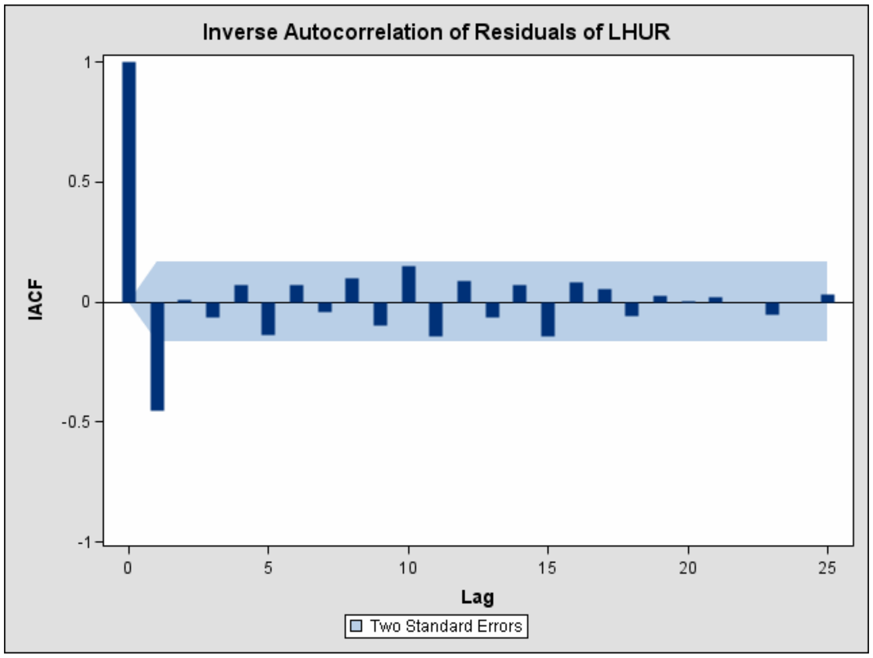

Figure 9.6. Inverse Autocorrelation of Residuals

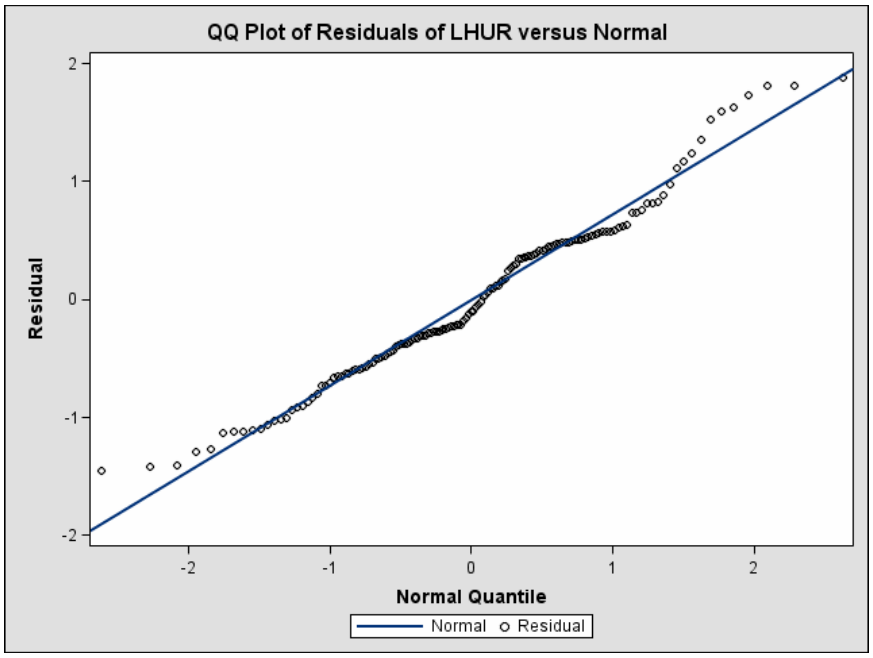

Figure 9.7. QQ Plot of Residuals

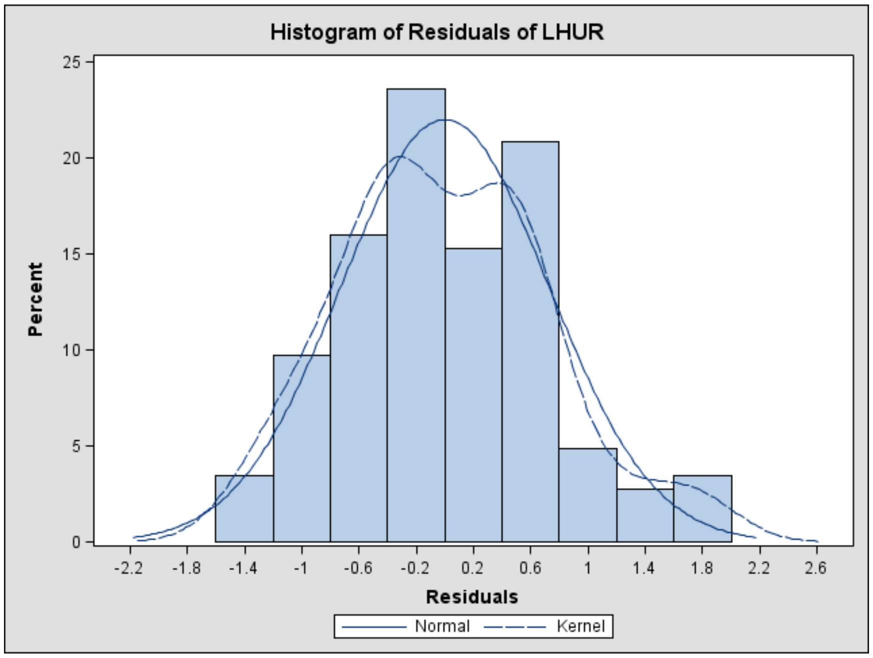

Figure 9.8. Histogram of Residuals

For more information about ODS Graphics available in the MODEL procedure, see the "ODS Graphics" section on page 1166 in Chapter 20, "The MODEL Procedure."

A sample program named odsgrgs.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Using the ODS GRAPHICS Statement and Procedure Options

In this example, new options of the UCM procedure are used to request graphical displays in addition to the ODS GRAPHICS statement.

The following data from the Connecticut Tumor Registry presents age-adjusted numbers of melanoma incidences per 100,000 people for 37 years from 1936 to 1972 The data have been used in Houghton, Flannery, and Viola (1980).

```
data melanoma;
   input Melanoma_Incidence_Rate @@;
   year = mdy(1,1, 1836 + _n_-1 );  /* start year 1936 */
   format year year4.;
   datalines;
   0.9 0.8 0.8 1.3 1.4 1.2 1.7 1.8 1.6 1.5
   1.5 2.0 2.5 2.7 2.9 2.5 3.1 2.4 2.2 2.9
   2.5 2.6 3.2 3.8 4.2 3.9 3.7 3.3 3.7 3.9
   4.1 3.8 4.7 4.4 4.8 4.8 4.8
   ;
run;
```

The following statements request the estimation and forecast of the following model and plots of the smoothed cycle component and forecasts.

```
Melanoma_Incidence_Rate = trend + cycle + error
```

```
ods html;
ods graphics on;

proc ucm data=melanoma noprint;
   id year interval=year;
   model Melanoma_Incidence_Rate;
   irregular;
   level variance=0 noest;
   slope variance=0 noest;
   cycle rho=1 noest=rho plot=smooth;
   estimate back=5;
   forecast back=5 lead=10 plot=forecasts print=none;
run;

ods graphics off;
ods html close;
```

The smoothed cycle component and forecasts plots are displayed in Figure 9.9 and Figure 9.10, respectively. This graphical display are requested by specifying the ODS GRAPHICS statement prior to the procedure statements, and the experimental PLOTS= options in the CYCLE and FORECAST statements. For more information about the graphics available in the UCM procedure, see the "ODS Graphics" section on page 1664 in Chapter 29, "The UCM Procedure."

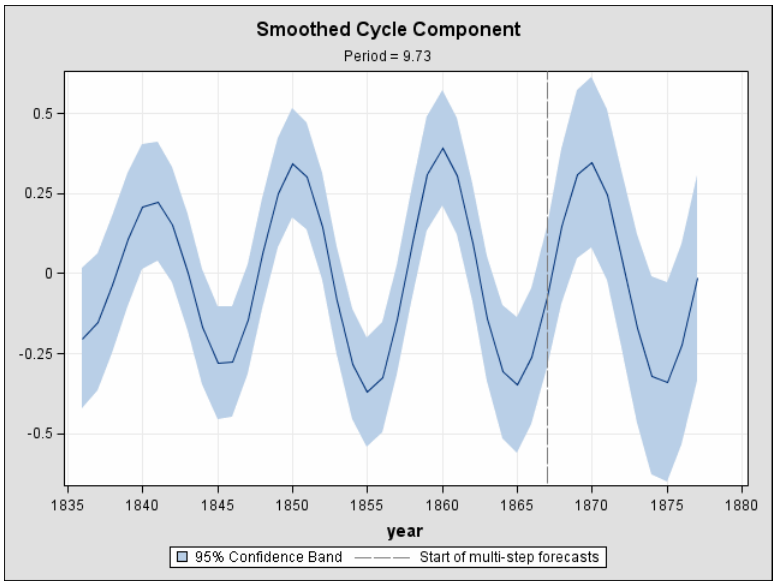

Figure 9.9. Smoothed Cycle Component Plot

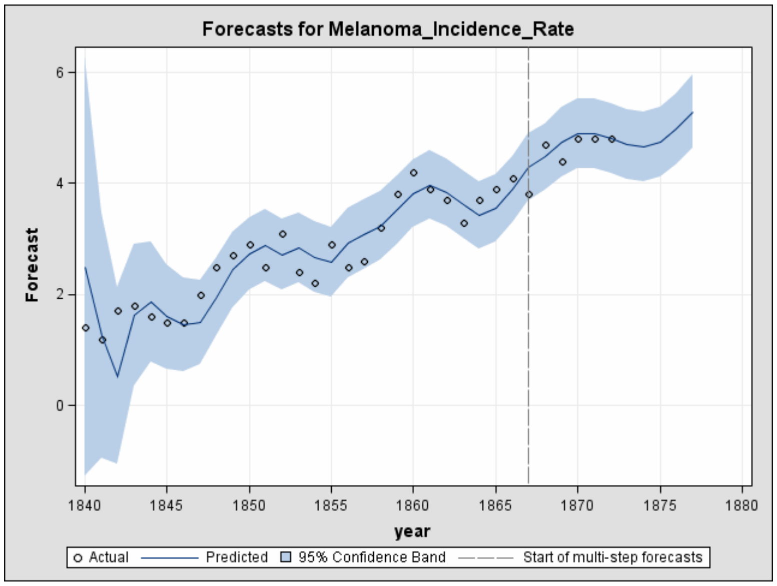

Figure 9.10. Forecasts Plot

A sample program named odsgrgs.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Managing Your Graphics

This section describes techniques for managing your graphics:

- specifying an ODS destination for graphics
- viewing your graphs in the SAS windowing environment
- referring to graphs by name when using ODS
- selecting and excluding graphs from your output
- modifying the appearance of all your graphs with styles

Specifying an ODS Destination for Graphics

Whenever you use ODS Graphics you must specify a valid ODS destination. The examples in "Getting Started" illustrate how to specify an HTML destination. Other destinations are specified in a similar way. For example, you can specify an RTF destination with the following statements.

```
ods rtf;
ods graphics on;

   ...SAS statements...

ods graphics off;
ods rtf close;
```

The supported ODS destinations are shown in Table 9.1.

Table 9.1. Destinations Supported by ODS Graphics

Destination	**Destination Family**	**Viewer**
DOCUMENT		Not Applicable
HTML	MARKUP	Browser
LATEX	MARKUP	Ghostview
PCL	PRINTER	Ghostview
PDF	PRINTER	Acrobat
PS	PRINTER	Ghostview
RTF		Microsoft Word

Note: In SAS 9.1 the LISTING destination does not support ODS Graphics. You must specify a supported ODS destination in order to produce ODS Graphics, as illustrated by all the examples in this chapter.

Specifying a File for ODS Output

You can specify a file name for your output with the FILE= option in the ODS destination statement, as in the following example:

```
ods html file = "test.htm";
```

The output is written to the file test.htm, which is saved in the SAS current folder. At startup, the SAS current folder is the same directory in which you start your SAS session. If you are running SAS with the windowing environment in the Windows operating system, then the current folder is displayed in the status line at the bottom of the main SAS window, as shown in Figure 9.11.

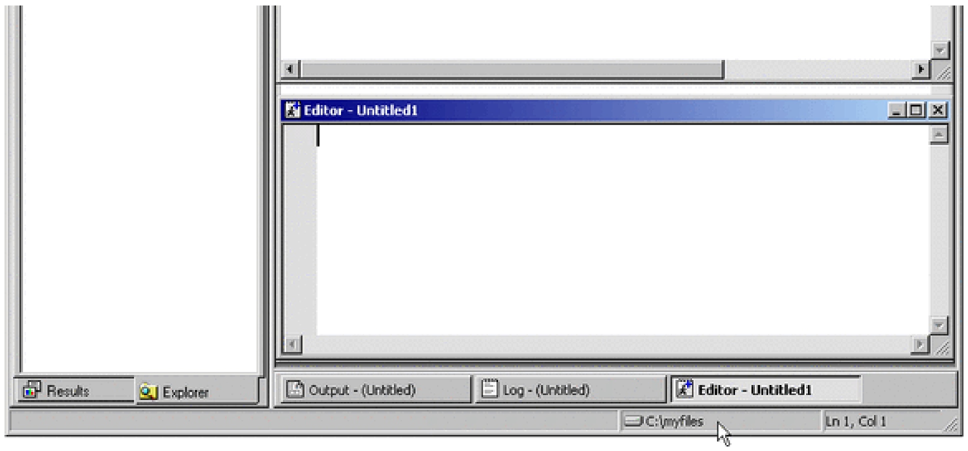

Figure 9.11. Current Folder (Right Bottom)

If you do not specify a file name for your output, then SAS provides a default file, which depends on the ODS destination. This file is saved in the SAS current folder. You can always check the SAS log to verify the name of the file in which your output is saved. For example, suppose you specify the following statement at startup:

```
ods html;
```

Then the following message is displayed in the SAS log:

```
NOTE: Writing HTML Body file: sashtml.htm
```

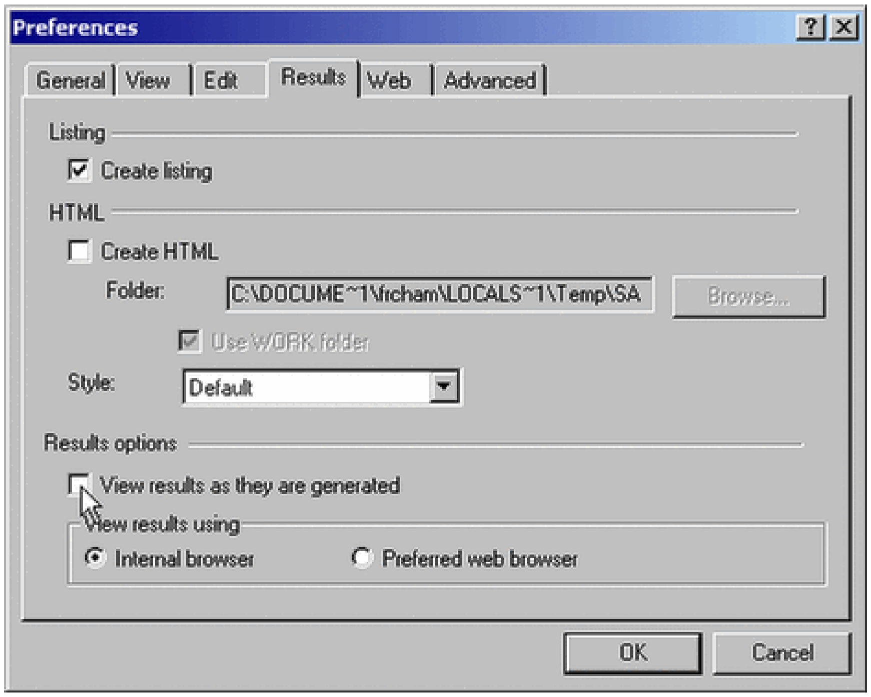
The default file names for each destination are specified in the SAS Registry. For more information, refer to the SAS Companion for your operating system.

Viewing Your Graphs in the SAS Windowing Environment

The mechanism for viewing graphics created with ODS can vary depending on your operating system, which viewers are installed on your computer, and the ODS destination you have selected.

If you are using the SAS windowing environment in the Windows operating system and you specify an HTML destination, then by default the results are displayed in the SAS Results Viewer as they are being generated. Depending on your configuration, this may also apply to the PDF and RTF destinations.* For information about the windowing environment in a different operating system, refer to the SAS Companion for that operating system.

If you do not want to view the results as they are being generated, then select **Tools** → **Options** → **Preferences...** from the menu at the top of the main SAS window. Then in the **Results** tab disable **View results as they are generated**, as shown in Figure 9.12.



Preferences

General | View | Edit | Results | Web | Advanced

Listing
[✓] Create listing

View results using
(●) Internal browser ( ) Preferred web browser

Figure 9.12. Disabling View of Results as Generated

*If you are using the LATEX or the PS destinations you must use a PostScript viewer, such as Ghostview.

You can change the default to use an external viewer instead of the Results Viewer. Select **Tools** → **Options** → **Preferences. . .** from the menu at the top of the main SAS window. Then in the **Results** tab select **Preferred web browser**, as shown in Figure 9.13. Your results will then be displayed in the default viewer that is configured in your computer for the corresponding destination.

Referring to Graphs by Name

Procedures assign a name to each graph they create with ODS Graphics. This enables you to refer to ODS graphs in the same way that you refer to ODS tables (see the "Using the Output Delivery System" section on page 244 in Chapter 8, "Using the Output Delivery System"). You can determine the names of graphs in several ways:

- You can look up graph names in the "ODS Graphics" section of chapters for procedures that use ODS Graphics. See, for example, the "ODS Graphics" section on page 1166 in Chapter 20, "The MODEL Procedure."
- You can use the Results window to view the names of ODS graphs created in your SAS session. See the section "Using ODS with the SAS Explorer" on page 247 for more information.
- You can use the ODS TRACE ON statement to list the names of graphs created by your SAS session. This statement adds identifying information in the SAS log (or, optionally, in the SAS listing) for each graph that is produced. See page 279 for an example, and the "Using the Output Delivery System" section on page 244 for more information.

Note that the graph name is not the same as the name of the file containing the graph (see page 284).

Selecting and Excluding Graphs

You can use graph names to specify which ODS graphs are displayed with the ODS SELECT and ODS EXCLUDE statements. See the section "Using the Output Delivery System" on page 244 for information on how to use these statements.

Example

This example revisits the analysis described in the section "Using the ODS GRAPHICS Statement and Procedure Options" on page 272.

To determine which output objects are created by ODS, you specify the ODS TRACE ON statement prior to the procedure statements.

```
ods trace on;

ods html;
ods graphics on;

proc ucm data=melanoma;
   id year interval=year;
   model Melanoma_Incidence_Rate;
   irregular;
   level variance=0 noest;
   slope variance=0 noest;
   cycle rho=1 noest=rho plot=smooth;
   estimate back=5;
   forecast back=5 lead=10 plot=forecasts print=none;
run;

ods graphics off;
ods html close;
```

Figure 9.15 displays an extract from the trace record, which is added to the SAS log. By default, the UCM procedure creates several table objects and two graph objects named "SmoothedCyclePlot" and "ModelForecastsPlots." In addition to the name, the trace record provides the label, template, and path for each output object. Graph templates are distinguished from table templates by a naming convention that uses the procedure name in the second level and the word "Graphics" in the third level. For example, the fully qualified template name for the forecasts plot created by PROC UCM, as shown in Figure 9.15, is

```
Ets.UCM.Graphics.ModelForecastsPlot
```

```
Output Added:
-------------
Name:       DataSet
Label:      Input Data Set
Template:   ETS.UCM.DataSet
Path:       UCM.DataSet
-------------
.
.
.

Output Added:
-------------
Name:       Forecasts
Label:      Forecasts
Template:   ets.UCM.Forecasts
Path:       UCM.Results.Forecasts
-------------
WARNING: Statistical graphics displays created with ODS are
         experimental in this release.

Output Added:
-------------
Name:       SmoothedCyclePlot
Label:      Smoothed Cycle Component
Template:   ets.UCM.Graphics.S_Cycle
Path:       UCM.Results.SmoothedCyclePlot
-------------

Output Added:
-------------
Name:       ModelForecastsPlot
Label:      Model and Forecast Plot
Template:   ets.UCM.Graphics.ModelForecastsPlot
Path:       UCM.Results.ModelForecastsPlot
-------------
```

Figure 9.15. Extract from the ODS Trace Record in SAS Log

Note that you can specify the LISTING option in the ODS TRACE ON statement to write the trace record to the LISTING destination:

```
   ods trace on / listing;
```

The following statements use the ODS SELECT statement to specify that only the two graph objects named “Contour” and “SurfacePlot” are to be included in the HTML output.

```
   ods html;
   ods graphics on;

   ods select ModelForecastsPlot;

   proc ucm data=melanoma noprint;
      id year interval=year;
      model Melanoma_Incidence_Rate;
      irregular;
      level variance=0 noest;
      slope variance=0 noest;
      cycle rho=1 noest=rho plot=smooth;
      estimate back=5;
      forecast back=5 lead=10 plot=(forecasts) print=none;
   run;

   ods graphics off;
   ods html close;
```

A sample program named odsgrgs.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Specifying Styles for Graphics

ODS styles control the overall look of your output. A style definition provides formatting information for specific visual aspects of your SAS output. For ODS tables this information typically includes a list of font definitions (each font defines a family, size, weight, and style) and a list of colors, which are associated with common areas of printed output, including titles, footnotes, by-groups, table headers, and table cells.

Starting with SAS 9, ODS styles also include graphical appearance information such as line and marker properties in addition to font and color information. Furthermore, in SAS 9.1, ODS styles include graphics appearance informats for common elements of statistical graphics created with ODS Graphics. These elements include fitted lines, confidence and prediction bands, and outliers.

For more information about styles, refer to the "TEMPLATE Procedure: Creating a Style Definition" in the *SAS Output Delivery System User's Guide*.

Specifying a Style

You can specify a style using the STYLE= option in a valid ODS destination,* such as HTML, PDF, RTF, or PRINTER. Each style produces output with the same content, but a somewhat different visual appearance. For example, the following statement request output using the "Journal" style.

```
   ods html style = Journal;
```

Any SAS-supplied or user-defined style can be used for ODS Graphics. However, of the SAS-supplied styles for SAS 9.1, four are specifically designed and recommended for use with ODS Graphics:

*Style definitions do not apply to the LISTING destination, which uses the SAS monospace format by default for output tables. The LISTING destination is not a valid destination for ODS Graphics in SAS 9.1.

- Analysis
- Default
- Journal
- Statistical

Figure 9.16 and Figure 9.17 illustrate the difference between the "Default" and the "Journal" styles for the HTML destination. Note that the appearance of tables and graphics is coordinated within a particular style. This is also illustrated in the series of examples starting with Example 9.11.

For more information about styles for ODS Graphics, see the section "Styles for Graphics" on page 293 or refer to the "ODS Statistical Graphics and ODS Styles: Usage and Reference (Experimental)" at
http://support.sas.com/documentation/onlinedoc/base/.

Graphics Image Files

Accessing your graphs as individual image files is useful when you want to include them in various types of documents. The default image file type depends on the ODS destination, but there are other supported image file types that you can specify. You can also specify the names for your graphics image files and the directory in which you want to save them.

This section describes the image file types supported by ODS Graphics, and it explains how to name and save graphics image files.

Describing Supported Image File Types

If you are using an HTML or a LATEX destination, your graphs are individually produced in a specific image file type, such as GIF or PostScript.

If you are using a destination in the PRINTER family or the RTF destination, the graphs are contained in the ODS output file and cannot be accessed as individual image files. However, you can open an RTF output file in Microsoft Word and then copy and paste the graphs into another document, such as a Microsoft PowerPoint presentation; this is illustrated in Example 9.3.

Table 9.2 shows the various ODS destinations supported by ODS Graphics, the viewer that is appropriate for displaying graphs in each destination, and the image file types supported for each destination.

Table 9.2. Destinations and Image File Types Supported by ODS Graphics

Destination	Destination Family	Viewer	Image File Types
DOCUMENT		Not Applicable	Not Applicable
HTML	MARKUP	Browser	GIF (default), JPEG, PNG
LATEX	MARKUP	Ghostview	PostScript (default), EPSI, GIF, JPEG, PNG
PCL	PRINTER	Ghostview	Contained in PostScript file
PDF	PRINTER	Acrobat	Contained in PDF file
PS	PRINTER	Ghostview	Contained in PostScript file
RTF		Microsoft Word	Contained in RTF file

Note: In SAS 9.1 the LISTING destination does not support ODS Graphics. You must specify a supported ODS destination in order to produce ODS Graphics, as illustrated by all the examples in this chapter.

Naming Graphics Image Files

The names of graphics image files are determined by a *base file name*, an *index counter*, and an *extension*. By default, the base file name is the ODS graph name (see page 278). The index counter is set to zero when you begin a SAS session, and it is increased by one after you create a graph, independently of the graph type or the SAS procedure that creates it. The extension indicates the image file type.

For instance, if you run the example on page 272 at the beginning of a SAS session, the two graphics image files created are SmoothedCyclePlot0.gif and ModelForecastsPlot1.gif. If you immediately rerun this example, then ODS creates the same graphs in different image files named SmoothedCyclePlot2.gif and ModelForecastsPlot3.gif.

You can specify the RESET option in the ODS GRAPHICS statement to reset the index counter to zero. This is useful to avoid duplication of graphics image files if you are rerunning a SAS program in the same session.

```
   ods graphics on / reset;
```

Note: The index counter is initialized to zero at the beginning of your SAS session or if you specify the RESET option in the ODS GRAPHICS statement. Graphics image files with the same name are overwritten.

You can specify a base file name for all your graphics image files with the IMAGENAME= option in the ODS GRAPHICS statement. For example:

```
ods graphics on / imagename = "MyName";
```

You can also specify

```
ods graphics on / imagename = "MyName" reset;
```

With the preceding statement, the graphics image files are named MyName0, MyName1, and so on.

You can specify the image file type for the HTML or LATEX destinations with the IMAGEFMT= option in the ODS GRAPHICS statement. For example:

```
ods graphics on / imagefmt = png;
```

For more information, see the "ODS GRAPHICS Statement" section on page 298.

Saving Graphics Image Files

Knowing where your graphics image files are saved and how they are named is particularly important if you are running in batch mode, if you have disabled the SAS Results Viewer (see page 276), or if you plan to access the files for inclusion in a document. The following discussion assumes you are running SAS under the Windows operating system. If you are running on a different operating system, refer to the SAS Companion for your operating system.

Your graphics image files are saved by default in the SAS current folder. If you are using the SAS windowing environment, the current folder is displayed in the status line at the bottom of the main SAS window (see also page 275). If you are running your SAS programs in batch mode, the graphs are saved by default in the same directory where you started your SAS session.

For instance, suppose the SAS current folder is C:\myfiles. If you specify the ODS GRAPHICS statement, then your graphics image files are saved in the directory C:\myfiles. Unlike traditional high resolution graphics created with SAS/GRAPH, ODS Graphics are not temporarily stored in a catalog in your Work directory.

With the HTML and the LATEX destinations, you can specify a directory for saving your graphics image files. With the PRINTER and RTF destinations, you can only specify a directory for your output file. The remainder of this discussion provides details for each destination type.

HTML Destination

If you are using the HTML destination, the individual graphs are created as GIF files by default. You can use the PATH= and GPATH= options in the ODS HTML statement to specify the directory where your HTML and graphics files are saved, respectively. This also gives you more control over your graphs. For example, if you want to save your HTML file named test.htm in the C:\myfiles directory, but you want to save your graphics image files in C:\myfiles\gif, then you specify

```
ods html path  = "C:\myfiles"
         gpath = "C:\myfiles\gif"
         file  = "test.htm";
```

When you specify the URL= suboption with the GPATH= option, SAS creates relative paths for the links and references to the graphics image files in the HTML file. This is useful for building output files that are easily moved from one location to another. For example, the following statements create a relative path to the gif directory in all the links and references contained in test.htm.

```
ods html path  = "C:\myfiles"
         gpath = "C:\myfiles\gif" (url="gif/")
         file  = "test.htm";
```

If you do not specify the URL= suboption, SAS creates absolute paths that are hard-coded in the HTML file; these may cause broken links if you move the files. For more information, refer to the ODS HTML statement in the “Dictionary of ODS Language Statements” (*SAS Output Delivery System User’s Guide*).

LATEX Destination

$\LaTeX$ is a document preparation system for high-quality typesetting. The experimental ODS LATEX statement produces output in the form of a $\LaTeX$ source file that is ready to compile in $\LaTeX$.

When you request ODS Graphics for a LATEX destination, ODS creates the requested graphs as PostScript files by default, and the $\LaTeX$ source file includes references to these image graphics files. You can compile the $\LaTeX$ file or you can access the individual PostScript files to include your graphs in a different $\LaTeX$ document, such as a paper that you are writing.

You can specify the PATH= and GPATH= options in the ODS LATEX statement, as explained previously for the ODS HTML statement. See Example 9.4 for an illustration.

The ODS LATEX statement is an alias for the ODS MARKUP statement using the TAGSET=LATEX option. For more information, refer to the ODS MARKUP statement in the “Dictionary of ODS Language Statements” (*SAS Output Delivery System User’s Guide*).

If you are using a LATEX destination with the default PostScript image file type, your ODS graphs are created in gray-scale, regardless of the style you are using. When you use this destination, it is recommended that you use the "Journal" style to obtain high quality graphics. For more information about styles, see the "Specifying Styles for Graphics" section on page 281.

To create color graphics using a LATEX destination, specify JPEG, GIF, or PNG with the IMAGEFMT= option in the ODS GRAPHICS statement. If you specify GIF you can use a distiller to obtain a PostScript or a PDF file. If you specify JPEG you may need to include the `\DeclareGraphicsExtensions` and the `\DeclareGraphicsRule` commands in the preamble of your LaTeX file. For more information, refer to the LaTeX documentation for the `graphicx` package.

PRINTER and RTF Destinations

If you are using a destination in the PRINTER family (PCL, PDF, PS) or the RTF destination, the graphs are contained in the output file and cannot be accessed as individual graphics image files. You can specify the path where the output file is to be saved using the FILE= option of the ODS destination statement. For example, suppose that you specify

```
ods pdf file = "test.pdf";
```

Then your ODS output is saved as the PDF file test.pdf in the SAS current folder (for example, in C:\myfiles).

You can specify a full path name for your output with the FILE= option. For instance to save your PDF file to the directory C:\temp you specify

```
ods pdf file = "C:\temp\test.pdf";
```

You can always check the SAS log to verify where your output is saved. For example, the preceding statement would result in the following log message:

```
NOTE: Writing ODS PDF output to DISK destination
   "C:\temp\test.pdf", printer "PDF".
```

Customizing Graphics with Templates

This section describes how to locate templates for ODS Graphics, and how to display, edit, and save these templates. It also provides an overview of the graph template language. Before presenting these details, a review of the TEMPLATE procedure terminology is helpful.

A *template definition* is a set of SAS statements that can be run with the TEMPLATE procedure to create a compiled template. Two common types of template definitions are *table definitions* and *style definitions*. A table definition describes how to display the output for an output object that is to be rendered as a table, and a style definition provides formatting information for specific visual aspects of your SAS output.

A third type of template definition is a *graph template definition* (or *graph definition* for short), which controls the layout and details of graphs produced with ODS Graphics. Graph definitions begin with a DEFINE STATGRAPH statement and end with an END statement.

A *template store* is a member of a SAS data library that stores compiled templates created by the TEMPLATE procedure. Default templates supplied by SAS are saved in the Sashelp.Tmplmst template store.

In common applications of ODS Graphics, it should not be necessary to modify the default template for each graph, which is supplied by SAS. However, when customization is necessary, you can modify the default template with the graph template language in the TEMPLATE procedure.

If you are using the SAS windowing environment, the easiest way to display, edit, and save your templates is by using the Templates window. For detailed information about managing templates, refer to the "TEMPLATE Procedure: Managing Template Stores" in the *SAS Output Delivery System User's Guide*.

For details concerning the syntax of the graph template language, refer to the "TEMPLATE Procedure: Creating ODS Statistical Graphics Output (Experimental)" at http://support.sas.com/documentation/onlinedoc/base/.

Locating Templates

The first step in customizing a graph is to determine which template was used to create the original graph. The easiest way to do this is to specify the ODS TRACE ON statement prior to the procedure statements that created the graph. The fully qualified template name is displayed in the SAS log. This is illustrated in Example 9.7 and the section "Using the Output Delivery System" on page 244. Note that the ODS TRACE ON statement applies to graphs just as it does to tables.

Displaying Templates

Once you have found the fully qualified name of a template, you can display its definition using one of these methods:

- Open the Templates window by typing **odstemplates** (or **odst** for short) in the command line, as shown in Figure 9.18. If you expand the **Sashelp.Tmplmst** icon, you can browse all the available templates and double-click on any template icon to display its definition. This is illustrated in Example 9.7.

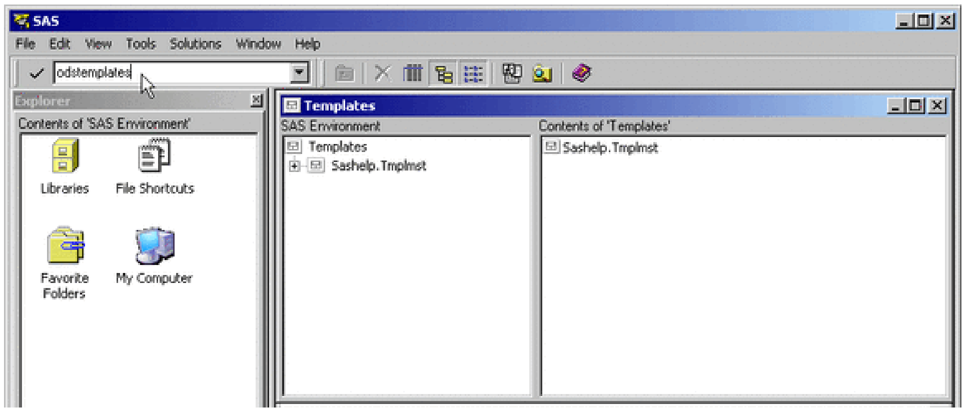

Figure 9.18. Requesting the Templates Window in the Command Line

- Use the SOURCE statement in PROC TEMPLATE to display a template definition in the SAS log. For example, the following statements display the default definition of the residual Q-Q plot in PROC MODEL.

```
proc template;
   source Ets.Model.Graphics.QQPlot;
run;
```

Editing Templates

You can modify the format and appearance of a particular graph by modifying its template. There are several ways to edit a template definition:

- Find the template icon in the Templates window, right-click on the icon, and select **Edit** from the pull-down menu. This opens a Template Editor window in which you can edit the template definition. This approach is illustrated in Example 9.7.
- Find the template icon in the Templates window and double-click on the template icon to display the template definition. Copy and paste the template definition into the Program Editor.
- Use the SOURCE statement with the FILE= option in PROC TEMPLATE. This writes the template definition to a file that you can modify. For example:

```
proc template;
   source Ets.Model.Graphics.QQPlot /
          file = "qqtpl.sas";
run;
```

By default the file is saved in the SAS current folder. Note that with this approach you have to add a PROC TEMPLATE statement before the template definition statements and a RUN statement at the end before submitting your modified definition.

Note: Graph definitions are self-contained and do not support parenting as do table definitions. For more information about graph definitions and the graph template language see the "Introducing the Template Language for Graphics" section on page 291.

Saving Customized Templates

After you edit the template definition you can submit your PROC TEMPLATE statements as you would for any other SAS program:

- If you are using the Template Editor window, select **Submit** from the **Run** menu. For example, see Example 9.7.
- Alternatively, submit your PROC TEMPLATE statements in the Program Editor.

ODS automatically saves the compiled template in the first template store that it can update, according to the currently defined ODS path. If you have not changed the ODS path, then the modified template is saved in the Sasuser.Templat template store. You can display the current ODS path with the following statement.

```
ods path show;
```

By default, the result of this statement is displayed in the SAS log, as illustrated in Figure 9.19.

```
Current ODS PATH list is:

1. SASUSER.TEMPLAT(UPDATE)
2. SASHELP.TMPLMST(READ)
```

Figure 9.19. Result of ODS PATH SHOW Statement

Using Customized Templates

When you create ODS output (either graphs or tables) with a SAS program, ODS searches sequentially through each element of the ODS PATH list for the first template that matches the ODS name of each output object requested. This template is used to produce the output object. If you have not changed the default ODS path, then the first template store searched is Sasuser.Templat, followed by Sashelp.Tmplmst.

Note that you can have templates with the same name in different template stores. The template that is used is the first one found in the ODS path.

The ODS PATH statement specifies which locations to search for definitions that were created by PROC TEMPLATE, as well as the order in which to search for them. You can change the default path by specifying different locations in the ODS PATH statement. For example, the following statement changes the default ODS path so that the first template store searched is Work.Mypath.

```
ods path work.mypath(update) sashelp.tmplmst(read);
```

The UPDATE option provides update access as well as read access to Work.Mypath. The READ option provides read-only access to Sashelp.Tmplmst.

For more information, refer to the ODS PATH Statement in the “Dictionary of ODS Language Statements” (*SAS Output Delivery System User’s Guide*).

Reverting to Default Templates

Customized templates are stored in Sasuser.Templat or in user-defined template stores. The default templates provided by SAS are saved in the read-only template store Sashelp.Tmplmst. Consequently, if you have modified any of the default templates and you want to create ODS Graphics with the original default templates, one way to do so is by changing your ODS path as follows.

```
ods path sashelp.tmplmst(read) sasuser.templat(update);
```

A second approach, which is highly recommended, is to save all your customized templates in a user-defined template store (for example Work.Mypath). Then you can reset the default ODS path with the ODS PATH RESET statement:

```
ods path reset;
```

A third approach is to save your customized definition as part of your SAS program and delete the corresponding template from your Sasuser.Templat template store.

Example 9.7 illustrates all the steps of displaying, editing, saving and using customized templates.

Introducing the Template Language for Graphics

Graph template definitions are written in a *graph template language*, which has been added to the TEMPLATE procedure in SAS 9.1. This language includes statements for specifying plot layouts (such as grids or overlays), plot types (such as scatter plots and histograms), and text elements (such as titles, footnotes, and insets). It also provides support for built-in computations (such as histogram binning) and evaluation of expressions. Options are available for specifying colors, marker symbols, and other attributes of plot features.

Graph template definitions begin with a DEFINE STATGRAPH statement in PROC TEMPLATE, and they end with an END statement. You can specify the DYNAMIC statement to define dynamic variables, the MVAR and NMVAR statements to define macro variables, and the NOTES statement to provide descriptive information about the graph.

The statements available in the graph template language can be classified as follows:

- **Control statements**, which specify conditional or iterative flow of control. By default, flow of control is sequential. In other words, each statement is used in the order in which it appears.
- **Layout statements**, which specify the arrangement of the components of the graph. Layout statements are arranged in blocks which begin with a LAYOUT statement and end with an ENDLAYOUT statement. The blocks can be nested. Within a layout block, you can specify plot, text, and other statement types to define one or more graph components. Statement options provide control for attributes of layouts and components.
- **Plot statements**, which specify a number of commonly used displays, including series plots, autocorrelation plots, histograms, and scatter plots. Plot statements are always provided within a layout block. The plot statements include options to specify which data columns from the source objects are used in the graph. For example, in the SCATTERPLOT statement used to define a scatter plot, there are mandatory X= and Y= options that specify which data columns are used for the x- and y-variables in the plot, and there is a GROUP= option that specifies a data column as an optional classification variable.
- **Text statements**, which specify descriptions accompanying the graphs. An entry is any textual description, including titles, footnotes, and legends, and it can include symbols to identify graph elements.

As an illustration, the following statements display the template definition of the Series plot available in PROC TIMESERIES (see "ODS Graphics" in Chapter 28, "The TIMESERIES Procedure").

```
proc template;
   link Ets.Timeseries.Graphics.SeriesPlot to
        Statgraph.TimeSeries.SeriesPlot;
   define statgraph Statgraph.TimeSeries.SeriesPlot;
      dynamic title Time Series IntegerTime;
      layout Gridded;
         EntryTitle TITLE / padbottom=5;
         layout Overlay /
            XGrid     = True
            YGrid     = True
            XAxisOpts = ( Integer = INTEGERTIME );
            SeriesPlot x = TIME y = SERIES /
               markers      = true
               markercolor  = GraphDataDefault:contrast
               markersymbol = GraphDataDefault:markersymbol
               markersize   = GraphDataDefault:markersize
               linecolor    = StatGraphDataLine:contrastcolor
               linepattern  = StatGraphFitLine:linestyle;
         EndLayout;
      EndLayout;
   end;
run;
```

The DEFINE STATGRAPH statement in PROC TEMPLATE creates the graph template definition. The DYNAMIC statement defines dynamic variables. The variable

TITLE provides the title of the graph. The variables TIME and SERIES contain the time variable and the time series. The variable INTEGERTIME is a binary variable that can assume a value of TRUE or FALSE depending on whether an ID statement is specified in the procedure. You can use these dynamic text variables in any text element of the graph definition.

The overall display is specified with the LAYOUT GRIDDED statement. The title of the graph is specified with the ENTRYTITLE statement inside a layout overlay block, which is nested within the main layout. The main plot is a series plot specified with the SERIESPLOT statement. The options in the SERIESPLOT statement, which are given after the slash, specify the color, symbol,and size for the markers, and color and pattern for the lines using indirect references to style attributes of the form ***style-element:attribute***. The values of these attributes are specified in the definition of the style you are using, and so they are automatically set to different values if you specify a different style. For more information about style references see the "Styles for Graphics" section on page 293.

The second ENDLAYOUT statement ends the main layout block and the END statement ends the graph template definition.

Note: Graph template definitions are self-contained and do not support parenting (inheritance) as do table definitions. The EDIT statement is not supported.

For details concerning the syntax of the graph template language, refer to the "TEMPLATE Procedure: Creating ODS Statistical Graphics Output (Experimental)" at http://support.sas.com/documentation/onlinedoc/base/.

Styles for Graphics

This section provides an overview of the style elements for ODS Graphics. It also describes how to customize a style definition and how to specify a default style for all your output.

Introducing Style Elements for Graphics

An ODS style definition is composed of a set of *style elements*. A style element is a collection of *style attributes* that apply to a particular feature or aspect of the output. A value is specified for each attribute in a style definition.

Style definitions control the overall appearance of ODS tables and graphs. For ODS tables, style definitions specify features such as background color, table borders, and color scheme, and they specify the fonts, sizes, and color for the text and values in a table and its headers. For ODS graphs, style definitions specify the following features:

- background color
- graph dimensions (height and width). See Example 9.13 for an illustration.
- borders
- line styles for axes and grid lines

- fonts, sizes, and colors for titles, footnotes, axis labels, axis values, and data labels. See Example 9.11 for an illustration.
- marker symbols, colors, and sizes for data points and outliers
- line styles for needles
- line and curve styles for fitted models and predicted values. See Example 9.12 for an illustration.
- line and curve styles for confidence and prediction limits
- fill colors for histogram bars, confidence bands, and confidence ellipses
- colors for box plot features
- colors for surfaces
- color ramps for contour plots

In the templates supplied by SAS for ODS graphs, options for plot features are always specified with a style reference of the form ***style-element:attribute*** rather than a hard-coded value. For example, the symbol, color, and size of markers for basic series plots are specified in a template SERIESPLOT statement as follows:

```
SeriesPlot x=TIME y=SERIES /
   markercolor  = GraphDataDefault:contrast
   markersymbol = GraphDataDefault:markersymbol
   markersize   = GraphDataDefault:markersize;
```

This guarantees a common appearance for markers used in all basic series plots, which is controlled by the **GraphDataDefault** element of the style definition that you are using.

In general, the ODS graph features listed above are determined by style element attributes unless they are overridden by a statement or option in the graph template.

In order to create your own style definition or to modify a style definition for use with ODS Graphics, you need to understand the relationships between style elements and graph features. This information is provided in the section “ODS Statistical Graphics and ODS Styles: Usage and Reference (Experimental)” at http://support.sas.com/documentation/onlinedoc/base/.

Style definitions are created and modified with the TEMPLATE procedure. For more information, refer to the “TEMPLATE Procedure: Creating a Style Definition” in the *SAS Output Delivery System User’s Guide*.

Customizing Style Definitions

The default style definitions that SAS provides are stored in the “Styles” directory of Sashelp.Tmplmst.

You can display, edit, and save style definitions using the same methods available for modifying template definitions, as explained in the sections beginning on page 288. In particular, you can display style definitions using one of these methods:

- If you are using the Templates window in the SAS windowing environment, expand the **Sashelp.Tmplmst** node under **Templates**, and then select **Styles** to display the contents of this folder.
- Use the SOURCE statement in PROC TEMPLATE. For example, the following statements display the "Journal" style definition in the SAS log.

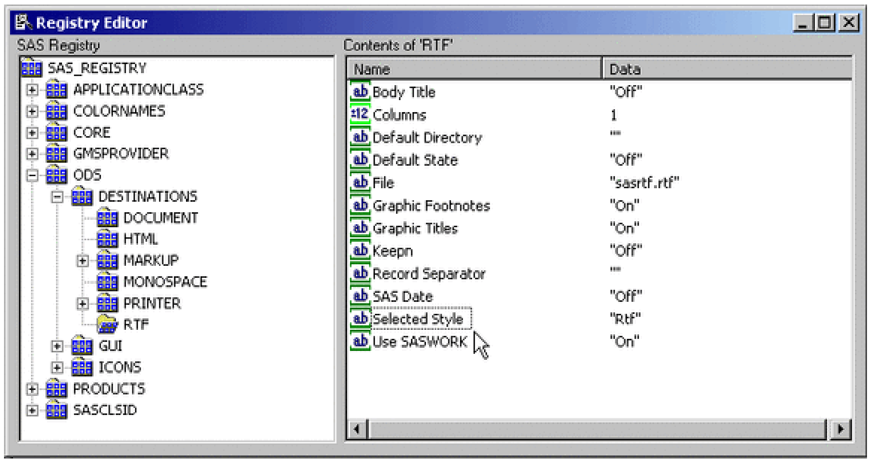
```
proc template;
   source Styles.Journal;
run;
```

Specifying a Default Style

The default style for each ODS destination is specified in the SAS Registry. For example, the default style for the HTML destination is "Default," and for the RTF destination it is "Rtf."

You can specify a default style for all your output in a particular ODS destination. This is useful if you want to use a different SAS-supplied style, if you have modified one of the SAS-supplied styles (see page 294), or if you have defined your own style. For example, you can specify the "Journal" style for all your RTF output.

The recommended approach for specifying a default style is as follows. Open the SAS Registry Editor by typing **regedit** in the command line. Expand the node **ODS** → **DESTINATIONS** and select a destination (for example, select **RTF**). Double-click the **Selected Style** item, as illustrated in Figure 9.20, and specify a style. This can be any SAS-supplied style or a user-defined style, as long as it can be found with the current ODS path (for example, specify **Journal**). You can specify a default style for the HTML, MARKUP, and PRINTER destinations in a similar way.



Name	Data
Body Title	"Off"
Columns	1
Default Directory	""
Default State	"Off"
File	"sasrtf.rtf"
Graphic Footnotes	"On"
Graphic Titles	"On"
Keepn	"Off"
Record Separator	""
SAS Date	"Off"
Selected Style	"Rtf"
Use SASWORK	"On"

Figure 9.20. SAS Registry Editor

Note: ODS searches sequentially through each element of the ODS PATH list for the first style definition that matches the name of the style specified in the SAS Registry. The first style definition found is used. If you are specifying a customized style as your default style, the following are useful suggestions:

- If you save your style in Sasuser.Templat, verify that the name of your default style matches the name of the style specified in the SAS Registry. For example suppose the “Rtf” style is specified for the RTF destination in the SAS Registry. You can name your style Rtf and save it in Sasuser.Templat. This blocks the “Rtf” style in Sashelp.Tmplmst.
- If you save your style in a user-defined template store, verify that this template store is the first in the current ODS PATH list. Include the ODS PATH statement in your SAS autoexec file so that it is executed at startup.

For the HTML destination, an alternative approach for specifying a default style is as follows. From the menu at the top of the main SAS window select **Tools** → **Options** → **Preferences. . . .** In the **Results** tab check the **Create HTML** box and select a style from the pull-down menu. This is illustrated in Figure 9.21.

Figure 9.21. Selecting a Default Style for HTML Destination

Details

Procedures Supporting ODS Graphics

The following SAS procedures support ODS Graphics in SAS 9.1:

Base SAS

- CORR

SAS/ETS

- ARIMA
- AUTOREG
- ENTROPY
- EXPAND
- MODEL
- SYSLIN
- TIMESERIES
- UCM
- VARMAX
- X12

SAS High-Performance Forecasting

- HPF

SAS/STAT

- ANOVA
- CORRESP
- GAM
- GENMOD
- GLM
- KDE
- LIFETEST
- LOESS
- LOGISTIC
- MI
- MIXED
- PHREG
- PRINCOMP
- PRINQUAL
- REG
- ROBUSTREG

For details on the specific graphs available with a particular procedure, see the “ODS Graphics” section in the corresponding procedure chapter.

Operating Environments Supporting ODS Graphics

The following operating systems are supported:

- Windows (32- and 64- bit)
- OpenVMS Alpha
- z/OS (OS/390)
- UNIX (AIX, HP-UX, Tru64 UNIX, Solaris, Linux)

For information specific to an operating system, refer to the SAS Companion for that operating system.

Creating ODS Graphics in z/OS

Creating ODS Graphics with the z/OS (OS/390) operating system requires the following to be configured by your System Administrator:

- Java
- UNIX File System components

For more information, refer to the sections “Installing UNIX File System Components” and “Configuring SAS Software for Use with the Java Platform” of the *SAS System Configuration Guide*.

In addition, when you specify an ODS HTML destination you must specify the PATH= or GPATH= option with a valid UNIX directory.

ODS GRAPHICS Statement

The basic syntax for enabling ODS Graphics is

```
ods graphics on;
```

You specify this statement prior to your procedure statements, as illustrated in the “Using the ODS GRAPHICS Statement” section on page 267. Any procedure that supports ODS Graphics then produces graphics, either by default or when you specify procedure options for requesting particular graphs.

To disable ODS Graphics, specify

```
ods graphics off;
```

The following is a summary of the ODS GRAPHICS statement syntax. You can find the complete syntax in the section ODS Graphics Statement in the “Dictionary of ODS Language Statements” (*SAS Output Delivery System User’s Guide*).

Syntax

ODS GRAPHICS < **OFF | ON** < / *options* > > **;**

enables ODS to create graphics automatically. The default is ON.

Options

ANTIALIAS | NOANTIALIAS
ANTIALIAS = ON | OFF

controls the use of antialiasing to smooth the components of a graph.

OFF

suppresses the use of antialiasing for components other than text.

ON

specifies that antialiasing is to be used to smooth jagged edges of all of the components in a graph.

Text displayed in a graph is always antialiased. If the number of observations in the ODS output object exceeds 250, then antialiasing is not used, even if you specify the option ANTIALIAS=ON. The default is ON.

IMAGEFMT = < *image-file-type* **| STATIC | STATICMAP** >

specifies the image file type (directly or indirectly) for displaying graphics in ODS output. The default image file type depends on the ODS destination; it is used when you specify IMAGEFMT=STATIC. You can also specify other supported image file types. This option only applies to ODS Graphics, and it has no effect on traditional high resolution graphics that rely on GOPTIONS values. The default is STATIC.

image-file-type

specifies the type of image you want to add to your graph. If the image file type is not valid for the active output destination, the default is used instead. Table 9.3 lists the image file types supported for the ODS destinations that are valid with ODS Graphics.

STATIC

specifies the best quality image file type for the active output destination.

STATICMAP

applies only with the HTML destination and specifies that an HTML image map is to be created for tool tip support. The image file type used is the same as with STATIC. For an illustration see Example 9.2. If the number of observations in the data set exceeds 500, the image map is not generated.

Table 9.3. Supported Destinations and Image File Types

Destination	**Values for IMAGEFMT= Option**
HTML	GIF (default), JPEG, PNG
LATEX	PS (default), EPSI, GIF, JPEG, PNG
PCL	Not applicable
PDF	Not applicable
PS	Not applicable
RTF	Not applicable

Note: For PCL, PDF, PS, and RTF, the IMAGEFMT= option is not applicable because the graph is contained in the output file. See Table 9.2.

IMAGENAME = <*file-name*>

specifies the base image file name. The default is the name of the output object. You can determine the name of the output object by using the ODS TRACE statement. The base image name should not include an extension. ODS automatically adds the increment value and the appropriate extension (which is specific to the output destination that has been selected).

RESET

resets the index counter appended to image file names.

Note: The index counter is initialized to zero at the beginning of your SAS session or if you specify the RESET option in the ODS GRAPHICS statement. Graphics image files with the same name are overwritten.

Examples

This section provides a series of examples which illustrate various tasks that can be performed with ODS Graphics. The examples are presented in increasing order of task complexity and should be read sequentially.

Example 9.1. Selecting and Excluding Graphs

This example illustrates how to select and exclude ODS graphs from your output.

The “Getting Started” example on page 267 uses the MODEL procedure to produce the plots shown in Figure 9.1 through Figure 9.8.

The ODS TRACE ON statement requests a record of the output objects created by ODS, which is displayed in the SAS log as shown in Output 9.1.1.

```
ods trace on;

ods html;
ods graphics on;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;

ods graphics off;
ods html close;
```

Output 9.1.1. Partial ODS Trace Record in SAS Log

```
Output Added:
-------------
Name:       ModSummary
Label:      Variable Counts
Template:   ets.model.ModSummary
Path:       Model.ModSum.ModSummary
-------------

.
.
.

Output Added:
-------------
Name:       EstSummaryStats
Label:      Estimation Summary Statistics
Template:   ets.model.EstSummaryStats
Path:       Model.OLS.EstSummaryStats
-------------
WARNING: Statistical graphics displays created with ODS are
         experimental in this release.

Output Added:
-------------
Name:       StudentResidualPlot
Label:      Studentized Residuals of LHUR
Template:   ETS.Model.Graphics.StudentResidualPlot
Path:       Model.OLS.StudentResidualPlot
-------------

Output Added:
-------------
Name:       CooksD
Label:      Cook’s D for the Residuals of LHUR
Template:   ETS.Model.Graphics.CooksD
Path:       Model.OLS.CooksD
-------------

.
.
.

Output Added:
-------------
Name:       ResidualHistogram
Label:      Histogram of Residuals of LHUR
Template:   ETS.Model.Graphics.ResidualHistogram
Path:       Model.OLS.ResidualHistogram
-------------
```

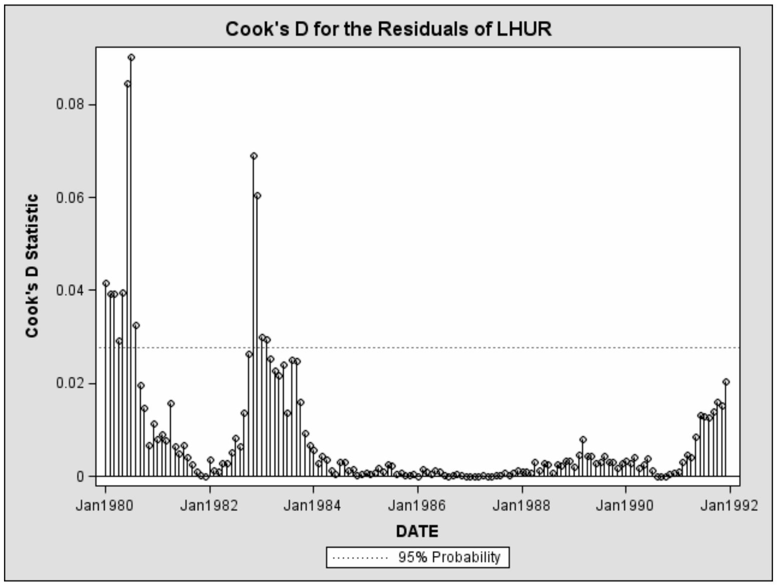
You can use the ODS SELECT statement to restrict your output to a particular subset of ODS tables or graphs. The following statements restrict the output to the Cook’s D plot, which is shown in Output 9.1.2.

```
ods html;
ods graphics on;

proc model data=sashelp.citimon;
   ods select CooksD;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;

ods graphics off;
ods html close;
```

Output 9.1.2. Cook's D Plot



Conversely, you can use the ODS EXCLUDE statement to display all the output with the exception of a particular subset of tables or graphs. For example, to exclude the studentized residuals plot from the output you specify

```
ods exclude StudentResidualPlot;
```

See the "Selecting and Excluding Graphs" section on page 279 for further information.

A sample program named odsgr01.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.2. Creating Graphs with Tool Tips in HTML

This example demonstrates how to request graphics in HTML with tool tip displays, which appear when you move a mouse over certain features of the graph. When you specify the HTML destination and the IMAGEFMT=STATICMAP option in the ODS GRAPHICS statement, then the HTML file output file is generated with an image map of coordinates for tool tips. The individual graphs are saved as GIF files.

Example 28.3 of Chapter 28, “The TIMESERIES Procedure” utilizes the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers.

The following statements request a plot of the series of electrical workers using the PLOT option in the PROC TIMESERIES statement.

```
ods html;
ods graphics on / imagefmt = staticmap;

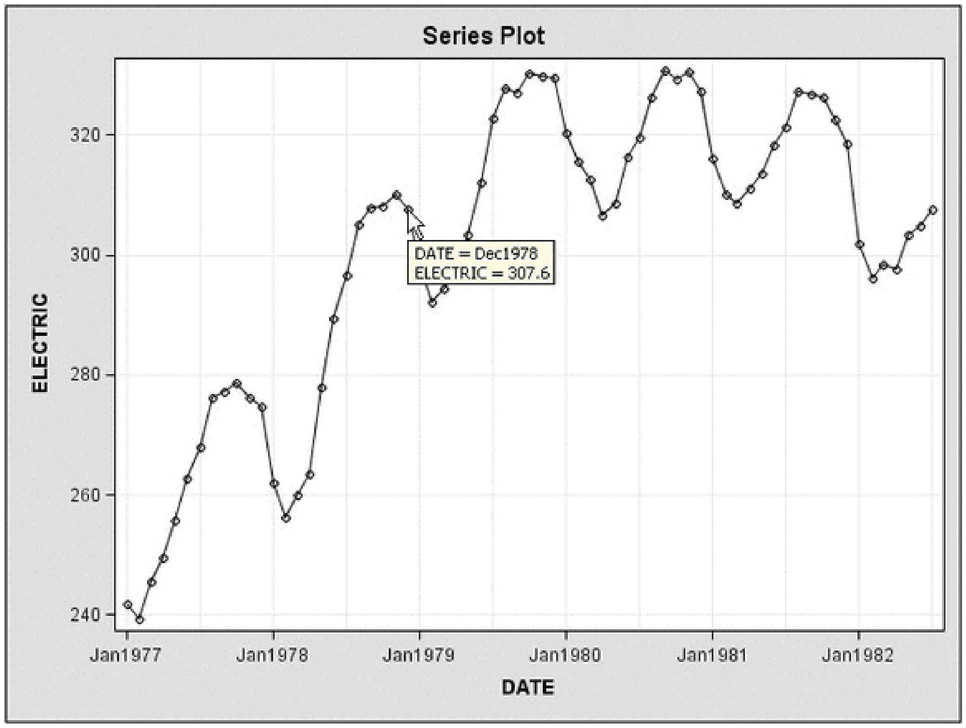
proc timeseries data=sashelp.workers out=_null_
   plot=series;
   id date interval=month;
   var electric;
   crossvar masonry;
run;

ods graphics off;
ods html close;
```

Output 9.2.1 displays the series plot that is included in the HTML output.

Moving the mouse over a data point shows a tool tip with the corresponding identifying information.

Output 9.2.1. Series Plot with Tool Tips



Note: Graphics with tool tips are only supported for the HTML destination.

A sample program named odsgr02.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.3. Creating Graphs for a Presentation

The RTF destination provides the easiest way to create ODS graphs for inclusion in a document or presentation. You can specify the ODS RTF statement to create a file that is easily imported into a word processor (such as Microsoft Word or WordPerfect) or a presentation (such as Microsoft PowerPoint).

In this example, the following statements request that the output of Example 9.1 be saved in the file model.rtf.

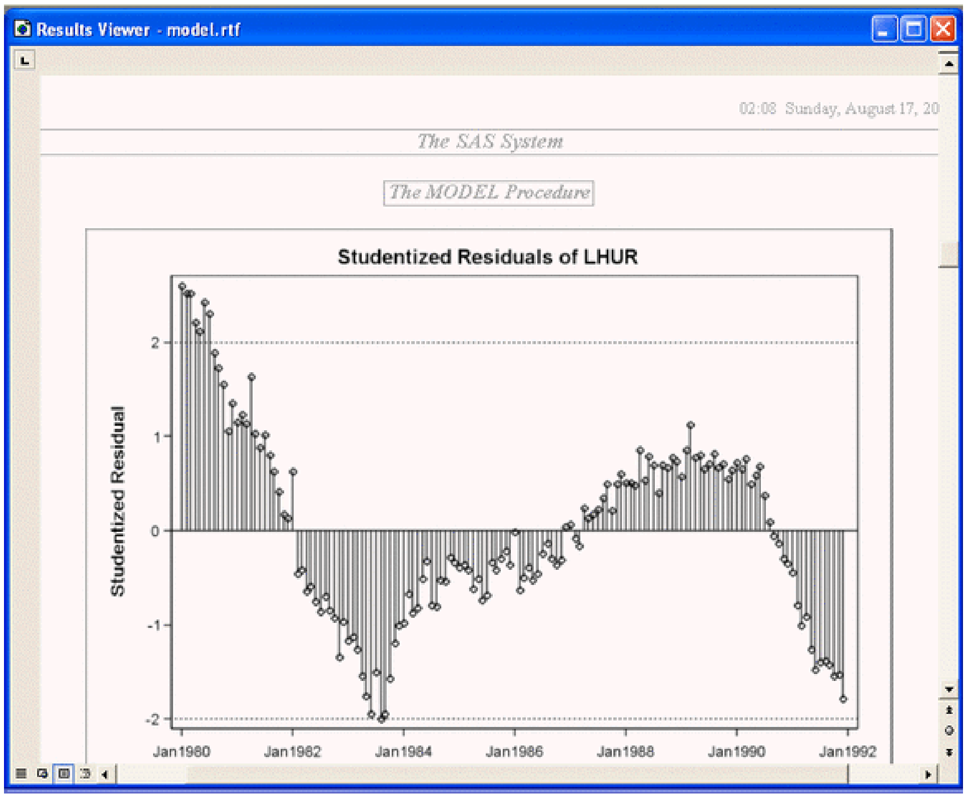
```
ods rtf file = "model.rtf";
ods graphics on;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;

ods graphics off;
ods rtf close;
```

The output file includes various tables and the following plots: a studentized residual plot, a Cook's D plot, a predicted by actual values plot, an autocorrelation of residuals, a partial autocorrelation of residuals, an inverse autocorrelation of residuals, a QQ plot of residuals, and a histogram of the residuals. The studentized residuals plot is shown in Output 9.3.1.

Output 9.3.1. Studentized Residuals Plot



If you are running SAS in the Windows operating system, it is easy to include your graphs in a Microsoft PowerPoint presentation when you generate RTF output. You can open the RTF file in Microsoft Word and simply copy and paste the graphs into Microsoft PowerPoint. In general, RTF output is convenient for exchange of graphical results between Windows applications through the clipboard.

Alternatively, if you request ODS Graphics using the HTML destination, then your individual graphs are created as GIF files by default. You can insert the GIF files into a Microsoft PowerPoint presentation. See "Naming Graphics Image Files" and "Saving Graphics Image Files" for information on how the image files are named and saved.

A sample program named odsgr03.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.4. Creating Graphs in PostScript Files

This example illustrates how to create individual graphs in PostScript files, which is particularly useful when you want to include them in a LaTeX document.

The following statements specify a LATEX destination[*] for the output in Example 9.3 with the “Journal” style.

```
ods latex style=Journal;
ods graphics on;

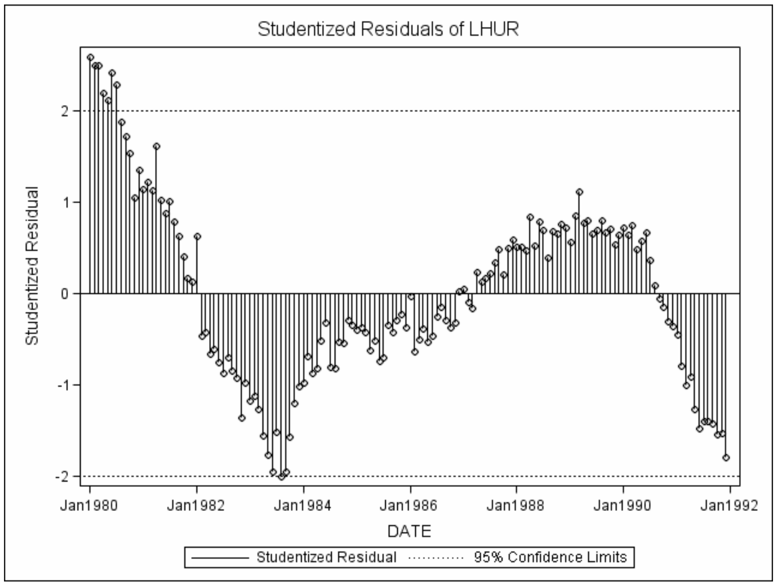
proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;

ods graphics off;
ods latex close;
```

The “Journal” style displays gray-scale graphs that are suitable for a journal. When you specify the ODS LATEX destination, ODS creates a PostScript file for each individual graph in addition to a LaTeX source file that includes the tabular output and references to the PostScript files. By default these files are saved in the SAS current folder. If you run this example at the beginning of your SAS session, the studentized residual plot shown in Output 9.4.1 is saved by default in a file named StudentResidualPlot0.ps. See page 284 for details about how graphics image files are named.

[*]The LATEX destination in ODS is experimental in SAS 9.1.

Output 9.4.1. Histogram Using Journal Style



If you are writing a paper, you can include the graphs in your own LaTeX source file by referencing the names of the individual PostScript graphics files. In this situation, you may not find necessary to use the LaTeX source file created by SAS.

If you specify PATH= and GPATH= options in the ODS LATEX statement, your tabular output is saved as a LaTeX source file in the directory specified with the PATH= option, and your graphs are saved as PostScript files in the directory specified with the GPATH= option. This is illustrated by the following statements:

```
ods latex path  = "C:\temp"
          gpath = "C:\temp\ps" (url="ps/")
          style = Journal;
ods graphics on;

   ...SAS statements...

ods graphics off;
ods latex close;
```

The URL= suboption is specified in the GPATH= option to create relative paths for graphs referenced in the LaTeX source file created by SAS. See the "HTML Destination" section on page 286 for further information.

A sample program named odsgr04.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.5. Creating Graphs in Multiple Destinations

This example illustrates how to send your output to more than one destination with a single execution of your SAS statements.

For instance, to create both HTML and RTF output, you can specify the ODS HTML and the ODS RTF statements before your procedure statements.

```
ods html;
ods rtf;

   ...SAS statements...

ods _all_ close;
```

The ODS _ALL_ CLOSE statement closes all open destinations.

You can also specify multiple instances of the same destination. For example, using the data in the "Using the ODS GRAPHICS Statement and Procedure Options" section on page 272, the following statements save the smoothed cycle component plot to the file smoothcycle.pdf and the forecasts plot to the file forecasts.pdf.

```
ods pdf file="smoothcycle.pdf";
ods pdf select SmoothedCyclePlot;

ods pdf(id=frcst) file="forecasts.pdf";
ods pdf(id=frcst) select ModelForecastsPlot;

ods graphics on;

proc ucm data=melanoma noprint;
   id year interval=year;
   model Melanoma_Incidence_Rate;
   irregular;
   level variance=0 noest;
   slope variance=0 noest;
   cycle rho=1 noest=rho plot=smooth;
   estimate back=5;
   forecast back=5 lead=10 plot=forecasts print=none;
run;

ods graphics off;
ods _all_ close;
```

The ID= option assigns the name srf to the second instance of the PDF destination. Without the ID= option, the second ODS PDF statement would close the destination that was opened by the previous ODS PDF statement, and it would open a new instance of the PDF destination. In that case, the file smoothcycle.pdf would contain no output. For more information, refer to the Example 1 of the ODS PDF statement in the "Dictionary of ODS Language Statements" (*SAS Output Delivery System User's Guide*).

Example 9.6. Displaying Graphs Using the DOCUMENT Procedure

This example illustrates the use of the DOCUMENT destination and the DOCUMENT procedure to display your ODS graphs. In particular, this is useful when you want to display your output (both tables and graphs) in one or more ODS destinations, or when you want to use different styles without rerunning your SAS program.

In general, when you send your output to the DOCUMENT destination you can use the DOCUMENT procedure to rearrange, duplicate, or remove output from the results of a procedure or a database query. You can also generate output for one or more ODS destinations. For more information, refer to the ODS DOCUMENT statement in the “Dictionary of ODS Language Statements” and “The DOCUMENT Procedure” (*SAS Output Delivery System User’s Guide*).

The following statements repeat the estimation of the model in Example 9.1. The ODS DOCUMENT statement stores the data for the tables and the plots from this analysis in an ODS document named lhurDoc. Neither the tables nor the plots are displayed.

```
ods listing close;
ods document name=lhurDoc(write);
ods graphics on;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;
quit;

ods graphics off;
ods document close;
ods listing;
```

If you want to display, for example, the Q-Q plot of residuals using PROC DOCUMENT, you first need to determine its name. You can do this by specifying the ODS TRACE ON statement prior to the procedure statements (see page 278 for more information). Alternatively, you can type **odsdocuments** (or **odsd** for short) in the command line to open the Documents window, which you can then use to manage your ODS documents.

The following statements specify an HTML destination and display the residual Q-Q plot using the REPLAY statement in PROC DOCUMENT.

```
ods html;

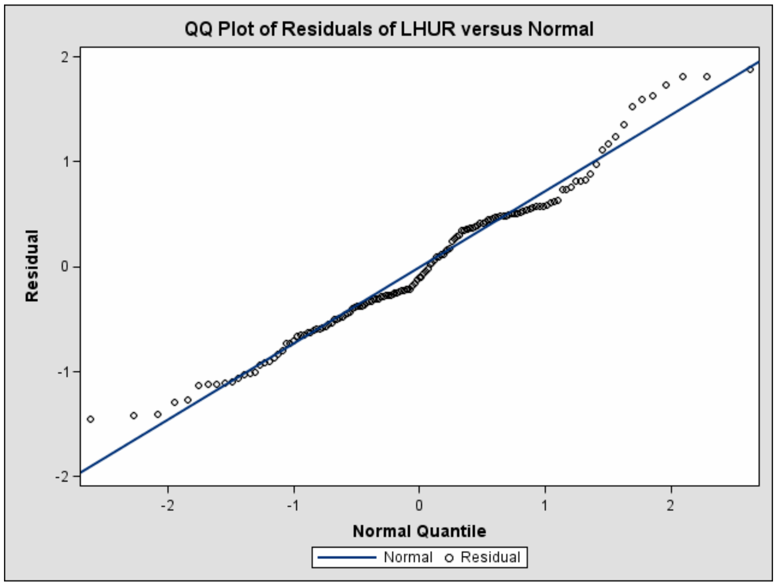
ods select QQPlot;

proc document name = lhurDoc;
   replay;
run;
quit;

ods html close;
```

By default, the REPLAY statement attempts to replay every output object stored in the document, but only the Q-Q plot is displayed as specified by the ODS SELECT statement. The plot is displayed in Output 9.6.1.

Output 9.6.1. Q-Q Plot Displayed by PROC DOCUMENT



As an alternative to running PROC DOCUMENT with an ODS SELECT statement, you can run PROC DOCUMENT specifying a *document path* for the Q-Q plot in the REPLAY statement. This approach is preferable when the document contains a large volume of output, because PROC DOCUMENT does not attempt to process every piece of output stored in the document.

You can determine the document path for the Q-Q plot by specifying the LIST statement with the LEVELS=ALL option in PROC DOCUMENT.

```
proc document name = lhurDoc;
   list / levels = all;
run;
quit;
```

This lists the entries of the QQDoc document, as shown in Output 9.6.2.

Output 9.6.2. Contents of lhurDoc

```
Listing of: \Work.Lhurdoc\
Order by: Insertion
Number of levels: All

  Obs    Path                                                                Type
--------------------------------------------------------------------------------
      1 \Model#1                                                             Dir
      2 \Model#1\ModSum#1                                                    Dir
      3 \Model#1\ModSum#1\ModSummary#1                                       Table
      4 \Model#1\ModSum#1\ModVars#1                                          Tree
      5 \Model#1\ModSum#1\Equations#1                                        Tree
      6 \Model#1\OLS#1                                                       Dir
      7 \Model#1\OLS#1\ConvergenceStatus#1                                   Table
      8 \Model#1\OLS#1\EstSum#1                                              Dir
      9 \Model#1\OLS#1\EstSum#1\DatasetOptions#1                             Table
     10 \Model#1\OLS#1\EstSum#1\MinSummary#1                                 Table
     11 \Model#1\OLS#1\EstSum#1\ConvCrit#1                                   Table
     12 \Model#1\OLS#1\EstSum#1\ObsUsed#1                                    Table
     13 \Model#1\OLS#1\ResidSummary#1                                        Table
     14 \Model#1\OLS#1\ParameterEstimates#1                                  Table
     15 \Model#1\OLS#1\EstSummaryStats#1                                     Table
     16 \Model#1\OLS#1\StudentResidualPlot#1                                 Graph
     17 \Model#1\OLS#1\CooksD#1                                              Graph
     18 \Model#1\OLS#1\ActualByPredicted#1                                   Graph
     19 \Model#1\OLS#1\ACFPlot#1                                             Graph
     20 \Model#1\OLS#1\PACFPlot#1                                            Graph
     21 \Model#1\OLS#1\IACFPlot#1                                            Graph
     22 \Model#1\OLS#1\QQPlot#1                                              Graph
     23 \Model#1\OLS#1\ResidualHistogram#1                                   Graph
```

The document path of the “QQPlot” entry in lhurDoc, as shown in Output 9.6.2, is

```
\Model#1\OLS#1\QQPlot#1
```

You can specify this path to display the residual Q-Q plot with PROC DOCUMENT as follows.

```
ods html;

proc document name = lhurDoc;
   replay \Model#1\OLS#1\QQPlot#1;
run;
quit;

ods html close;
```

You can also determine the document path from the Results window or the Documents window. Right-click on the object icon and select **Properties**.

A sample program named odsgr06.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.7. Customizing Graph Titles and Axes Labels

This example shows how to use PROC TEMPLATE to customize the appearance and content of an ODS graph. It illustrates the discussion in the section "Customizing Graphics with Templates" on page 287 in the context of changing the default title and y-axis label for a Q-Q plot created with the MODEL procedure.

The following statements request a Q-Q plot for residuals using PROC MODEL with the LHUR series in the library SASHELP.CITIMON for the model in Example 9.1.

```
ods trace on;
ods html;
ods graphics on;

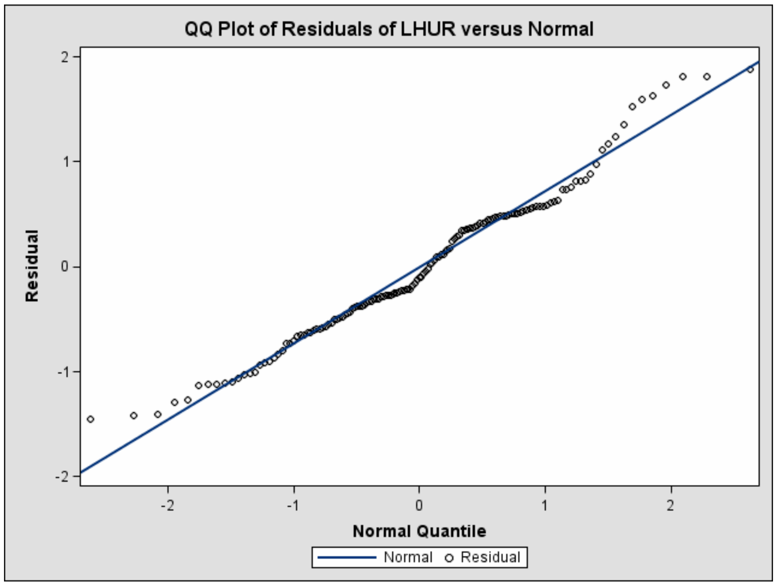
ods select QQPlot;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;
quit;

ods graphics off;
ods html close;
ods trace off;
```

The Q-Q plot is shown in Output 9.7.1.

Output 9.7.1. Default Q-Q Plot from PROC MODEL



The ODS TRACE ON statement requests a record of all the ODS output objects created by PROC MODEL. A partial listing of the trace record, which is displayed in the SAS log, is shown in Output 9.7.2.

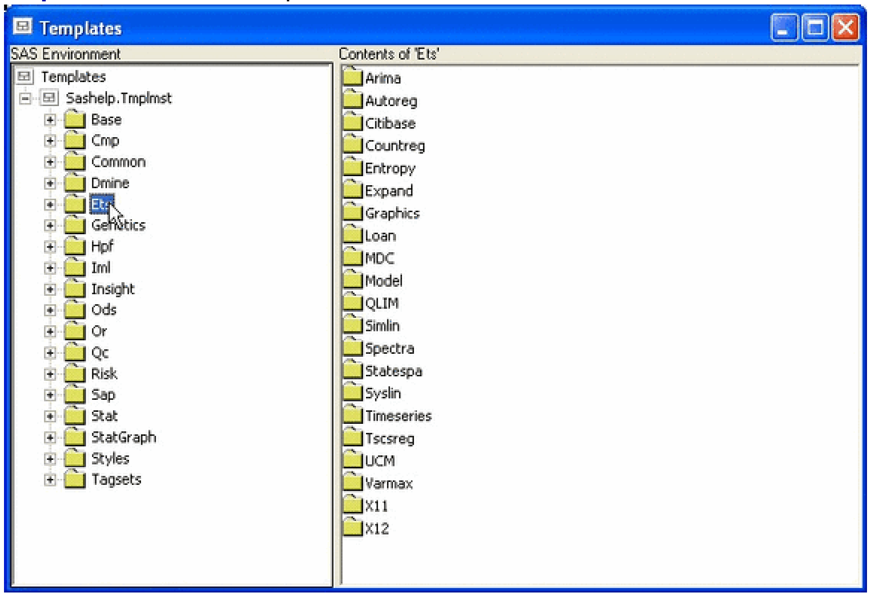
Output 9.7.2. Trace Record for Q-Q Plot

```
Output Added:
-------------
Name:       QQPlot
Label:      QQ Plot of Residuals of LHUR versus Normal
Template:   ETS.Model.Graphics.QQPlot
Path:       Model.OLS.QQPlot
-------------
```

As shown in Output 9.7.2, ODS Graphics creates the Q-Q plot using an ODS output data object named “QQPlot” and a graph template named “Ets.Model.Graphics.QQPlot,” which is the default template provided by SAS. Default templates supplied by SAS are saved in the Sashelp.Tmplmst template store (see page 287).

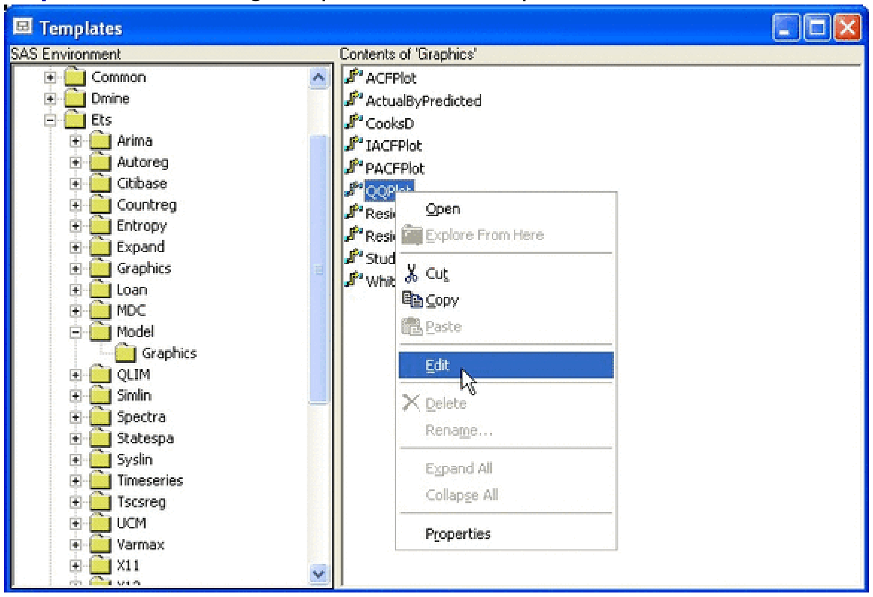
To display the default template definition, open the Templates window by typing **odstemplates** (or **odst** for short) in the command line. Expand **Sashelp.Tmplmst** and click on the **Ets** folder, as shown in Output 9.7.3.

Output 9.7.3. The Templates Window



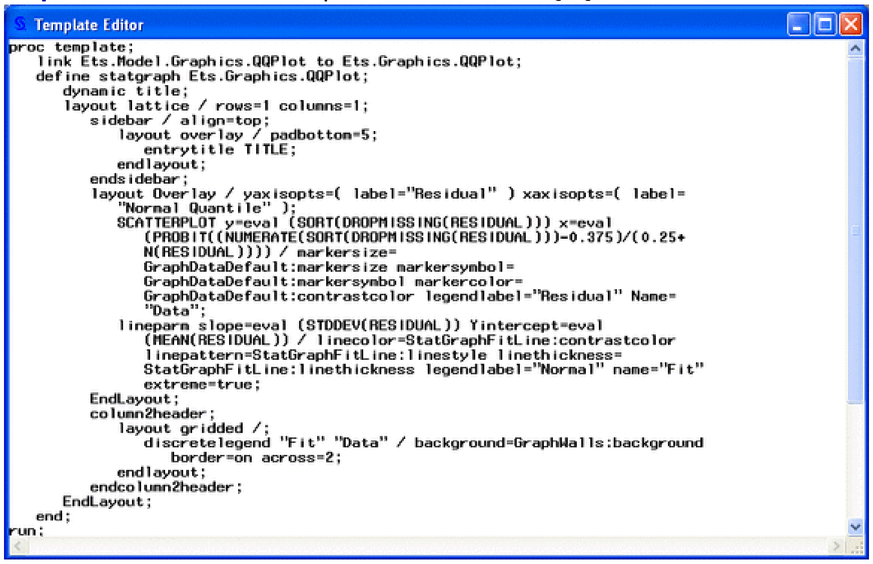
Next, open the **Model** folder and then open the **Graphics** folder. Then right-click on the “QQPlot” template icon and select **Edit**, as shown in Output 9.7.4.

Output 9.7.4. Editing Templates in the Template Window



Selecting **Edit** opens a Template Editor window, as shown in Output 9.7.5. You can use this window to edit the template.

Output 9.7.5. Default Template Definition for Q-Q Plot



```
proc template;
   link Ets.Model.Graphics.QQPlot to Ets.Graphics.QQPlot;
   define statgraph Ets.Graphics.QQPlot;
      dynamic title;
      layout lattice / rows=1 columns=1;
         sidebar / align=top;
            layout overlay / padbottom=5;
               entrytitle TITLE;
            endlayout;
         endsidebar;
         layout Overlay / yaxisopts=( label="Residual" ) xaxisopts=( label=
            "Normal Quantile" );
            SCATTERPLOT y=eval (SORT(DROPMISSING(RESIDUAL))) x=eval
               (PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL)))-0.375)/(0.25+
               N(RESIDUAL)))) / markersize=
               GraphDataDefault:markersize markersymbol=
               GraphDataDefault:markersymbol markercolor=
               GraphDataDefault:contrastcolor legendlabel="Residual" Name=
               "Data";
            lineparm slope=eval (STDDEV(RESIDUAL)) Yintercept=eval
               (MEAN(RESIDUAL)) / linecolor=StatGraphFitLine:contrastcolor
               linepattern=StatGraphFitLine:linestyle linethickness=
               StatGraphFitLine:linethickness legendlabel="Normal" name="Fit"
               extreme=true;
         EndLayout;
         column2header;
            layout gridded /;
               discretelegend "Fit" "Data" / background=GraphWalls:background
                  border=on across=2;
            endlayout;
         endcolumn2header;
      EndLayout;
   end;
run;
```

The template definition in Output 9.7.5 is discussed below and in subsequent examples. It is listed in a more convenient format by the following statements:

```
proc template;
   link Ets.Model.Graphics.QQPlot to Ets.Graphics.QQPlot;
   define statgraph Ets.Graphics.QQPlot;
   dynamic title;
   layout lattice / rows = 1 columns = 1;
      sidebar / align=top;
         layout overlay / padbottom=5;
            entrytitle Title;
         endlayout;
      endsidebar;
      layout Overlay /
            yaxisopts = ( label = "Residuals" )
            xaxisopts = ( label = "Normal Quantile" );
         SCATTERPLOT
            y = eval(SORT(DROPMISSING(RESIDUAL)))
            x = eval(PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL)))-0.375)/
                    (0.25+N(RESIDUAL)))) /
            markersize   = GraphDataDefault:markersize
            markersymbol = GraphDataDefault:markersymbol
            markercolor  = GraphDataDefault:contrastcolor
            legendlabel  = "Residual"
            Name         = "Data";
         lineparm
            slope      = eval(STDDEV(RESIDUAL))
            Yintercept = eval(MEAN(RESIDUAL)) /
               linecolor     = StatGraphFitLine:contrastcolor
               linepattern   = StatGraphFitLine:linestyle
               linethickness = StatGraphFitLine:linethickness
               legendlabel   = "Normal"
               name          = "Fit"
               extreme       = true;
      EndLayout;
      column2header;
         layout Gridded /;
            DiscreteLegend "Fit" "Data" /
               background = GraphWalls:background
               border     = on
               across     = 2;
         EndLayout;
      endcolumn2header;
   EndLayout;
end;
run;
```

As an alternative to using the Template Editor window, you can submit the following statements, which display the “Plot” template definition in the SAS log.

```
proc template;
   source Ets.Model.Graphics.QQPlot;
run;
```

The SOURCE statement specifies the fully qualified template name. You can copy and paste the template source into the Program Editor, modify it, and submit it using PROC TEMPLATE. See the “Editing Templates” section on page 289 for more information.

In the template, the default title of the Q-Q plot is specified by the ENTRYTITLE statement. Note that TITLE is a dynamic text variable whose values is passed by the MODEL procedure, and is QQ Plot of Residual vs Normal in Output 9.7.1). The default label for the y-axis is specified by the LABEL= suboption of the YAXISOPTS= option for the LAYOUT OVERLAY statement.

Suppose you want to change the default title to My Favorite Title, and you want the y-axis label to be Residuals of LHUR. First, replace the two ENTRYTITLE statements with the single statement

```
ENTRYTITLE "My Favorite Title" / padbottom = 5;
```

The PADBOTTOM= option specifies the amount of empty space (in pixel units) at the bottom of the layout component. In this case it creates an empty space of 5 pixels between the title and the adjacent layout component, which defines the plot itself.

Next, replace the LABEL= suboption with the following:

```
label = "Residuals of LHUR"
```

Note that you can reuse dynamic text variables such as Title in any text element.

You can then submit the modified template definition as you would any SAS program, for example, by selecting **Submit** from the **Run** menu.

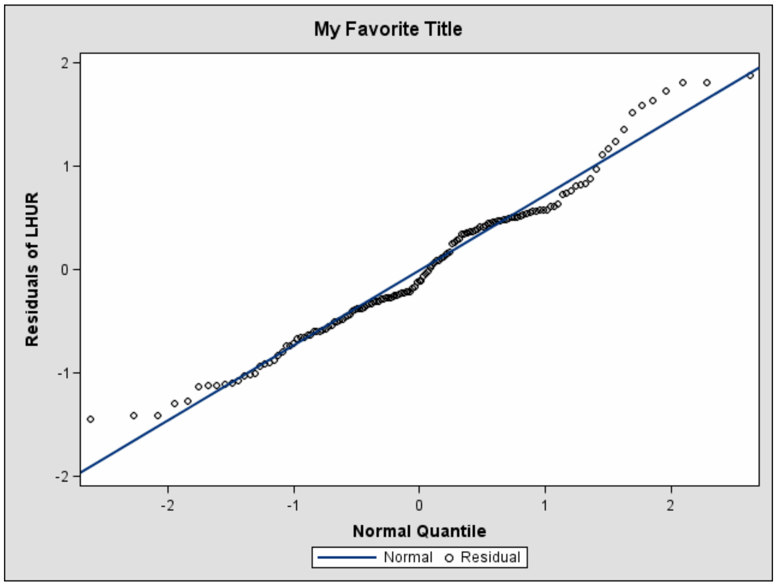
After submitting the PROC TEMPLATE statements you should see the following message in the SAS log:

```
NOTE: STATGRAPH ’Ets.Model.Graphics.QQPlot’ has been
  saved to: SASUSER.TEMPLAT
```

Note: Graph definitions are self-contained and do not support parenting as do table definitions. For more information about graph definitions and the graph template language, see the “Introducing the Template Language for Graphics” section on page 291.

Finally, resubmit the PROC MODEL statements on page 312 to display the Q-Q plot created with your modified template, as shown in Output 9.7.6.

Output 9.7.6. Q-Q Plot with Modified Title and Y-Axis Label



If you have not changed the default ODS path, the modified template “QQplot” is used automatically because Sasuser.Templat occurs before Sashelp.Tmplmst in the ODS search path. See the “Using Customized Templates” section on page 290 for additional information.

Note that you do not need to rerun the PROC MODEL analysis after you modify a graph template. After you modify your template, you can submit the PROC DOCUMENT statements in Example 9.6 to replay the Q-Q plot with the modified template.

See the “Reverting to Default Templates” section on page 291 for information on how to revert to the default template.

A sample program named odsgr07.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.8. Modifying Colors, Line Styles, and Markers

This example is a continuation of Example 9.7. Here the objective is to customize colors, line attributes, and marker symbol attributes by modifying the graph template.

In the “QQPlot” template definition shown in Output 9.7.5, the SCATTERPLOT statement specifies a scatter plot of normal quantiles versus ordered standardized residuals. The default marker symbol in the scatter plot is specified by the MARKERSYMBOL= option of the SCATTERPLOT statement:

```
   markersymbol = GraphDataDefault:markersymbol
```

The default value is a reference to the style attribute **`markersymbol`** of the style element **`GraphDataDefault`**. See the "Introducing Style Elements for Graphics" section on page 293 for more information. The actual value of the marker symbol depends on the style that you are using. In this case, since the "Default" style is used, the value of the marker symbol is Circle.

You can specify a filled circle as the marker symbol by modifying the value of the MARKERSYMBOL= option as follows.

```
markersymbol = CircleFilled
```

Note that the value of the option can be any valid marker symbol or a reference to a style attribute of the form ***`style-element:attribute`***. It is recommended that you use style attributes since these are chosen to provide consistency and appropriate emphasis based on display principles for statistical graphics. If you specify values directly in a template, you are overriding the style and run the risk of creating a graph that is inconsistent with the style definition.

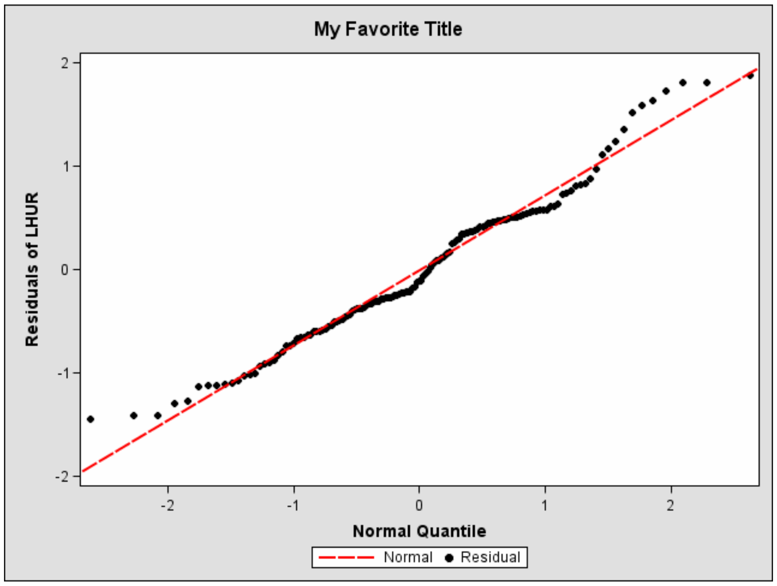
For more information about the syntax of the graphics template language and style elements for graphics, refer to the sections "TEMPLATE Procedure: Creating ODS Statistical Graphics Output (Experimental)" and "ODS Statistical Graphics and ODS Styles: Usage and Reference (Experimental)" at http://support.sas.com/documentation/onlinedoc/base/.

Similarly, you can change the line color and pattern with the LINECOLOR= and LINEPATTERN= options in the LINEPARM statement. The LINEPARM statement displays a straight line specified by slope and intercept parameters. The following statements change the default color of the Q-Q plot line to red, and the line pattern to dashed.

```
linecolor   = red
linepattern = dash
```

To display these modifications, shown in Output 9.8.1, submit the modified template definition and then resubmit the PROC MODEL statements on page 312. Alternatively, you can replay the plot using PROC DOCUMENT, as in Example 9.6.

Output 9.8.1. Q-Q Plot with Modified Marker Symbols and Line



A sample program named odsgr08.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.9. Swapping the Axes in a Graph

Sometimes a Q-Q plot is displayed with the normal quantiles plotted along the y-axis and the ordered variable values plotted along the x-axis. This example, which is a continuation of Example 9.7 and Example 9.8, illustrates how to interchange the axes with a simple modification of the graph template.

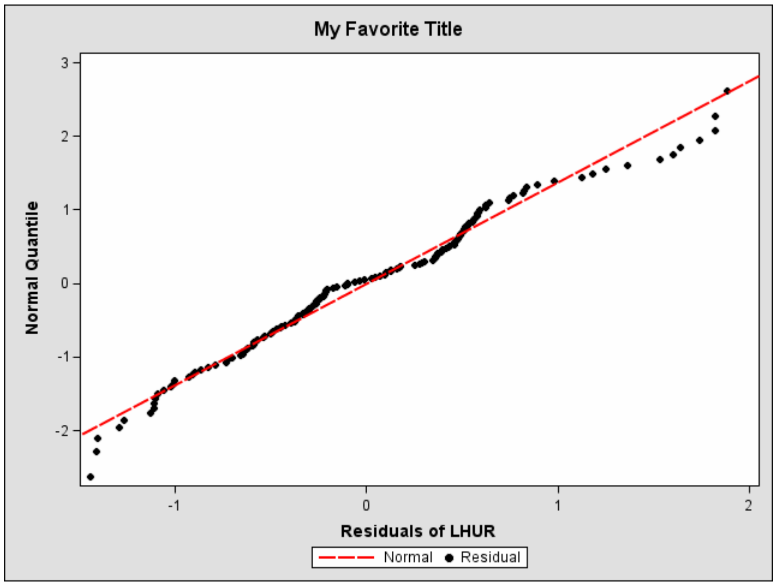
Begin by swapping the YAXISOPTS= and XAXISOPTS= options, and by swapping the X= and Y= options in the SCATTERPLOT statement.

Next, modify the LINEPARM statement. In Output 9.8.1, the slope of the line in the Q-Q plot is $\hat{\sigma}$, and y-intercept is $\hat{\mu}$. When you swap the axes, the values of the slope and y-intercept become $1/\hat{\sigma}$ and $-\hat{\mu}/\hat{\sigma}$, respectively. The modified template definition (including the changes from Example 9.7 and Example 9.8) is as follows:

```
proc template;
   link Ets.Model.Graphics.QQPlot to Ets.Graphics.QQPlot;
   define statgraph Ets.Graphics.QQPlot;
   dynamic title;
   layout lattice / rows = 1 columns = 1;
      sidebar / align = top;
         layout overlay / padbottom = 5;
            entrytitle "My Favorite Title" / padbottom=5;
         endlayout;
      endsidebar;
      layout Overlay /
             xaxisopts = ( label = "Residuals of LHUR" )
             yaxisopts = ( label = "Normal Quantile" );
         SCATTERPLOT
             x = eval(SORT(DROPMISSING(RESIDUAL)))
             y = eval(PROBIT((NUMERATE(SORT(DROPMISSING(RESIDUAL)))-0.375)/
                     (0.25+N(RESIDUAL)))) /
             markersize   = GraphDataDefault:markersize
             markersymbol = CircleFilled
             markercolor  = GraphDataDefault:contrastcolor
             legendlabel  = "Residual"
             Name         = "Data";
         lineparm
             slope      = eval(1/STDDEV(RESIDUAL))
             Yintercept = eval(-MEAN(RESIDUAL)/STDDEV(RESIDUAL)) /
                linecolor     = red
                linepattern   = dash
                linethickness = StatGraphFitLine:linethickness
                legendlabel   = "Normal"
                name          = "Fit"
                extreme       = true;
      EndLayout;
      column2header;
         layout Gridded /;
            DiscreteLegend "Fit" "Data" /
               background = GraphWalls:background
               border     = on
               across     = 2;
         EndLayout;
      endcolumn2header;
   EndLayout;
end;
run;
```

The resulting Q-Q plot, after submitting the preceding statements and the PROC MODEL statements on page 312, is shown in Output 9.9.1.

Output 9.9.1. Q-Q Plot with Swapped Axes



A sample program named odsgr09.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.10. Modifying Tick Marks and Adding Grid Lines

This example, which is a continuation of Example 9.7, Example 9.8, and Example 9.9, illustrates how to modify the tick marks for an axis and suppress grid lines.

You can use the TICKS= suboption in the XAXISOPTS= or YAXISOPTS= options to specify the tick marks for an axis. For example, you can specify the following to request tick marks ranging from -3 to 3 in the y-axis for the Q-Q plots in Output 9.9.1:

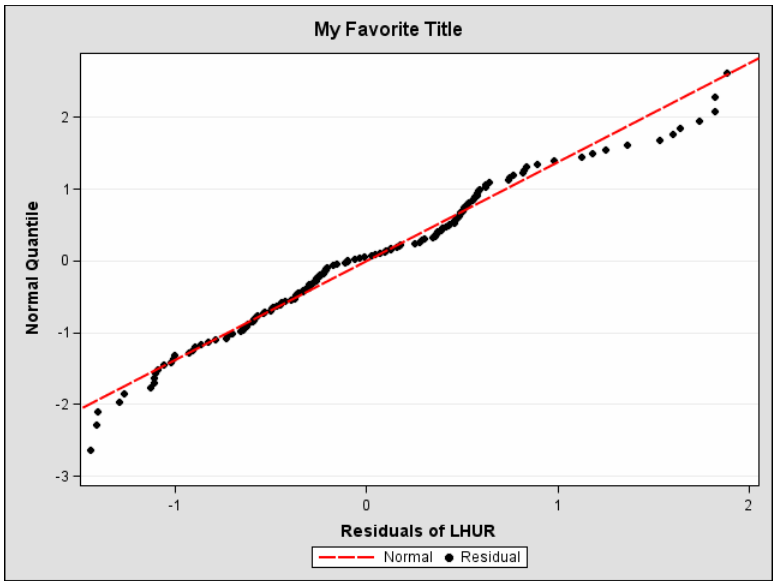
```
   yaxisopts = (label = "Normal Quantile"
                ticks = (-3 -2 -1 0 1 2))
```

By default, the Q-Q plot in Output 9.9.1 does not display grid lines. You can request vertical grid lines only by specifying

```
   XGrid = False YGrid = True
```

The result of these changes, after submitting the modified template definition and the corresponding PROC MODEL statements on page 312, is displayed in Output 9.10.1.

Output 9.10.1. Q-Q Plot with Modified Y-Axis Tick Marks and Grids



A sample program named odsgr10.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.11. Modifying Graph Fonts in Styles

You can modify an ODS style to customize the general appearance of ODS Graphics, just as you can modify a style to customize the general appearance of ODS tables. The goal of this example is to customize the fonts used in ODS graphs. It is a continuation of Example 9.10.

The following statements define a style named NewStyle that replaces the graph fonts in the “Default” style with italic Times New Roman fonts.

```
proc template;
   define style Styles.NewStyle;
   parent = Styles.Default;
   replace GraphFonts
      "Fonts used in graph styles" /
      'GraphDataFont'     = ("Times New Roman",8pt,Italic)
      'GraphValueFont'    = ("Times New Roman",10pt,Italic)
      'GraphLabelFont'    = ("Times New Roman",12pt,Italic)
      'GraphFootnoteFont' = ("Times New Roman",12pt,Italic)
      'GraphTitleFont'    = ("Times New Roman",14pt,Italic Bold);
end;
run;
```

In general, the following graph fonts are specified in the ODS styles provided by SAS:

- **`'GraphDataFont'`** is the smallest font. It is used for text that needs to be small (labels for points in scatter plots, labels for contours, and so on)
- **`'GraphValueFont'`** is the next largest font. It is used for axis value (tick marks) labels and legend entry labels.
- **`'GraphLabelFont'`** is the next largest font. It is used for axis labels and legend titles.
- **`'GraphFootnoteFont'`** is the next largest font. It is used for all footnotes.
- **`'GraphTitleFont'`** is the largest font. It is used for all titles.

For more information about the DEFINE, PARENT, and REPLACE statements, refer to the "TEMPLATE Procedure: Creating a Style Definition" in the *SAS Output Delivery System User's Guide*.

The Q-Q plots in the preceding examples, beginning with Example 9.6, were created with the "Default" style; see, for instance, Output 9.10.1. In contrast, the Q-Q plot displayed in Output 9.11.1 was produced by specifying the NewStyle style in the following statements.

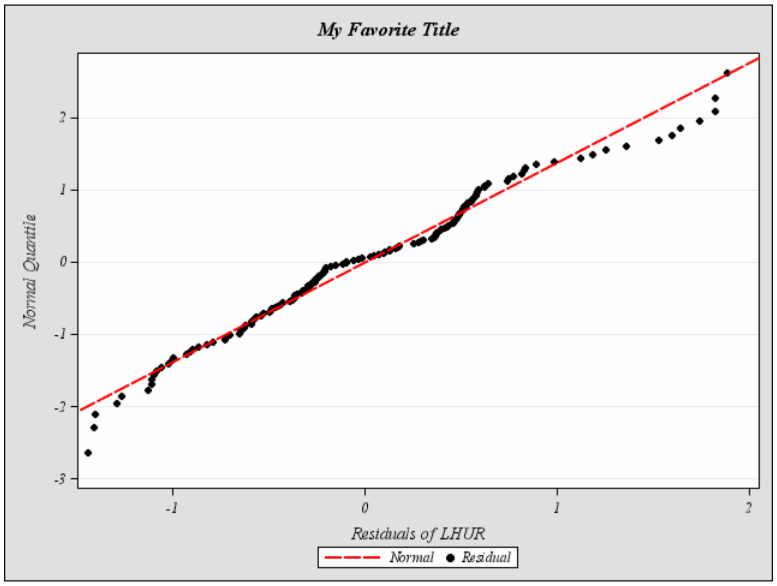
```
ods html style = NewStyle;
ods graphics on;

ods select QQPlot;

proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
   id date;
run;
quit;

ods graphics off;
ods html close;
```

Output 9.11.1. Q-Q Plot Using NewStyle



Although this example illustrates the use of a style with output from a particular procedure, note that a style is applied to *all* of your output (graphs and tables) in the destination for which you specify the style. See the "Specifying a Default Style" section on page 295 for information about specifying a default style for all your output.

A sample program named odsgr11.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.12. Modifying Other Graph Elements in Styles

This example, which is a continuation of Example 9.11, illustrates how to modify additional style elements for graphics, such as the thickness of a line.

The attributes of fitted lines in ODS Graphics are controlled by the style element **StatGraphFitLine**, which is defined in the "Default" style. For example, the line thickness of the normal distribution reference line in Output 9.11.1 is specified in the graph template by

```
linethickness = StatGraphFitLine:linethickness
```

To specify a line thickness of 4 pixels for the line, add the following statements to the definition of the NewStyle style in Example 9.11.

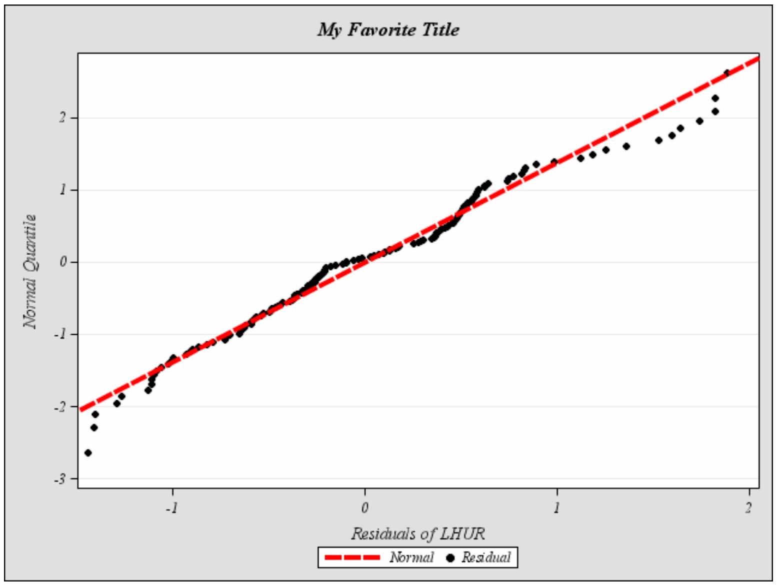
```
replace StatGraphFitLine /
   linethickness = 4px;
```

The complete revised NewStyle style is now defined by the following statements:

```
proc template;
   define style Styles.NewStyle;
   parent = Styles.Default;
   replace GraphFonts
      "Fonts used in graph styles" /
      'GraphDataFont'     = ("Times New Roman",8pt,Italic)
      'GraphValueFont'    = ("Times New Roman",10pt,Italic)
      'GraphLabelFont'    = ("Times New Roman",12pt,Italic)
      'GraphFootnoteFont' = ("Times New Roman",12pt,Italic)
      'GraphTitleFont'    = ("Times New Roman",14pt,Italic Bold);
   replace StatGraphFitLine /
      linethickness = 4px;
end;
run;
```

Output 9.12.1 shows the Q-Q plot created by the MODEL statements on page 323 with the new version of NewStyle.

Output 9.12.1. Q-Q Plot Using NewStyle with Thicker Line



You can use this approach to modify other attributes of the line, such as **`transparency`**, **`linestyle`**, **`contrastcolor`**, and **`foreground`**.

Note: Values specified directly in a graph template override style attributes. If you have customized a template, changes in a style may not have any effect. For more information, refer to the "ODS Statistical Graphics and ODS Styles: Usage and Reference (Experimental)" at http://support.sas.com/documentation/onlinedoc/base/.

A sample program named odsgr12.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Example 9.13. Modifying Graph Sizes Using Styles

This example demonstrates how to modify the size of your ODS graphs using a style definition.

You can specify the size of a graph in a graph template definition or in a style definition:

- To modify the size of a *particular* graph, specify the dimensions with the HEIGHT= and WIDTH= options in the outermost layout of the graph template definition.
- To modify the size of *all* your ODS graphs, specify the dimensions with the OUTPUTHEIGHT= and OUTPUTWIDTH= options in the style definition.

Dimensions specified in a graph template override those specified in a style.

Continuing the discussion in Example 9.12, you can add the following style element to the definition of NewStyle to change the size of all your graphs:

```
style Graph from Graph /
   outputwidth  = 400px
   outputheight = 300px;
```

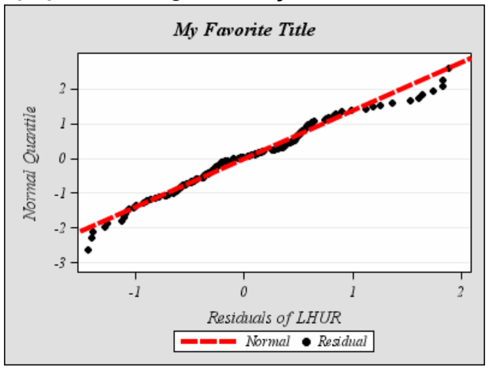
With all the changes introduced so far, NewStyle is defined as follows:

```
proc template;
   define style Styles.NewStyle;
   parent = Styles.Default;
   replace GraphFonts
      "Fonts used in graph styles" /
      'GraphDataFont'     = ("Times New Roman",8pt,Italic)
      'GraphValueFont'    = ("Times New Roman",10pt,Italic)
      'GraphLabelFont'    = ("Times New Roman",12pt,Italic)
      'GraphFootnoteFont' = ("Times New Roman",12pt,Italic)
      'GraphTitleFont'    = ("Times New Roman",14pt,Italic Bold);
   replace StatGraphFitLine /
      linethickness = 4px;
   style Graph from Graph /
      outputwidth  = 400px
      outputheight = 300px;
end;
run;
```

The dimensions of the graph must be specified in pixels. The actual size of the graph in inches depends on your printer or display device. For example, if the resolution of your printer is 100 dpi (100 dots per inch) and you want a graph that is 4 inches wide, you should set the width to 400 pixels.

You can create a smaller version of Output 9.12.1, shown in Output 9.13.1, by specifying the preceding PROC TEMPLATE statements followed by the MODEL statements on page 323.

Output 9.13.1. Q-Q Plot Using NewStyle with Smaller Dimensions



An alternative method for including smaller graphs in a document is to start with a style provided by SAS and define a modified style that *increases* the size of the graph fonts while preserving the default width and height attributes. Then you can include the graph in a document (for example in Microsoft Word) and manually rescale the graph to a smaller size while maintaining the fonts in a size that is still readable.*

The following style increases the size of the fonts but retains all the other style elements as assigned in the “Default” style:

```
proc template;
   define style Styles.BigFontStyle;
   parent = Styles.Default;
   replace GraphFonts
      "Fonts used in graph styles" /
      'GraphDataFont'     = ("Arial",12pt)
      'GraphValueFont'    = ("Arial",15pt)
      'GraphLabelFont'    = ("Arial",18pt)
      'GraphFootnoteFont' = ("Arial",18pt)
      'GraphTitleFont'    = ("Arial",21pt);
end;
run;
```

A sample program named odsgr13.sas is available for this example in the SAS Sample Library for SAS/ETS software.

*In a markup language, such as HTML or LaTeX, you can use a resize command.

Example 9.14. Modifying Panels

This example is taken from the “Getting Started” section of Chapter 61, “The REG Procedure” (*SAS/STAT User’s Guide*). It illustrates how to modify the regression fit diagnostics panel whose annotated version is shown in Output 9.14.1 so that it displays a subset of component plots. The original panel consists of eight plots and a summary statistics box. These components are labeled 1 to 9 in Output 9.14.1.

The following data are from a study of 19 children. The variables Height, Weight, and Age are measured for each child.

```
data Class;
   input Name $ Height Weight Age @@;
   datalines;
Alfred  69.0 112.5 14  Alice   56.5  84.0 13  Barbara 65.3  98.0 13
Carol   62.8 102.5 14  Henry   63.5 102.5 14  James   57.3  83.0 12
Jane    59.8  84.5 12  Janet   62.5 112.5 15  Jeffrey 62.5  84.0 13
John    59.0  99.5 12  Joyce   51.3  50.5 11  Judy    64.3  90.0 14
Louise  56.3  77.0 12  Mary    66.5 112.0 15  Philip  72.0 150.0 16
Robert  64.8 128.0 12  Ronald  67.0 133.0 15  Thomas  57.5  85.0 11
William 66.5 112.0 15
;
```

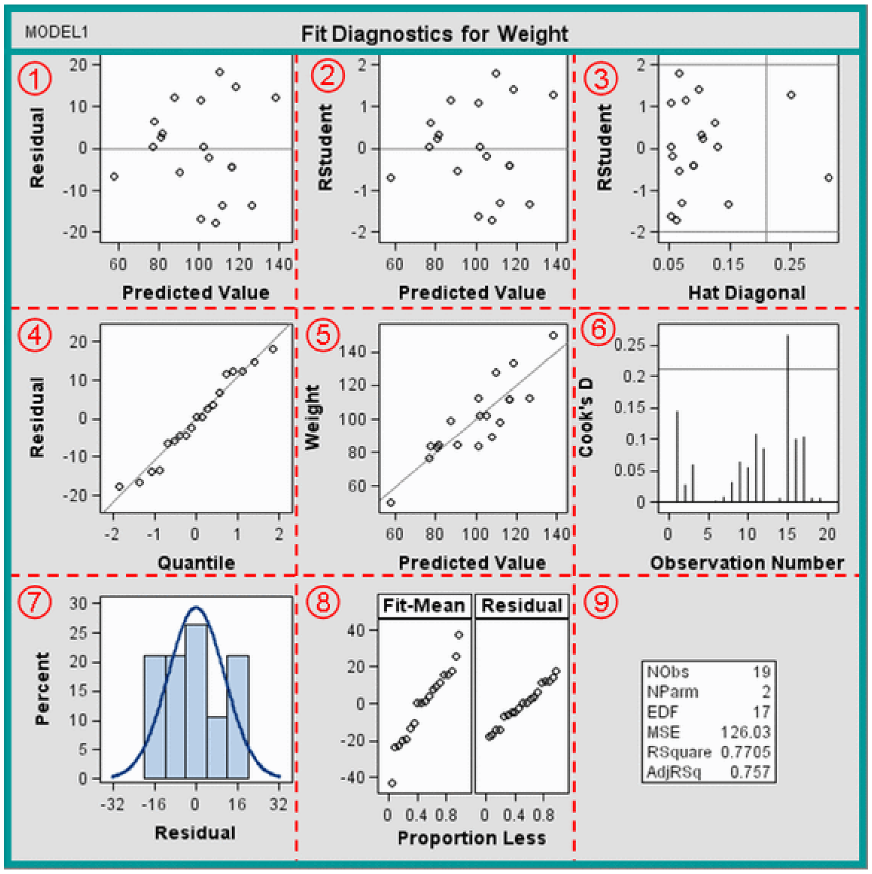
The following statements invoke the REG procedure to fit a simple linear regression model in which Weight is the response variable and Height is the independent variable, and select the diagnostic panel in Output 9.14.1.

```
ods html;
ods graphics on;
ods select DiagnosticsPanel;

proc reg data = Class;
   model Weight = Height;
run;
quit;

ods graphics off;
ods html close;
```

Output 9.14.1. Diagnostics Panel Annotated to Indicate Layout Structure



In the discussion that follows, the panel is modified so that it includes only the following components:

1. residual by predicted plot
4. residual Q-Q plot
6. Cook's D plot
7. residual histogram
9. summary statistics box

The panel to be produced is shown in Output 9.14.2. It displays components 1, 4, 6, and 7 in a 2×2 lattice, and it displays four of the summary statistics in component 9 in a box at the bottom.

The template that defines the original panel is "Ets.Reg.Graphics.DiagnosticPanel." The following listing is abbreviated to show the main structure of the template definition (see page 288 for details on how to display the complete template definition).

```
proc template;
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;

   /* Dynamic variables */
   dynamic _TITLE _MODELLABEL _DEPLABEL _NOBS _NPARM _EDF _MSE
      _RSquare _AdjRSq;

   /* 3x3 LATTICE layout */
   layout lattice / columns = 3 rows = 3 ... ;

      sidebar / align=top;
         /* Statements for model label and graph title */
      endsidebar;

      /* 1. Residual By Predicted */
      layout overlay / ... ;
         lineparm slope = 0 yintercept = 0;
         scatterplot y = RESIDUAL x = PREDICTEDVALUE;
      endlayout;

      ...

      /* LAYOUT statements for components 2-8 */

      ...

      /* 9. Summary Statistics Box */
      layout overlay;
         layout gridded / ... ;
            entry "NObs";
            entry _NOBS / format=best6.;
               .
               .
               .
            entry "AdjRSq";
            entry _ADJRSQ / format=best6.;
         endlayout;
      endlayout;

   endlayout;   /* End of 3x3 LATTICE layout */
end;
run;
```

The overall display is defined by the LAYOUT LATTICE statement, which specifies a lattice of components, indicated by the solid grid annotated in Output 9.14.1. The COLUMNS=3 and ROWS=3 options in the LAYOUT LATTICE statement specify a 3×3 lattice, indicated by the dashed grid.

The model label and the graph title (top rectangle in Output 9.14.1) are specified inside the LATTICE layout with a SIDEBAR statement. The ALIGN=TOP option positions the sidebar at the top.

Each of the nine components of the lattice is defined by a LAYOUT statement. These statements define the components from left to right and top to bottom. Components 1 through 7 are defined with LAYOUT OVERLAY statements. Component 8 (RF plot) is defined with a LAYOUT LATTICE statement. The last LAYOUT OVERLAY statement defines a box with summary statistics for the fitted model.

The following abbreviated listing shows the basic structure of the template definition for a simplified panel that displays components 1, 4, 6, and 7 in a 2×2 lattice.[*] For the complete template definition, refer to the sample program odsgex14.sas in the SAS Sample Library for SAS/ETS software.

```
proc template;
define statgraph Stat.Reg.Graphics.DiagnosticsPanel;
   dynamic _TITLE _MODELLABEL _DEPLABEL _NOBS _NPARM _EDF _MSE
      _RSquare _AdjRSq;

   /* 2x2 LATTICE layout */
   /* Change COLUMNS= and ROWS= options */
   layout lattice / columns = 2 rows = 2 ... ;

      sidebar / align=top;
         /* Statements for model label and graph title */
      endsidebar;

      /* 1. Residual By Predicted */
      layout overlay / ... ;
         lineparm slope = 0 yintercept = 0;
         scatterplot y = RESIDUAL x = PREDICTEDVALUE;
      endlayout;

      /* 4. Q-Q Plot */
      layout overlay / ... ;
         lineparm slope      = eval(STDDEV(RESIDUAL))
                  yintercept = eval(...);
         scatterplot y = eval(...) x = eval(...);
      endlayout;

      /* Statements for components 6 and 7 (not listed) */

      /* Summary Statistics Box in a SIDEBAR */
      sidebar / align=bottom;
         layout gridded;
            layout lattice / rows=1 columns=4 ... ;
               .
               .
               .
            endlayout;
         endlayout;
      endsidebar;

   endlayout;   /* End of 2x2 LATTICE layout */
end;
run;
```

This template is a straightforward modification of the original template. The COLUMNS=2 and ROWS=2 options in the LAYOUT LATTICE statement request a 2×2 lattice. The LAYOUT statements for components 2, 3, 5, and 8 are deleted.

[*]See page 289 for details on how to edit the template definition.

A subset of the summary statistics are displayed at the bottom of the graph using a SIDEBAR statement with the ALIGN=BOTTOM option.

After submitting the preceding statements, which create the modified template and save it in Sasuser.Templat, you can run the following PROC REG statements to obtain the simplified panel, which is shown in Output 9.14.2.

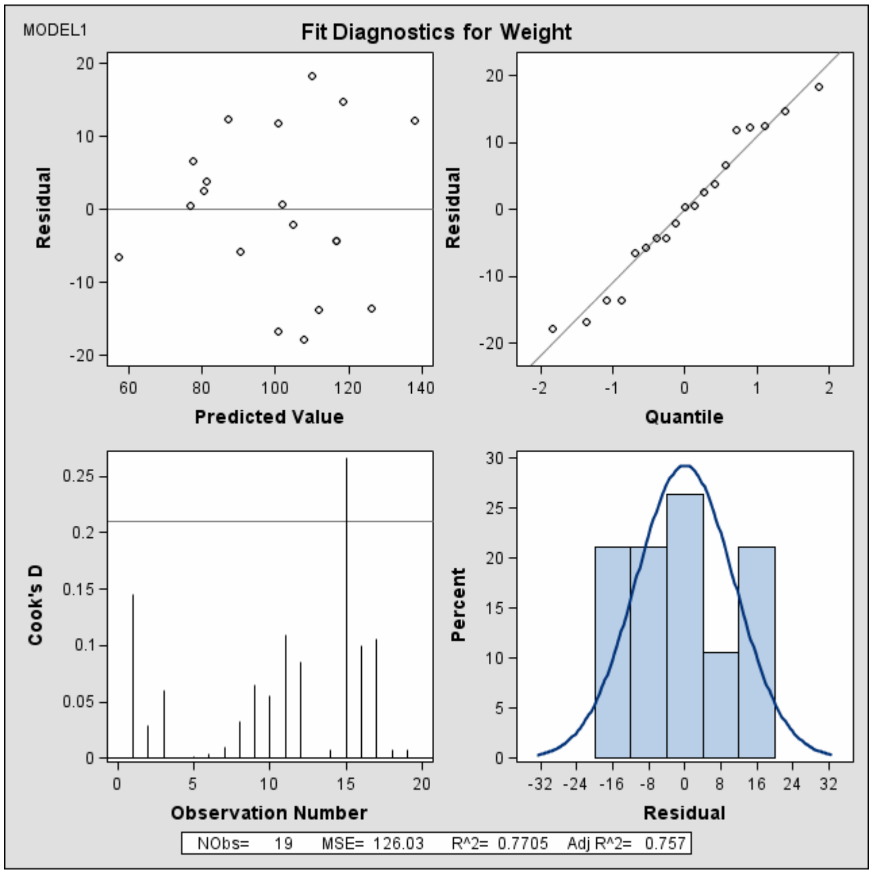
```
ods html;
ods graphics on;

ods select DiagnosticsPanel;

proc reg data = Class;
   model Weight = Height;
run;
quit;

ods graphics off;
ods html close;
```

Output 9.14.2. Simplified Diagnostics Panel



```
NObs=    19    MSE= 126.03    R^2= 0.7705    Adj R^2= 0.757
```

A sample program named odsgr14.sas is available for this example in the SAS Sample Library for SAS/ETS software.

Nonlinear Optimization Methods

Chapter Contents

Chapter 10
Nonlinear Optimization Methods

Overview

Several SAS/ETS procedures (ENTROPY, MDC, QLIM, UCM, VARMAX) use the NonLinear Optimization (NLO) subsystem to perform nonlinear optimization. This chapter describes the options of the NLO system and some technical details of the available optimization methods. Note that not all options have been implemented for all procedures that use the NLO susbsystem. You should check each procedure chapter for more details on which options are available.

Options

The following table summarizes the options available in the NLO system.

Table 10.1. NLO options

Option	Description
Optimization Specifications	
TECHNIQUE=	minimization technique
UPDATE=	update technique
LINESEARCH=	line-search method
LSPRECISION=	line-search precision
HESCAL=	type of Hessian scaling
INHESSIAN=	start for approximated Hessian
RESTART=	iteration number for update restart
Termination Criteria Specifications	
MAXFUNC=	maximum number of function calls
MAXITER=	maximum number of iterations
MINITER=	minimum number of iterations
MAXTIME=	upper limit seconds of CPU time
ABSCONV=	absolute function convergence criterion
ABSFCONV=	absolute function convergence criterion
ABSGCONV=	absolute gradient convergence criterion
ABSXCONV=	absolute parameter convergence criterion
FCONV=	relative function convergence criterion
FCONV2=	relative function convergence criterion
GCONV=	relative gradient convergence criterion
XCONV=	relative parameter convergence criterion
FSIZE=	used in FCONV, GCONV criterion
XSIZE=	used in XCONV criterion
Step Length Options	
DAMPSTEP=	damped steps in line search
MAXSTEP=	maximum trust region radius

Table 10.1. (continued)

Option	Description
INSTEP=	initial trust region radius
Printed Output Options	
PALL	display (almost) all printed output
PHISTORY	display optimization history
PHISTPARMS	display parameter estimates in each iteration
PSHORT	reduce some default output
PSUMMARY	reduce most default output
NOPRINT	suppress all printed output
Remote Monitoring Options	
SOCKET=	specify the fileref for remote monitoring

These options are described in alphabetical order.

ABSCONV=r
ABSTOL=r
specifies an absolute function convergence criterion. For minimization, termination requires $f(\theta^{(k)}) \leq r$. The default value of r is the negative square root of the largest double precision value, which serves only as a protection against overflows.

ABSFCONV=$r[n]$
ABSFTOL=$r[n]$
specifies an absolute function convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\theta^{(k-1)}) - f(\theta^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 0$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV=$r[n]$
ABSGTOL=$r[n]$
specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\theta^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1\text{E}{-5}$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV=$r[n]$
ABSXTOL=$r[n]$
specifies an absolute parameter convergence criterion. For all techniques except

NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \theta^{(k)} - \theta^{(k-1)} \|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\xi^{(k)}$ with the smallest function value to the other n simplex points $\theta_l^{(k)} \neq \xi^{(k)}$:

$$\delta^{(k)} = \sum_{\theta_l \neq y} \| \theta_l^{(k)} - \xi^{(k)} \|_1$$

The default is $r = 1\text{E} - 8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

DAMPSTEP[=r]

specifies that the initial step length value $\alpha^{(0)}$ for each line search (used by the QUANEW, HYQUAN, CONGRA, or NEWRAP technique) cannot be larger than r times the step length value used in the former iteration. If the DAMPSTEP option is specified but r is not specified, the default is $r = 2$. The DAMPSTEP=r option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating point overflows during the computation of objective functions and their derivatives. The DAMPSTEP=r option can save time-costly function calls during the line searches of objective functions that result in very small steps.

FCONV=$r[n]$
FTOL=$r[n]$

specifies a relative function convergence criterion. For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\theta^{(k)}) - f(\theta^{(k-1)})|}{\max(|f(\theta^{(k-1)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value may depend on the procedure. In most cases, you can use the PALL option to find it.

FCONV2=$r[n]$
FTOL2=$r[n]$

specifies another function convergence criterion. For all techniques except NMSIMP, termination requires a small predicted reduction

$$df^{(k)} \approx f(\theta^{(k)}) - f(\theta^{(k)} + s^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -g^{(k)T}s^{(k)} - \frac{1}{2}s^{(k)T}H^{(k)}s^{(k)} \\ &= -\frac{1}{2}s^{(k)T}g^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step.

$$s^{(k)} = -[H^{(k)}]^{-1}g^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the $n+1$ simplex vertices $\theta_l^{(k)}$, $l = 0, \ldots, n$,

$$\sqrt{\frac{1}{n+1}\sum_l \left[f(\theta_l^{(k)}) - \overline{f}(\theta^{(k)})\right]^2} \leq r$$

where $\overline{f}(\theta^{(k)}) = \frac{1}{n+1}\sum_l f(\theta_l^{(k)})$. If there are n_{act} boundary constraints active at $\theta^{(k)}$, the mean and standard deviation are computed only for the $n+1-n_{act}$ unconstrained vertices. The default value is $r = 1\text{E}-6$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FSIZE=r

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is $r = 0$. For more details, see the FCONV= and GCONV= options.

GCONV=$r[n]$
GTOL=$r[n]$

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction is small,

$$\frac{g(\theta^{(k)})^T[H^{(k)}]^{-1}g(\theta^{(k)})}{\max(|f(\theta^{(k)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate H is not available), the following criterion is used:

$$\frac{\parallel g(\theta^{(k)}) \parallel_2^2 \quad \parallel s(\theta^{(k)}) \parallel_2}{\parallel g(\theta^{(k)}) - g(\theta^{(k-1)}) \parallel_2 \max(|f(\theta^{(k)})|, \text{FSIZE})} \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1E-8$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=$0|1|2|3$
HS=$0|1|2|3$

specifies the scaling version of the Hessian matrix used in NRRIDG, TRUREG, NEWRAP, or DBLDOG optimization. If HS is not equal to 0, the first iteration and each restart iteration sets the diagonal scaling matrix $D^{(0)} = \mathrm{diag}(d_i^{(0)})$:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian. In every other iteration, the diagonal scaling matrix $D^{(0)} = \mathrm{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0	specifies that no scaling is done.
HS=1	specifies the Moré (1978) scaling update: $$d_i^{(k+1)} = \max\left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$
HS=2	specifies the Dennis, Gay, & Welsch (1981) scaling update: $$d_i^{(k+1)} = \max\left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$
HS=3	specifies that d_i is reset in each iteration: $$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time consuming in the case where general linear constraints are active.

INHESSIAN[= r**]**
INHESS[= r**]**

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the r specification, the initial estimate of the approximate Hessian is set to the Hessian at $\theta^{(0)}$.
- If you do use the r specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI.

By default, if you do not specify the option INHESSIAN=r, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI, where the scalar r is computed from the magnitude of the initial gradient.

INSTEP=r

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as INSTEP=1E $-$ 1, INSTEP=1E $-$ 2, INSTEP=1E $-$ 4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the INSTEP= option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, using TECH=NMSIMP, the INSTEP=r option defines the size of the start simplex.

LINESEARCH=i
LIS=i

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. Refer to Fletcher (1987) for an introduction to line-search techniques. The value of i can be $1, \ldots, 8$. For CONGRA, QUANEW and NEWRAP, the default value is $i = 2$.

LIS=1	specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.
LIS=2	specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.
LIS=3	specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.
LIS=4	specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.
LIS=5	specifies a line-search method that is a modified version of LIS=4.
LIS=6	specifies golden section line search (Polak 1971), which uses only function values for linear approximation.
LIS=7	specifies bisection line search (Polak 1971), which uses only function values for linear approximation.
LIS=8	specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION=r
LSP=r

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search may be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in the following table.

TECH=	**UPDATE=**	**LSP default**
QUANEW	DBFGS, BFGS	r = 0.4
QUANEW	DDFP, DFP	r = 0.06
CONGRA	all	r = 0.1
NEWRAP	no update	r = 0.9

For more details, refer to Fletcher (1987).

MAXFUNC=i
MAXFU=i

specifies the maximum number i of function calls in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=i
MAXIT=i

specifies the maximum number i of iterations in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 50
- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when i is specified as a missing value.

MAXSTEP=$r[n]$

specifies an upper bound for the step length of the line-search algorithms during the first n iterations. By default, r is the largest double precision value and n is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=r

specifies an upper limit of r seconds of CPU time for the optimization process. The default value is the largest floating point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

MINITER=i
MINIT=i

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

NOPRINT

suppresses the output. (See proc documentation for availability of this option.)

PALL

displays all optional output for optimization. (See proc documentation for availability of this option.)

PHISTORY

displays the optimization history. (See proc documentation for availability of this option.)

PHISTPARMS

display parameter estimates in each iteration. (See proc documentation for availability of this option.)

PINIT

displays the initial values and derivatives (if available). (See proc documentation for availability of this option.)

PSHORT

restricts the amount of default output. (See proc documentation for availability of this option.)

PSUMMARY

restricts the amount of default displayed output to a short form of iteration history and notes, warnings, and errors. (See proc documentation for availability of this option.)

RESTART=$i > 0$
REST=$i > 0$

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most, i iterations. Default values are

- CONGRA: UPDATE=PB: restart is performed automatically, i is not used.

- CONGRA: UPDATE≠PB: $i = \min(10n, 80)$, where n is the number of parameters.
- QUANEW: i is the largest integer available.

SOCKET=*fileref*
Specifies the fileref that contains the information needed for remote monitoring. See the section "Remote Monitoring" on page 353 for more details.

TECHNIQUE=*value*
TECH=*value*
specifies the optimization technique. Valid values are

- CONGRA
  performs a conjugate-gradient optimization, which can be more precisely specified with the UPDATE= option and modified with the LINESEARCH= option. When you specify this option, UPDATE=PB by default.
- DBLDOG
  performs a version of double dogleg optimization, which can be more precisely specified with the UPDATE= option. When you specify this option, UPDATE=DBFGS by default.
- NMSIMP
  performs a Nelder-Mead simplex optimization.
- NONE
  does not perform any optimization. This option can be used
  - to perform a grid search without optimization
  - to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
- NEWRAP
  performs a Newton-Raphson optimization combining a line-search algorithm with ridging. The line-search algorithm LIS=2 is the default method.
- NRRIDG
  performs a Newton-Raphson optimization with ridging.
- QUANEW
  performs a quasi-Newton optimization, which can be defined more precisely with the UPDATE= option and modified with the LINESEARCH= option. This is the default estimation method.
- TRUREG
  performs a trust region optimization.

UPDATE=*method*
UPD=*method*
specifies the update method for the quasi-Newton, double dogleg, or conjugate-gradient optimization technique. Not every update method can be used with each optimizer.

Valid methods are

- BFGS
  performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- DBFGS
  performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- DDFP
  performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- DFP
  performs the original DFP update of the inverse Hessian matrix.
- PB
  performs the automatic restart update method of Powell (1977) and Beale (1972).
- FR
  performs the Fletcher-Reeves update (Fletcher 1987).
- PR
  performs the Polak-Ribiere update (Fletcher 1987).
- CD
  performs a conjugate-descent update of Fletcher (1987).

XCONV=$r[n]$
XTOL=$r[n]$

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations.

$$\frac{\max_j |\theta_j^{(k)} - \theta_j^{(k-1)}|}{\max(|\theta_j^{(k)}|, |\theta_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but $\theta_j^{(k)}$ is defined as the vertex with the lowest function value and $\theta_j^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 1\text{E} - 8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=$r > 0$

specifies the XSIZE parameter of the relative parameter termination criterion. The default value is $r = 0$. For more detail, see the XCONV= option.

Details of Optimization Algorithms

Overview

There are several optimization techniques available. You can choose a particular optimizer with the TECH=$name$ option in the PROC statement or NLOPTIONS statement.

Algorithm	TECH=
trust region Method	TRUREG
Newton-Raphson method with line search	NEWRAP
Newton-Raphson method with ridging	NRRIDG
quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)	QUANEW
double-dogleg method (DBFGS, DDFP)	DBLDOG
conjugate gradient methods (PB, FR, PR, CD)	CONGRA
Nelder-Mead simplex method	NMSIMP

No algorithm for optimizing general nonlinear functions exists that always finds the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, NLO provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in NLO can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem.

All optimization techniques in NLO use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters. Since the techniques are iterative, they require the repeated computation of

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)

However, since each of the optimizers requires different derivatives, some computational efficiencies can be gained. The following table shows, for each optimization technique, which derivatives are required (FOD: first-order derivatives; SOD: second-order derivatives).

Algorithm	FOD	SOD
TRUREG	x	x
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

Each optimization method employs one or more convergence criteria that determine when it has converged. The various termination criteria are listed and described in the previous section. An algorithm is considered to have converged when any one of the convergence criterion is satisfied. For example, under the default settings, the QUANEW algorithm will converge if $ABSGCONV < 1\text{E}-5$, $FCONV < 10^{-FDIGITS}$, or $GCONV < 1\text{E}-8$.

Choosing an Optimization Algorithm

The factors that go into choosing a particular optimization technique for a particular problem are complex and may involve trial and error.

For many optimization problems, computing the gradient takes more computer time than computing the function value, and computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and as a result the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can more easily terminate at stationary points rather than at global optima.

A few general remarks about the various optimization techniques follow.

- The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $n(n+1)/2$ double words; TRUREG and NEWRAP require two such matrices.
- The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $n(n+1)/2$ double words). QUANEW is the default optimization method.

- The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Since CONGRA requires only a factor of n double-word memory, many large applications can be solved only by CONGRA.
- The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Algorithm Descriptions

Some details about the optimization techniques are as follows.

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function $f(\theta)$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size corresponding to the quality of the quadratic approximation. The trust region method is implemented using Dennis, Gay, and Welsch (1981), Gay (1983), and Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms may be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method may perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite (Eskow and Schnabel 1991).

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LIS=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms may be more efficient.

Since the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $g(\theta_{(k)})$, and it does not need to compute second-order derivatives since they are approximated. It works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian; but, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending upon the value of the UPDATE= option.

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the LIS= option.

The QUANEW algorithm performs its own line-search technique. All options and parameters (except the INSTEP= option) controlling the line search in the other algorithms do not apply here. In several applications, large steps in the first iterations are troublesome. You can use the INSTEP= option to impose an upper bound for the step size α during the first five iterations. You can also use the INHESSIAN[=r] option to specify a different starting approximation for the Hessian. If you specify only the INHESSIAN option, the Cholesky factor of a (possibly ridged) finite difference approximation of the Hessian is used to initialize the quasi-Newton update process. The values of the LCSINGULAR=, LCEPSILON=, and LCDEACT= options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the QUANEW algorithm.

Double Dogleg Optimization (DBLDOG)

The double dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double dogleg algorithm computes the step $s^{(k)}$ as the linear combination of the steepest descent or ascent search direction $s_1^{(k)}$ and a quasi-Newton search direction $s_2^{(k)}$.

$$s^{(k)} = \alpha_1 s_1^{(k)} + \alpha_2 s_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; refer to Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double dogleg optimization technique works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, or NRRIDG technique, which requires second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only $O(n)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the UPDATE= option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default, UPDATE=PB, behaved best in most test examples. You are advised to avoid the option UPDATE=CD, which behaved worst in most test examples.

The CONGRA subroutine should be used for optimization problems with large n. For the unconstrained or boundary constrained case, CONGRA requires only $O(n)$ bytes of working memory, whereas all other optimization methods require order $O(n^2)$ bytes of working memory. During n successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of n conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the LIS= option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it may be unable to generate precise results for $n \gg 40$.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criteria.

Remote Monitoring

The SAS/EmMonitor is an application for Windows that enables you to monitor and stop from your PC a CPU-intensive application performed by the NLO subsystem running on a remote server.

On the server side, a FILENAME statement assigns a fileref to a SOCKET-type device that defines the ip address of the client and the port number for listening. The fileref is then specified in the SOCKET= option to control the EmMonitor. The following statements show an example of server-side code for PROC ENTROPY.

```
data one;
 do t = 1 to 10;
    x1 = 5 * ranuni(456);
    x2 = 10 * ranuni( 456);
    x3 = 2 * rannor(1456);
    e1 = rannor(1456);
    e2 = rannor(4560);
    tmp1 = 0.5 * e1 - 0.1 * e2;
    tmp2 = -0.1 * e1 - 0.3 * e2;
    y1 = 7 + 8.5*x1 + 2*x2 + tmp1;
    y2 = -3 + -2*x1 + x2 + 3*x3 + tmp2;
    output;
   end;
run;

filename sock socket 'your.pc.address.com:6943';

proc entropy data=one tech=tr gmenm gconv=2.e-5 socket=sock;
   model y1 = x1 x2 x3;
run;
```

On the client side, the EmMonitor application is started with the following syntax:

EmMonitor *options*

The options are:

-p port_number	define the port number
-t title	define the title of the EmMonitor window
-k	keep the monitor alive when the iteration is completed

The default port number is 6943.

The server does not need to be running when you start the EmMonitor, and you can start or dismiss it at any time during the iteration process. You only need to remember the port number.

If you do not start the PC client, or you close it prematurely, it will not have any effect on the server side. In other words, the iteration process will continue until one of the criteria for termination is met.

Figure 10.1 through Figure 10.4 show screenshots of the application on the client side.

ODS Table Names

The NLO subsystem assigns a name to each table it creates. You can use these names when using the Output Delivery System (ODS) to select tables and create output data sets. Not all tables are created by all SAS/ETS procedures that use the NLO subsystem. You should check the procedure chapter for more details. The names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 10.2. ODS Tables Produced by the NLO Subsystem

ODS Table Name	Description
ConvergenceStatus	Convergence status
InputOptions	Input options
IterHist	Iteration history
IterStart	Iteration start
IterStop	Iteration stop
Lagrange	Lagrange multipliers at the solution
LinCon	Linear constraints
LinConDel	Deleted linear constraints
LinConSol	Linear constraints at the solution

Chapter 11 The ARIMA Procedure

Overview

The ARIMA procedure analyzes and forecasts equally spaced univariate time series data, transfer function data, and intervention data using the **A**uto**R**egressive **I**ntegrated **M**oving-**A**verage (ARIMA) or autoregressive moving-average (ARMA) model. An ARIMA model predicts a value in a response time series as a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series.

The ARIMA approach was first popularized by Box and Jenkins, and ARIMA models are often referred to as Box-Jenkins models. The general transfer function model employed by the ARIMA procedure was discussed by Box and Tiao (1975). When an ARIMA model includes other time series as input variables, the model is sometimes referred to as an ARIMAX model. Pankratz (1991) refers to the ARIMAX model as *dynamic regression*.

The ARIMA procedure provides a comprehensive set of tools for univariate time series model identification, parameter estimation, and forecasting, and it offers great flexibility in the kinds of ARIMA or ARIMAX models that can be analyzed. The ARIMA procedure supports seasonal, subset, and factored ARIMA models; intervention or interrupted time series models; multiple regression analysis with ARMA errors; and rational transfer function models of any complexity.

Experimental graphics are now available with the ARIMA procedure. For more information, see the "ODS Graphics" section on page 443.

The design of PROC ARIMA closely follows the Box-Jenkins strategy for time series modeling with features for the identification, estimation and diagnostic checking, and forecasting steps of the Box-Jenkins method.

Before using PROC ARIMA, you should be familiar with Box-Jenkins methods, and you should exercise care and judgment when using the ARIMA procedure. The ARIMA class of time series models is complex and powerful, and some degree of expertise is needed to use them correctly.

If you are unfamiliar with the principles of ARIMA modeling, refer to textbooks on time series analysis. Also refer to *SAS/ETS Software: Applications Guide 1, Version 6, First Edition*. You might consider attending the SAS Training Course "Introduction to Time Series Forecasting Using SAS/ETS Software." This course provides in-depth training on ARIMA modeling using PROC ARIMA, as well as training on the use of other forecasting tools available in SAS/ETS software.

Getting Started

This section outlines the use of the ARIMA procedure and gives a cursory description of the ARIMA modeling process for readers less familiar with these methods.

The Three Stages of ARIMA Modeling

The analysis performed by PROC ARIMA is divided into three stages, corresponding to the stages described by Box and Jenkins (1976).

1. In the *identification* stage, you use the IDENTIFY statement to specify the response series and identify candidate ARIMA models for it. The IDENTIFY statement reads time series that are to be used in later statements, possibly differencing them, and computes autocorrelations, inverse autocorrelations, partial autocorrelations, and cross correlations. Stationarity tests can be performed to determine if differencing is necessary. The analysis of the IDENTIFY statement output usually suggests one or more ARIMA models that could be fit. Options enable you to test for stationarity and tentative ARMA order identification.
2. In the *estimation and diagnostic checking* stage, you use the ESTIMATE statement to specify the ARIMA model to fit to the variable specified in the previous IDENTIFY statement, and to estimate the parameters of that model. The ESTIMATE statement also produces diagnostic statistics to help you judge the adequacy of the model.

   Significance tests for parameter estimates indicate whether some terms in the model may be unnecessary. Goodness-of-fit statistics aid in comparing this model to others. Tests for white noise residuals indicate whether the residual series contains additional information that might be utilized by a more complex model. The OUTLIER statement provides another useful tool to check whether the currently estimated model accounts for all the variation in the series. If the diagnostic tests indicate problems with the model, you try another model, then repeat the estimation and diagnostic checking stage.
3. In the *forecasting* stage you use the FORECAST statement to forecast future values of the time series and to generate confidence intervals for these forecasts from the ARIMA model produced by the preceding ESTIMATE statement.

These three steps are explained further and illustrated through an extended example in the following sections.

Identification Stage

Suppose you have a variable called SALES that you want to forecast. The following example illustrates ARIMA modeling and forecasting using a simulated data set TEST containing a time series SALES generated by an ARIMA(1,1,1) model. The output produced by this example is explained in the following sections. The simulated SALES series is shown in Figure 11.1.

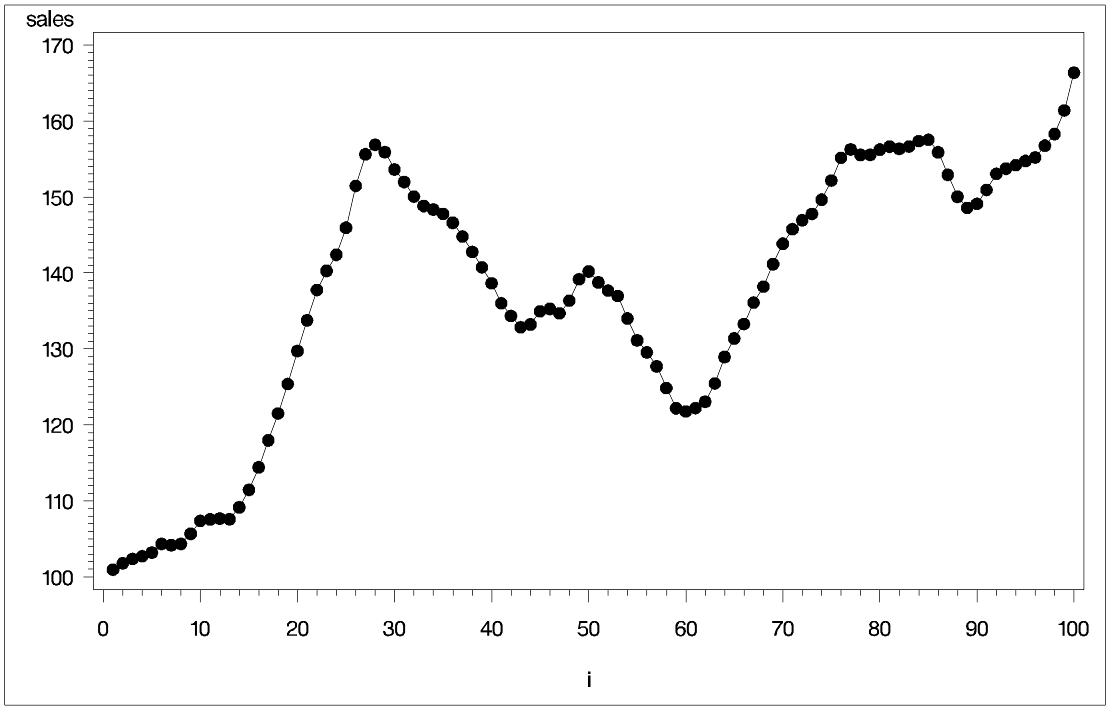

Figure 11.1. Simulated ARIMA(1, 1, 1) Series SALES

Using the IDENTIFY Statement

You first specify the input data set in the PROC ARIMA statement. Then, you use an IDENTIFY statement to read in the SALES series and plot its autocorrelation function. You do this using the following statements:

```
proc arima data=test;
   identify var=sales nlag=8;
   run;
```

Descriptive Statistics

The IDENTIFY statement first prints descriptive statistics for the SALES series. This part of the IDENTIFY statement output is shown in Figure 11.2.

```
                              The ARIMA Procedure

                            Name of Variable = sales

                       Mean of Working Series    137.3662
                       Standard Deviation        17.36385
                       Number of Observations         100
```

Figure 11.2. IDENTIFY Statement Descriptive Statistics Output

Autocorrelation Function Plots

The IDENTIFY statement next prints three plots of the correlations of the series with its past values at different lags. These are the

- sample autocorrelation function plot
- sample partial autocorrelation function plot
- sample inverse autocorrelation function plot

The sample autocorrelation function plot output of the IDENTIFY statement is shown in Figure 11.3.

```
                              The ARIMA Procedure

                                Autocorrelations

Lag   Covariance   Correlation   -1 9 8 7 6 5 4 3 2 1 0 1 2 3 4 5 6 7 8 9 1

  0      301.503       1.00000   |                    |********************|
  1      288.454       0.95672   |                .   |******************* |
  2      273.437       0.90691   |             .      |******************  |
  3      256.787       0.85169   |            .       |*****************   |
  4      238.518       0.79110   |          .         |****************    |
  5      219.033       0.72647   |         .          |***************     |
  6      198.617       0.65876   |         .          |*************       |
  7      177.150       0.58755   |        .           |************        |
  8      154.914       0.51381   |       .            |**********  .       |

                         "." marks two standard errors
```

Figure 11.3. IDENTIFY Statement Autocorrelations Plot

The autocorrelation plot shows how values of the series are correlated with past values of the series. For example, the value 0.95672 in the “Correlation” column for the Lag 1 row of the plot means that the correlation between SALES and the SALES value for the previous period is .95672. The rows of asterisks show the correlation values graphically.

These plots are called autocorrelation functions because they show the degree of correlation with past values of the series as a function of the number of periods in the past (that is, the lag) at which the correlation is computed.

The NLAG= option controls the number of lags for which autocorrelations are shown. By default, the autocorrelation functions are plotted to lag 24; in this example the NLAG=8 option is used, so only the first 8 lags are shown.

Most books on time series analysis explain how to interpret autocorrelation plots and partial autocorrelation plots. See the section "The Inverse Autocorrelation Function" on page 409 for a discussion of inverse autocorrelation plots.

By examining these plots, you can judge whether the series is *stationary* or *nonstationary*. In this case, a visual inspection of the autocorrelation function plot indicates that the SALES series is nonstationary, since the ACF decays very slowly. For more formal stationarity tests, use the STATIONARITY= option. (See the section "Stationarity" on page 382.)

The inverse and partial autocorrelation plots are printed after the autocorrelation plot. These plots have the same form as the autocorrelation plots, but display inverse and partial autocorrelation values instead of autocorrelations and autocovariances. The partial and inverse autocorrelation plots are not shown in this example.

White Noise Test

The last part of the default IDENTIFY statement output is the check for white noise. This is an approximate statistical test of the hypothesis that none of the autocorrelations of the series up to a given lag are significantly different from 0. If this is true for all lags, then there is no information in the series to model, and no ARIMA model is needed for the series.

The autocorrelations are checked in groups of 6, and the number of lags checked depends on the NLAG= option. The check for white noise output is shown in Figure 11.4.

```
                         The ARIMA Procedure

                  Autocorrelation Check for White Noise

 To        Chi-             Pr >
Lag      Square     DF     ChiSq    ---------------Autocorrelations---------------

  6      426.44      6    <.0001     0.957     0.907     0.852     0.791     0.726     0.659
```

Figure 11.4. IDENTIFY Statement Check for White Noise

In this case, the white noise hypothesis is rejected very strongly, which is expected since the series is nonstationary. The *p* value for the test of the first six autocorrelations is printed as <0.0001, which means the *p* value is less than .0001.

Identification of the Differenced Series

Since the series is nonstationary, the next step is to transform it to a stationary series by differencing. That is, instead of modeling the SALES series itself, you model the change in SALES from one period to the next. To difference the SALES series, use another IDENTIFY statement and specify that the first difference of SALES be analyzed, as shown in the following statements:

```
identify var=sales(1) nlag=8;
run;
```

The second IDENTIFY statement produces the same information as the first but for the change in SALES from one period to the next rather than for the total sales in each period. The summary statistics output from this IDENTIFY statement is shown in Figure 11.5. Note that the period of differencing is given as 1, and one observation was lost through the differencing operation.

```
                              The ARIMA Procedure

                           Name of Variable = sales

             Period(s) of Differencing                           1
             Mean of Working Series                       0.660589
             Standard Deviation                           2.011543
             Number of Observations                             99
             Observation(s) eliminated by differencing           1
```

Figure 11.5. IDENTIFY Statement Output for Differenced Series

The autocorrelation plot for the differenced series is shown in Figure 11.6.

```

Figure 11.6. Autocorrelations Plot for Change in SALES

The autocorrelations decrease rapidly in this plot, indicating that the change in SALES is a stationary time series.

The next step in the Box-Jenkins methodology is to examine the patterns in the autocorrelation plot to choose candidate ARMA models to the series. The partial and inverse autocorrelation function plots are also useful aids in identifying appropriate ARMA models for the series. The partial and inverse autocorrelation function plots are shown in Figure 11.7 and Figure 11.8.

Figure 11.8. Partial Autocorrelation Plot for Change in SALES

In the usual Box and Jenkins approach to ARIMA modeling, the sample autocorrelation function, inverse autocorrelation function, and partial autocorrelation function are compared with the theoretical correlation functions expected from different kinds of ARMA models. This matching of theoretical autocorrelation functions of different ARMA models to the sample autocorrelation functions computed from the response series is the heart of the identification stage of Box-Jenkins modeling. Most textbooks on time series analysis discuss the theoretical autocorrelation functions for different kinds of ARMA models.

Since the input data are only a limited sample of the series, the sample autocorrelation functions computed from the input series will only approximate the true autocorrelation functions of the process generating the series. This means that the sample autocorrelation functions will not exactly match the theoretical autocorrelation functions for any ARMA model and may have a pattern similar to that of several different ARMA models.

If the series is white noise (a purely random process), then there is no need to fit a model. The check for white noise, shown in Figure 11.9, indicates that the change in sales is highly autocorrelated. Thus, an autocorrelation model, for example an AR(1) model, might be a good candidate model to fit to this process.

```
                              The ARIMA Procedure

Figure 11.9. IDENTIFY Statement Check for White Noise

Estimation and Diagnostic Checking Stage

The autocorrelation plots for this series, as shown in the previous section, suggest an AR(1) model for the change in SALES. You should check the diagnostic statistics to see if the AR(1) model is adequate. Other candidate models include an MA(1) model, and low-order mixed ARMA models. In this example, the AR(1) model is tried first.

Estimating an AR(1) Model

The following statements fit an AR(1) model (an autoregressive model of order 1), which predicts the change in sales as an average change, plus some fraction of the previous change, plus a random error. To estimate an AR model, you specify the order of the autoregressive model with the P= option on an ESTIMATE statement, as shown in the following statements:

```
estimate p=1;
run;
```

The ESTIMATE statement fits the model to the data and prints parameter estimates and various diagnostic statistics that indicate how well the model fits the data. The first part of the ESTIMATE statement output, the table of parameter estimates, is shown in Figure 11.10.

```
                              The ARIMA Procedure

                      Conditional Least Squares Estimation

     MU               0.90280       0.65984       1.37       0.1744        0
     AR1,1            0.86847       0.05485      15.83       <.0001        1
```

Figure 11.10. Parameter Estimates for AR(1) Model

The table of parameter estimates is titled “Conditional Least Squares Estimation,” which indicates the estimation method used. You can request different estimation methods with the METHOD= option.

The table of parameter estimates lists the parameters in the model; for each parameter, the table shows the estimated value and the standard error and *t* value for the estimate. The table also indicates the lag at which the parameter appears in the model.

In this case, there are two parameters in the model. The mean term is labeled MU; its estimated value is .90280. The autoregressive parameter is labeled AR1,1; this is the coefficient of the lagged value of the change in SALES, and its estimate is .86847.

The *t* values provide significance tests for the parameter estimates and indicate whether some terms in the model may be unnecessary. In this case, the *t* value for the autoregressive parameter is 15.83, so this term is highly significant. The *t* value for MU indicates that the mean term adds little to the model.

The standard error estimates are based on large sample theory. Thus, the standard errors are labeled as approximate, and the standard errors and *t* values may not be reliable in small samples.

The next part of the ESTIMATE statement output is a table of goodness-of-fit statistics, which aid in comparing this model to other models. This output is shown in Figure 11.11.

```

                              The ARIMA Procedure

                  * AIC and SBC do not include log determinant.
```

Figure 11.11. Goodness-of-Fit Statistics for AR(1) Model

The “Constant Estimate” is a function of the mean term MU and the autoregressive parameters. This estimate is computed only for AR or ARMA models, but not for strictly MA models. See the section “General Notation for ARIMA Models” on page 379 for an explanation of the constant estimate.

The “Variance Estimate” is the variance of the residual series, which estimates the innovation variance. The item labeled “Std Error Estimate” is the square root of the variance estimate. In general, when comparing candidate models, smaller AIC and SBC statistics indicate the better fitting model. The section The section “Estimation Details” on page 418 explains the AIC and SBC statistics.

The ESTIMATE statement next prints a table of correlations of the parameter estimates, as shown in Figure 11.12. This table can help you assess the extent to which collinearity may have influenced the results. If two parameter estimates are very highly correlated, you might consider dropping one of them from the model.

```
                              The ARIMA Procedure

                           Correlations of Parameter
                                   Estimates

                         MU             1.000      0.114
                         AR1,1          0.114      1.000
```

Figure 11.12. Correlations of the Estimates for AR(1) Model

The next part of the ESTIMATE statement output is a check of the autocorrelations of the residuals. This output has the same form as the autocorrelation check for white noise that the IDENTIFY statement prints for the response series. The autocorrelation check of residuals is shown in Figure 11.13.

```
                              The ARIMA Procedure

                        Autocorrelation Check of Residuals

  To      Chi-          Pr >
 Lag    Square   DF   ChiSq   ---------------Autocorrelations--------------

   6     19.09    5  0.0019   0.327  -0.220  -0.128   0.068  -0.002  -0.096
  12     22.90   11  0.0183   0.072   0.116  -0.042  -0.066   0.031  -0.091
  18     31.63   17  0.0167  -0.233  -0.129  -0.024   0.056  -0.014  -0.008
  24     32.83   23  0.0841   0.009  -0.057  -0.057  -0.001   0.049  -0.015
```

Figure 11.13. Check for White Noise Residuals for AR(1) Model

The χ^2 test statistics for the residuals series indicate whether the residuals are uncorrelated (white noise) or contain additional information that might be utilized by a more complex model. In this case, the test statistics reject the no-autocorrelation hypothesis at a high level of significance. (p=0.0019 for the first six lags.) This means that the residuals are not white noise, and so the AR(1) model is not a fully adequate model for this series.

The final part of the ESTIMATE statement output is a listing of the estimated model using the back shift notation. This output is shown in Figure 11.14.

```
                          The ARIMA Procedure

                       Model for variable sales

                 Estimated Mean               0.902799
                 Period(s) of Differencing           1

                        Autoregressive Factors

                    Factor 1:  1 - 0.86847 B**(1)
```

Figure 11.14. Estimated ARIMA(1, 1, 0) Model for SALES

This listing combines the differencing specification given in the IDENTIFY statement with the parameter estimates of the model for the change in sales. Since the AR(1) model is for the change in sales, the final model for sales is an ARIMA(1,1,0) model. Using B, the back shift operator, the mathematical form of the estimated model shown in this output is as follows:

$$(1 - B)sales_t = 0.902799 + \frac{1}{(1 - 0.86847B)}a_t$$

See the section "General Notation for ARIMA Models" on page 379 for further explanation of this notation.

Estimating an ARMA(1,1) Model

The IDENTIFY statement plots suggest a mixed autoregressive and moving average model, and the previous ESTIMATE statement check of residuals indicates that an AR(1) model is not sufficient. You now try estimating an ARMA(1,1) model for the change in SALES.

An ARMA(1,1) model predicts the change in SALES as an average change, plus some fraction of the previous change, plus a random error, plus some fraction of the random error in the preceding period. An ARMA(1,1) model for the change in sales is the same as an ARIMA(1,1,1) model for the level of sales.

To estimate a mixed autoregressive moving average model, you specify the order of the moving average part of the model with the Q= option on an ESTIMATE statement in addition to specifying the order of the autoregressive part with the P= option. The following statements fit an ARMA(1,1) model to the differenced SALES series:

```
   estimate p=1 q=1;
   run;
```

The parameter estimates table and goodness-of-fit statistics for this model are shown in Figure 11.15.

```
                              The ARIMA Procedure

                 * AIC and SBC do not include log determinant.

                                Standard                 Approx
       Parameter      Estimate     Error    t Value    Pr > |t|     Lag

       MU              0.89288   0.49391       1.81      0.0738       0
       MA1,1          -0.58935   0.08988      -6.56      <.0001       1
       AR1,1           0.74755   0.07785       9.60      <.0001       1

                        Constant Estimate      0.225409
                        Variance Estimate      0.904034
                        Std Error Estimate     0.950807
                        AIC                    273.9155
                        SBC                    281.7009
                        Number of Residuals          99
                 * AIC and SBC do not include log determinant.
```

Figure 11.15. Estimated ARMA(1, 1) Model for Change in SALES

The moving average parameter estimate, labeled “MA1,1”, is -0.58935. Both the moving average and the autoregressive parameters have significant *t* values. Note that the variance estimate, AIC, and SBC are all smaller than they were for the AR(1) model, indicating that the ARMA(1,1) model fits the data better without overparameterizing.

The check for white noise residuals is shown in Figure 11.16. The χ^2 tests show that you cannot reject the hypothesis that the residuals are uncorrelated. Thus, you conclude that the ARMA(1,1) model is adequate for the change in sales series, and there is no point in trying more complex models.

                      Moving Average Factors

                    Factor 1:  1 + 0.58935 B**(1)
```

Figure 11.17. Estimated ARIMA(1, 1, 1) Model for SALES

The estimated model shown in this output is

$$(1-B)sales_t = 0.892875 + \frac{(1+0.58935B)}{(1-0.74755B)}a_t$$

The OUTLIER statement enables you to detect whether there are changes in the time series that are not accounted for by the currently estimated model. For a long series, this task can be computationally burdensome, therefore, in general, it is better left to when a model that fits the data reasonably well has been found. Figure 11.18 shows the output of the simplest form of the statement:

```
   outlier;
```

Two possible outliers have been found for the model in question. See the "Detecting Outliers" section on page 430, Example 11.6 on page 476, and Example 11.7 on page 478 for more details on modeling in the presence of outliers.

```

```

Figure 11.18. Outliers for the ARIMA(1, 1, 1) Model for SALES

Since the model diagnostic tests show that all the parameter estimates are significant and the residual series is white noise, the estimation and diagnostic checking stage is complete. You can now proceed to forecasting the SALES series with this ARIMA(1,1,1) model.

Forecasting Stage

To produce the forecast, use a FORECAST statement after the ESTIMATE statement for the model you decide is best. If the last model fit were not the best, then repeat the ESTIMATE statement for the best model before using the FORECAST statement.

Suppose that the SALES series is monthly, that you wish to forecast one year ahead from the most recently available sales figure, and that the dates for the observations are given by a variable DATE in the input data set TEST. You use the following FORECAST statement:

```
forecast lead=12 interval=month id=date out=results;
run;
```

The LEAD= option specifies how many periods ahead to forecast (12 months, in this case). The ID= option specifies the ID variable used to date the observations of the SALES time series. The INTERVAL= option indicates that data are monthly and enables PROC ARIMA to extrapolate DATE values for forecast periods. The OUT= option writes the forecasts to an output data set RESULTS. See the section "OUT= Data Set" on page 432 for information on the contents of the output data set.

By default, the FORECAST statement also prints the forecast values, as shown in Figure 11.19. This output shows for each forecast period the observation number, forecast value, standard error estimate for the forecast value, and lower and upper limits for a 95% confidence interval for the forecast.

```

```

Figure 11.19. Estimated ARIMA(1, 1, 1) Model for SALES

Normally, you want the forecast values stored in an output data set, and you are not interested in seeing this printed list of the forecast. You can use the NOPRINT option on the FORECAST statement to suppress this output.

Using ARIMA Procedure Statements

The IDENTIFY, ESTIMATE, and FORECAST statements are related in a hierarchy. An IDENTIFY statement brings in a time series to be modeled; several ESTIMATE statements can follow to estimate different ARIMA models for the series; for each model estimated, several FORECAST statements can be used. Thus, a FORECAST statement must be preceded at some point by an ESTIMATE statement, and an ESTIMATE statement must be preceded at some point by an IDENTIFY statement. Additional IDENTIFY statements can be used to switch to modeling a different response series or to change the degree of differencing used.

The ARIMA procedure can be used interactively in the sense that all ARIMA procedure statements can be executed any number of times without reinvoking PROC ARIMA. You can execute ARIMA procedure statements singly or in groups by following the single statement or group of statements with a RUN statement. The output for each statement or group of statements is produced when the RUN statement is entered.

A RUN statement does not terminate the PROC ARIMA step but tells the procedure to execute the statements given so far. You can end PROC ARIMA by submitting a QUIT statement, a DATA step, another PROC step, or an ENDSAS statement.

The example in the preceding section illustrates the interactive use of ARIMA procedure statements. The complete PROC ARIMA program for that example is as follows:

```
proc arima data=test;
   identify var=sales nlag=8;
   run;
   identify var=sales(1) nlag=8;
   run;
   estimate p=1;
   run;
   estimate p=1 q=1;
   run;
   forecast lead=12 interval=month id=date out=results;
   run;
quit;
```

General Notation for ARIMA Models

The order of an ARIMA (AutoRegressive Integrated Moving-Average) model is usually denoted by the notation ARIMA(p,d,q), where

p	is the order of the autoregressive part
d	is the order of the differencing

q	is the order of the moving-average process

If no differencing is done (*d* = 0), the models are usually referred to as ARMA(*p*,*q*) models. The final model in the preceding example is an ARIMA(1,1,1) model since the IDENTIFY statement specified *d* = 1, and the final ESTIMATE statement specified *p* = 1 and *q* = 1.

Notation for Pure ARIMA Models

Mathematically the pure ARIMA model is written as

$$W_t = \mu + \frac{\theta(B)}{\phi(B)} a_t$$

where

t	indexes time
W_t	is the response series Y_t or a difference of the response series
μ	is the mean term
B	is the backshift operator; that is, $BX_t = X_{t-1}$
$\phi(B)$	is the autoregressive operator, represented as a polynomial in the back shift operator: $\phi(B) = 1 - \phi_1 B - \ldots - \phi_p B^p$
$\theta(B)$	is the moving-average operator, represented as a polynomial in the back shift operator: $\theta(B) = 1 - \theta_1 B - \ldots - \theta_q B^q$
a_t	is the independent disturbance, also called the random error.

The series W_t is computed by the IDENTIFY statement and is the series processed by the ESTIMATE statement. Thus, W_t is either the response series Y_t or a difference of Y_t specified by the differencing operators in the IDENTIFY statement.

For simple (nonseasonal) differencing, $W_t = (1 - B)^d Y_t$. For seasonal differencing $W_t = (1 - B)^d (1 - B^s)^D Y_t$, where *d* is the degree of nonseasonal differencing, *D* is the degree of seasonal differencing, and *s* is the length of the seasonal cycle.

For example, the mathematical form of the ARIMA(1,1,1) model estimated in the preceding example is

$$(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)} a_t$$

Model Constant Term

The ARIMA model can also be written as

$$\phi(B)(W_t - \mu) = \theta(B) a_t$$

or

$$\phi(B)W_t = const + \theta(B)a_t$$

where

$$const = \phi(B)\mu = \mu - \phi_1\mu - \phi_2\mu - \ldots - \phi_p\mu$$

Thus, when an autoregressive operator and a mean term are both included in the model, the constant term for the model can be represented as $\phi(B)\mu$. This value is printed with the label “Constant Estimate” in the ESTIMATE statement output.

Notation for Transfer Function Models

The general ARIMA model with input series, also called the ARIMAX model, is written as

$$W_t = \mu + \sum_i \frac{\omega_i(B)}{\delta_i(B)} B^{k_i} X_{i,t} + \frac{\theta(B)}{\phi(B)} a_t$$

where

$X_{i,t}$	is the *i*th input time series or a difference of the *i*th input series at time *t*
k_i	is the pure time delay for the effect of the *i*th input series
$\omega_i(B)$	is the numerator polynomial of the transfer function for the *i*th input series
$\delta_i(B)$	is the denominator polynomial of the transfer function for the *i*th input series.

The model can also be written more compactly as

$$W_t = \mu + \sum_i \Psi_i(B) X_{i,t} + n_t$$

where

$\Psi_i(B)$	is the transfer function weights for the *i*th input series modeled as a ratio of the ω and δ polynomials: $\Psi_i(B) = (\omega_i(B)/\delta_i(B))B^{k_i}$
n_t	is the noise series: $n_t = (\theta(B)/\phi(B))a_t$

This model expresses the response series as a combination of past values of the random shocks and past values of other input series. The response series is also called the *dependent series* or *output series*. An input time series is also referred to as an *independent series* or a *predictor series*. Response variable, dependent variable, independent variable, or predictor variable are other terms often used.

Notation for Factored Models

ARIMA models are sometimes expressed in a factored form. This means that the ϕ, θ, ω, or δ polynomials are expressed as products of simpler polynomials. For example, you could express the pure ARIMA model as

$$W_t = \mu + \frac{\theta_1(B)\theta_2(B)}{\phi_1(B)\phi_2(B)}a_t$$

where $\phi_1(B)\phi_2(B) = \phi(B)$ and $\theta_1(B)\theta_2(B) = \theta(B)$.

When an ARIMA model is expressed in factored form, the order of the model is usually expressed using a factored notation also. The order of an ARIMA model expressed as the product of two factors is denoted as ARIMA(*p*,*d*,*q*)$\times$(*P*,*D*,*Q*).

Notation for Seasonal Models

ARIMA models for time series with regular seasonal fluctuations often use differencing operators and autoregressive and moving average parameters at lags that are multiples of the length of the seasonal cycle. When all the terms in an ARIMA model factor refer to lags that are a multiple of a constant *s*, the constant is factored out and suffixed to the ARIMA(*p*,*d*,*q*) notation.

Thus, the general notation for the order of a seasonal ARIMA model with both seasonal and nonseasonal factors is ARIMA(*p*,*d*,*q*)$\times$(*P*,*D*,*Q*)$_s$. The term (*p*,*d*,*q*) gives the order of the nonseasonal part of the ARIMA model; the term (*P*,*D*,*Q*)$_s$ gives the order of the seasonal part. The value of *s* is the number of observations in a seasonal cycle: 12 for monthly series, 4 for quarterly series, 7 for daily series with day-of-week effects, and so forth.

For example, the notation ARIMA(0,1,2)$\times$(0,1,1)$_{12}$ describes a seasonal ARIMA model for monthly data with the following mathematical form:

$$(1-B)(1-B^{12})Y_t = \mu + (1-\theta_{1,1}B - \theta_{1,2}B^2)(1-\theta_{2,1}B^{12})a_t$$

Stationarity

The noise (or residual) series for an ARMA model must be *stationary*, which means that both the expected values of the series and its autocovariance function are independent of time.

The standard way to check for nonstationarity is to plot the series and its autocorrelation function. You can visually examine a graph of the series over time to see if it has a visible trend or if its variability changes noticeably over time. If the series is nonstationary, its autocorrelation function will usually decay slowly.

Another way of checking for stationarity is to use the stationarity tests described in the section "Stationarity Tests" on page 416.

Most time series are nonstationary and must be transformed to a stationary series before the ARIMA modeling process can proceed. If the series has a nonstationary variance, taking the log of the series may help. You can compute the log values in a DATA step and then analyze the log values with PROC ARIMA.

If the series has a trend over time, seasonality, or some other nonstationary pattern, the usual solution is to take the difference of the series from one period to the next and then analyze this differenced series. Sometimes a series may need to be differenced more than once or differenced at lags greater than one period. (If the trend or seasonal effects are very regular, the introduction of explanatory variables may be an appropriate alternative to differencing.)

Differencing

Differencing of the response series is specified with the VAR= option of the IDENTIFY statement by placing a list of differencing periods in parentheses after the variable name. For example, to take a simple first difference of the series SALES, use the statement

```
identify var=sales(1);
```

In this example, the change in SALES from one period to the next will be analyzed.

A deterministic seasonal pattern will also cause the series to be nonstationary, since the expected value of the series will not be the same for all time periods but will be higher or lower depending on the season. When the series has a seasonal pattern, you may want to difference the series at a lag corresponding to the length of the cycle of seasons. For example, if SALES is a monthly series, the statement

```
identify var=sales(12);
```

takes a seasonal difference of SALES, so that the series analyzed is the change in SALES from its value in the same month one year ago.

To take a second difference, add another differencing period to the list. For example, the following statement takes the second difference of SALES:

```
identify var=sales(1,1);
```

That is, SALES is differenced once at lag 1 and then differenced again, also at lag 1. The statement

```
identify var=sales(2);
```

creates a 2-span difference, that is current period sales minus sales from two periods ago. The statement

```
identify var=sales(1,12);
```

takes a second-order difference of SALES, so that the series analyzed is the difference between the current period-to-period change in SALES and the change 12 periods ago. You might want to do this if the series had both a trend over time and a seasonal pattern.

There is no limit to the order of differencing and the degree of lagging for each difference.

Differencing not only affects the series used for the IDENTIFY statement output but also applies to any following ESTIMATE and FORECAST statements. ESTIMATE statements fit ARMA models to the differenced series. FORECAST statements forecast the differences and automatically sum these differences back to undo the differencing operation specified by the IDENTIFY statement, thus producing the final forecast result.

Differencing of input series is specified by the CROSSCORR= option and works just like differencing of the response series. For example, the statement

```
identify var=y(1) crosscorr=(x1(1) x2(1));
```

takes the first difference of Y, the first difference of X1, and the first difference of X2. Whenever X1 and X2 are used in INPUT= options in following ESTIMATE statements, these names refer to the differenced series.

Subset, Seasonal, and Factored ARMA Models

The simplest way to specify an ARMA model is to give the order of the AR and MA parts with the P= and Q= options. When you do this, the model has parameters for the AR and MA parts for all lags through the order specified. However, you can control the form of the ARIMA model exactly as shown in the following section.

Subset Models

You can control which lags have parameters by specifying the P= or Q= option as a list of lags in parentheses. A model like this that includes parameters for only some lags is sometimes called a *subset* or *additive model*. For example, consider the following two ESTIMATE statements:

```
identify var=sales;
estimate p=4;
estimate p=(1 4);
```

Both specify AR(4) models, but the first has parameters for lags 1, 2, 3, and 4, while the second has parameters for lags 1 and 4, with the coefficients for lags 2 and 3 constrained to 0. The mathematical form of the autoregressive models produced by these two specifications is shown in Table 11.1.

Table 11.1. Saturated versus Subset Models

Option	Autoregressive Operator
P=4	$(1 - \phi_1 B - \phi_2 B^2 - \phi_3 B^3 - \phi_4 B^4)$
P=(1 4)	$(1 - \phi_1 B - \phi_4 B^4)$

Seasonal Models

One particularly useful kind of subset model is a *seasonal model*. When the response series has a seasonal pattern, the values of the series at the same time of year in previous years may be important for modeling the series. For example, if the series SALES is observed monthly, the statements

```
   identify var=sales;
   estimate p=(12);
```

model SALES as an average value plus some fraction of its deviation from this average value a year ago, plus a random error. Although this is an AR(12) model, it has only one autoregressive parameter.

Factored Models

A factored model (also referred to as a multiplicative model) represents the ARIMA model as a product of simpler ARIMA models. For example, you might model SALES as a combination of an AR(1) process reflecting short term dependencies and an AR(12) model reflecting the seasonal pattern.

It might seem that the way to do this is with the option P=(1 12), but the AR(1) process also operates in past years; you really need autoregressive parameters at lags 1, 12, and 13. You can specify a subset model with separate parameters at these lags, or you can specify a factored model that represents the model as the product of an AR(1) model and an AR(12) model. Consider the following two ESTIMATE statements:

```
   identify var=sales;
   estimate p=(1 12 13);
   estimate p=(1)(12);
```

The mathematical form of the autoregressive models produced by these two specifications are shown in Table 11.2.

Table 11.2. Subset versus Factored Models

Option	Autoregressive Operator
P=(1 12 13)	$(1 - \phi_1 B - \phi_{12} B^{12} - \phi_{13} B^{13})$
P=(1)(12)	$(1 - \phi_1 B)(1 - \phi_{12} B^{12})$

Both models fit by these two ESTIMATE statements predict SALES from its values 1, 12, and 13 periods ago, but they use different parameterizations. The first model has three parameters, whose meanings may be hard to interpret.

The factored specification P=(1)(12) represents the model as the product of two different AR models. It has only two parameters: one that corresponds to recent effects and one that represents seasonal effects. Thus the factored model is more parsimonious, and its parameter estimates are more clearly interpretable.

Input Variables and Regression with ARMA Errors

In addition to past values of the response series and past errors, you can also model the response series using the current and past values of other series, called *input series*.

Several different names are used to describe ARIMA models with input series. *Transfer function model*, *intervention model*, *interrupted time series model*, *regression model with ARMA errors*, *Box-Tiao model*, and *ARIMAX model* are all different names for ARIMA models with input series. Pankratz (1991) refers to these models as *dynamic regression*.

Using Input Series

To use input series, list the input series in a CROSSCORR= option on the IDENTIFY statement and specify how they enter the model with an INPUT= option on the ESTIMATE statement. For example, you might use a series called PRICE to help model SALES, as shown in the following statements:

```
proc arima data=a;
   identify var=sales crosscorr=price;
   estimate input=price;
   run;
```

This example performs a simple linear regression of SALES on PRICE, producing the same results as PROC REG or another SAS regression procedure. The mathematical form of the model estimated by these statements is

$$Y_t = \mu + \omega_0 X_t + a_t$$

The parameter estimates table for this example (using simulated data) is shown in Figure 11.20. The intercept parameter is labeled MU. The regression coefficient for PRICE is labeled NUM1. (See the section "Naming of Model Parameters" on page 426 for information on how parameters for input series are named.)

```
                               The ARIMA Procedure

                      Conditional Least Squares Estimation

                            Standard                 Approx
Parameter     Estimate         Error    t Value    Pr > |t|    Lag  Variable  Shift

MU           199.83602       2.99463      66.73      <.0001      0  sales         0
NUM1          -9.99299       0.02885    -346.38      <.0001      0  price         0
```

Figure 11.20. Parameter Estimates Table for Regression Model

Any number of input variables can be used in a model. For example, the following statements fit a multiple regression of SALES on PRICE and INCOME:

```
proc arima data=a;
   identify var=sales crosscorr=(price income);
   estimate input=(price income);
   run;
```

The mathematical form of the regression model estimated by these statements is

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + a_t$$

Lagging and Differencing Input Series

You can also difference and lag the input series. For example, the following statements regress the change in SALES on the change in PRICE lagged by one period. The difference of PRICE is specified with the CROSSCORR= option and the lag of the change in PRICE is specified by the 1 $ in the INPUT= option.

```
proc arima data=a;
   identify var=sales(1) crosscorr=price(1);
   estimate input=( 1 $ price );
   run;
```

These statements estimate the model

$$(1-B)Y_t = \mu + \omega_0(1-B)X_{t-1} + a_t$$

Regression with ARMA Errors

You can combine input series with ARMA models for the errors. For example, the following statements regress SALES on INCOME and PRICE but with the error term of the regression model (called the *noise series* in ARIMA modeling terminology) assumed to be an ARMA(1,1) process.

```
proc arima data=a;
   identify var=sales crosscorr=(price income);
   estimate p=1 q=1 input=(price income);
   run;
```

These statements estimate the model

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + \frac{(1-\theta_1 B)}{(1-\phi_1 B)} a_t$$

Stationarity and Input Series

Note that the requirement of stationarity applies to the noise series. If there are no input variables, the response series (after differencing and minus the mean term) and the noise series are the same. However, if there are inputs, the noise series is the residual after the effect of the inputs is removed.

There is no requirement that the input series be stationary. If the inputs are nonstationary, the response series will be nonstationary, even though the noise process may be stationary.

When nonstationary input series are used, you can fit the input variables first with no ARMA model for the errors and then consider the stationarity of the residuals before identifying an ARMA model for the noise part.

Identifying Regression Models with ARMA Errors

Previous sections described the ARIMA modeling identification process using the autocorrelation function plots produced by the IDENTIFY statement. This identification process does not apply when the response series depends on input variables. This is because it is the noise process for which you need to identify an ARIMA model, and when input series are involved the response series adjusted for the mean is no longer an estimate of the noise series.

However, if the input series are independent of the noise series, you can use the residuals from the regression model as an estimate of the noise series, then apply the ARIMA modeling identification process to this residual series. This assumes that the noise process is stationary.

The PLOT option on the ESTIMATE statement produces for the model residuals the same plots as the IDENTIFY statement produces for the response series. The PLOT option prints an autocorrelation function plot, an inverse autocorrelation function plot, and a partial autocorrelation function plot for the residual series.

The following statements show how the PLOT option is used to identify the ARMA(1,1) model for the noise process used in the preceding example of regression with ARMA errors:

```
proc arima data=a;
   identify var=sales crosscorr=(price income) noprint;
   estimate input=(price income) plot;
   run;
   estimate p=1 q=1 input=(price income) plot;
   run;
```

In this example, the IDENTIFY statement includes the NOPRINT option since the autocorrelation plots for the response series are not useful when you know that the response series depends on input series.

The first ESTIMATE statement fits the regression model with no model for the noise process. The PLOT option produces plots of the autocorrelation function, inverse autocorrelation function, and partial autocorrelation function for the residual series of the regression on PRICE and INCOME.

By examining the PLOT option output for the residual series, you verify that the residual series is stationary and identify an ARMA(1,1) model for the noise process. The second ESTIMATE statement fits the final model.

Although this discussion addresses regression models, the same remarks apply to identifying an ARIMA model for the noise process in models that include input series with complex transfer functions.

Intervention Models and Interrupted Time Series

One special kind of ARIMA model with input series is called an *intervention model* or *interrupted time series* model. In an intervention model, the input series is an indicator variable containing discrete values that flag the occurrence of an event affecting the response series. This event is an intervention in or an interruption of the normal evolution of the response time series, which, in the absence of the intervention, is usually assumed to be a pure ARIMA process.

Intervention models can be used both to model and forecast the response series and to analyze the impact of the intervention. When the focus is on estimating the effect of the intervention, the process is often called *intervention analysis* or *interrupted time series analysis*.

Impulse Interventions

The intervention can be a one-time event. For example, you might want to study the effect of a short-term advertising campaign on the sales of a product. In this case, the input variable has the value of 1 for the period during which the advertising campaign took place and the value 0 for all other periods. Intervention variables of this kind are sometimes called *impulse functions* or *pulse functions*.

Suppose that SALES is a monthly series, and a special advertising effort was made during the month of March 1992. The following statements estimate the effect of this intervention assuming an ARMA(1,1) model for SALES. The model is specified just like the regression model, but the intervention variable AD is constructed in the DATA step as a zero-one indicator for the month of the advertising effort.

```
data a;
   set a;
   ad = date = '1mar1992'd;
run;

proc arima data=a;
   identify var=sales crosscorr=ad;
   estimate p=1 q=1 input=ad;
run;
```

Continuing Interventions

Other interventions can be continuing, in which case the input variable flags periods before and after the intervention. For example, you might want to study the effect of a change in tax rates on some economic measure. Another example is a study of the effect of a change in speed limits on the rate of traffic fatalities. In this case, the input variable has the value 1 after the new speed limit went into effect and the value 0 before. Intervention variables of this kind are called *step functions*.

Another example is the effect of news on product demand. Suppose it was reported in July 1996 that consumption of the product prevents heart disease (or causes cancer), and SALES is consistently higher (or lower) thereafter. The following statements model the effect of this news intervention:

```
data a;
   set a;
   news = date >= '1jul1996'd;
run;

proc arima data=a;
   identify var=sales crosscorr=news;
   estimate p=1 q=1 input=news;
run;
```

Interaction Effects

You can include any number of intervention variables in the model. Intervention variables can have any pattern–impulse and continuing interventions are just two possible cases. You can mix discrete valued intervention variables and continuous regressor variables in the same model.

You can also form interaction effects by multiplying input variables and including the product variable as another input. Indeed, as long as the dependent measure forms a regular time series, you can use PROC ARIMA to fit any general linear model in conjunction with an ARMA model for the error process by using input variables that correspond to the columns of the design matrix of the linear model.

Rational Transfer Functions and Distributed Lag Models

How an input series enters the model is called its *transfer function*. Thus, ARIMA models with input series are sometimes referred to as transfer function models.

In the preceding regression and intervention model examples, the transfer function is a single scale parameter. However, you can also specify complex transfer functions composed of numerator and denominator polynomials in the backshift operator. These transfer functions operate on the input series in the same way that the ARMA specification operates on the error term.

Numerator Factors

For example, suppose you want to model the effect of PRICE on SALES as taking place gradually with the impact distributed over several past lags of PRICE. This is illustrated by the following statements:

```
proc arima data=a;
  identify var=sales crosscorr=price;
  estimate input=( (1 2 3) price );
  run;
```

These statements estimate the model

$$Y_t = \mu + (\omega_0 - \omega_1 B - \omega_2 B^2 - \omega_3 B^3)X_t + a_t$$

This example models the effect of PRICE on SALES as a linear function of the current and three most recent values of PRICE. It is equivalent to a multiple linear regression of SALES on PRICE, LAG(PRICE), LAG2(PRICE), and LAG3(PRICE).

This is an example of a transfer function with one *numerator factor*. The numerator factors for a transfer function for an input series are like the MA part of the ARMA model for the noise series.

Denominator Factors

You can also use transfer functions with *denominator factors*. The denominator factors for a transfer function for an input series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

To specify transfer functions with denominator factors, place the denominator factors after a slash (/) in the INPUT= option. For example, the following statements estimate the PRICE effect as an infinite distributed lag model with exponentially declining weights:

```
proc arima data=a;
  identify var=sales crosscorr=price;
  estimate input=( / (1) price );
  run;
```

The transfer function specified by these statements is as follows:

$$\frac{\omega_0}{(1 - \delta_1 B)} X_t$$

This transfer function also can be written in the following equivalent form:

$$\omega_0 \left(1 + \sum_{i=1}^{\infty} \delta_1^i B^i \right) X_t$$

This transfer function can be used with intervention inputs. When it is used with a pulse function input, the result is an intervention effect that dies out gradually over time. When it is used with a step function input, the result is an intervention effect that increases gradually to a limiting value.

Rational Transfer Functions

By combining various numerator and denominator factors in the INPUT= option, you can specify *rational transfer functions* of any complexity. To specify an input with a general rational transfer function of the form

$$\frac{\omega(B)}{\delta(B)} B^k X_t$$

use an INPUT= option in the ESTIMATE statement of the form

input=(*k* $ (ω-*lags*) / (δ-*lags*) x)

See the section "Specifying Inputs and Transfer Functions" on page 423 for more information.

Identifying Transfer Function Models

The CROSSCORR= option of the IDENTIFY statement prints sample cross-correlation functions showing the correlations between the response series and the input series at different lags. The sample cross-correlation function can be used to help identify the form of the transfer function appropriate for an input series. See textbooks on time series analysis for information on using cross-correlation functions to identify transfer function models.

For the cross-correlation function to be meaningful, the input and response series must be filtered with a prewhitening model for the input series. See the section "Prewhitening" on page 416 for more information on this issue.

Forecasting with Input Variables

To forecast a response series using an ARIMA model with inputs, you need values of the input series for the forecast periods. You can supply values for the input variables for the forecast periods in the DATA= data set, or you can have PROC ARIMA forecast the input variables.

If you do not have future values of the input variables in the input data set used by the FORECAST statement, the input series must be forecast before the ARIMA procedure can forecast the response series. If you fit an ARIMA model to each of the input series for which you need forecasts before fitting the model for the response series, the FORECAST statement automatically uses the ARIMA models for the input series to generate the needed forecasts of the inputs.

For example, suppose you want to forecast SALES for the next 12 months. In this example, the change in SALES is predicted as a function of the lagged change in PRICE, plus an ARMA(1,1) noise process. To forecast SALES using PRICE as an input, you also need to fit an ARIMA model for PRICE.

The following statements fit an AR(2) model to the change in PRICE before fitting and forecasting the model for SALES. The FORECAST statement automatically forecasts PRICE using this AR(2) model to get the future inputs needed to produce the forecast of SALES.

```
proc arima data=a;
   identify var=price(1);
   estimate p=2;
   identify var=sales(1) crosscorr=price(1);
   estimate p=1 q=1 input=price;
   forecast lead=12 interval=month id=date out=results;
run;
```

Fitting a model to the input series is also important for identifying transfer functions. (See the section "Prewhitening" on page 416 for more information.)

Input values from the DATA= data set and input values forecast by PROC ARIMA can be combined. For example, a model for SALES might have three input series: PRICE, INCOME, and TAXRATE. For the forecast, you assume that the tax rate will be unchanged. You have a forecast for INCOME from another source but only for the first few periods of the SALES forecast you want to make. You have no future values for PRICE, which needs to be forecast as in the preceding example.

In this situation, you include observations in the input data set for all forecast periods, with SALES and PRICE set to a missing value, with TAXRATE set to its last actual value, and with INCOME set to forecast values for the periods you have forecasts for and set to missing values for later periods. In the PROC ARIMA step, you estimate ARIMA models for PRICE and INCOME before estimating the model for SALES, as shown in the following statements:

```
proc arima data=a;
  identify var=price(1);
  estimate p=2;
  identify var=income(1);
  estimate p=2;
  identify var=sales(1) crosscorr=( price(1) income(1) taxrate );
  estimate p=1 q=1 input=( price income taxrate );
  forecast lead=12 interval=month id=date out=results;
  run;
```

In forecasting SALES, the ARIMA procedure uses as inputs the value of PRICE forecast by its ARIMA model, the value of TAXRATE found in the DATA= data set, and the value of INCOME found in the DATA= data set, or, when the INCOME variable is missing, the value of INCOME forecast by its ARIMA model. (Because SALES is missing for future time periods, the estimation of model parameters is not affected by the forecast values for PRICE, INCOME, or TAXRATE.)

Data Requirements

PROC ARIMA can handle time series of moderate size; there should be at least 30 observations. With 30 or fewer observations, the parameter estimates may be poor. With thousands of observations, the method requires considerable computer time and memory.

Syntax

The ARIMA procedure uses the following statements:

PROC ARIMA *options*;
  BY *variables*;
  IDENTIFY *VAR=variable options*;
  ESTIMATE *options*;
  OUTLIER *options*;
  FORECAST *options*;

Functional Summary

The statements and options controlling the ARIMA procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	PROC ARIMA	DATA=
	IDENTIFY	DATA=
specify the output data set	PROC ARIMA	OUT=
	FORECAST	OUT=
include only forecasts in the output data set	FORECAST	NOOUTALL
write autocovariances to output data set	IDENTIFY	OUTCOV=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write correlation of parameter estimates	ESTIMATE	OUTCORR
write covariance of parameter estimates	ESTIMATE	OUTCOV
write estimated model to an output data set	ESTIMATE	OUTMODEL=
write statistics of fit to an output data set	ESTIMATE	OUTSTAT=
Options for Identifying the Series		
difference time series and plot autocorrelations	IDENTIFY	
specify response series and differencing	IDENTIFY	VAR=
specify and cross correlate input series	IDENTIFY	CROSSCORR=
center data by subtracting the mean	IDENTIFY	CENTER
exclude missing values	IDENTIFY	NOMISS
delete previous models and start fresh	IDENTIFY	CLEAR
specify the significance level for tests	IDENTIFY	ALPHA=
perform tentative ARMA order identification using the ESACF Method	IDENTIFY	ESACF
perform tentative ARMA order identification using the MINIC Method	IDENTIFY	MINIC

Description	Statement	Option
perform tentative ARMA order identification using the SCAN Method	IDENTIFY	SCAN
specify the range of autoregressive model orders for estimating the error series for the MINIC Method	IDENTIFY	PERROR=
determines the AR dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	P=
determines the MA dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	Q=
perform stationarity tests	IDENTIFY	STATIONARITY=
selection of White Noise test statistic in the presence of missing values	IDENTIFY	WHITENOISE=
Options for Defining and Estimating the Model		
specify and estimate ARIMA models	ESTIMATE	
specify autoregressive part of model	ESTIMATE	P=
specify moving average part of model	ESTIMATE	Q=
specify input variables and transfer functions	ESTIMATE	INPUT=
drop mean term from the model	ESTIMATE	NOINT
specify the estimation method	ESTIMATE	METHOD=
use alternative form for transfer functions	ESTIMATE	ALTPARM
suppress degrees-of-freedom correction in variance estimates	ESTIMATE	NODF
selection of White Noise test statistic in the presence of missing values	ESTIMATE	WHITENOISE=
Options for Outlier Detection		
specify the significance level for tests	OUTLIER	ALPHA=
identify detected outliers with variable	OUTLIER	ID=
limit the number of outliers	OUTLIER	MAXNUM=
limit the number of outliers to a percentage of the series	OUTLIER	MAXPCT=
specify the variance estimator used for testing	OUTLIER	SIGMA=
specify the type of level shifts	OUTLIER	TYPE=
Printing Control Options		
limit number of lags shown in correlation plots	IDENTIFY	NLAG=
suppress printed output for identification	IDENTIFY	NOPRINT
plot autocorrelation functions of the residuals	ESTIMATE	PLOT
print log likelihood around the estimates	ESTIMATE	GRID
control spacing for GRID option	ESTIMATE	GRIDVAL=

Description	Statement	Option
print details of the iterative estimation process	ESTIMATE	PRINTALL
suppress printed output for estimation	ESTIMATE	NOPRINT
suppress printing of the forecast values	FORECAST	NOPRINT
print the one-step forecasts and residuals	FORECAST	PRINTALL
Options to Specify Parameter Values		
specify autoregressive starting values	ESTIMATE	AR=
specify moving average starting values	ESTIMATE	MA=
specify a starting value for the mean parameter	ESTIMATE	MU=
specify starting values for transfer functions	ESTIMATE	INITVAL=
Options to Control the Iterative Estimation Process		
specify convergence criterion	ESTIMATE	CONVERGE=
specify the maximum number of iterations	ESTIMATE	MAXITER=
specify criterion for checking for singularity	ESTIMATE	SINGULAR=
suppress the iterative estimation process	ESTIMATE	NOEST
omit initial observations from objective	ESTIMATE	BACKLIM=
specify perturbation for numerical derivatives	ESTIMATE	DELTA=
omit stationarity and invertibility checks	ESTIMATE	NOSTABLE
use preliminary estimates as starting values for ML and ULS	ESTIMATE	NOLS
Options for Forecasting		
forecast the response series	FORECAST	
specify how many periods to forecast	FORECAST	LEAD=
specify the ID variable	FORECAST	ID=
specify the periodicity of the series	FORECAST	INTERVAL=
specify size of forecast confidence limits	FORECAST	ALPHA=
start forecasting before end of the input data	FORECAST	BACK=
specify the variance term used to compute forecast standard errors and confidence limits	FORECAST	SIGSQ=
control the alignment of SAS Date values	FORECAST	ALIGN=
BY Groups		
specify BY group processing	BY	

PROC ARIMA Statement

PROC ARIMA *options;*

The following options can be used in the PROC ARIMA statement:

DATA= *SAS-data-set*
specifies the name of the SAS data set containing the time series. If different DATA= specifications appear in the PROC ARIMA and IDENTIFY statements, the one in the IDENTIFY statement is used. If the DATA= option is not specified in either the PROC ARIMA or IDENTIFY statement, the most recently created SAS data set is used.

OUT= *SAS-data-set*
specifies a SAS data set to which the forecasts are output. If different OUT= specifications appear in the PROC ARIMA and FORECAST statement, the one in the FORECAST statement is used.

BY Statement

BY *variables;*

A BY statement can be used in the ARIMA procedure to process a data set in groups of observations defined by the BY variables. Note that all IDENTIFY, ESTIMATE, and FORECAST statements specified are applied to all BY groups.

Because of the need to make data-based model selections, BY-group processing is not usually done with PROC ARIMA. You usually want different models for the different series contained in different BY-groups, and the PROC ARIMA BY statement does not let you do this.

Using a BY statement imposes certain restrictions. The BY statement must appear before the first RUN statement. If a BY statement is used, the input data must come from the data set specified in the PROC statement; that is, no input data sets can be specified in IDENTIFY statements.

When a BY statement is used with PROC ARIMA, interactive processing only applies to the first BY group. Once the end of the PROC ARIMA step is reached, all ARIMA statements specified are executed again for each of the remaining BY groups in the input data set.

IDENTIFY Statement

IDENTIFY *VAR=variable options;*

The IDENTIFY statement specifies the time series to be modeled, differences the series if desired, and computes statistics to help identify models to fit. Use an IDENTIFY statement for each time series that you want to model.

If other time series are to be used as inputs in a subsequent ESTIMATE statement, they must be listed in a CROSSCORR= list in the IDENTIFY statement.

The following options are used in the IDENTIFY statement. The VAR= option is required.

ALPHA= *significance-level*

The ALPHA= option specifies the significance level for tests in the IDENTIFY statement. The default is 0.05.

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

CLEAR

deletes all old models. This option is useful when you want to delete old models so that the input variables are not prewhitened. (See the section "Prewhitening" on page 416 for more information.)

CROSSCORR= *variable* **(***d11, d12, ..., d1k***)**
CROSSCORR= (*variable* **(***d11, d12, ..., d1k***) ...** *variable* **(***d21, d22, ..., d2k***))**

names the variables cross correlated with the response variable given by the VAR= specification.

Each variable name can be followed by a list of differencing lags in parentheses, the same as for the VAR= specification. If differencing is specified for a variable in the CROSSCORR= list, the differenced series is cross correlated with the VAR= option series, and the differenced series is used when the ESTIMATE statement INPUT= option refers to the variable.

DATA= *SAS-data-set*

specifies the input SAS data set containing the time series. If the DATA= option is omitted, the DATA= data set specified in the PROC ARIMA statement is used; if the DATA= option is omitted from the PROC ARIMA statement as well, the most recently created data set is used.

ESACF

computes the extended sample autocorrelation function and uses these estimates to tentatively identify the autoregressive and moving average orders of mixed models.

The ESACF option generates two tables. The first table displays extended sample autocorrelation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The P=$(p_{min} : p_{max})$ and Q=$(q_{min} : q_{max})$ options determine the size of the table.

The autoregressive and moving average orders are tentatively identified by finding a triangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates an ESACF table with dimensions of p=(0:7) and q=(0:8).

```
proc arima data=test;
   identify var=x esacf p=(0:7) q=(0:8);
run;
```

See the "The ESACF Method" section on page 411 for more information.

MINIC

uses information criteria or penalty functions to provide tentative ARMA order identification. The MINIC option generates a table containing the computed information criterion associated with various ARMA model orders. The PERROR=$(p_{\epsilon,min} : p_{\epsilon,max})$ option determines the range of the autoregressive model orders used to estimate the error series. The P=$(p_{min} : p_{max})$ and Q=$(q_{min} : q_{max})$ options determine the size of the table. The ARMA orders are tentatively identified by those orders that minimize the information criterion.

The following code generates a MINIC table with default dimensions of p=(0:5) and q=(0:5) and with the error series estimated by an autoregressive model with an order, p_ϵ, that minimizes the AIC in the range from 8 to 11.

```
proc arima data=test;
   identify var=x minic perror=(8:11);
run;
```

See the "The MINIC Method" section on page 412 for more information.

NLAG= *number*

indicates the number of lags to consider in computing the autocorrelations and cross-correlations. To obtain preliminary estimates of an ARIMA(*p*,*d*,*q*) model, the NLAG= value must be at least *p*+*q*+*d*. The number of observations must be greater than or equal to the NLAG= value. The default value for NLAG= is 24 or one-fourth the number of observations, whichever is less. Even though the NLAG= value is specified, the NLAG= value can be changed according to the data set.

NOMISS

uses only the first continuous sequence of data with no missing values. By default, all observations are used.

NOPRINT

suppresses the normal printout (including the correlation plots) generated by the IDENTIFY statement.

OUTCOV= *SAS-data-set*

writes the autocovariances, autocorrelations, inverse autocorrelations, partial autocorrelations, and cross covariances to an output SAS data set. If the OUTCOV= option is not specified, no covariance output data set is created. See the section "OUTCOV= Data Set" on page 433 for more information.

P= ($p_{min} : p_{max}$**)**

see the ESACF, MINIC, and SCAN options for details.

PERROR= ($p_{\epsilon,min} : p_{\epsilon,max}$**)**

see the ESACF, MINIC, and SCAN options for details.

Q= ($q_{min} : q_{max}$**)**

see the ESACF, MINIC, and SCAN options for details.

SCAN

computes estimates of the squared canonical correlations and uses these estimates to tentatively identify the autoregressive and moving average orders of mixed models.

The SCAN option generates two tables. The first table displays squared canonical correlation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The P=$(p_{min} : p_{max})$ and Q=$(q_{min} : q_{max})$ options determine the size of each table.

The autoregressive and moving average orders are tentatively identified by finding a rectangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates a SCAN table with default dimensions of p=(0:5) and q=(0:5). The recommended orders are based on a significance level of 0.1.

```
proc arima data=test;
   identify var=x scan alpha=0.1;
run;
```

See the "The SCAN Method" section on page 414 for more information.

STATIONARITY=

performs stationarity tests. Stationarity tests can be used to determine whether differencing terms should be included in the model specification. In each stationarity test, the autoregressive orders can be specified by a range, *test*=ar_{max}, or as a list of values, *test*=$(ar_1, .., ar_n)$, where *test* is ADF, PP, or RW. The default is (0,1,2).

See the "Stationarity Tests" section on page 416 for more information.

STATIONARITY=(ADF= *AR orders* **DLAG=** *s***)**
STATIONARITY=(DICKEY= *AR orders* **DLAG=** *s***)**

performs augmented Dickey-Fuller tests. If the DLAG=s option specified with s is greater than one, seasonal Dickey-Fuller tests are performed. The maximum allowable value of s is 12. The default value of s is one. The following code performs augmented Dickey-Fuller tests with autoregressive orders 2 and 5.

```
proc arima data=test;
   identify var=x stationarity=(adf=(2,5));
run;
```

STATIONARITY=(PP= *AR orders***)**
STATIONARITY=(PHILLIPS= *AR orders***)**

performs Phillips-Perron tests. The following code performs Augmented Phillips-Perron tests with autoregressive orders ranging from 0 to 6.

```
proc arima data=test;
   identify var=x stationarity=(pp=6);
run;
```

STATIONARITY=(RW= *AR orders***)**
STATIONARITY=(RANDOMWALK= *AR orders***)**
performs random-walk with drift tests. The following code performs random-walk with drift tests with autoregressive orders ranging from 0 to 2.

```
proc arima data=test;
   identify var=x stationarity=(rw);
run;
```

VAR= *variable*
VAR= *variable* **(** *d1, d2, ..., dk* **)**
names the variable containing the time series to analyze. The VAR= option is required.

A list of differencing lags can be placed in parentheses after the variable name to request that the series be differenced at these lags. For example, VAR=X(1) takes the first differences of X. VAR=X(1,1) requests that X be differenced twice, both times with lag 1, producing a second difference series, which is
$(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$.

VAR=X(2) differences X once at lag two $(X_t - X_{t-2})$.

If differencing is specified, it is the differenced series that is processed by any subsequent ESTIMATE statement.

WHITENOISE= ST | IGNOREMISS
When the series contains missing values you can use this option to choose the type of test statistic that is used in the White Noise test of the series. If WHITENOISE=IGNOREMISS the standard Ljung-Box test statistic is used. If WHITENOISE=ST a modification of this statistic suggested by Stoffer and Toloi (1992) is used. The WHITENOISE=ST is the default.

ESTIMATE Statement

ESTIMATE *options;*

The ESTIMATE statement specifies an ARMA model or transfer function model for the response variable specified in the previous IDENTIFY statement, and produces estimates of its parameters. The ESTIMATE statement also prints diagnostic information by which to check the model. Include an ESTIMATE statement for each model that you want to estimate.

Options used in the ESTIMATE statement are described in the following sections.

Options for Defining the Model and Controlling Diagnostic Statistics

The following options are used to define the model to be estimated and to control the output that is printed.

ALTPARM

specifies the alternative parameterization of the overall scale of transfer functions in the model. See the section "Alternative Model Parameterization" on page 423 for details.

INPUT= *variable*
INPUT= (*transfer-function variable* **...)**

specifies input variables and their transfer functions.

The variables used on the INPUT= option must be included in the CROSSCORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSSCORR= list, then the differenced series is used as the input to the transfer function.

The transfer function specification for an input variable is optional. If no transfer function is specified, the input variable enters the model as a simple regressor. If specified, the transfer function specification has the following syntax:

$$S\$(L_{1,1}, L_{1,2}, \ldots)(L_{2,1}, \ldots)\ldots/(L_{j,1}, \ldots)\ldots$$

Here, *S* is a shift or lag of the input variable, the terms before the slash (/) are numerator factors, and the terms after the slash (/) are denominator factors of the transfer function. All three parts are optional. See the section "Specifying Inputs and Transfer Functions" on page 423 for details.

METHOD=ML
METHOD=ULS
METHOD=CLS

specifies the estimation method to use. METHOD=ML specifies the maximum likelihood method. METHOD=ULS specifies the unconditional least-squares method. METHOD=CLS specifies the conditional least-squares method. METHOD=CLS is the default. See the "Estimation Details" section on page 418 for more information.

NOCONSTANT
NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

NODF

estimates the variance by dividing the error sum of squares (SSE) by the number of residuals. The default is to divide the SSE by the number of residuals minus the number of free parameters in the model.

NOPRINT

suppresses the normal printout generated by the ESTIMATE statement. If the NOPRINT option is specified for the ESTIMATE statement, then any error and warning messages are printed to the SAS log.

P= *order*
P= (*lag, ..., lag***) ... (***lag, ..., lag***)**

specifies the autoregressive part of the model. By default, no autoregressive parameters are fit.

P=(l_1, l_2, ..., l_k) defines a model with autoregressive parameters at the specified lags. P= *order* is equivalent to P=(1, 2, ..., *order*).

A concatenation of parenthesized lists specifies a factored model. For example, P=(1,2,5)(6,12) specifies the autoregressive model

$$(1 - \phi_{1,1}B - \phi_{1,2}B^2 - \phi_{1,3}B^5)(1 - \phi_{2,1}B^6 - \phi_{2,2}B^{12})$$

PLOT

plots the residual autocorrelation functions. The sample autocorrelation, the sample inverse autocorrelation, and the sample partial autocorrelation functions of the model residuals are plotted.

Q= *order*
Q= (*lag, ..., lag***) ... (***lag, ..., lag***)**

specifies the moving-average part of the model. By default, no moving-average part is included in the model.

Q=(l_1, l_2, ..., l_k) defines a model with moving-average parameters at the specified lags. Q= *order* is equivalent to Q=(1, 2, ..., *order*). A concatenation of parenthesized lists specifies a factored model. The interpretation of factors and lags is the same as for the P= option.

WHITENOISE= ST | IGNOREMISS

When the series contains missing values you can use this option to choose the type of test statistic that is used in the White Noise test of residuals. If WHITENOISE=IGNOREMISS the standard Ljung-Box test statistic is used. If WHITENOISE=ST a modification of this statistic suggested by Stoffer and Toloi (1992) is used. The WHITENOISE=ST is the default.

Options for Output Data Sets

The following options are used to store results in SAS data sets:

OUTEST= *SAS-data-set*

writes the parameter estimates to an output data set. If the OUTCORR or OUTCOV option is used, the correlations or covariances of the estimates are also written to the OUTEST= data set. See the section "OUTEST= Data Set" on page 434 for a description of the OUTEST= output data set.

OUTCORR

writes the correlations of the parameter estimates to the OUTEST= data set.

OUTCOV

writes the covariances of the parameter estimates to the OUTEST= data set.

OUTMODEL= *SAS-data-set*

writes the model and parameter estimates to an output data set. If OUTMODEL= is not specified, no model output data set is created. See "OUTMODEL= Data Set" for a description of the OUTMODEL= output data set.

OUTSTAT= *SAS-data-set*

writes the model diagnostic statistics to an output data set. If OUTSTAT= is not specified, no statistics output data set is created. See the section "OUTSTAT= Data Set" on page 438 for a description of the OUTSTAT= output data set.

Options to Specify Parameter Values

The following options enable you to specify values for the model parameters. These options can provide starting values for the estimation process, or you can specify fixed parameters for use in the FORECAST stage and suppress the estimation process with the NOEST option. By default, the ARIMA procedure finds initial parameter estimates and uses these estimates as starting values in the iterative estimation process.

If values for any parameters are specified, values for all parameters should be given. The number of values given must agree with the model specifications.

AR= *value* **...**

lists starting values for the autoregressive parameters. See the "Initial Values" section on page 424 for more information.

INITVAL= (*initializer-spec variable* **...)**

specifies starting values for the parameters in the transfer function parts of the model. See the "Initial Values" section on page 424 for more information.

MA= *value* **...**

lists starting values for the moving-average parameters. See the "Initial Values" section on page 424 for more information.

MU= *value*

specifies the MU parameter.

NOEST

uses the values specified with the AR=, MA=, INITVAL=, and MU= options as final parameter values. The estimation process is suppressed except for estimation of the residual variance. The specified parameter values are used directly by the next FORECAST statement. When NOEST is specified, standard errors, *t* values, and the correlations between estimates are displayed as 0 or missing. (The NOEST option is useful, for example, when you wish to generate forecasts corresponding to a published model.)

Options to Control the Iterative Estimation Process

The following options can be used to control the iterative process of minimizing the error sum of squares or maximizing the log likelihood function. These tuning options are not usually needed but may be useful if convergence problems arise.

BACKLIM= $-n$

omits the specified number of initial residuals from the sum of squares or likelihood function. Omitting values can be useful for suppressing transients in transfer function models that are sensitive to start-up values.

CONVERGE= *value*

specifies the convergence criterion. Convergence is assumed when the largest change in the estimate for any parameter is less that the CONVERGE= option value. If the absolute value of the parameter estimate is greater than 0.01, the relative change is used; otherwise, the absolute change in the estimate is used. The default is CONVERGE=.001.

DELTA= *value*

specifies the perturbation value for computing numerical derivatives. The default is DELTA=.001.

GRID

prints the error sum of squares (SSE) or concentrated log likelihood surface in a small grid of the parameter space around the final estimates. For each pair of parameters, the SSE is printed for the nine parameter-value combinations formed by the grid, with a center at the final estimates and with spacing given by the GRIDVAL= specification. The GRID option may help you judge whether the estimates are truly at the optimum, since the estimation process does not always converge. For models with a large number of parameters, the GRID option produces voluminous output.

GRIDVAL= *number*

controls the spacing in the grid printed by the GRID option. The default is GRIDVAL=0.005.

MAXITER= n
MAXIT= n

specifies the maximum number of iterations allowed. The default is MAXITER=50. (The default was 15 in previous releases of SAS/ETS software.)

NOLS

begins the maximum likelihood or unconditional least-squares iterations from the preliminary estimates rather than from the conditional least-squares estimates that are produced after four iterations. See the "Estimation Details" section on page 418 for more information.

NOSTABLE

specifies that the autoregressive and moving-average parameter estimates for the noise part of the model not be restricted to the stationary and invertible regions, respectively. See the section "Stationarity and Invertibility" on page 425 for more information.

PRINTALL

prints preliminary estimation results and the iterations in the final estimation process.

SINGULAR= *value*

specifies the criterion for checking singularity. If a pivot of a sweep operation is less than the SINGULAR= value, the matrix is deemed singular. Sweep operations are performed on the Jacobian matrix during final estimation and on the covariance matrix when preliminary estimates are obtained. The default is SINGULAR=1E-7.

OUTLIER Statement

OUTLIER *options;*

The OUTLIER statement can be used to detect shifts in the level of the response series that are not accounted for by the previously estimated model. An ESTIMATE statement must precede the OUTLIER statement. The following options are used in the OUTLIER statement:

TYPE = ADDITIVE
TYPE = SHIFT
TYPE = TEMP ($d_1, \ldots, d_k$ **)**
TYPE = (< ADDITIVE > < SHIFT > < TEMP ($d_1, \ldots, d_k$ **) >)**

The TYPE= option specifies the types of level shifts to search for. The default is TYPE= (ADDITIVE SHIFT), which requests searching for additive outliers and permanent level shifts. The option TEMP($d_1, \ldots, d_k$) requests searching for temporary changes in the level of durations $d_1, \ldots, d_k$. These options can also be abbreviated as AO, LS, and TC.

ALPHA= *significance-level*

The ALPHA= option specifies the significance level for tests in the OUTLIER statement. The default is 0.05.

SIGMA= ROBUST | MSE

The statistical tests performed during the outlier detection require an estimate of error variance. Using the SIGMA= option you can choose between two types of error variance estimates. SIGMA= MSE corresponds to the usual mean squared error (MSE) estimate, and SIGMA= ROBUST corresponds to a robust estimate of the error variance. The default is SIGMA= ROBUST.

MAXNUM= *number*

This option is used to limit the number of outliers to search. The default is MAXNUM= 5.

MAXPCT= *number*

This option is similar to MAXNUM= option. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT= 2. When both of these options are specified the minimum of the two search numbers is used.

ID= *Date-Time ID variable*

This option can be used to specify a SAS Date, Time, or Datetime identification variable to label the detected outliers. This variable must be present in the input data set.

The following examples illustrate a few possibilities for the OUTLIER statement.

The most basic usage

```
outlier;
```

sets all the options to their default values, that is, it is equivalent to

```
outlier type=(ao ls) alpha=0.05 sigma=robust maxnum=5 maxpct=2;
```

The following statement requests a search for permanent level shifts and for temporary level changes of durations 6 and 12. The search is limited to at most three changes and the significance level of the underlying tests is 0.001. MSE is used as the estimate of error variance. It also requests labeling of the detected shifts using an ID variable *date*.

```
outlier type=(ls tc(6 12)) alpha=0.001 sigma=mse maxnum=3 ID=date;
```

FORECAST Statement

FORECAST *options;*

The FORECAST statement generates forecast values for a time series using the parameter estimates produced by the previous ESTIMATE statement. See the section "Forecasting Details" on page 427 for more information on calculating forecasts.

The following options can be used in the FORECAST statement:

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

ALPHA= *n*

sets the size of the forecast confidence limits. The ALPHA= value must be between 0 and 1. When you specify ALPHA=α, the upper and lower confidence limits will have a $1 - \alpha$ confidence level. The default is ALPHA=.05, which produces 95% confidence intervals. ALPHA values are rounded to the nearest hundredth.

BACK= *n*

specifies the number of observations before the end of the data that the multistep forecasts are to begin. The BACK= option value must be less than or equal to the number of observations minus the number of parameters.

The default is BACK=0, which means that the forecast starts at the end of the available data. The end of the data is the last observation for which a noise value can be calculated. If there are no input series, the end of the data is the last nonmissing value of the response time series. If there are input series, this observation can precede the last nonmissing value of the response variable, since there may be missing values for some of the input series.

ID= *variable*

names a variable in the input data set that identifies the time periods associated with the observations. The ID= variable is used in conjunction with the INTERVAL= option to extrapolate ID values from the end of the input data to identify forecast periods in the OUT= data set.

If the INTERVAL= option specifies an interval type, the ID variable must be a SAS date or datetime variable with the spacing between observations indicated by the INTERVAL= value. If the INTERVAL= option is not used, the last input value of the ID= variable is incremented by one for each forecast period to extrapolate the ID values for forecast observations.

INTERVAL= *interval*
INTERVAL= *n*

specifies the time interval between observations. See Chapter 3, "Date Intervals, Formats, and Functions," for information on valid INTERVAL= values.

The value of the INTERVAL= option is used by PROC ARIMA to extrapolate the ID values for forecast observations and to check that the input data are in order with no missing periods. See the section "Specifying Series Periodicity" on page 429 for more details.

LEAD= *n*

specifies the number of multistep forecast values to compute. For example, if LEAD=10, PROC ARIMA forecasts for ten periods beginning with the end of the input series (or earlier if BACK= is specified). It is possible to obtain fewer than the requested number of forecasts if a transfer function model is specified and insufficient data are available to compute the forecast. The default is LEAD=24.

NOOUTALL

includes only the final forecast observations in the output data set, not the one-step forecasts for the data before the forecast period.

NOPRINT

suppresses the normal printout of the forecast and associated values.

OUT= *SAS-data-set*

writes the forecast (and other values) to an output data set. If OUT= is not specified, the OUT= data set specified in the PROC ARIMA statement is used. If OUT= is also not specified in the PROC ARIMA statement, no output data set is created. See the section "OUT= Data Set" on page 432 for more information.

PRINTALL

prints the FORECAST computation throughout the whole data set. The forecast values for the data before the forecast period (specified by the BACK= option) are one-step forecasts.

SIGSQ=

specifies the variance term used in the formula for computing forecast standard errors and confidence limits. The default value is the Variance Estimate computed by the preceding ESTIMATE statement. This option is useful when you wish to generate forecast standard errors and confidence limits based on a published model. It would often be used in conjunction with the NOEST option in the preceding ESTIMATE statement.

Details

The Inverse Autocorrelation Function

The sample inverse autocorrelation function (SIACF) plays much the same role in ARIMA modeling as the sample partial autocorrelation function (SPACF) but generally indicates subset and seasonal autoregressive models better than the SPACF.

Additionally, the SIACF may be useful for detecting over-differencing. If the data come from a nonstationary or nearly nonstationary model, the SIACF has the characteristics of a noninvertible moving average. Likewise, if the data come from a model with a noninvertible moving average, then the SIACF has nonstationary characteristics and, therefore, decays slowly. In particular, if the data have been over-differenced, the SIACF looks like a SACF from a nonstationary process.

The inverse autocorrelation function is not often discussed in textbooks, so a brief description is given here. More complete discussions can be found in Cleveland (1972), Chatfield (1980), and Priestly (1981).

Let W_t be generated by the ARMA(*p*,*q*) process

$$\phi(B)W_t = \theta(B)a_t$$

where a_t is a white noise sequence. If $\theta(B)$ is invertible (that is, if θ considered as a polynomial in B has no roots less than or equal to 1 in magnitude), then the model

$$\theta(B)Z_t = \phi(B)a_t$$

is also a valid ARMA(*q*,*p*) model. This model is sometimes referred to as the dual model. The autocorrelation function (ACF) of this dual model is called the inverse autocorrelation function (IACF) of the original model.

Notice that if the original model is a pure autoregressive model, then the IACF is an ACF corresponding to a pure moving-average model. Thus, it cuts off sharply when the lag is greater than *p*; this behavior is similar to the behavior of the partial autocorrelation function (PACF).

The sample inverse autocorrelation function (SIACF) is estimated in the ARIMA procedure by the following steps. A high-order autoregressive model is fit to the data by means of the Yule-Walker equations. The order of the autoregressive model used to calculate the SIACF is the minimum of the NLAG= value and one-half the number of observations after differencing. The SIACF is then calculated as the autocorrelation function that corresponds to this autoregressive operator when treated as a moving-average operator. That is, the autoregressive coefficients are convolved with themselves and treated as autocovariances.

Under certain conditions, the sampling distribution of the SIACF can be approximated by the sampling distribution of the SACF of the dual model (Bhansali 1980). In the plots generated by ARIMA, the confidence limit marks (.) are located at $\pm 2/\sqrt{n}$. These limits bound an approximate 95% confidence interval for the hypothesis that the data are from a white noise process.

The Partial Autocorrelation Function

The approximation for a standard error for the estimated partial autocorrelation function at lag *k* is based on a null hypothesis that a pure autoregressive Gaussian process of order *k*-1 generated the time series. This standard error is $1/\sqrt{n}$ and is used to produce the approximate 95% confidence intervals depicted by the dots in the plot.

The Cross-Correlation Function

The autocorrelation, partial and inverse autocorrelation functions described in the preceding sections help when you want to model a series as a function of its past values and past random errors. When you want to include the effects of past and current values of other series in the model, the correlations of the response series and the other series must be considered.

The CROSSCORR= option on the IDENTIFY statement computes cross correlations of the VAR= series with other series and makes these series available for use as inputs in models specified by later ESTIMATE statements.

When the CROSSCORR= option is used, PROC ARIMA prints a plot of the cross-correlation function for each variable in the CROSSCORR= list. This plot is similar in format to the other correlation plots, but shows the correlation between the two series at both lags and leads. For example

```
   identify var=y crosscorr=x ...;
```

plots the cross-correlation function of Y and X, $\mathrm{Cor}(\mathrm{y_t}, \mathrm{x_{t-s}})$, for $s = -L$ to L, where L is the value of the NLAG= option. Study of the cross-correlation functions can indicate the transfer functions through which the input series should enter the model for the response series.

The cross-correlation function is computed after any specified differencing has been done. If differencing is specified for the VAR= variable or for a variable in the CROSSCORR= list, it is the differenced series that is cross correlated (and the differenced series is processed by any following ESTIMATE statement).

For example,

```
   identify var=y(1) crosscorr=x(1);
```

computes the cross correlations of the changes in Y with the changes in X. Any following ESTIMATE statement models changes in the variables rather than the variables themselves.

The ESACF Method

The **E**xtended **S**ample **A**uto**c**orrelation **F**unction (ESACF) method can tentatively identify the orders of a *stationary or nonstationary* ARMA process based on iterated least squares estimates of the autoregressive parameters. Tsay and Tiao (1984) proposed the technique, and Choi (1992) provides useful descriptions of the algorithm.

Given a stationary or nonstationary time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$, with a true autoregressive order of $p + d$, and with a true moving-average order of q, you can use the ESACF method to estimate the unknown orders $p + d$ and q by analyzing the autocorrelation functions associated with filtered series of the form

$$w_t^{(m,j)} = \hat{\Phi}_{(m,j)}(B)\tilde{z}_t = \tilde{z}_t - \sum_{i=1}^{m} \hat{\phi}_i^{(m,j)} \tilde{z}_{t-i}$$

where B represents the backshift operator, where $m = p_{min}, \ldots, p_{max}$ are the autoregressive *test* orders, where $j = q_{min} + 1, \ldots, q_{max} + 1$ are the moving average *test* orders, and where $\hat{\phi}_i^{(m,j)}$ are the autoregressive parameter estimates under the assumption that the series is an ARMA(m, j) process.

For purely autoregressive models ($j = 0$), ordinary least squares (OLS) is used to consistently estimate $\hat{\phi}_i^{(m,0)}$. For ARMA models, consistent estimates are obtained by the iterated least squares recursion formula, which is initiated by the pure autoregressive estimates:

$$\hat{\phi}_i^{(m,j)} = \hat{\phi}_i^{(m+1,j-1)} - \hat{\phi}_{i-1}^{(m,j-1)} \frac{\hat{\phi}_{m+1}^{(m+1,j-1)}}{\hat{\phi}_m^{(m,j-1)}}$$

The jth lag of the sample autocorrelation function of the filtered series, $w_t^{(m,j)}$, is the *extended sample autocorrelation function*, and it is denoted as $r_{j(m)} = r_j(w^{(m,j)})$.

The standard errors of $r_{j(m)}$ are computed in the usual way using Bartlett's approximation of the variance of the sample autocorrelation function, $var(r_{j(m)}) \approx (1 + \sum_{t=1}^{j-1} r_j^2(w^{(m,j)}))$.

If the true model is an ARMA $(p + d, q)$ process, the filtered series, $w_t^{(m,j)}$, follows an MA(q) model for $j \geq q$ so that

$$r_{j(p+d)} \approx 0 \quad j > q$$

$$r_{j(p+d)} \neq 0 \quad j = q$$

Additionally, Tsay and Tiao (1984) show that the extended sample autocorrelation satisfies

$$r_{j(m)} \approx 0 \qquad\qquad j - q > m - p - d \leq 0$$

$$r_{j(m)} \neq c(m-p-d, j-q) \qquad 0 \leq j-q \leq m-p-d$$

where $c(m-p-d, j-q)$ is a nonzero constant or a continuous random variable bounded by -1 and 1.

An ESACF table is then constructed using the $r_{j(m)}$ for $m = p_{min}, \ldots, p_{max}$ and $j = q_{min}+1, \ldots, q_{max}+1$ to identify the ARMA orders (see Table 11.3). The orders are tentatively identified by finding a right (maximal) triangular pattern with vertices located at $(p+d, q)$ and $(p+d, q_{max})$ and in which all elements are insignificant (based on asymptotic normality of the autocorrelation function). The vertex $(p+d, q)$ identifies the order. Table 11.4 depicts the theoretical pattern associated with an ARMA(1,2) series.

The MINIC Method

The **MIN**imum **I**nformation **C**riterion (MINIC) method can tentatively identify the order of a *stationary and invertible* ARMA process. Note that Hannan and Rissannen (1982) proposed this method, and Box et al. (1994) and Choi (1992) provide useful descriptions of the algorithm.

Given a stationary and invertible time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$, with a true autoregressive order of p, and with a true moving-average order of q, you can use the MINIC method to compute information criteria (or penalty functions) for various autoregressive and moving average orders. The following paragraphs provide a brief description of the algorithm.

If the series is a stationary and invertible ARMA(*p*,*q*) process of the form

$$\Phi_{(p,q)}(B)\tilde{z}_t = \Theta_{(p,q)}(B)\epsilon_t$$

the error series can be approximated by a high-order AR process

$$\hat{\epsilon}_t = \hat{\Phi}_{(p_\epsilon,q)}(B)\tilde{z}_t \approx \epsilon_t$$

where the parameter estimates $\hat{\Phi}_{(p_\epsilon,q)}$ are obtained from the Yule-Walker estimates. The choice of the autoregressive order, p_ϵ, is determined by the order that minimizes the Akaike information criterion (AIC) in the range $p_{\epsilon,min} \leq p_\epsilon \leq p_{\epsilon,max}$

$$AIC(p_\epsilon,0) = \ln(\tilde{\sigma}^2_{(p_\epsilon,0)}) + 2(p_\epsilon + 0)/n$$

where

$$\tilde{\sigma}^2_{(p_\epsilon,0)} = \frac{1}{n}\sum_{t=p_\epsilon+1}^{n}\hat{\epsilon}_t^2$$

Note that Hannan and Rissannen (1982) use the Bayesian information criterion (BIC) to determine the autoregressive order used to estimate the error series. Box et al. (1994) and Choi (1992) recommend the AIC.

Once the error series has been estimated for autoregressive *test* order $m = p_{min}, \ldots, p_{max}$ and for moving-average *test* order $j = q_{min}, \ldots, q_{max}$, the OLS estimates $\hat{\Phi}_{(m,j)}$ and $\hat{\Theta}_{(m,j)}$ are computed from the regression model

$$\tilde{z}_t = \sum_{i=1}^{m}\phi_i^{(m,j)}\tilde{z}_{t-i} + \sum_{k=1}^{j}\theta_k^{(m,j)}\hat{\epsilon}_{t-k} + error$$

From the preceding parameter estimates, the BIC is then computed

$$BIC(m,j) = \ln(\tilde{\sigma}^2_{(m,j)}) + 2(m+j)\ln(n)/n$$

where

$$\tilde{\sigma}^2_{(m,j)} = \frac{1}{n}\sum_{t=t_0}^{n}\left(\tilde{z}_t - \sum_{i=1}^{m}\phi_i^{(m,j)}\tilde{z}_{t-i} + \sum_{k=1}^{j}\theta_k^{(m,j)}\hat{\epsilon}_{t-k}\right)$$

where $t_0 = p_\epsilon + \max(\mathrm{m},\mathrm{j})$.

A MINIC table is then constructed using $BIC(m, j)$ (see Table 11.5). If $p_{max} > p_{\epsilon,min}$, the preceding regression may fail due to linear dependence on the estimated error series and the mean-corrected series. Values of $BIC(m, j)$ that cannot be computed are set to missing. For large autoregressive and moving average test orders with relatively few observations, a nearly perfect fit can result. This condition can be identified by a large negative $BIC(m, j)$ value.

The SCAN Method

The **S**mallest **CAN**onical (SCAN) correlation method can tentatively identify the orders of a *stationary or nonstationary* ARMA process. Tsay and Tiao (1985) proposed the technique, and Box et al. (1994) and Choi (1992) provide useful descriptions of the algorithm.

Given a stationary or nonstationary time series $\{z_t : 1 \le t \le n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$, with a true autoregressive order of $p + d$, and with a true moving-average order of q, you can use the SCAN method to analyze eigenvalues of the correlation matrix of the ARMA process. The following paragraphs provide a brief description of the algorithm.

For autoregressive *test* order $m = p_{min}, \ldots, p_{max}$ and for moving-average *test* order $j = q_{min}, \ldots, q_{max}$, perform the following steps.

1. Let $Y_{m,t} = (\tilde{z}_t, \tilde{z}_{t-1}, \ldots, \tilde{z}_{t-m})'$. Compute the following $(m+1) \times (m+1)$ matrix

$$\begin{aligned}
\hat{\beta}(m, j+1) &= \left(\sum_t Y_{m,t-j-1} Y'_{m,t-j-1}\right)^{-1} \left(\sum_t Y_{m,t-j-1} Y'_{m,t}\right) \\
\hat{\beta}^*(m, j+1) &= \left(\sum_t Y_{m,t} Y'_{m,t}\right)^{-1} \left(\sum_t Y_{m,t} Y'_{m,t-j-1}\right) \\
\hat{A}^*(m, j) &= \hat{\beta}^*(m, j+1)\hat{\beta}(m, j+1)
\end{aligned}$$

   where t ranges from $j + m + 2$ to n.

2. Find the *smallest* eigenvalue, $\hat{\lambda}^*(m, j)$, of $\hat{A}^*(m, j)$ and its corresponding *normalized* eigenvector, $\Phi_{m,j} = (1, -\phi_1^{(m,j)}, -\phi_2^{(m,j)}, \ldots, -\phi_m^{(m,j)})$. The squared canonical correlation estimate is $\hat{\lambda}^*(m, j)$.

3. Using the $\Phi_{m,j}$ as AR(m) coefficients, obtain the residuals for $t = j + m + 1$ to n, by following the formula: $w_t^{(m,j)} = \tilde{z}_t - \phi_1^{(m,j)} \tilde{z}_{t-1} - \phi_2^{(m,j)} \tilde{z}_{t-2} - \ldots - \phi_m^{(m,j)} \tilde{z}_{t-m}$.
4. From the sample autocorrelations of the residuals, $r_k(w)$, approximate the standard error of the squared canonical correlation estimate by

   $$var(\hat{\lambda}^*(m,j)^{1/2}) \approx d(m,j)/(n-m-j)$$

   where $d(m,j) = (1 + 2\sum_{i=1}^{j-1} r_k(w^{(m,j)}))$.

The test statistic to be used as an identification criterion is

$$c(m,j) = -(n-m-j)\ln(1 - \hat{\lambda}^*(m,j)/d(m,j))$$

which is asymptotically χ_1^2 if $m = p + d$ and $j \geq q$ or if $m \geq p + d$ and $j = q$. For $m > p$ and $j < q$, there is more than one theoretical zero canonical correlation between $Y_{m,t}$ and $Y_{m,t-j-1}$. Since the $\hat{\lambda}^*(m,j)$ are the smallest canonical correlations for each (m,j), the percentiles of $c(m,j)$ are less than those of a χ_1^2; therefore, Tsay and Tiao (1985) state that it is safe to assume a χ_1^2. For $m < p$ and $j < q$, no conclusions about the distribution of $c(m,j)$ are made.

A SCAN table is then constructed using $c(m,j)$ to determine which of the $\hat{\lambda}^*(m,j)$ are significantly different from zero (see Table 11.6). The ARMA orders are tentatively identified by finding a (maximal) rectangular pattern in which the $\hat{\lambda}^*(m,j)$ are insignificant for all test orders $m \geq p + d$ and $j \geq q$. There may be more than one pair of values $(p + d, q)$ that permit such a rectangular pattern. In this case, parsimony and the number of insignificant items in the rectangular pattern should help determine the model order. Table 11.7 depicts the theoretical pattern associated with an ARMA(2,2) series.

Stationarity Tests

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey (1976) and Dickey and Fuller (1979) studied the limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root. Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots. Hamilton (1994) discusses the various types of unit root testing.

For a description of Dickey-Fuller tests, refer to the section "PROBDF Function for Dickey-Fuller Tests" on page 152 in Chapter 4. Refer to Chapter 12, "The AUTOREG Procedure," for a description of Phillips-Perron tests.

The random walk with drift test recommends whether or not an integrated times series has a drift term. Hamilton (1994) discusses this test.

Prewhitening

If, as is usually the case, an input series is autocorrelated, the direct cross-correlation function between the input and response series gives a misleading indication of the relation between the input and response series.

One solution to this problem is called *prewhitening*. You first fit an ARIMA model for the input series sufficient to reduce the residuals to white noise; then, filter the input series with this model to get the white noise residual series. You then filter the response series with the same model and cross correlate the filtered response with the filtered input series.

The ARIMA procedure performs this prewhitening process automatically when you precede the IDENTIFY statement for the response series with IDENTIFY and ESTIMATE statements to fit a model for the input series. If a model with no inputs was previously fit to a variable specified by the CROSSCORR= option, then that model is used to prewhiten both the input series and the response series before the cross correlations are computed for the input series.

For example,

```
proc arima data=in;
   identify var=x;
   estimate p=1 q=1;
   identify var=y crosscorr=x;
```

Both X and Y are filtered by the ARMA(1,1) model fit to X before the cross correlations are computed.

Note that prewhitening is done to estimate the cross-correlation function; the unfiltered series are used in any subsequent ESTIMATE or FORECAST statements, and the correlation functions of Y with its own lags are computed from the unfiltered Y series. But initial values in the ESTIMATE statement are obtained with prewhitened data; therefore, the result with prewhitening can be different from the result without prewhitening.

To suppress prewhitening for all input variables, use the CLEAR option on the IDENTIFY statement to make PROC ARIMA forget all previous models.

Prewhitening and Differencing

If the VAR= and CROSSCORR= options specify differencing, the series are differenced before the prewhitening filter is applied. When the differencing lists specified on the VAR= option for an input and on the CROSSCORR= option for that input are not the same, PROC ARIMA combines the two lists so that the differencing operators used for prewhitening include all differences in either list (in the least common multiple sense).

Identifying Transfer Function Models

When identifying a transfer function model with multiple input variables, the cross-correlation functions may be misleading if the input series are correlated with each other. Any dependencies among two or more input series will confound their cross correlations with the response series.

The prewhitening technique assumes that the input variables do not depend on past values of the response variable. If there is feedback from the response variable to an input variable, as evidenced by significant cross-correlation at negative lags, both the input and the response variables need to be prewhitened before meaningful cross correlations can be computed.

PROC ARIMA cannot handle feedback models. The STATESPACE procedure is more appropriate for models with feedback.

Missing Values and Autocorrelations

To compute the sample autocorrelation function when missing values are present, PROC ARIMA uses only cross products that do not involve missing values and employs divisors that reflect the number of cross products used rather than the total length of the series. Sample partial autocorrelations and inverse autocorrelations are then computed using the sample autocorrelation function. If necessary, a taper is employed to transform the sample autocorrelations into a positive definite sequence before calculating the partial autocorrelation and inverse correlation functions. The confidence intervals produced for these functions may not be valid when there are missing values. The distributional properties for sample correlation functions are not clear for finite samples. See Dunsmuir (1984) for some asymptotic properties of the sample correlation functions.

Estimation Details

The ARIMA procedure primarily uses the computational methods outlined by Box and Jenkins. Marquardt's method is used for the nonlinear least-squares iterations. Numerical approximations of the derivatives of the sum-of-squares function are taken using a fixed delta (controlled by the DELTA= option).

The methods do not always converge successfully for a given set of data, particularly if the starting values for the parameters are not close to the least-squares estimates.

Back-forecasting

The unconditional sum of squares is computed exactly; thus, back-forecasting is not performed. Early versions of SAS/ETS software used the back-forecasting approximation and allowed a positive value of the BACKLIM= option to control the extent of the back-forecasting. In the current version, requesting a positive number of back-forecasting steps with the BACKLIM= option has no effect.

Preliminary Estimation

If an autoregressive or moving-average operator is specified with no missing lags, preliminary estimates of the parameters are computed using the autocorrelations computed in the IDENTIFY stage. Otherwise, the preliminary estimates are arbitrarily set to values that produce stable polynomials.

When preliminary estimation is not performed by PROC ARIMA, then initial values of the coefficients for any given autoregressive or moving average factor are set to 0.1 if the degree of the polynomial associated with the factor is 9 or less. Otherwise, the coefficients are determined by expanding the polynomial $(1-0.1B)$ to an appropriate power using a recursive algorithm.

These preliminary estimates are the starting values in an iterative algorithm to compute estimates of the parameters.

Estimation Methods

Maximum Likelihood

The METHOD= ML option produces maximum likelihood estimates. The likelihood function is maximized via nonlinear least squares using Marquardt's method. Maximum likelihood estimates are more expensive to compute than the conditional least-squares estimates, however, they may be preferable in some cases (Ansley and Newbold 1980; Davidson 1981).

The maximum likelihood estimates are computed as follows. Let the univariate ARMA model be

$$\phi(B)(W_t - \mu_t) = \theta(B)a_t$$

where a_t is an independent sequence of normally distributed innovations with mean 0 and variance σ^2. Here μ_t is the mean parameter μ plus the transfer function inputs. The log likelihood function can be written as follows:

$$-\frac{1}{2\sigma^2}\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x} - \frac{1}{2}\ln(|\mathbf{\Omega}|) - \frac{n}{2}\ln(\sigma^2)$$

In this equation, *n* is the number of observations, $\sigma^2\mathbf{\Omega}$ is the variance of **x** as a function of the ϕ and θ parameters, and $|\bullet|$ denotes the determinant. The vector **x** is the time series W_t minus the structural part of the model μ_t, written as a column vector, as follows:

$$\mathbf{x} = \begin{bmatrix} W_1 \\ W_2 \\ \vdots \\ W_n \end{bmatrix} - \begin{bmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_n \end{bmatrix}$$

The maximum likelihood estimate (MLE) of σ^2 is

$$s^2 = \frac{1}{n}\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x}$$

Note that the default estimator of the variance divides by $n - r$, where *r* is the number of parameters in the model, instead of by *n*. Specifying the NODF option causes a divisor of *n* to be used.

The log likelihood concentrated with respect to σ^2 can be taken up to additive constants as

$$-\frac{n}{2}\ln(\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x}) - \frac{1}{2}\ln(|\mathbf{\Omega}|)$$

Let **H** be the lower triangular matrix with positive elements on the diagonal such that $\mathbf{HH}' = \mathbf{\Omega}$. Let **e** be the vector $\mathbf{H}^{-1}\mathbf{x}$. The concentrated log likelihood with respect to σ^2 can now be written as

$$-\frac{n}{2}\ln(\mathbf{e}'\mathbf{e}) - \ln(|\mathbf{H}|)$$

or

$$-\frac{n}{2}\ln(|\mathbf{H}|^{1/n}\mathbf{e}'\mathbf{e}|\mathbf{H}|^{1/n})$$

The MLE is produced by using a Marquardt algorithm to minimize the following sum of squares:

$$|\mathbf{H}|^{1/n}\mathbf{e}'\mathbf{e}|\mathbf{H}|^{1/n}$$

The subsequent analysis of the residuals is done using **e** as the vector of residuals.

Unconditional Least Squares

The METHOD=ULS option produces unconditional least-squares estimates. The ULS method is also referred to as the *exact least-squares* (ELS) method. For METHOD=ULS, the estimates minimize

$$\sum_{t=1}^{n} \tilde{a}_t^2 = \sum_{t=1}^{n} (x_t - \mathbf{C}_t \mathbf{V}_t^{-1}(x_1, \cdots, x_{t-1})')^2$$

where $\mathbf{C}_t$ is the covariance matrix of x_t and $(x_1, \cdots, x_{t-1})$, and $\mathbf{V}_t$ is the variance matrix of $(x_1, \cdots, x_{t-1})$. In fact, $\sum_{t=1}^{n} \tilde{a}_t^2$ is the same as $\mathbf{x}'\mathbf{\Omega^{-1}}\mathbf{x}$ and, hence, $\mathbf{e}'\mathbf{e}$. Therefore, the unconditional least-squares estimates are obtained by minimizing the sum of squared residuals rather than using the log likelihood as the criterion function.

Conditional Least Squares

The METHOD=CLS option produces conditional least-squares estimates. The CLS estimates are conditional on the assumption that the past unobserved errors are equal to 0. The series x_t can be represented in terms of the previous observations, as follows:

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

The π weights are computed from the ratio of the ϕ and θ polynomials, as follows:

$$\frac{\phi(B)}{\theta(B)} = 1 - \sum_{i=1}^{\infty} \pi_i B^i$$

The CLS method produces estimates minimizing

$$\sum_{t=1}^{n} \hat{a}_t^2 = \sum_{t=1}^{n} (x_t - \sum_{i=1}^{\infty} \hat{\pi}_i x_{t-i})^2$$

where the unobserved past values of x_t are set to 0 and $\hat{\pi}_i$ are computed from the estimates of ϕ and θ at each iteration.

For METHOD=ULS and METHOD=ML, initial estimates are computed using the METHOD=CLS algorithm.

Start-up for Transfer Functions

When computing the noise series for transfer function and intervention models, the start-up for the transferred variable is done assuming that past values of the input series are equal to the first value of the series. The estimates are then obtained by applying least squares or maximum likelihood to the noise series. Thus, for transfer function models, the ML option does not generate the full (multivariate ARMA) maximum likelihood estimates, but it uses only the univariate likelihood function applied to the noise series.

Because PROC ARIMA uses all of the available data for the input series to generate the noise series, other start-up options for the transferred series can be implemented by prefixing an observation to the beginning of the real data. For example, if you fit a transfer function model to the variable Y with the single input X, then you can employ a start-up using 0 for the past values by prefixing to the actual data an observation with a missing value for Y and a value of 0 for X.

Information Criteria

PROC ARIMA computes and prints two information criteria, Akaike's information criterion (AIC) (Akaike 1974; Harvey 1981) and Schwarz's Bayesian criterion (SBC) (Schwarz 1978). The AIC and SBC are used to compare competing models fit to the same series. The model with the smaller information criteria is said to fit the data better. The AIC is computed as

$$-2\ln(L) + 2k$$

where *L* is the likelihood function and *k* is the number of free parameters. The SBC is computed as

$$-2\ln(L) + \ln(n)k$$

where *n* is the number of residuals that can be computed for the time series. Sometimes Schwarz's Bayesian criterion is called the Bayesian Information criterion (BIC).

If METHOD=CLS is used to do the estimation, an approximation value of *L* is used, where *L* is based on the conditional sum of squares instead of the exact sum of squares, and a Jacobian factor is left out.

Tests of Residuals

A table of test statistics for the hypothesis that the model residuals are white noise is printed as part of the ESTIMATE statement output. The chi-square statistics used in the test for lack of fit are computed using the Ljung-Box formula

$$\chi^2_m = n(n+2)\sum_{k=1}^{m}\frac{r^2_k}{(n-k)}$$

where

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^{n} a^2_t}$$

and a_t is the residual series.

This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution than the Box-Pierce Q statistic. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978). When the time series has missing values, Stoffer and Toloi (1992) suggest a modification of this test statistic that has improved distributional properties over the standard Ljung-Box formula given above. When the series contains missing values this modified test statistic is used by default.

Each chi-square statistic is computed for all lags up to the indicated lag value and is not independent of the preceding chi-square values. The null hypotheses tested is that the current set of autocorrelations is white noise.

t-values

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. When the length of the observed series is short and the number of estimated parameters is large with respect to the series length, the *t* approximation is usually poor. Probability values corresponding to a *t* distribution should be interpreted carefully as they may be misleading.

Cautions During Estimation

The ARIMA procedure uses a general nonlinear least-squares estimation method that can yield problematic results if your data do not fit the model. Output should be examined carefully. The GRID option can be used to ensure the validity and quality of the results. Problems you may encounter include the following:

- Preliminary moving-average estimates may not converge. Should this occur, preliminary estimates are derived as described previously in "Preliminary Estimation" on page 418. You can supply your own preliminary estimates with the ESTIMATE statement options.
- The estimates can lead to an unstable time series process, which can cause extreme forecast values or overflows in the forecast.
- The Jacobian matrix of partial derivatives may be singular; usually, this happens because not all the parameters are identifiable. Removing some of the parameters or using a longer time series may help.
- The iterative process may not converge. PROC ARIMA's estimation method stops after *n* iterations, where *n* is the value of the MAXITER= option. If an iteration does not improve the SSE, the Marquardt parameter is increased by a factor of ten until parameters that have a smaller SSE are obtained or until the limit value of the Marquardt parameter is exceeded.
- For METHOD=CLS, the estimates may converge but not to least-squares estimates. The estimates may converge to a local minimum, the numerical calculations may be distorted by data whose sum-of-squares surface is not smooth, or the minimum may lie outside the region of invertibility or stationarity.

- If the data are differenced and a moving-average model is fit, the parameter estimates may try to converge exactly on the invertibility boundary. In this case, the standard error estimates that are based on derivatives may be inaccurate.

Specifying Inputs and Transfer Functions

Input variables and transfer functions for them may be specified using the INPUT= option on the ESTIMATE statement. The variables used on the INPUT= option must be included in the CROSSCORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSSCORR= list, then the differenced variable is used as the input to the transfer function.

General Syntax of the INPUT= Option

The general syntax of the INPUT= option is

ESTIMATE . . . **INPUT=***(transfer-function variable . . .)*

The transfer function for an input variable is optional. The name of a variable by itself can be used to specify a pure regression term for the variable.

If specified, the syntax of the transfer function is

$$S\ \$\ (L_{1,1}, L_{1,2}, \ldots)(L_{2,1}, \ldots)\ldots/(L_{i,1}, L_{i,2}, \ldots)(L_{i+1,1}, \ldots)\ldots$$

S is the number of periods of time delay (lag) for this input series. Each term in parentheses specifies a polynomial factor with parameters at the lags specified by the $L_{i,j}$ values. The terms before the slash (/) are numerator factors. The terms after the slash (/) are denominator factors. All three parts are optional.

Commas can optionally be used between input specifications to make the INPUT= option more readable. The $ sign after the shift is also optional.

Except for the first numerator factor, each of the terms $L_{i,1}, L_{i,2}, \ldots, L_{i,k}$ indicates a factor of the form

$$(1 - \omega_{i,1}B^{L_{i,1}} - \omega_{i,2}B^{L_{i,2}} - \ldots - \omega_{i,k}B^{L_{i,k}})$$

The form of the first numerator factor depends on the ALTPARM option. By default, the constant 1 in the first numerator factor is replaced with a free parameter ω_0.

Alternative Model Parameterization

When the ALTPARM option is specified, the ω_0 parameter is factored out so it multiplies the entire transfer function, and the first numerator factor has the same form as the other factors.

The ALTPARM option does not materially affect the results; it just presents the results differently. Some people prefer to see the model written one way, while others prefer the alternative representation. Table 11.8 illustrates the effect of the ALTPARM option.

Table 11.8. The ALTPARM Option

INPUT= Option	ALTPARM	Model
INPUT=((1 2)(12)/(1)X);	No	$(\omega_0 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12})/(1 - \delta_1 B)X_t$
	Yes	$\omega_0(1 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12})/(1 - \delta_1 B)X_t$

Differencing and Input Variables

If you difference the response series and use input variables, take care that the differencing operations do not change the meaning of the model. For example, if you want to fit the model

$$Y_t = \frac{\omega_0}{(1-\delta_1 B)} X_t + \frac{(1-\theta_1 B)}{(1-B)(1-B^{12})} a_t$$

then the IDENTIFY statement must read

```
identify var=y(1,12) crosscorr=x(1,12);
estimate q=1 input=(/(1)x) noconstant;
```

If instead you specify the differencing as

```
identify var=y(1,12) crosscorr=x;
estimate q=1 input=(/(1)x) noconstant;
```

then the model being requested is

$$Y_t = \frac{\omega_0}{(1-\delta_1 B)(1-B)(1-B^{12})} X_t + \frac{(1-\theta_1 B)}{(1-B)(1-B^{12})} a_t$$

which is a very different model.

The point to remember is that a differencing operation requested for the response variable specified by the VAR= option is applied only to that variable and not to the noise term of the model.

Initial Values

The syntax for giving initial values to transfer function parameters in the INITVAL= option parallels the syntax of the INPUT= option. For each transfer function in the INPUT= option, the INITVAL= option should give an initialization specification followed by the input series name. The initialization specification for each transfer function has the form

$$C\ \$\ (V_{1,1}, V_{1,2}, \ldots)(V_{2,1}, \ldots)\ldots/(V_{i,1}, \ldots)\ldots$$

where C is the lag 0 term in the first numerator factor of the transfer function (or the overall scale factor if the ALTPARM option is specified), and $V_{i,j}$ is the coefficient of the $L_{i,j}$ element in the transfer function.

To illustrate, suppose you want to fit the model

$$Y_t = \mu + \frac{(\omega_0 - \omega_1 B - \omega_2 B^2)}{(1 - \delta_1 B - \delta_2 B^2 - \delta_3 B^3)} X_{t-3} + \frac{1}{(1 - \phi_1 B - \phi_2 B^3)} a_t$$

and start the estimation process with the initial values μ=10, ω_0=1, ω_1=.5, ω_2=.03, δ_1=.8, δ_2=-.1, δ_3=.002, ϕ_1=.1, ϕ_2=.01. (These are arbitrary values for illustration only.) You would use the following statements:

```
identify var=y crosscorr=x;
estimate p=(1,3) input=(3$(1,2)/(1,2,3)x)
         mu=10 ar=.1 .01 initval=(1$(.5,.03)/(.8,-.1,.002)x);
```

Note that the lags specified for a particular factor will be sorted, so initial values should be given in sorted order. For example, if the P= option had been entered as P=(3,1) instead of P=(1,3), the model would be the same and so would the AR= option. Sorting is done within all factors, including transfer function factors, so initial values should always be given in order of increasing lags.

Here is another illustration, showing initialization for a factored model with multiple inputs. The model is

$$\begin{aligned} Y_t = \mu \quad & + \quad \frac{\omega_{1,0}}{(1 - \delta_{1,1} B)} W_t + (\omega_{2,0} - \omega_{2,1} B) X_{t-3} \\ & + \quad \frac{1}{(1 - \phi_1 B)(1 - \phi_2 B^6 - \phi_3 B^{12})} a_t \end{aligned}$$

and the initial values are μ=10, $\omega_{1,0}$=5, $\delta_{1,1}$=.8, $\omega_{2,0}$=1, $\omega_{2,1}$=.5, ϕ_1=.1, ϕ_2=.05, and ϕ_3=.01. You would use the following statements:

```
identify var=y crosscorr=(w x);
estimate p=(1)(6,12) input=(/(1)w, 3$(1)x)
         mu=10 ar=.1 .05 .01 initval=(5$/(.8)w 1$(.5)x);
```

Stationarity and Invertibility

By default PROC ARIMA requires that the parameter estimates for the AR and MA parts of the model always remain in the stationary and invertible regions, respectively. The NOSTABLE option removes this restriction and for high-order models may save some computer time. Note that using the NOSTABLE option does not necessarily result in an unstable model being fit, since the estimates may leave the stable region for some iterations, but still ultimately converge to stable values.

Naming of Model Parameters

In the table of parameter estimates produced by the ESTIMATE statement, model parameters are referred to using the naming convention described in this section.

The parameters in the noise part of the model are named as AR*i*,*j* or MA*i*,*j*, where AR refers to autoregressive parameters and MA to moving-average parameters. The subscript *i* refers to the particular polynomial factor, and the subscript *j* refers to the *j*th term within the *i*th factor. These terms are sorted in order of increasing lag within factors, so the subscript *j* refers to the *j*th term after sorting.

When inputs are used in the model, the parameters of each transfer function are named NUM*i*,*j* and DEN*i*,*j*. The *j*th term in the *i*th factor of a numerator polynomial is named NUM*i*,*j*. The *j*th term in the *i*th factor of a denominator polynomial is named DEN*i*,*j*.

This naming process is repeated for each input variable, so if there are multiple inputs, parameters in transfer functions for different input series have the same name. The table of parameter estimates shows in the "Variable" column the input with which each parameter is associated. The parameter name shown in the "Parameter" column and the input variable name shown in the "Variable" column must be combined to fully identify transfer function parameters.

The lag 0 parameter in the first numerator factor for the first input variable is named NUM1. For subsequent input variables, the lag 0 parameter in the first numerator factor is named NUM*k*, where *k* is the position of the input variable in the INPUT= option list. If the ALTPARM option is specified, the NUM*k* parameter is replaced by an overall scale parameter named SCALE*k*.

For the mean and noise process parameters, the response series name is shown in the "Variable" column. The Lag and Shift for each parameter are also shown in the table of parameter estimates when inputs are used.

Missing Values and Estimation and Forecasting

Estimation and forecasting are carried out in the presence of missing values by forecasting the missing values with the current set of parameter estimates. The maximum likelihood algorithm employed was suggested by Jones (1980) and is used for both unconditional least-squares (ULS) and maximum likelihood (ML) estimation.

The CLS algorithm simply fills in missing values with infinite memory forecast values, computed by forecasting ahead from the nonmissing past values as far as required by the structure of the missing values. These artificial values are then employed in the nonmissing value CLS algorithm. Artificial values are updated at each iteration along with parameter estimates.

For models with input variables, embedded missing values (that is, missing values other than at the beginning or end of the series) are not generally supported. Embedded missing values in input variables are supported for the special case of a multiple regression model having ARIMA errors. A multiple regression model is specified by an INPUT= option that simply lists the input variables (possibly with lag shifts) without any numerator or denominator transfer function factors. One-step-ahead forecasts are not available for the response variable when one or more of the input variables have missing values.

When embedded missing values are present for a model with complex transfer functions, PROC ARIMA uses the first continuous nonmissing piece of each series to do the analysis. That is, PROC ARIMA skips observations at the beginning of each series until it encounters a nonmissing value and then uses the data from there until it encounters another missing value or until the end of the data is reached. This makes the current version of PROC ARIMA compatible with earlier releases that did not allow embedded missing values.

Forecasting Details

If the model has input variables, a forecast beyond the end of the data for the input variables is possible only if univariate ARIMA models have previously been fit to the input variables or future values for the input variables are included in the DATA= data set.

If input variables are used, the forecast standard errors and confidence limits of the response depend on the estimated forecast error variance of the predicted inputs. If several input series are used, the forecast errors for the inputs should be independent; otherwise, the standard errors and confidence limits for the response series will not be accurate. If future values for the input variables are included in the DATA= data set, the standard errors of the forecasts will be underestimated since these values are assumed to be known with certainty.

The forecasts are generated using forecasting equations consistent with the method used to estimate the model parameters. Thus, the estimation method specified on the ESTIMATE statement also controls the way forecasts are produced by the FORECAST statement. If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. If METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. A complete description of the steps to produce the series forecasts and their standard errors using either of these methods is quite involved and only a brief explanation of the algorithm is given in the next two sections. Additional details about the finite and infinite memory forecasts can be found in Brockwell and Davis (1991). The prediction of stationary ARMA processes is explained in Chapter 5 and the prediction of nonstationary ARMA processes is given in Chapter 9.

Infinite Memory Forecasts

If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. The term *conditional* is used because the forecasts are computed by assuming that the unknown values of the response series before the start of the data are equal to the mean of the series. Thus, the forecasts are conditional on this assumption.

The series x_t can be represented as

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

where $\phi(B)/\theta(B) = 1 - \sum_{i=1}^{\infty} \pi_i B^i$.

The *k*-step forecast of x_{t+k} is computed as

$$\hat{x}_{t+k} = \sum_{i=1}^{k-1} \hat{\pi}_i \hat{x}_{t+k-i} + \sum_{i=k}^{\infty} \hat{\pi}_i x_{t+k-i}$$

where unobserved past values of x_t are set to zero, and $\hat{\pi}_i$ is obtained from the estimated parameters $\hat{\phi}$ and $\hat{\theta}$.

Finite Memory Forecasts

For METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. For finite memory forecasts, the covariance function of the ARMA model is used to derive the best linear prediction equation.

That is, the *k*-step forecast of x_{t+k}, given $(x_1, \cdots, x_{t-1})$, is

$$\tilde{x}_{t+k} = \mathbf{C}_{k,t} \mathbf{V}_t^{-1} (x_1, \cdots, x_{t-1})'$$

where $\mathbf{C}_{k,t}$ is the covariance of x_{t+k} and $(x_1, \cdots, x_{t-1})$, and $\mathbf{V}_t$ is the covariance matrix of the vector $(x_1, \cdots, x_{t-1})$. $\mathbf{C}_{k,t}$ and $\mathbf{V}_t$ are derived from the estimated parameters.

Finite memory forecasts minimize the mean-squared error of prediction if the parameters of the ARMA model are known exactly. (In most cases, the parameters of the ARMA model are estimated, so the predictors are not true best linear forecasts.)

If the response series is differenced, the final forecast is produced by summing the forecast of the differenced series. This summation, and, thus, the forecast, is conditional on the initial values of the series. Thus, when the response series is differenced, the final forecasts are not true finite memory forecasts because they are derived assuming that the differenced series begins in a steady-state condition. Thus, they fall somewhere between finite memory and infinite memory forecasts. In practice, there is seldom any practical difference between these forecasts and true finite memory forecasts.

Forecasting Log Transformed Data

The log transformation is often used to convert time series that are nonstationary with respect to the innovation variance into stationary time series. The usual approach is to take the log of the series in a DATA step and then apply PROC ARIMA to the transformed data. A DATA step is then used to transform the forecasts of the logs back to the original units of measurement. The confidence limits are also transformed using the exponential function.

As one alternative, you can simply exponentiate the forecast series. This procedure gives a forecast for the median of the series, but the antilog of the forecast log series underpredicts the mean of the original series. If you want to predict the expected value of the series, you need to take into account the standard error of the forecast, as shown in the following example, which uses an AR(2) model to forecast the log of a series Y:

```
data in;
   set in;
   ylog = log( y );
run;

proc arima data=in;
   identify var=ylog;
   estimate p=2;
   forecast lead=10 out=out;
run;

data out;
   set out;
   y   = exp( ylog );
   l95 = exp( l95 );
   u95 = exp( u95 );
   forecast = exp( forecast + std*std/2 );
run;
```

Specifying Series Periodicity

The INTERVAL= option is used together with the ID= variable to describe the observations that make up the time series. For example, INTERVAL=MONTH specifies a monthly time series in which each observation represents one month. See Chapter 3, “Date Intervals, Formats, and Functions,” for details on the interval values supported.

The variable specified by the ID= option in the PROC ARIMA statement identifies the time periods associated with the observations. Usually, SAS date or datetime values are used for this variable. PROC ARIMA uses the ID= variable in the following ways:

- to validate the data periodicity. When the INTERVAL= option is specified, PROC ARIMA uses the ID variable to check the data and verify that successive observations have valid ID values corresponding to successive time intervals.

When the INTERVAL= option is not used, PROC ARIMA verifies that the ID values are nonmissing and in ascending order.

- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for April 1970 follows an observation for January 1970, there is a gap in the input data with two omitted observations (namely February and March 1970). A warning message is printed when a gap in the input data is found.
- to label the forecast observations in the output data set. PROC ARIMA extrapolates the values of the ID variable for the forecast observations from the ID value at the end of the input data according to the frequency specifications of the INTERVAL= option. If the INTERVAL= option is not specified, PROC ARIMA extrapolates the ID variable by incrementing the ID variable value for the last observation in the input data by 1 for each forecast period. Values of the ID variable over the range of the input data are copied to the output data set.

The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

Detecting Outliers

You can use the OUTLIER statement to detect changes in the level of the response series that are not accounted for by the estimated model. The types of changes considered are Additive Outliers (AO), Level Shifts (LS), and Temporary Changes (TC).

Let η_t be a regression variable describing some type of change in the mean response. In time series literature η_t is called a shock signature. An additive outlier at some time point s corresponds to a shock signature η_t such that $\eta_s = 1.0$ and η_t is 0.0 at all other points. Similarly a permanent level shift originating at time s has a shock signature such that η_t is 0.0 for $t < s$ and 1.0 for $t \geq s$. A temporary level shift of duration d originating at time s will have η_t equal to 1.0 between s and $s + d$ and 0.0 otherwise.

Suppose that you are estimating the ARIMA model

$$D(B)Y_t = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

where Y_t is the response series, $D(B)$ is the differencing polynomial in the backward shift operator B (possibly identity), μ_t is the transfer function input, $\phi(B)$ and $\theta(B)$ are the AR and MA polynomials, and a_t is the Gaussian white noise series.

The problem of detection of level shifts in the OUTLIER statement is formulated as a problem of sequential selection of shock signatures that improve the model in the ESTIMATE statement. This is similar to the forward selection process in the stepwise regression procedure. The selection process starts with considering shock signatures of the type specified in the TYPE= option, originating at each nonmissing measurement. This involves testing $H_0\colon \beta = 0$ versus $H_a\colon \beta \neq 0$ in the model

$$D(B)(Y_t - \beta\eta_t) = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

for each of these shock signatures. The most significant shock signature, if it also satisfies the significance criterion in ALPHA= option, is included in the model. If no significant shock signature is found then the outlier detection process stops, otherwise this augmented model, which incorporates the selected shock signature in its transfer function input, becomes the null model for the subsequent selection process. This iterative process stops if at any stage no more significant shock signatures are found or if the number of iterations exceed the maximum search number resulting due to the MAXNUM= and MAXPCT= settings. In all these iterations the parameters of the ARIMA model in the ESTIMATE statement are held fixed.

The precise details of the testing procedure for a given shock signature η_t are as follows:

The preceding testing problem is equivalent to testing $H_0\colon \beta = 0$ versus $H_a\colon \beta \neq 0$ in the following "regression with ARMA errors" model

$$N_t = \beta\zeta_t + \frac{\theta(B)}{\phi(B)}a_t$$

where $N_t = (D(B)Y_t - \mu_t)$ is the "noise" process and $\zeta_t = D(B)\eta_t$ is the "effective" shock signature.

In this setting, under H_0, $N = (N_1, N_2, \ldots, N_n)^T$ is a mean zero Gaussian vector with variance covariance matrix $\sigma^2\Sigma$. Here σ^2 is the variance of the white noise process a_t and Σ is the variance covariance matrix associated with the ARMA model. Moreover, under H_a, N has $\beta\zeta$ as the mean vector where $\zeta = (\zeta_1, \zeta_2, \ldots, \zeta_n)^T$. Additionally, the generalized least squares estimate of β and its variance is given by

$$\begin{aligned} \hat{\beta} &= \delta/\kappa \\ \mathrm{Var}(\hat{\beta}) &= \sigma^2/\kappa \end{aligned}$$

where $\delta = \zeta^T\Sigma^{-1}N$ and $\kappa = \zeta^T\Sigma^{-1}\zeta$. The test statistic $\tau^2 = \delta^2/(\sigma^2\kappa)$ is used to test the significance of β, which has an approximate chi-squared distribution with 1 degree of freedom under H_0. The type of estimate of σ^2 used in the calculation of τ^2 can be specified by the SIGMA= option. The default setting is SIGMA=ROBUST that corresponds to a robust estimate suggested in an outlier detection procedure in X-12-ARIMA, the Census Bureau's time series analysis program; refer to Findley et al. (1998) for additional information. The setting SIGMA=MSE corresponds to the usual mean squared error estimate (MSE) computed the same way as in the ESTIMATE statement with the NODF option. The robust estimate of σ^2 is computed by the formula

$$\hat{\sigma}^2 = (1.49 \times \mathrm{Median}(|\hat{a}_t|))^2$$

where $\hat{a}_t$ are the standardized residuals of the null ARIMA model.

The quantities δ and κ are efficiently computed by a method described in de Jong and Penzer (1998); refer also to Kohn and Ansley (1985).

Modeling in the Presence of Outliers

In practice, modeling and forecasting time series data in the presence of outliers is a difficult problem for several reasons. The presence of outliers can adversely affect the model identification and estimation steps. Their presence close to the end of the observation period can have a serious impact on the forecasting performance of the model. In some cases level shifts are associated with changes in the mechanism driving the observation process, and separate models may be appropriate to different sections of the data. In view of all these difficulties, diagnostic tools such as outlier detection and residual analysis are essential in any modeling process.

The following modeling strategy, which incorporates level shift detection in the familiar Box-Jenkins modeling methodology, seems to work in many cases:

1. Proceed with model identification and estimation as usual. Suppose this results in a tentative ARIMA model, say M.
2. Check for additive and permanent level shifts unaccounted for by the model M using the OUTLIER statement. In this step, unless there is evidence to justify it, the number of level shifts searched should be kept small.
3. Augment the original dataset with the regression variables corresponding to the detected outliers.
4. Include the first few of these regression variables in M, and call this model M1. Re-estimate all the parameters of M1. It is important not to include too many of these outlier variables in the model in order to avoid the danger of over-fitting.
5. Check the adequacy of M1 by examining the parameter estimates, residual analysis, and outlier detection. Refine it more if necessary.

OUT= Data Set

The output data set produced by the OUT= option of the PROC ARIMA or FORECAST statements contains the following:

- the BY variables
- the ID variable
- the variable specified by the VAR= option in the IDENTIFY statement, which contains the actual values of the response series
- FORECAST, a numeric variable containing the one-step-ahead predicted values and the multistep forecasts
- STD, a numeric variable containing the standard errors of the forecasts

- a numeric variable containing the lower confidence limits of the forecast. This variable is named L95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.
- RESIDUAL, a numeric variable containing the differences between actual and forecast values
- a numeric variable containing the upper confidence limits of the forecast. This variable is named U95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.

The ID variable, the BY variables, and the time series variable are the only ones copied from the input to the output data set.

Unless the NOOUTALL option is specified, the data set contains the whole time series. The FORECAST variable has the one-step forecasts (predicted values) for the input periods, followed by *n* forecast values, where *n* is the LEAD= value. The actual and RESIDUAL values are missing beyond the end of the series.

If you specify the same OUT= data set on different FORECAST statements, the latter FORECAST statements overwrite the output from the previous FORECAST statements. If you want to combine the forecasts from different FORECAST statements in the same output data set, specify the OUT= option once on the PROC ARIMA statement and omit the OUT= option on the FORECAST statements.

When a global output data set is created by the OUT= option in the PROC ARIMA statement, the variables in the OUT= data set are defined by the first FORECAST statement that is executed. The results of subsequent FORECAST statements are vertically concatenated onto the OUT= data set. Thus, if no ID variable is specified in the first FORECAST statement that is executed, no ID variable appears in the output data set, even if one is specified in a later FORECAST statement. If an ID variable is specified in the first FORECAST statement that is executed but not in a later FORECAST statement, the value of the ID variable is the same as the last value processed for the ID variable for all observations created by the later FORECAST statement. Furthermore, even if the response variable changes in subsequent FORECAST statements, the response variable name in the output data set will be that of the first response variable analyzed.

OUTCOV= Data Set

The output data set produced by the OUTCOV= option of the IDENTIFY statement contains the following variables:

- LAG, a numeric variable containing the lags corresponding to the values of the covariance variables. The values of LAG range from 0 to N for covariance functions and from -N to N for cross-covariance functions, where N is the value of the NLAG= option.
- VAR, a character variable containing the name of the variable specified by the VAR= option.

- CROSSVAR, a character variable containing the name of the variable specified in the CROSSCORR= option, which labels the different cross-covariance functions. The CROSSVAR variable is blank for the autocovariance observations. When there is no CROSSCORR= option, this variable is not created.
- N, a numeric variable containing the number of observations used to calculate the current value of the covariance or cross-covariance function.
- COV, a numeric variable containing the autocovariance or cross-covariance function values. COV contains the autocovariances of the VAR= variable when the value of the CROSSVAR variable is blank. Otherwise COV contains the cross covariances between the VAR= variable and the variable named by the CROSSVAR variable.
- CORR, a numeric variable containing the autocorrelation or cross-correlation function values. CORR contains the autocorrelations of the VAR= variable when the value of the CROSSVAR variable is blank. Otherwise CORR contains the cross correlations between the VAR= variable and the variable named by the CROSSVAR variable.
- STDERR, a numeric variable containing the standard errors of the autocorrelations. The standard error estimate is based on the hypothesis that the process generating the time series is a pure moving-average process of order LAG-1. For the cross correlations, STDERR contains the value $1/\sqrt{n}$, which approximates the standard error under the hypothesis that the two series are uncorrelated.
- INVCORR, a numeric variable containing the inverse autocorrelation function values of the VAR= variable. For cross-correlation observations, (that is, when the value of the CROSSVAR variable is not blank), INVCORR contains missing values.
- PARTCORR, a numeric variable containing the partial autocorrelation function values of the VAR= variable. For cross-correlation observations (that is, when the value of the CROSSVAR variable is not blank), PARTCORR contains missing values.

OUTEST= Data Set

PROC ARIMA writes the parameter estimates for a model to an output data set when the OUTEST= option is specified in the ESTIMATE statement. The OUTEST= data set contains the following:

- the BY variables
- _NAME_, a character variable containing the name of the parameter for the covariance or correlation observations, or blank for the observations containing the parameter estimates. (This variable is not created if neither OUTCOV nor OUTCORR is specified.)
- _TYPE_, a character variable that identifies the type of observation. A description of the _TYPE_ variable values is given below.

- variables for model parameters

The variables for the model parameters are named as follows:

ERRORVAR	This numeric variable contains the variance estimate. The _TYPE_=EST observation for this variable contains the estimated error variance, and the remaining observations are missing.
MU	This numeric variable contains values for the mean parameter for the model. (This variable is not created if NOCONSTANT is specified.)
MA*j_k*	These numeric variables contain values for the moving average parameters. The variables for moving average parameters are named MA*j_k*, where *j* is the factor number, and *k* is the index of the parameter within a factor.
AR*j_k*	These numeric variables contain values for the autoregressive parameters. The variables for autoregressive parameters are named AR*j_k*, where *j* is the factor number, and *k* is the index of the parameter within a factor.
I*j_k*	These variables contain values for the transfer function parameters. Variables for transfer function parameters are named I*j_k*, where *j* is the number of the INPUT variable associated with the transfer function component, and *k* is the number of the parameter for the particular INPUT variable. INPUT variables are numbered according to the order in which they appear in the INPUT= list.
STATUS	This variable describes the convergence status of the model. A value of 0_CONVERGED indicates that the model converged.

The value of the _TYPE_ variable for each observation indicates the kind of value contained in the variables for model parameters for the observation. The OUTEST= data set contains observations with the following _TYPE_ values:

EST	the observation contains parameter estimates
STD	the observation contains approximate standard errors of the estimates
CORR	the observation contains correlations of the estimates. OUTCORR must be specified to get these observations.
COV	the observation contains covariances of the estimates. OUTCOV must be specified to get these observations.
FACTOR	the observation contains values that identify for each parameter the factor that contains it. Negative values indicate denominator factors in transfer function models.
LAG	the observation contains values that identify the lag associated with each parameter

SHIFT	the observation contains values that identify the shift associated with the input series for the parameter

The values given for _TYPE_=FACTOR, _TYPE_=LAG, or _TYPE_=SHIFT observations enable you to reconstruct the model employed when provided with only the OUTEST= data set.

OUTEST= Examples

This section clarifies how model parameters are stored in the OUTEST= data set with two examples.

Consider the following example:

```
proc arima data=input;
   identify var=y cross=(x1 x2);
   estimate p=(1)(6) q=(1,3)(12) input=(x1 x2) outest=est;
quit;
proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \omega_{1,0}X_{1,t} + \omega_{2,0}X_{2,t} + \frac{(1-\theta_{11}B-\theta_{12}B^3)(1-\theta_{21}B^{12})}{(1-\phi_{11}B)(1-\phi_{21}B^6)}a_t$$

The OUTEST= data set contains the values shown in Table 11.9.

Table 11.9. OUTEST= Data Set for First Example

Obs	_TYPE_	Y	MU	MA1_1	MA1_2	MA2_1	AR1_1	AR2_1	I1_1	I2_1
1	EST	σ^2	μ	θ_{11}	θ_{12}	θ_{21}	ϕ_{11}	ϕ_{21}	$\omega_{1,0}$	$\omega_{2,0}$
2	STD	.	se μ	se θ_{11}	se θ_{12}	se θ_{21}	se ϕ_{11}	se ϕ_{21}	se $\omega_{1,0}$	se $\omega_{2,0}$
3	FACTOR	.	0	1	1	2	1	2	1	1
4	LAG	.	0	1	3	12	1	6	0	0
5	SHIFT	.	0	0	0	0	0	0	0	0

Note that the symbols in the rows for _TYPE_=EST and _TYPE_=STD in Table 11.9 would be numeric values in a real data set.

Next, consider the following example:

```
proc arima data=input;
   identify var=y cross=(x1(2) x2(1));
   estimate p=1 q=1 input=(2 $ (1)/(1,2)x1 1 $ /(1)x2) outest=est;
quit;
proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \frac{\omega_{10}-\omega_{11}B}{1-\delta_{11}B-\delta_{12}B^2}X_{1,t-2} + \frac{\omega_{20}}{1-\delta_{21}B}X_{2,t-1} + \frac{(1-\theta_1B)}{(1-\phi_1B)}a_t$$

The OUTEST= data set contains the values shown in Table 11.10.

Table 11.10. OUTEST= Data Set for Second Example

Obs	_TYPE_	Y	MU	MA1_1	AR1_1	I1_1	I1_2	I1_3	I1_4	I2_1	I2_2
1	EST	σ^2	μ	θ_1	ϕ_1	ω_{10}	ω_{11}	δ_{11}	δ_{12}	ω_{20}	δ_{21}
2	STD	.	se μ	se θ_1	se ϕ_1	se ω_{10}	se ω_{11}	se δ_{11}	se δ_{12}	se ω_{20}	se δ_{21}
3	FACTOR	.	0	1	1	1	1	-1	-1	1	-1
4	LAG	.	0	1	1	0	1	1	2	0	1
5	SHIFT	.	0	0	0	2	2	2	2	1	1

OUTMODEL= Data Set

The OUTMODEL= option in the ESTIMATE statement writes an output data set that enables you to reconstruct the model. The OUTMODEL= data set contains much the same information as the OUTEST= data set but in a transposed form that may be more useful for some purposes. In addition, the OUTMODEL= data set includes the differencing operators.

The OUTMODEL data set contains the following:

- the BY variables
- _NAME_, a character variable containing the name of the response or input variable for the observation.
- _TYPE_, a character variable that contains the estimation method that was employed. The value of _TYPE_ can be CLS, ULS, or ML.
- _STATUS_, a character variable that describes the convergence status of the model. A value of 0_CONVERGED indicates that the model converged.
- _PARM_, a character variable containing the name of the parameter given by the observation. _PARM_ takes on the values ERRORVAR, MU, AR, MA, NUM, DEN, and DIF.
- _VALUE_, a numeric variable containing the value of the estimate defined by the _PARM_ variable.
- _STD_, a numeric variable containing the standard error of the estimate.
- _FACTOR_, a numeric variable indicating the number of the factor to which the parameter belongs.
- _LAG_, a numeric variable containing the number of the term within the factor containing the parameter.
- _SHIFT_, a numeric variable containing the shift value for the input variable associated with the current parameter.

The values of _FACTOR_ and _LAG_ identify which particular MA, AR, NUM, or DEN parameter estimate is given by the _VALUE_ variable. The _NAME_ variable contains the response variable name for the MU, AR, or MA parameters. Otherwise, _NAME_ contains the input variable name associated with NUM or DEN parameter estimates. The _NAME_ variable contains the appropriate variable name associated with the current DIF observation as well. The _VALUE_ variable is 1 for all DIF observations, and the _LAG_ variable indicates the degree of differencing employed.

The observations contained in the OUTMODEL= data set are identified by the _PARM_ variable. A description of the values of the _PARM_ variable follows:

NUMRESID	_VALUE_ contains the number of residuals.
NPARMS	_VALUE_ contains the number of parameters in the model.
NDIFS	_VALUE_ contains the sum of the differencing lags employed for the response variable.
ERRORVAR	_VALUE_ contains the estimate of the innovation variance.
MU	_VALUE_ contains the estimate of the mean term.
AR	_VALUE_ contains the estimate of the autoregressive parameter indexed by the _FACTOR_ and _LAG_ variable values.
MA	_VALUE_ contains the estimate of a moving average parameter indexed by the _FACTOR_ and _LAG_ variable values.
NUM	_VALUE_ contains the estimate of the parameter in the numerator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DEN	_VALUE_ contains the estimate of the parameter in the denominator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DIF	_VALUE_ contains the difference operator defined by the difference lag given by the value in the _LAG_ variable.

OUTSTAT= Data Set

PROC ARIMA writes the diagnostic statistics for a model to an output data set when the OUTSTAT= option is specified in the ESTIMATE statement. The OUTSTAT data set contains the following:

- the BY variables.
- _TYPE_, a character variable that contains the estimation method used. _TYPE_ can have the value CLS, ULS, or ML.
- _STAT_, a character variable containing the name of the statistic given by the _VALUE_ variable in this observation. _STAT_ takes on the values AIC, SBC, LOGLIK, SSE, NUMRESID, NPARMS, NDIFS, ERRORVAR, MU, CONV, and NITER.
- _VALUE_, a numeric variable containing the value of the statistic named by the _STAT_ variable.

The observations contained in the OUTSTAT= data set are identified by the _STAT_ variable. A description of the values of the _STAT_ variable follows:

AIC	Akaike's information criterion
SBC	Schwarz's Bayesian criterion
LOGLIK	the log likelihood, if METHOD=ML or METHOD=ULS is specified
SSE	the sum of the squared residuals
NUMRESID	the number of residuals
NPARMS	the number of parameters in the model
NDIFS	the sum of the differencing lags employed for the response variable
ERRORVAR	the estimate of the innovation variance
MU	the estimate of the mean term
CONV	tells if the estimation converged
NITER	the number of iterations

Printed Output

The ARIMA procedure produces printed output for each of the IDENTIFY, ESTIMATE, and FORECAST statements. The output produced by each ARIMA statement is described in the following sections.

IDENTIFY Statement Printed Output

The printed output of the IDENTIFY statement consists of the following:

1. a table of summary statistics, including the name of the response variable, any specified periods of differencing, the mean and standard deviation of the response series after differencing, and the number of observations after differencing
2. a plot of the sample autocorrelation function for lags up to and including the NLAG= option value. Standard errors of the autocorrelations also appear to the right of the autocorrelation plot if the value of LINESIZE= option is sufficiently large. The standard errors are derived using Bartlett's approximation (Box and Jenkins 1976, p. 177). The approximation for a standard error for the estimated autocorrelation function at lag *k* is based on a null hypothesis that a pure moving-average Gaussian process of order *k*-1 generated the time series. The relative position of an approximate 95% confidence interval under this null hypothesis is indicated by the dots in the plot, while the asterisks represent the relative magnitude of the autocorrelation value.
3. a plot of the sample inverse autocorrelation function. See the section "The Inverse Autocorrelation Function" on page 409 for more information on the inverse autocorrelation function.
4. a plot of the sample partial autocorrelation function
5. a table of test statistics for the hypothesis that the series is white noise. These test statistics are the same as the tests for white noise residuals produced by the ESTIMATE statement and are described in the section "Estimation Details" on page 418.

6. if the CROSSCORR= option is used, a plot of the sample cross-correlation function for each series specified in the CROSSCORR= option. If a model was previously estimated for a variable in the CROSSCORR= list, the cross correlations for that series are computed for the prewhitened input and response series. For each input variable with a prewhitening filter, the cross-correlation report for the input series includes
   (a) a table of test statistics for the hypothesis of no cross correlation between the input and response series
   (b) the prewhitening filter used for the prewhitening transformation of the predictor and response variables
7. if the ESACF option is used, ESACF tables are printed
8. if the MINIC option is used, a MINIC table is printed
9. if the SCAN option is used, SCAN table is printed
10. if the STATIONARITY option is used, STATIONARITY tests results are printed

ESTIMATE Statement Printed Output

The printed output of the ESTIMATE statement consists of the following:

1. when the PRINTALL option is specified, the preliminary parameter estimates and an iteration history showing the sequence of parameter estimates tried during the fitting process
2. a table of parameter estimates showing the following for each parameter: the parameter name, the parameter estimate, the approximate standard error, t value, approximate probability ($Pr > |t|$), the lag for the parameter, the input variable name for the parameter, and the lag or “Shift” for the input variable
3. the estimates of the constant term, the innovation variance (Variance Estimate), the innovation standard deviation (Std Error Estimate), Akaike’s information criterion (AIC), Schwarz’s Bayesian criterion (SBC), and the number of residuals
4. the correlation matrix of the parameter estimates
5. a table of test statistics for hypothesis that the residuals of the model are white noise titled “Autocorrelation Check of Residuals”
6. if the PLOT option is specified, autocorrelation, inverse autocorrelation, and partial autocorrelation function plots of the residuals
7. if an INPUT variable has been modeled in such a way that prewhitening is performed in the IDENTIFY step, a table of test statistics titled “Crosscorrelation Check of Residuals.” The test statistic is based on the chi-square approximation suggested by Box and Jenkins (1976, pp. 395–396). The cross-correlation function is computed using the residuals from the model as one series and the prewhitened input variable as the other series.

8. if the GRID option is specified, the sum-of-squares or likelihood surface over a grid of parameter values near the final estimates
9. a summary of the estimated model showing the autoregressive factors, moving average factors, and transfer function factors in back shift notation with the estimated parameter values.

OUTLIER Statement Printed Output

The printed output of the FORECAST statement consists of the following:

1. a summary that contains the information about the maximum number of outliers searched, the number of outliers actually detected, and the significance level used in the outlier detection.
2. a table that contains the results of the outlier detection process. The outliers are listed in the order in which they are found. This table contains the following columns:

   - The "Obs" column contains the observation number of the start of the level shift.
   - If an ID= option is specified then the "Time ID" column contains the time identification labels of the start of the level shift.
   - The "Type" column lists the type of the level shift.
   - The "Estimate" column contains $\hat{\beta}$, the estimate of the regression coefficient of the shock signature.
   - The "Chi-Square" column lists the value of the test statistic τ^2.
   - The "Approx Prob > ChiSq" column lists the approximate *p*-value of the test statistic.

FORECAST Statement Printed Output

The printed output of the FORECAST statement consists of the following:

1. a summary of the estimated model
2. a table of forecasts, with columns for the observation numbers (Obs), the forecast values (Forecast), the forecast standard errors (Std Error), lower and upper limits of the approximate 95% confidence interval (95% confidence limits). The ALPHA= option can be used to change the confidence interval for forecasts. If the PRINTALL option is specified, the forecast table also includes columns for the actual values of the response series (Actual) and the residual values (Residual), and the table includes the input observations used to estimate the model.

ODS Table Names

PROC ARIMA assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 11.11. ODS Tables Produced in PROC ARIMA

ODS Table Name	Description	Option
ODS Tables Created by the IDENTIFY Statement		
ChiSqAuto	Chi-Square statistics table for autocorrelation	
ChiSqCross	Chi-Square statistics table for cross-correlations	CROSSCORR=
CorrGraph	Correlations graph	
DescStats	Descriptive Statistics	
ESACF	Extended Sample Autocorrelation Function	ESACF option
ESACFPValues	ESACF Probability Values	ESACF option
IACFGraph	Inverse autocorrelations graph	
InputDescStats	Input Descriptive Statistics	
MINIC	Minimum Information Criterion	MINIC option
PACFGraph	Partial autocorrelations graph	
SCAN	Squared Canonical Correlation Estimates	SCAN option
SCANPValues	SCAN Chi-Square[1] Probability Values	SCAN option
StationarityTests	Stationarity tests	STATIONARITY option
TentativeOrders	Tentative Order Selection	MINIC, ESACF, or SCAN option
ODS Tables Created by the ESTIMATE Statement		
ARPolynomial	Filter Equations	
ChiSqAuto	Chi-Square statistics table for autocorrelation	
ChiSqCross	Chi-Square statistics table for cross-correlations	
CorrB	Correlations of the Estimates	
DenPolynomial	Filter Equations	
FitStatistics	Fit Statistics	
IterHistory	Conditional Least Squares Estimation	METHOD=CLS
InitialAREstimates	Initial autoregressive parameter estimates	
InitialMAEstimates	Initial moving average parameter estimates	
InputDescription	Input description	
MAPolynomial	Filter Equations	
ModelDescription	Model description	
NumPolynomial	Filter Equations	
ParameterEstimates	Parameter Estimates	
PrelimEstimates	Preliminary Estimation

Forecasts	Forecast	

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the ARIMA procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, “Statistical Graphics Using ODS.”

When the ODS GRAPHICS are in effect, the ARIMA procedure can produce a variety of plots. The main types of plots available are as follows:

- If the NOPRINT option in the IDENTIFY statement is off, the correlation plots of the dependent series are produced after the series is appropriately differenced. These include plots of the autocorrelation, partial autocorrelation, and inverse autocorrelation functions.
- If in the ESTIMATE statement the NOPRINT option is off while the PLOT option is on, the correlation plots of the model residuals are produced. These include plots of the autocorrelation, partial autocorrelation, and inverse autocorrelation functions.
- If the NOPRINT option in the FORECAST statement is off, the time series plot of the series forecasts is produced. If ID= option is used in the FORECAST statement, the ticks on the time axis use this information; otherwise the observation numbers are used as the time axis. If PRINTALL option is on, the forecast plot contains one-step-ahead forecasts as well as the multi-step-ahead forecasts.

For an example of the use of ODS GRAPHICS in PROC ARIMA, see Example 11.8.

ODS Graph Names

PROC ARIMA assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 11.12.

Table 11.12. ODS Graphics Produced by PROC ARIMA

ODS Graph Name	Plot Description	Associated Statement

ResidualPACFPlot	Residual Partial Autocorrelation Plot	ESTIMATE
SeriesACFPlot	Series Autocorrelation Plot	IDENTIFY
SeriesIACFPlot	Series Inverse Autocorrelation Plot	IDENTIFY
SeriesPACFPlot	Series Partial Autocorrelation Plot	IDENTIFY

Examples

Example 11.1. Simulated IMA Model

This example illustrates the ARIMA procedure results for a case where the true model is known. An integrated moving average model is used for this illustration.

The following DATA step generates a pseudo-random sample of 100 periods from the ARIMA(0,1,1) process $u_t = u_{t-1} + a_t - .8a_{t-1}$, a_t iid $\mathrm{N}(0, 1)$.

```
title1 'Simulated IMA(1,1) Series';
data a;
  u1 = 0.9; a1 = 0;
  do i = -50 to 100;
     a = rannor( 32565 );
     u = u1 + a - .8 * a1;
     if i > 0 then output;
     a1 = a;
     u1 = u;
     end;
run;
```

The following ARIMA procedure statements identify and estimate the model.

```
proc arima data=a;
  identify var=u nlag=15;
  run;
  identify var=u(1) nlag=15;
  run;
  estimate q=1 ;
  run;
quit;
```

The results of the first IDENTIFY statement are shown in Output 11.1.1. The output shows the behavior of the sample autocorrelation function when the process is nonstationary. Note that in this case the estimated autocorrelations are not very high, even at small lags. Nonstationarity is reflected in a pattern of significant autocorrelations that do not decline quickly with increasing lag, not in the size of the autocorrelations.

Output 11.1.1. Output from the First IDENTIFY Statement

```
                           Simulated IMA(1,1) Series

The ESTIMATE statement fits an ARIMA(0,1,1) model to the simulated data. Note that in this case the parameter estimates are reasonably close to the values used to generate the simulated data. ($\mu = 0,\ \hat{\mu} = .02.\ \ \theta_1 = .8,\ \hat{\theta}_1 = .79.\ \ \sigma^2 = 1,\ \hat{\sigma}^2 = .82.$)

The ESTIMATE statement results are shown in Output 11.1.3.

Example 11.2. Seasonal Model for the Airline Series

The airline passenger data, given as Series G in Box and Jenkins (1976), has been used in time series analysis literature as an example of a nonstationary seasonal time series. This example uses PROC ARIMA to fit the Airline model, ARIMA(0,1,1)$\times$(0,1,1)$_{12}$, to Box and Jenkins' "Series G."

The following statements read the data and log transform the series. The PROC GPLOT step plots the series, as shown in Output 11.2.1.

```
title1 'International Airline Passengers';
title2 '(Box and Jenkins Series-G)';
data seriesg;
   input x @@;
   xlog = log( x );
   date = intnx( 'month', '31dec1948'd, _n_ );
   format date monyy.;
   datalines;
112 118 132 129 121 135 148 148 136 119 104 118

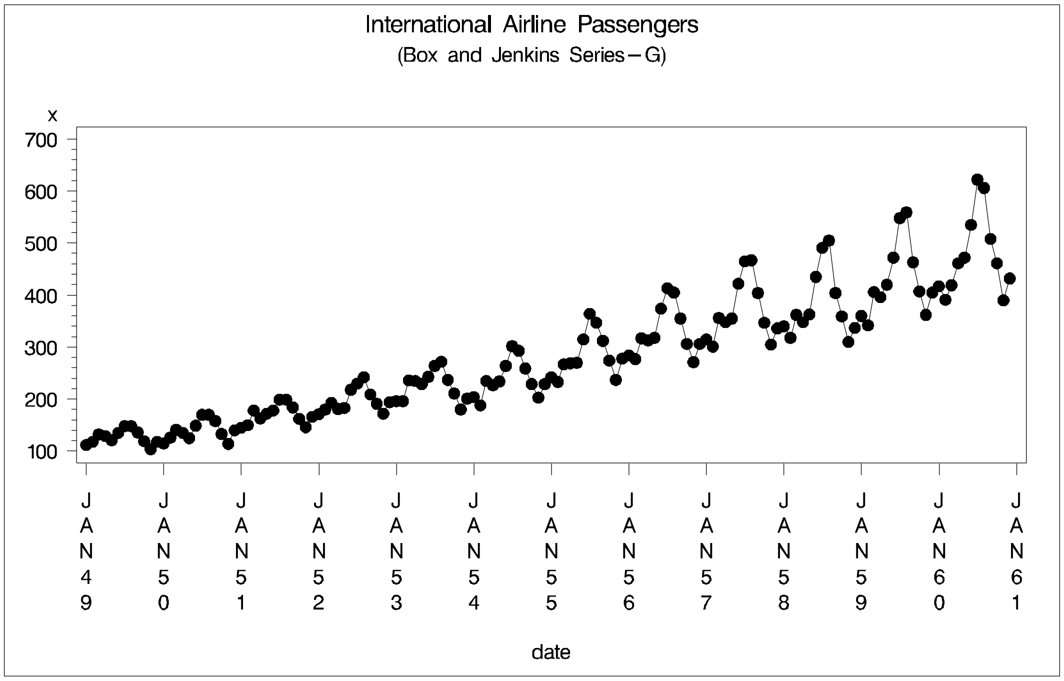
;

symbol1 i=join  v=dot;
proc gplot data=seriesg;
   plot x * date = 1 / haxis= '1jan49'd to '1jan61'd by year;
run;
```

Output 11.2.1. Plot of Data



The following PROC ARIMA step fits an ARIMA(0,1,1)×(0,1,1)$_{12}$ model without a mean term to the logarithms of the airline passengers series. The model is forecast, and the results stored in the data set B.

```
proc arima data=seriesg;
```

```
   identify var=xlog(1,12) nlag=15;
   run;
   estimate q=(1)(12) noconstant method=uls;
   run;
   forecast out=b lead=24 id=date interval=month noprint;
quit;
```

The printed output from the IDENTIFY statement is shown in Output 11.2.2. The autocorrelation plots shown are for the twice differenced series $(1 - B)(1 - B^{12})X$. Note that the autocorrelation functions have the pattern characteristic of a first-order moving average process combined with a seasonal moving average process with lag 12.

```

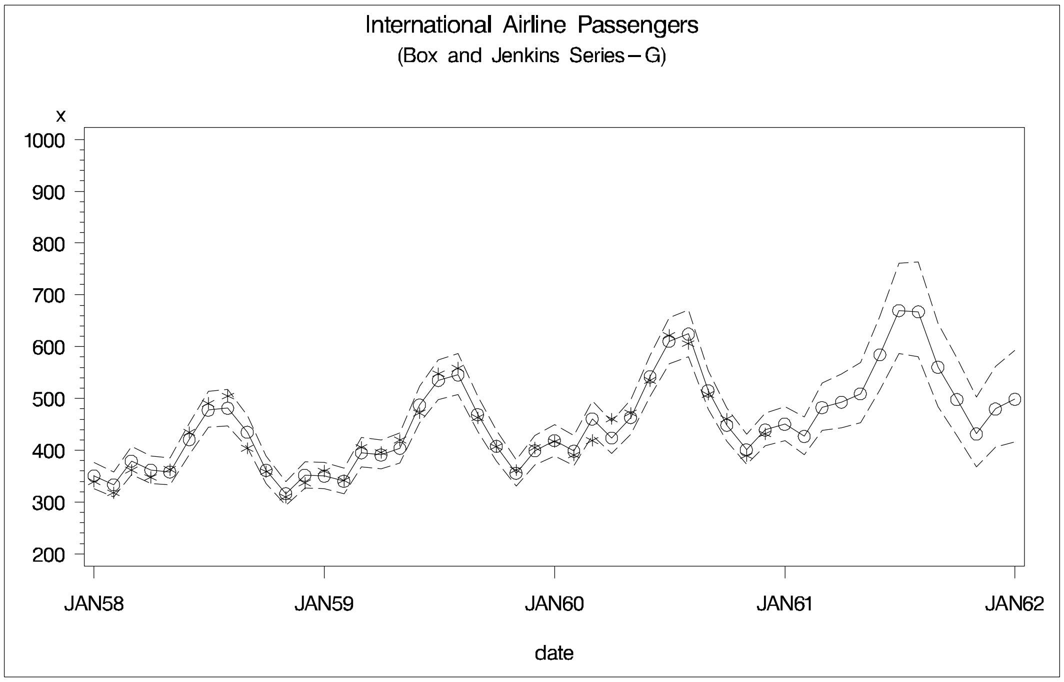
The following statements retransform the forecast values to get forecasts in the original scales. See the section "Forecasting Log Transformed Data" on page 429 for more information.

```
   data c;
      set b;
      x        = exp( xlog );
      forecast = exp( forecast + std*std/2 );
      l95      = exp( l95 );
      u95      = exp( u95 );
   run;
```

The forecasts and their confidence limits are plotted using the following PROC GPLOT step. The plot is shown in Output 11.2.4.

```
symbol1 i=none  v=star;
symbol2 i=join  v=circle;
symbol3 i=join  v=none l=3;
proc gplot data=c;
   where date >= '1jan58'd;
   plot x * date = 1 forecast * date = 2
        l95 * date = 3 u95 * date = 3 /
        overlay haxis= '1jan58'd to '1jan62'd by year;
run;
```

Output 11.2.4. Plot of the Forecast for the Original Series



Example 11.3. Model for Series J Data from Box and Jenkins

This example uses the Series J data from Box and Jenkins (1976). First the input series, *X*, is modeled with a univariate ARMA model. Next, the dependent series, *Y*, is cross correlated with the input series. Since a model has been fit to *X*, both *Y* and *X* are prewhitened by this model before the sample cross correlations are computed. Next, a transfer function model is fit with no structure on the noise term. The residuals from this model are identified by means of the PLOT option; then, the full model, transfer function and noise is fit to the data.

The following statements read Input Gas Rate and Output CO_2 from a gas furnace. (Data values are not shown. See "Series J" in Box and Jenkins (1976) for the values.)

```
title1 'Gas Furnace Data';
title2 '(Box and Jenkins, Series J)';
```

```
data seriesj;
   input x y @@;
   label x = 'Input Gas Rate'
         y = 'Output CO2';
datalines;
;
```

The following statements produce Output 11.3.1 through Output 11.3.5.

```
proc arima data=seriesj;

   /*--- Look at the input process -------------------*/
   identify var=x nlag=10;
   run;

   /*--- Fit a model for the input -------------------*/
   estimate p=3;
   run;

   /*--- Crosscorrelation of prewhitened series ------*/
   identify var=y crosscorr=(x) nlag=10;
   run;

   /*--- Fit transfer function - look at residuals ---*/
   estimate input=( 3 $ (1,2)/(1,2) x ) plot;
   run;

   /*--- Estimate full model ------------------------*/
   estimate p=2 input=( 3 $ (1,2)/(1) x );
   run;

quit;
```

The results of the first IDENTIFY statement for the input series X are shown in Output 11.3.1.

Output 11.3.1. IDENTIFY Statement Results for X

Example 11.4. An Intervention Model for Ozone Data

This example fits an intervention model to ozone data as suggested by Box and Tiao (1975). Notice that since the response variable, OZONE, is differenced, the innovation, X1, must also be differenced to generate a step function change in the response. If X1 had not been differenced, the change in the response caused by X1 would be a (seasonal) ramp and not a step function. Notice that the final model for the differenced data is a multiple regression model with a moving-average structure assumed for the residuals.

The model is fit by maximum likelihood. The seasonal moving-average parameter and its standard error are fairly sensitive to which method is chosen to fit the model, in agreement with the observations of Davidson (1981) and Ansley and Newbold (1980); thus, fitting the model by the unconditional or conditional least squares methods produce somewhat different estimates for these parameters.

Some missing values are appended to the end of the input data to generate additional values for the independent variables. Since the independent variables are not modeled, values for them must be available for any times at which predicted values are desired. In this case, predicted values are requested for 12 periods beyond the end of the data. Thus, values for X1, WINTER, and SUMMER must be given for 12 periods ahead.

The following statements read in the data and compute dummy variables for use as intervention inputs:

```
title1 'Intervention Data for Ozone Concentration';
title2 '(Box and Tiao, JASA 1975 P.70)';

data air;
   input ozone @@;
   label ozone  = 'Ozone Concentration'
         x1     = 'Intervention for post 1960 period'
         summer = 'Summer Months Intervention'
         winter = 'Winter Months Intervention';
   date = intnx( 'month', '31dec1954'd, _n_ );
   format date monyy.;
   month = month( date );
   year = year( date );
   x1 = year >= 1960;
   summer = ( 5 < month < 11 ) * ( year > 1965 );
   winter = ( year > 1965 ) - summer;
datalines;

Example 11.5. Using Diagnostics to Identify ARIMA models

Fitting ARIMA models is as much an art as it is a science. The ARIMA procedure has diagnostic options to help tentatively identify the orders of both stationary and nonstationary ARIMA processes.

Consider the Series A in Box et al. (1994), which consists of 197 concentration readings taken every two hours from a chemical process. Let Series A be a data set containing these readings in a variable named X. The following SAS statements use the SCAN option of the IDENTIFY statement to generate Output 11.5.1 and Output 11.5.2. See "The SCAN Method" for details of the SCAN method.

```
proc arima data=SeriesA;
   identify var=x scan;
run;
```

Output 11.5.1. Example of SCAN Tables

```
                SERIES A: Chemical Process Concentration Readings

                               The ARIMA Procedure

```

In Output 11.5.1, there is one (maximal) rectangular region in which all the elements are insignificant with 95% confidence. This region has a vertex at (1,1). Output 11.5.2 gives recommendations based on the significance level specified by the ALPHA=*siglevel* option.

Output 11.5.2. Example of SCAN Option Tentative Order Selection

```
                              The ARIMA Procedure

                                  ARMA(p+d,q)
                                   Tentative
                                     Order
                                   Selection
                                     Tests

                                  ----SCAN---
                                  p+d       q

                                    1       1

                            (5% Significance Level)
```

Another order identification diagnostic is the extended sample autocorrelation function or ESACF method. See "The ESACF Method" for details of the ESACF method.

The following statements generate Output 11.5.3 and Output 11.5.4.

```
proc arima data=SeriesA;
   identify var=x esacf;
run;
```

Output 11.5.3. Example of ESACF Tables

```

In Output 11.5.3, there are three right-triangular regions in which all elements are insignificant at the 5% level. The triangles have vertices (1,1), (3,1), and (4,1). Since the triangle at (1,1) covers more insignificant terms, it is recommended first. Similarly, the remaining recommendations are ordered by the number of insignificant terms contained in the triangle. Output 11.5.4 gives recommendations based on the significance level specified by the ALPHA=*siglevel* option.

Output 11.5.4. Example of ESACF Option Tentative Order Selection

```
                              The ARIMA Procedure

                                  ARMA(p+d,q)
                                   Tentative
                                     Order
                                   Selection
                                     Tests

                                  ---ESACF---
                                  p+d       q

                                    1       1
                                    3       1
                                    4       1

                            (5% Significance Level)
```

If you also specify the SCAN option in the same IDENTIFY statement, the two recommendations are printed side by side.

```
proc arima data=SeriesA;
   identify var=x scan esacf;
run;
```

Output 11.5.5. Example of SCAN and ESACF Option Combined

```
                              The ARIMA Procedure

                              ARMA(p+d,q) Tentative
                              Order Selection Tests

                             ---SCAN--    --ESACF--
                             p+d     q    p+d     q

                               1     1      1     1
                                            3     1
                                            4     1

                            (5% Significance Level)
```

From above, the autoregressive and moving average orders are tentatively identified by both SCAN and ESACF tables to be $(p + d, q)$=(1,1). Because both the SCAN and ESACF indicate a $p + d$ term of 1, a unit root test should be used to determine whether this autoregressive term is a unit root. Since a moving average term appears to be present, a large autoregressive term is appropriate for the Augmented Dickey-Fuller test for a unit root.

Submitting the following code generates Output 11.5.6.

```
proc arima data=SeriesA;
   identify var=x stationarity=(adf=(5,6,7,8));
run;
```

Output 11.5.6. Example of STATIONARITY Option Output

```

The preceding test results show that a unit root is very likely and that the series should be differenced. Based on this test and the previous results, an ARIMA(0,1,1) would be a good choice for a tentative model for Series A.

Using the recommendation that the series be differenced, the following statements generate Output 11.5.7.

```
proc arima data=SeriesA;
   identify var=x(1) minic;
run;
```

Output 11.5.7. Example of MINIC Table

```
                              The ARIMA Procedure

                          Minimum Information Criterion

         Lags      MA 0       MA 1       MA 2       MA 3       MA 4       MA 5

```

The error series is estimated using an AR(7) model, and the minimum of this MINIC table is $BIC(0, 1)$. This diagnostic confirms the previous result indicating that an ARIMA(0,1,1) is a tentative model for Series A.

If you also specify the SCAN or MINIC option in the same IDENTIFY statement, the BIC associated with the SCAN table and ESACF table recommendations are listed.

```
proc arima data=SeriesA;
   identify var=x(1) minic scan esacf;
run;
```

Example 11.6. Detection of Level Changes in the Nile River Data

This example is discussed in de Jong and Penzer (1998). The data consist of readings of the annual flow volume of the Nile River at Aswan from 1871 to 1970. These data have also been studied by Cobb (1978). These studies indicate that levels in the years 1877 and 1913 are strong candidates for additive outliers, and that there was a shift in the flow levels starting from the year 1899. This shift in 1899 is attributed partly to the weather changes and partly to the start of construction work for a new dam at Aswan.

```
data nile;
   input level @@;
   year = intnx( 'year', '1jan1871'd, _n_-1 );
   format year year4.;
   datalines;

```

You can start the modeling process with the ARIMA(0, 1, 1) model, an ARIMA model close to the Structural model suggested in de Jong and Penzer (1998), and examine the parameter estimates, the residual autocorrelations, and the outliers.

```
proc arima data=nile;
   identify var= level(1) noprint;
   estimate q = 1 noint method= ml plot;
   outlier maxnum= 5 id=year;
run;
```

A portion of the estimation and the outlier detection output is shown in Output 11.6.1.

Output 11.6.1. ARIMA(0, 1, 1) Model

```
                                  The ARIMA Procedure

                               Outlier Detection Summary

                           Maximum number searched           5
                           Number found                      5
                           Significance used              0.05

                                    Outlier Details
                                                                           Approx
                                                                   Chi-     Prob>
 Obs    Time ID         Type                      Estimate       Square     ChiSq

  29           1899    Shift                    -315.75346        13.13    0.0003
  43           1913    Additive                 -403.97105        11.83    0.0006
   7           1877    Additive                 -335.49351         7.69    0.0055
  94           1964    Additive                  305.03568         6.16    0.0131
  18           1888    Additive                 -287.81484         6.00    0.0143
```

Note that the first three outliers detected are indeed the ones discussed earlier. You can include the shock signatures corresponding to these three outliers in the Nile data set.

```
data nile;
   set nile;
      if year = '1jan1877'd then AO1877 = 1.0;
      else AO1877 = 0.0;
      if year = '1jan1913'd then AO1913 = 1.0;
      else AO1913 = 0.0;
      if year >= '1jan1899'd then LS1899 = 1.0;
      else LS1899 = 0.0;
run;
```

Now you can refine the earlier model by including these outliers. After examining the parameter estimates and residuals (not shown) of the ARIMA(0, 1, 1) model with these regressors, the following stationary MA1 model (with regressors) appears to fit the data well.

```
proc arima data=nile;
   identify var= level crosscorr= ( AO1877 AO1913 LS1899 ) noprint;
   estimate q = 1
   input= (AO1877 AO1913 LS1899) method= ml plot;
   outlier maxnum= 5 alpha= 0.01 id=year;
run;
```

The relevant outlier detection process output is shown in Output 11.6.2. No outliers, at significance level 0.01, were detected.

Output 11.6.2. MA1 Model with Outliers

```
                         The ARIMA Procedure

                      Outlier Detection Summary

                 Maximum number searched           5
                 Number found                      0
                 Significance used              0.01
```

Example 11.7. Iterative Outlier Detection

This example illustrates the iterative nature of the outlier detection process. This is done using a simple test example where an additive outlier at observation number 50 and a level shift at observation number 100 are artificially introduced in the International Airline Passenger data used in an earlier example (See Example 11.2). The following Data step shows the modifications introduced in the data set.

```
data airline;
   set sashelp.air;
   logair = log(air);
   if _n_ = 50 then logair = logair - 0.25;
   if _n_ >= 100 then logair = logair + 0.5;
run;
```

In Example 11.2 the Airline model, ARIMA$(0, 1, 1) \times (0, 1, 1)_{12}$, was seen to be a good fit to the unmodified log-transformed airline passenger series. The preliminary identification steps (not shown) again suggest the Airline model as a suitable initial model for the modified data.

```
proc arima data=airline;
   identify var=logair( 1, 12 )  noprint;
   estimate q = (1)(12) noint method= ml;
   outlier maxnum= 3 alpha= 0.01;
run;
```

A portion of the estimation and outlier detection output is shown in Output 11.7.1.

Output 11.7.1. Initial Model

```
                                The ARIMA Procedure

                             Outlier Detection Summary

                        Maximum number searched           3
                        Number found                      3
                        Significance used              0.01

                                  Outlier Details
                                                                  Approx
                                                          Chi-     Prob>
           Obs     Type                  Estimate       Square     ChiSq

           100     Shift                  0.49325       199.36    <.0001
            50     Additive              -0.27508       104.78    <.0001
           135     Additive              -0.10488        13.08    0.0003
```

Clearly the level shift at observation number 100 and the additive outlier at observation number 50 are the dominant outliers. Moreover, the corresponding regression coefficients seem to correctly estimate the size and sign of the change. You can augment the airline data with these two regressors.

```
   data airline;
      set airline;
      if _n_ = 50 then AO = 1;
      else AO = 0.0;
      if _n_ >= 100 then LS  = 1;
      else LS = 0.0;
   run;
```

You can now refine the previous model by including these regressors. Note that the differencing order of the dependent series is matched to the differencing orders of the outlier regressors to get the correct “effective” outlier signatures.

```
proc arima data=airline;
   identify var= logair(1, 12)
      crosscorr= ( AO(1, 12) LS(1, 12) ) noprint;
   estimate q = (1)(12) noint
      input= (AO LS) method= ml plot;
   outlier maxnum= 3 alpha= 0.01;
run;
```

The estimation and outlier detection results are shown in Output 11.7.2.

Output 11.7.2. Airline Model with Outliers

```
                              The ARIMA Procedure

                           Outlier Detection Summary

                      Maximum number searched          3
                      Number found                     3
                      Significance used             0.01

                                Outlier Details
                                                                    Approx
                                                           Chi-      Prob>
            Obs     Type                   Estimate      Square      ChiSq

            135     Additive               -0.10310       12.63     0.0004
             62     Additive               -0.08872       12.33     0.0004
             29     Additive                0.08686       11.66     0.0006
```

The output shows that a few outliers still remain to be accounted for and that the model could be refined further.

Example 11.8. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. The graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the ARIMA procedure, see the "ODS Graphics" section on page 443.

The following code shows how you can use the ODS GRAPHICS environment to get useful plots for the Airline Passenger example discussed previously in Example 11.2. Recall that when the ODS GRAPHICS environment is in effect, the printing options in the IDENTIFY, ESTIMATE, and FORECAST statements control the plotting behavior. In addition, the PLOT option must be on in the ESTIMATE statement in order to produce the residual correlation plots.

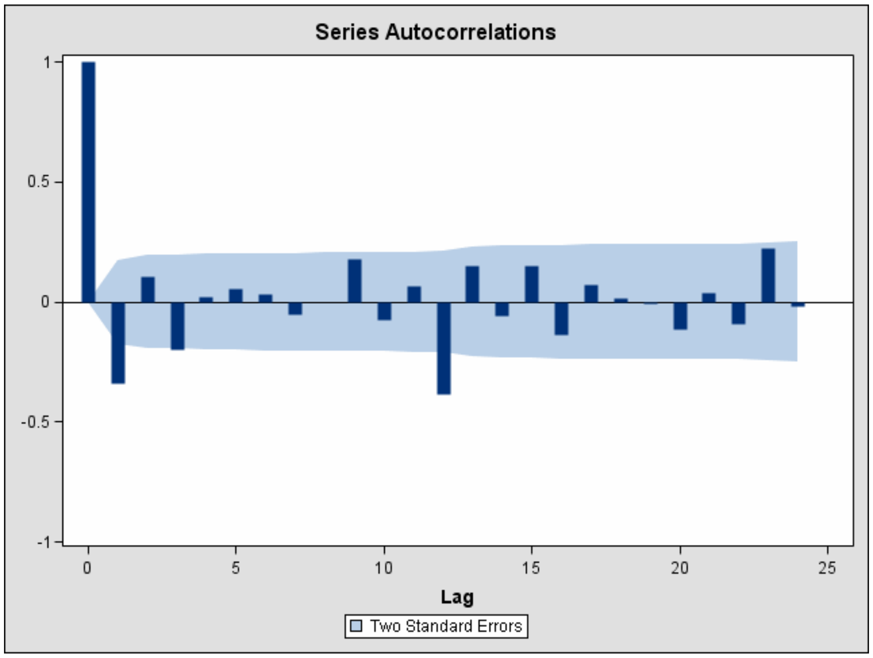
```
ods html;
ods graphics on;

proc arima data=seriesg;
   identify var=xlog(1 12);
   estimate q=(1)(12) noint plot;
   forecast printall id=date interval=month;
run;

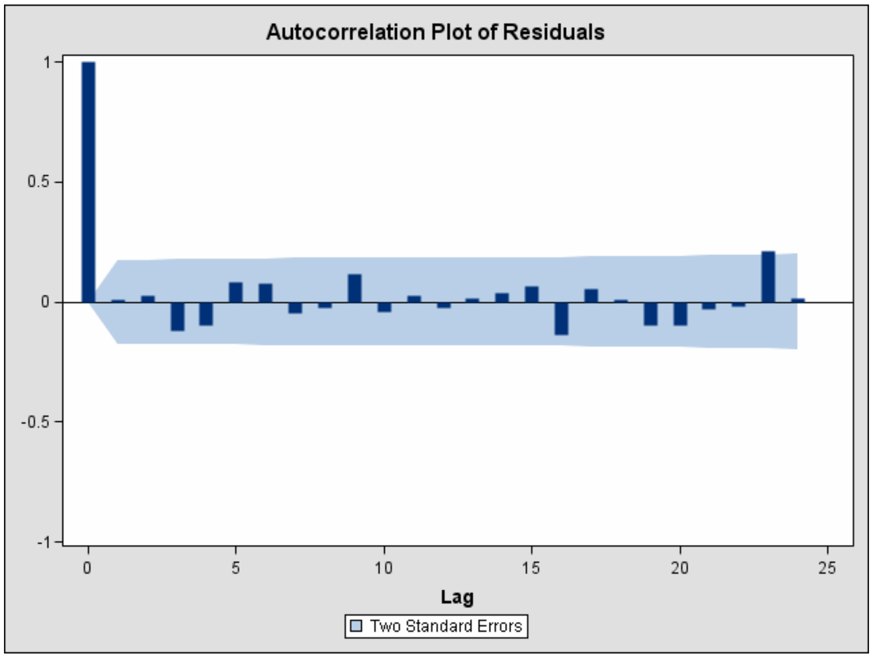
ods graphics off;
ods html close;
```

Output 11.8.1 through Output 11.8.4 show a selection of the plots created.

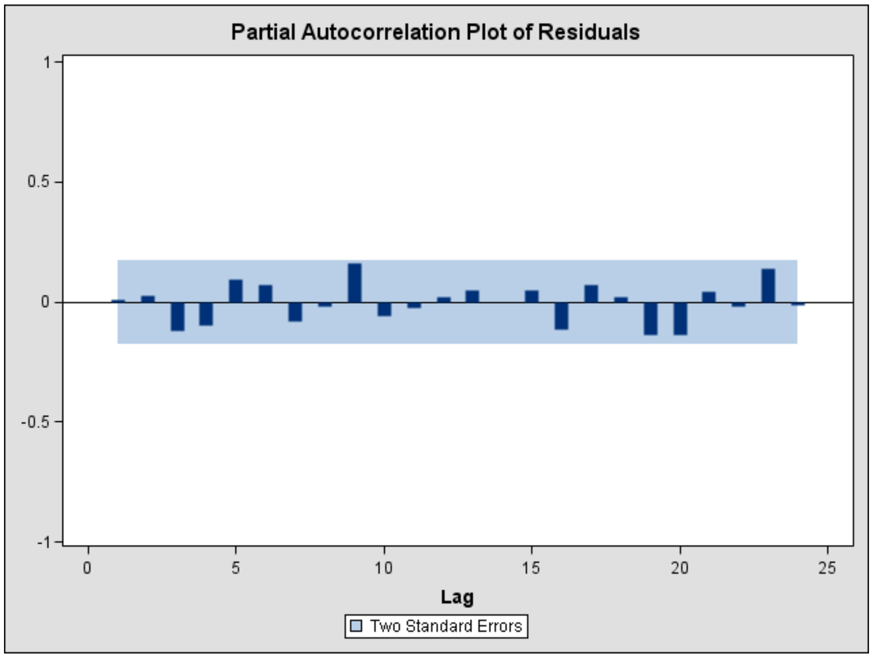
Output 11.8.1. ACF Plot for xlog(1 12) (Experimental)



Output 11.8.2. Residual Autocorrelations for xlog (Experimental)



Output 11.8.3. Residual Partial Autocorrelations for xlog (Experimental)



Output 11.8.4. Forecast Plot (Experimental)

Chapter 12
The AUTOREG Procedure

Overview

The AUTOREG procedure estimates and forecasts linear regression models for time series data when the errors are autocorrelated or heteroscedastic. The autoregressive error model is used to correct for autocorrelation, and the generalized autoregressive conditional heteroscedasticity (GARCH) model and its variants are used to model and correct for heteroscedasticity.

When time series data are used in regression analysis, often the error term is not independent through time. Instead, the errors are *serially correlated* or *autocorrelated*. If the error term is autocorrelated, the efficiency of ordinary least-squares (OLS) parameter estimates is adversely affected and standard error estimates are biased.

The autoregressive error model corrects for serial correlation. The AUTOREG procedure can fit autoregressive error models of any order and can fit subset autoregressive models. You can also specify stepwise autoregression to select the autoregressive error model automatically.

To diagnose autocorrelation, the AUTOREG procedure produces generalized Durbin-Watson (DW) statistics and their marginal probabilities. Exact *p*-values are reported for generalized DW tests to any specified order. For models with lagged dependent regressors, PROC AUTOREG performs the Durbin *t*-test and the Durbin *h*-test for first-order autocorrelation and reports their marginal significance levels.

Ordinary regression analysis assumes that the error variance is the same for all observations. When the error variance is not constant, the data are said to be *heteroscedastic*, and ordinary least-squares estimates are inefficient. Heteroscedasticity also affects the accuracy of forecast confidence limits. More efficient use of the data and more accurate prediction error estimates can be made by models that take the heteroscedasticity into account.

To test for heteroscedasticity, the AUTOREG procedure uses the portmanteau test statistics and the Engle Lagrange multiplier tests. Test statistics and significance *p*-values are reported for conditional heteroscedasticity at lags 1 through 12. The Bera-Jarque normality test statistic and its significance level are also reported to test for conditional nonnormality of residuals.

The family of GARCH models provides a means of estimating and correcting for the changing variability of the data. The GARCH process assumes that the errors, although uncorrelated, are not independent and models the conditional error variance as a function of the past realizations of the series.

The AUTOREG procedure supports the following variations of the GARCH models:

- generalized ARCH (GARCH)

- integrated GARCH (IGARCH)
- exponential GARCH (EGARCH)
- GARCH-in-mean (GARCH-M)

For GARCH-type models, the AUTOREG procedure produces the conditional prediction error variances as well as parameter and covariance estimates.

The AUTOREG procedure can also analyze models that combine autoregressive errors and GARCH-type heteroscedasticity. PROC AUTOREG can output predictions of the conditional mean and variance for models with autocorrelated disturbances and changing conditional error variances over time.

Four estimation methods are supported for the autoregressive error model:

- Yule-Walker
- iterated Yule-Walker
- unconditional least squares
- exact maximum likelihood

The maximum likelihood method is used for GARCH models and for mixed AR-GARCH models.

The AUTOREG procedure produces forecasts and forecast confidence limits when future values of the independent variables are included in the input data set. PROC AUTOREG is a useful tool for forecasting because it uses the time series part of the model as well as the systematic part in generating predicted values. The autoregressive error model takes into account recent departures from the trend in producing forecasts.

The AUTOREG procedure permits embedded missing values for the independent or dependent variables. The procedure should be used only for ordered and equally spaced time series data.

Experimental graphics are now available with the AUTOREG procedure. For more information, see the "ODS Graphics" section on page 560.

Getting Started

Regression with Autocorrelated Errors

Ordinary regression analysis is based on several statistical assumptions. One key assumption is that the errors are independent of each other. However, with time series data, the ordinary regression residuals usually are correlated over time. It is not desirable to use ordinary regression analysis for time series data since the assumptions on which the classical linear regression model is based will usually be violated.

Violation of the independent errors assumption has three important consequences for ordinary regression. First, statistical tests of the significance of the parameters and the confidence limits for the predicted values are not correct. Second, the estimates of the regression coefficients are not as efficient as they would be if the autocorrelation were taken into account. Third, since the ordinary regression residuals are not independent, they contain information that can be used to improve the prediction of future values.

The AUTOREG procedure solves this problem by augmenting the regression model with an autoregressive model for the random error, thereby accounting for the autocorrelation of the errors. Instead of the usual regression model, the following autoregressive error model is used:

$$y_t = \mathbf{x}_t'\beta + \nu_t$$
$$\nu_t = -\varphi_1\nu_{t-1} - \varphi_2\nu_{t-2} - \ldots - \varphi_m\nu_{t-m} + \epsilon_t$$
$$\epsilon_t \sim \mathrm{IN}(0, \sigma^2)$$

The notation $\epsilon_t \sim \mathrm{IN}(0, \sigma^2)$ indicates that each ϵ_t is normally and independently distributed with mean 0 and variance σ^2.

By simultaneously estimating the regression coefficients β and the autoregressive error model parameters φ_i, the AUTOREG procedure corrects the regression estimates for autocorrelation. Thus, this kind of regression analysis is often called *autoregressive error correction* or *serial correlation correction*.

Example of Autocorrelated Data

A simulated time series is used to introduce the AUTOREG procedure. The following statements generate a simulated time series Y with second-order autocorrelation:

```
data a;
   ul = 0; ull = 0;
   do time = -10 to 36;
      u = + 1.3 * ul - .5 * ull + 2*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
      ull = ul; ul = u;
      end;
run;
```

The series Y is a time trend plus a second-order autoregressive error. The model simulated is

$$y_t = 10 + .5t + \nu_t$$
$$\nu_t = 1.3\nu_{t-1} - .5\nu_{t-2} + \epsilon_t$$
$$\epsilon_t \sim \mathrm{IN}(0, 4)$$

The following statements plot the simulated time series Y. A linear regression trend line is shown for reference. (The regression line is produced by plotting the series a second time using the regression interpolation feature of the SYMBOL statement. Refer to *SAS/GRAPH Software: Reference, Version 6, First Edition, Volume 1* for further explanation.)

```
title \quotes{Autocorrelated Time Series};
proc gplot data=a;
```

```
      symbol1 v=dot i=join;
      symbol2 v=none i=r;
      plot y * time = 1 y * time = 2 / overlay;
   run;
```

The plot of series Y and the regression line are shown in Figure 12.1.

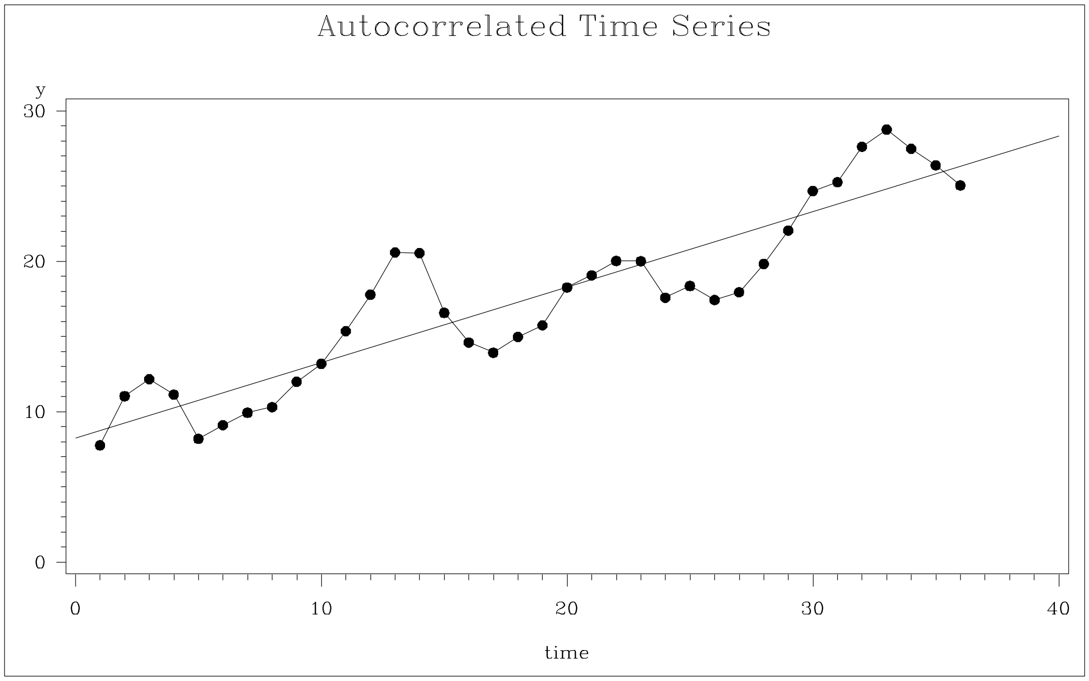

Figure 12.1. Autocorrelated Time Series

Note that when the series is above (or below) the OLS regression trend line, it tends to remain above (below) the trend for several periods. This pattern is an example of *positive autocorrelation*.

Time series regression usually involves independent variables other than a time-trend. However, the simple time-trend model is convenient for illustrating regression with autocorrelated errors, and the series Y shown in Figure 12.1 is used in the following introductory examples.

Ordinary Least-Squares Regression

To use the AUTOREG procedure, specify the input data set in the PROC AUTOREG statement and specify the regression model in a MODEL statement. Specify the model by first naming the dependent variable and then listing the regressors after an equal sign, as is done in other SAS regression procedures. The following statements regress Y on TIME using ordinary least squares:

```
   proc autoreg data=a;
      model y = time;
   run;
```

The AUTOREG procedure output is shown in Figure 12.2.

```

Figure 12.2. AUTOREG Results for OLS estimation

The output first shows statistics for the model residuals. The model root mean square error (Root MSE) is 2.51, and the model R^2 is .82. Notice that two R^2 statistics are shown, one for the regression model (Reg Rsq) and one for the full model (Total Rsq) that includes the autoregressive error process, if any. In this case, an autoregressive error model is not used, so the two R^2 statistics are the same.

Other statistics shown are the sum of square errors (SSE), mean square error (MSE), error degrees of freedom (DFE, the number of observations minus the number of parameters), the information criteria SBC and AIC, and the Durbin-Watson statistic. (Durbin-Watson statistics and SBC and AIC are discussed in the "Details" section later in this chapter.)

The output then shows a table of regression coefficients, with standard errors and *t*-tests. The estimated model is

$$y_t = 8.23 + .502t + \epsilon_t$$
$$Est.\ Var(\epsilon_t) = 6.32$$

The OLS parameter estimates are reasonably close to the true values, but the estimated error variance, 6.32, is much larger than the true value, 4.

Autoregressive Error Model

The following statements regress Y on TIME with the errors assumed to follow a second-order autoregressive process. The order of the autoregressive model is specified by the NLAG=2 option. The Yule-Walker estimation method is used by default. The example uses the METHOD=ML option to specify the exact maximum likelihood method instead.

```
proc autoreg data=a;
   model y = time / nlag=2 method=ml;
   run;
```

The first part of the results are shown in Figure 12.3. The initial OLS results are produced first, followed by estimates of the autocorrelations computed from the OLS residuals. The autocorrelations are also displayed graphically.

```

```

Figure 12.4. Maximum Likelihood Estimates of AR(2) Error Model

The diagnostic statistics and parameter estimates tables in Figure 12.4 have the same form as in the OLS output, but the values shown are for the autoregressive error model. The MSE for the autoregressive model is 1.71, which is much smaller than the true value of 4. In small samples, the autoregressive error model tends to underestimate σ^2, while the OLS MSE overestimates σ^2.

Notice that the total R^2 statistic computed from the autoregressive model residuals is .954, reflecting the improved fit from the use of past residuals to help predict the next Y value. The Reg Rsq value .728 is the R^2 statistic for a regression of transformed variables adjusted for the estimated autocorrelation. (This is not the R^2 for the estimated trend line. For details, see "R^2 Statistics and Other Measures of Fit" later in this chapter.)

The parameter estimates table shows the ML estimates of the regression coefficients and includes two additional rows for the estimates of the autoregressive parameters, labeled A(1) and A(2).

The estimated model is

$$y_t = 7.88 + .5096t + \nu_t$$

$$\nu_t = 1.25\nu_{t-1} - .628\nu_{t-2} + \epsilon_t$$

$$Est.\ Var(\epsilon_t) = 1.71$$

Note that the signs of the autoregressive parameters shown in this equation for ν_t are the reverse of the estimates shown in the AUTOREG procedure output. Figure 12.4 also shows the estimates of the regression coefficients with the standard errors recomputed on the assumption that the autoregressive parameter estimates equal the true values.

Predicted Values and Residuals

The AUTOREG procedure can produce two kinds of predicted values and corresponding residuals and confidence limits. The first kind of predicted value is obtained from only the structural part of the model, $\mathbf{x}_t'\mathbf{b}$. This is an estimate of the unconditional mean of the response variable at time *t*. For the time trend model, these predicted values trace the estimated trend. The second kind of predicted values include both the structural part of the model and the predicted values of the autoregressive error process. The full model (conditional) predictions are used to forecast future values.

Use the OUTPUT statement to store predicted values and residuals in a SAS data set and to output other values such as confidence limits and variance estimates. The P= option specifies an output variable to contain the full model predicted values. The PM= option names an output variable for the predicted mean. The R= and RM= options specify output variables for the corresponding residuals, computed as the actual value minus the predicted value.

The following statements store both kinds of predicted values in the output data set. (The printed output is the same as previously shown in Figure 12.3 and Figure 12.4.)

```
proc autoreg data=a;
   model y = time / nlag=2 method=ml;
   output out=p p=yhat pm=trendhat;
run;
```

The following statements plot the predicted values from the regression trend line and from the full model together with the actual values.

```
title \quotes{Predictions for Autocorrelation Model};
proc gplot data=p;
   symbol1 v=star i=none;
   symbol2 v=circle i=join;
   symbol3 v=none i=join;
   plot y * time = 1 yhat * time = 2
        trendhat * time = 3 / overlay ;
run;
```

The plot of predicted values is shown in Figure 12.5.

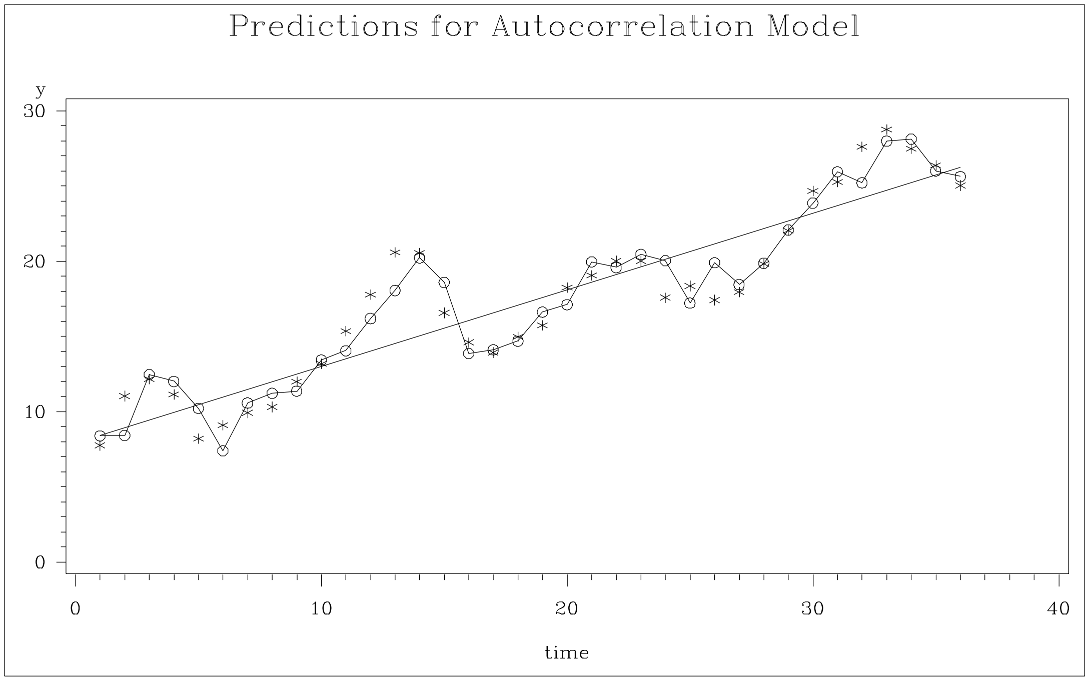

Figure 12.5. PROC AUTOREG Predictions

In Figure 12.5 the straight line is the autocorrelation corrected regression line, traced out by the structural predicted values TRENDHAT. The jagged line traces the full model prediction values. The actual values are marked by asterisks. This plot graphically illustrates the improvement in fit provided by the autoregressive error process for highly autocorrelated data.

Forecasting Autoregressive Error Models

To produce forecasts for future periods, include observations for the forecast periods in the input data set. The forecast observations must provide values for the independent variables and have missing values for the response variable.

For the time trend model, the only regressor is time. The following statements add observations for time periods 37 through 46 to the data set A to produce an augmented data set B:

```
data b;
   y = .;
   do time = 37 to 46; output; end;
run;
```

```
   data b; merge a b; by time; run;
```

To produce the forecast, use the augmented data set as input to PROC AUTOREG, and specify the appropriate options in the OUTPUT statement. The following statements produce forecasts for the time trend with autoregressive error model. The output data set includes all the variables in the input data set, the forecast values (YHAT), the predicted trend (YTREND), and the upper (UCL) and lower (LCL) 95% confidence limits.

```
   proc autoreg data=b;
      model y = time / nlag=2 method=ml;
      output out=p p=yhat pm=ytrend
                   lcl=lcl ucl=ucl;
   run;
```

The following statements plot the predicted values and confidence limits, and they also plot the trend line for reference. The actual observations are shown for periods 16 through 36, and a reference line is drawn at the start of the out-of-sample forecasts.

```
   title \quotes{Forecasting Autocorrelated Time Series};
   proc gplot data=p;
      plot y*time=1 yhat*time=2 ytrend*time=3
           lcl*time=3 ucl*time=3 /
           overlay href=36.5;
      where time >= 16;
      symbol1 v=star i=none;
      symbol2 v=circle i=join;
      symbol3 v=none i=join;
   run;
```

The plot is shown in Figure 12.6. Notice that the forecasts take into account the recent departures from the trend but converge back to the trend line for longer forecast horizons.

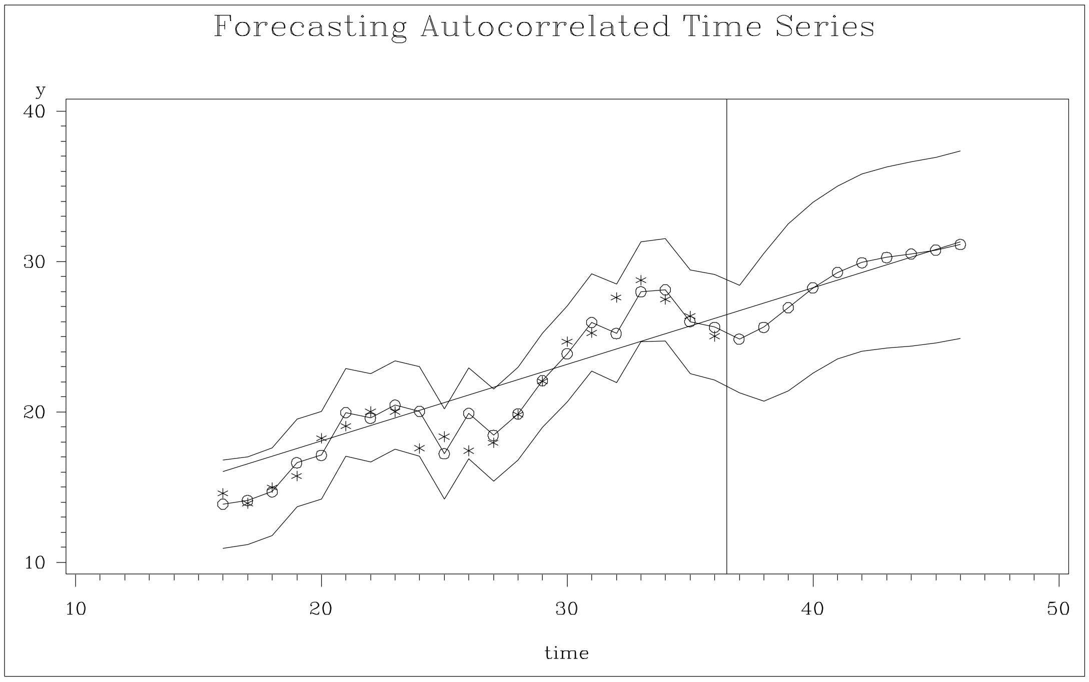

Figure 12.6. PROC AUTOREG Forecasts

Testing for Autocorrelation

In the preceding section, it is assumed that the order of the autoregressive process is known. In practice, you need to test for the presence of autocorrelation.

The Durbin-Watson test is a widely used method of testing for autocorrelation. The first-order Durbin-Watson statistic is printed by default. This statistic can be used to test for first-order autocorrelation. Use the DWPROB option to print the significance level (*p*-values) for the Durbin-Watson tests. (Since the Durbin-Watson *p*-values are computationally expensive, they are not reported by default.)

You can use the DW= option to request higher-order Durbin-Watson statistics. Since the ordinary Durbin-Watson statistic only tests for first-order autocorrelation, the Durbin-Watson statistics for higher-order autocorrelation are called *generalized Durbin-Watson statistics*.

The following statements perform the Durbin-Watson test for autocorrelation in the OLS residuals for orders 1 through 4. The DWPROB option prints the marginal significance levels (*p*-values) for the Durbin-Watson statistics.

```
proc autoreg data=a;
   model y = time / dw=4 dwprob;
run;
```

The AUTOREG procedure output is shown in Figure 12.7. In this case, the first-order Durbin-Watson test is highly significant, with $p < .0001$ for the hypothesis of no first-order autocorrelation. Thus, autocorrelation correction is needed.

```

Figure 12.7. Durbin-Watson Test Results for OLS Residuals

Using the Durbin-Watson test, you can decide if autocorrelation correction is needed. However, generalized Durbin-Watson tests should not be used to decide on the autoregressive order. The higher-order tests assume the absence of lower-order autocorrelation. If the ordinary Durbin-Watson test indicates no first-order autocorrelation, you can use the second-order test to check for second-order autocorrelation. Once autocorrelation is detected, further tests at higher orders are not appropriate. In Figure 12.7, since the first-order Durbin-Watson test is significant, the order 2, 3, and 4 tests can be ignored.

When using Durbin-Watson tests to check for autocorrelation, you should specify an order at least as large as the order of any potential seasonality, since seasonality produces autocorrelation at the seasonal lag. For example, for quarterly data use DW=4, and for monthly data use DW=12.

Lagged Dependent Variables

The Durbin-Watson tests are not valid when the lagged dependent variable is used in the regression model. In this case, the Durbin *h*-test or Durbin *t*-test can be used to test for first-order autocorrelation.

For the Durbin *h*-test, specify the name of the lagged dependent variable in the LAGDEP= option. For the Durbin *t*-test, specify the LAGDEP option without giving the name of the lagged dependent variable.

For example, the following statements add the variable YLAG to the data set A and regress Y on YLAG instead of TIME.

```
data b;
   set a;
   ylag = lag1( y );
run;

proc autoreg data=b;
   model y = ylag / lagdep=ylag;
run;
```

The results are shown in Figure 12.8. The Durbin *h* statistic 2.78 is significant with a *p*-value of .0027, indicating autocorrelation.

Stepwise Autoregression

Once you determine that autocorrelation correction is needed, you must select the order of the autoregressive error model to use. One way to select the order of the autoregressive error model is *stepwise autoregression*. The stepwise autoregression method initially fits a high-order model with many autoregressive lags and then sequentially removes autoregressive parameters until all remaining autoregressive parameters have significant *t*-tests.

To use stepwise autoregression, specify the BACKSTEP option, and specify a large order with the NLAG= option. The following statements show the stepwise feature, using an initial order of 5:

```
proc autoreg data=a;
   model y = time / method=ml nlag=5 backstep;
run;
```

The results are shown in Figure 12.9.

```

Figure 12.9. Stepwise Autoregression

The estimates of the autocorrelations are shown for 5 lags. The backward elimination of autoregressive terms report shows that the autoregressive parameters at lags 3, 4, and 5 were insignificant and eliminated, resulting in the second-order model shown previously in Figure 12.4. By default, retained autoregressive parameters must be significant at the .05 level, but you can control this with the SLSTAY= option. The remainder of the output from this example is the same as that in Figure 12.3 and Figure 12.4, and it is not repeated here.

The stepwise autoregressive process is performed using the Yule-Walker method. The maximum likelihood estimates are produced after the order of the model is determined from the significance tests of the preliminary Yule-Walker estimates.

When using stepwise autoregression, it is a good idea to specify an NLAG= option value larger than the order of any potential seasonality, since seasonality produces autocorrelation at the seasonal lag. For example, for monthly data use NLAG=13, and for quarterly data use NLAG=5.

Subset and Factored Models

In the previous example, the BACKSTEP option dropped lags 3, 4, and 5, leaving an order 2 model. However, in other cases a parameter at a longer lag may be kept while some smaller lags are dropped. For example, the stepwise autoregression method might drop lags 2, 3, and 5 but keep lags 1 and 4. This is called a *subset model*, since the number of estimated autoregressive parameters is smaller than the order of the model.

Subset models are common for seasonal data and often correspond to *factored* autoregressive models. A factored model is the product of simpler autoregressive models. For example, the best model for seasonal monthly data may be the combination of a first-order model for recent effects with a twelfth-order subset model for the seasonality, with a single parameter at lag 12. This results in an order 13 subset model with nonzero parameters at lags 1, 12, and 13. See Chapter 11, “The ARIMA Procedure,” for further discussion of subset and factored autoregressive models.

You can specify subset models with the NLAG= option. List the lags to include in the autoregressive model within parentheses. The following statements show an example of specifying the subset model resulting from the combination of a first-order process for recent effects with a fourth-order seasonal process:

```
proc autoreg data=a;
   model y = time / nlag=(1 4 5);
run;
```

The MODEL statement specifies the following fifth-order autoregressive error model:

$$y_t = a + bt + \nu_t$$

$$\nu_t = -\varphi_1\nu_{t-1} - \varphi_4\nu_{t-4} - \varphi_5\nu_{t-5} + \epsilon_t$$

Testing for Heteroscedasticity

One of the key assumptions of the ordinary regression model is that the errors have the same variance throughout the sample. This is also called the *homoscedasticity* model. If the error variance is not constant, the data are said to be *heteroscedastic*.

Since ordinary least-squares regression assumes constant error variance, heteroscedasticity causes the OLS estimates to be inefficient. Models that take into account the changing variance can make more efficient use of the data. Also, heteroscedasticity can make the OLS forecast error variance inaccurate since the predicted forecast variance is based on the average variance instead of the variability at the end of the series.

To illustrate heteroscedastic time series, the following statements re-create the simulated series Y. The variable Y has an error variance that changes from 1 to 4 in the middle part of the series. The length of the series is also extended 120 observations.

```
data a;
   ul = 0; ull = 0;
   do time = -10 to 120;
      s = 1 + (time >= 60 & time < 90);
      u = + 1.3 * ul - .5 * ull + s*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
      ull = ul; ul = u;
      end;
run;

title \quotes{Heteroscedastic Autocorrelated Time Series};
proc gplot data=a;
   symbol1 v=dot i=join;
   symbol2 v=none i=r;
   plot y * time = 1 y * time = 2 / overlay;
run;
```

The simulated series is plotted in Figure 12.10.

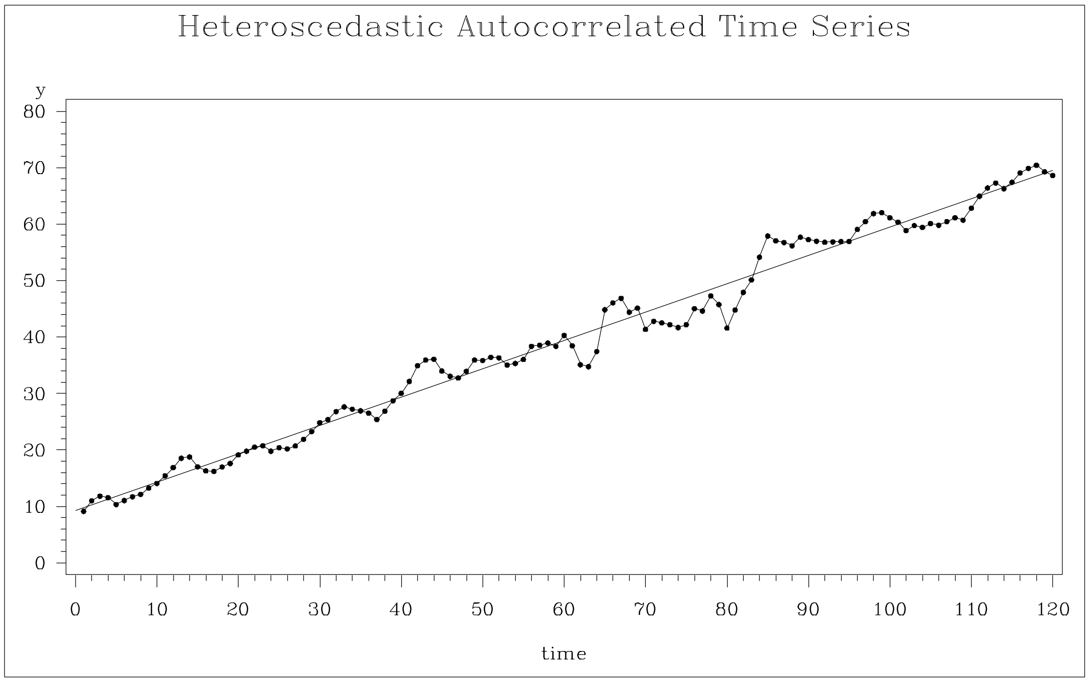

Figure 12.10. Heteroscedastic and Autocorrelated Series

To test for heteroscedasticity with PROC AUTOREG, specify the ARCHTEST option. The following statements regress Y on TIME and use the ARCHTEST option to test for heteroscedastic OLS residuals. The DWPROB option is also used to test for autocorrelation.

```
proc autoreg data=a;
   model y = time / nlag=2 archtest dwprob;
   output out=r r=yresid;
run;
```

The PROC AUTOREG output is shown in Figure 12.11. The Q statistics test for changes in variance across time using lag windows ranging from 1 through 12. (See "Heteroscedasticity and Normality Tests" for details.) The *p*-values for the test statistics are given in parentheses. These tests strongly indicate heteroscedasticity, with $p < 0.0001$ for all lag windows.

The Lagrange multiplier (LM) tests also indicate heteroscedasticity. These tests can also help determine the order of the ARCH model appropriate for modeling the heteroscedasticity, assuming that the changing variance follows an autoregressive conditional heteroscedasticity model.

Figure 12.11. Heteroscedasticity Tests

Heteroscedasticity and GARCH Models

There are several approaches to dealing with heteroscedasticity. If the error variance at different times is known, weighted regression is a good method. If, as is usually the case, the error variance is unknown and must be estimated from the data, you can model the changing error variance.

The *generalized autoregressive conditional heteroscedasticity* (GARCH) model is one approach to modeling time series with heteroscedastic errors. The GARCH regression model with autoregressive errors is

$$y_t = \mathbf{x}_t'\beta + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1\nu_{t-1} - \ldots - \varphi_m\nu_{t-m}$$

$$\epsilon_t = \sqrt{h_t}e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

$$e_t \sim \mathrm{IN}(0,1)$$

This model combines the *m*th-order autoregressive error model with the GARCH(*p*,*q*) variance model. It is denoted as the AR(*m*)-GARCH(*p*,*q*) regression model.

The Lagrange multiplier (LM) tests shown in Figure 12.11 can help determine the order of the ARCH model appropriate for the data. The tests are significant (p<.0001) through order 12, which indicates that a very high-order ARCH model is needed to model the heteroscedasticity.

The basic ARCH(*q*) model (*p*=0) is a *short memory* process in that only the most recent *q* squared residuals are used to estimate the changing variance. The GARCH model (*p*>0) allows *long memory* processes, which use all the past squared residuals to estimate the current variance. The LM tests in Figure 12.11 suggest the use of the GARCH model (*p*>0) instead of the ARCH model.

The GARCH(*p*,*q*) model is specified with the GARCH=(P=*p*,Q=*q*) option in the MODEL statement. The basic ARCH(*q*) model is the same as the GARCH(0,*q*) model and is specified with the GARCH=(Q=*q*) option.

The following statements fit an AR(2)-GARCH(1,1) model for the Y series regressed on TIME. The GARCH=(P=1,Q=1) option specifies the GARCH(1,1) conditional variance model. The NLAG=2 option specifies the AR(2) error process. Only the maximum likelihood method is supported for GARCH models; therefore, the METHOD= option is not needed. The CEV= option in the OUTPUT statement stores the estimated conditional error variance at each time period in the variable VHAT in an output data set named OUT.

```
proc autoreg data=a;
   model y = time / nlag=2 garch=(q=1,p=1) maxit=50;
   output out=out cev=vhat;
run;
```

The results for the GARCH model are shown in Figure 12.12. (The preliminary estimates are not shown.)

      ARCH1            1       0.2103       0.0847       2.48      0.0130
      GARCH1           1       0.7376       0.0960       7.68      <.0001
```

Figure 12.12. AR(2)-GARCH(1, 1) Model

The normality test is not significant ($p = 0.957$), which is consistent with the hypothesis that the residuals from the GARCH model, $\epsilon_t/\sqrt{h_t}$, are normally distributed. The parameter estimates table includes rows for the GARCH parameters. ARCH0 represents the estimate for the parameter ω, ARCH1 represents α_1, and GARCH1 represents γ_1.

The following statements transform the estimated conditional error variance series VHAT to the estimated standard deviation series SHAT. Then, they plot SHAT together with the true standard deviation S used to generate the simulated data.

```
data out;
   set out;
   shat = sqrt( vhat );
run;

title \quotes{Predicted and Actual Standard Deviations};
proc gplot data=out;
   plot s*time=1 shat*time=2 / overlay;
   symbol1 v=dot  i=none;
   symbol2 v=none i = join;
run;
```

The plot is shown in Figure 12.13.

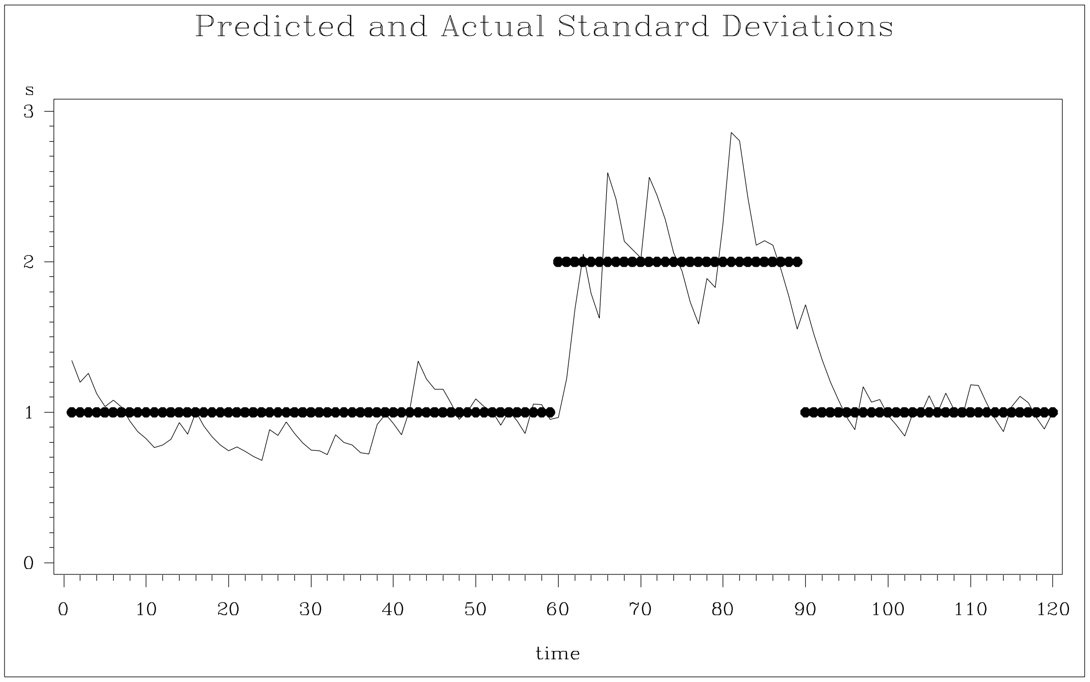

Figure 12.13. Estimated and Actual Error Standard Deviation Series

Note that in this example the form of heteroscedasticity used in generating the simulated series Y does not fit the GARCH model. The GARCH model assumes *conditional* heteroscedasticity, with homoscedastic unconditional error variance. That is, the GARCH model assumes that the changes in variance are a function of the realizations of preceding errors and that these changes represent temporary and random departures from a constant unconditional variance. The data generating process used to simulate series Y, contrary to the GARCH model, has exogenous unconditional heteroscedasticity that is independent of past errors.

Nonetheless, as shown in Figure 12.13, the GARCH model does a reasonably good job of approximating the error variance in this example, and some improvement in the efficiency of the estimator of the regression parameters can be expected.

The GARCH model may perform better in cases where theory suggests that the data generating process produces true autoregressive conditional heteroscedasticity. This is the case in some economic theories of asset returns, and GARCH-type models are often used for analysis of financial markets data.

Using the HETERO Statement with GARCH Models

The HETERO statement can be combined with the GARCH= option on the MODEL statement to include input variables in the GARCH conditional variance model. For example, the GARCH(1,1) variance model with two dummy input variables D1 and D2 is

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1} + \eta_1 D1_t + \eta_2 D2_t$$

The following statements estimate this GARCH model:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1);
   hetero d1 d2;
run;
```

The parameters for the variables D1 and D2 can be constrained using the COEF= option. For example, the constraints $\eta_1 = \eta_2 = 1$ are imposed by the following statements:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1);
   hetero d1 d2 / coef=unit;
run;
```

Limitations of GARCH and Heteroscedasticity Specifications

When you specify both the GARCH= option and the HETERO statement, the GARCH=(TYPE=EXP) option is not valid. The COVEST= option is not applicable to the EGARCH model.

EGARCH, IGARCH, GARCH-M Models

The AUTOREG procedure supports several variations of the generalized conditional heteroscedasticity model.

Using the TYPE= suboption of the GARCH= option, you can control the constraints placed on the estimated GARCH parameters. You can specify unconstrained, nonnegativity constrained (default), stationarity constrained, or integration constrained. The integration constraint produces the integrated GARCH or IGARCH model.

You can also use the TYPE= option to specify the exponential form of the GARCH model, called the EGARCH model. The MEAN suboption of the GARCH= option specifies the GARCH-in-mean or GARCH-M model.

The following statements illustrate the use of the TYPE= option to fit an AR(2)-EGARCH(1,1) model to the series Y. (Output is not shown.)

```
proc autoreg data=a;
   model y = time / nlag=2 garch=(p=1,q=1,type=exp);
run;
```

See the section “GARCH, IGARCH, EGARCH, and GARCH-M Models” later in this chapter for details.

Syntax

The AUTOREG procedure is controlled by the following statements:

PROC AUTOREG *options* **;**
BY *variables* **;**
MODEL *dependent = regressors / options* **;**
HETERO *variables / options* **;**
RESTRICT *equation , . . . , equation* **;**
TEST *equation , . . . , equation / option* **;**
OUTPUT *OUT = SAS data set options* **;**

At least one MODEL statement must be specified. One OUTPUT statement can follow each MODEL statement. One HETERO statement can follow each MODEL statement.

Functional Summary

The statements and options used with the AUTOREG procedure are summarized in the following table:

Description	Statement	Option
Data Set Options		
specify the input data set	AUTOREG	DATA=
write parameter estimates to an output data set	AUTOREG	OUTEST=
include covariances in the OUTEST= data set	AUTOREG	COVOUT
write predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify BY-group processing	BY	
Printing Control Options		
request all printing options	MODEL	ALL
print transformed coefficients	MODEL	COEF
print correlation matrix of the estimates	MODEL	CORRB
print covariance matrix of the estimates	MODEL	COVB
print DW statistics up to order j	MODEL	DW=j
print marginal probability of the generalized Durbin-Watson test statistics for large sample sizes	MODEL	DWPROB
print the *p*-values for the Durbin-Watson test be computed using a linearized approximation of the design matrix	MODEL	LDW

Description	Statement	Option
print inverse of Toeplitz matrix	MODEL	GINV
print the Godfrey LM serial correlation test	MODEL	GODFREY=
print details at each iteration step	MODEL	ITPRINT
print the Durbin *t* statistic	MODEL	LAGDEP
print the Durbin *h* statistic	MODEL	LAGDEP=
print the log likelihood value of the regression model	MODEL	LOGLIKL
print the Jarque-Bera normality test	MODEL	NORMAL
print tests for ARCH process	MODEL	ARCHTEST
print the Lagrange multiplier test	HETERO	TEST=LM
print the Chow test	MODEL	CHOW=
print the predictive Chow test	MODEL	PCHOW=
suppress printed output	MODEL	NOPRINT
print partial autocorrelations	MODEL	PARTIAL
print Ramsey's RESET test	MODEL	RESET
print tests for stationarity or unit roots	MODEL	STATIONARITY=(PHILLIPS=)
print tests of linear hypotheses	TEST	
specify the test statistics to use	TEST	TYPE=
prints the uncentered regression R^2	MODEL	URSQ
Model Estimation Options		
specify the order of autoregressive process	MODEL	NLAG=
center the dependent variable	MODEL	CENTER
suppress the intercept parameter	MODEL	NOINT
remove nonsignificant AR parameters	MODEL	BACKSTEP
specify significance level for BACKSTEP	MODEL	SLSTAY=
specify the convergence criterion	MODEL	CONVERGE=
specify the type of covariance matrix	MODEL	COVEST=
set the initial values of parameters used by the iterative optimization algorithm	MODEL	INITIAL=
specify iterative Yule-Walker method	MODEL	ITER
specify maximum number of iterations	MODEL	MAXITER=
specify the estimation method	MODEL	METHOD=
use only first sequence of nonmissing data	MODEL	NOMISS
specify the optimization technique	MODEL	OPTMETHOD=
imposes restrictions on the regression estimates	RESTRICT	
estimate and test heteroscedasticity models	HETERO	
GARCH Related Options		
specify order of GARCH process	MODEL	GARCH=(Q=,P=)
specify type of GARCH model	MODEL	GARCH=(. . .,TYPE=)
specify various forms of the GARCH-M model	MODEL	GARCH=(. . .,MEAN=)

Description	Statement	Option
suppress GARCH intercept parameter	MODEL	GARCH=(. . .,NOINT)
specify the trust region method	MODEL	GARCH=(. . .,TR)
estimate the GARCH model for the conditional *t*-distribution	MODEL	GARCH=(. . .) DIST=
estimates the start-up values for the conditional variance equation	MODEL	GARCH=(. . .,STARTUP=)
specify the functional form of the heteroscedasticity model	HETERO	LINK=
specify that the heteroscedasticity model does not include the unit term	HETERO	NOCONST
impose constraints on the estimated parameters the heteroscedasticity model	HETERO	COEF=
impose constraints on the estimated standard deviation of the heteroscedasticity model	HETERO	STD=
output conditional error variance	OUTPUT	CEV=
output conditional prediction error variance	OUTPUT	CPEV=
specify the flexible conditional variance form of the GARCH model	HETERO	
Output Control Options		
specify confidence limit size	OUTPUT	ALPHACLI=
specify confidence limit size for structural predicted values	OUTPUT	ALPHACLM=
specify the significance level for the upper and lower bounds of the CUSUM and CUSUMSQ statistics	OUTPUT	ALPHACSM=
specify the name of a variable to contain the values of the Theil's BLUS residuals	OUTPUT	BLUS=
output the value of the error variance σ_t^2	OUTPUT	CEV=
output transformed intercept variable	OUTPUT	CONSTANT=
specify the name of a variable to contain the CUSUM statistics	OUTPUT	CUSUM=
specify the name of a variable to contain the CUSUMSQ statistics	OUTPUT	CUSUMSQ=
specify the name of a variable to contain the upper confidence bound for the CUSUM statistic	OUTPUT	CUSUMUB=
specify the name of a variable to contain the lower confidence bound for the CUSUM statistic	OUTPUT	CUSUMLB=
specify the name of a variable to contain the upper confidence bound for the CUSUMSQ statistic	OUTPUT	CUSUMSQUB=

Description	Statement	Option
option specify the name of a variable to contain the lower confidence bound for the CUSUMSQ statistic	OUTPUT	CUSUMSQLB=
output lower confidence limit	OUTPUT	LCL=
output lower confidence limit for structural predicted values	OUTPUT	LCLM=
output predicted values	OUTPUT	P=
output predicted values of structural part	OUTPUT	PM=
output residuals	OUTPUT	R=
output residuals from structural predictions	OUTPUT	RM=
specify the name of a variable to contain the part of the predictive error variance (v_t)	OUTPUT	RECPEV=
specify the name of a variable to contain recursive residuals	OUTPUT	RECRES=
output transformed variables	OUTPUT	TRANSFORM=
output upper confidence limit	OUTPUT	UCL=
output upper confidence limit for structural predicted values	OUTPUT	UCLM=

PROC AUTOREG Statement

PROC AUTOREG *options ;*

The following options can be used in the PROC AUTOREG statement:

DATA= SAS-data-set

specifies the input SAS data set. If the DATA= option is not specified, PROC AUTOREG uses the most recently created SAS data set.

OUTEST= SAS-data-set

writes the parameter estimates to an output data set. See “OUTEST= Data Set” later in this chapter for information on the contents of this data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

In addition, any of the following MODEL statement options can be specified in the PROC AUTOREG statement, which is equivalent to specifying the option for every MODEL statement: ALL, ARCHTEST, BACKSTEP, CENTER, COEF, CONVERGE=, CORRB, COVB, DW=, DWPROB, GINV, ITER, ITPRINT, MAXITER=, METHOD=, NOINT, NOMISS, NOPRINT, and PARTIAL.

BY Statement

BY *variables;*

A BY statement can be used with PROC AUTOREG to obtain separate analyses on observations in groups defined by the BY variables.

MODEL Statement

MODEL *dependent = regressors / options ;*

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the MODEL statement, only the mean is fitted. (This is a way to obtain autocorrelations of a series.)

Models can be given labels of up to eight characters. Model labels are used in the printed output to identify the results for different models. The model label is specified as follows:

label **: MODEL** . . . **;**

The following options can be used in the MODEL statement after a slash (/).

CENTER
centers the dependent variable by subtracting its mean and suppresses the intercept parameter from the model. This option is only valid when the model does not have regressors (explanatory variables).

NOINT
suppresses the intercept parameter.

Autoregressive Error Options

NLAG= *number*
NLAG= *(number-list)*
specifies the order of the autoregressive error process or the subset of autoregressive error lags to be fitted. Note that NLAG=3 is the same as NLAG=(1 2 3). If the NLAG= option is not specified, PROC AUTOREG does not fit an autoregressive model.

GARCH Estimation Options

DIST= *value*
specifies the distribution assumed for the error term in GARCH-type esimation. If no GARCH= option is specified, the option is ignored. If EGARCH is specified, the distribution is always normal distribution. The values of the DIST= option are

T	specifies Student's *t* distribution.
NORMAL	specifies the standard normal distribution. The default is DIST=NORMAL.

GARCH= *(option-list)*

Specifies a GARCH-type conditional heteroscedasticity model. The GARCH= option in the MODEL statement specifies the family of ARCH models to be estimated. The GARCH(1,1) regression model is specified in the following statement:

```
   model y = x1 x2 / garch=(q=1,p=1);
```

When you want to estimate the subset of ARCH terms, for example, ARCH(1 3), you can write the SAS statement as follows:

```
   model y = x1 x2 / garch=(q=(1 3));
```

With the TYPE= option, you can specify various GARCH models. The IGARCH(2,1) model without trend in variance is estimated as follows:

```
   model y = / garch=(q=2,p=1,type=integ,noint);
```

The following options can be used in the GARCH=( ) option. The options are listed within parentheses and separated by commas.

Q= *number*
Q= *(number-list)*

specifies the order of the process or the subset of ARCH terms to be fitted.

P= *number*
P= *(number-list)*

specifies the order of the process or the subset of GARCH terms to be fitted. If only the P= option is specified, Q=1 is assumed.

TYPE= *value*

specifies the type of GARCH model. The values of the TYPE= option are

EXP	specifies the exponential GARCH or EGARCH model.
INTEGRATED	specifies the integrated GARCH or IGARCH model.
NELSON | NELSONCAO	specifies the Nelson-Cao inequality constraints.
NONNEG	specifies the GARCH model with nonnegativity constraints.
STATIONARY	constrains the sum of GARCH coefficients to be less than 1.

The default is TYPE=NELSON.

MEAN= *value*

specifies the functional form of the GARCH-M model. The values of the MEAN= option are

LINEAR specifies the linear function.

$$y_t = \mathbf{x}_t^{'}\beta + \delta h_t + \epsilon_t$$

LOG specifies the log function.

$$y_t = \mathbf{x}_t^{'}\beta + \delta \mathrm{ln h_t} + \mathrm{\epsilon_t}$$

SQRT specifies the square root function.

$$y_t = \mathbf{x}_t^{'}\beta + \delta\sqrt{h_t} + \epsilon_t$$

NOINT

suppresses the intercept parameter in the conditional variance model. This option is valid only with the TYPE=INTEG option.

STARTUP= MSE | ESTIMATE

STARTUP=ESTIMATE requests that the positive constant *c* for the start-up values of the GARCH conditional error variance process be estimated. By default or if STARTUP=MSE is specified, the value of the mean squared error is used as the default constant.

TR

uses the trust region method for GARCH estimation. This algorithm is numerically stable, though computation is expensive. The double quasi-Newton method is the default.

Printing Options

ALL

requests all printing options.

ARCHTEST

requests the Q and LM statistics testing for the absence of ARCH effects.

CHOW= *(obs*$_1$ *... obs*$_n$ *)*

The CHOW= option computes Chow tests to evaluate the stability of the regression coefficient. The Chow test is also called the analysis-of-variance test.

Each value obs_i listed on the CHOW= option specifies a break point of the sample. The sample is divided into parts at the specified break point, with observations before obs_i in the first part and obs_i and later observations in the second part, and the fits of the model in the two parts are compared to whether both parts of the sample are consistent with the same model.

The break points obs_i refer to observations within the time range of the dependent variable, ignoring missing values before the start of the dependent series. Thus, CHOW=20 specifies the twentieth observation after the first nonmissing observation for the dependent variable. For example, if the dependent variable Y contains 10 missing values before the first observation with a nonmissing Y value, then CHOW=20 actually refers to the 30th observation in the data set.

When you specify the break point, you should note the number of pre-sample missing values.

COEF
prints the transformation coefficients for the first p observations. These coefficients are formed from a scalar multiplied by the inverse of the Cholesky root of the Toeplitz matrix of autocovariances.

CORRB
prints the estimated correlations of the parameter estimates.

COVB
prints the estimated covariances of the parameter estimates.

COVEST= OP | HESSIAN | QML
The COVEST= option specifies the type of covariance matrix for the GARCH or heteroscedasticity model. When COVEST=OP is specified, the outer product matrix is used to compute the covariance matrix of the parameter estimates. The COVEST=HESSIAN option produces the covariance matrix using the Hessian matrix. The quasi-maximum likelihood estimates are computed with COVEST=QML. The default is COVEST=OP.

DW= *n*
prints Durbin-Watson statistics up to the order *n*. The default is DW=1. When the LAGDEP option is specified, the Durbin-Watson statistic is not printed unless the DW= option is explicitly specified.

DWPROB
The DWPROB option now produces *p*-values for the generalized Durbin-Watson test statistics for large sample sizes. Previously, the Durbin-Watson probabilities were calculated only for small sample sizes. The new method of calculating Durbin-Watson probabilities is based on the algorithm of Ansley, Kohn, and Shively (1992).

GINV
prints the inverse of the Toeplitz matrix of autocovariances for the Yule-Walker solution. See “Computational Methods” later in this chapter for details.

GODFREY
GODFREY= *r*
The GODFREY option produces Godfrey’s general Lagrange multiplier test against ARMA errors.

ITPRINT
prints the objective function and parameter estimates at each iteration. The objective function is the full log likelihood function for the maximum likelihood method, while the error sum of squares is produced as the objective function of unconditional least squares. For the ML method, the ITPRINT option prints the value of the full log likelihood function, not the concentrated likelihood.

LAGDEP
LAGDV

prints the Durbin *t* statistic, which is used to detect residual autocorrelation in the presence of lagged dependent variables. See "Generalized Durbin-Watson Tests" later in this chapter for details.

LAGDEP= *name*
LAGDV= *name*

prints the Durbin *h* statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. If the Durbin *h* statistic cannot be computed, the asymptotically equivalent *t* statistic is printed instead. See "Generalized Durbin-Watson Tests" for details.

When the regression model contains several lags of the dependent variable, specify the lagged dependent variable for the smallest lag in the LAGDEP= option, for example,

```
model y = x1 x2 ylag2 ylag3 / lagdep=ylag2;
```

LOGLIKL

The LOGLIKL option prints the log likelihood value of the regression model, assuming normally distributed errors.

NOPRINT

suppresses all printed output.

NORMAL

The NORMAL option specifies the Jarque-Bera's normality test statistic for regression residuals.

PARTIAL

prints partial autocorrelations.

PCHOW= *(obs*$_1$ *... obs*$_n$ *)*

The PCHOW= option computes the predictive Chow test. The form of the PCHOW= option is the same as the CHOW= option; see the discussion of the CHOW= option earlier in this chapter.

RESET

The RESET option produces Ramsey's RESET test statistics. The RESET option tests the null model

$$y_t = \mathbf{x}_t\beta + u_t$$

against the alternative

$$y_t = \mathbf{x}_t\beta + \sum_{j=2}^{p} \phi_j \hat{y}_t^j + u_t$$

where $\hat{y}_t$ is the predicted value from the OLS estimation of the null model. The RESET option produces three RESET test statistics for $p = 2$, 3, and 4.

STATIONARITY= *(PHILLIPS)*
STATIONARITY= *(PHILLIPS=(value ... value))*

The STATIONARITY= option specifies tests of stationarity or unit roots. The STATIONARITY= option provides Phillips-Perron tests.

The PHILLIPS or PHILLIPS= suboption of the STATIONARITY= option produces the Phillips-Perron unit root test when there are no regressors in the MODEL statement. When the model includes regressors, the PHILLIPS option produces the Phillips-Ouliaris cointegration test. The PHILLIPS option can be abbreviated as PP.

The PHILLIPS option performs the Phillips-Perron test for three null hypothesis cases: zero mean, single mean, and deterministic trend. For each case, the PHILLIPS option computes two test statistics, Z($\hat{\alpha}$) and $\mathrm{Z}(\mathrm{t}_{\hat{\alpha}})$, and reports their *p*-values. These test statistics have the same limiting distributions as the corresponding Dickey-Fuller tests.

The three types of the Phillips-Perron unit root test reported by the PHILLIPS option are as follows.

Zero Mean	computes the Phillips-Perron test statistic based on the zero mean autoregressive model $$y_t = \alpha y_{t-1} + u_t$$
Single Mean	computes the Phillips-Perron test statistic based on the autoregressive model with a constant term $$y_t = \mu + \alpha y_{t-1} + u_t$$
Trend	computes the Phillips-Perron test statistic based on the autoregressive model with constant and time trend terms $$y_t = \mu + \alpha y_{t-1} + \delta t + u_t$$

You can specify several truncation points l for weighted variance estimators using the PHILLIPS=($l_1 \ldots l_n$) specification. The statistic for each truncation point l is computed as

$$\sigma^2_{Tl} = \frac{1}{T}\sum_{i=1}^{T}\hat{u}_i^2 + \frac{2}{T}\sum_{s=1}^{l} w_{sl}\sum_{t=s+1}^{T}\hat{u}_t\hat{u}_{t-s}$$

where $w_{sl} = 1 - s/(l+1)$ and $\hat{u}_t$ are OLS residuals. If you specify the PHILLIPS option without specifying truncation points, the default truncation point is $\max(1, \sqrt{T}/5)$, where T is the number of observations.

The Phillips-Perron test can be used in general time series models since its limiting distribution is derived in the context of a class of weakly dependent and heterogeneously distributed data. The marginal probability for the Phillips-Perron test is computed assuming that error disturbances are normally distributed.

When there are regressors in the MODEL statement, the PHILLIPS option computes the cointegration test statistic using the least squares residuals. The normalized cointegrating vector is estimated using OLS regression. Therefore, the cointegrating vector estimates might vary with regressand (normalized element) unless the regression R-square is 1.

The marginal probabilities for cointegration testing are not produced. You can refer to Phillips and Ouliaris (1990) tables Ia-Ic for the $Z(\hat{\alpha})$ test and tables IIa-IIc for the $Z(t_{\hat{\alpha}})$ test. The standard residual-based cointegration test can be obtained using the NOINT option in the MODEL statement, while the demeaned test is computed by including the intercept term. To obtain the demeaned and detrended cointegration tests, you should include the time trend variable in the regressors. Refer to Phillips and Ouliaris (1990) or Hamilton (1994) for information about the Phillips-Ouliaris cointegration test.

URSQ

The URSQ option prints the uncentered regression R^2. The uncentered regression R^2 is useful to compute Lagrange multiplier test statistics, since most LM test statistics are computed as *T**URSQ, where *T* is the number of observations used in estimation.

Stepwise Selection Options

BACKSTEP

removes insignificant autoregressive parameters. The parameters are removed in order of least significance. This backward elimination is done only once on the Yule-Walker estimates computed after the initial ordinary least-squares estimation. The BACKSTEP option can be used with all estimation methods since the initial parameter values for other estimation methods are estimated using the Yule-Walker method.

SLSTAY= *value*

specifies the significance level criterion to be used by the BACKSTEP option. The default is SLSTAY=.05.

Estimation Control Options

CONVERGE= *value*

specifies the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this amount, then convergence is assumed. The default is CONVERGE=.001.

INITIAL= *(initial-values)*
START= *(initial-values)*

The INITIAL= option specifies initial values for some or all of the parameter estimates. The values specified are assigned to model parameters in the same order as the parameter estimates are printed in the AUTOREG procedure output. The order of values in the INITIAL= or START= option is: the intercept, the regressor coefficients, the autoregressive parameters, the ARCH parameters, the GARCH parameters, the inverted degrees of freedom for Student's *t* distribution, the start-up value for conditional variance, and the heteroscedasticity model parameters η specified by the HETERO statement.

The following is an example of specifying initial values for an AR(1)-GARCH(1,1) model with regressors X1 and X2:

```
model y = w x / nlag=1 garch=(p=1,q=1)
                initial=(1 1 1 .5 .8 .1 .6);
```

The model specified by this MODEL statement is

$$y_t = \beta_0 + \beta_1 w_t + \beta_2 x_t + \nu_t$$

$$\nu_t = \epsilon_t - \phi_1 \nu_{t-1}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1}$$

$$\epsilon_t \ \mathrm{N}(0, \sigma_{\mathrm{t}}^2)$$

The initial values for the regression parameters, INTERCEPT (β_0), X1 (β_1), and X2 (β_2), are specified as 1. The initial value of the AR(1) coefficient (ϕ_1) is specified as 0.5. The initial value of ARCH0 (ω) is 0.8, the initial value of ARCH1 (α_1) is 0.1, and the initial value of GARCH1 (γ_1) is 0.6.

When you use the RESTRICT statement, the initial values specified by the INITIAL= option should satisfy the restrictions specified for the parameter estimates. If they do not, the initial values you specify are adjusted to satisfy the restrictions.

LDW

The LDW option specifies that *p*-values for the Durbin-Watson test be computed using a linearized approximation of the design matrix when the model is nonlinear due to the presence of an autoregressive error process. (The Durbin-Watson tests of the OLS linear regression model residuals are not affected by the LDW option.) Refer to White (1992) for Durbin-Watson testing of nonlinear models.

MAXITER= *number*

sets the maximum number of iterations allowed. The default is MAXITER=50.

METHOD= *value*

requests the type of estimates to be computed. The values of the METHOD= option are

METHOD=ML	specifies maximum likelihood estimates
METHOD=ULS	specifies unconditional least-squares estimates
METHOD=YW	specifies Yule-Walker estimates
METHOD=ITYW	specifies iterative Yule-Walker estimates

If the GARCH= or LAGDEP option is specified, the default is METHOD=ML. Otherwise, the default is METHOD=YW.

NOMISS

requests the estimation to the first contiguous sequence of data with no missing values. Otherwise, all complete observations are used.

OPTMETHOD= QN | TR

The OPTMETHOD= option specifies the optimization technique when the GARCH or heteroscedasticity model is estimated. The OPTMETHOD=QN option specifies the quasi-Newton method. The OPTMETHOD=TR option specifies the trust region method. The default is OPTMETHOD=QN.

HETERO Statement

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance of the regression.

The syntax of the HETERO statement is

HETERO *variables / options* **;**

The heteroscedastic regression model supported by the HETERO statement is

$$y_t = \mathbf{x}_t\beta + \epsilon_t$$

$$\epsilon_t \ \mathrm{N}(0, \sigma_{\mathrm{t}}^2)$$

$$\sigma_t^2 = \sigma^2 h_t$$

$$h_t = l(\mathbf{z}_t^{'}\eta)$$

The HETERO statement specifies a model for the conditional variance h_t. The vector $\mathbf{z}_t$ is composed of the variables listed on the HETERO statement, η is a parameter vector, and $l(\cdot)$ is a link function that depends on the value of the LINK= option.

The keyword XBETA can be used in the *variables* list to refer to the model predicted value $\mathbf{x}_t^{'}\beta$. If XBETA is specified in the *variables* list, other variables in the HETERO statement will be ignored. In addition, XBETA cannot be specified in the GARCH process.

The errors ϵ_t are assumed to be uncorrelated– the heteroscedasticity models specified by the HETERO statement cannot be combined with an autoregressive model for the errors. Thus, the HETERO statement cannot be used if the NLAG= option is specified in the MODEL statement.

You can specify the following options in the HETERO statement:

LINK= *value*

The LINK= option specifies the functional form of the heteroscedasticity model. If you want to estimate the GARCH model whose conditional error variance contains exogenous variables, you do not need to specify the LINK= option. The default is LINK=EXP. Values of the LINK= option are

EXP specifies the exponential link function. The following model is estimated when you specify LINK=EXP:

$$h_t = \exp(\mathbf{z}_t^{'}\eta)$$

SQUARE specifies the square link function. The following model is estimated when you specify LINK=SQUARE:

$$h_t = (1 + \mathbf{z}_t^{'}\eta)^2$$

LINEAR specifies the linear function; that is, the HETERO statement variables predict the error variance linearly. The following model is estimated when you specify LINK=LINEAR:

$$h_t = (1 + \mathbf{z}_t^{'}\eta)$$

COEF= *value*

The COEF= option imposes constraints on the estimated parameters η of the heteroscedasticity model. The values of the COEF= option are

NONNEG specifies that the estimated heteroscedasticity parameters η must be nonnegative. When the HETERO statement is used in conjunction with the GARCH= option, the default is COEF=NONNEG.

UNIT	constrains all heteroscedasticity parameters η to equal 1.
ZERO	constrains all heteroscedasticity parameters η to equal 0.
UNREST	specifies unrestricted estimation of η. When the GARCH= option is not specified, the default is COEF=UNREST.

STD= *value*

The STD= option imposes constraints on the estimated standard deviation σ of the heteroscedasticity model. The values of the STD= option are

NONNEG	specifies that the estimated standard deviation parameter σ must be nonnegative.
UNIT	constrains the standard deviation parameter σ to equal 1.
UNREST	specifies unrestricted estimation of σ. This is the default.

TEST= *LM*

The TEST=LM option produces a Lagrange multiplier test for heteroscedasticity. The null hypothesis is homoscedasticity; the alternative hypothesis is heteroscedasticity of the form specified by the HETERO statement. The power of the test depends on the variables specified in the HETERO statement.

The test may give different results depending on the functional form specified by the LINK= option. However, in many cases the test does not depend on the LINK= option. The test is invariant to the form of h_t when $h_t(0) = 1$ and $h_t'(0) ne 0$. (The condition $h_t(0) = 1$ is satisfied except when the NOCONST option is specified with LINK=SQUARE or LINK=LINEAR.)

NOCONST

The NOCONST option specifies that the heteroscedasticity model does not include the unit term for the LINK=SQUARE and LINK=LINEAR options. For example, the following model is estimated when you specify the options LINK=SQUARE NOCONST:

$$h_t = (\mathbf{z}_t'\eta)^2$$

RESTRICT Statement

The RESTRICT statement provides constrained estimation.

RESTRICT *equation , ... , equation ;*

The RESTRICT statement places restrictions on the parameter estimates for covariates in the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Several restrictions can be specified in a single RESTRICT statement by separating the individual restrictions with commas.

Each restriction is written as a linear equation composed of constants and parameter names. Refer to model parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

The following is an example of a RESTRICT statement:

```
model y = a b c d;
restrict a+b=0, 2*d-c=0;
```

When restricting a linear combination of parameters to be 0, you can omit the equal sign. For example, the following RESTRICT statement is equivalent to the preceding example:

```
restrict a+b, 2*d-c;
```

The following RESTRICT statement constrains the parameters estimates for three regressors (X1, X2, and X3) to be equal:

```
restrict x1 = x2, x2 = x3;
```

The preceding restriction can be abbreviated as follows.

```
restrict x1 = x2 = x3;
```

Only simple linear combinations of parameters can be specified in RESTRICT statement expressions; complex expressions involving parentheses, division, functions, or complex products are not allowed.

TEST Statement

The AUTOREG procedure now supports a TEST statement for linear hypothesis tests.

TEST *equation* , ... , *equation* / *option* **;**

The TEST statement tests hypotheses about the covariates in the model estimated by the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Each test is written as a linear equation composed of constants and parameter names. Refer to parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

You can specify the following option in the TEST statement:

TYPE= *value*

The TYPE= option specifies the test statistics to use, *F* or Wald. TYPE=F produces an *F*-test. TYPE=WALD produces a Wald test. The default is TYPE=F.

The following example of a TEST statement tests the hypothesis that the coefficients of two regressors A and B are equal:

```
model y = a b c d;
test a = b;
```

To test separate null hypotheses, use separate TEST statements. To test a joint hypothesis, specify the component hypotheses on the same TEST statement, separated by commas.

For example, consider the following linear model:

$$y_t = \beta_0 + \beta_1 x1_t + \beta_2 x2_t + \epsilon_t$$

The following statements test the two hypotheses $H_0 : \beta_0 = 1$ and $H_0 : \beta_1 + \beta_2 = 0$:

```
model y = x1 x2;
test intercept = 1;
test x1 + x2 = 0;
```

The following statements test the joint hypothesis $H_0 : \beta_0 = 1$ and $\beta_1 + \beta_2 = 0$:

```
model y = x1 x2;
test intercept = 1, x1 + x2 = 0;
```

OUTPUT Statement

OUTPUT OUT= *SAS-data-set keyword = options . . .;*

The OUTPUT statement creates an output SAS data set as specified by the following options:

OUT= *SAS-data-set*

names the output SAS data set containing the predicted and transformed values. If the OUT= option is not specified, the new data set is named according to the DATA*n* convention.

ALPHACLI= *number*

sets the confidence limit size for the estimates of future values of the response time series. The ALPHACLI= value must be between 0 and 1. The resulting confidence interval has 1-*number* confidence. The default is ALPHACLI=.05, corresponding to a 95% confidence interval.

ALPHACLM= *number*

sets the confidence limit size for the estimates of the structural or regression part of the model. The ALPHACLI= value must be between 0 and 1. The resulting confidence interval has 1-*number* confidence. The default is ALPHACLM=.05, corresponding to a 95% confidence interval.

ALPHACSM= .01 | .05 | .10

The ALPHACSM= option specifies the significance level for the upper and lower bounds of the CUSUM and CUSUMSQ statistics output by the CUSUMLB=, CUSUMUB=, CUSUMSQLB=, and CUSUMSQUB= options. The significance level specified by the ALPHACSM= option can be .01, .05, or .10. Other values are not supported.

The following options are of the form *KEYWORD=name*, where *KEYWORD* specifies the statistic to include in the output data set and *name* gives the name of the variable in the OUT= data set containing the statistic.

BLUS= *variable*

The BLUS= option specifies the name of a variable to contain the values of the Theil's BLUS residuals. Refer to Theil (1971) for more information on BLUS residuals.

CEV= *variable*
HT= *variable*

The CEV= option writes to the output data set the value of the error variance σ_t^2 from the heteroscedasticity model specified by the HETERO statement or the value of the conditional error variance h_t by the GARCH= option in the MODEL statement.

CPEV= *variable*

writes the conditional prediction error variance to the output data set. The value of conditional prediction error variance is equal to that of the conditional error variance when there are no autoregressive parameters. For the exponential GARCH model, conditional prediction error variance cannot be calculated. See "Predicted Values" later in this chapter for details.

CONSTANT= *variable*

writes the transformed intercept to the output data set. The details of the transformation are described in "Computational Methods" later in this chapter.

CUSUM= *variable*

The CUSUM= option specifies the name of a variable to contain the CUSUM statistics.

CUSUMSQ= *variable*

The CUSUMSQ= option specifies the name of a variable to contain the CUSUMSQ statistics.

CUSUMUB= *variable*

The CUSUMUB= option specifies the name of a variable to contain the upper confidence bound for the CUSUM statistic.

CUSUMLB= *variable*
The CUSUMLB= option specifies the name of a variable to contain the lower confidence bound for the CUSUM statistic.

CUSUMSQUB= *variable*
The CUSUMSQUB= option specifies the name of a variable to contain the upper confidence bound for the CUSUMSQ statistic.

CUSUMSQLB= *variable*
The CUSUMSQLB= option specifies the name of a variable to contain the lower confidence bound for the CUSUMSQ statistic.

LCL= *name*
writes the lower confidence limit for the predicted value (specified in the PREDICTED= option) to the output data set. The size of the confidence interval is set by the ALPHACLI= option. When a GARCH model is estimated, the lower confidence limit is calculated assuming that the disturbances have homoscedastic conditional variance. See "Predicted Values" later in this chapter for details.

LCLM= *name*
writes the lower confidence limit for the structural predicted value (specified in the PREDICTEDM= option) to the output data set under the name given. The size of the confidence interval is set by the ALPHACLM= option.

PREDICTED= *name*
P= *name*
writes the predicted values to the output data set. These values are formed from both the structural and autoregressive parts of the model. See "Predicted Values" later in this chapter for details.

PREDICTEDM= *name*
PM= *name*
writes the structural predicted values to the output data set. These values are formed from only the structural part of the model. See "Predicted Values" later in this chapter for details.

RECPEV= *variable*
The RECPEV= option specifies the name of a variable to contain the part of the predictive error variance (v_t) that is used to compute the recursive residuals.

RECRES= *variable*
The RECRES= option specifies the name of a variable to contain recursive residuals. The recursive residuals are used to compute the CUSUM and CUSUMSQ statistics.

RESIDUAL= *name*
R= *name*
writes the residuals from the predicted values based on both the structural and time series parts of the model to the output data set.

RESIDUALM= *name*
RM= *name*
writes the residuals from the structural prediction to the output data set.

TRANSFORM= *variables*
transforms the specified variables from the input data set by the autoregressive model and writes the transformed variables to the output data set. The details of the transformation are described in “Computational Methods” later in this chapter. If you need to reproduce the data suitable for reestimation, you must also transform an intercept variable. To do this, transform a variable that is all 1s or use the CONSTANT= option.

UCL= *name*
writes the upper confidence limit for the predicted value (specified in the PREDICTED= option) to the output data set. The size of the confidence interval is set by the ALPHACLI= option. When the GARCH model is estimated, the upper confidence limit is calculated assuming that the disturbances have homoscedastic conditional variance. See “Predicted Values” later in this chapter for details.

UCLM= *name*
writes the upper confidence limit for the structural predicted value (specified in the PREDICTEDM= option) to the output data set. The size of the confidence interval is set by the ALPHACLM= option.

Details

Missing Values

PROC AUTOREG skips any missing values at the beginning of the data set. If the NOMISS option is specified, the first contiguous set of data with no missing values is used; otherwise, all data with nonmissing values for the independent and dependent variables are used. Note, however, that the observations containing missing values are still needed to maintain the correct spacing in the time series. PROC AUTOREG can generate predicted values when the dependent variable is missing.

Autoregressive Error Model

The regression model with autocorrelated disturbances is as follows:

$$y_t = \mathbf{x}_t'\beta + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1\nu_{t-1} - \ldots - \varphi_m\nu_{t-m}$$

$$\epsilon_t \; \mathrm{N}(0, \sigma^2)$$

In these equations, y_t are the dependent values, $\mathbf{x}_t$ is a column vector of regressor variables, β is a column vector of structural parameters, and ϵ_t is normally and independently distributed with a mean of 0 and a variance of σ^2. Note that in this parameterization, the signs of the autoregressive parameters are reversed from the parameterization documented in most of the literature.

PROC AUTOREG offers four estimation methods for the autoregressive error model. The default method, Yule-Walker (YW) estimation, is the fastest computationally. The Yule-Walker method used by PROC AUTOREG is described in Gallant and Goebel (1976). Harvey (1981) calls this method the *two-step full transform method*. The other methods are iterated YW, unconditional least squares (ULS), and maximum likelihood (ML). The ULS method is also referred to as nonlinear least squares (NLS) or exact least squares (ELS).

You can use all of the methods with data containing missing values, but you should use ML estimation if the missing values are plentiful. See the section "Alternative Autocorrelation Correction Methods" later in this chapter for further discussion of the advantages of different methods.

The Yule-Walker Method

Let φ represent the vector of autoregressive parameters

$$\varphi = (\varphi_1, \varphi_2, \ldots, \varphi_m)'$$

and let the variance matrix of the error vector $\nu = (\nu_1, \ldots, \nu_N)'$ be Σ

$$E(\nu\nu') = \mathbf{\Sigma} = \sigma^2\mathbf{V}$$

If the vector of autoregressive parameters φ is known, the matrix **V** can be computed from the autoregressive parameters. Σ is then $\sigma^2\mathbf{V}$. Given Σ, the efficient estimates of regression parameters β can be computed using generalized least squares (GLS). The GLS estimates then yield the unbiased estimate of the variance σ^2,

The Yule-Walker method alternates estimation of β using generalized least squares with estimation of φ using the Yule-Walker equations applied to the sample autocorrelation function. The YW method starts by forming the OLS estimate of β. Next, φ is estimated from the sample autocorrelation function of the OLS residuals using the Yule-Walker equations. Then **V** is estimated from the estimate of φ, and Σ is estimated from **V** and the OLS estimate of σ^2. The autocorrelation corrected estimates of the regression parameters β are then computed by GLS using the estimated Σ matrix. These are the Yule-Walker estimates.

If the ITER option is specified, the Yule-Walker residuals are used to form a new sample autocorrelation function, the new autocorrelation function is used to form a new estimate of φ and **V**, and the GLS estimates are recomputed using the new variance matrix. This alternation of estimates continues until either the maximum change in the $\widehat{\varphi}$ estimate between iterations is less than the value specified by the CONVERGE= option or the maximum number of allowed iterations is reached. This produces the Iterated Yule-Walker estimates. Iteration of the estimates may not yield much improvement.

The Yule-Walker equations, solved to obtain $\widehat{\varphi}$ and a preliminary estimate of σ^2, are

$$\mathbf{R}\hat{\varphi} = -\mathbf{r}$$

Here $\mathbf{r} = (r_1, \ldots, r_m)'$, where r_i is the lag *i* sample autocorrelation. The matrix **R** is the Toeplitz matrix whose *i,j*th element is $r_{|i-j|}$. If you specify a subset model, then only the rows and columns of **R** and **r** corresponding to the subset of lags specified are used.

If the BACKSTEP option is specified, for purposes of significance testing, the matrix $[\mathbf{R}\ \mathbf{r}]$ is treated as a sum-of-squares-and-crossproducts matrix arising from a simple regression with $N - k$ observations, where *k* is the number of estimated parameters.

The Unconditional Least Squares and Maximum Likelihood Methods

Define the transformed error, $\mathbf{e}$, as

$$\mathbf{e} = \mathbf{L}^{-1}\mathbf{n}$$

where $\mathbf{n} = \mathbf{y} - \mathbf{X}\beta$.

The unconditional sum of squares for the model, S, is

$$S = \mathbf{n}'\mathbf{V}^{-1}\mathbf{n} = \mathbf{e}'\mathbf{e}$$

The ULS estimates are computed by minimizing S with respect to the parameters β and φ_i.

The full log likelihood function for the autoregressive error model is

$$l = -\frac{N}{2}\ln(2\pi) - \frac{N}{2}\ln(\sigma^2) - \frac{1}{2}\ln(|\mathbf{V}|) - \frac{S}{2\sigma^2}$$

where $|\mathbf{V}|$ denotes determinant of $\mathbf{V}$. For the ML method, the likelihood function is maximized by minimizing an equivalent sum-of-squares function.

Maximizing *l* with respect to σ^2 (and concentrating σ^2 out of the likelihood) and dropping the constant term $-\frac{N}{2}\ln(2\pi) + 1 - \ln(N)$ produces the concentrated log likelihood function

$$l_c = -\frac{N}{2}\ln(S|\mathbf{V}|^{1/N})$$

Rewriting the variable term within the logarithm gives

$$S_{ml} = |\mathbf{L}|^{1/N}\mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$$

PROC AUTOREG computes the ML estimates by minimizing the objective function $S_{ml} = |\mathbf{L}|^{1/N}\mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$.

The maximum likelihood estimates may not exist for some data sets (Anderson and Mentz 1980). This is the case for very regular data sets, such as an exact linear trend.

Computational Methods

Sample Autocorrelation Function

The sample autocorrelation function is computed from the structural residuals or noise $\mathbf{n_t} = y_t - \mathbf{x}_t'\mathbf{b}$, where $\mathbf{b}$ is the current estimate of β. The sample autocorrelation function is the sum of all available lagged products of $\mathbf{n}_t$ of order *j* divided by $\ell + j$, where ℓ is the number of such products.

If there are no missing values, then $\ell + j = N$, the number of observations. In this case, the Toeplitz matrix of autocorrelations, **R**, is at least positive semidefinite. If there are missing values, these autocorrelation estimates of *r* can yield an **R** matrix that is not positive semidefinite. If such estimates occur, a warning message is printed, and the estimates are tapered by exponentially declining weights until **R** is positive definite.

Data Transformation and the Kalman Filter

The calculation of **V** from φ for the general AR(*m*) model is complicated, and the size of **V** depends on the number of observations. Instead of actually calculating **V** and performing GLS in the usual way, in practice a Kalman filter algorithm is used to transform the data and compute the GLS results through a recursive process.

In all of the estimation methods, the original data are transformed by the inverse of the Cholesky root of **V**. Let **L** denote the Cholesky root of **V**, that is $\mathbf{V} = \mathbf{LL}'$ with **L** lower triangular. For an AR(*m*) model, $\mathbf{L}^{-1}$ is a band diagonal matrix with *m* anomalous rows at the beginning and the autoregressive parameters along the remaining rows. Thus, if there are no missing values, after the first *m*-1 observations the data are transformed as

$$z_t = x_t + \hat{\varphi}_1 x_{t-1} + \ldots + \hat{\varphi}_m x_{t-m}$$

The transformation is carried out using a Kalman filter, and the lower triangular matrix **L** is never directly computed. The Kalman filter algorithm, as it applies here, is described in Harvey and Phillips (1979) and Jones (1980). Although **L** is not computed explicitly, for ease of presentation the remaining discussion is in terms of **L**. If there are missing values, then the submatrix of **L** consisting of the rows and columns with nonmissing values is used to generate the transformations.

Gauss-Newton Algorithms

The ULS and ML estimates employ a Gauss-Newton algorithm to minimize the sum of squares and maximize the log likelihood, respectively. The relevant optimization is performed simultaneously for both the regression and AR parameters. The OLS estimates of β and the Yule-Walker estimates of φ are used as starting values for these methods.

The Gauss-Newton algorithm requires the derivatives of **e** or $|\mathbf{L}|^{1/N}\mathbf{e}$ with respect to the parameters. The derivatives with respect to the parameter vector β are

$$\frac{\partial \mathbf{e}}{\partial \beta'} = -\mathbf{L}^{-1}\mathbf{X}$$

$$\frac{\partial|\mathbf{L}|^{1/N}\mathbf{e}}{\partial\beta'} = -|\mathbf{L}|^{1/N}\mathbf{L}^{-1}\mathbf{X}$$

These derivatives are computed by the transformation described previously. The derivatives with respect to φ are computed by differentiating the Kalman filter recurrences and the equations for the initial conditions.

Variance Estimates and Standard Errors

For the Yule-Walker method, the estimate of the error variance, s^2, is the error sum of squares from the last application of GLS, divided by the error degrees of freedom (number of observations *N* minus the number of free parameters).

The variance-covariance matrix for the components of **b** is taken as $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$ for the Yule-Walker method. For the ULS and ML methods, the variance-covariance matrix of the parameter estimates is computed as $s^2(\mathbf{J}'\mathbf{J})^{-1}$. For the ULS method, **J** is the matrix of derivatives of **e** with respect to the parameters. For the ML method, **J** is the matrix of derivatives of $|\mathbf{L}|^{1/N}\mathbf{e}$ divided by $|\mathbf{L}|^{1/N}$. The estimate of the variance-covariance matrix of **b** assuming that φ is known is $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$.

Park and Mitchell (1980) investigated the small sample performance of the standard error estimates obtained from some of these methods. In particular, simulating an AR(1) model for the noise term, they found that the standard errors calculated using GLS with an estimated autoregressive parameter underestimated the true standard errors. These estimates of standard errors are the ones calculated by PROC AUTOREG with the Yule-Walker method.

The estimates of the standard errors calculated with the ULS or ML methods take into account the joint estimation of the AR and the regression parameters and may give more accurate standard-error values than the YW method. At the same values of the autoregressive parameters, the ULS and ML standard errors will always be larger than those computed from Yule-Walker. However, simulations of the models used by Park and Mitchell suggest that the ULS and ML standard error estimates can also be underestimates. Caution is advised, especially when the estimated autocorrelation is high and the sample size is small.

High autocorrelation in the residuals is a symptom of lack of fit. An autoregressive error model should not be used as a nostrum for models that simply do not fit. It is often the case that time series variables tend to move as a random walk. This means that an AR(1) process with a parameter near one absorbs a great deal of the variation. See Example 12.3 later in this chapter, which fits a linear trend to a sine wave.

For ULS or ML estimation, the joint variance-covariance matrix of all the regression and autoregression parameters is computed. For the Yule-Walker method, the variance-covariance matrix is computed only for the regression parameters.

Lagged Dependent Variables

The Yule-Walker estimation method is not directly appropriate for estimating models that include lagged dependent variables among the regressors. Therefore, the maximum likelihood method is the default when the LAGDEP or LAGDEP= option is specified in the MODEL statement. However, when lagged dependent variables are used, the maximum likelihood estimator is not exact maximum likelihood but is conditional on the first few values of the dependent variable.

Alternative Autocorrelation Correction Methods

Autocorrelation correction in regression analysis has a long history, and various approaches have been suggested. Moreover, the same method may be referred to by different names.

Pioneering work in the field was done by Cochrane and Orcutt (1949). The *Cochrane-Orcutt method* refers to a more primitive version of the Yule-Walker method that drops the first observation. The Cochrane-Orcutt method is like the Yule-Walker method for first-order autoregression, except that the Yule-Walker method retains information from the first observation. The iterative Cochrane-Orcutt method is also in use.

The Yule-Walker method used by PROC AUTOREG is also known by other names. Harvey (1981) refers to the Yule-Walker method as the *two-step full transform method*. The Yule-Walker method can be considered as generalized least squares using the OLS residuals to estimate the covariances across observations, and Judge et al. (1985) use the term *estimated generalized least squares* (EGLS) for this method. For a first-order AR process, the Yule-Walker estimates are often termed *Prais-Winsten estimates* (Prais and Winsten 1954). There are variations to these methods that use different estimators of the autocorrelations or the autoregressive parameters.

The unconditional least squares (ULS) method, which minimizes the error sum of squares for all observations, is referred to as the nonlinear least squares (NLS) method by Spitzer (1979).

The *Hildreth-Lu* method (Hildreth and Lu 1960) uses nonlinear least squares to jointly estimate the parameters with an AR(1) model, but it omits the first transformed residual from the sum of squares. Thus, the Hildreth-Lu method is a more primitive version of the ULS method supported by PROC AUTOREG in the same way Cochrane-Orcutt is a more primitive version of Yule-Walker.

The maximum likelihood method is also widely cited in the literature. Although the maximum likelihood method is well defined, some early literature refers to estimators that are called maximum likelihood but are not full unconditional maximum likelihood estimates. The AUTOREG procedure produces full unconditional maximum likelihood estimates.

Harvey (1981) and Judge et al. (1985) summarize the literature on various estimators for the autoregressive error model. Although asymptotically efficient, the various methods have different small sample properties. Several Monte Carlo experiments have been conducted, although usually for the AR(1) model.

Harvey and McAvinchey (1978) found that for a one-variable model, when the independent variable is trending, methods similar to Cochrane-Orcutt are inefficient in estimating the structural parameter. This is not surprising since a pure trend model is well modeled by an autoregressive process with a parameter close to 1.

Harvey and McAvinchey (1978) also made the following conclusions:

- The Yule-Walker method appears to be about as efficient as the maximum likelihood method. Although Spitzer (1979) recommended ML and NLS, the Yule-Walker method (labeled Prais-Winsten) did as well or better in estimating the structural parameter in Spitzer's Monte Carlo study (table A2 in their article) when the autoregressive parameter was not too large. Maximum likelihood tends to do better when the autoregressive parameter is large.
- For small samples, it is important to use a full transformation (Yule-Walker) rather than the Cochrane-Orcutt method, which loses the first observation. This was also demonstrated by Maeshiro (1976), Chipman (1979), and Park and Mitchell (1980).
- For large samples (Harvey used 100), losing the first few observations does not make much difference.

GARCH, IGARCH, EGARCH, and GARCH-M Models

Consider the series y_t, which follows the GARCH process. The conditional distribution of the series Y for time *t* is written

$$y_t|\Psi_{t-1}{\sim}\mathrm{N}(0,\mathrm{h_t})$$

where Ψ_{t-1} denotes all available information at time $t-1$. The conditional variance h_t is

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i y_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

where

$$p{\geq}0, q > 0$$

$$\omega > 0, \alpha_i{\geq}0, \gamma_j{\geq}0$$

The GARCH(p,q) model reduces to the ARCH(q) process when $p = 0$. At least one of the ARCH parameters must be nonzero ($q > 0$). The GARCH regression model can be written

$$y_t = \mathbf{x}_t'\beta + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t}e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

where $e_t \sim \mathrm{IN}(0,1)$.

In addition, you can consider the model with disturbances following an autoregressive process and with the GARCH errors. The AR(m)-GARCH(p,q) regression model is denoted

$$y_t = \mathbf{x}_t' \beta + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1} - \ldots - \varphi_m \nu_{t-m}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

GARCH Estimation with Nelson-Cao Inequality Constraints

The GARCH(p,q) model is written in ARCH(∞) form as

$$\begin{aligned} h_t &= \left(1 - \sum_{j=1}^{p} \gamma_j B^j\right)^{-1} \left[\omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2\right] \\ &= \omega^* + \sum_{i=1}^{\infty} \phi_i \epsilon_{t-i}^2 \end{aligned}$$

where *B* is a backshift operator. Therefore, $h_t \geq 0$ if $\omega^* \geq 0$ and $\phi_i \geq 0, \forall i$. Assume that the roots of the following polynomial equation are inside the unit circle:

$$\sum_{j=0}^{p} -\gamma_j Z^{p-j}$$

where $\gamma_0 = -1$ and *Z* is a complex scalar. $\sum_{j=0}^{p} -\gamma_j Z^{p-j}$ and $\sum_{i=1}^{q} \alpha_i Z^{q-i}$, do not share common factors. Under these conditions, $|\omega^*| < \infty$, $|\phi_i| < \infty$, and these coefficients of the ARCH(∞) process are well defined.

Define $n = max(p,q)$. The coefficient ϕ_i is written

$$\phi_0 = \alpha_1$$

$$\begin{aligned}\phi_1 &= \gamma_1\phi_0 + \alpha_2 \\ \cdots & \\ \phi_{n-1} &= \gamma_1\phi_{n-2} + \gamma_2\phi_{n-3} + \cdots + \gamma_{n-1}\phi_0 + \alpha_n \\ \phi_k &= \gamma_1\phi_{k-1} + \gamma_2\phi_{k-2} + \cdots + \gamma_n\phi_{k-n} \quad \text{for}\ \ \text{k}\geq\text{n}\end{aligned}$$

where $\alpha_i = 0$ for $i > q$ and $\gamma_j = 0$ for $j > p$.

Nelson and Cao (1992) proposed the finite inequality constraints for GARCH(1,q) and GARCH(2,q) cases. However, it is not straightforward to derive the finite inequality constraints for the general GARCH(p,q) model.

For the GARCH(1,q) model, the nonlinear inequality constraints are

$$\begin{aligned}\omega &\geq 0 \\ \gamma_1 &\geq 0 \\ \phi_k &\geq 0 \quad \text{for}\ \ \text{k} = 0, 1, \cdots, \text{q} - 1\end{aligned}$$

For the GARCH(2,q) model, the nonlinear inequality constraints are

$$\begin{aligned}\Delta_i &\in R \quad \text{for}\ \ \text{i} = 1, 2 \\ \omega^* &\geq 0 \\ \Delta_1 &> 0 \\ \sum_{j=0}^{q-1} \Delta_1^{-j}\alpha_{j+1} &> 0 \\ \phi_k &\geq 0 \quad \text{for}\ \ \text{k} = 0, 1, \cdots, \text{q}\end{aligned}$$

where Δ_1 and Δ_2 are the roots of $(Z^2 - \gamma_1 Z - \gamma_2)$.

For the GARCH(p,q) model with $p > 2$, only max(q-1,p)+1 nonlinear inequality constraints ($\phi_k \geq 0$ for $k = 0$ to max$(q-1, p)$) are imposed, together with the in-sample positivity constraints of the conditional variance h_t.

Using the HETERO Statement with GARCH Models

The HETERO statement can be combined with the GARCH= option on the MODEL statement to include input variables in the GARCH conditional variance model. For example, the GARCH(1,1) variance model with two dummy input variables D1 and D2 is

$$\begin{aligned}\epsilon_t &= \sqrt{h_t}e_t \\ h_t &= \omega + \alpha_1\epsilon_{t-1}^2 + \gamma_1 h_{t-1} + \eta_1 DI_t + \eta_2 DI_t\end{aligned}$$

The following statements estimate this GARCH model:

```
   proc autoreg data=one;
      model y = x z / garch=(p=1,q=1);
      hetero d1 d2;
   run;
```

The parameters for the variables D1 and D2 can be constrained using the COEF= option. For example, the constraints $\eta_1 = \eta_2 = 1$ are imposed by the following statements:

```
   proc autoreg data=one;
      model y = x z / garch=(p=1,q=1);
      hetero d1 d2 / coef=unit;
   run;
```

Limitations of GARCH and Heteroscedasticity Specifications

When you specify both the GARCH= option and the HETERO statement, the GARCH=(TYPE=EXP) option is not valid. The COVEST= option is not applicable to the EGARCH model.

IGARCH and Stationary GARCH Model

The condition $\sum_{i=1}^{q}\alpha_i + \sum_{j=1}^{p}\gamma_j < 1$ implies that

the GARCH process is weakly stationary since the mean, variance, and autocovariance are finite and constant over time. However, this condition is not sufficient for weak stationarity in the presence of autocorrelation. For example, the stationarity condition for an AR(1)-GARCH(p,q) process is

$$\frac{1}{1-\varphi_1^2}\sum_{i=1}^{q}\alpha_i + \sum_{j=1}^{p}\gamma_j < 1$$

When the GARCH process is stationary, the unconditional variance of ϵ_t is computed as

$$\mathbf{V}(\epsilon_t) = \frac{\omega}{(1-\sum_{i=1}^{q}\alpha_i - \sum_{j=1}^{p}\gamma_j)}$$

where $\epsilon_t = \sqrt{h_t}e_t$ and h_t is the

GARCH(*p*,*q*) conditional variance.

Sometimes, the multistep forecasts of the variance do not approach the unconditional variance when the model is integrated in variance; that is, $\sum_{i=1}^{q}\alpha_i + \sum_{j=1}^{p}\gamma_j = 1$.

The unconditional variance for the IGARCH model does not exist. However, it is interesting that the IGARCH model can be strongly stationary even though it is not weakly stationary. Refer to Nelson (1990) for details.

EGARCH Model

The EGARCH model was proposed by Nelson (1991). Nelson and Cao (1992) argue that the nonnegativity constraints in the linear GARCH model are too restrictive. The GARCH model imposes the nonnegative constraints on the parameters, α_i and γ_j, while there are no restrictions on these parameters in the EGARCH model. In the EGARCH model, the conditional variance, h_t, is an asymmetric function of lagged disturbances ϵ_{t-i}:

$$\ln(h_t) = \omega + \sum_{i=1}^{q} \alpha_i g(z_{t-i}) + \sum_{j=1}^{p} \gamma_j \ln(h_{t-j})$$

where

$$g(z_t) = \theta z_t + \gamma[|z_t| - E|z_t|]$$

$$z_t = \epsilon_t / \sqrt{h_t}$$

The coefficient of the second term in $g(z_t)$ is set to be 1 (γ=1) in our formulation. Note that $E|z_t| = (2/\pi)^{1/2}$ if $z_t{\sim}\mathrm{N}(0,1)$. The properties of the EGARCH model are summarized as follows:

- The function $g(z_t)$ is linear in z_t with slope coefficient $\theta + 1$ if z_t is positive while $g(z_t)$ is linear in z_t with slope coefficient $\theta - 1$ if z_t is negative
- Suppose that $\theta = 0$. Large innovations increase the conditional variance if $|z_t| - E|z_t| > 0$ and decrease
- the conditional variance if $|z_t| - E|z_t| < 0$.
- Suppose that $\theta < 1$. The innovation in variance, $g(z_t)$, is positive if the innovations z_t are less than $(2/\pi)^{1/2}/(\theta - 1)$. Therefore, the negative innovations in returns, ϵ_t, cause the innovation to the conditional variance to be positive if θ is much less than 1.

GARCH-in-Mean

The GARCH-M model has the added regressor that is the conditional standard deviation:

$$y_t = \mathbf{x}_t'\beta + \delta\sqrt{h_t} + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t} e_t$$

where h_t follows the ARCH or GARCH process.

Maximum Likelihood Estimation

The family of GARCH models are estimated using the maximum likelihood method. The log-likelihood function is computed from the product of all conditional densities of the prediction errors.

When e_t is assumed to have a standard normal distribution ($e_t \sim \mathrm{N}(0,1)$), the likelihood function is given by

$$l = \sum_{t=1}^{N} \frac{1}{2} \left[-\ln(2\pi) - \ln(h_t) - \frac{\epsilon_t^2}{h_t} \right]$$

where $\epsilon_t = y_t - \mathbf{x}_t'\beta$ and h_t is the conditional variance. When the GARCH(p,q)-M model is estimated, $\epsilon_t = y_t - \mathbf{x}_t'\beta - \delta\sqrt{h_t}$. When there are no regressors, the residuals ϵ_t are denoted as y_t or $y_t - \delta\sqrt{h_t}$.

If e_t has the standardized Student's *t* distribution the log likelihood function for the conditional *t* distribution is

$$\ell = \sum_{t=1}^{N} \left[\log\left(\Gamma\left(\frac{\nu+1}{2}\right)\right) - \log\left(\Gamma\left(\frac{\nu}{2}\right)\right) - \frac{1}{2}\log((\nu-2)h_t) \right.$$
$$\left. -\frac{1}{2}(\nu+1)\log\left(1 + \frac{\epsilon_t^2}{h_t(\nu-2)}\right) \right]$$

where $\Gamma(\cdot)$ is the gamma function and ν is the degree of freedom ($\nu > 2$). Under the conditional *t* distribution, the additional parameter $1/\nu$ is estimated. The log likelihood function for the conditional *t* distribution converges to the log likelihood function of the conditional normal GARCH model as $1/\nu \rightarrow 0$.

The likelihood function is maximized via either the dual quasi-Newton or trust region algorithm. The default is the dual quasi-Newton algorithm. The starting values for the regression parameters β are obtained from the OLS estimates. When there are autoregressive parameters in the model, the initial values are obtained from the Yule-Walker estimates. The starting value 1.0^{-6} is used for the GARCH process parameters.

The variance-covariance matrix is computed using the Hessian matrix. The dual quasi-Newton method approximates the Hessian matrix while the quasi-Newton method gets an approximation of the inverse of Hessian. The trust region method uses the Hessian matrix obtained using numerical differentiation. When there are active constraints, that is, $\mathbf{q}(\theta) = \mathbf{0}$, the variance-covariance matrix is given by

$$\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1}[\mathbf{I} - \mathbf{Q}'(\mathbf{Q}\mathbf{H}^{-1}\mathbf{Q}')^{-1}\mathbf{Q}\mathbf{H}^{-1}]$$

where $\mathbf{H} = -\partial^2 l/\partial\theta\partial\theta'$ and $\mathbf{Q} = \partial\mathbf{q}(\theta)/\partial\theta'$. Therefore, the variance-covariance matrix without active constraints reduces to $\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1}$.

R^2 Statistics and Other Measures of Fit

This section discusses various goodness-of-fit statistics produced by the AUTOREG procedure.

Total R^2

The total R^2 statistic (Total Rsq) is computed as

$$R^2_{\mathrm{tot}} = 1 - \frac{SSE}{SST}$$

where *SST* is the sum of squares for the original response variable corrected for the mean and SSE is the final error sum of squares. The Total Rsq is a measure of how well the next value can be predicted using the structural part of the model and the past values of the residuals. If the NOINT option is specified, *SST* is the uncorrected sum of squares.

Regression R^2

The regression R^2 (Reg RSQ) is computed as

$$R^2_{\mathrm{reg}} = 1 - \frac{TSSE}{TSST}$$

where *TSST* is the total sum of squares of the transformed response variable corrected for the transformed intercept, and *TSSE* is the error sum of squares for this transformed regression problem. If the NOINT option is requested, no correction for the transformed intercept is made. The Reg RSQ is a measure of the fit of the structural part of the model after transforming for the autocorrelation and is the R^{2}for the transformed regression.

The regression R^2 and the total R^2 should be the same when there is no autocorrelation correction (OLS regression).

Calculation of Recursive Residuals and CUSUM Statistics

The recursive residuals w_t are computed as

$$w_t = \frac{e_t}{\sqrt{v_t}}$$

$$v_t = 1 + \mathbf{x}_t^{'} \left[\sum_{i=1}^{t-1} \mathbf{x}_i \mathbf{x}_i^{'} \right]^{-1} \mathbf{x}_t$$

Note that the forecast error variance of e_t is the scalar multiple of v_t such that $V(e_t) = \sigma^2 v_t$.

The CUSUM and CUSUMSQ statistics are computed using the preceding recursive residuals.

$$\mathrm{CUSUM_t} = \sum_{\mathrm{i=k+1}}^{\mathrm{t}} \frac{\mathrm{w_i}}{\sigma_{\mathrm{w}}}$$

$$\mathrm{CUSUMSQ_t} = \frac{\sum_{\mathrm{i=k+1}}^{\mathrm{t}} \mathrm{w_i^2}}{\sum_{\mathrm{i=k+1}}^{\mathrm{T}} \mathrm{w_i^2}}$$

where w_i are the recursive residuals,

$$\sigma_w = \sqrt{\frac{\sum_{i=k+1}^{T} (w_i - \hat{w})^2}{(T-k-1)}}$$

$$\hat{w} = \frac{1}{T-k} \sum_{i=k+1}^{T} w_i$$

and k is the number of regressors.

The CUSUM statistics can be used to test for misspecification of the model. The upper and lower critical values for CUSUM$_t$ are

$$\pm a \left[\sqrt{T-k} + 2 \frac{(t-k)}{(T-k)^{\frac{1}{2}}} \right]$$

where *a* = 1.143 for a significance level .01, 0.948 for .05, and 0.850 for .10. These critical values are output by the CUSUMLB= and CUSUMUB= options for the significance level specified by the ALPHACSM= option.

The upper and lower critical values of CUSUMSQ$_t$ are given by

$$\pm a + \frac{(t-k)}{T-k}$$

where the value of *a* is obtained from the table by Durbin (1969) if the $\frac{1}{2}(T-k)-1 \leq 60$. Edgerton and Wells (1994) provided the method of obtaining the value of *a* for large samples.

These critical values are output by the CUSUMSQLB= and CUSUMSQUB= options for the significance level specified by the ALPHACSM= option.

Information Criteria AIC and SBC

The Akaike's information criterion (AIC) and the Schwarz's Bayesian information criterion (SBC) are computed as follows:

$$\mathrm{AIC} = -2\mathrm{ln}(\mathrm{L}) + 2\mathrm{k}$$

$$\mathrm{SBC} = -2\mathrm{ln}(\mathrm{L}) + \mathrm{ln}(\mathrm{N})\mathrm{k}$$

In these formulas, *L* is the value of the likelihood function evaluated at the parameter estimates, *N* is the number of observations, and *k* is the number of estimated parameters. Refer to Judge et al. (1985) and Schwarz (1978) for additional details.

Generalized Durbin-Watson Tests

Consider the following linear regression model:

$$\mathbf{Y} = \mathbf{X}\beta + \nu$$

where **X** is an $N*k$ data matrix, β is a $k*1$ coefficient vector, and ν is a $N*1$ disturbance vector. The error term ν is assumed to be generated by the *j*th order autoregressive process ν_t=ϵ_t-$\varphi_j\nu_{t-j}$ where $|\varphi_j| < 1$, ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2. Usually, the Durbin-Watson statistic is used to test the null hypothesis $H_0 : \varphi_1 = 0$ against $H_1 : -\varphi_1 > 0$. Vinod (1973) generalized the Durbin-Watson statistic:

$$d_j = \frac{\sum_{t=j+1}^{N} (\hat{\nu}_t - \hat{\nu}_{t-j})^2}{\sum_{t=1}^{N} \hat{\nu}_t^2}$$

where $\hat{\nu}$ are OLS residuals. Using the matrix notation,

$$d_j = \frac{\mathbf{Y'MA'_jA_jMY}}{\mathbf{Y'MY}}$$

where $\mathbf{M} = \mathbf{I}_N - \mathbf{X}(\mathbf{X'X})^{-1}\mathbf{X'}$ and $\mathbf{A}_j$ is a $(N-j)\times N$ matrix:

$$\mathbf{A}_j = \begin{bmatrix} -1 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & -1 & 0 & \cdots & 0 & 1 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & -1 & 0 & \cdots & 0 & 1 \end{bmatrix}$$

and there are $j-1$ zeros between -1 and 1 in each row of matrix $\mathbf{A}_j$.

The QR factorization of the design matrix **X** yields a $N*N$ orthogonal matrix **Q**

$$\mathbf{X} = \mathbf{QR}$$

where R is a $N * k$ upper triangular matrix. There exists a $N * (N-k)$ submatrix of **Q** such that $\mathbf{Q}_1\mathbf{Q}_1' = \mathbf{M}$ and $\mathbf{Q}_1'\mathbf{Q}_1 = \mathbf{I}_{N-k}$. Consequently, the generalized Durbin-Watson statistic is stated as a ratio of two quadratic forms:

$$d_j = \frac{\sum_{l=1}^{n} \lambda_{jl}{\xi_l}^2}{\sum_{l=1}^{n} \xi_l^2}$$

where $\lambda_{j1} \ldots \lambda_{jn}$ are upper *n* eigenvalues of $\mathbf{M}\mathbf{A}_j^{'}\mathbf{A}_j\mathbf{M}$ and ξ_l is a standard normal variate, and $n = \min(N-k, N-j)$. These eigenvalues are obtained by a singular value decomposition of $\mathbf{Q}_1^{'}\mathbf{A}_j^{'}$ (Golub and Loan 1989; Savin and White 1978).

The marginal probability (or *p*-value) for d_j given c_0 is

$$\mathrm{Prob}(\frac{\sum_{\mathrm{l=1}}^{\mathrm{n}} \lambda_{\mathrm{jl}}\xi_{\mathrm{l}}^2}{\sum_{\mathrm{l=1}}^{\mathrm{n}} \xi_{\mathrm{l}}^2} < \mathrm{c_0}) = \mathrm{Prob}(\mathrm{q_j} < 0)$$

where

$$q_j = \sum_{l=1}^{n} (\lambda_{jl} - c_0)\xi_l^2$$

When the null hypothesis $H_0 : \varphi_j = 0$ holds, the quadratic form q_j has the characteristic function

$$\phi_j(t) = \prod_{l=1}^{n} (1 - 2(\lambda_{jl} - c_0)it)^{-1/2}$$

The distribution function is uniquely determined by this characteristic function:

$$F(x) = \frac{1}{2} + \frac{1}{2\pi} \int_0^\infty \frac{e^{itx}\phi_j(-t) - e^{-itx}\phi_j(t)}{it} dt$$

For example, to test $H_0 : \varphi_4 = 0$ given $\varphi_1 = \varphi_2 = \varphi_3 = 0$ against $H_1 : -\varphi_4 > 0$, the marginal probability (*p*-value) can be used:

$$F(0) = \frac{1}{2} + \frac{1}{2\pi} \int_0^\infty \frac{(\phi_4(-t) - \phi_4(t))}{it} dt$$

where

$$\phi_4(t) = \prod_{l=1}^{n} (1 - 2(\lambda_{4l} - \hat{d}_4)it)^{-1/2}$$

and $\hat{d}_4$ is the calculated value of the fourth-order Durbin-Watson statistic.

In the Durbin-Watson test, the marginal probability indicates positive autocorrelation ($-\varphi_j > 0$) if it is less than the level of significance (α), while you can conclude that a negative autocorrelation ($-\varphi_j < 0$) exists if the marginal probability based on the computed Durbin-Watson statistic is greater than 1-α. Wallis (1972) presented tables for bounds tests of fourth-order autocorrelation and Vinod (1973) has given tables for a five percent significance level for orders two to four. Using the AUTOREG procedure, you can calculate the exact *p*-values for the general order of Durbin-Watson test statistics. Tests for the absence of autocorrelation of order *p* can be performed sequentially; at the *j*th step, test $H_0 : \varphi_j = 0$ given $\varphi_1 = \ldots = \varphi_{j-1} = 0$ against $\varphi_j \neq 0$. However, the size of the sequential test is not known.

The Durbin-Watson statistic is computed from the OLS residuals, while that of the autoregressive error model uses residuals that are the difference between the predicted values and the actual values. When you use the Durbin-Watson test from the residuals of the autoregressive error model, you must be aware that this test is only an approximation. See “Regression with Autoregressive Errors” earlier in this chapter. If there are missing values, the Durbin-Watson statistic is computed using all the nonmissing values and ignoring the gaps caused by missing residuals. This does not affect the significance level of the resulting test, although the power of the test against certain alternatives may be adversely affected. Savin and White (1978) have examined the use of the Durbin-Watson statistic with missing values.

Enhanced Durbin-Watson Probability Computation

The Durbin-Watson probability calculations have been enhanced to compute the p-value of the generalized Durbin-Watson statistic for large sample sizes. Previously, the Durbin-Watson probabilities were only calculated for small sample sizes.

Consider the following linear regression model:

$$\mathbf{Y} = \mathbf{X}\beta + \mathbf{u}$$

$$u_t + \varphi_j u_{t-j} = \epsilon_t, \qquad t = 1, \ldots, N$$

where $\mathbf{X}$ is an $N \times k$ data matrix, β is a $k \times 1$ coefficient vector, $\mathbf{u}$ is a $N \times 1$ disturbance vector, ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2.

The generalized Durbin-Watson statistic is written as

$$\mathrm{DW}_j = \frac{\hat{\mathbf{u}}'\mathbf{A}_j'\mathbf{A}_j\hat{\mathbf{u}}}{\hat{\mathbf{u}}'\hat{\mathbf{u}}}$$

where $\hat{\mathbf{u}}$ is a vector of OLS residuals and $\mathbf{A}_j$ is a $(T-j)\times T$ matrix. The generalized Durbin-Watson statistic DW$_j$ can be rewritten as

$$\mathrm{DW}_j = \frac{\mathbf{Y}'\mathbf{M}\mathbf{A}_j'\mathbf{A}_j\mathbf{M}\mathbf{Y}}{\mathbf{Y}'\mathbf{M}\mathbf{Y}} = \frac{\eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1)\eta}{\eta'\eta}$$

where $\mathbf{Q}_1'\mathbf{Q}_1 = \mathbf{I}_{T-k},\ \mathbf{Q}_1'\mathbf{X} = 0$, and $\eta = \mathbf{Q}_1'\mathbf{u}$.

The marginal probability for the Durbin-Watson statistic is

$$\Pr(\mathrm{DW}_j < c) = \Pr(h < 0)$$

where $h = \eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I})\eta$.

The p-value or the marginal probability for the generalized Durbin-Watson statistic is computed by numerical inversion of the characteristic function $\phi(u)$ of the quadratic form $h = \eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I})\eta$. The trapezoidal rule approximation to the marginal probability $\Pr(h < 0)$ is

$$\Pr(h<0) = \frac{1}{2} - \sum_{k=0}^{K} \frac{\mathrm{Im}\left[\phi((k+\frac{1}{2})\Delta)\right]}{\pi(k+\frac{1}{2})} + \mathrm{E}_I(\Delta) + \mathrm{E}_T(K)$$

where $\mathrm{Im}\left[\phi(\cdot)\right]$ is the imaginary part of the characteristic function, $\mathrm{E}_I(\Delta)$ and $\mathrm{E}_T(K)$ are integration and truncation errors, respectively. Refer to Davies (1973) for numerical inversion of the characteristic function.

Ansley, Kohn, and Shively (1992) proposed a numerically efficient algorithm which requires O(N) operations for evaluation of the characteristic function $\phi(u)$. The characteristic function is denoted as

$$\begin{aligned} \phi(u) &= \left|\mathbf{I} - 2iu(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I}_{N-k})\right|^{-1/2} \\ &= |\mathbf{V}|^{-1/2}\left|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right|^{-1/2}\left|\mathbf{X}'\mathbf{X}\right|^{1/2} \end{aligned}$$

where $\mathbf{V} = (1 + 2iuc)\mathbf{I} - 2iu\mathbf{A}_j'\mathbf{A}_j$ and $i = \sqrt{-1}$. By applying the Cholesky decomposition to the complex matrix $\mathbf{V}$, you can obtain the lower triangular matrix $\mathbf{G}$ which satisfies $\mathbf{V} = \mathbf{G}\mathbf{G}'$. Therefore, the characteristic function can be evaluated in O(N) operations using the following formula:

$$\phi(u) = |\mathbf{G}|^{-1}\left|\mathbf{X}^{*\prime}\mathbf{X}^*\right|^{-1/2}\left|\mathbf{X}'\mathbf{X}\right|^{1/2}$$

where $\mathbf{X}^* = \mathbf{G}^{-1}\mathbf{X}$. Refer to Ansley, Kohn, and Shively (1992) for more information on evaluation of the characteristic function.

Tests for Serial Correlation with Lagged Dependent Variables

When regressors contain lagged dependent variables, the Durbin-Watson statistic (d_1) for the first-order autocorrelation is biased toward 2 and has reduced power. Wallis (1972) shows that the bias in the Durbin-Watson statistic (d_4) for the fourth-order autocorrelation is smaller than the bias in d_1 in the presence of a first-order lagged dependent variable. Durbin (1970) proposed two alternative statistics (Durbin *h* and *t*) that are asymptotically equivalent. The *h* statistic is written as

$$h = \hat{\rho}\sqrt{N/(1 - N\hat{V})}$$

where $\hat{\rho} = \sum_{t=2}^{N} \hat{\nu}_t \hat{\nu}_{t-1} / \sum_{t=1}^{N} \hat{\nu}_t^2$ and $\hat{V}$ is the least-squares variance estimate for the coefficient of the lagged dependent variable. Durbin's *t*-test consists of regressing the OLS residuals $\hat{\nu}_t$ on explanatory variables and $\hat{\nu}_{t-1}$ and testing the significance of the estimate for coefficient of $\hat{\nu}_{t-1}$.

Inder (1984) shows that the Durbin-Watson test for the absence of first-order autocorrelation is generally more powerful than the *h*-test in finite samples. Refer to Inder (1986) and King and Wu (1991) for the Durbin-Watson test in the presence of lagged dependent variables.

Testing

Heteroscedasticity and Normality Tests

Portmanteau Q-Test

For nonlinear time series models, the portmanteau test statistic based on squared residuals is used to test for independence of the series (McLeod and Li 1983):

$$Q(q) = N(N+2)\sum_{i=1}^{q} \frac{r(i; \hat{\nu}_t^2)}{(N-i)}$$

where

$$r(i; \hat{\nu}_t^2) = \frac{\sum_{t=i+1}^{N} (\hat{\nu}_t^2 - \hat{\sigma}^2)(\hat{\nu}_{t-i}^2 - \hat{\sigma}^2)}{\sum_{t=1}^{N} (\hat{\nu}_t^2 - \hat{\sigma}^2)^2}$$

$$\hat{\sigma}^2 = \frac{1}{N}\sum_{t=1}^{N} \hat{\nu}_t^2$$

This *Q* statistic is used to test the nonlinear effects (for example, GARCH effects) present in the residuals. The GARCH(p,q) process can be considered as an ARMA(max(p,q),p) process. See the section "Predicting the Conditional Variance" later in this chapter. Therefore, the *Q* statistic calculated from the squared residuals can be used to identify the order of the GARCH process.

Lagrange Multiplier Test for ARCH Disturbances

Engle (1982) proposed a Lagrange multiplier test for ARCH disturbances. The test statistic is asymptotically equivalent to the test used by Breusch and Pagan (1979). Engle's Lagrange multiplier test for the *q*th order ARCH process is written

$$LM(q) = \frac{N\mathbf{W}'\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'\mathbf{W}}{\mathbf{W}'\mathbf{W}}$$

where

$$\mathbf{W} = \left(\frac{\hat{\nu}_1^2}{\hat{\sigma}^2}, \ldots, \frac{\hat{\nu}_N^2}{\hat{\sigma}^2}\right)'$$

and

$$\mathbf{Z} = \begin{bmatrix} 1 & \hat{\nu}_0^2 & \cdots & \hat{\nu}_{-q+1}^2 \\ \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ 1 & \hat{\nu}_{N-1}^2 & \cdots & \hat{\nu}_{N-q}^2 \end{bmatrix}$$

The presample values (ν_0^2,. . ., ν_{-q+1}^2) have been set to 0. Note that the LM(q) tests may have different finite sample properties depending on the presample values, though they are asymptotically equivalent regardless of the presample values. The LM and *Q* statistics are computed from the OLS residuals assuming that disturbances are white noise. The *Q* and LM statistics have an approximate $\chi^2_{(q)}$ distribution under the white-noise null hypothesis.

Normality Test

Based on skewness and kurtosis, Bera and Jarque (1982) calculated the test statistic

$$T_N = \left[\frac{N}{6}b_1^2 + \frac{N}{24}(b_2 - 3)^2\right]$$

where

$$b_1 = \frac{\sqrt{N}\sum_{t=1}^{N}\hat{u}_t^3}{\left(\sum_{t=1}^{N}\hat{u}_t^2\right)^{\frac{3}{2}}}$$

$$b_2 = \frac{N\sum_{t=1}^{N}\hat{u}_t^4}{\left(\sum_{t=1}^{N}\hat{u}_t^2\right)^{2}}$$

The χ^2(2)-distribution gives an approximation to the normality test T_N.

When the GARCH model is estimated, the normality test is obtained using the standardized residuals $\hat{u}_t = \hat{\epsilon}_t/\sqrt{h_t}$. The normality test can be used to detect misspecification of the family of ARCH models.

Computation of the Chow Test

Consider the linear regression model

$$\mathbf{y} = X\beta + \mathbf{u}$$

where the parameter vector β contains k elements.

Split the observations for this model into two subsets at the break point specified by the CHOW= option, so that $\mathbf{y} = (\mathbf{y}_1^{'}, \mathbf{y}_2^{'})^{'}$,

$X = (X_1^{'}, X_2^{'})^{'}$, and

$\mathbf{u} = (\mathbf{u}_1^{'}, \mathbf{u}_2^{'})^{'}$.

Now consider the two linear regressions for the two subsets of the data modeled separately,

$$\mathbf{y}_1 = X_1\beta_1 + \mathbf{u}_1$$

$$\mathbf{y}_2 = X_2\beta_2 + \mathbf{u}_2$$

where the number of observations from the first set is n_1 and the number of observations from the second set is n_2.

The Chow test statistic is used to test the null hypothesis $H_0 : \beta_1 = \beta_2$ conditional on the same error variance $V(\mathbf{u}_1) = V(\mathbf{u}_2)$. The Chow test is computed using three sums of square errors.

$$\mathrm{F}_{chow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}_1^{'}\hat{\mathbf{u}}_1 - \hat{\mathbf{u}}_2^{'}\hat{\mathbf{u}}_2)/\mathrm{k}}{(\hat{\mathbf{u}}_1^{'}\hat{\mathbf{u}}_1 + \hat{\mathbf{u}}_2^{'}\hat{\mathbf{u}}_2)/(\mathrm{n}_1 + \mathrm{n}_2 - 2\mathrm{k})}$$

where $\hat{\mathbf{u}}$ is the regression residual vector from the full set model, $\hat{\mathbf{u}}_1$ is the regression residual vector from the first set model, and $\hat{\mathbf{u}}_2$ is the regression residual vector from the second set model. Under the null hypothesis, the Chow test statistic has an *F*-distribution with k and $(n_1 + n_2 - 2k)$ degrees of freedom, where k is the number of elements in β.

Chow (1960) suggested another test statistic that tests the hypothesis that the mean of prediction errors is 0. The predictive Chow test can also be used when $n_2 < k$.

The PCHOW= option computes the predictive Chow test statistic

$$\mathrm{F}_{pchow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}_1^{'}\hat{\mathbf{u}}_1)/\mathrm{n}_2}{\hat{\mathbf{u}}_1^{'}\hat{\mathbf{u}}_1/(\mathrm{n}_1 + \mathrm{k})}$$

The predictive Chow test has an *F*-distribution with n_2 and $(n_1 - k)$ degrees of freedom.

Unit Root and Cointegration Testing

Consider the random walk process

$$y_t = y_{t-1} + u_t$$

where the disturbances might be serially correlated with possible heteroscedasticity. Phillips and Perron (1988) proposed the unit root test of the OLS regression model.

$$y_t = \alpha y_{t-1} + u_t$$

Let $s^2 = \frac{1}{T-k}\sum_{t=1}^{T}\hat{u}_t^2$ and let $\hat{\sigma}^2$ be the variance estimate of the OLS estimator $\hat{\alpha}$, where $\hat{u}_t$ is the OLS residual. You can estimate the asymptotic variance of $\frac{1}{T}\sum_{t=1}^{T}\hat{u}_t^2$using the truncation lag *l*.

$$\hat{\lambda} = \sum_{j=0}^{l}\kappa_j[1 - j/(l+1)]\hat{\gamma}_j$$

where $\kappa_0 = 1$, $\kappa_j = 2$ for $j > 0$, and $\hat{\gamma}_j = \frac{1}{T}\sum_{t=j+1}^{T}\hat{u}_t\hat{u}_{t-j}$.

Then the Phillips-Perron Z($\hat{\alpha}$) test (zero mean case) is written

$$\mathrm{Z}(\hat{\alpha}) = T(\hat{\alpha} - 1) - \frac{1}{2}T^2\hat{\sigma}^2(\hat{\lambda} - \hat{\gamma}_0)/\mathrm{s}^2$$

and has the following limiting distribution:

$$\frac{\frac{1}{2}\{B(1)^2 - 1\}}{\int_0^1 [B(x)]^2 dx}$$

where *B*(·) is a standard Brownian motion. Note that the realization Z(x) from the the stochastic process B(·) is distributed as N(0,x) and thus $B(1)^2 \sim \chi_1^2$.

Therefore, you can observe that $\mathrm{P}(\hat{\alpha} < 1) \approx 0.68$ as $T \to \infty$, which shows that the limiting distribution is skewed to the left.

Let $t_{\hat{\alpha}}$ be the *t*-test statistic for $\hat{\alpha}$. The Phillips-Perron $\mathrm{Z}(\mathrm{t}_{\hat{\alpha}})$ test is written

$$\mathrm{Z}(\mathrm{t}_{\hat{\alpha}}) = (\hat{\gamma}_0/\hat{\lambda})^{1/2}\mathrm{t}_{\hat{\alpha}} - \frac{1}{2}T\hat{\sigma}(\hat{\lambda} - \hat{\gamma}_0)/(\mathrm{s}\hat{\lambda}^{1/2})$$

and its limiting distribution is derived as

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\}}{\{\int_0^1 [B(x)]^2 dx\}^{1/2}}$$

When you test the regression model $y_t = \mu + \alpha y_{t-1} + u_t$ for the true random walk process (single mean case), the limiting distribution of the statistic $Z(\hat{\alpha})$ is written

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1)\int_0^1 B(x)dx}{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x)dx\right]^2}$$

while the limiting distribution of the statistic $\mathrm{Z}(\mathrm{t}_{\hat{\alpha}})$ is given by

$$\frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1)\int_0^1 B(x)dx}{\{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x)dx\right]^2\}^{1/2}}$$

Finally, the limiting distribution of the Phillips-Perron test for the random walk with drift process $y_t = \mu + y_{t-1} + u_t$ (trend case) can be derived as

$$[0 \quad c \quad 0]\, V^{-1} \begin{bmatrix} B(1) \\ \frac{B(1)^2 - 1}{2} \\ B(1) - \int_0^1 B(x)dx \end{bmatrix}$$

where $c = 1$ for $Z(\hat{\alpha})$ and $c = \frac{1}{\sqrt{Q}}$ for $\mathrm{Z}(\mathrm{t}_{\hat{\alpha}})$,

$$V = \begin{bmatrix} 1 & \int_0^1 B(x)dx & \frac{1}{2} \\ \int_0^1 B(x)dx & \int_0^1 B(x)^2 dx & \int_0^1 xB(x)dx \\ \frac{1}{2} & \int_0^1 xB(x)dx & \frac{1}{3} \end{bmatrix}$$

$$Q = [0 \quad c \quad 0]\, V^{-1} \begin{bmatrix} 0 \\ c \\ 0 \end{bmatrix}$$

When several variables $\mathbf{z}_t = (z_{1t}, \cdots, z_{kt})'$ are cointegrated, there exists

a (k×1) cointegrating vector **c** such that **c'z**$_t$ is stationary and **c** is a nonzero vector. The residual based cointegration test is based on the following regression model:

$$y_t = \beta_1 + \mathbf{x}_t'\beta + u_t$$

where $y_t = z_{1t}$, $\mathbf{x}_t = (z_{2t}, \cdots, z_{kt})'$, and $\beta = (\beta_2, \cdots, \beta_k)'$. You can estimate the consistent cointegrating vector using OLS if all variables are difference stationary, that is, I(1). The Phillips-Ouliaris test is computed using the OLS residuals from the preceding regression model, and it performs the test for the null hypothesis of no cointegration. The estimated cointegrating vector is $\hat{\mathbf{c}} = (1, -\hat{\beta}_2, \cdots, -\hat{\beta}_k)'$.

Since the AUTOREG procedure does not produce the *p*-value of the cointegration test, you need to refer to the tables by Phillips and Ouliaris (1990). Before you apply the cointegration test, you might perform the unit root test for each variable.

Predicted Values

The AUTOREG procedure can produce two kinds of predicted values for the response series and corresponding residuals and confidence limits. The residuals in both cases are computed as the actual value minus the predicted value. In addition, when GARCH models are estimated, the AUTOREG procedure can output predictions of the conditional error variance.

Predicting the Unconditional Mean

The first type of predicted value is obtained from only the structural part of the model, $\mathbf{x}_t'\mathbf{b}$. These are useful in predicting values of new response time series, which are assumed to be described by the same model as the current response time series. The predicted values, residuals, and upper and lower confidence limits for the structural predictions are requested by specifying the PREDICTEDM=, RESIDUALM=, UCLM=, or LCLM= options in the OUTPUT statement. The ALPHACLM= option controls the confidence level for UCLM= and LCLM=. These confidence limits are for estimation of the mean of the dependent variable, $\mathbf{x}_t'\mathbf{b}$, where $\mathbf{x}_t$ is the column vector of independent variables at observation *t*.

The predicted values are computed as

$$\hat{y}_t = \mathbf{x}_t'\mathbf{b}$$

and the upper and lower confidence limits as

$$\hat{u}_t = \hat{y}_t + t_{\alpha/2}\mathrm{v}$$

$$\hat{l}_t = \hat{y}_t - t_{\alpha/2}\mathrm{v}$$

where v^2 is an estimate of the variance of $\hat{y}_t$ and $t_{\alpha/2}$ is the upper α/2 percentage point of the *t* distribution.

$$\mathrm{Prob}(\mathrm{T} > \mathrm{t}_{\alpha/2}) = \alpha/2$$

where *T* is an observation from a *t* distribution with *q* degrees of freedom. The value of α can be set with the ALPHACLM= option. The degrees of freedom parameter, *q*, is taken to be the number of observations minus the number of free parameters in the regression and autoregression parts of the model. For the YW estimation method, the value of v is calculated as

$$\mathrm{v} = \sqrt{\mathrm{s}^2\mathbf{x}_\mathrm{t}'(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{x}_\mathrm{t}}$$

where s^2 is the error sum of squares divided by *q*. For the ULS and ML methods, it is calculated as

$$\mathrm{v} = \sqrt{\mathrm{s}^2\mathbf{x}_\mathrm{t}'\mathbf{W}\mathbf{x}_\mathrm{t}}$$

where **W** is the $k \times k$ submatrix of $(\mathbf{J}'\mathbf{J})^{-1}$ that corresponds to the regression parameters. For details, see “Computational Methods” earlier in this chapter.

Predicting Future Series Realizations

The other predicted values use both the structural part of the model and the predicted values of the error process. These conditional mean values are useful in predicting future values of the current response time series. The predicted values, residuals, and upper and lower confidence limits for future observations conditional on past values are requested by the PREDICTED=, RESIDUAL=, UCL=, or LCL= options in the OUTPUT statement. The ALPHACLI= option controls the confidence level for UCL= and LCL=. These confidence limits are for the predicted value,

$$\tilde{y}_t = \mathbf{x}_t'\mathbf{b} + \nu_{t|t-1}$$

where $\mathbf{x}_t$ is the vector of independent variables and $\nu_{t|t-1}$ is the minimum variance linear predictor of the error term given the available past values of $\nu_{t-j}, j = 1, 2, \ldots, t-1$, and the autoregressive

model for ν_t. If the *m* previous values of the structural residuals are available, then

$$\nu_{t|t-1} = -\hat{\varphi}_1\nu_{t-1} - \ldots - \hat{\varphi}_m\nu_{t-m}$$

where $\hat{\varphi}_1, \ldots, \hat{\varphi}_m$ are the estimated AR parameters. The upper and lower confidence limits are computed as

$$\tilde{u}_t = \tilde{y}_t + t_{\alpha/2}\mathrm{v}$$

$$\tilde{l}_t = \tilde{y}_t - t_{\alpha/2}\mathrm{v}$$

where v, in this case, is computed as

$$\mathrm{v} = \sqrt{\mathrm{s}^2(\mathbf{x}_\mathrm{t}'(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{x}_\mathrm{t} + \mathrm{r})}$$

where the value rs^2 is the estimate of the variance of $\nu_{t|t-1}$. At the start of the series, and after missing values, *r* is generally greater than 1. See “Predicting the Conditional Variance” for computational details of *r*. The plot of residuals and confidence limits in Example 12.4 later in this chapter illustrates this behavior.

Except to adjust the degrees of freedom for the error sum of squares, the preceding formulas do not account for the fact that the autoregressive parameters are estimated. In particular, the confidence limits are likely to be somewhat too narrow. In large samples, this is probably not an important effect, but it may be appreciable in small samples. Refer to Harvey (1981) for some discussion of this problem for AR(1) models.

Note that at the beginning of the series (the first *m* observations, where *m* is the value of the NLAG= option) and after missing values, these residuals do not match the residuals obtained by using OLS on the transformed variables. This is because, in these cases, the predicted noise values must be based on less than a complete set of past noise values and, thus, have larger variance. The GLS transformation for these observations includes a scale factor as well as a linear combination of past values. Put another way, the $\mathbf{L}^{-1}$ matrix defined in the section "Computational Methods" has the value 1 along the diagonal, except for the first *m* observations and after missing values.

Predicting the Conditional Variance

The GARCH process can be written

$$\epsilon_t^2 = \omega + \sum_{i=1}^{n} (\alpha_i + \gamma_i)\epsilon_{t-i}^2 - \sum_{j=1}^{p} \gamma_j \eta_{t-j} + \eta_t$$

where $\eta_t = \epsilon_t^2 - h_t$and $n = \max(p, q)$. This representation shows that the squared residual ϵ_t^2 follows an ARMA(*n*,*p*) process. Then for any $d > 0$, the conditional expectations are as follows:

$$\mathbf{E}(\epsilon_{t+d}^2|\Psi_t) = \omega + \sum_{i=1}^{n} (\alpha_i + \gamma_i)\mathbf{E}(\epsilon_{t+d-i}^2|\Psi_t) - \sum_{j=1}^{p} \gamma_j \mathbf{E}(\eta_{t+d-j}|\Psi_t)$$

The *d*-step-ahead prediction error, ξ_{t+d} = $y_{t+d} - y_{t+d|t}$, has the conditional variance

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \sum_{j=0}^{d-1} g_j^2 \sigma_{t+d-j|t}^2$$

where

$$\sigma_{t+d-j|t}^2 = \mathbf{E}(\epsilon_{t+d-j}^2|\Psi_t)$$

Coefficients in the conditional *d*-step prediction error variance are calculated recursively using the following formula:

$$g_j = -\varphi_1 g_{j-1} - \ldots - \varphi_m g_{j-m}$$

where $g_0 = 1$ and $g_j = 0$ if $j < 0$; φ_1, …, φ_m are autoregressive parameters. Since the parameters are not known, the conditional variance is computed using the estimated autoregressive parameters. The *d*-step-ahead prediction error variance is simplified when there are no autoregressive terms:

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \sigma_{t+d|t}^2$$

Therefore, the one-step-ahead prediction error variance is equivalent to the conditional error variance defined in the GARCH process:

$$h_t = E(\epsilon_t^2|\Psi_{t-1}) = \sigma_{t|t-1}^2$$

Note that the conditional prediction error variance of the EGARCH and GARCH-M models cannot be calculated using the preceding formula. Therefore, the confidence intervals for the predicted values are computed assuming the homoscedastic conditional error variance. That is, the conditional prediction error variance is identical to the unconditional prediction error variance:

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \mathbf{V}(\xi_{t+d}) = \sigma^2 \sum_{j=0}^{d-1} g_j^2$$

since $\sigma_{t+d-j|t}^2 = \sigma^2$. You can compute $s^2 r$, which is the second term of the variance for the predicted value $\tilde{y}_t$ explained previously in "Predicting Future Series Realizations," using the formula $\sigma^2 \sum_{j=0}^{d-1} g_j^2$; r is estimated from $\sum_{j=0}^{d-1} g_j^2$ using the estimated autoregressive parameters.

Consider the following conditional prediction error variance:

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \sigma^2 \sum_{j=0}^{d-1} g_j^2 + \sum_{j=0}^{d-1} g_j^2 (\sigma_{t+d-j|t}^2 - \sigma^2)$$

The second term in the preceding equation can be interpreted as the noise from using the homoscedastic conditional variance when the errors follow the GARCH process. However, it is expected that if the GARCH process is covariance stationary, the difference between the conditional prediction error variance and the unconditional prediction error variance disappears as the forecast horizon *d* increases.

OUT= Data Set

The output SAS data set produced by the OUTPUT statement contains all the variables in the input data set and the new variables specified by the OUTPUT statement options. See the section "OUTPUT Statement" earlier in this chapter for information on the output variables that can be created. The output data set contains one observation for each observation in the input data set.

OUTEST= Data Set

The OUTEST= data set contains all the variables used in any MODEL statement. Each regressor variable contains the estimate for the corresponding regression parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

_A_*i*	the *i*th order autoregressive parameter estimate. There are *m* such variables _A_1 through _A_*m*, where *m* is the value of the NLAG= option.
_AH_*i*	the *i*th order ARCH parameter estimate, if the GARCH= option is specified. There are *q* such variables _AH_1 through _AH_*q*, where *q* is the value of the Q= option. The variable _AH_0 contains the estimate of ω.
DELTA	the estimated mean parameter for the GARCH-M model, if a GARCH-in-mean model is specified
DEPVAR	the name of the dependent variable
_GH_*i*	the *i*th order GARCH parameter estimate, if the GARCH= option is specified. There are *p* such variables _GH_1 through _GH_*p*, where *p* is the value of the P= option.
INTERCEPT	the intercept estimate. INTERCEP contains a missing value for models for which the NOINT option is specified.
METHOD	the estimation method that is specified in the METHOD= option
MODEL	the label of the MODEL statement if one is given, or blank otherwise
MSE	the value of the mean square error for the model
NAME	the name of the row of covariance matrix for the parameter estimate, if the COVOUT option is specified
LIKLHD	the log likelihood value of the GARCH model
SSE	the value of the error sum of squares
STDERR	standard error of the parameter estimate, if the COVOUT option is specified
THETA	the estimate of the θ parameter in the EGARCH model, if an EGARCH model is specified
TYPE	OLS for observations containing parameter estimates, or COV for observations containing covariance matrix elements.

The OUTEST= data set contains one observation for each MODEL statement giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for each MODEL statement giving the rows of the covariance of parameter estimates matrix. For covariance observations, the value of the _TYPE_ variable is COV, and the _NAME_ variable identifies the parameter associated with that row of the covariance matrix.

Printed Output

The AUTOREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least-squares estimates
3. estimates of autocorrelations, which include the estimates of the autocovariances, the autocorrelations, and (if there is sufficient space) a graph of the autocorrelation at each LAG
4. if the PARTIAL option is specified, the partial autocorrelations
5. the preliminary MSE, which results from solving the Yule-Walker equations. This is an estimate of the final MSE.
6. the estimates of the autoregressive parameters (Coefficient), their standard errors (Std Error), and the ratio of estimate to standard error (*t* Ratio).
7. the statistics of fit are printed for the final model. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the root mean square error (Root MSE), the Schwarz information criterion (SBC), the Akaike information criterion (AIC), the regression R^2 (Reg Rsq), and the total R^2 (Total Rsq). For GARCH models, the following additional items are printed:

   - the value of the log likelihood function
   - the number of observations that are used in estimation (OBS)
   - the unconditional variance (UVAR)
   - the normality test statistic and its *p*-value

8. the parameter estimates for the structural model (B Value), a standard error estimate (Std Error), the ratio of estimate to standard error (*t* Ratio), and an approximation to the significance probability for the parameter being 0 (Approx Prob)
9. the regression parameter estimates, printed again assuming that the autoregressive parameter estimates are known to be correct. The Std Error and related statistics for the regression estimates will, in general, be different when the autoregressive parameters are assumed to be given.

ODS Table Names

PROC AUTOREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, “Using the Output Delivery System.”

Table 12.1. ODS Tables Produced in PROC AUTOREG

ODS Table Name	Description	Option
ODS Tables Created by the Model Statement		
FitSummary	Summary of regression	default

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the AUTOREG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS." By default, only the residual, predicted vs actual, and autocorrelation of residuals plots are produced. If, in addition to the ODS GRAPHICS statement, you also specify the ALL option in either the PROC AUTOREG statement or MODEL statement, all plots are created. However, if the NLAG= option is specified, the Cook's D plot and the studentized residuals plot are not produced.

ODS Graph Names

PROC AUTOREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 12.2.

Table 12.2. ODS Graphics Produced by PROC AUTOREG

ODS Graph Name	Plot Description	Option
ACFPlot	Autocorrelation of residuals	Default
ActualByPredicted	Predicted vs actual plot	Default
CooksD	Cook's D plot	ALL (no NLAG=)
IACFPlot	Inverse autocorrelation of residuals	ALL
QQPlot	QQ plot of residuals	ALL
PACFPlot	Partial autocorrelation of residuals	ALL
ResidualHistogram	Histogram of the residuals	ALL
ResidualPlot	Residual plot	Default
StudentResidualPlot	Studentized Residual plot	ALL (no NLAG=)
WhiteNoisePlot	Tests for White Noise Residuals	ALL

Examples

Example 12.1. Analysis of Real Output Series

In this example, the annual real output series is analyzed over the period 1901 to 1983 (Gordon 1986, pp 781-783). With the DATA step, the original data is transformed using the natural logarithm, and the differenced series DY is created for further analysis. The log of real output is plotted in Output 12.1.1.

```

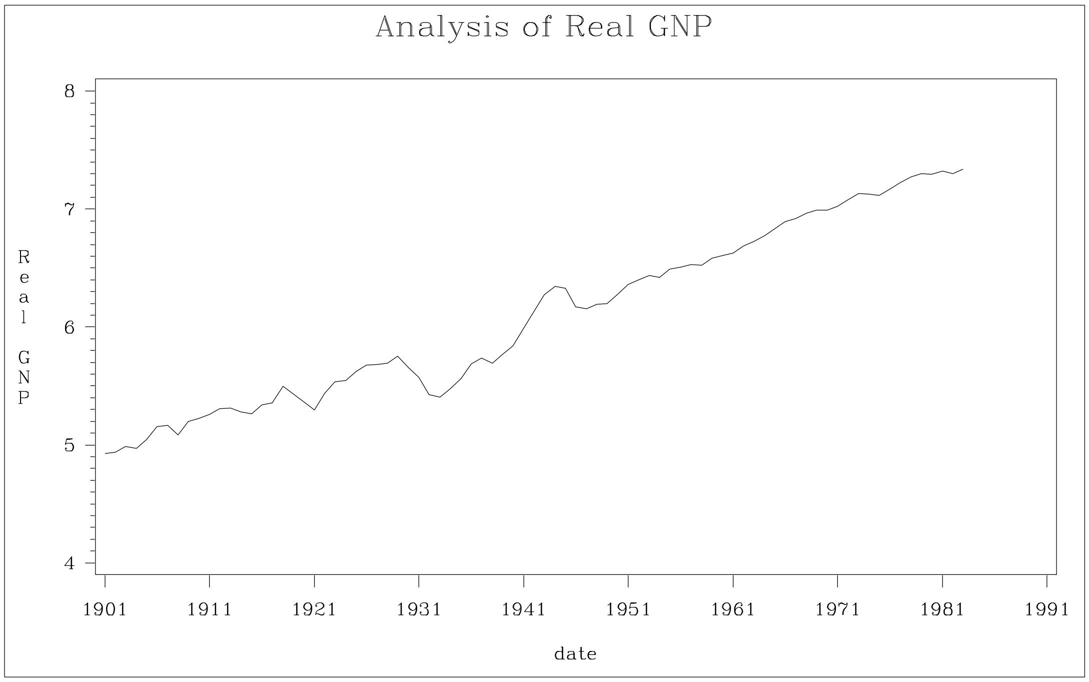
   symbol i=join;
run;
```

Output 12.1.1. Real Output Series: 1901 - 1983



The (linear) trend-stationary process is estimated using the following form:

$$y_t = \beta_0 + \beta_1 t + \nu_t$$

where

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1} - \varphi_2 \nu_{t-2}$$

$$\epsilon_t \sim \mathrm{IN}(0, \sigma_\epsilon)$$

The preceding trend-stationary model assumes that uncertainty over future horizons is bounded since the error term, ν_t, has a finite variance. The maximum likelihood AR estimates are shown in Output 12.1.2.

```
proc autoreg data=gnp;
   model y = t / nlag=2 method=ml;
run;
```

```

Nelson and Plosser (1982) failed to reject the hypothesis that macroeconomic time series are nonstationary and have no tendency to return to a trend line. In this context, the simple random walk process can be used as an alternative process:

$$y_t = \beta_0 + y_{t-1} + \nu_t$$

where $\nu_t = \epsilon_t$ and $y_0 = 0$. In general, the difference-stationary process is written as

$$\phi(L)(1 - L)y_t = \beta_0\phi(1) + \theta(L)\epsilon_t$$

where L is the lag operator. You can observe that the class of a difference-stationary process should have at least one unit root in the AR polynomial $\phi(L)(1 - L)$.

The Dickey-Fuller procedure is used to test the null hypothesis that the series has a unit root in the AR polynomial. Consider the following equation for the augmented Dickey-Fuller test:

$$\Delta y_t = \beta_0 + \delta t + \beta_1 y_{t-1} + \sum_{i=1}^{m} \gamma_i \Delta y_{t-i} + \epsilon_t$$

where $\Delta = 1 - L$. The test statistic τ_τ is the usual *t* ratio for the parameter estimate $\hat{\beta}_1$, but the τ_τ does not follow a *t* distribution.

The %DFTEST macro computes the test statistic τ_τ and its *p* value to perform the Dickey-Fuller test. The default value of *m* is 3, but you can specify *m* with the AR= option. The option TREND=2 implies that the Dickey-Fuller test equation contains linear time trend. See Chapter 4, “SAS Macros and Functions,” for details.

```
%dftest(gnp,y,trend=2,outstat=stat1)

proc print data=stat1;
run;
```

The augmented Dickey-Fuller test indicates that the output series may have a difference-stationary process. The statistic _TAU_ has a value of -2.61903 and its *p*-value is 0.29104. See Output 12.1.3.

The AR(1) model for the differenced series DY is estimated using the maximum likelihood method for the period 1902 to 1983. The difference-stationary process is written

$$\Delta y_t = \beta_0 + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1}$$

The estimated value of φ_1 is -0.297 and that of β_0 is 0.0293. All estimated values are statistically significant.

```
proc autoreg data=gnp;
   model dy = / nlag=1 method=ml;
run;

Example 12.2. Comparing Estimates and Models

In this example, the Grunfeld series are estimated using different estimation methods. Refer to Maddala (1977) for details of the Grunfeld investment data set. For comparison, the Yule-Walker method, the ULS method, and maximum likelihood method estimates are shown. With the DWPROB option, the *p*-value of the Durbin-Watson statistic is printed. The Durbin-Watson test indicates the positive autocorrelation of the regression residuals.

```

Example 12.3. Lack of Fit Study

Many time series exhibit high positive autocorrelation, having the smooth appearance of a random walk. This behavior can be explained by the partial adjustment and adaptive expectation hypotheses.

Short-term forecasting applications often use autoregressive models because these models absorb the behavior of this kind of data. In the case of a first-order AR process where the autoregressive parameter is exactly 1 (a *random walk*), the best prediction of the future is the immediate past.

PROC AUTOREG can often greatly improve the fit of models, not only by adding additional parameters but also by capturing the random walk tendencies. Thus, PROC AUTOREG can be expected to provide good short-term forecast predictions.

However, good forecasts do not necessarily mean that your structural model contributes anything worthwhile to the fit. In the following example, random noise is fit to part of a sine wave. Notice that the structural model does not fit at all, but the autoregressive process does quite well and is very nearly a first difference (A(1) = -.976).

```
title1 'Lack of Fit Study';
title2 'Fitting White Noise Plus Autoregressive Errors to a Sine Wave';

data a;
   pi=3.14159;
   do time = 1 to 75;
      if time > 75 then y = .;
      else y = sin( pi * ( time / 50 ) );
      x = ranuni( 1234567 );
      output;
      end;
run;

proc autoreg data=a;
   model y = x / nlag=1;
   output out=b p=pred pm=xbeta;
run;

proc gplot data=b;
   plot y*time=1 pred*time=2 xbeta*time=3 / overlay;
   symbol1  v='none' i=spline;
   symbol2  v=triangle;
   symbol3  v=circle;
run;
```

The printed output produced by PROC AUTOREG is shown in Output 12.3.1 and Output 12.3.2. Plots of observed and predicted values are shown in Output 12.3.3.

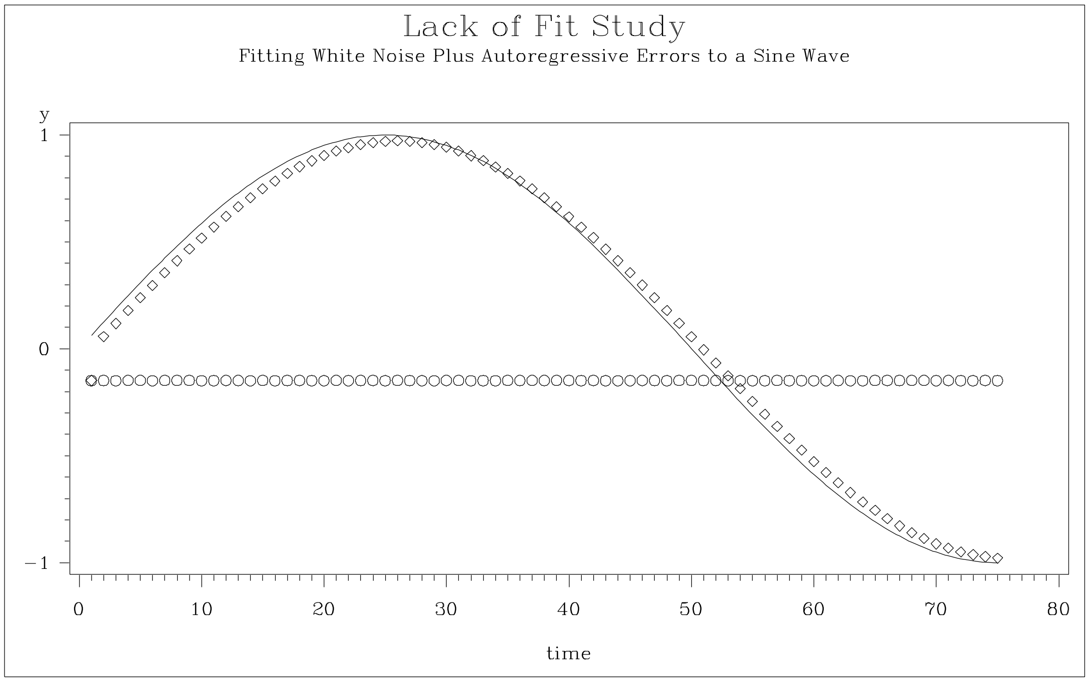
Output 12.3.3. Plot of Autoregressive Prediction



Example 12.4. Missing Values

In this example, a pure autoregressive error model with no regressors is used to generate 50 values of a time series. Approximately fifteen percent of the values are randomly chosen and set to missing. The following statements generate the data.

```
title  'Simulated Time Series with Roots:';
title2 ' (X-1.25)(X**4-1.25)';
title3 'With 15% Missing Values';
data ar;
   do i=1 to 550;
      e = rannor(12345);
      n = sum( e, .8*n1, .8*n4, -.64*n5 ); /* ar process  */
      y = n;
      if ranuni(12345) > .85 then y = .;    /* 15% missing */
      n5=n4; n4=n3; n3=n2; n2=n1; n1=n;    /* set lags    */
      if i>500 then output;
      end;
run;
```

The model is estimated using maximum likelihood, and the residuals are plotted with 99% confidence limits. The PARTIAL option prints the partial autocorrelations. The following statements fit the model:

```
proc autoreg data=ar partial;
   model y = / nlag=(1 4 5) method=ml;
   output out=a predicted=p residual=r ucl=u lcl=l alphacli=.01;
run;
```

The printed output produced by the AUTOREG procedure is shown in Output 12.4.1.

Output 12.4.1. Autocorrelation-Corrected Regression Results

```

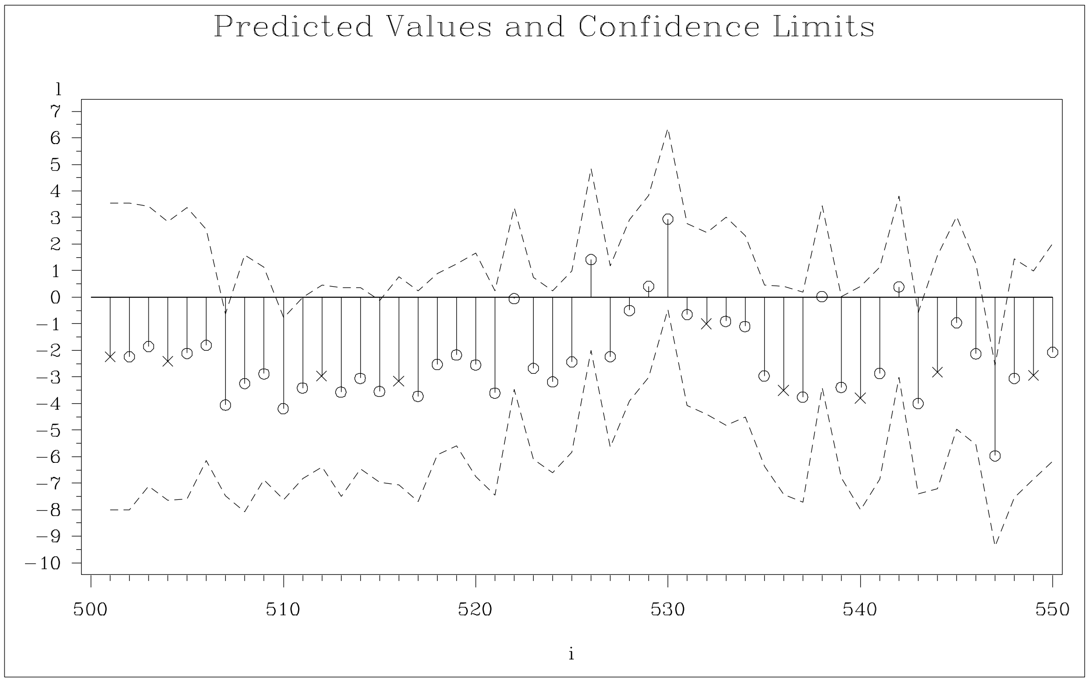
The following statements plot the residuals and confidence limits:

```
data reshape1;
   set a;
   miss = .;
   if r=. then do;
      miss = p;
      p = .;
      end;
run;

title 'Predicted Values and Confidence Limits';
proc gplot data=reshape1;
   plot l*i=1 miss*i=2 p*i=3 u*i=4 / overlay;
   symbol1  i=join v=none l=2;
   symbol2  i=needle v='X';
   symbol3  i=needle v=circle;
   symbol4  i=join v=none l=2;
run;
```

The plot of the predicted values and the upper and lower confidence limits is shown in Output 12.4.2. Note that the confidence interval is wider at the beginning of the series (when there are no past noise values to use in the forecast equation) and after missing values where, again, there is an incomplete set of past residuals.

Output 12.4.2. Plot of Residuals and Confidence Interval



Example 12.5. Money Demand Model

The following example estimates the log-log money demand equation using the maximum likelihood method. The money demand model contains four explanatory variables. The lagged nominal money stock M1 is divided by the current price level GDF to calculate a new variable M1CP since the money stock is assumed to follow the partial adjustment process. The variable M1CP is then used to estimate the coefficient of adjustment. All variables are transformed using the natural logarithm with a DATA step. Refer to Balke and Gordon (1986) for data description.

The first eight observations are printed using the PRINT procedure and are shown in Output 12.5.1. Note that the first observation of the variables M1CP and INFR are missing. Therefore, the money demand equation is estimated for the period 1968:2 to 1983:4 since PROC AUTOREG ignores the first missing observation.

```
data money;
   date = intnx( 'qtr', '01jan1968'd, _n_-1 );
   format date yyqc6.;
   input m1 gnp gdf ycb @@;
   m = log( 100 * m1 / gdf );
   m1cp = log( 100 * lag(m1) / gdf );
   y = log( gnp );
   intr = log( ycb );
   infr = 100 * log( gdf / lag(gdf) );
   label m    = 'Real Money Stock (M1)'
```

```
            m1cp = 'Lagged M1/Current GDF'
            y    = 'Real GNP'
            intr = 'Yield on Corporate Bonds'
            infr = 'Rate of Prices Changes';
   datalines;

```

The money demand equation is first estimated using OLS. The DW=4 option produces generalized Durbin-Watson statistics up to the fourth order. Their exact marginal probabilities (*p*-values) are also calculated with the DWPROB option. The Durbin-Watson test indicates positive first-order autocorrelation at, say, the 10% confidence level. You can use the Durbin-Watson table, which is available only for 1% and 5% significance points. The relevant upper (d_U) and lower (d_L) bounds are $d_U = 1.731$ and $d_L = 1.471$, respectively, at 5% significance level. However, the bounds test is inconvenient since sometimes you may get the statistic in the inconclusive region while the interval between the upper and lower bounds becomes smaller with the increasing sample size.

The autoregressive model is estimated using the maximum likelihood method. Though the Durbin-Watson test statistic is calculated after correcting the autocorrelation, it should be used with care since the test based on this statistic is not justified theoretically.

```
   proc autoreg data=money;
      model m = m1cp y intr infr / nlag=1 method=ml maxit=50;
      output out=a p=p pm=pm r=r rm=rm ucl=ucl lcl=lcl
                   uclm=uclm lclm=lclm;
   run;

   proc print data=a(obs=8);
      var p pm r rm ucl lcl uclm lclm;
   run;
```

A difference is shown between the OLS estimates in Output 12.5.2 and the AR(1)-ML estimates in Output 12.5.3. The estimated autocorrelation coefficient is significantly negative (-0.88345). Note that the negative coefficient of A(1) should be interpreted as a positive autocorrelation.

Two predicted values are produced dash predicted values computed for the structural model and predicted values computed for the full model. The full model includes both the structural and error-process parts. The predicted values and residuals are stored in the output data set A, as are the upper and lower 95% confidence limits for the predicted values. Part of the data set A is shown in Output 12.5.4. The first observation is missing since the explanatory variables, M1CP and INFR, are missing for the corresponding observation.

Example 12.6. Estimation of ARCH(2) Process

Stock returns show a tendency for small changes to be followed by small changes while large changes are followed by large changes. The plot of daily price changes of the IBM common stock (Box and Jenkins 1976, p 527) are shown in Output 12.6.1. The time series look serially uncorrelated, but the plot makes us skeptical of their independence.

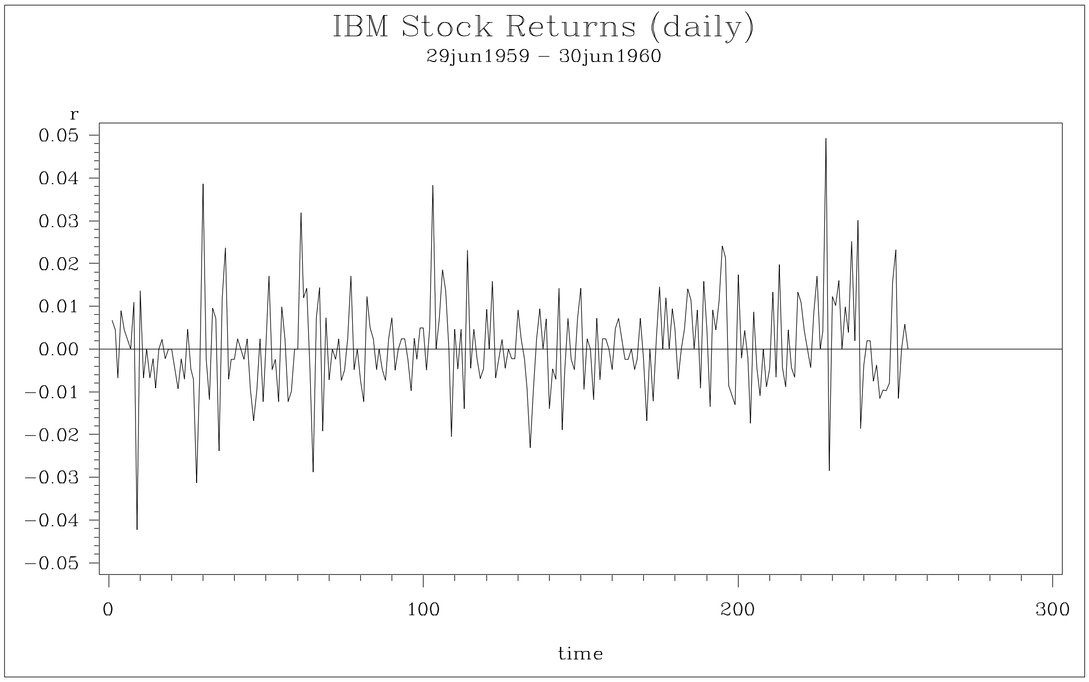
With a DATA step, the stock (capital) returns are computed from the closing prices. To forecast the conditional variance, an additional 46 observations with missing values are generated.

```
title 'IBM Stock Returns (daily)';
title2 '29jun1959 - 30jun1960';

data ibm;
   infile datalines eof=last;
   input x @@;
   r = dif( log( x ) );
   time = _n_-1;
   output;
   return;
last:
   do i = 1 to 46;
      r = .;
      time + 1;
      output;
   end;
   return;
datalines;
;

proc gplot data=ibm;
   plot r*time / vref=0;
   symbol1 i=join v=none;
run;
```

Output 12.6.1. IBM Stock Returns: Daily



The simple ARCH(2) model is estimated using the AUTOREG procedure. The MODEL statement option GARCH=(Q=2) specifies the ARCH(2) model. The OUTPUT statement with the CEV= option produces the conditional variances V. The conditional variance and its forecast is calculated using parameter estimates:

$$h_t = \hat{\omega} + \hat{\alpha}_1 \epsilon_{t-1}^2 + \hat{\alpha}_2 \epsilon_{t-2}^2$$

$$E(\epsilon_{t+d}^2 | \Psi_t) = \hat{\omega} + \sum_{i=1}^{2} \hat{\alpha}_i E(\epsilon_{t+d-i}^2 | \Psi_t)$$

where $d > 1$.

```
proc autoreg data=ibm maxit=50;
   model r = / noint garch=(q=2);
   output out=a cev=v;
run;
```

The parameter estimates for ω, α_1, and α_2 are 0.00011, 0.04136, and 0.06976, respectively. The normality test indicates that the conditional normal distribution may not fully explain the leptokurtosis in the stock returns (Bollerslev 1987).

The ARCH model estimates are shown in Output 12.6.2, and conditional variances are also shown in Output 12.6.3.

Output 12.6.2. ARCH(2) Estimation Results

Example 12.7. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. This is a continuation of "Forecasting Autoregressive Error Models" in the section "Getting Started" on page 490. ODS graphics enables you to generate graphics similar to Figure 12.6 without resorting to the GPLOT procedure.

These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the AUTOREG procedure, see the "ODS Graphics" section on page 560.

The following statements show how to generate ODS graphics plots with the AUTOREG procedure. In this case, all plots are requested using the ALL option in the PROC AUTOREG statement, in addition to the ODS GRAPHICS statement. The plots are displayed in Output 12.7.1 through Output 12.7.8.

```
ods html;
ods graphics on;

proc autoreg data=b all;
   model y = time / nlag=2 method=ml;
   output out=p p=yhat pm=ytrend
             lcl=lcl ucl=ucl;
run;
```

```
ods graphics off;
ods html close;
```

Output 12.7.1. Residuals Plot (Experimental)

The COMPUTAB Procedure

Chapter Contents

Chapter 13
The COMPUTAB Procedure

Overview

The COMPUTAB procedure (**COMPU**ting and **TAB**ular reporting) produces tabular reports generated using a programmable data table.

The COMPUTAB procedure is especially useful when you need both the power of a programmable spreadsheet and a report generation system, but you want to set up a program to run in a batch mode and generate routine reports.

With PROC COMPUTAB, you can select a subset of observations from the input data set, define the format of a table, operate on its row and column values, and create new columns and rows. Access to individual table values is available when needed.

The COMPUTAB procedure can tailor reports to almost any desired specification and provide consolidation reports over summarization variables. The generated report values can be stored in an output data set. It is especially useful in creating tabular reports such as income statements, balance sheets, and other row and column reports.

Getting Started

The following example shows the different types of reports that can be generated by PROC COMPUTAB.

Suppose a company has monthly expense data on three of its divisions and wants to produce the year-to-date expense report shown in Figure 13.1. This section starts out with the default report produced by the COMPUTAB procedure and modifies it until the desired report is achieved.

```
                             Year to Date Expenses

                                   Division  Division  Division          All
                                          A         B         C    Divisions
       Travel Expenses within U.S.    18700    211000     12800     $242,500
       Advertising                    18500    176000     34500     $229,000
       Permanent Staff Salaries      186000   1270000    201000   $1,657,000
       Benefits Including Insurance    3900     11100     17500      $32,500
                                   ========  ========  ========   ==========
       Total                         227100   1668100    265800   $2,161,000
```

Figure 13.1. Year to Date Expense Report

Producing a Simple Report

Without any specifications, the COMPUTAB procedure transposes and prints the input data set. The variables in the input data set become rows in the report, and the observations in the input data set become columns. The variable names are used as the row titles. The column headings default to COL1 through COLn. For example, the following input data set contains the monthly expenses reported by different divisions of the company:

```
data report;
   input compdiv $ date:date7. salary travel insure advrtise;
   format date date7.;
   label travel   = 'Travel Expenses within U.S.'
         advrtise = 'Advertising'
         salary   = 'Permanent Staff Salaries'
         insure   = 'Benefits Including Insurance';
   datalines;
A 31JAN1989 95000  10500  2000 6500
B 31JAN1989 668000 112000 5600 90000
C 31JAN1989 105000 6800   9000 18500
A 28FEB1989 91000  8200   1900 12000
B 28FEB1989 602000 99000  5500 86000
C 28FEB1989 96000  6000   8500 16000
;
```

You can get a listing of the data set by using the PRINT procedure, as follows:

```
title 'Listing of Monthly Divisional Expense Data';
proc print data=report;
run;
```

```
                  Listing of Monthly Divisional Expense Data

    Obs    compdiv         date     salary    travel    insure    advrtise

     1        A       31JAN1989      95000     10500     2000        6500
     2        B       31JAN1989     668000    112000     5600       90000
     3        C       31JAN1989     105000      6800     9000       18500
     4        A       28FEB1989      91000      8200     1900       12000
     5        B       28FEB1989     602000     99000     5500       86000
     6        C       28FEB1989      96000      6000     8500       16000
```

Figure 13.2. Listing of Data Set by PROC PRINT

To get a simple, transposed report of the same data set, use the following PROC COMPUTAB statement:

```
title 'Monthly Divisional Expense Report';
proc computab data=report;
run;
```

```
                        Monthly Divisional Expense Report

                 COL1        COL2        COL3        COL4        COL5        COL6

compdiv             A           B           C           A           B           C
date        31JAN1989   31JAN1989   31JAN1989   28FEB1989   28FEB1989   28FEB1989
salary       95000.00   668000.00   105000.00    91000.00   602000.00    96000.00
travel       10500.00   112000.00     6800.00     8200.00    99000.00     6000.00
insure        2000.00     5600.00     9000.00     1900.00     5500.00     8500.00
advrtise      6500.00    90000.00    18500.00    12000.00    86000.00    16000.00
```

Figure 13.3. Listing of Data Set by PROC COMPUTAB

Using PROC COMPUTAB

The COMPUTAB procedure is best understood by examining the following features:

- definition of the report layout with ROWS and COLUMNS statements
- input block
- row blocks
- column blocks

PROC COMPUTAB builds a table according to the specifications in the ROWS and COLUMNS statements. Row names and column names define the rows and columns of the table. Options in the ROWS and COLUMNS statements control titles, spacing, and formatting.

The input block places input observations into the appropriate columns of the report. It consists of programming statements used to select observations to be included in the report, to determine the column into which the observation should be placed, and to calculate row and column values that are not in the input data set.

Row blocks and column blocks perform operations on the values of rows and columns of the report after the input block has executed. Row blocks are a block of programming statements labeled ROW*xxxxx*: that create or modify row values; column blocks are a block of programming statements labeled COL*xxxxx*: that create or modify column values. Row and column blocks can make multiple passes through the report for final calculations.

For most reports, these features are sufficient. More complicated applications may require knowledge of the program data vector and the COMPUTAB data table. These topics are discussed in the section "Details" later in this chapter.

Defining Report Layout

ROWS and COLUMNS statements define the rows and columns of the report. The order of row and column names on these statements determines the order of rows and columns in the report. Additional ROWS and COLUMNS statements can be used to specify row and column formatting options.

The following statements select and order the variables from the input data set and produce the report in Figure 13.4:

```
proc computab data=report;
   rows travel advrtise salary;
run;
```

```
                   COL1        COL2        COL3        COL4        COL5        COL6

TRAVEL         10500.00   112000.00     6800.00     8200.00    99000.00     6000.00
ADVRTISE        6500.00    90000.00    18500.00    12000.00    86000.00    16000.00
SALARY         95000.00   668000.00   105000.00    91000.00   602000.00    96000.00
INSURE          2000.00     5600.00     9000.00     1900.00     5500.00     8500.00
```

Figure 13.4. Report Produced Using a ROWS Statement

When a COLUMNS statement is not specified, each observation becomes a new column. If you use a COLUMNS statement, you must specify to which column each observation belongs by using program statements for column selection. When more than one observation is selected for the same column, values are summed.

The following statements produce Figure 13.5:

```
proc computab data= report;
   rows travel advrtise salary insure;
   columns a b c;
   *----select column for company division,
        based on value of compdiv----*;
   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';
run;
```

The statement A=COMPDIV='A'; illustrates the use of logical operators as a selection technique. If COMPDIV='A', then the current observation is added to the A column. Refer to *SAS Language: Reference, Version 6, First Edition* for more information on logical operators.

```
                            A           B           C

            TRAVEL     18700.00  211000.00   12800.00
            ADVRTISE   18500.00  176000.00   34500.00
            SALARY    186000.00  1270000.0  201000.00
            INSURE      3900.00   11100.00   17500.00
```

Figure 13.5. Report Produced Using ROWS and COLUMNS Statements

Adding Computed Rows and Columns

In addition to the variables and observations in the input data set, you can create additional rows or columns by using SAS programming statements in PROC COMPUTAB. You can

- modify input data and select columns in the input block
- create or modify columns in column blocks
- create or modify rows in row blocks

The following statements add one computed row (SUM) and one computed column (TOTAL) to the report in Figure 13.5. In the input block the logical operators indicate the observations corresponding to each column of the report. After the input block reads in the values from the input data set, the column block creates the column variable TOTAL by summing the columns A, B, and C. The additional row variable, SUM, is calculated as the sum of the other rows. The result is shown in Figure 13.6.

```
proc computab data= report;
   rows travel advrtise salary insure sum;
   columns a b c total;
   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';
   colblk: total = a + b + c;
   rowblk: sum   = travel + advrtise + salary + insure;
run;
```

```
                      A           B           C       TOTAL

      TRAVEL     18700.00  211000.00   12800.00  242500.00
      ADVRTISE   18500.00  176000.00   34500.00  229000.00
      SALARY    186000.00  1270000.0  201000.00  1657000.0
      INSURE      3900.00   11100.00   17500.00   32500.00
      SUM       227100.00  1668100.0  265800.00  2161000.0
```

Figure 13.6. Report Produced Using Row and Column Blocks

Enhancing the Report

To enhance the appearance of the final report, you can use

- TITLE and LABEL statements
- column headings
- row titles
- row and column spacing control
- overlining and underlining
- formats

The following example enhances the report in the previous example. The enhanced report is shown in Figure 13.7.

The TITLE statement assigns the report title. The column headings in Figure 13.7 (Division A, Division B, and Division C) are assigned in the first COLUMNS statement by “Division” _name_ specification. The second COLUMNS statement assigns the column heading (“All” “Divisions”), sets the spacing (+4), and formats the values in the TOTAL column.

Similarly, the first ROWS statement uses previously assigned variable labels for row labels by specifying the _LABEL_ option. The DUL option in the second ROWS statement double underlines the INSURE row. The third ROWS statement assigns the row label TOTAL to the SUM row.

```
title 'Year to Date Expenses';

proc computab cwidth=8 cdec=0;

   columns a  b  c / 'Division' _name_;
   columns total / 'All' 'Divisions' +4 f=dollar10.0;

   rows travel advrtise salary insure / _label_;
   rows insure / dul;
   rows sum / 'Total';

   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';

   colblk: total = a + b + c;
   rowblk: sum   = travel + advrtise + salary + insure;
run;
```

```
                        Year to Date Expenses

                                Division  Division  Division        All
                                       A         B         C  Divisions
   Travel Expenses within U.S.     18700    211000     12800   $242,500
   Advertising                     18500    176000     34500   $229,000
   Permanent Staff Salaries       186000   1270000    201000 $1,657,000
   Benefits Including Insurance     3900     11100     17500    $32,500
                                ========  ========  ======== ==========
   Total                          227100   1668100    265800 $2,161,000
```

Figure 13.7. Report Produced by PROC COMPUTAB Using Enhancements

Syntax

The following statements are used with the COMPUTAB procedure:

PROC COMPUTAB *options*;
  BY *variables*;
  COLUMNS *names / options*;
  ROWS *names / options*;
  CELL *names /* **FORMAT=** *format*;
  INIT *anchor-name* ***locator-name*** *values* ***locator-name values***;
  programming *statements*;
  SUMBY *variables*;

The PROC COMPUTAB statement is the only required statement. The COLUMNS, ROWS, and CELL statements define the COMPUTAB table. The INIT statement initializes the COMPUTAB table values. Programming statements process COMPUTAB table values. The BY and SUMBY statements provide BY-group processing and consolidation (roll up) tables.

Functional Summary

COMPUTAB procedure statements and options are summarized in the following table:

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the format for printing a particular cell	CELL	
define columns of the report	COLUMNS	
initialize values in the COMPUTAB data table	INIT	
define rows of the report	ROWS	
produce consolidation tables	SUMBY	

Description	Statement	Option
Data Set Options		
specify the input data set	COMPUTAB	DATA=
specify an output data set	COMPUTAB	OUT=
Input Options		
specify a value to use when testing for 0	COMPUTAB	FUZZ=
initialize the data table to missing	COMPUTAB	INITMISS
prevent the transposition of the input data set	COMPUTAB	NOTRANS
Printing Control Options		
suppress printing of the listed columns	COLUMNS	NOPRINT
suppress all printed output	COMPUTAB	NOPRINT
suppress printing of the listed rows	ROWS	NOPRINT
suppress columns with all 0 or missing values	COLUMNS	NOZERO
suppress rows with all 0 or missing values	ROWS	NOZERO
list option values	COMPUTAB	OPTIONS
overprint titles, values, overlining, and underlining associated with listed rows	ROWS	OVERPRINT
print only consolidation tables	COMPUTAB	SUMONLY
Report Formatting Options		
specify number of decimal places to print	COMPUTAB	CDEC=
specify number of spaces between columns	COMPUTAB	CSPACE=
specify column width for the report	COMPUTAB	CWIDTH=
overlines the listed rows with double lines	ROWS	DOL
underline the listed rows with double lines	ROWS	DUL
specify a format for printing the cell values	CELL	FORMAT=
specify a format for printing column values	COLUMNS	FORMAT=
specify a format for printing the row values	ROWS	FORMAT=
left align the column headings	COLUMNS	LJC
left-justify character rows in each column	ROWS	LJC
specify indentation from the margin	ROWS	+n
suppress printing of row titles on later pages	COMPUTAB	NORTR
overlines the listed rows with a single line	ROWS	OL
starts a new page before printing the listed rows	ROWS	_PAGE_
specify number of spaces before row titles	COMPUTAB	RTS=
print a blank row	ROWS	SKIP
underline the listed rows with a single line	ROWS	UL
specify text to print if column is 0 or missing	COLUMNS	ZERO=
specify text to print if row is 0 or missing	ROWS	ZERO=
Row and Column Type Options		

Description	Statement	Option
specify that columns contain character data	COLUMNS	CHAR
specify that rows contain character data	ROWS	CHAR
Options for Column Headings		
specify literal column headings	COLUMNS	‘column heading’
use variable labels in column headings	COLUMNS	_LABEL_
specify a master title centered over columns	COLUMNS	MTITLE=
use column names in column headings	COLUMNS	_NAME_
Options for Row Titling		
use labels in row titles	ROWS	_LABEL_
use row names in row titles	ROWS	_NAME_
specify literal row titles	ROWS	‘row title’

PROC COMPUTAB Statement

PROC COMPUTAB *options;*

The following options can be used in the PROC COMPUTAB statement:

Input Options

DATA= *SAS-data-set*
names the SAS data set containing the input data. If this option is not specified, the last created data set is used. If you are not reading a data set, use DATA=_NULL_.

FUZZ= *value*
specifies the criterion to use when testing for 0. If a number is within the FUZZ= value of 0, the number is set to 0.

INITMISS
initializes the COMPUTAB data table to missing rather than to 0. The COMPUTAB data table is discussed further in the section "Details" later in this chapter.

NOTRANSPOSE
NOTRANS
prevents the transposition of the input data set in building the COMPUTAB report tables. The NOTRANS option causes input data set variables to appear among the columns of the report rather than among the rows.

Report Formatting Options

The formatting options specify default values. Many of the formatting options can be modified for specific columns in COLUMNS statements and for rows in ROWS statements.

CDEC= *d*
specifies the default number of decimal places for printing. The default is CDEC=2. See the FORMAT= option in the sections on COLUMN, ROWS, and CELL statements later in this chapter.

CSPACE= *n*
specifies the default number of spaces to insert between columns. The value of the CSPACE= option is used as the default value for the +*n* option in the COLUMNS statement. The default is CSPACE=2.

CWIDTH= *w*
specifies a default column width for the report. The default is CWIDTH=9. The width must be in the range of 1-32.

NORTR
suppresses the printing of row titles on each page. The NORTR (no row-title repeat) option is useful to suppress row titles when report pages are to be joined together in a larger report.

RTS= *n*
specifies the default number of spaces to be inserted before row titles when row titles appear after the first printed column. The default row-title spacing is RTS=2.

Output Options

NOPRINT
suppresses all printed output. Use the NOPRINT option with the OUT= option to produce an output data set but no printed reports.

OPTIONS
lists PROC COMPUTAB option values. The option values appear on a separate page preceding the procedure's normal output.

OUT= *SAS-data-set*
names the SAS data set to contain the output data. See the section "Details" for a description of the structure of the output data set.

SUMONLY
suppresses printing of detailed reports. When the SUMONLY option is used, PROC COMPUTAB generates and prints only consolidation tables as specified in the SUMBY statement.

COLUMNS Statement

COLUMNS *column-list* **/** *options*;

COLUMNS statements define the columns of the report. The COLUMNS statement can be abbreviated COLUMN, COLS, or COL.

The specified column names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many COLUMNS statements as you need. A COLUMNS statement can describe more than one column, and one column of the report can be described with several different COLUMNS statements. The order of the columns on the report is determined by the order of appearance of column names in COLUMNS statements. The first occurrence of the name determines where in the sequence of columns a particular column is located.

The following options can be used in the COLUMNS statement:

Option for Column Type

CHAR
indicates that the columns contain character data.

Options for Column Headings

You can specify as many lines of column headings as needed. If no options are specified, the column names from the COLUMNS statement are used as column headings. Any or all of the following options can be used in a column heading:

“column heading”
specifies that the characters enclosed in quotes is to be used in the column heading for the variable or variables listed in the COLUMNS statement. Each quoted string appears on a separate line of the heading.

LABEL
uses labels, if provided, in the heading for the column or columns listed in the COLUMNS statement. If a label has not been provided, the name of the column is used. Refer to *SAS Language: Reference* for information on the LABEL statement.

MTITLE= *“text”*
specifies that the string of characters enclosed in quotes is a master title to be centered over all the columns listed in the COLUMNS statement. The list of columns must be consecutive. Special characters (“+”, “*”, “=”, and so forth) placed on either side of the text expand to fill the space. The MTITLE= option can be abbreviated M=.

NAME
uses column names in column headings for the columns listed in the COLUMNS statement. This option allows headings (*“text”*) and names to be combined in a heading.

Options for Column Print Control

+n
inserts *n* spaces before each column listed in the COLUMNS statement. The default spacing is given by the CSPACE= option in the PROC COMPUTAB statement.

NOPRINT
suppresses printing of columns listed in the COLUMNS statement. This option enables you to create columns to be used for intermediate calculations without having those columns printed.

NOZERO
suppresses printing of columns when all the values in a column are 0 or missing. Numbers within the FUZZ= value of 0 are treated as 0.

PAGE
starts a new page of the report before printing each of the columns in the list that follows.

TITLES
prints row titles before each column in the list. The _TITLES_ option can be abbreviated as _TITLE_.

Options for Column Formatting

Column formats override row formats for particular table cells only when the input data set is not transposed (when the NOTRANS option is specified).

FORMAT= *format*
specifies a format for printing the values of the columns listed in the COLUMNS statement. The FORMAT= option can be abbreviated F=.

LJC
left-justifies the column headings for the columns listed. By default, columns are right-justified. When the LJC (left-justify character) option is used, any character row values in the column are also left-justified rather than right-justified.

ZERO= *"text"*
substitutes *"text"* when the value in the column is 0 or missing.

ROWS Statement

ROWS *row-list* **/** *options***;**

ROWS statements define the rows of the report. The ROWS statement can be abbreviated ROW.

The specified row names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many ROWS statements as you need. A ROWS statement can describe more than one row, and one row of the report can be described with several different ROWS statements. The order of the rows in the report is determined by the order of appearance of row names in ROWS statements. The first occurrence of the name determines where the row is located.

The following options can be used in the ROWS statement:

Option for Row Type

CHAR
indicates that the rows contain character data.

Options for Row Titling

You can specify as many lines of row titles as needed. If no options are specified, the names from the ROWS statement are used as row titles. Any or all of the following options can be used in a row title:

LABEL
: uses labels as row titles for the row or rows listed in the ROWS statement. If a label is not provided, the name of the row is substituted. Refer to *SAS Language: Reference* for more information on the LABEL statement.

NAME
: uses row names in row titles for the row or rows listed in the ROWS statement.

"row title"
: specifies that the string of characters enclosed in quotes is to be used in the row title for the row or rows listed in the ROWS statement. Each quoted string appears on a separate line of the heading.

Options for Row Print Control

+n
: indents *n* spaces from the margin for the rows in the ROWS statement.

DOL
: overlines the rows listed in the ROWS statement with double lines. Overlines are printed on the line before any row titles or data for the row.

DUL
: underlines the rows listed in the ROWS statement with double lines. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

NOPRINT
: suppresses printing of the rows listed in the ROWS statement. This option enables you to create rows to be used for intermediate calculations without having those rows printed.

NOZERO
: suppresses the printing of a row when all the values are 0 or missing.

OL
: overlines the rows listed in the ROWS statement with a single line. Overlines are printed on the line before any row titles or data for the row.

OVERPRINT
: overprints titles, values, overlining, and underlining associated with rows listed in the ROWS statement. The OVERPRINT option can be abbreviated OVP. This option is valid only when the system option OVP is in effect. Refer to *SAS Language: Reference* for more information about the OVP option.

PAGE
starts a new page of the report before printing these rows.

SKIP
prints a blank line after the data lines for these rows.

UL
underlines the rows listed in the ROWS statement with a single line. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

Options for Row Formatting

Row formatting options take precedence over column-formatting options when the input data set is transposed. Row print width can never be wider than column width. Character values are truncated on the right.

FORMAT= *format*
specifies a format for printing the values of the rows listed in the ROWS statement. The FORMAT= option can be abbreviated as F=.

LJC
left-justifies character rows in each column.

ZERO= *“text”*
substitutes *text* when the value in the row is 0 or missing.

CELL Statement

CELL *cell_names* **/ FORMAT=** *format***;**

The CELL statement specifies the format for printing a particular cell in the COMPUTAB data table. Cell variable names are compound SAS names of the form *name1.name2*, where *name1* is the name of a row variable and *name2* is the name of a column variable. Formats specified with the FORMAT= option in CELL statements override formats specified in ROWS and COLUMNS statements.

INIT Statement

INIT *anchor-name* **[***locator-name***]** *values* **[***locator-name values***];**

The INIT statement initializes values in the COMPUTAB data table at the beginning of each execution of the procedure and at the beginning of each BY group if a BY statement is present.

The INIT statement in the COMPUTAB procedure is similar in function to the RETAIN statement in the DATA step, which initializes values in the program data vector. The INIT statement can be used at any point after the variable to which it refers has been defined in COLUMNS or ROWS statements. Each INIT statement initializes one row or column. Any number of INIT statements can be used.

The first term after the keyword INIT, *anchor-name*, anchors initialization to a row or column. If *anchor-name* is a row name, then all *locator-name* values in the statement are columns of that row. If *anchor-name* is a column name, then all *locator-name* values in the statement are rows of that column.

The following terms appear in the INIT statement:

anchor-name
: names the row or column in which values are to be initialized. This term is required.

locator-name
: identifies the starting column in the row (or starting row in the column) into which values are to be placed. For example, in a table with a row SALES and a column for each month of the year, the following statement initializes values for columns JAN, FEB, and JUN:

```
init sales jan 500 feb 600 jun 800;
```

If you do not specify *locator-name* values, the first value is placed into the first row or column, the second value into the second row or column, and so on. For example,

```
init sales 500 600 450;
```

assigns 500 to column JAN, 600 to FEB, and 450 to MAR.

+n
: specifies the number of columns in a row (or rows in a column) that are to be skipped when initializing values. For example, the statement

```
init sales jan 500 +5 900;
```

assigns 500 to JAN and 900 to JUL.

n*value
: assigns *value* to *n* columns in the row (or rows in the column). For example, the statement

```
init sales jan 6*500 jul 6*1000;
```

and the statement

```
init sales 6*500 6*1000;
```

both assign 500 to columns JAN through JUN and 1000 to JUL through DEC.

Programming Statements

You can use most SAS programming statements the same way you use them in the DATA step. Also, all DATA step functions can be used in the COMPUTAB procedure.

Lines written by the PUT statement are not integrated with the COMPUTAB report. PUT statement output is written to the SAS log.

The automatic variable _N_ can be used; its value is the number of observations read or the number read in the current BY group, if a BY statement is used. FIRST.*variable* and LAST.*variable* references cannot be used.

The following statements are also available in PROC COMPUTAB:

```
ABORT                       FORMAT
ARRAY                       GOTO
ATTRIB                      IF-THEN/ELSE
assignment statement        LABEL
CALL                        LINK
DELETE                      PUT
DO                          RETAIN
iterative DO                SELECT
DO UNTIL                    STOP
DO WHILE                    sum statement
END                         TITLE
FOOTNOTE
```

The programming statements can be assigned labels ROW*xxxxx*: or COL*xxxxx*: to indicate the start of a row and column block, respectively. Statements in a row block create or change values in all the columns in the specified rows. Similarly, statements in a column block create or change values in all the rows in the specified columns.

There is an implied RETURN statement before each new row or column block. Thus, the flow of execution does not leave the current row (column) block before the block repeats for all columns (rows.) Row and column variables and nonretained variables are initialized prior to each execution of the block.

The next COL*xxxxx*: label, ROW*xxxxx*: label, or the end of the PROC COMPUTAB step signals the end of a row (column) block. Column blocks and row blocks can be mixed in any order. In some cases, performing calculations in different orders can lead to different results.

See "Program Flow Example," "Order of Calculations," and "Controlling Execution within Row and Column Blocks" in the section "Details" for more information.

BY Statement

BY *variables;*

A BY statement can be used with PROC COMPUTAB to obtain separate reports for observations in groups defined by the BY variables. At the beginning of each BY group, before PROC COMPUTAB reads any observations, all table values are set to 0 unless the INITMISS option or an INIT statement is specified.

SUMBY Statement

SUMBY *variables;*

The SUMBY statement produces consolidation tables for variables whose names are in the SUMBY list. Only one SUMBY statement can be used.

To use a SUMBY statement, you must use a BY statement. The SUMBY and BY variables must be in the same relative order in both statements, for example:

```
by a b c;
sumby a b;
```

This SUMBY statement produces tables that consolidate over values of C within levels of B and over values of B within levels of A. Suppose A has values 1,2; B has values 1,2; and C has values 1,2,3. Table 13.1 indicates the consolidation tables produced by the SUMBY statement.

Table 13.1. Consolidation Tables Produced by the SUMBY Statement

SUMBY Consolidations	**Consolidated BY Groups**		
A=1,B=1	C=1	C=2	C=3
A=1,B=2	C=1	C=2	C=3

A=1	B=1,C=1
	B=2,C=1
		B=1,C=2
		B=2,C=2
			B=1,C=3
			B=2,C=3

A=2,B=1	C=1	C=2	C=3
A=2,B=2	C=1	C=2	C=3

A=2	B=1,C=1
	B=2,C=1
		B=1,C=2
		B=2,C=2
			B=1,C=3
			B=2,C=3

Two consolidation tables for B are produced for each value of A. The first table consolidates the three tables produced for the values of C while B is 1; the second table consolidates the three tables produced for C while B is 2.

Tables are similarly produced for values of A. Nested consolidation tables are produced for B (as described previously) for each value of A. Thus, this SUMBY statement produces a total of six consolidation tables in addition to the tables produced for each BY group.

To produce a table that consolidates the entire data set (the equivalent of using PROC COMPUTAB with neither BY nor SUMBY statements), use the special name _TOTAL_ as the first entry in the SUMBY variable list, for example,

```
sumby _total_ a b;
```

PROC COMPUTAB then produces consolidation tables for SUMBY variables as well as a consolidation table for all observations.

To produce only consolidation tables, use the SUMONLY option in the PROC COMPUTAB statement.

Details

NOTRANS Option

The NOTRANS option in the PROC COMPUTAB statement prevents the transposition of the input data set. NOTRANS affects the input block, the precedence of row and column options, and the structure of the output data set if the OUT= option is specified.

When the input data set is transposed, input variables are among the rows of the COMPUTAB report, and observations compose columns. The reverse is true if the data set is not transposed; therefore, the input block must select rows to receive data values, and input variables are among the columns.

Variables from the input data set dominate the format specification and data type. When the input data set is transposed, input variables are among the rows of the report, and row options take precedence over column options. When the input data set is not transposed, input variables are among the columns, and column options take precedence over row options.

Variables for the output data set are taken from the dimension (row or column) that contains variables from the input data set. When the input data set is transposed, this dimension is the row dimension; otherwise, the output variables come from the column dimension.

Program Flow Example

This example shows how the COMPUTAB procedure processes observations in the program working storage and the COMPUTAB data table (CDT).

Assume you have three years of sales and cost of goods sold (CGS) figures, and you want to determine total sales and cost of goods sold and calculate gross profit and the profit margin.

```
data example;
   input year sales cgs;
   datalines;
1988    83      52
1989   106      85
1990   120     114
;

proc computab data=example;

   columns c88 c89 c90 total;
   rows sales cgs gprofit pctmarg;

   /* calculate gross profit */
   gprofit = sales - cgs;

   /* select a column */
```

```
      c88 = year = 1988;
      c89 = year = 1989;
      c90 = year = 1990;

      /* calculate row totals for sales */
      /* and cost of goods sold */
      col: total = c88 + c89 + c90;

      /* calculate profit margin */
      row: pctmarg = gprofit / cgs * 100;
   run;
```

Table 13.2 shows the CDT before any observation is read in. All the columns and rows are defined with the values initialized to 0.

Table 13.2. CDT Before any Input

	C88	C89	C90	TOTAL
SALES	0	0	0	0
CGS	0	0	0	0
GPROFIT	0	0	0	0
PCTMARG	0	0	0	0

When the first input is read in (year=1988, sales=83, and cgs=52), the input block puts the values for SALES and CGS in the C88 column since year=1988. Also the value for the gross profit for that year (GPROFIT) is calculated as indicated in the following:

```
      gprofit = sales-cgs;
      c88 = year = 1988;
      c89 = year = 1989;
      c90 = year = 1990;
```

Table 13.3 shows the CDT after the first observation is input.

Table 13.3. CDT After First Observation Input (C88=1)

	C88	C89	C90	TOTAL
SALES	83	0	0	0
CGS	52	0	0	0
GPROFIT	31	0	0	0
PCTMARG	0	0	0	0

Similarly, the second observation (year=1989, sales=106, cgs=85) is put in the second column and the GPROFIT is calculated to be 21. The third observation (year=1990, sales=120, cgs=114) is put in the third column and the GPROFIT is calculated to be 6. Table 13.4 shows the CDT after all observations are input.

Table 13.4. CDT After All Observations Input

	C88	C89	C90	TOTAL
SALES	83	106	120	0
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

After the input block is executed for each observation in the input data set, the first row or column block is processed. In this case, the column block is

```
col: total = c88 + c89 + c90;
```

The column block executes for each row, calculating the TOTAL column for each row. Table 13.5 shows the CDT after the column block has executed for the first row (total=83 + 106 + 120). The total sales for the three years is 309.

Table 13.5. CDT After Column Block Executed for First Row

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

Table 13.6 shows the CDT after the column block has executed for all rows and the values for total cost of goods sold and total gross profit have been calculated.

Table 13.6. CDT After Column Block Executed for All Rows

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	0	0	0	0

Once the column block has been executed for all rows, the next block is processed. The row block is

```
row: pctmarg = gprofit / cgs * 100;
```

The row block executes for each column, calculating the PCTMARG for each year and the total (TOTAL column) for three years. Table 13.7 shows the CDT after the row block has executed for all columns.

Table 13.7. CDT After Row Block Executed for All Columns

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	59.62	24.71	5.26	23.11

Order of Calculations

The COMPUTAB procedure provides alternative programming methods for performing most calculations. New column and row values are formed by adding values from the input data set, directly or with modification, into existing columns or rows. New columns can be formed in the input block or in column blocks. New rows can be formed in the input block or in row blocks.

This example illustrates the different ways to collect totals. Table 13.8 is the total sales report for two products, SALES1 and SALES2, during the years 1988-1990. The values for SALES1 and SALES2 in columns C88, C89, and C90 come from the input data set.

Table 13.8. Total Sales Report

	C88	C89	C90	SALESTOT
SALES1	15	45	80	140
SALES2	30	40	50	120
YRTOT	45	85	130	260

The new column SALESTOT, which is the total sales for each product over three years, can be computed in several different ways:

- in the input block by selecting SALESTOT for each observation

```
salestot = 1;
```

- in a column block

```
coltot: salestot = c88 + c89 + c90;
```

In a similar fashion, the new row YRTOT, which is the total sales for each year, can be formed as follows:

- in the input block

```
yrtot = sales1 + sales2;
```

in a row block

```
rowtot: yrtot = sales1 + sales2;
```

Performing some calculations in PROC COMPUTAB in different orders can yield different results, since many operations are not commutative. Be sure to perform calculations in the proper sequence. It may take several column and row blocks to produce the desired report values.

Notice that in the previous example, the grand total for all rows and columns is 260 and is the same whether it is calculated from row subtotals or column subtotals. It makes no difference in this case whether you compute the row block or the column block first.

However, consider the following example where a new column and a new row are formed:

Table 13.9. Report Sensitive to Order of Calculations

	STORE1	STORE2	STORE3	MAX
PRODUCT1	12	13	27	27
PRODUCT2	11	15	14	15
TOTAL	23	28	41	?

The new column MAX contains the maximum value in each row, and the new row TOTAL contains the column totals. MAX is calculated in a column block:

```
   col: max = max(store1,store2,store3);
```

TOTAL is calculated in a row block:

```
   row: total = product1 + product2;
```

Notice that either of two values, 41 or 42, is possible for the element in column MAX and row TOTAL. If the row block is first, the value is the maximum of the column totals (41). If the column block is first, the value is the sum of the MAX values (42). Whether to compute a column block before a row block can be a critical decision.

Column Selection

The following discussion assumes that the NOTRANS option has not been specified. When NOTRANS is specified, this section applies to rows rather than columns.

If a COLUMNS statement appears in PROC COMPUTAB, a target column must be selected for the incoming observation. If there is no COLUMNS statement, a new column is added for each observation. When a COLUMNS statement is present and the selection criteria fail to designate a column, the current observation is ignored. Faulty column selection can result in columns or entire tables of 0s (or missing values if the INITMISS option is specified).

During execution of the input block, when an observation is read, its values are copied into row variables in the Program Data Vector (PDV).

To select columns, use either the column variable names themselves or the special variable _COL_. Use the column names by setting a column variable equal to some nonzero value. The example in the section "Getting Started" earlier in this chapter uses the logical expression COMPDIV= *value* which is evaluated to produce 0 or 1, and the result is assigned to the corresponding column variable.

```
a = compdiv = ’A’;
b = compdiv = ’B’;
c = compdiv = ’C’;
```

IF statements can also be used to select columns. The following statements are equivalent to the preceding example:

```
if      compdiv = ’A’ then a = 1;
else if compdiv = ’B’ then b = 1;
else if compdiv = ’C’ then c = 1;
```

At the end of the input block for each observation, PROC COMPUTAB multiplies numeric input values by any nonzero selector values and adds the result to selected columns. Character values simply overwrite the contents already in the table. If more than one column is selected, the values are added to each of the selected columns.

Use the _COL_ variable to select a column by assigning the column number to it. The COMPUTAB procedure automatically initializes column variables and sets the _COL_ variable to 0 at the start of each execution of the input block. At the end of the input block for each observation, PROC COMPUTAB examines the value of _COL_. If the value is nonzero and within range, the row variable values are added to the CDT cells of the _COL_th column, for example,

```
data rept;
   input div sales cgs;
   datalines;
2   106    85
3   120   114
1    83    52
;

proc computab data=rept;
   row div sales cgs;
   columns div1 div2 div3;
   _col_ = div;
run;
```

The code in this example places the first observation (DIV=2) in column 2 (DIV2), the second observation (DIV=3) in column 3 (DIV3), and the third observation (DIV=1) in column 1 (DIV1).

Controlling Execution within Row and Column Blocks

Row names, column names, and the special variables _ROW_ and _COL_ can be used to limit the execution of programming statements to selected rows or columns. A row block operates on all columns of the table for a specified row unless restricted in some way. Likewise, a column block operates on all rows for a specified column. Use column names or _COL_ in a row block to execute programming statements conditionally; use row names or _ROW_ in a column block.

For example, consider a simple column block consisting of only one statement:

```
col: total = qtr1 + qtr2 + qtr3 + qtr4;
```

This column block assigns a value to each row in the TOTAL column. As each row participates in the execution of a column block,

- its row variable in the program data vector is set to 1
- the value of _ROW_ is the number of the participating row
- the value from each column of the row is copied from the COMPUTAB data table to the program data vector

To avoid calculating TOTAL on particular rows, use row names or _ROW_, for example,

```
col: if sales|cost then total = qtr1 + qtr2 + qtr3 + qtr4;
```

or

```
col: if _row_ < 3  then total = qtr1 + qtr2 + qtr3 + qtr4;
```

Row and column blocks can appear in any order, and rows and columns can be selected in each block.

Program Flow

This section describes in detail the different steps in PROC COMPUTAB execution.

Step 1: Define Report Organization and Set Up the COMPUTAB Data Table

Before the COMPUTAB procedure reads in data or executes programming statements, the columns list from the COLUMNS statements and the rows list from the ROWS statements are used to set up a matrix of all columns and rows in the report. This matrix is called the COMPUTAB data table (CDT). When you define columns and rows of the CDT, the COMPUTAB procedure also sets up corresponding variables in working storage called the program data vector (PDV) for programming statements. Data values reside in the CDT but are copied into the program data vector as they are needed for calculations.

Step 2: Select Input Data with Input Block Programming Statements

The input block copies input observations into rows or columns of the CDT. By default, observations go to columns; if the data set is not transposed (NOTRANS option), observations go to rows of the report table. The input block consists of all executable statements before any ROW*xxxxx*: or COL*xxxxx*: statement label. Use programming statements to perform calculations and select a given observation to be added into the report.

Input Block

The input block is executed once for each observation in the input data set. If there is no input data set, the input block is not executed. The program logic of the input block is as follows:

1. Determine which variables, row or column, are selector variables and which are data variables. Selector variables determine which rows or columns receive values at the end of the block. Data variables contain the values that the selected rows or columns receive. By default, column variables are selector variables and row variables are data variables. If the input data set is not transposed (NOTRANS option), the roles are reversed.
2. Initialize nonretained program variables (including selector variables) to 0 (or missing if the INITMISS option is specified). Selector variables are temporarily associated with a numeric data item supplied by the procedure. Using these variables to control row and column selection does not affect any other data values.
3. Transfer data from an observation in the data set to data variables in the PDV.
4. Execute the programming statements in the input block using values from the PDV and storing results in the PDV.
5. Transfer data values from the PDV into the appropriate columns of the CDT. If a selector variable for a row or column has a nonmissing, nonzero value, multiply each PDV value for variables used in the report by the selector variable and add the results to the selected row or column of the CDT.

Step 3: Calculate Final Values Using Column Blocks and Row Blocks

Column Blocks

A column block is executed once for each row of the CDT. The program logic of a column block is as follows:

1. Indicate the current row by setting the corresponding row variable in the PDV to 1 and the other row variables to missing. Assign the current row number to the special variable _ROW_.
2. Move values from the current row of the CDT to the respective column variables in the PDV.
3. Execute programming statements in the column block using the column values in the PDV. Here, new columns can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current row of the CDT.

Row Blocks

A row block is executed once for each column of the CDT. The program logic of a row block is as follows:

1. Indicate the current column by setting the corresponding column variable in the PDV to 1 and the other column variables to missing. Assign the current column number to the special variable _COL_.
2. Move values from the current column of the CDT to the respective row variables in the PDV.
3. Execute programming statements in the row block using the row values in the PDV. Here new rows can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current column of the CDT.

See "Controlling Execution within Row and Column Blocks" later in this chapter for details.

Any number of column blocks and row blocks can be used. Each may include any number of programming statements.

The values of row variables and column variables are determined by the order in which different row-block and column-block programming statements are processed. These values can be modified throughout the COMPUTAB procedure, and final values are printed in the report.

Direct Access to Table Cells

You can insert or retrieve numeric values from specific table cells using the special reserved name TABLE with row and column subscripts. References to the TABLE have the form

```
TABLE[ row-index, column-index ]
```

where *row-index* and *column-index* can be numbers, character literals, numeric variables, character variables, or expressions that produce a number or a name. If an index is numeric, it must be within range; if it is character, it must name a row or column.

References to TABLE elements can appear on either side of an equal sign in an assignment statement and can be used in a SAS expression.

Reserved Words

Certain words are reserved for special use by the COMPUTAB procedure, and using these words as variable names can lead to syntax errors or warnings. They are:

- COLUMN
- COLUMNS
- COL
- COLS
- _COL_
- ROW
- ROWS
- _ROW_
- INIT
- _N_
- TABLE

Missing Values

Missing values for variables in programming statements are treated in the same way that missing values are treated in the DATA step; that is, missing values used in expressions propagate missing values to the result. Refer to *SAS Language: Reference* for more information about missing values.

Missing values in the input data are treated as follows in the COMPUTAB report table. At the end of the input block, either one or more rows or one or more columns may have been selected to receive values from the program data vector (PDV). Numeric data values from variables in the PDV are added into selected report table rows or columns. If a PDV value is missing, the values already in the selected rows or columns for that variable are unchanged by the current observation. Other values from the current observation are added to table values as usual.

OUT= Data Set

The output data set contains the following variables:

- BY variables
- a numeric variable _TYPE_
- a character variable _NAME_
- the column variables from the COMPUTAB data table

The BY variables contain values for the current BY group. For observations in the output data set from consolidation tables, the consolidated BY variables have missing values.

The special variable _TYPE_ is a numeric variable that can have one of three values: 1, 2, or 3. _TYPE_= 1 indicates observations from the normal report table produced for each BY group; _TYPE_= 2 indicates observations from the _TOTAL_ consolidation table; _TYPE_= 3 indicates observations from other consolidation tables. _TYPE_= 2 and 3 observations have one or more BY variables with missing values.

The special variable _NAME_ is a character variable of length 8 that contains the row or column name associated with the observation from the report table. If the input data set is transposed, _NAME_ contains column names; otherwise, _NAME_ contains row names.

If the input data set is transposed, the remaining variables in the output data set are row variables from the report table. They are column variables if the input data set is not transposed.

Examples

Example 13.1. Using Programming Statements

This example illustrates two ways of operating on the same input variables and producing the same tabular report. To simplify the example, no report enhancements are shown.

The manager of a hotel chain wants a report that shows the number of bookings at its hotels in each of four cities, the total number of bookings in the current quarter, and the percentage of the total coming from each location for each quarter of the year. Input observations contain the following variables: REPTDATE (report date), LA (number of bookings in Los Angeles), ATL (number of bookings in Atlanta), CH (number of bookings in Chicago), and NY (number of bookings in New York).

The following DATA step creates the SAS data set BOOKINGS:

```
data bookings;
   input reptdate date9. la atl ch ny;
   datalines;
01JAN1989 100 110 120 130
01FEB1989 140 150 160 170
01MAR1989 180 190 200 210
01APR1989 220 230 240 250
01MAY1989 260 270 280 290
01JUN1989 300 310 320 330
01JUL1989 340 350 360 370
01AUG1989 380 390 400 410
01SEP1989 420 430 440 450
01OCT1989 460 470 480 490
01NOV1989 500 510 520 530
01DEC1989 540 550 560 570
;
```

The following PROC COMPUTAB statements select columns by setting _COL_ to an appropriate value. The PCT1, PCT2, PCT3, and PCT4 columns represent the percentage contributed by each city to the total for the quarter. These statements produce Output 13.1.1.

```
proc computab data=bookings cspace=1 cwidth=6;

   columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
   columns qtr1-qtr4 / format=6.;
   columns pct1-pct4 / format=6.2;
   rows la atl ch ny total;

   /* column selection */
   _col_ = qtr( reptdate ) * 2 - 1;

   /* copy qtr column values temporarily into pct columns */
   colcopy:
      pct1 = qtr1;
      pct2 = qtr2;
      pct3 = qtr3;
      pct4 = qtr4;

   /* calculate total row for all columns */
   /* calculate percentages for all rows in pct columns only  */
   rowcalc:
      total = la + atl + ch + ny;
      if mod( _col_, 2 ) = 0 then do;
         la  = la  / total * 100;
         atl = atl / total * 100;
         ch  = ch  / total * 100;
         ny  = ny  / total * 100;
         total = 100;
         end;
run;
```

Output 13.1.1. Quarterly Report of Hotel Bookings

```
                 QTR1   PCT1   QTR2   PCT2   QTR3   PCT3   QTR4   PCT4

       LA         420  22.58    780  23.64   1140  24.05   1500  24.27
       ATL        450  24.19    810  24.55   1170  24.68   1530  24.76
       CH         480  25.81    840  25.45   1200  25.32   1560  25.24
       NY         510  27.42    870  26.36   1230  25.95   1590  25.73
       TOTAL     1860 100.00   3300 100.00   4740 100.00   6180 100.00
```

Using the same input data, the next set of statements shows the usefulness of arrays in allowing PROC COMPUTAB to work in two directions at once. Arrays in larger programs can both reduce the amount of program source code and simplify otherwise complex methods of referring to rows and columns. The same report as in Output 13.1.1 is produced.

```
proc computab data=bookings cspace=1 cwidth=6;
```

```
      columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
      columns qtr1-qtr4 / format=6.;
      columns pct1-pct4 / format=6.2;
      rows la atl ch ny total;

      array pct[4] pct1-pct4;
      array qt[4] qtr1-qtr4;
      array rowlist[5] la atl ch ny total;

      /* column selection */
      _col_ = qtr(reptdate) * 2 - 1;

      /* copy qtr column values temporarily into pct columns */
      colcopy:
         do i = 1 to 4;
            pct[i] = qt[i];
            end;

      /* calculate total row for all columns */
      /* calculate percentages for all rows in pct columns only */

      rowcalc:
         total = la + atl + ch + ny;
         if mod(_col_,2) = 0 then
            do i = 1 to 5;
               rowlist[i] = rowlist[i] / total * 100;
            end;
   run;
```

Example 13.2. Enhancing a Report

The following example shows how a report can be enhanced from a simple listing to a complex report. The simplest COMPUTAB report is a transposed listing of the data in the SAS data set INCOMREP shown in Output 13.2.1. To produce this output, nothing is specified except the PROC COMPUTAB statement and a TITLE statement.

```
data incomrep;
   input type :$8. date :monyy7.
         sales retdis tcos selling randd
         general admin deprec other taxes;
   format date monyy7.;
datalines;
BUDGET JAN1989 4600 300 2200 480 110 500 210 14 -8 510
BUDGET FEB1989 4700 330 2300 500 110 500 200 14  0 480
BUDGET MAR1989 4800 360 2600 500 120 600 250 15  2 520
ACTUAL JAN1989 4900 505 2100 430 130 410 200 14 -8 500
ACTUAL FEB1989 5100 480 2400 510 110 390 230 15  2 490
;
title 'Computab Report without Any Specifications';
proc computab data=incomrep;
run;
```

Output 13.2.1. Simple Report

```
                    Computab Report without Any Specifications

                       COL1       COL2       COL3       COL4       COL5

         type        BUDGET     BUDGET     BUDGET     ACTUAL     ACTUAL

         sales      4600.00    4700.00    4800.00    4900.00    5100.00
         retdis      300.00     330.00     360.00     505.00     480.00
         tcos       2200.00    2300.00    2600.00    2100.00    2400.00
         selling     480.00     500.00     500.00     430.00     510.00
         randd       110.00     110.00     120.00     130.00     110.00
         general     500.00     500.00     600.00     410.00     390.00
         admin       210.00     200.00     250.00     200.00     230.00
         deprec       14.00      14.00      15.00      14.00      15.00
         other        -8.00       0.00       2.00      -8.00       2.00
         taxes       510.00     480.00     520.00     500.00     490.00
```

To exclude the budgeted values from your report, select columns for ACTUAL observations only. To remove unwanted variables, specify the variables you want in a ROWS statement.

```
title 'Column Selection by Month';

proc computab data=incomrep;
   rows sales--other;
   columns jana feba mara;
   mnth = month(date);
   if type = 'ACTUAL';
      jana = mnth = 1;
      feba = mnth = 2;
      mara = mnth = 3;
run;
```

The report is shown in Output 13.2.2.

Output 13.2.2. Report Using Column Selection Techniques

```
                            Column Selection by Month

                                  JANA       FEBA       MARA

                    sales      4900.00    5100.00       0.00
                    retdis      505.00     480.00       0.00
                    tcos       2100.00    2400.00       0.00
                    selling     430.00     510.00       0.00
                    randd       130.00     110.00       0.00
                    general     410.00     390.00       0.00
                    admin       200.00     230.00       0.00
                    deprec       14.00      15.00       0.00
                    other        -8.00       2.00       0.00
```

To complete the report, compute new rows from existing rows. This is done in a row block (although it can also be done in the input block). Add a new column (QTR1) that accumulates all the actual data. The NOZERO option suppresses the zero column for March. The output produced by these statements is shown in Output 13.2.3.

```
proc computab data=incomrep;

   /* add a new column to be selected */
   /* qtr1 column will be selected several times */
   columns actual1-actual3 qtr1 / nozero;
   array collist[3] actual1-actual3;
   rows sales retdis netsales tcos grosspft selling randd general
        admin deprec operexp operinc other taxblinc taxes netincom;

   if type='ACTUAL';
   i = month(date);
   if i <= 3 then qtr1 = 1;
   collist[i]=1;

   rowcalc:
      if sales = . then return;
      netsales = sales - retdis;
      grosspft = netsales - tcos;
      operexp  = selling + randd + general + admin + deprec;
      operinc  = grosspft - operexp;
      taxblinc = operinc + other;
      netincom = taxblinc - taxes;
run;
```

Output 13.2.3. Report Using Techniques to Compute New Rows

```
                           Column Selection by Month

                           ACTUAL1    ACTUAL2       QTR1

                 SALES     4900.00    5100.00   10000.00

Example 13.3. Comparison of Actual and Budget

This example shows a more complex report that compares the actual data with the budgeted values. The same input data as in the previous example is used.

The report produced by these statements is shown in Output 13.3.1. The report shows the values for the current month and the year-to-date totals for budgeted amounts, actual amounts, and the actuals as a percentage of the budgeted amounts. The data have the values for January and February. Therefore, the CURMO variable (current month) in the RETAIN statement is set to 2. The values for the observations where the month of the year is 2 (February) are accumulated for the Current Month values. The year-to-date values are accumulated from those observations where the month of the year is less than or equal to 2 (January and February).

```

Example 13.4. Consolidations

This example consolidates product tables by region and region tables by corporate division. Output 13.4.1 shows the North Central and Northeast regional summaries for the Equipment division for the first quarter. Output 13.4.2 shows the profit summary for the Equipment division. Similar tables for the Publishing division are produced but not shown here.

Example 13.5. Creating an Output Data Set

This example uses data and reports similar to those in Example 13.3 to illustrate the creation of an output data set.

```
data product;
   input pcode div region month sold revenue recd cost;
   datalines;
1 1 1 1 56 5600 29 2465
1 1 1 2 13 1300 30 2550
1 1 1 3 17 1700 65 5525
2 1 1 1  2  240 50 4900
2 1 1 2 82 9840 17 1666
more data lines
;

proc sort data=product out=sorted;
   by div region;
run;

/* create data set, profit */
proc computab data=sorted notrans out=profit noprint;
```

```
      by div region;
      sumby div;

      /* specify order of rows and row titles */
      row     jan feb mar qtr1;
      row     apr may jun qtr2;
      row     jul aug sep qtr3;
      row     oct nov dec qtr4;

      /* specify order of columns and column titles */
      columns sold revenue recd cost profit pctmarg;

      /* select row for appropriate month */
      _row_ = month + ceil( month / 3 ) - 1;

      /* calculate quarterly summary rows */
      rowcalc:
         qtr1 = jan + feb + mar;
         qtr2 = apr + may + jun;
         qtr3 = jul + aug + sep;
         qtr4 = oct + nov + dec;

      /* calculate profit columns */
      colcalc:
         profit = revenue - cost;
         if cost > 0 then pctmarg = profit / cost * 100;
   run;

      /* make a partial listing of the output data set */
   proc print data=profit (obs=10) noobs;
   run;
```

Since the NOTRANS option is specified, column names become variables in the data set. REGION has missing values in the output data set for observations associated with consolidation tables. The output data set PROFIT, in conjunction with the option NOPRINT, illustrates how you can use the computational features of PROC COMPUTAB for creating additional rows and columns as in a spread sheet without producing a report. Output 13.5.1 shows a partial listing of the output data set PROFIT.

Output 13.5.1. Partial Listing of the PROFIT Data Set

```

Example 13.6. A What-If Market Analysis

PROC COMPUTAB can be used with other SAS/ETS procedures and with macros to implement commonly needed decision support tools for financial and marketing analysis.

The following input data set reads quarterly sales figures:

```
data market;
   input date :yyq6. units @@;
   datalines;
1980Q1  3608.9  1980Q2  5638.4  1980Q3  6017.9  1980Q4  4929.6
1981Q1  4962.0  1981Q2  5804.6  1981Q3  5498.6  1981Q4  7687.1
1982Q1  6864.1  1982Q2  7625.8  1982Q3  7919.7  1982Q4  8294.7

;
```

PROC FORECAST makes a total market forecast for the next four quarters.

```
/* forecast the total number of units to be */
/* sold in the next four quarters */
proc forecast out=outcome trend=2 interval=qtr lead=4;
   id date;
   var units;
run;
```

The macros WHATIF and SHOW build a report table and provide the flexibility of examining alternate what-if situations. The row and column calculations of PROC COMPUTAB compute the income statement. With macros stored in a macro library, the only statements required with PROC COMPUTAB are macro invocations and TITLE statements.

```
/* set up rows and columns of report and initialize */
/* market share and program constants */
%macro whatif(mktshr=,price=,ucost=,taxrate=,numshar=,overhead=);

   columns mar / ' ' 'March';
   columns jun / ' ' 'June';
   columns sep / ' ' 'September';
   columns dec / ' ' 'December';
   columns total / 'Calculated' 'Total';

The DATASOURCE Procedure

Chapter Contents

Chapter 14
The DATASOURCE Procedure

Overview

The DATASOURCE procedure extracts time series data from many different kinds of data files distributed by various data vendors and stores them in a SAS data set. Once stored in a SAS data set, the time series variables can be processed by other SAS procedures.

The DATASOURCE procedure has statements and options to extract only a subset of time series data from an input data file. It gives you control over the frequency of data to be extracted, time series variables to be selected, cross sections to be included, and the time range of data to be output.

The DATASOURCE procedure can create auxiliary data sets containing descriptive information on the time series variables and cross sections. More specifically, the OUTCONT= data set contains information on time series variables, the OUTBY= data set reports information on the cross-sectional variables, and the OUTALL= data set combines both time series variables and cross-sectional information.

The output variables in the output and auxiliary data sets can be assigned various attributes by the DATASOURCE procedure. These attributes are labels, formats, new names, and lengths. While the first three attributes in this list are used to enhance the output, the length attribute is used to control the memory and disk-space usage of the DATASOURCE procedure.

Data files currently supported by the DATASOURCE procedure include

- U.S. Bureau of Economic Analysis data files:
  - National Income and Product Accounts tapes
  - National Income and Product Accounts diskettes
  - S-page diskettes
- U.S. Bureau of Labor Statistics data files:
  - Consumer Price Index Surveys
  - Producer Price Index Survey
  - National Employment, Hours, and Earnings Survey
  - State and Area Employment, Hours, and Earnings Survey
- Standard & Poor’s Compustat Services Financial Database Files:
  - COMPUSTAT Annual
  - COMPUSTAT 48 Quarter

- Center for Research in Security Prices (CRSP) data files:
  - Daily Binary Format Files
  - Monthly Binary Format Files
  - Daily Character Format Files
  - Monthly Character Format Files
  - Daily IBM Binary Format Files
  - Monthly IBM Binary Format Files
  - 1995 CDROM Character Format Files
  - 1995 CDROM UNIX (SUN) Binary Format Files
  - ACCESS97 CDROM Binary Format Files
- DRI/McGraw-Hill data files:
  - Basic Economics Data (formerly CITIBASE)
  - DRI Data Delivery Service files
  - Tape Format CITIBASE Data Files
  - DRI Data Delivery Service Time Series
  - PC Diskette format CITIBASE Databases
- FAME Information Services Databases
- Haver Analytics data files
- International Monetary Fund's Economic Information System data files:
  - International Financial Statistics
  - Direction of Trade Statistics
  - Balance of Payment Statistics
  - Government Finance Statistics
- Organization for Economic Cooperation and Development:
  - Annual National Accounts
  - Quarterly National Accounts
  - Main Economic Indicators

Getting Started

Structure of a SAS Data Set Containing Time Series Data

SAS procedures require time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods.

The time periods at which observations are recorded can be included in the data set as a time ID variable. The DATASOURCE procedure does include a time ID variable by the name of DATE.

For example, the following data set, extracted from a CITIBASE data file, gives the foreign exchange rates for Japan, Switzerland, and the United Kingdom, respectively.

Time ID variable	Time Series Variables		
DATE	EXRJAN	EXRSW	EXRUK
SEP1987	143.290	1.50290	164.460
OCT1987	143.320	1.49400	166.200
NOV1987	135.400	1.38250	177.540
DEC1987	128.240	1.33040	182.880
JAN1988	127.690	1.34660	180.090
FEB1988	129.170	1.39160	175.820

Figure 14.1. The Form of SAS Data Sets Required by Most SAS/ETS Procedures

Reading Data Files

The DATASOURCE procedure is designed to read data from many different files and to place them in a SAS data set. For example, if you have a DRI Basic Economics data file you want to read, use the following statements:

```
proc datasource filetype=dribasic infile=citifile out=dataset;
run;
```

Here, the FILETYPE= option indicates that you want to read DRI's Basic Economics data file, the INFILE= option specifies the fileref CITIFILE of the external file you want to read, and the OUT= option names the SAS data set to contain the time series data.

Subsetting Input Data Files

When only a subset of a data file is needed, it is inefficient to extract all the data and then subset it in a subsequent DATA step. Instead, you can use the DATASOURCE procedure options and statements to extract only needed information from the data file.

The DATASOURCE procedure offers the following subsetting capabilities:

- the INTERVAL= option controls the frequency of data output
- the KEEP or DROP statements selects a subset of time series variables
- the RANGE statement restricts the time range of data
- the WHERE statement selects a subset of cross sections

Controlling the Frequency of Data – The INTERVAL= Option

The OUT= data set can only contain data with the same frequency. If the data file you want to read contains time series data with several frequencies, you can indicate the frequency of data you want to extract with the INTERVAL= option. For example, the following statements extract all monthly time series from the DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
run;
```

When the INTERVAL= option is not given, the default frequency defined for the FILETYPE= type file is used. For example, the statements in the previous section extract yearly series since INTERVAL=YEAR is the default frequency for DRI's Basic Economic Data files.

To extract data for several frequencies, you need to execute the DATASOURCE procedure once for each frequency.

Selecting Time Series Variables – The KEEP and DROP Statements

If you want to include specific series in the OUT= data set, list them in a KEEP statement. If, on the other hand, you want to exclude some variables from the OUT= data set, list them in a DROP statement. For example, the following statements extract monthly foreign exchange rates for Japan (EXRJAN), Switzerland (EXRSW), and the United Kingdom (EXRUK) from a DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
   keep  exrjan exrsw exruk;
run;
```

The KEEP statement also allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not valid SAS name syntax, put the series name in quotes to select it. Another way to allow the use of special characters in your SAS variable names, is to use the SAS options statement to designate VALIDVARNAME= ANY. This option will allow PROC DATASOURCE to include special characters in your SAS variable names. The following is an example of extracting series from a FAME database using the DATASOURCE procedure.

```
proc datasource filetype=fame dbname='fame_nys /disk1/prc/prc'
                interval=weekday out=outds outcont=attrds;
   range '1jan90'd to '1feb90'd;
   keep cci.close
        '{ibm.high,ibm.low,ibm.close}'
        'mave(ibm.close,30)'
        'crosslist({gm,f,c},{volume})'
        'cci.close+ibm.close';
   rename 'mave(ibm.close,30)' = ibm30day
          'cci.close+ibm.close' = cci_ibm;
run;
```

The resulting output data set OUTDS contains the following series: DATE, CCI_CLOS, IBM_HIGH, IBM_LOW, IBM_CLOS, IBM30DAY, GM_VOLUM, F_VOLUME, C_VOLUME, CCI_IBM.

Obviously, to be able to use KEEP and DROP statements, you need to know the name of time series variables available in the data file. The OUTCONT= option gives you this information. More specifically, the OUTCONT= option creates a data set containing descriptive information on the same frequency time series. This descriptive information includes series names, a flag indicating if the series is selected for output, series variable types, lengths, position of series in the OUT= data set, labels, format names, format lengths, format decimals, and a set of FILETYPE= specific descriptor variables. For example, the following statements list some of the monthly series available in the CITIFILE:

```
filename citifile 'host-specific-file-name' <host-options>;
proc datasource filetype=dribasic infile=citifile
                interval=month  outcont=vars;
run;

title1 'Some Time Series Variables Available in CITIFILE';
proc print data=vars noobs;
run;
```

```
                Some Time Series Variables Available in CITIFILE

          s
          e
          l         l    v

```

Figure 14.2. Partial Listing of the OUTCONT= Data Set

Controlling the Time Range of Data – The RANGE Statement

The RANGE statement is used to control the time range of observations included in the output data set. For example, if you want to extract the foreign exchange rates from September, 1987 to February, 1988, you can use the following statements:

```
filename citifile 'host-specific-file-name' <host-options>;
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
   keep  exrjan exrsw exruk;
   range from 1987:9 to 1988:2;
run;

title1 'Printout of the OUT= Data Set';
proc print data=dataset noobs;
run;
```

```
                    Printout of the OUT= Data Set

                  date      exrjan      exrsw       exruk

                SEP1987     143.290     1.50290     164.460
                OCT1987     143.320     1.49400     166.200
                NOV1987     135.400     1.38250     177.540
                DEC1987     128.240     1.33040     182.880
                JAN1988     127.690     1.34660     180.090
                FEB1988     129.170     1.39160     175.820
```

Figure 14.3. Subset Obtained by KEEP and RANGE Statements

Reading in Data Files Containing Cross Sections

Some data files group time series data with respect to cross-section identifiers; for example, International Financial Statistics files, distributed by IMF, group data with respect to countries (COUNTRY). Within each country, data are further grouped by Control Source Code (CSC), Partner Country Code (PARTNER), and Version Code (VERSION).

If a data file contains cross-section identifiers, the DATASOURCE procedure adds them to the output data set as BY variables. For example, the data set in Table 14.1 contains three cross sections:

- the first one is identified by (COUNTRY='112' CSC='F' PARTNER=' ' VERSION='Z')
- the second one is identified by (COUNTRY='146' CSC='F' PARTNER=' ' VERSION='Z')
- the third one is identified by (COUNTRY='158' CSC='F' PARTNER=' ' VERSION='Z').

Table 14.1. The Form of a SAS Data Set Containing BY Variables

BY Variables				Time ID Variable	Time Series Variables	
COUNTRY	CSC	PARTNER	VERSION	DATE	EFFEXR	EXRINDEX
112	F		Z	SEP1987	9326	12685
112	F		Z	OCT1987	9393	12813
112	F		Z	NOV1987	9626	13694
112	F		Z	DEC1987	9675	14099
112	F		Z	JAN1988	9581	13910
112	F		Z	FEB1988	9493	13549
146	F		Z	SEP1987	12046	16192
146	F		Z	OCT1987	12067	16266
146	F		Z	NOV1987	12558	17596
146	F		Z	DEC1987	12759	18301
146	F		Z	JAN1988	12642	18082
146	F		Z	FEB1988	12409	17470
158	F		Z	SEP1987	13841	16558
158	F		Z	OCT1987	13754	16499
158	F		Z	NOV1987	14222	17505
158	F		Z	DEC1987	14768	18423
158	F		Z	JAN1988	14933	18565
158	F		Z	FEB1988	14915	18331

Note that the data sets in Figure 14.1 and Table 14.1 are two different ways of representing the same data, namely foreign exchange rates for three different countries: the United Kingdom (COUNTRY='112'), Switzerland (COUNTRY='146') and Japan (COUNTRY='158'). The first representation (Figure 14.1) incorporates country names into the series names, while the second representation (Table 14.1) represents countries as different cross sections. See "Time Series and SAS Data Sets" in Chapter 2, "Working with Time Series Data."

Obtaining Descriptive Information on Cross Sections

If you want to know the unique set of values BY variables assume for each cross section in the data file, use the OUTBY= option. For example, the following statements list some of the cross sections available for an IFS file.

```
filename ifsfile 'host-specific-file-name' <host-options>;
proc datasource filetype=imfifsp infile=ifsfile
                interval=month outby=xsection;
run;

title1 'Some Cross Sections Available in IFSFILE';
proc print data=xsection noobs;
run;
```

```
                    Some Cross Sections Available in IFSFILE

                                     e
  c      p   v        s          n              n   n
  o      a   e        t          d              s   s  c
  u      r   r        _          _    n         e   e  _
  n      t   s        d          d    t    n    r   l  n
  t  c   n   i        a          a    i    o    i   e  a
  r  s   e   o        t          t    m    b    e   c  m
  y  c   r   n        e          e    e    s    s   t  e

Figure 14.4. Partial Listing of the OUTBY= Data Set

The OUTBY= data set reports the total number of series, NSERIES, defined in each cross section, NSELECT of which represent the selected variables. If you want to see the descriptive information on each of these NSELECT variables for each cross section, specify the OUTALL= option. For example, the following statements print descriptive information on the eight series defined for cross section (COUNTRY='1' CSC='T' PARTNER=' ' and VERSION='Z'):

```
filename ifsfile 'host-specific-file-name' <host-options>;
proc datasource filetype=imfifsp infile=ifsfile interval=month
                outall=ifsall;
run;

title1 'Time Series Defined in Cross Section';
title2 "COUNTRY='1'  CSC='T'  PARTNER=' '  VERSION='Z'";
proc print data=ifsall noobs;
   where country='1' and csc='T' and  partner=' ' and version='Z';
run;
```

```
                   Time Series Defined in Cross Section
              COUNTRY='1'  CSC='T'  PARTNER=' '  VERSION='Z'

Figure 14.5. Partial Listing of the OUTALL= Data Set

The OUTCONT= data set contains one observation for each time series variable with the descriptive information summarized over BY groups. When the data file contains no cross sections, the OUTCONT= and OUTALL= data sets are equivalent, except that the OUTALL= data set also reports time ranges for which data are available. The OUTBY= data set in this case contains a single observation reporting the number of series and time ranges for the whole data file.

Subsetting a Data File Containing Cross Sections

Data files containing cross sections can be subsetted by controlling which cross sections to include in the output data set. Selecting a subset of cross sections is accomplished using the WHERE statement. The WHERE statement gives a condition the BY variables must satisfy for a cross section to be selected. For example, the following statements extract the monthly effective exchange rate (F_X_AM) and exchange rate index (F_X_AF) for the United Kingdom (COUNTRY='112'), Switzerland (COUNTRY='146'), and Japan (COUNTRY='158') for the period from September, 1987 to February, 1988.

```
filename ifsfile 'host-specific-file-name' <host-options>;
proc datasource filetype=imfifsp infile=ifsfile interval=month
                out=exchange;
   where country in ('112','146','158') and partner=' ';
   keep  f_x_ah f_x_am;
   range from '01sep87'd to '01feb88'd;
run;

title1 'Printout of the OUT= Data Set';
proc print data=exchange noobs;
run;
```

Renaming Time Series Variables

Sometimes the time series variable names as given by data vendors are not descriptive enough, or you may prefer a different naming convention. In such cases, you can use the RENAME statement to assign more meaningful names to time series variables. You can also use LABEL statements to associate descriptive labels with your series variables.

For example, the series names for effective exchange rate (F_X_AM) and exchange rate index (F_X_AH) used by IMF can be given more descriptive names and labels by the following statements:

```
filename ifsfile 'host-specific-file-name' <host-options>;
proc datasource filetype=imfifsp infile=ifsfile interval=month
                out=exchange outcont=exchvars;
   where country in ('112','146','158') and partner=' ';
   keep  f_x_ah f_x_am;
   range from '01jun87'd to '01feb88'd;
   rename  f_x_ah=exrindex  f_x_am=effexr;
   label   f_x_ah='F_X_AH: Exchange Rate Index 1985=100'
           f_x_am='F_X_AM: Effective Exchange Rate(MERM)';
run;

title1 'Printout of OUTCONT= Showing New NAMEs and LABELs';
proc print data=exchvars noobs;
   var  name label length;
run;

title1 'Contents of OUT= Showing New NAMEs and LABELs';
proc contents data=exchange;
run;
```

The RENAME statement allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not valid SAS name syntax, use the SAS option VALIDVARNAME= ANY or put the series name in quotes to rename it. See the FAME example using rename in the "Selecting Time Series Variables – The KEEP and DROP Statements" section (page 648).

```
                Printout of OUTCONT= Showing New NAMEs and LABELs

             name                       label                    length

           EFFEXR      F_X_AM: Effective Exchange Rate(MERM)       5
           EXRINDEX    F_X_AH: Exchange Rate Index 1985=100        5
```

```

Figure 14.6. Renaming and Labeling Variables

Notice that even though you changed the names of F_X_AH and F_X_AM to EXRINDEX and EFFEXR, respectively, you still used their old names in the KEEP and LABEL statements because renaming takes place at the output stage.

Changing the Lengths of Numeric Variables

The length attribute indicates the number of bytes the SAS System uses for storing the values of variables in output data sets. Therefore, the shorter the variable lengths, the more efficient the disk-space usage. However, there is a trade-off. The lengths of numeric variables are closely tied to their precision, and reducing their lengths arbitrarily can cause precision loss.

The DATASOURCE procedure uses default lengths for series variables appropriate to each file type. For example, the default lengths for numeric variables are 5 for IMFIFSP type files. In some cases, however, you may want to assign different lengths. Assigning lengths less than the defaults reduces memory and disk-space usage at the expense of reduced precision. Specifying lengths longer than the defaults increases the precision but causes the DATASOURCE procedure to use more memory and disk space. The following statements define a default length of 4 for all numeric variables in the IFSFILE and then assign a length of 6 to the exchange rate index:

```
filename ifsfile ’host-specific-file-name’ <host-options>;
proc datasource filetype=imfifsp infile=ifsfile interval=month
                out=exchange outcont=exchvars;
   where country in (’112’,’146’,’158’) and partner=’   ’;
   keep  f_x_am f_x_ah;
   range from ’01jun87’d to ’01feb88’d;
   rename  f_x_ah=exrindex  f_x_am=effexr;
   label   f_x_ah=’F_X_AH: Exchange Rate Index 1985=100’
           f_x_am=’F_X_AM: Effective Exchange Rate(MERM)’;
   length _numeric_ 4; length f_x_ah 6;
run;

title1 ’Printout of OUTCONT= Showing LENGTH Variable’;
proc print data=exchvars noobs;
   var  name label length;
run;

title1 ’Contents of the OUT= Data Set Showing LENGTHs’;
proc contents data=exchange;
run;
```

```
                  Printout of OUTCONT= Showing LENGTH Variable

      name                        label                        length

    EFFEXR      F_X_AM: Effective Exchange Rate(MERM)            4
    EXRINDEX    F_X_AH: Exchange Rate Index 1985=100             6
```

Figure 14.7. Changing the Lengths of Numeric Variables

The default lengths of the character variables are set to the minimum number of characters that can hold the longest possible value.

Syntax

The DATASOURCE procedure uses the following statements:

> **PROC DATASOURCE** *options***;**
>   **KEEP** *variable-list***;**
>   **DROP** *variable-list***;**
>   **KEEPEVENT** *event-list***;**
>   **DROPEVENT** *event-list***;**
>   **WHERE** *where-expression***;**
>   **RANGE FROM** *from* **TO** *to***;**
>   **ATTRIBUTE** *variable-list attribute-list* . . . **;**
>   **FORMAT** *variable-list format* . . . **;**
>   **LABEL** *variable="label"* . . . **;**
>   **LENGTH** *variable-list length* . . . **;**
>   **RENAME** *old-name=new-name* . . . **;**

The PROC DATASOURCE statement is required. All the rest of the statements are optional.

The DATASOURCE procedure uses two kinds of statements:

1. subsetting statements, which control what time series, time periods, and cross sections are extracted from the input data file
2. attribute statements, which control the attributes of the variables in the output SAS data set

The subsetting statements are the KEEP, DROP, KEEPEVENT, and DROPEVENT statements (which select output variables); the RANGE statement (which selects time ranges); and the WHERE statement (which selects cross sections). The attribute statements are the ATTRIBUTE, FORMAT, LABEL, LENGTH, and RENAME statements.

The statements and options used by PROC DATASOURCE are summarized in Table 14.2.

Table 14.2. Summary of Syntax

Description	Statement	Option
Input Data File Options		
specify the character set of the incoming	PROC DATASOURCE	ASCII
data	PROC DATASOURCE	EBCDIC

Description	Statement	Option
specify the type of input data file to read	PROC DATASOURCE	FILETYPE=
specify the fileref(s) of the input data file(s)	PROC DATASOURCE	INFILE=
specify the lrecl(s) of the input data files(s)	PROC DATASOURCE	LRECL=
specify the recfm(s) of the input data files(s)	PROC DATASOURCE	RECFM=
Output Data Set Options		
write the extracted time series data	PROC DATASOURCE	OUT=
output the descriptive information on the time series variables and cross sections	PROC DATASOURCE	OUTALL=
output the descriptive information on the cross sections	PROC DATASOURCE	OUTBY=
output the descriptive information on the time series variables	PROC DATASOURCE	OUTCONT=
write event-oriented data	PROC DATASOURCE	OUTEVENT=
control whether all or only selected series and cross sections be reported	PROC DATASOURCE	OUTSELECT=
create single indexes from BY variables for the OUT= data set	PROC DATASOURCE	INDEX
control the alignment of SAS Date values	PROC DATASOURCE	ALIGN=
Subsetting		
specify the periodicity of series to be extracted	PROC DATASOURCE	INTERVAL=
specify the time series variables to be included in the OUT= data set	KEEP	
specify the time series variables to be excluded from the OUT= data set	DROP	
specify the events to be included in the OUTEVENT= data set	KEEPEVENT	
specify the events to be excluded from the OUTEVENT= data set	DROPEVENT	
select cross sections for output	WHERE	
specify the time range of observations to be output	RANGE	

Description	**Statement**	**Option**
Assigning Attributes		
assign formats to the output variables	FORMAT	
	ATTRIBUTE	FORMAT=
assign labels to variables in the output data sets	LABEL	
	ATTRIBUTE	LABEL=
control the lengths of the output variables	LENGTH	
	ATTRIBUTE	LENGTH=
assign new names to the output variables	RENAME	

PROC DATASOURCE Statement

PROC DATASOURCE *options;*

The following options can be used in the PROC DATASOURCE statement:

ALIGN= *option*
: controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

ASCII
: specifies the incoming data is ascii. This option is needed when the native character set of your host machine is ebcdic.

DBNAME= **'***database name***'**
: specifies the FAME database to access. Only use this option with the filetype=FAME option. The character string you specify on the DBNAME= option is passed through to FAME. Specify the value of this option as you would in accessing the database from within FAME software.

EBCDIC
: specifies the incoming data is ebcdic. This option is needed when the native character set of your host machine is ascii.

FAMEPRINT
: prints the FAME command file generated by PROC DATASOURCE and the log file produced by the FAME component of the interface system. Only use this option with the filetype=FAME option.

FILETYPE= *entry*
DBTYPE= *dbtype*
: specifies the kind of input data file to process. See the "Supported File Types" section on page 677 for a list of supported file types. The FILETYPE= option is required.

INDEX
: creates a set of single indexes from BY variables for the OUT= data set. Under some circumstances, creating indexes for a SAS data set may increase the efficiency in

locating observations when BY or WHERE statements are used in subsequent steps. Refer to *SAS Language: Reference, Version 7, First Edition* for more information on SAS indexes. The INDEX option is ignored when no OUT= data set is created or when the data file does not contain any BY variables. The INDEX= data set option can be used to override the index variable definitions.

INFILE= *fileref*
INFILE= *(fileref1 fileref2 ... filerefn)*
specifies the *fileref* assigned to the input data file. The default value is DATAFILE. The fileref used in INFILE= option (or if no INFILE= option is specified, the fileref DATAFILE) must be associated with the physical data file in a FILENAME statement. (On some operating systems, the fileref assignment can be made with the system's control language, and a FILENAME statement may not be needed. Refer to *SAS Language: Reference Version 7, First Edition* for more details on the FILENAME statement). Physical data files can reside on tapes, disks, diskettes, CD-ROM, or other media.

For some file types, the data are distributed over several files. In this case, the INFILE= option is required, and it lists in parentheses the filerefs for each of the files making up the database. The order in which these FILEREFS are listed is important and must conform to the specifics of each file type as explained in the "Supported File Types" section on page 677.

LRECL= *lrecl*
LRECL= *(lrecl1 lrecl2 ... lrecln)*
The logical record length in bytes of the infile. Only use this if you need to override the default LRECL of the file. For some file types, the data are distributed over several files. In this case, the LRECL= option lists in parentheses the LRECLS for each of the files making up the database. The order in which these lrecls are listed is important and must conform to the specifics of each file type as explained in the "Supported File Types" section on page 677.

RECFM= *recfm*
RECFM= *(recfm1 recfm2 ... recfmn)*
The record format of the infile. Only use this if you need to override the default record format of the file. For some file types, the data are distributed over several files. In this case, the RECFM= option lists in parentheses the recfms for each of the files making up the database. The order in which these RECFMS are listed is important and must conform to the specifics of each file type as explained in the "Supported File Types" section on page 677. The possible values of RECFM are:

- F or FIXED for fixed length records
- N or BIN for binary records
- D or VAR for varying length records
- U or DEF for host default record format
- DOM_V or DOMAIN_VAR or BIN_V or BIN_VAR for unix binary record format

INTERVAL= *interval*
FREQUENCY= *interval*
TYPE= *interval*

specifies the periodicity of series selected for output to the OUT= data set. The OUT= data set created by PROC DATASOURCE can contain only time series with the same periodicity. Some data files contain time series with different periodicities; for example, a file may contain both monthly series and quarterly series. Use the INTERVAL= option to indicate which periodicity you want. If you want to extract series with different periodicities, use different PROC DATASOURCE invocations with the desired INTERVAL= options.

Common values for INTERVAL= are YEAR, QUARTER, MONTH, WEEK, and DAY. The values allowed, as well as the default value of the INTERVAL= option, depend on the file type. See the "Supported File Types" section on page 677 for the INTERVAL= values appropriate to the data file type you are reading.

OUT= *SAS-data-set*

names the output data set for the time series extracted from the data file. If none of the output data set options are specified, including the OUT= data set itself, an OUT= data set is created and named according to the DATA*n* convention. However, when you create any of the other output data sets, such as OUTCONT=, OUTBY=, OUTALL=, or OUTEVENT=, you must explicitly specify the OUT= data set; otherwise, it will not be created. See the "OUT= Data Set" section on page 672 for further details.

OUTALL= *SAS-data-set*

writes information on the contents of the input data file to an output data set. The OUTALL= data set includes descriptive information, time ranges, and observation counts for all the time series within each BY group. By default, no OUTALL= data set is created.

The OUTALL= data set contains the Cartesian product of the information output by the OUTCONT= and OUTBY= options. In data files for which there are no cross sections, the OUTALL= and OUTCONT= data sets are almost equivalent, except that OUTALL= data set also reports time ranges and observation counts of series. See the "OUTALL= Data Set" section on page 675 for further details.

OUTBY= *SAS-data-set*

writes information on the BY variables to an output data set. The OUTBY= data set contains the list of cross sections in the database delimited by the unique set of values that the BY variables assume. Unless the OUTSELECT=OFF option is present, only the selected BY groups get written to the OUTBY= data set. If you omit the OUTBY= option, no OUTBY= data set is created. See the "OUTBY= Data Set" section on page 674 for further details.

OUTCONT= *SAS-data-set*

writes information on the contents of the input data file to an output data set. By default, the OUTCONT= data set includes descriptive information on all of the unique series of the selected periodicity in the data file. When the OUTSELECT=OFF option is omitted, the OUTCONT= data set includes observations only for the series selected for output to the OUT= data set. By default, no OUTCONT= data set is created. See the "OUTCONT= Data Set" section on page 673 for further details.

OUTEVENT= *SAS-data-set*
names the output data set to output event-oriented time series data. This option can only be used when CRSP stock files are being processed. For all other file types, it will be ignored. See the "OUTEVENT= Data Set" section on page 676 for further details.

OUTSELECT= ON | OFF
determines whether to output all observations (OUTSELECT=OFF) or only those corresponding to the selected time series and selected BY groups (OUTSELECT=ON) to OUTCONT=, OUTBY=, and OUTALL= data sets. The default is OUTSELECT=ON. The OUTSELECT= option is only relevant when any one of the auxiliary data sets is specified. The option writes observations to OUTCONT=, OUTBY=, and OUTALL= data sets for only the selected time series and selected BY groups if it is set ON. The OUTSELECT= option is only relevant when any one of the OUTCONT=, OUTBY= and OUTALL= options are specified. The default is OUTSELECT=ON.

KEEP Statement

KEEP *variable-list;*

The KEEP statement specifies which variables in the data file are to be included in the OUT= data set. Only the time series and event variables can be specified in a KEEP statement. All the BY variables and the time ID variable DATE are always included in the OUT= data set; they cannot be referenced in a KEEP statement. If they are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See the section "Variable Lists" on page 670 for details.

There is a default KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you give a KEEP statement, the default list becomes undefined.

Only one KEEP or one DROP statement can be used. KEEP and DROP are mutually exclusive.

You can also use the KEEP= data set option to control which variables to include in the OUT= data set. However, the KEEP statement differs from the KEEP= data set option in several aspects:

- The KEEP statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the KEEP statement instead of the KEEP= data set option is much more efficient.
- If the KEEP statement causes no series variables to be selected, then no observations are output to the OUT= data set.

- The KEEP statement variable specifications are applied to each cross section independently. This behavior may produce different variables than those produced by the KEEP= data set option when order-range variable list specifications are used.

DROP Statement

DROP *variable-list;*

The DROP statement specifies that some variables be excluded from the OUT= data set. Only the time series and event variables can be specified in a DROP statement. None of the BY variables or the time ID variable DATE can be excluded from the OUT= data set. If they are referenced in a DROP statement, a warning message is given and the reference is ignored. Use the WHERE statement for selection based on BY variables, and use the RANGE statement for date selections.

The variable list can contain variable names or name range specifications. See the section "Variable Lists" on page 670 for details.

Only one DROP or one KEEP statements can be used. KEEP and DROP are mutually exclusive.

There is a default KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you specify a DROP statement, the default list becomes undefined.

You can also use the DROP= data set option to control which variables to exclude from the OUT= data set. However, the DROP statement differs from the DROP= data set option in several aspects:

- The DROP statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the DROP statement instead of the DROP= data set option is much more efficient.
- If the DROP statement causes all series variables to be excluded, then no observations are output to the OUT= data set.
- The DROP statement variable specifications are applied to each cross section independently. This behavior may produce different variables than those produced by the DROP= data set option when order-range variable list specifications are used.

KEEPEVENT Statement

KEEPEVENT *variable-list;*

The KEEPEVENT statement specifies which event variables in the data file are to be included in the OUTEVENT= data set. As a result, the KEEPEVENT statement is valid only for data files containing event-oriented time series data, that is, only for CRSP files. All the BY variables, the time ID variable DATE and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables can not be referenced in the KEEPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See the section "Variable Lists" on page 670 for details.

Only one KEEPEVENT or one DROPEVENT statement can be used. KEEPEVENT and DROPEVENT are mutually exclusive.

You can also use the KEEP= data set option to control which event variables to include in the OUTEVENT= data set. However, the KEEPEVENT statement differs from the KEEP= data set option in several aspects:

- The KEEPEVENT statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the KEEPEVENT statement instead of the KEEP= data set option is much more efficient.
- If the KEEPEVENT statement causes no event variables to be selected, then no observations are output to the OUTEVENT= data set.

DROPEVENT Statement

DROPEVENT *variable-list;*

The DROPEVENT statement specifies that some event variables be excluded from the OUTEVENT= data set. As a result, the DROPEVENT statement is valid only for data files containing event-oriented time series data, that is, only for CRSP files. All the BY variables, the time ID variable DATE, and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables cannot be referenced in the DROPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The variable list can contain variable names or name range specifications. See the section "Variable Lists" on page 670 for details.

Only one DROPEVENT or one KEEPEVENT statement can be used. DROPEVENT and KEEPEVENT are mutually exclusive.

You can also use the DROP= data set option to control which event variables to exclude from the OUTEVENT= data set. However, the DROPEVENT statement differs from the DROP= data set option in several aspects:

- The DROPEVENT statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the DROPEVENT statement instead of the DROP= data set option is much more efficient.
- If the DROPEVENT statement causes all series variables to be excluded, then no observations are output to the OUTEVENT= data set.

WHERE Statement

WHERE *where-expression;*

The WHERE statement specifies conditions that BY variables must satisfy in order for a cross section to be included in the OUT= and OUTEVENT= data sets. By default, all BY groups are selected.

The *where-expression* must refer only to BY variables defined for the file type you are reading. The section "Supported File Types" on page 677 lists the names of the BY variables for each file type.

For example, DOTS (Direction of Trade Statistics) files, distributed by International Monetary Fund, have four BY variables: COUNTRY, CSC, PARTNER, and VERSION. Both COUNTRY and PARTNER are three-digit country codes. To select the direction of trade statistics of the United States (COUNTRY='111') with Turkey (COUNTRY='186'), Japan (COUNTRY='158'), and the oil exporting countries group (COUNTRY='985'), you should specify

```
where country='111' and partner in ('186','158','985');
```

You can use any SAS language operators and special WHERE expression operators in the WHERE statement condition. Refer to *SAS Language: Reference, Version 7, First Edition* for a more detailed discussion of WHERE expressions.

If you want to see the names of the BY variables and the values they assume for each cross section, you can first run PROC DATASOURCE with only the OUTBY= option. The information contained in the OUTBY= data set will aid you in selecting the appropriate BY groups for subsequent PROC DATASOURCE steps.

RANGE Statement

RANGE FROM *from* **TO** *to;*

The RANGE statement selects the time range of observations written to the OUT= and OUTEVENT= data sets. The *from* and *to* values can be SAS date, time, or datetime constants, or they can be specified as *year* or *year***:***period*, where *year* is a two-digit or four-digit year, and *period* (when specified) is a period within the year corresponding to the INTERVAL= option. (For example, if INTERVAL=QTR, then *period* refers to quarters.) When *period* is omitted, the beginning of the year is assumed for the *from* value, and the end of the year is assumed for the *to* value.

If a 2-digit year is specified, PROC DATASOURCE complies to year 2000 guidelines by using the current value of the YEARCUTOFF option to determine the century of your data. Warnings are issued in the SAS log whenever DATASOURCE needs to determine the century from a 2-digit year specification.

The default YEARCUTOFF is 1920. To use a different yearcutoff, specify

```
options yearcutoff=yyyy;
```

where yyyy is the yearcutoff you want to use. See the *SAS Language: Reference, Version 7, First Edition* for a more detailed discussion of the YEARCUTOFF option.

Both the FROM and TO specifications are optional, and both the FROM and TO keywords are optional. If the FROM limit is omitted, the output observations start with the minimum date for which data is available for any selected series. Similarly, if the TO limit is omitted, the output observations end with the maximum date for which data are available.

The following are some examples of RANGE statements:

```
range from 1980 to 1990;
range 1980 - 1990;
range from 1980;
range 1980;
range to 1990;
range to 1990:2;
range from ’31aug89’d to ’28feb1990’d;
```

The RANGE statement applies to each BY group independently. If all the selected series contain no data in the specified range for a given BY group, then there will be no observations for that BY group in the OUT= and OUTEVENT= data sets.

If you want to know the time ranges for which periodic time series data is available, you can first run PROC DATASOURCE with the OUTBY= or OUTALL= options. OUTBY= data set reports the union of the time ranges over all the series within each BY group, while the OUTALL= data set gives time ranges for each series separately in each BY group.

ATTRIBUTE Statement

ATTRIBUTE *variable-list attribute-list ... ;*

The ATTRIBUTE statement assigns formats, labels, and lengths to variables in the output data sets.

The *variable-list* can contain variable names and variable name range specifications. See the section “Variable Lists” on page 670 for details. The attributes specified in the following attribute list apply to all variables in the variable list:

An *attribute-list* consists of one or more of the following options:

FORMAT= *format*
associates a format with variables in *variable-list*. The *format* can be either a standard SAS format or a format defined with the FORMAT procedure. The default formats for variables depend on the file type.

LABEL= *"label"*
assigns a label to the variables in the variable list. The default labels for variables depend on the file type. Labels can be up to 256 bytes in length.

LENGTH= *length*
specifies the number of bytes used to store the values of variables in the variable list.

The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes. (For CRSP files, the default lengths are 6 bytes).

The length specification also controls the amount of memory that PROC DATASOURCE uses to hold variable values while processing the input data file. Thus, specifying a LENGTH= value smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of reduced precision of output data values.

FORMAT Statement

FORMAT *variable-list format ... ;*

The FORMAT statement assigns formats to variables in output data sets. The *variable-list* can contain variable names and variable name range specifications. See the section "Variable Lists" on page 670 for details. The format specified applies to all variables in the variable list.

A single FORMAT statement can assign the same format to several variables or different formats to different variables. The FORMAT statement can use standard SAS formats or formats defined using the FORMAT procedure.

Any later format specification for a variable, using either the FORMAT statement or the FORMAT= option in the ATTRIBUTE statement, always overrides the previous one.

LABEL Statement

LABEL *variable = "label" ... ;*

The LABEL statement assigns SAS variable labels to variables in the output data sets. You can give labels for any number of variables in a single LABEL statement. The default labels for variables depend on the file type. Extra long labels (> 256 bytes) reside in the OUTCONT data set as the DESCRIPT variable.

Any later label specification for a variable, using either the LABEL statement or the LABEL= option in the ATTRIBUTE statement, always overrides the previous one.

LENGTH Statement

LENGTH *variable-list length ... ;*

The LENGTH statement, like the LENGTH= option in the ATTRIBUTE statement, specifies the number of bytes used to store values of variables in output data sets. The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes. (For CRSP files, the default lengths are 6 bytes).

The default lengths of character variables are defined as the minimum number of characters that can hold the longest possible value.

For some file types, the LENGTH statement also controls the amount of memory used to store values of numeric variables while processing the input data file. Thus, specifying LENGTH values smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of reduced precision of output data values.

Any later length specification for a variable, using either the LENGTH statement or the LENGTH= option in the ATTRIBUTE statement, always overrides the previous one.

RENAME Statement

RENAME *old-name = new-name ... ;*

The RENAME statement is used to change the names of variables in the output data sets. Any number of variables can be renamed in a single RENAME statement. The most recent RENAME specification overrides any previous ones for a given variable. The new-name is limited to thirty-two characters.

Renaming of variables is done at the output stage. Therefore, you need to use the old variable names in all other PROC DATASOURCE statements. For example, the series variable names DATA1-DATA350 used with annual COMPUSTAT files are not very descriptive, so you may choose to rename them to reflect the financial aspect they represent. You may rename "DATA51" to "INVESTTAX" with the RENAME statement

```
rename data51=investtax;
```

since it contains investment tax credit data. However, in all other DATASOURCE statements, you must use the old name, DATA51.

Details

Variable Lists

Variable lists used in PROC DATASOURCE statements can consist of any combination of variable names and name range specifications. Items in variable lists can have the following forms:

- a name, for example, PZU.
- an alphabetic range *name1-name2*. For example, A-DZZZZZZZ specifies all variables with names starting with A, B, C, or D.
- a prefix range *prefix*:. For example, IP: selects all variables with names starting with the letters IP.
- an order range *name1--name2*. For example, GLR72--GLRD72 specifies all variables in the input data file between GLR72 and GRLD72 inclusive.
- a numeric order range *name1*-NUMERIC-*name2*. For example, GLR72-NUMERIC-GLRD72 specifies all numeric variables between GLR72 and GRLD72 inclusive.

- a character order range *name1*-CHARACTER-*name2*. For example, GLR72-CHARACTER-GLRD72 specifies all character variables between GLR72 and GRLD72 inclusive.
- one of the keywords _NUMERIC_, _CHARACTER_, or _ALL_. _NUMERIC_ specifies all numeric variables. _CHARACTER_ specifies all character variables. _ALL_ specifies all variables.

To determine the order of series in a data file, run PROC DATASOURCE with the OUTCONT= option, and print the output data set. Note that order and alphabetic range specifications are inclusive, meaning that the beginning and ending names of the range are also included in the variable list.

For order ranges, the names used to define the range must actually name variables in the input data file. For alphabetic ranges, however, the names used to define the range need not be present in the data file.

Note that variable specifications are applied to each cross section independently. This may cause the order-range variable list specification to behave differently than its DATA step and data set option counterparts. This is because PROC DATASOURCE knows which variables are defined for which cross sections, while the DATA step applies order range specification to the whole collection of time series variables.

If the ending variable name in an order range specification is not in the current cross section, all variables starting from the beginning variable to the last variable defined in that cross section get selected. If the first variable is not in the current cross section, then order range specification has no effect for that cross section.

The variable names used in variable list specifications can refer to either series names appearing in the input data file or to the SAS names assigned to series data fields internally if the series names are not recorded to the INFILE= file. When the latter is the case, internally defined variable names are listed in the section "Data Files" later in this chapter.

The following are examples of the use of variable lists:

```
keep  ip: pw112-pw117 pzu;
drop  data1-data99  data151-data350;
length data1-numeric-aftnt350  ucode 4;
```

The first statement keeps all the variables starting with IP:, all the variables between PW112 and PW117 including the PW112 and PW117 themselves, and a single variable PZU. The second statement drops all the variables that fall alphabetically between DATA1 and DATA99, and DATA151 and DATA350. Finally, the third statement assigns a length of 4 bytes to all the numeric variables defined between DATA1 and AFTNT350, and UCODE.

OUT= Data Set

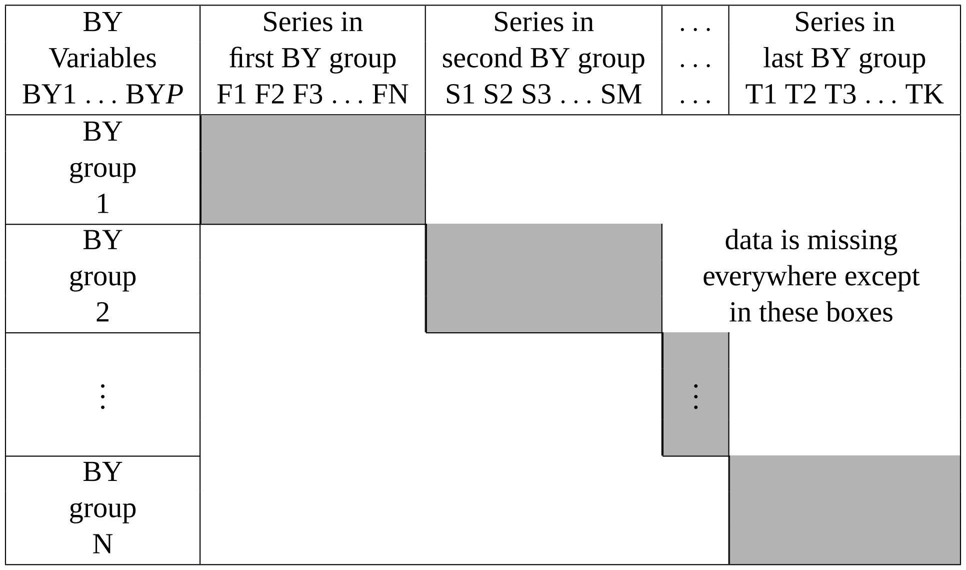
The OUT= data set can contain the following variables:

- the BY variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the BY variables. Use the BY variables in a WHERE statement to process the OUT= data set by cross sections. The order in which BY variables are defined in the OUT= data set corresponds to the order in which the data file is sorted.
- DATE, a SAS date-, time-, or datetime- valued variable that reports the time period of each observation. The values of the DATE variable may span different time ranges for different BY groups. The format of the DATE variable depends on the INTERVAL= option.
- the periodic time series variables, which are included in the OUT= data set only if they have data in at least one selected BY group and they are not discarded by a KEEP or DROP statement
- the event variables, which are included in the OUT= data set if they are not discarded by a KEEP or DROP statement. By default, these variables are not output to OUT= data set.

The values of BY variables remain constant in each cross section. Observations within each BY group correspond to the sampling of the series variables at the time periods indicated by the DATE variable.

You can create a set of single indexes for the OUT= data set by using the INDEX option, provided there are BY variables. Under some circumstances, this may increase the efficiency of subsequent PROC and DATA steps that use BY and WHERE statements. However, there is a cost associated with creation and maintenance of indexes. The *SAS Language: Reference, Version 7, First Edition* lists the conditions under which the benefits of indexes outweigh the cost.

With data files containing cross sections, there can be various degrees of overlap among the series variables. One extreme is when all the series variables contain data for all the cross sections. In this case, the output data set is very compact. In the other extreme case, however, the set of time series variables are unique for each cross section, making the output data set very sparse, as depicted in Figure 14.8.



BY Variables BY1 . . . BY*P*
Series in first BY group F1 F2 F3 . . . FN
Series in second BY group S1 S2 S3 . . . SM
. . .
Series in last BY group T1 T2 T3 . . . TK
BY group 1
BY group 2
⋮
BY group N
data is missing everywhere except in these boxes

Figure 14.8. The OUT= Data Set containing unique Series for each BY Group

The data in Figure 14.8 can be represented more compactly if cross-sectional information is incorporated into series variable names.

OUTCONT= Data Set

The OUTCONT= data set contains descriptive information for the time series variables. This descriptive information includes various attributes of the time series variables. The OUTCONT= data set contains the following variables:

- NAME, a character variable that contains the series name.
- KEPT, a numeric variable that indicates whether the series was selected for output by the DROP or KEEP statements, if any. KEPT will usually be the same as SELECTED, but may differ if a WHERE statement is used.
- SELECTED, a numeric variable that indicates whether the series is selected for output to the OUT= data set. The series is included in the OUT= data set (SELECTED=1) if it is kept (KEPT=1) and it has data for at least one selected BY group.
- TYPE, a numeric variable that indicates the type of the time series variable. TYPE=1 for numeric series; TYPE=2 for character series.
- LENGTH, a numeric variable that gives the number of bytes allocated for the series variable in the OUT= data set.
- VARNUM, a numeric variable that gives the variable number of the series in the OUT= data set. If the series variable is not selected for output (SELECTED=0), then VARNUM has a missing value. Likewise, if no OUT= option is given, VARNUM has all missing values.
- LABEL, a character variable that contains the label of the series variable. LABEL contains only the first 256 characters of the labels. If they are longer

than 256 characters, then the variable, DESCRIPT, is defined to hold the whole length of series labels. Note that if a data file assigns different labels to the same series variable within different cross sections, only the first occurrence of labels will be transferred to the LABEL column.

- the variables FORMAT, FORMATL, and FORMATD, which give the format name, length, and number of format decimals, respectively.
- the GENERIC variables, whose values may vary from one series to another, but whose values remain constant across BY groups for the same series.

By default, the OUTCONT= data set contains observations for only the selected series, that is, for series where SELECTED=1. If the OUTSELECT=OFF option is specified, the OUTCONT= data set contains one observation for each unique series of the specified periodicity contained in the input data file.

If you do not know what series are in the data file, you can run PROC DATASOURCE with the OUTCONT= option and OUTSELECT=OFF. The information contained in the OUTCONT= data set can then help you to determine which time series data you want to extract.

OUTBY= Data Set

The OUTBY= data set contains information on the cross sections contained in the input data file. These cross sections are represented as BY groups in the OUT= data set. The OUTBY= data set contains the following variables:

- the BY variables, whose values identify the different cross sections in the data file. The BY variables depend on the file type.
- BYSELECT, a numeric variable that reports the outcome of the WHERE statement condition for the BY variable values for this observation. The value of BYSELECT is 1 for BY groups selected by the WHERE statement for output to the OUT= data set and is 0 for BY groups that are excluded by the WHERE statement. BYSELECT is added to the data set only if a WHERE statement is given. When there is no WHERE statement, then all the BY groups are selected.
- ST_DATE, a numeric variable that gives the starting date for the BY group. The starting date is the earliest of the starting dates of all the series that have data for the current BY group.
- END_DATE, a numeric variable that gives the ending date for the BY group. The ending date is the latest of the ending dates of all the series that have data for the BY group.
- NTIME, a numeric variable that gives the number of time periods between ST_DATE and END_DATE, inclusive. Usually, this is the same as NOBS, but they may differ when time periods are not equally spaced and when the OUT= data set is not specified. NTIME is a maximum limit on NOBS.
- NOBS, a numeric variable that gives the number of time series observations in OUT= data set between ST_DATE and END_DATE, inclusive. When a given

BY group is discarded by a WHERE statement, the NOBS variable corresponding to this BY group becomes 0, since the OUT= data set does not contain any observations for this BY group. Note that BYSELECT=0 for every discarded BY group.

- NINRANGE, a numeric variable that gives the number of observations in the range (*from,to*) defined by the RANGE statement. This variable is only added to the OUTBY= data set when the RANGE statement is specified.
- NSERIES, a numeric variable that gives the total number of unique time series variables having data for the BY group.
- NSELECT, a numeric variable that gives the total number of selected time series variables having data for the BY group.
- the generic variables, whose values remain constant for all the series in the current BY group.

In this list, you can only control the attributes of the BY and GENERIC variables.

The variables NOBS, NTIME, and NINRANGE give observation counts, while the variables NSERIES and NSELECT give series counts.

By default, observations for only the selected BY groups (where BYSELECT=1) are output to the OUTBY= data set, and the date and time range variables are computed over only the selected time series variables. If the OUTSELECT=OFF option is specified, the OUTBY= data set contains an observation for each BY group, and the date and time range variables are computed over all the time series variables.

For file types that have no BY variables, the OUTBY= data set contains one observation giving ST_DATE, END_DATE, NTIME, NOBS, NINRANGE, NSERIES, and NSELECT for all the series in the file.

If you do not know the BY variable names or their possible values, you can do an initial run of PROC DATASOURCE with the OUTBY= option. The information contained in the OUTBY= data set can help you design your WHERE expression and RANGE statement for the subsequent executions of PROC DATASOURCE to obtain different subsets of the same data file.

OUTALL= Data Set

The OUTALL= data set combines and expands the information provided by the OUTCONT= and OUTBY= data sets. That is, the OUTALL= data set not only reports the OUTCONT= information separately for each BY group, but also reports the OUTBY= information separately for each series. Each observation in the OUTBY= data set gets expanded to NSERIES or NSELECT observations in the OUTALL= data set, depending on whether the OUTSELECT=OFF option is specified.

By default, only the selected BY groups and series are included in the OUTALL= data set. If the OUTSELECT=OFF option is specified, then all the series within all the BY groups are reported.

The OUTALL= data set contains all the variables defined in the OUTBY= and OUTCONT= data sets and also contains the GENERIC variables (whose values may vary from one series to another and also from one BY group to another). Another additional variable is BLKNUM, which gives the data block number in the data file containing the series variable.

The OUTALL= data set is useful when BY groups do not contain the same time series variables or when the time ranges for series change across BY groups.

You should be careful in using the OUTALL= option, since the OUTALL= data set can get very large for many file types. Some file types have the same series and time ranges for each BY group; the OUTALL= option should not be used with these file types. For example, you should not specify the OUTALL= option with COMPUSTAT files, since all the BY groups contain the same series variables.

The OUTALL= and OUTCONT= data sets are equivalent when there are no BY variables, except that the OUTALL= data set contains extra information about the time ranges and observation counts of the series variables.

OUTEVENT= Data Set

The OUTEVENT= data set is used to output event-oriented time series data. Events occurring at discrete points in time are recorded along with the date they occurred. Only CRSP stock files contain event-oriented time series data. For all other types of files, the OUTEVENT= option is ignored.

The OUTEVENT= data set contains the following variables:

- the BY variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the BY variables. Use the BY variables in a WHERE statement to process the OUTEVENT= data set by cross sections. The order in which BY variables are defined in the OUTEVENT= data set corresponds to the order in which the data file is sorted.
- DATE, a SAS date-, time- or datetime- valued variable that reports the discrete time periods at which events occurred. The format of the DATE variable depends on the INTERVAL= option, and should accurately report the date based on the SAS YEARCUTOFF option. The default value for YEARCUTOFF is 1920. The dates used may span up to 250 years.
- EVENT, a character variable that contains the event group name. The EVENT variable is another cross-sectional variable.
- the event variables, included in the OUTEVENT= data set only if they have data in at least one selected BY group, are not discarded by a KEEPEVENT or DROPEVENT statement.

Note that each event group contains a nonoverlapping set of event variables; therefore, the OUTEVENT= data set is very sparse. You should exercise care when selecting event variables to be included in the OUTEVENT= data set.

Also note that even though the OUTEVENT= data set can not contain any periodic time series variables, the OUT= data set can contain event variables if they are explicitly specified in a KEEP statement. In other words, you can specify event variables in a KEEP statement, but you cannot specify periodic time series variables in a KEEPEVENT statement.

While variable selection for OUT= and OUTEVENT= data sets are controlled by a different set of statements (KEEP versus KEEPEVENT or DROP versus DROPEVENT), cross-section and range selections are controlled by the same statements. In other words, the WHERE and the RANGE statements are effective for both output data sets.

Supported File Types

PROC DATASOURCE can process only certain kinds of data files. For certain time series databases, the DATASOURCE procedure has built-in information on the layout of files comprising the database. PROC DATASOURCE knows how to read only these kinds of data files. To access these databases, you must indicate the data file type in the FILETYPE= option. For more detailed information, see the corresponding document for each filetype. See the section "References" on page 729.

The currently supported file types are summarized in Table 14.3.

S&P	Standard & Poor's Compustat Services Inc.

BEA Data Files

The Bureau of Economic Analysis, U.S. Department of Commerce, supplies national income, product accounting, and various other macro economic data at the regional, national, and international levels in the form of data files with various formats and on various media.

The following BEA data file types are supported:

FILETYPE=BEANIPA–National Income and Product Accounts Tape Format

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1-9 (character)
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1-24 (character)
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

FILETYPE=BEANIPAD–National Income and Product Accounts Diskette Format

The diskette format National Income and Product Accounts files contain the same information as the tape format files described previously.

Data Files	Database is stored in a single diskette file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1-9 (character)
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1-24 (character)
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

BLS Data Files

The Bureau of Labor Statistics, U.S. Department of Labor, compiles and distributes data on employment, expenditures, prices, productivity, injuries and illnesses, and wages.

The following BLS file types are supported:

FILETYPE=BLSCPI–Consumer Price Index Surveys (=CU,CW)

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR, SEMIYEAR1.6, MONTH (default)	
BY variables	SURVEY	Survey type: CU=All Urban Consumers, CW=Urban Wage Earners and Clerical Workers (character)
	SEASON	Seasonality: S=Seasonally adjusted, U=Unadjusted (character)
	AREA	Geographic Area (character)

	EE53	Spendable Average Weekly Earnings; No Dependents; Base 1977 Dollars
	EE54	Spendable Average Weekly Earnings; 3 Dependents; Current Dollars
	EE55	Spendable Average Weekly Earnings; 3 Dependents; Base 1977 Dollars
	EE60	Average Hourly Earnings Excluding Overtime
	EE61	Index of Diffusion; 1-month Span; Base 1977
	EE62	Index of Diffusion; 3-month Span; Base 1977
	EE63	Index of Diffusion; 6-month Span; Base 1977
	EE64	Index of Diffusion; 12-month Span; Base 1977
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

FILETYPE=BLSEESA–State and Area Employment, Hours, and Earnings Survey

Data Files	Database is stored in a single tape file.	
INTERVAL=	YEAR, MONTH (default)	
BY variables	STATE	State FIPS codes (numeric)
	AREA	Area Codes (character)
	DIVISION	Major Industrial Division (character)
	INDUSTRY	Industry Code (character)
	DETAIL	Private/Government Detail
Sorting Order	BY STATE AREA DIVISION INDUSTRY DETAIL	
Series Variables	Series variable names are the same as data type codes prefixed by SA.	
	SA1	All employees
	SA2	Women workers
	SA3	Production Workers
	SA4	Average weekly earnings
	SA5	Average weekly hours
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

DRI/McGraw-Hill Data Files

The DRIBASIC (formerly CITIBASE) database contains economic and financial indicators of the U.S. and international economies gathered from various government and private sources by DRI/McGraw-Hill, Inc. There are over 8000 yearly, quarterly, monthly, weekly, and daily time series.

DRI/McGraw-Hill distributes Basic Economic data files on various media. DRI also offers Data Delivery Service (DDS)data files via DRIPRO’s data retrieval software called Xtract. Most DDS data files can be read by DATASOURCE using the DRIDDS filetype.

The following DRI file types are supported:

FILETYPE=DRIBASIC–DRI Basic Economic Data Files

Data Files	Database is stored in a single file.
INTERVAL=	YEAR (default), QUARTER, MONTH, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY
BY variables	None
Series Variables	Variable names are taken from the series descriptor records in the data file . Note that series codes can be 20 bytes.
Missing Codes	MISSING=(’1.000000E9’=. ’NA’-’ND’=.)

Note that when you specify the INTERVAL=WEEK option, all the weekly series will be aggregated, and the DATE variable in the OUT= data set will be set to the date of Sundays. The date of first observation for each series is the Sunday marking the beginning of the week that contains the starting date of that variable.

FILETYPE=DRIDDS–DRI Data Delivery Service Data Files

Data Files	Database is stored in a single file.
INTERVAL=	YEAR (default), SEMIYEAR, QUARTER, MONTH, SEMIMONTH, TENDAY, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY, DAY
BY variables	None
Series Variables	Variable names are taken from the series descriptor records in the data file . Note that series names can be 24 bytes.
Missing Codes	MISSING=(’NA’-’ND’=.)

FILETYPE=CITIOLD–Old format CITIBASE data files

This file type is used for CITIBASE data tapes distributed prior to May, 1987.

Data Files	Database is stored in a single file.
INTERVAL=	YEAR (default), QUARTER, MONTH
BY variables	None
Series Variables	Variable names are taken from the series descriptor records in the data file and are the same as the series codes reported in the *CITIBASE Directory*.
Missing Codes	1.0E9=.

FILETYPE=CITIDISK–PC Diskette Format CITIBASE Databases

Data Files	Database is stored in groups of three associated files having the same file name but different extensions: KEY, IND, or DB. The INFILE= option should contain three filerefs in the following order: INFILE=(*keyfile indfile dbfile*)
INTERVAL=	YEAR (default), QUARTER, MONTH
BY variables	None
Series Variables	Series variable names are the same as series codes reported in the *CITIBASE Directory*.
Missing Codes	1.0E9=.

COMPUSTAT Data Files

COMPUSTAT data files, distributed by Standard and Poor's Compustat Services, Inc., consist of a collection of financial, statistical, and market information covering several thousand industrial and nonindustrial companies. Data are available in both an IBM 360/370 format and a "Universal Character" format, both of which further subdivide into annual and quarterly formats.

The BY variables are used to select individual companies or a group of companies. Individual companies can be selected by their unique six-digit CUSIP issuer code (CNUM). A number of specific groups of companies can be extracted from the tape by the following key fields:

FILE	specifies the file identification code used to group companies by files
ZLIST	specifies the exchange listing code that can be used to group companies by exchange
DNUM	is used to extract companies in a specific SIC industry group

Series names are internally constructed from the data array names documented in the COMPUSTAT manual. Each column of data array is treated as a SAS variable. The names of these variables are generated by concatenating the corresponding column numbers to the array name.

Missing values use four codes. Missing code '.C' represents a combined figure where the data item has been combined into another data item, '.I' reports an insignificant figure, '.S' represents a semi-annual figure in the second and fourth quarters, '.A' represents an annual figure in the fourth quarter, and '.' indicates that the data item is not available. The missing codes '.C' and '.I' are not used for Aggregate or Prices, Dividends, and Earnings (PDE) files. The missing codes '.S' and '.A' are used only on the Industrial Quarterly File and not on the Aggregate Quarterly, Business Information, or PDE files.

FILETYPE=CSAIBM–COMPUSTAT Annual, IBM 360/370 Format

FILETYPE=CSAIY2–Four-Digit Year COMPUSTAT Annual, IBM 360/370 Format

CRSP Stock Files

The Center for Research in Security Prices provides comprehensive security price data through two primary stock files, the NYSE/AMEX file and the NASDAQ file. These files are composed of master and return components, available separately or combined. CRSP stock files are further differentiated by the frequency at which prices and returns are reported, daily or monthly. Both daily and monthly files contain annual data fields.

CRSP data files come either in binary or character tape format, or in CRSPAccess CDROM format. See Chapter 5, “The SASECRSP Interface Engine,” for more about accessing your CRSPAccess database. Use the Datasource procedure for serial access of the tape file formats.

CRSP stock data are provided in two files, a main data file containing security information and a calendar/indices file containing a list of trading dates and market information associated with those trading dates. If security data do not fit on one tape, they are split into two or more files, each one of which resides on a different self-contained tape. The calendar/indices file is on the first tape only.

The file types for CRSP stock files are constructed by concatenating CRSP with a D or M to indicate the frequency of data, followed by B,C, or I to indicate file formats. B is for host binary, C is for character, and I is for IBM binary formats. The last character in the file type indicates if you are reading the Calendar/Indices file (I), or if you are extracting the security (S) or annual data (A). For example, the file type for the daily NYSE/AMEX combined tape in IBM binary format is CRSPDIS. Its calendar/indices file can be read by CRSPDII, and its annual data can be extracted by CRSPDIA.

Starting in 1995, binary data tapes use split records (RICFAC=2) so the 1995 filetypes (CR95*) should be used for 1995 and 1996 binary data.

If you use utility routines supplied by CRSP to convert a character format file to a binary format file on a given host, then you need to use host binary file types (RIDFAC=1) to read those files in. Note that you can not do the conversion on one host and transfer and read the file on another host.

If you are using the CRSP Access97 Database, you will need to use the utility routine (stk_dump_bin) supplied by CRSP to generate the UNIX binary format of the data. You can access the UNIX (or SUN) binary data by using PROC DATASOURCE with the CRSPDUS for daily or CRSPMUS for monthly stock data. See the example on Example 14.11 later in this chapter.

For the four-digit year data, use the Y2K compliant filetypes for that data type.

For CRSP file types, the INFILE= option must be of the form

```
   INFILE=( calfile security1 < security2 ... > )
```

where *calfile* is the fileref assigned to the calendar/indices file, and *securty1* < *securty2* ... > are the filerefs given to the security files, in the order in which they should be read.

CRSP Calendar/Indices Files

Data Files	Database is stored in a single file.	
INTERVAL=	DAY	for products DA, DR, DX, EX, NX and RA
	MONTH	for products MA, MX and MZ

BY variables	None

FAME Information Services Databases

The DATASOURCE procedure provides access to FAME Information Services databases for UNIX-based systems only. For a more flexible FAME database access use the SASEFAME interface engine in Chapter 6, "The SASEFAME Interface Engine," which is supported for Release 8.2 on Windows, Solaris2, AIX, and HP-UX hosts. SASEFAME for Version 9 supports Windows, Solaris 8, AIX, LINUX, and DEC/OSF Digital UNIX.

The DATASOURCE interface to FAME requires a component supplied by FAME Information Services, Inc. Once this FAME component is installed on your system, you can use the DATASOURCE procedure to extract data from your FAME databases as follows:

- Specify FILETYPE=FAME on the PROC DATASOURCE statement.
- Specify the FAME database to access with a DBNAME='*fame-database*' option on the PROC DATASOURCE statement. The character string you specify

on the DBNAME= option is passed through to FAME; specify the value of this option as you would in accessing the database from within FAME software.

- Specify the output SAS data set to be created, the frequency of the series to be extracted, and other usual DATASOURCE procedure options as appropriate.
- Specify the time range to extract with a RANGE statement. The RANGE statement is required when extracting series from FAME databases.
- Specify the FAME series to be extracted with a KEEP statement. The items on the KEEP statement are passed through to FAME software; therefore, you can use any valid FAME expression to specify the series to be extracted. Put in quotes any FAME series name or expression that is not a valid SAS name.
- Specify the SAS variable names you want to use for the extracted series on a RENAME statement. Give the FAME series name or expression (in quotes if needed) followed by an equal sign and the SAS name. The RENAME statement is not required; however, if the FAME series name is not a valid SAS variable name, the DATASOURCE procedure will construct a SAS name by translating and truncating the FAME series name. This process may not produce the desired name for the variable in the output SAS data set, so a rename statement could be used to produce a more appropriate variable name. The VALIDVARNAME=ANY option on your SAS options statement can be used to allow special characters in the SAS variable name.

For an alternative solution to PROC DATASOURCE's access to FAME, see "The SASEFAME Interface Engine" in Chapter 6, "The SASEFAME Interface Engine."

	WEEK2.13	correspond to FAME's BIWEEKLY(BTHURSDAY)
	WEEK2.14	correspond to FAME's BIWEEKLY(BFRIDAY)
	WEEKDAY, DAY	are supported frequencies
BY variables	None	
Series Variables	Variable names are constructed from the FAME series codes. Note that series names are limited to 32 bytes.	

Haver Analytics Data Files

Haver Analytics offers a broad range of economic, financial, and industrial data for the U.S. and other countries. See "The SASEHAVR Interface Engine" in Chapter 7, "The SASEHAVR Interface Engine," for accessing your HAVER DLX database. SASEHAVR for Version 9 is experiemental and is supported on Windows only. Use the DATASOURCE procedure for serial access of the tape file formats. The tape format of Haver Analytics data files is similar to the CITIBASE format.

FILETYPE=HAVER–Haver Analytics Data Files HAVERO–Old format Haver Files

Data Files	Database is stored in a single file.
INTERVAL=	YEAR (default), QUARTER, MONTH
BY variables	1.0E9=.
Series Variables	Variable names are taken from the series descriptor records in the data file. NOTE: HAVER filetype reports the UPDATE and SOURCE in the OUTCONT= data set, while HAVERO does not.
Missing Codes	1.0E9=.

IMF Data Files

The International Monetary Fund's Economic Information System (EIS) offers tape subscriptions for their International Financial Statistics (IFS), Direction of Trade Statistics (DOTS), Balance of Payment Statistics (BOPS), and the Government Finance Statistics (GFS) databases. The first three contain annual, quarterly, and monthly data, while the GFS file has only annual data.

IMF data tapes are available for IBM mainframe systems (EBCDIC character coding) in both a packed and an unpacked format. PROC DATASOURCE supports only the packed format at this time.

FILETYPE=IMFIFSP–International Financial Statistics, Packed format

The IFS data files contain over 23,000 time series including interest and exchange rates, national income and product accounts, price and production indexes, money and banking, export commodity prices, and balance of payments for nearly 200 countries and regional aggregates.

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	COUNTRY	Country Code (character, three-digits)
	CSC	Control Source Code (character)
	PARTNER	Partner Country Code (character, three-digits)
	VERSION	Version Code (character)
Sorting Order	BY COUNTRY CSC PARTNER VERSION	
Series Variables	Series variable names are the same as series codes reported in *IMF Documentation* prefixed by F for data and F_F for footnote indicators.	
Default KEEP List	By default all the footnote indicators will be dropped.	

FILETYPE=IMFDOTSP–Direction of Trade Statistics, Packed Format

The DOTS files contain time series on the distribution of exports and imports for about 160 countries and country groups by partner country and areas.

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	COUNTRY	Country Code (character, three-digits)
	CSC	Control Source Code (character)
	PARTNER	Partner Country Code (character, three-digits)
	VERSION	Version Code (character)
Sorting Order	BY COUNTRY CSC PARTNER VERSION	
Series Variables	Series variable names are the same as series codes reported in *IMF Documentation* prefixed by D for data and F_D for footnote indicators.	
Default KEEP List	By default all the footnote indicators will be dropped.	

FILETYPE=IMFBOPSP–Balance of Payment Statistics, Packed Format

The BOPS data files contain approximately 43,000 time series on balance of payments for about 120 countries.

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	COUNTRY	Country Code (character, three-digits)
	CSC	Control Source Code (character)
	PARTNER	Partner Country Code (character, three-digits)
	VERSION	Version Code (character)
Sorting Order	BY COUNTRY CSC PARTNER VERSION	
Series Variables	Series variable names are the same as series codes reported in *IMF Documentation* prefixed by B for data and F_B for footnote indicators.	
Default KEEP List	By default all the footnote indicators will be dropped.	

FILETYPE=IMFGFSP–Government Finance Statistics, Packed Format

The GFS data files encompass approximately 28,000 time series that give a detailed picture of federal government revenue, grants, expenditures, lending minus repayment financing and debt, and summary data of state and local governments, covering 128 countries.

Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY variables	COUNTRY	Country Code (character, three-digits)
	CSC	Control Source Code (character)
	PARTNER	Partner Country Code (character, three-digits)
	VERSION	Version Code (character)
Sorting Order	BY COUNTRY CSC PARTNER VERSION	
Series Variables	Series variable names are the same as series codes reported in *IMF Documentation* prefixed by G for data and F_G for footnote indicators.	
Default KEEP List	By default all the footnote indicators will be dropped.	

OECD Data Files

The Organization for Economic Cooperation and Development compiles and distributes statistical data, including National Accounts and Main Economic Indicators.

FILETYPE=OECDANA–Annual National Accounts

The ANA data files contain both main national aggregates accounts (Volume I) and detailed tables for each OECD Member country (Volume II).

Data Files	Database is stored on a single tape file.	
INTERVAL=	YEAR (default), SEMIYR1.6, QUARTER, MONTH, WEEK, WEEKDAY	
BY variables	PREFIX	Table number prefix (character)
	CNTRYZ	Country Code (character)
Series Variables	Series variable names are the same as the mnemonic name of the element given on the element 'E' record. They are taken from the 12 byte time series 'T' record time series indicative.	

```
rename p0discgdpe=p0digdpe;
rename doll2gdpe=dol2gdpe;
rename doll3gdpe=dol3gdpe;
rename doll1gdpe=dol1gdpe;
rename ppp1gdpd=pp1gdpd;
rename ppp1gdpd1=pp1gdpd1;
rename p0itxgdpc=p0itgdpc;
rename p0itxgdps=p0itgdps;
rename p0subgdpc=p0sugdpc;
rename p0subgdps=p0sugdps;
rename p0cfcgdpc=p0cfgdpc;
rename p0cfcgdps=p0cfgdps;
rename p0discgdpc=p0dicgdc;
rename p0discgdps=p0dicgds;
```

Missing Codes	A data value of * is interpreted as MISSING.

FILETYPE=OECDQNA–Quarterly National Accounts

The QNA file contains the main aggregates of quarterly national accounts for 16 OECD Member Countries and on a selected number of aggregates for 4 groups of member countries: OECD-Total, OECD-Europe, EEC, and the 7 major countries.

Data Files	Database is stored on a single file.	
INTERVAL=	QUARTER(default),YEAR	
BY variables	COUNTRY	Country Code (character)
	SEASON	Seasonality S=Seasonally adjusted 0=raw data, not seasonally adjusted
	PRICETAG	Prices C=data at current prices R,L,M=data at constant prices P,K,J,V=implicit price index or volume index
Series Variables	Subject code used to distinguish series within countries. Series variables are prefixed by _ for data, C for control codes, and D for relative date.	
Default DROP List	By default all the control codes and relative dates will be dropped.	
Missing Codes	A data value of + or - is interpreted as MISSING.	

FILETYPE=OECDMEI–Main Economic Indicators

The MEI file contains all series found in Parts 1 and 2 of the publication *Main Economic Indicators*.

Data Files	Database is stored on a single file.	
INTERVAL=	YEAR(default),QUARTER,MONTH	
BY variables	COUNTRY	Country Code (character)
	CURRENCY	Unit of expression of the series.
	ADJUST	Adjustment 0,H,S,A,L=no adjustment 1,I=calendar or working day adjusted 2,B,J,M=seasonally adjusted by National Authorities 3,K,D=seasonally adjusted by OECD
Series Variables	Series variables are prefixed by _ for data, C for control codes, and D for relative date in weeks since last updated.	
Default DROP List	By default, all the control codes and relative dates will be dropped.	
Missing Codes	A data value of + or - is interpreted as MISSING.	

Examples

Example 14.1. BEA National Income and Product Accounts

In this example, exports and imports of goods and services are extracted to demonstrate how to work with a National Income and Product Accounts Tape file.

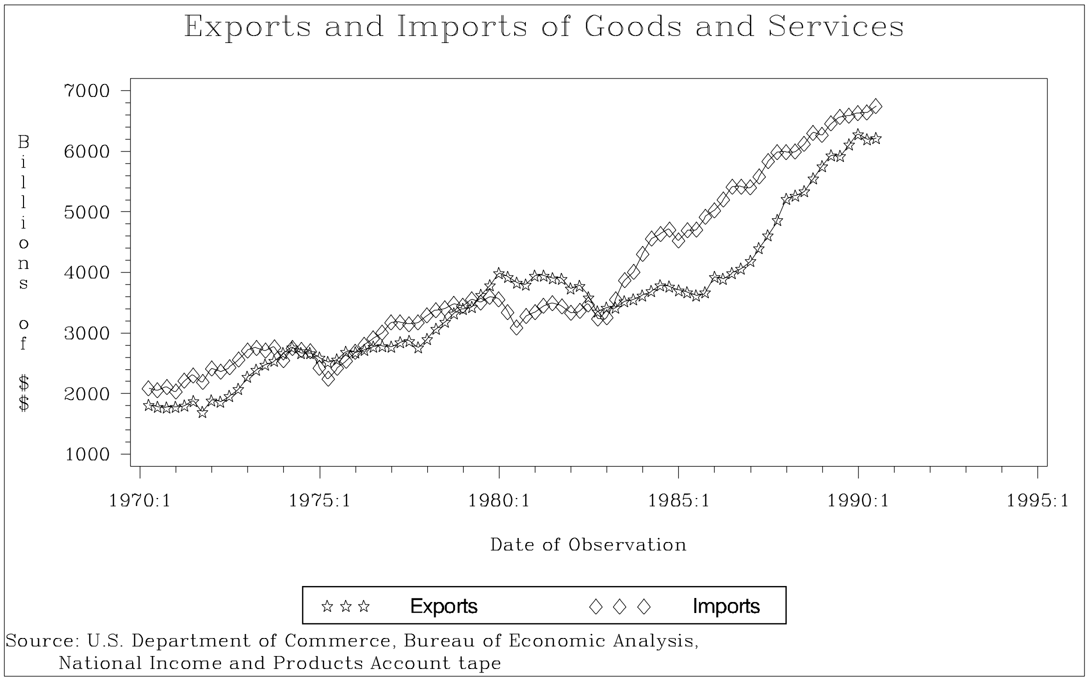
From the "Statistical Tables" published by the United States Department of Commerce, Bureau of Economic Analysis, exports and imports of goods and services are given in the second table (TABNUM='02') of the "Foreign Transactions" section (PARTNO='4'). This table does not have any table suffix A or B. Moreover, the first line in the table gives exports, while the eighth gives imports. Therefore, the series names for exports and imports are __00100 and __00800, where the first underscore is inserted by the procedure, the second underscore is the place holder for the table suffix, the following three-digits are the line numbers, and the last two-digits are the column numbers.

The following statements put this information together to extract quarterly exports and imports from a BEANIPA type file:

```
filename  datafile 'host-specific-path-name' host-options;
proc datasource filetype=beanipa infile=datafile
                interval=qtr out=foreign;
   keep __00100 __00800;
   where partno='4' and tabnum='02';
   label __00100='Exports of Goods and Services';
   label __00800='Imports of Goods and Services';
   rename __00100=exports __00800=imports;
run;
```

The plot of EXPORTS and IMPORTS against DATE is shown in Output 14.1.1.

Output 14.1.1. Plot of Time Series in the OUT= Data Set for FILETYPE=BEANIPA



This example illustrates the following features:

- You need to know the series variables names used by a particular vendor in order to construct the KEEP statement.
- You need to know the BY variable names and their values for the required cross sections.
- You can use RENAME and LABEL statements to associate more meaningful names and labels with your selected series variables.

Example 14.2. BLS Consumer Price Index Surveys

This example compares changes of the prices in medical care services with respect to different regions for all urban consumers (SURVEY='CU') since May, 1975. The source of data is the Consumer Price Index Surveys distributed by the U.S. Department of Labor, Bureau of Labor Statistics.

An initial run of PROC DATASOURCE gives the descriptive information on different regions available (the OUTBY= data set), as well as the series variable name corresponding to medical care services (the OUTCONT= data set).

```
filename datafile 'host-specific-file-name' <host-options>;
proc datasource filetype=blscpi interval=month
                outby=cpikey outcont=cpicont;
   where survey='CU';
run;
```

```
title1 'Partial Listing of the OUTBY= Data Set';
proc print data=cpikey noobs;
   where upcase(areaname) in
         ('NORTHEAST','NORTH CENTRAL','SOUTH','WEST');
run;

title1 'Partial Listing of the OUTCONT= Data Set';
proc print data=cpicont noobs;
   where index( upcase(label), 'MEDICAL CARE' );
run;
```

The OUTBY= data set in Output 14.2.1 lists all cross sections available for the four geographical regions: Northeast (AREA='0100'), North Central (AREA='0200'), Southern (AREA='0300'), and Western (AREA='0400'). The OUTCONT= data set gives the variable names for medical care related series.

Output 14.2.1. Partial Listings of the OUTBY= and OUTCONT= Data Sets

```
                    Partial Listing of the OUTBY= Data Set

1  123    ALL URBAN CONSUM    NORTHEAST        CUUR0100SA512         1
2  123    ALL URBAN CONSUM    NORTH CENTRAL    CUUR0200SA512         1
3  123    ALL URBAN CONSUM    SOUTH            CUUR0300SA512         1
4  123    ALL URBAN CONSUM    WEST             CUUR0400SA512         1
```

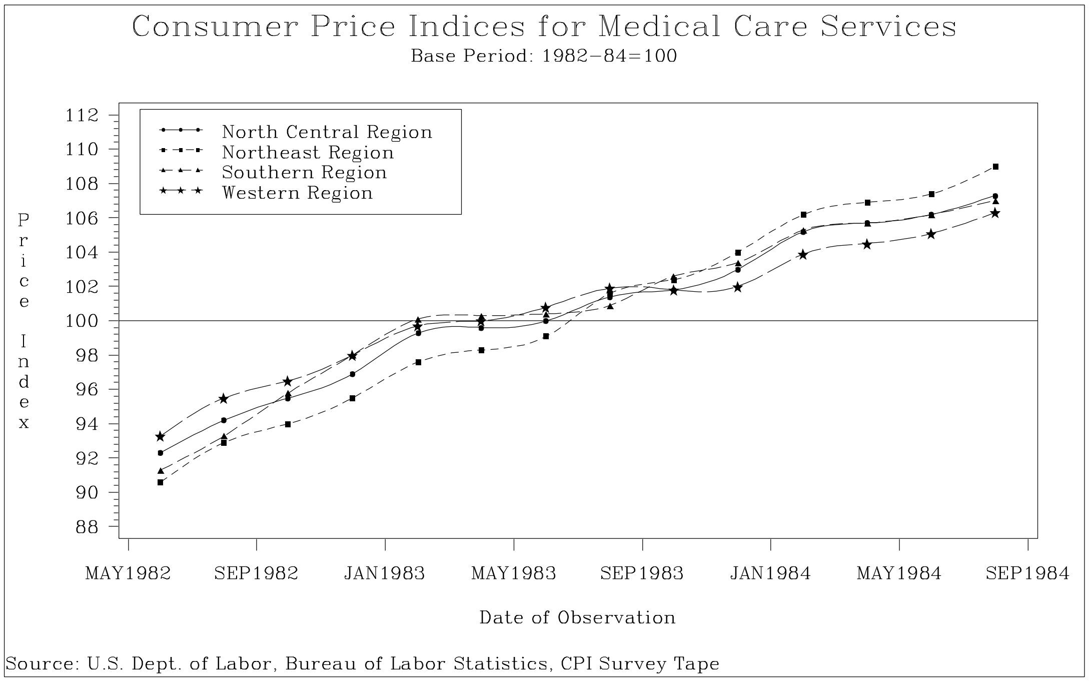
Note that only the cross sections with BASEPER='1982-84=100' are listed in the OUTALL= data set (see Output 14.2.2). This is because only those cross sections contain data for MEDCARE.

The OUTALL= data set indicates that data values are stored with one decimal place (see the NDEC variable). Therefore, they need to be rescaled, as follows:

```
data medical;
   set medical;
   medcare = medcare * 0.1;
run;
```

The variation of MEDCARE against DATE with respect to different geographic regions can be demonstrated graphically, as follows:

Output 14.2.3. Plot of Time Series in the OUT= Data Set for FILETYPE=BLSCPI



This example illustrates the following features:

- Descriptive information needed to write KEEP and WHERE statements can be obtained with an initial run of the DATASOURCE procedure.
- The OUTCONT= and OUTALL= data sets may contain information on how data values are stored, such as the precision, the units, and so on.
- The OUTCONT= and OUTALL= data sets report the new series names assigned by the RENAME statement, not the old names (see the NAME variable in Output 14.2.2).
- You can use PROC FORMAT to define formats for series or BY variables to enhance your output. Note that PROC DATASOURCE associated a permanent format, $AREAFMT., with the BY variable AREA. As a result, the formatted values are displayed in the printout of the OUTALL=MEDINFO data set (see Output 14.2.2) and in the legend created by PROC GPLOT.
- The base period for all the geographical areas is the same (BASEPER='1982-84=100') as indicated by the intersections of plots with the horizontal reference line drawn at 100. This makes comparisons meaningful.

Example 14.3. BLS State and Area, Employment, Hours and Earnings Surveys

This example illustrates how to extract specific series from a State and Area, Employment, Hours and Earnings Survey. The series to be extracted is total employment in manufacturing industries with respect to states as of March, 1990.

The State and Area, Employment, Hours and Earnings survey designates the totals for manufacturing industries by DIVISION='3', INDUSTRY='0000', and DETAIL='1'. Also, statewide figures are denoted by AREA='0000'.

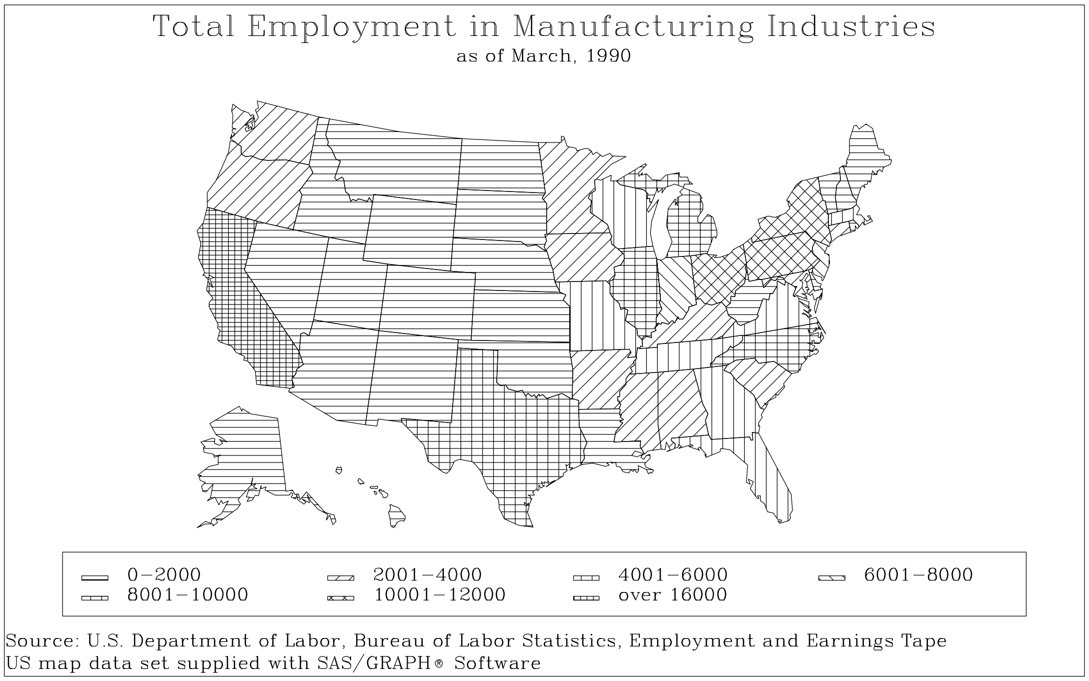
The data type code for total employment is reported to be 1. Therefore, the series name for this variable is SA1, since series names are constructed by adding an SA prefix to the data type codes given by BLS.

The following statements extract statewide figures for total employment (SA1) in manufacturing industries for March, 1990:

```
filename datafile 'host-specific-file-name' <host-options>;
proc datasource filetype=blseesa out=totemp;
   where division='3' and industry='0000' and detail='1' and
         area='0000';
   keep sa1;
   range from 1990:3 to 1990:3;
   rename sa1=totemp;
run;
```

Variations of women workers in manufacturing industries with respect to states can best be demonstrated on a map of the United States, as shown in Output 14.3.1.

Output 14.3.1. Map of the Series in the OUT= Data Set for FILETYPE=BLSEESA



Total Employment in Manufacturing Industries
as of March, 1990
0−2000
2001−4000
4001−6000
6001−8000
8001−10000
10001−12000
over 16000
Source: U.S. Department of Labor, Bureau of Labor Statistics, Employment and Earnings Tape
US map data set supplied with SAS/GRAPH® Software

Note the following for the preceding example:

- The INFILE= option is omitted, since the fileref assigned to the BLSEESA file is the default value DATAFILE.
- When the FROM and TO values in the RANGE statement are the same, only one observation for each cross section is extracted. This observation corresponds to a monthly data point since the INTERVAL= option defaults to MONTH.

Example 14.4. DRI/McGraw-Hill Tape Format CITIBASE Files

This example illustrates how to extract daily series from a sample CITIBASE file. Also, it shows how the OUTSELECT= option affects the contents of the auxiliary data sets.

The daily series contained in the sample data file CITIDEMO are listed by the following statements:

```
proc datasource filetype=citibase infile=citidemo interval=weekday
                outall=citiall outby=citikey;
run;

title1 'Summary Information on Daily Data for CITIDEMO File';
proc print data=citikey noobs;
run;

title1 'Daily Series Available in CITIDEMO File';
proc print data=citiall( drop=label );
run;
```

Output 14.4.1. Printout of the OUTBY= and OUTALL= Data Sets

```
             Summary Information on Daily Data for CITIDEMO File

 10    0         0      04JAN1988   08MAR1991    830     830       1         2
```

Note the following from Output 14.4.1:

- The OUTALL= data set reports the time ranges of variables.
- There are ten observations in the OUTALL= data set, the same number as reported by NSERIES and NSELECT variables in the OUTBY= data set.
- The VARNUM variable contains all MISSING values, since no OUT= data set is created.

The next step is to demonstrate how the OUTSELECT= option affects the contents of the OUTBY= and OUTALL= data sets when a KEEP statement is present. First, set the OUTSELECT= option to OFF.

```
proc datasource filetype=citibase infile=citidemo interval=weekday
                outall=alloff outby=keyoff outselect=off;
   keep dsiusnysecm dc:;
run;
```

```
title1 'Summary Information on Daily Data for CITIDEMO File';
proc print data=keyoff;
run;

title1 'Daily Series Available in CITIDEMO File';
proc print data=alloff( keep=name kept selected st_date
                              end_date ntime nobs );
run;
```

Output 14.4.2. Printout of the OUTBY= and OUTALL= Data Sets with OUTSELECT=OFF

```
             Summary Information on Daily Data for CITIDEMO File

   OBS     ST_DATE    END_DATE    NTIME    NOBS    NSERIES    NSELECT

     1    DSIUSNYSECM      1         1       04JAN1988    14MAR1991     834      834
     2    DCP05            1         1       04JAN1988    24FEB1989     300      300
     3    DCD1M            1         1       04JAN1988    08MAR1991     830      830
```

Comparison of Output 14.4.2 and Output 14.4.3 reveals the following:

- The OUTALL= data set contains ten (NSERIES) observations when OUTSELECT=OFF, and three (NSELECT) observations when OUTSELECT=ON.
- The observations in OUTALL=ALLON are those for which SELECTED=1 in OUTALL=ALLOFF.
- The time ranges in the OUTBY= data set are computed over all the variables (selected or not) for OUTSELECT=OFF, resulting in ST_DATE='01JAN88'd and END_DATE='14MAR91'd; and over only the selected variables for OUTSELECT=ON, resulting in ST_DATE='04JAN88'd and END_DATE='14MAR91'd. This corresponds to computing time ranges over all the series reported in the OUTALL= data set.
- The variable NTIME is the number of time periods between ST_DATE and END_DATE, while NOBS is the number of observations the OUT= data set is to contain. Thus, NTIME is different depending on whether the OUTSELECT= option is set to ON or OFF, while NOBS stays the same.

Also the use of the KEEP statement in the last two examples illustrates the use of an additional variable, KEPT, in the OUTALL= data sets of Output 14.4.2 and Output 14.4.3. KEPT, which reports the outcome of the KEEP statement, is only added to the OUTALL= data set when there is KEEP statement, as shown in Output 14.4.1.

Adding the RANGE statement to the last example generates the data sets in Output 14.4.4:

```
proc datasource filetype=citibase infile=citidemo interval=weekday
                outby=keyrange out=citiday outselect=on;
   keep dsiusnysecm dc:;
   range to '12jan88'd;
run;
```

```
title1 'Summary Information

title1 'Daily Data in CITIDEMO File';
proc print data=citiday;
run;
```

Output 14.4.4. Printout of the OUT=CITIDAY Data Set for FILETYPE=CITIBASE

```
                       Daily Series Available in CITIDEMO File

OBS      ST_DATE      END_DATE     NTIME     NOBS     NINRANGE     NSERIES     NSELECT

 1     04JAN1988     14MAR1991      834       834         7           10          3
```

```
                              Daily Data in CITIDEMO File

              Obs          DATE     DSIUSNYSECM      DCP05       DCD1M

               1      04JAN1988       142.900      6.81000    6.89000
               2      05JAN1988       144.540      6.84000    6.85000
               3      06JAN1988       144.820      6.79000    6.87000
               4      07JAN1988       145.890      6.77000    6.88000
               5      08JAN1988       137.030      6.73000    6.88000
               6      11JAN1988       138.810      6.81000    6.89000
               7      12JAN1988       137.740      6.73000    6.83000
```

The OUTBY= data set in this last example contains an additional variable NINRANGE. This variable is added since there is a RANGE statement. Its value, 7, is the number of observations in the OUT= data set. In this case, NOBS gives the number of observations the OUT= data set would contain if there were not a RANGE statement.

Note that the OUT= data set does not contain data for 09JAN1988 and 10JAN1988. This is because the WEEKDAY interval skips over weekends.

Example 14.5. DRI Data Delivery Service Database

This example demonstrates the DRIDDS filetype for the daily Federal Reserve Series fxrates_dds. Use VALIDVARNAME=ANY on your SAS options statement to allow special characters such as @, $, and % to be allowed in the series name. Note the use of long variable names in the OUT= data set and long labels in the OUTCONT= data set.

The following statements extract the daily series starting from January 1,1997:

```
filename datafile 'host-specific-file-name' <host-options>;
proc format;
   value distekfm 0 = 'Unspecified'
                  2 = 'Linear'
                  4 = 'Triag'
                  6 = 'Polynomial'
                  8 = 'Even'
                 10 = 'Step'
                 12 = 'Stocklast'
                 14 = 'LinearUnadjusted'
                 16 = 'PolyUnadjusted'
                 18 = 'StockWithNAS'
                 99 = 'None'
                255 = 'None';

   value convtkfm 0 = 'Unspecified'
                  1 = 'Average'
                  3 = 'AverageX'
                  5 = 'Sum'
                  7 = 'SumAnn'
                  9 = 'StockEnd'
                 11 = 'StockBegin'
                 13 = 'AvgNP'
                 15 = 'MaxNP'
                 17 = 'MinNP'
                 19 = 'StockEndNP'
                 21 = 'StockBeginNP'
                 23 = 'Max'
                 25 = 'Min'
                 27 = 'AvgXNP'
                 29 = 'SumNP'
                 31 = 'SumAnnNP'
                 99 = 'None'
                255 = 'None';

 /*---------------------------------------------------------------*
  *                 process daily series                          *
  *---------------------------------------------------------------*/
title3 'Reading DAILY Federal Reserve Series with fxrates_.dds';
proc datasource filetype=dridds
                infile=datafile
                interval=day
                out=fixr
```

```
                     outcont=fixrcnt
                     outall=fixrall;

      range from '01jan97'd to '31dec99'd;
      format disttek distekfm.;
      format convtek convtkfm.;
   run;
```

Example 14.6. PC Diskette Format CITIBASE Database

This example uses a diskette format CITIBASE database (FILETYPE=CITIDISK) to extract annual population estimates for females and males with respect to various age groups since 1980.

Population estimate series for females with five-year age intervals are given by PANF1 through PANF16, where PANF1 is for females under 5 years of age, PANF2 is for females between 5 and 9 years of age, and so on. Similarly, PANM1 through PANM16 gives population estimates for males with five-year age intervals.

The following statements extract the required population estimates series:

```
   filename keyfile 'host-specific-key-file-name' <host-options>;
   filename indfile 'host-specific-ind-file-name' <host-options>;
   filename dbfile  'host-specific-db-file-name'  <host-options>;
   proc datasource filetype=citidisk  infile=( keyfile indfile dbfile )
                   out=popest outall=popinfo;
      keep panf1-panf16 panm1-panm16;
      range from 1980;
   run;
```

This example demonstrates the following:

- The INFILE= options lists the filerefs of the key, index, and database files, in that order.
- The INTERVAL= option is omitted since the default interval for CITIDISK type files is YEAR.

Example 14.7. Quarterly COMPUSTAT Data Files

This example shows how to extract data from a 48-quarter Compustat Database File. For COMPUSTAT data files, the series variable names are constructed by concatenating the name of the data array DATA and the column number containing the required information. For example, for quarterly files the common stock data is in column 56. Therefore, the variable name for this series is DATA56. Similarly, the series variable names for quarterly footnotes are constructed by adding the column number to the array name, QFTNT. For example, the variable name for common stock footnotes is QFTNT14 since the 14th column of the QFTNT array contains this information.

The following example extracts common stock series (DATA56) and its footnote (QFTNT14) for Computer Programming Service Companies (DNUM=7371) and Prepackaged Software Companies (DNUM=7370) whose stocks are traded over-the-counter and not in the S&P 500 Index (ZLIST=06) and whose data reside in the over-the-counter file (FILE=06).

```
filename compstat 'host-specific-Compustat-file-name' <host-options>;
proc datasource filetype=cs48qibm infile=compstat
                out=stocks outby=company;
   keep data56 qftnt14;
   rename data56=comstock  qftnt14=ftcomstk;
   label  data56='Common Stock'
          qftnt14='Footnote for Common Stock';
   where dnum in (7370,7371) and zlist=06 and file=06;
run;

/*- add company name to the out= data set    */
data stocks;
   merge stocks company( keep=dnum cnum cic coname );
   by dnum cnum cic;
run;

title1 'Common Stocks for Software Companies for 1990';
proc print data=stocks noobs;
   where date between '01jan90'd and '31dec90'd;
run;
```

The Output 14.7.1 contains a partial listing of the STOCKS data set.

Output 14.7.1. Partial Listing of the OUT=STOCKS Data Set

```
                    Common Stocks for Software Companies for 1990

```

Note that quarterly Compustat data are also available in Universal Character format. If you have this type of file instead of IBM 360/370 General format, use the FILETYPE=CS48QUC option instead.

Example 14.8. Annual COMPUSTAT Data Files

This example shows how to extract a subset of cross sections when the required cross sections are listed in an external file. In the case of a COMPUSTAT file, the required cross sections are a list of companies. For example, you may want to extract annual data for a list of companies whose industry classification codes (DNUM), CUSIP issuer codes (CNUM), and CUSIP issue number and check-digits (CIC) are given in an external file, COMPLIST, as follows:

```
2640   346377   104
3714   017634   106
5812   171583   107
6025   446150   104
8051   087851   101
```

When the required companies are listed in an external file, you can either use the SAS macro processor to construct your WHERE statement expression or restructure your data file and include it after the WHERE key word.

The following steps use the first approach to construct the WHERE statement expression in the macro variable WHEXPR:

```
filename compfile ’host-specific-file-name’ <host-options>;
%macro whstmt( fileref );
   %global whexpr;
   data _null_;
      infile &fileref end=last;
      length cnum $ 6;
      input  dnum cnum cic;
      call symput( ’dnum’||left(_n_), left(dnum) );
      call symput( ’cnum’||left(_n_), cnum );
      call symput( ’cic’ ||left(_n_), left(cic) );
      if last then call symput( ’n’, left(_n_) );
   run;
   %do i = 1 %to &n;
      %let whexpr = &whexpr
       (DNUM=&&dnum&i and CNUM="&&cnum&i" and CIC=&&cic&i);
      %if &i ^= &n %then %let whexpr = &whexpr or;
      %end;
   %mend whstmt;
%whstmt( compfile );
filename compustat ’host-specific-Compustat-file-name’ <host-options>;
proc datasource filetype=csaibm infile=compstat
                outby=company  out=dataset;
   where &whexpr;
run;
```

The same result can also be obtained by creating an external file, WHEXPR, from the COMPFILE and including it after the WHERE key word, as shown in the following statements:

```
filename whexpr ’host-specific-WHEXPR-file-name’ <host-options>;
data _null_;
   infile compfile end=last; file   whexpr;
   length cnum $ 6;
   input  dnum cnum cic;
   put "( "  dnum=  "and CNUM=’"  cnum $6.  "’ and "  cic= ")"  @;
   if not last then put ’ or’; else put ’;’ ;
run;

filename compstat ’host-specific-Compustat-file-name’ <host-options>;
proc datasource filetype=csaibm infile=compustat
                outby=company  out=dataset;
   where %inc ’host-specific-WHEXPR-file-name’;
run;

title1 ’Information on Selected Companies’;
proc print data=company;
run;
```

The Output 14.8.1 shows the OUTBY= data set created by the preceding statements. As you can see, the companies listed in the COMPLIST file are reported in this data set.

Output 14.8.1. Printout of the OUTBY= Data Set Listing Selected Companies

```
                       Information on Selected Companies

                                                                       C
                                Z                               S      O

```

Note that annual COMPUSTAT data are available in either IBM 360/370 General format or the Universal Character format. The first example expects an IBM 360/370 General format file since the FILETYPE= is set to CSAIBM, while the second example uses a Universal Character format file (FILETYPE=CSAUC).

Example 14.9. CRSP Daily NYSE/AMEX Combined Stocks

This example reads all the data on a three-volume daily NYSE/AMEX combined character data set. Assume that the following filerefs are assigned to the calendar/indices file and security files comprising this database:

Fileref	VOLSER	File Type
calfile	DXAA1	calendar/indices file on volume 1
secfile1	DXAA1	security file on volume 1
secfile2	DXAA2	security file on volume 2
secfile3	DXAA3	security file on volume 3

The data set CALDATA is created by the following statements to contain the calendar/indices file:

```
proc datasource filetype=crspdci infile=calfile out=caldata;
run;
```

Here the FILETYPE=CRSPDCI indicates that you are reading a character format (indicated by a C in the 6th position) daily (indicated by a D in the 5th position) calendar/indices file (indicated by an I in the 7th position).

The annual data in security files can be obtained by the following statements:

```
proc datasource filetype=crspdca
                infile=( secfile1 secfile2 secfile3 )
                out=annual;
run;
```

Similarly, the data sets to contain the daily security data (the OUT= data set) and the event data (the OUTEVENT= data set) are obtained by the following statements:

```
proc datasource filetype=crspdcs
                infile=( calfile secfile1 secfile2 secfile3 )
                out=periodic index outevent=events;
run;
```

Note that the FILETYPE= has an S at the 7th position, since you are reading the security files. Also, the INFILE= option first expects the fileref of the calendar/indices file since the dating variable (CALDT) is contained in that file. Following the fileref of calendar/indices file, you give the list of security files in the order you want to read them.

The Output 14.9.1 is generated by the following statements:

```
title1 'First 5 Observations in the Calendar/Indices File';
proc print data=caldata( obs=5 );
run;

title1 'Last 5 Observations in the Calendar/Indices File';
proc print data=caldata( firstobs=6659 ) noobs;
run;

title1 "Periodic Series for CUSIP='09523220'";
title2 "DATE >= '22dec88'd";
proc print data=periodic;
   where cusip='09523220' and date >= '22dec88'd;
run;

title1 "Events for CUSIP='09523220'";
proc print data=events;
   where cusip='09523220';
run;
```

Output 14.9.1. Partial Listing of the Output Data Sets

```

```

This example illustrates the following points:

- When data span more than one physical volume, the filerefs of the security files residing on each volume must be given following the fileref of the calendar/indices file. The DATASOURCE procedure reads each of these files in the order they are specified. Therefore, you can request that all three volumes be mounted to the same tape drive, if you choose to do so.
- The INDEX option in the second PROC DATASOURCE run creates an index file for the OUT=PERIODIC data set. This index file provides random access to the OUT= data set and may increase the efficiency of the subsequent PROC and DATA steps that use BY and WHERE statements. The index variables are CUSIP, CRSP permanent number (PERMNO), NASDAQ company number (COMPNO), NASDAQ issue number (ISSUNO), header exchange code (HEXCD) and header SIC code (HSICCD). Each one of these variables forms a different key, that is, a single index. If you want to form keys from a combination of variables (composite indexes) or use some other variables as indexes, you should use the INDEX= data set option for the OUT= data set.
- The OUTEVENT=EVENTS data set is sparse. In fact, for each EVENT type, a unique set of event variables are defined. For example, for EVENT='SHARES', only the variables SHROUT and SHRFLG are defined, and they have missing values for all other EVENT types. Pictorially, this structure is similar to the data set shown in Figure 14.8. Because of this sparse representation, you should create the OUTEVENT= data set only when you need a subset of securities and events.

By default, the OUT= data set contains only the periodic data. However, you may also want to include the event-oriented data in the OUT= data set. This is accomplished by listing the event variables together with periodic variables in a KEEP statement. For example, if you want to extract the historical CUSIP (NCUSIP), number of shares outstanding (SHROUT), and dividend cash amount (DIVAMT) together with all the periodic series, use the following statements:

```
proc datasource filetype=crspdcs
                infile=( calfile secfile1 secfile2 secfile3 )
                out=both outevent=events;
   where cusip='09523220';
   keep  bidlo askhi prc vol ret sxret bxret ncusip shrout divamt;
run;

proc datasource filetype=crspdcs
                infile=( calfile secfile1 )
                out=both outevent=events;
   where cusip='09523220';
   keep  bidlo askhi prc vol ret sxret bxret ncusip shrout divamt;
run;

proc datasource filetype=crspdcs
                infile=( calfile secfile1 )
                out=both2 outevent=events2;
   where cusip='09523220';
   keep  bidlo askhi prc vol ret sxret bxret ncusip shrout divamt;
   keepevent ncusip shrflg;
```

```

     09523220    04OCT1988    110600    09523220        .       706842
```

Events referring to distributions and delistings have entries only in observations whose dates match the event dates. For example, DIVAMT has a value for only 18JUL88, as shown in the second printout in Output 14.9.2. The NAME and SHARES events refer to a date of change, therefore their values are expanded such that there is a value for each observation. For example, the date of NAMES record is 03MAY88, therefore NCUSIP has the same value from that date on. The SHROUT on the other hand changes its value twice, once on 03MAY88, the other time on 30SEP88. The third listing shows how the value of SHROUT remains constant at 72757 from 03MAY88 to 30SEP88, at which date it changes to 706842.

The events occurring on days other than the trading dates are not output to the OUT= data set.

The KEEP statement in the preceding example has no effect on the event variables output to the OUTEVENT= data set. If you want to extract only a subset of event variables, you need to use the KEEPEVENT statement. For example, the following code outputs only NCUSIP and SHROUT to the OUTEVENT= data set for CUSIP='09523220':

```
proc datasource filetype=crspdxc
                infile=( calfile secfile1 secfile2 secfile3 )
                outevent=subevts;
   where cusip='09523220';
   keepevent  ncusip shrout;
run;

proc datasource filetype=crspdxc
                infile=( calfile secfile1)
                outevent=subevts;
   where cusip='09523220';
   keepevent  ncusip shrout;
run;

title1 "NCUSIP and SHROUT for CUSIP='09523220'";
proc print data=subevts noobs;
run;
```

Output 14.9.3. Listing of the OUTEVENT= Data Set with a KEEPEVENT Statement

```
                     NCUSIP and SHROUT for CUSIP='09523220'

  CUSIP   PERMNO COMPNO ISSUNO HEXCD HSICCD EVENT       DATE  NCUSIP   SHROUT

09523220  75285    0      0      1    7361  NAMES  03MAY1988 09523220      .
09523220  75285    0      0      1    7361  SHARES 03MAY1988            72757
09523220  75285    0      0      1    7361  SHARES 30SEP1988           706842
09523220  75285    0      0      1    7361  SHARES 30DEC1988           706842
```

The OUTEVENT= data set in Output 14.9.3 is missing observations for which the EVENT variable is DIST or DELIST, since these event groups do not contain any selected events.

Example 14.10. CRSP 1995 CDROM Data Files

The normal character filetypes used for tape files may also be used for the CDROM character data. They are CRSPDCS, CRSPDCI, CRSPDCA for daily data and CRSPMCS, CRSPMCI, CRSPMCA for monthly data. It is necessary to use the LRECL=(130 401) option on the DATASOURCE statement when processing CDROM character data as shown in the first DATASOURCE run.

The CRSP 1995 UNIX (SUN)Binary data is readable by PROC DATASOURCE using the filetypes CRSPDUS, CRSPDUI, CRSPDUA for daily files and filetypes CRSPMUS, CRSPMUI, CRSPMUA for monthly files. Both IEEE Big Endian and IEEE Little Endian machines may use the same CDROM UNIX Binary filetypes. PROC DATASOURCE can not read the PC Binary Data from CDROM, but the UNIX (SUN) Binary may be used from the same CDROM instead, even on PC's. The second DATASOURCE run shows how to access the 1995 UNIX Binary data.

```
filename csec 'machar.dat' recfm=f lrecl=401;
filename ccal 'msix.dat' recfm=f lrecl=130;

/*-------------------------------------------------------------*
 *       create output data sets without any subsetting        *
 *       character data from MA CDROM                          *
 *-------------------------------------------------------------*/
/*- create calendar/indices output data sets using DATASOURCE  -*/
/*- statements                                                 -*/
proc datasource filetype=crspmcs
               infile=( ccal csec )
               lrecl=( 130 401 )
               interval=month
               outselect=off
               outcont=maccont outkey=mackey
               out=mac outevent=macevent;
   keep _all_;
   keepevent _all_;
run;

title3 'MA/CDROM Security File Outputs';
title4 'OUTKEY= Data Set';
proc print data=mackey; run;

title4 'OUTCONT= Data Set';
proc print data=maccont; run;

title4 'Listing of OUT= Data Set';
proc print data=mac; run;

title4 'Listing of OUTEVENT= Data Set';
proc print data=macevent; run ;

filename macal 'maucal95.data' lrecl=48;
filename masec 'mausub95.data' recfm=v lrecl=32760;

/*------------------------------------------------------------*
 *       create output data sets without any subsetting       *
 *       UNIX (SUN) binary data from MA CDROM                 *
 *------------------------------------------------------------*/
```

```
/*- create calendar/indices output data sets using DATASOURCE -*/
/*- statements                                                 -*/
proc datasource filetype=crspmus
               infile=( macal masec )
               interval=month
               outselect=off
               outcont=macont outkey=makey
               out=ma outevent=maevent;
   keep _all_;
   keepevent _all_;
run;

title3 'MA/CDROM Security File Outputs';
title4 'OUTKEY= Data Set';
proc print data=makey; run;

title4 'OUTCONT= Data Set';
proc print data=macont; run;

title4 'Listing of OUT= Data Set';
proc print data=ma; run;

title4 'Listing of OUTEVENT= Data Set';
proc print data=maevent; run ;
```

Example 14.11. CRSP ACCESS97 CDROM Data Files

This example demonstrates how to work with the CRSP ACCESS97 CDROM data files by first running the CRSP supplied *stk_dump_bin* utility, to create a UNIX (SUN) binary file. The UNIX binary file can then be processed by PROC DATASOURCE using the CRSPMUS filetype for monthly data or the CRSPDUS filetype for DAILY data.

The DATASOURCE procedure expects the data file to use IEEE big Endian byte ordering. The exact command that you need to use to convert the data depends on whether you extracted the big Endian or little Endian data off of the CD, and whether you are running on a host whose native binary representation is big or little Endian. Consult your *1997 CRSP ACCESS97 Stock File User's Guide*, *Appendix C* for details on the reverse/keep option for the byte-ordering flag. Assuming a Windows NT platform and daily data:

```
ind_dump_bin %crsp_dstk% filename1 460 1000080 1000081 1000502 reverse unix
stk_dump_bin %crsp_dstk% filename2 10 1 0 0 0 reverse unix permlist_filename
```

Once you have converted the ACCESS97 data into the unix binary format, you are ready to invoke PROC DATASOURCE:

```
filename calfile 'filename1';
filename secfile 'filename2' lrecl=36000;

proc datasource filetype=crspdus
   infile=( calfile secfile )
   interval=day
```

```
      outselect=off
      out=da outkey=dakey outcont=dacont outevent=daevent;
      keep _all_;
      keepevent _all_;
   run;
```

The above example uses an LRECL to accommodate the size of the 1997 daily data. Subsequent years may need a larger lrecl.

Example 14.12. IMF Direction of Trade Statistics

This example illustrates how to extract data from a Direction of Trade Statistics (DOTS) data file. The DOTS data files contain only two series, EXPORTS and IMPORTS, for various sets of countries. The foreign trade figures between any two countries can be extracted by specifying their three-digit codes for COUNTRY and PARTNER BY variables. The following statements can then be used to extract quarterly EXPORTS and IMPORTS between the United States of America (COUNTRY='111') and Japan (PARTNER='158').

```
filename dotsfile 'host-specific-gfs-file-name' <host-options>;
proc datasource filetype=imfdotsp infile=dotsfile interval=qtr
                out=foreign outall=forngvar;
   where country='111' and partner='158';
run;
```

The ENTROPY Procedure (Experimental)

Chapter Contents

Chapter 15
The ENTROPY Procedure (Experimental)

Overview

The ENTROPY procedure implements a parametric method of linear estimation based on Generalized Maximum Entropy. The ENTROPY procedure is suitable when there are outliers in the data and robustness is required, or when the model is ill-posed or underdetermined for the observed data, or for regressions involving small data sets.

The main features of the ENTROPY procedure are as follows:

- estimates simultaneous systems of linear regression models
- estimates Markov models
- estimates Seemingly Unrelated Regression (SUR) models
- estimates Unordered Multinomial Discrete Choice models
- solves pure inverse problems
- allows bounds and restrictions on parameters
- performs tests on parameters
- allows data and moment constrained generalized cross entropy

Experimental graphics are now available with the ENTROPY procedure. For more information, see the "ODS Graphics" section on page 774.

It is often the case that the statistical-economic model of interest is ill-posed or underdetermined for the observed data. For the general linear model this can imply that high degrees of collinearity exist among explanatory variables or that there are more parameters to estimate than observations to estimate them with. These conditions lead to high variances or nonestimability for traditional Generalized Least Squares (GLS) estimates.

Under these situations it may be in the researcher's or practitioner's best interest to consider a nontraditional technique for model fitting. The principle of maximum entropy is the foundation for an estimation methodology that is characterized by its robustness to ill-conditioned designs and its ability to fit over-parameterized models. See Mittelhammer, Judge, and Miller (2000), and Golan, Judge, and Miller (1996) for a discussion of Shannon's maximum entropy measure and the related Kullback-Leibler information.

Generalized Maximum Entropy (GME) is a means of selecting among probability distributions so as to choose the distribution that maximizes uncertainty or uniformity remaining in the distribution, subject to information already known about the distribution. Information takes the form of data or moment constraints in the estimation procedure. PROC ENTROPY creates a GME distribution for each parameter in the linear model, based upon support points supplied by the user. The mean of each distribution is used as the estimate of the parameter. Estimates tend to be biased, as they are a type of shrinkage estimate, but will typically portray smaller variances than OLS counterparts, making them more desirable from a mean squared error viewpoint (see Figure 15.1).

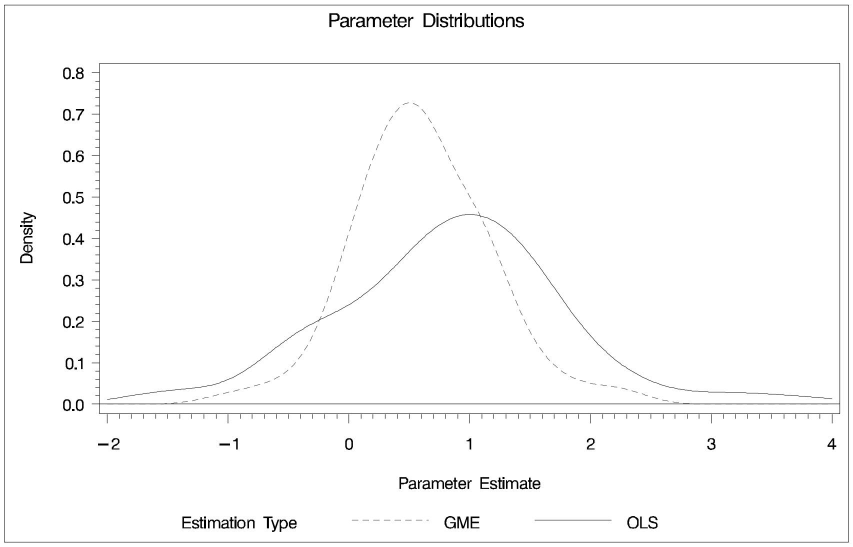

Figure 15.1. Distribution of Maximum Entropy Estimates Versus OLS

Maximum entropy techniques are most widely used in the econometric and time series fields. Some important uses of maximum entropy include

- size distribution of firms
- stationary Markov Process
- Social Accounting Matrix (SAM)
- consumer brand preference
- exchange rate regimes
- wage-dependent firm relocation
- oil market dynamics

Getting Started

This section introduces the ENTROPY procedure and shows how to use PROC ENTROPY for several kinds of regression analyses.

Simple Regression Analysis

The ENTROPY procedure is similar in syntax to the other regression procedures in the SAS System. To demonstrate the similarity, suppose the endogenous/dependent variable is `y`, and `x1` and `x2` are two exogenous/independent variables of interest. To estimate the parameters in this single equation model using PROC ENTROPY, use the following SAS statements:

```
proc entropy;
   model y = x1 x2 ;
run;
```

Test Scores Data Set

Consider the following test score data compiled by Coleman et al. (1966) :

```
Title "Test Scores compiled by Coleman et al. (1966)";
data coleman;

   input test_score 6.2 teach_sal 6.2 prcnt_prof
         8.2 socio_stat 9.2 teach_score 8.2 mom_ed 7.2;

   label test_score="Average sixth grade test scores in observed district";
   label teach_sal="Average teacher salaries per student ($1000)";
   label prcnt_prof="Percent of students’ fathers with professional employment";
   label socio_stat="Composite measure of socio-economic status in the district"
;
   label teach_score="Average verbal score for teachers";
   label mom_ed="Average level of education (years) of the students’ mothers";

datalines;
37.01   3.83   28.87     7.20   26.60   6.19
26.51   2.89   20.10   -11.71   24.40   5.17
36.51   2.86   69.05    12.32   25.70   7.04
40.70   2.92   65.40    14.28   25.70   7.10
37.10   3.06   29.59     6.31   25.40   6.15
33.90   2.07   44.82     6.16   21.60   6.41
41.80   2.52   77.37    12.70   24.90   6.86
33.40   2.45   24.67    -0.17   25.01   5.78
41.01   3.13   65.01     9.85   26.60   6.51
37.20   2.44    9.99    -0.05   28.01   5.57
23.30   2.09   12.20   -12.86   23.51   5.62
35.20   2.52   22.55     0.92   23.60   5.34
34.90   2.22   14.30     4.77   24.51   5.80
33.10   2.67   31.79    -0.96   25.80   6.19
22.70   2.71   11.60   -16.04   25.20   5.62
39.70   3.14   68.47    10.62   25.01   6.94
31.80   3.54   42.64     2.66   25.01   6.33
31.70   2.52   16.70   -10.99   24.80   6.01
```

```
   43.10   2.68   86.27    15.03   25.51   7.51
   41.01   2.37   76.73    12.77   24.51   6.96
   ;
```

This data set contains outliers and the condition number of the matrix of regressors, X, is large. Since the Entropy estimates are both robust with respect to the outliers and less sensitive to a high condition number of the X matrix, maximum entropy estimation is a good choice for this problem.

To fit a simple linear model to this data using PROC ENTROPY use the following statements:

```
   proc entropy data=coleman;
      model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
   run;
```

This requests the estimation of a linear model for TEST_SCORE with the following form

$$\begin{aligned} test\_score &= a * teach\_sal + b * prcnt\_prof + c * socio\_stat \\ &\quad + d * teach\_score + e * mom\_ed + intercept + \epsilon; \end{aligned}$$

This estimation produces the Model Summary table in Figure 15.2 showing the equation variables used in the estimation.

```
                 Test Scores compiled by Coleman et al. (1966)

                             The ENTROPY Procedure

 Variables(Supports(Weights))  teach_sal prcnt_prof socio_stat
                               teach_score mom_ed Intercept
 Equations(Supports(Weights))  test_score
```

Figure 15.2. Model Summary Table

The next four tables displayed are the Data Set Options table, the Minimization Summary, the Final Information Measures table, and the Observations Processed tables, shown in Figure 15.3.

```
                         GME-NM Estimation Summary

                              Data Set Options

                             Minimization Summary

                       Parameters Estimated           6
                       Covariance Estimator      GME-NM

                           Final Information Measures

                   Entropy                          9.553698
                   Parameter Information Index      0.009024
                   Error Information Index          0.000214

                            Observations Processed

                                  Read    20
                                  Used    20
```

Figure 15.3. Estimation Summary Tables

The item labeled "Entropy" is the value of the entropy estimation criterion for this estimation problem. This measure is analogous to the log-likelihood value in a maximum likelihood estimation. The "Parameter Information Index" and the "Error Information Index" are normalized entropy values that measure the proximity of the solution to the prior or target distributions.

The next table displayed is the ANOVA table, shown in Figure 15.4. This is in the same form as the ANOVA table for the MODEL procedure, since this is also a multivariate procedure.

```
                    GME-NM Summary of Residual Errors

                DF      DF
Equation     Model   Error       SSE       MSE  Root MSE  R-Square  Adj RSq

test_score       6      14     175.7    8.7866    2.9642    0.7267   0.6291
```

Figure 15.4. Summary of Residual Errors

The last table displayed is the "Parameter Estimates" table, shown in Figure 15.5. The difference between this parameter estimates table and the parameter estimates table produced by other regression procedures is that the standard error and the probabilities are labeled as approximate.

```
                         GME-NM Variable Estimates

                                       Approx                     Approx
           Variable         Estimate     Std Err     t Value      Pr > |t|

           teach_sal        0.287969     0.00551       52.27        <.0001
           prcnt_prof        0.02266     0.00323        7.01        <.0001
           socio_stat       0.199787      0.0308        6.48        <.0001
           teach_score      0.497114      0.0180       27.61        <.0001
           mom_ed           1.644449      0.0921       17.85        <.0001
           Intercept        10.50156      0.3958       26.53        <.0001
```

Figure 15.5. Parameter Estimates

The parameter estimates produced by the REG procedure for this same model are shown in Figure 15.6. Note that the parameters and standard errors from PROC REG are much different than estimates produced by PROC ENTROPY.

```
                              The REG Procedure
                                Model: MODEL1
                       Dependent Variable: test_score '

                             Parameter Estimates

                                      Parameter      Standard
  Variable       Label        DF       Estimate         Error    t Value    Pr > |t|

  Intercept      Intercept     1       19.94857      13.62755       1.46      0.1653
  teach_sal      '             1       -1.79333       1.23340      -1.45      0.1680
  prcnt_prof     '             1        0.04360       0.05326       0.82      0.4267
  socio_stat     '             1        0.55576       0.09296       5.98      <.0001
  teach_score    '             1        1.11017       0.43377       2.56      0.0227
  mom_ed         '             1       -1.81092       2.02739      -0.89      0.3868
```

Figure 15.6. REG Procedure Parameter Estimates

This data set contains two outliers, observations 3 and 18. These can be seen in a plot of the residuals shown in Figure 15.7

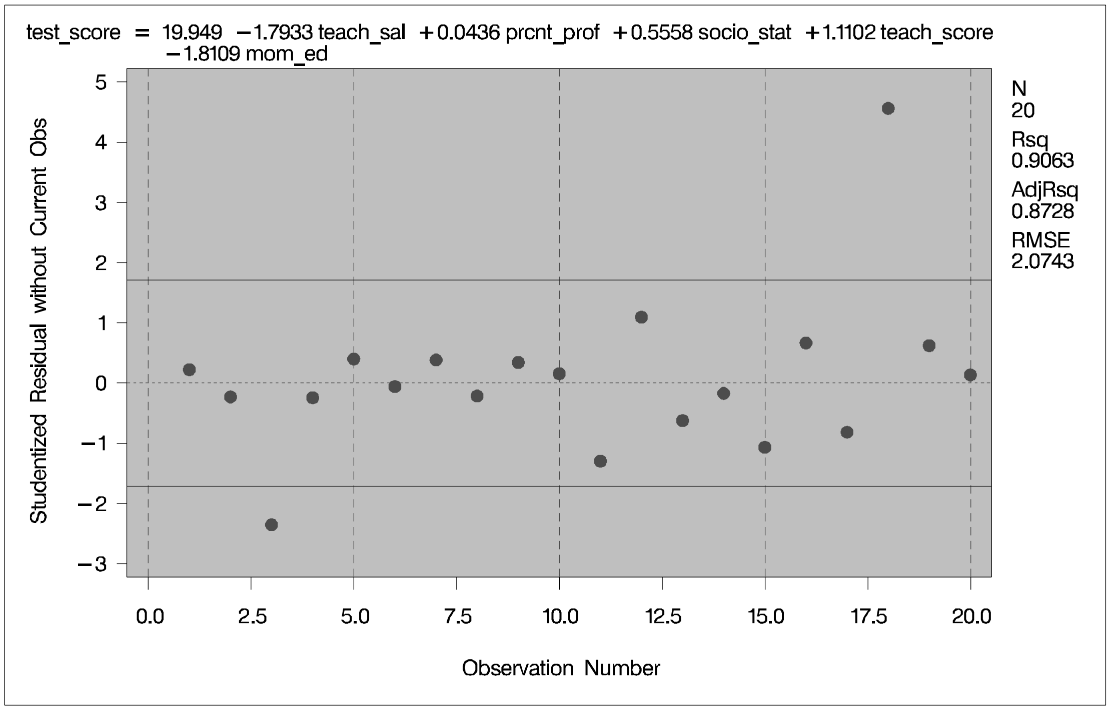

Figure 15.7. Residuals with Outliers

The presence of outliers suggests that a robust estimator such as M-estimator in the ROBUSTREG procedure should be used. The following statements use the ROBUSTREG procedure to estimate the model.

```
proc robustreg data=coleman;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

The results of the estimation are shown in Figure 15.8.

```
                         The ROBUSTREG Procedure

                           Parameter Estimates

Figure 15.8. M-Estimation Results

Note that TEACH_SAL(VAR1) and MOM_ED(VAR5) change greatly when the robust estimation is used. Unfortunately, these two coefficients are negative, which implies that the test scores increase with decreasing teacher salaries and decreasing levels of the mother's education. Since ROBUSTREG is robust to outliers, they are not causing the counter-intuitive parameter estimates.

The condition number of the regressor matrix X also plays a important role in parameter estimation. The condition number of the matrix can be obtained by specifying the COLLIN option on the PROC ENTROPY statement.

```
proc entropy data=coleman collin;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

The output produced by the COLLIN option is shown in Figure 15.9.

Figure 15.9. Collinearity Diagnostics

The condition number of the X matrix is reported to be 84.85. This means that the condition number of $X'X$ is $84.85^2 = 7199.5$, which is very large.

Ridge regression can be used to offset some of the problems associated with ill-conditioned X matrices. Using the formula for the ridge value as

$$\lambda_R = \frac{kS^2}{\hat{\beta}'\hat{\beta}} \approx .9$$

where $\hat{\beta}$ and S^2 are the least-squares estimators of β and σ^2 and $k = 6$. 0.9 a ridge regression of the test score model was performed using the data set with the outliers removed. The following PROC REG code performs the ridge regression:

```
proc reg data=coleman ridge=0.9 outest=t noprint;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
proc print data=t;run;
```

The results of the estimation are shown in Figure 15.10.

```

Figure 15.10. Ridge Regression Estimates

Note that the ridge regression estimates are much closer to the estimates produced by the ENTROPY procedure using the original data set.

Using Prior Information

You can use prior information about the parameters or the residuals to improve the efficiency of the estimates. Some authors prefer the terms *pre-sample* or *pre-data* over the term *prior* when used with Maximum Entropy to avoid confusion with Bayesian methods. The Maximum Entropy method described here does not use Bayes' rule when including prior information in the estimation.

To perform regression, the ENTROPY procedure uses generalization of Maximum Entropy called *Generalized Maximum Entropy*. In Maximum Entropy estimation the unknowns are probabilities. Generalized maximum entropy expands the set of problems that can be solved by introducing the concept of *Support points*. Generalized maximum entropy still estimates probabilities, but these are the probabilities of a support point. Support points are used to map the zero one domain of the maximum entropy to the any finite range of values.

Prior information, such as expected ranges for the parameters or the residuals, is added by specifying support points for the parameters or the residuals. Support points are points in one dimension that specify the expected domain of the parameter or the residual. The wider the domain specified, the less efficient (more variance) your parameter estimates will be. Specifying more support points in the same width interval also improves the efficiency of the parameter estimates at the cost of more computation. Golan, Judge, and Miller (1996) show that the gains in efficiency fall off for adding more than five support points. You can specify between 2 to 256 support points in the ENTROPY procedure.

If you have only a small amount of data, the estimates will be very sensitive to your selection of support points and weights. For larger data sets incorrect priors are discounted if they are not supported by the data.

Consider the data set generated by the following SAS statements:

```
data prior;
    do by = 1 to 100;
       do t = 1 to 10;
          y = 2*t + 5 * rannor(456);
          output;
       end;
    end;
run;
```

The PRIOR data set contains 100 samples of 10 observations each from the population

$$\begin{aligned} y &= 2 * t + \epsilon \\ \epsilon &\sim N(0, 5) \end{aligned}$$

You can estimate these samples using PROC ENTROPY as

```
proc entropy data = prior outest=parm1;
   model y = t ;
   by by;
run;
```

The 100 estimates are summarized using the following SAS statements:

```
proc univariate data=parm1 ;
  var t;
run;
```

The summary statistics from PROC UNIVARIATE are shown in Figure 15.11. The true value of the coefficient t is 2.0, demonstrating that maximum entropy estimates tend to be biased.

```
                     The UNIVARIATE Procedure
                           Variable:  t

                    Basic Statistical Measures

          Location                    Variability

      Mean     1.674803     Std Deviation            0.32418
      Median   1.708555     Variance                 0.10509
      Mode      .           Range                    1.80200
                            Interquartile Range      0.34135
```

Figure 15.11. No Prior Information Monte Carlo Summary

Now assume that you have prior information about the slope and the intercept for this model. You are reasonably confident that the slope is 2 and you are less confident that intercept is zero. To specify prior information on the parameters use the PRIORS statement. There are two parts to the prior information specified in the PRIORS statement. The first part is the support points for a parameter. The support points specify the domain of the parameter. For example

```
priors t -1000 1000;
```

sets the support points -1000 and 1000 for the parameter associated with variable t. This means that the coefficient lies in the interval $[-1000, 1000]$. If the estimated value of the coefficient is actually outside of this interval, the estimation will not converge. In the previous PRIORS statement, no weights were specified for the support points, so uniform weights are assumed. This implies that the coefficient has a uniform probability of being in the interval $[-1000, 1000]$.

The second part of the prior information is the weights on the support points. For example

```
   priors t 10(1) 15(5) 20(5) 25(1);
```

sets the support points 10, 15, 20, and 25 with weights 1, 5, 5, and 1 respectively for the coefficient of t. This creates the prior distribution on the coefficient shown in Figure 15.12. The weights are automatically normalized so that they sum to one.

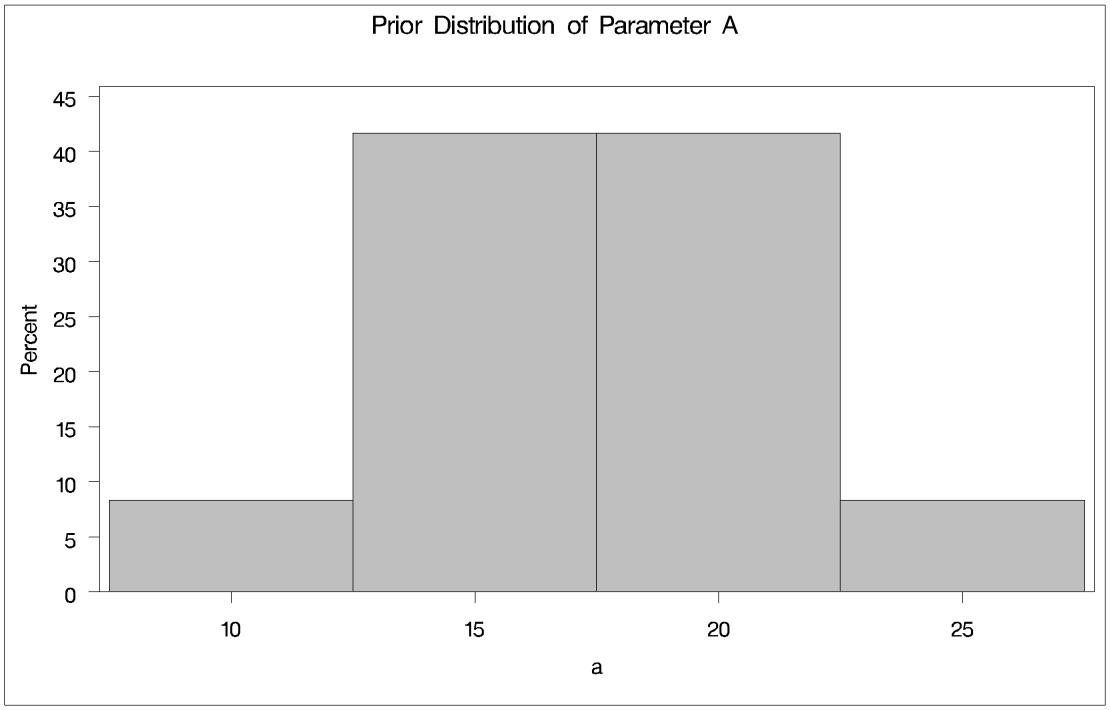

Figure 15.12. Prior Distribution of Parameter T

For the PRIOR data set created previously, the expected value of the coefficient of t is 2. The following SAS statements reestimate the parameters with prior specified for each one.

```
proc entropy data = prior outest=parm2;
   priors t 0(1) 2(3) 4(1)
      intercept -100(.5) -10(1.5) 0(2) 10(1.5) 100(0.5);
   model y = t;
   by by;
run;
```

The priors on the coefficient of t express a confident view of the value of the coefficient. The priors on INTERCEPT express a more diffuse view on the value of the intercept. The following PROC UNIVARIATE statement was used to compute summary statistics from the estimations:

```
proc univariate data=parm2 ;
  var t;
run;
```

The summary statistics for the distribution of the estimates of t are shown in Figure 15.13.

```
                         The UNIVARIATE Procedure
                               Variable:  t

                        Basic Statistical Measures

             Location                    Variability

         Mean     1.999872     Std Deviation            0.01404
         Median   2.000952     Variance               0.0001973
         Mode      .           Range                    0.06807
                               Interquartile Range      0.01641
```

Figure 15.13. Prior Information Monte Carlo Summary

The prior information improves the estimation of the coefficient of t dramatically. The downside of specifying priors comes when they are incorrect. For example, say the priors for this model were specified as

```
   priors t -2(1) 0(3) 2(1) ;
```

to indicate a prior centered on zero instead of two.

The resulting summary statistics shown in Figure 15.14 indicate how the estimation is biased away from the solution.

```
                         The UNIVARIATE Procedure
                               Variable:  t

                        Basic Statistical Measures

             Location                    Variability

         Mean     0.097888     Std Deviation            0.01193
         Median   0.096959     Variance               0.0001423
         Mode      .           Range                    0.06588
                               Interquartile Range      0.01607
```

Figure 15.14. Incorrect Prior Information Monte Carlo Summary

The more data available for estimation the less sensitive the parameters will be to the priors. If the number of observations in each sample was 50 instead of 10, then the summary statistics shown in Figure 15.15 are produced. The prior information is not supported by the data, so it is discounted.

```
                          The UNIVARIATE Procedure
                               Variable:  t

                          Basic Statistical Measures

                Location                    Variability

            Mean     0.838043     Std Deviation            0.01365
            Median   0.837825     Variance               0.0001864
            Mode      .           Range                    0.06555
                                  Interquartile Range      0.02008
```

Figure 15.15. Incorrect Prior Information with More Data

Pure Inverse Problems

A special case of systems of equations estimation is the pure inverse problem. A pure problem is one that contains an exact relationship between the dependent variable and the independent variables and does not have an error component. A pure inverse problem can be written as

$$\mathbf{y} = X\beta$$

where $\mathbf{y}$ is a n-dimensional vector of observations, X is a $n \times k$ matrix of regressors, and β is a k-dimensional vector of unknowns. Notice that there is no error term.

A classic example is Jaynes' (1963) dice problem. Given a six-sided die that can take on the values $x = 1, 2, 3, 4, 5, 6$ and the average outcome of the die $y = A$, compute the probabilities $\beta = (p_1, p_2, \cdots, p_6)'$ of rolling each number. This is two pieces of information to infer six values. The data points are the expected value of y and the sum of the probabilities is one. Given $E(y) = 4.0$, this problem is solved using the following SAS code:

```
data one;
   array x[6] ( 1 2 3 4 5 6 );
   y=4.0;
run;

proc entropy data=one pure;
   priors x1 0 1 x2 0 1 x3 0 1 x4 0 1 x5 0 1 x6 0 1;
   model y = x1-x6/ noint;
   restrict x1 + x2 +x3 +x4 + x5 + x6 =1;
run;
```

The probabilities are given in Figure 15.16.

```
                           The ENTROPY Procedure

                          GME Variable Estimates

                                          Information
         Variable         Estimate              Index    Label

         x1               0.101763             0.5254
         x2               0.122658             0.4630
         x3               0.147141             0.3974
         x4               0.175533             0.3298
         x5               0.208066             0.2622
         x6               0.244839             0.1970
         Restrict0        2.388082               .        x1 + x2 + x3 + x4
                                                         + x5 + x6  =  1
```

Figure 15.16. Jaynes' Dice Pure Inverse Problem

First Order Markov Process Estimation

A more useful inverse problem is the First Order Markov Process. Companies have a share of the marketplace where they do business. Generally customers for a specific market space can move from company to company. Graphically the movement of customers can be visualized as a flow diagram, as in Figure 15.17. The arrows represent movements of customers from one company to the next.

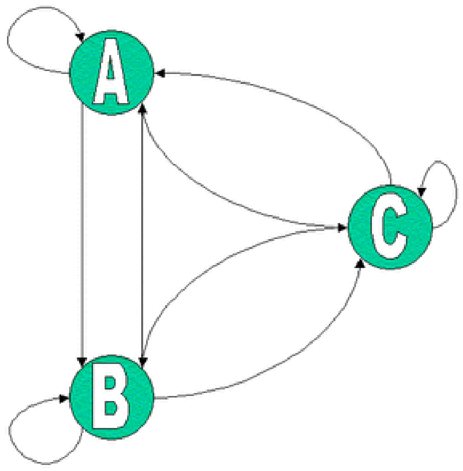

Figure 15.17. Markov Transition Diagram

You can model the probability that a customer moves from one company to another using a first-order Markov model. Mathematically that is

$$y_t = P y_{t-1}$$

where y_t is vector of k market shares at time t and P is a $k \times k$ matrix of unknown transition probabilities. p_{ij} represents the probability that a customer who is currently using company j at time $t-1$ will transition to using company i at time t. The diagonal elements then represent the probability that a customer stays with the current company. The columns in P sum to one.

Given market share information over time you can estimate the transition probabilities P. In order to estimate P using traditional methods you need at least k observations. If you have fewer than k transitions, you can use the ENTROPY procedure to estimate the probabilities.

Suppose you are studying the market share for four companies. If you wanted to estimate the transition probabilities for these four companies, you would need a time series with four observations of the shares. Assume the current transition probability matrix is as follows:

$$\begin{bmatrix} 0.7 & 0.4 & 0.0 & 0.1 \\ 0.1 & 0.5 & 0.4 & 0.0 \\ 0.0 & 0.1 & 0.6 & 0.0 \\ 0.2 & 0.0 & 0.0 & 0.9 \end{bmatrix}$$

The following SAS DATA step code is used to generate a series of market shares generated from this probability matrix. A transition is represented as the current period shares, y, and the previous period shares, x.

```
data m;
            /* Transition matrix */
  array p[4,4] (0.7 .4 .0 .1
                0.1 .5 .4 .0
                0.0 .1 .6 .0
                0.2 .0 .0 .9 ) ;
            /* Initial Market shares */
  array y[4] y1-y4 ( .4 .3 .2 .1 );
  array x[4] x1-x4;
  drop p1-p16 i;

  do i = 1 to 3;
    x[1] = y[1]; x[2] = y[2];
    x[3] = y[3]; x[4] = y[4];
    y[1] = p[1,1] * x1 + p[1,2] * x2 + p[1,3] * x3 + p[1,4] * x4;
    y[2] = p[2,1] * x1 + p[2,2] * x2 + p[2,3] * x3 + p[2,4] * x4;
    y[3] = p[3,1] * x1 + p[3,2] * x2 + p[3,3] * x3 + p[3,4] * x4;
    y[4] = p[4,1] * x1 + p[4,2] * x2 + p[4,3] * x3 + p[4,4] * x4;
    output;
  end;
run;
```

The following SAS statements estimate the transition matrix using only the first transition.

```
   proc entropy markov pure data=m(obs=1);
      model y1-y4 = x1-x4;
   run;
```

The MARKOV option implies NOINT for each model, and that the sum of the parameters in each column is one, and chooses support points of 0 and 1. This model can be expressed equivalently as

```
proc entropy pure data=m(obs=1) ;
   priors y1.x1 0 1 y1.x2 0 1 y1.x3 0 1 y1.x4 0 1;
   priors y2.x1 0 1 y2.x2 0 1 y2.x3 0 1 y2.x4 0 1;
   priors y3.x1 0 1 y3.x2 0 1 y3.x3 0 1 y3.x4 0 1;
   priors y4.x1 0 1 y4.x2 0 1 y4.x3 0 1 y4.x4 0 1;

   model y1 = x1-x4 / noint;
   model y2 = x1-x4 / noint;
   model y3 = x1-x4 / noint;
   model y4 = x1-x4 / noint;

   restrict y1.x1 + y2.x1 + y3.x1 + y4.x1 = 1;
   restrict y1.x2 + y2.x2 + y3.x2 + y4.x2 = 1;
   restrict y1.x3 + y2.x3 + y3.x3 + y4.x3 = 1;
   restrict y1.x4 + y2.x4 + y3.x4 + y4.x4 = 1;
run;
```

The transition matrix is given in Figure 15.18.

```

          y4.x2            0.00559              0.9501
          y4.x3           0.000133              0.9981
          y4.x4           0.903214              0.5413
```

Figure 15.19. Estimate of P using Two Transitions

This transition matrix is much closer to the actual transition matrix.

If in addition to the transitions, you had other information about the transition matrix, such as your own company's transition values, that information can be added as restrictions to the parameter estimates. For noisy data, the PURE option should be dropped. Note that this example had six zero probabilities in the transition matrix, the accurate estimation of transition matrices with fewer zero probabilities generally requires more transition observations.

Analyzing Multinomial Response Data

Multinomial discrete choice models suffer the same problems with collinearity of the regressors and small sample sizes as linear models. Unordered multinomial discrete choice models can be estimated using a variant of GME for discrete models called GME-D.

Consider the model shown in Golan, Judge, and Perloff (1996). In this model there are five occupational categories and the categories where considered a function of four individual characteristics plus an intercept. The sample contains 337 individuals.

```
data kpdata;
   input job x1 x2 x3 x4;
datalines;
0 1 3 11 1
0 1 14 12 1
0 1 44 12 1
0 1 18 12 1

  ...

4 1 12 16 1
;
run;
```

The dependent variable in this data, job, takes on values 1 through 5. Support points are used only for the error terms so priors are specified on the MODEL statement.

```
proc entropy data = kpdata gmed;
   model job = x1 x2 x3 x4 / noint
      priors=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 );
run;
```

```
                           The ENTROPY Procedure

Figure 15.20. Estimate of Jobs Model Using GME-D

Note there are five estimates of the parameters produced for each regressor, one for each choice. The first choice is restricted to zero for normalization purposes.

Syntax

The following statements can be used with the ENTROPY procedure:

PROC ENTROPY *options*;
  BOUNDS *bound1 [, bound2, . . .]* ;
  BY *variable [variable . . .]* ;
  ID *variable [variable . . .]* ;
  MODEL *variable = variable [variable] . . . [/ options] ;*
  PRIORS *variable [support points] variable [value] . . .* ;
  RESTRICT *restriction1 [, restriction2 . . .]* ;
  TEST *[* **"name"** *] test1 [, test2 . . .] [/ options]* ;
  WEIGHT *variable*;

Functional Summary

The statements and options in the ENTROPY procedure are summarized in the following table.

Description	**Statement**	**Option**
Data Set Options		
specify the input data set for the variables	ENTROPY	DATA=
specify the input data set for support points and priors	ENTROPY	PDATA=
specify the output data set for residual, predicted, or actual values	ENTROPY	OUT=
specify the output data set for the support points and priors	ENTROPY	OUTP=
write the covariance matrix of the estimates to OUTEST= data set	ENTROPY	OUTCOV
write the parameter estimates to a data set	ENTROPY	OUTEST=
write the Lagrange multiplier estimates to a data set	ENTROPY	OUTL=
write the covariance matrix of the equation errors to a data set	ENTROPY	OUTS=
write the **S** matrix used in the objective function definition to a data set	ENTROPY	OUTSUSED=
read the covariance matrix of the equation errors	ENTROPY	SDATA=
Printing Options		
print collinearity diagnostics	ENTROPY	COLLIN
Options to Control Iteration Output		

Description	**Statement**	**Option**
print a summary iteration listing	ENTROPY	ITPRINT
Options to Control the Minimization Process		
specify the convergence criteria	ENTROPY	CONVERGE=
specify the maximum number of iterations allowed	ENTROPY	MAXITER=
specify the maximum number of subiterations allowed	ENTROPY	MAXSUBITER=
select the iterative minimization method to use	ENTROPY	METHOD=
specify a weight variable	WEIGHT	
General Printing Control Options		
suppress the normal printed output	ENTROPY	NOPRINT
Statements That Declare Variables		
subset the data set with *by* variables	BY	
specify identifying variables	ID	
General ENTROPY Statement Options		
specify seemingly unrelated regression	ENTROPY	SUR
specify iterated seemingly unrelated regression	ENTROPY	ITSUR
specify data-constrained generalized maximum entropy	ENTROPY	GME
specify normed moment generalized maximum entropy	ENTROPY	GMENM
specify the denominator for computing variances and covariances	ENTROPY	VARDEF=
General TEST Statement Options		
specify that a Wald test be computed	TEST	WALD
specify that a Lagrange multiplier test be computed	TEST	LM
specify that a likelihood ratio test be computed	TEST	LR
requests all three types of tests	TEST	ALL

PROC ENTROPY Statement

PROC ENTROPY *options;*

The following options can be specified in the PROC ENTROPY statement.

General Options

COLLIN
requests that the collinearity analysis of the $X'X$ matrix be performed.

GME|GCE
requests generalized maximum entropy or generalized cross entropy.

GMENM|GCENM
requests normed moment maximum entropy.

MARKOV
specifies that the model is a Markov model.

PURE
specifies a regression without an error term.

SUR | ITSUR
specifies seemingly unrelated regression estimation.

VARDEF=N | WGT | DF | WDF
specifies the denominator to be used in computing variances and covariances. VARDEF=N specifies that the number of nonmissing observations be used. VARDEF=WGT specifies that the sum of the weights be used. VARDEF=DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used. VARDEF=WDF specifies that the sum of the weights minus the model degrees of freedom be used. The default is VARDEF=DF.

Data Set Options

DATA= *SAS-data-set*
specifies the input data set. Values for the variables in the model are read from this data set.

COVBEST= CROSS | GME | GMENM *SAS-data-set*
specifies the method for producing the covariance matrix for output and for standard error calculations. The default is GME or GMENM, depending on which method is selected for estimation. If a GME estimation is performed, COVBEST=GMENM or COVBEST=GME results in GME being used to estimate the covariance matrix. The same is true for GMENM.

OUT= *SAS-data-set*
names the SAS data set to contain the residuals, from each estimation.

OUTCOV
COVOUT
writes the covariance matrix of the estimates to the OUTEST= data set in addition to the parameter estimates. The OUTCOV option is applicable only if the OUTEST= option is also specified.

OUTEST= *SAS-data-set*
names the SAS data set to contain the parameter estimates and optionally the covariance of the estimates.

OUTL= *SAS-data-set*
names the SAS data set to contain the estimated Lagrange multipliers for the models.

OUTP= *SAS-data-set*
names the SAS data set to contain the support points and estimated probabilities.

OUTS= *SAS-data-set*
names the SAS data set to contain the estimated covariance matrix of the equation errors. This is the covariance of the residuals computed from the parameter estimates.

OUTSUSED= *SAS-data-set*
names the SAS data set to contain the S matrix used in the objective function definition. The OUTSUSED= data set is the same as the OUTS= data set for the methods that iterate the S matrix.

SDATA= *SAS-data-set*
specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation covariance matrix (S matrix) in the estimation. (The SDATA= S matrix is used to provide only the initial estimate of *S* for the methods that iterate the S matrix.)

Printing Options

ITPRINT
prints the parameter estimates, objective function value, and convergence criteria at each iteration.

NOPRINT
suppresses the normal printed output but does not suppress error listings. Using any other print option turns the NOPRINT option off.

Options to Control the Minimization Process

The following options may be helpful when you experience a convergence problem. In addition to the options listed here, in the PROC ENTROPY statement you can also use any option supported by the NLO subsystem. See Chapter 10, “Nonlinear Optimization Methods,” for more details.

CONVERGE= *value*
GCONV= *value*
specifies the convergence criteria for *S*-iterated methods. The convergence measure must be less than *value* before convergence is assumed. The default value is CONVERGE=.001.

DUAL | PRIMAL
specifies whether the optimization problem is solved using the dual or primal form. The dual formalization is the default.

MAXITER= *n*
specifies the maximum number of iterations allowed. The default is MAXITER=100.

MAXSUBITER= *n*
specifies the maximum number of subiterations allowed for an iteration. The MAXSUBITER= option limits the number of step halvings. The default is MAXSUBITER=30.

METHOD= TR | NEWRAP | NRR | QN
TECHNIQUE= TR | NEWRAP | NRR | QN
TECH= TR | NEWRAP | NRR | QN
specifies the iterative minimization method to use. METHOD=TR specifies the Trust Region method, METHOD=NEWRAP specifies the Newton Raphson method, METHOD=NRR specifies the Newton Raphson-Ridge method, and METHOD=QN specifies the Quasi-Newton method. See Chapter 10, "Nonlinear Optimization Methods," for more details on optimization methods. The default is METHOD=QN for the dual estimation and METHOD=NEWRAP for the primal estimation.

BOUNDS Statement

BOUNDS *bound1 [, bound2 ...] ;*

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the ENTROPY Procedure. You can specify any number of BOUNDS statements.

Each *bound* is composed of variables and constants and inequality operators:

item operator item [operator item [operator item . . .]]

Each *item* is a constant, the name of an regressor variable, or a list of regressor names. Each *operator* is '<', '>', '<=', or '>='.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the "RESTRICT Statement" section on page 759 for more information on the computational details of estimation with inequality restrictions.

Lagrange multipliers are reported for all the active boundary constraints. In the printed output and in the OUTEST= data set, the Lagrange multiplier estimates are identified with the names BOUND1, BOUND2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive or nonbinding bounds have no effect on the estimation results and are not noted in the output. To give the constraints more descriptive names, use the RESTRICT statement instead of the BOUNDS statement.

The following BOUNDS statement constrains the estimates of the coefficients of WAGE and TARGET and the 10 coefficients of $x1$ through $x10$ to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < wage target x1-x10 < 1;
```

The following is an example of the use of the BOUNDS statement:

```
proc entropy data=zero ;
   bounds .1 <= x1 <= 100,
          0 <= x2 <=  25.6,
          0 <= x3 <=   5;

   model y = x1 x2 x3;
run;
```

The parameter estimates from this run are shown in Figure 15.21.

```
                       GME-NM Variable Estimates

                         Approx             Approx
Variable     Estimate   Std Err t Value   Pr > |t| Label

x1                0.1         0      .         .
x2              4E-16         0      .         .
x3           5.12E-18         0      .         .

Bound2       0.009384         0      .         .   0  <=  x2
Bound4       0.000032         0      .         .   0  <=  x3
```

Figure 15.21. Output from Bounded Estimation

BY Statement

BY *variables;*

A BY statement is used to obtain separate estimates for observations in groups defined by the BY variables. To save parameter estimates for each BY group, use the OUTEST= option.

ID Statement

ID *variables;*

The ID statement specifies variables to identify observations in error messages or other listings and in the OUT= data set. The ID variables are normally SAS date or datetime variables. If more than one ID variable is used, the first variable is used to identify the observations; the remaining variables are added to the OUT= data set.

Model Statement

MODEL *dependent = regressors / options ;*

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the MODEL statement, only the mean (intercept) is estimated.

The following options can be used in the MODEL statement after a slash (/).

PRIORS=(support (prior) . . . **)**

specifies the support points and prior weights on the residuals for this equation. The default is the following five support values

$$-10 * value, -value, 0, value, 10 * value$$

where $value$ is computed as

$$value = (max(y) - \bar{y}) * multiplier$$

for GME and

$$value = (max(y) - \bar{y}) * multiplier * nobs * max(X) * 0.1$$

for GME-NM. The $multiplier$ depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities default to

$$0.0005, .333, .333, .333, 0.0005$$

The probabilities and supports are selected so that hypothesis tests can be performed without adding significant bias to the estimation. These values are ad hoc.

NOINT

suppresses the intercept parameter.

PRIORS Statement

PRIORS *variable [support points [(priors)]] [variable [[support points [(priors)]]] ... ;*

The PRIORS statement specifies the support points and priors for the coefficients on the variables.

Support points for coefficients default to five points, determined as follows:

$$-2 * value, -value, 0, value, 2 * value$$

where $value$ is computed as

$$value = (\|mean\| + 3 * stderr) * multiplier$$

where the $mean$ and the $stderr$ are obtained from OLS, and the $multiplier$ depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities for each support point default to the uniform distribution.

The number of support points must be at least two. If priors are specified, they must be positive and there must be the same number of priors as there are support points. Priors and support points can also be specified through the PDATA= data set.

RESTRICT Statement

RESTRICT *restriction1 [, restriction2 ...] ;*

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an optional name, followed by an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

["name"] expression operator expression

The optional *"name"* is a string used to identify the restriction in the printed output and in the OUTEST= data set. The *operator* can be =, <, >, <= , or >=. The operator and second expression are optional, as in the TEST statement it defaults to $= 0$.

Restriction expressions can be composed of variable names, times ($*$), and plus ($+$) operators, and constants. Variable names in test expressions must be among the variables estimated by the model. The restriction expressions must be a linear function of the variables.

The following is an example of the use of the RESTRICT statement:

```
proc entropy data=one;
   restrict y1.x1*2 <= x2 + y2.x1;
   model y1 = x1 x2;
   model y2 = x1 x3;
run;
```

This example illustrates the use of compound names, y1.x1, to specify coefficients of specific equations.

TEST Statement

TEST *["name"] test1 [, test2 ...] [,/ options] ;*

The TEST statement performs tests of linear hypotheses on the model parameters.

The TEST statement applies only to parameters estimated in the model. You can specify any number of TEST statements.

Each test is written as an expression optionally followed by an equal sign (=) and a second expression:

[expression] [= expression]

Test expressions can be composed of variable names, times ($*$), plus ($+$), and minus ($-$) operators, and constants. Variables named in test expressions must be among the variables estimated by the model.

If you specify only one expression in a test, that expression is tested against zero. For example, the following two TEST statements are equivalent:

```
test a + b;

test a + b = 0;
```

When you specify multiple tests on the same TEST statement, a joint test is performed. For example, the following TEST statement tests the joint hypothesis that both of the coefficients on a and b are equal to zero.

```
test a, b;
```

To perform separate tests rather than a joint test, use separate TEST statements. For example, the following TEST statements test the two separate hypotheses that a is equal to zero and that b is equal to zero.

```
test a;
test b;
```

You can use the following options in the TEST statement.

WALD
specifies that a Wald test be computed. WALD is the default.

LM
RAO
LAGRANGE
specifies that a Lagrange multiplier test be computed.

LR
LIKE
specifies that a pseudo likelihood ratio test be computed.

ALL
requests all three types of tests.

OUT=
specifies the name of an output SAS data set that contains the test results. The format of the OUT= data set produced by the TEST statement is similar to that of the OUTEST= data set produced by the ENTROPY statement.

WEIGHT Statement

WEIGHT *variable;*

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used for the estimation. *variable* must be a numeric variable in the input data set. The regressors and the dependent variables are multiplied by the square root of the weight to form the X matrix and the left-hand side of the regression.

Details

Shannon's measure of entropy for a distribution is given by:

$$\begin{aligned} &\textbf{Maximize} && -\sum_{i=1}^{n} p_i \ln(p_i) \\ &\textit{subject to:} && \sum_{i=1}^{n} p_i = 1 \end{aligned}$$

where p_i is the probability associated with the *i*th support point. Properties that characterize the entropy measure are set forth by Kapur and Kesavan (1992).

The idea is to maximize the entropy of the distribution with respect to the probabilities p_i subject to constraints that reflect any other known information about the distribution (Jaynes 1957). This measure, in the absence of additional information, reaches a maximum when the probabilities are uniform. A distribution other than the uniform distribution arises from information already known.

Generalized Maximum Entropy

Reparameterization of the errors in a regression equation is the process of specifying a support for the errors, observation by observation. If a two-point support is used, the error for the *t*th observation is reparameterized by setting $e_t = w_{t1}\, v_{t1} + w_{t2}\, v_{t2}$ where v_{t1} and v_{t2} are the upper and lower bounds for the *t*th error e_t, and w_{t1} and w_{t2} represent the weight associated with the point v_{t1} and v_{t2}. The error distribution is usually chosen to be symmetric, centered about zero, and the same across observations so that $v_{t1} = -v_{t2} = R$, where *R* is the support value chosen for the problem (Golan, Judge, and Miller (1996)).

The Generalized Maximum Entropy (GME) formulation was proposed for the ill-posed or underdetermined case where there is insufficient data to estimate the system with traditional methods. β is reparameterized by defining a support for β (and a set of weights in the cross entropy case), which define a prior distribution for β.

In the simplest case, each β_k is reparameterized as $\beta_k \;=\; p_{k1}\, z_{k1} \;+\; p_{k2}\, z_{k2}$ where p_{k1} and p_{k2} represent the probabilities ranging from [0,1] for each β, and z_{k1} and z_{k2} represent the lower and upper bounds placed on β_k. The support points, z_{k1} and z_{k2}, are usually distributed symmetrically around the most likely value for β_k based on some prior knowledge.

With these reparameterizations, the GME estimation problem is

$$\begin{array}{ll}
\textbf{Maximize} & H(p,w) \;=\; -p' \ln(p) \;-\; w' \ln(w) \\
\textit{subject to:} & y \;=\; X\, Z\, p \;+\; V\, w \\
 & 1_K \;=\; (I_K \,\otimes\, 1_L')\, p \\
 & 1_T \;=\; (I_T \,\otimes\, 1_L')\, w
\end{array}$$

where

$$\beta \;=\; Z\,p \;=\; \left[\begin{array}{cccccccccc}
z_{11} & \cdots & z_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & z_{12} & \cdots & z_{L2} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1K} & \cdots & z_{LK}
\end{array}\right]
\left[\begin{array}{c}
p_{11} \\ \vdots \\ p_{L1} \\ p_{12} \\ \vdots \\ p_{L2} \\ \vdots \\ p_{1K} \\ \vdots \\ p_{LK}
\end{array}\right]$$

$$e \;=\; V\,w \;=\; \left[\begin{array}{cccccccccc}
v_{11} & \cdots & v_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & v_{12} & \cdots & v_{L2} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{1T} & \cdots & v_{LT}
\end{array}\right]
\left[\begin{array}{c}
w_{11} \\ \vdots \\ w_{L1} \\ w_{12} \\ \vdots \\ w_{L2} \\ \vdots \\ w_{1T} \\ \vdots \\ w_{LT}
\end{array}\right]$$

y denotes the *T* column vector of observations of the dependent variables; *X* denotes the $(T \times K)$ matrix of observations of the independent variables; *p* denotes the *LK* column vector of weights associated with the points in *Z*; *w* denotes the *LT* column vector of weights associated with the points in *V*; 1_K, 1_L, and 1_T are *K*-, *L*-, and

T-dimensional column vectors, respectively, of ones; and I_K and I_T are $(K \times K)$ and $(T \times T)$ dimensional identity matrices.

These equations can be rewritten using set notation.

$$\textbf{Maximize} \quad H(p,w) \;=\; -\sum_{l=1}^{L}\sum_{k=1}^{K} p_{kl}\,\ln(p_{kl}) \;-\; \sum_{l=1}^{L}\sum_{t=1}^{T} w_{tl}\,\ln(w_{tl})$$

$$\textit{subject to:} \quad y_t \;=\; \sum_{l=1}^{L}\left[\sum_{k=1}^{K}\left(X_{kt}\,Z_{kl}\,p_{kl}\right) \;+\; V_{tl}\,w_{tl}\right]$$

$$\sum_{l=1}^{L} p_{kl} \;=\; 1 \;\text{ and }\; \sum_{l=1}^{L} w_{tl} \;=\; 1$$

The subscript *l* denotes the support point (l=1,2,..,L), *k* denotes the parameter (k=1,2,..K), and *t* denotes the observation (t=1,2,..,T).

The GME objective is strictly concave; therefore, a unique solution exists. The optimal estimated probabilities, *p* and *w*, and the prior supports, *Z* and *V*, can be used to form the point estimates of the unknown parameters, β, and the unknown errors, *e* .

Generalized Cross Entropy

Kullback and Leibler's (1951) cross entropy measures the "discrepancy" between one distribution and another. Cross entropy is called a measure of discrepancy rather than distance because it does not satisfy some of the properties one would expect of a distance measure. (See Kapur and Kesavan [1992] for a discussion of cross entropy as a measure of discrepancy.) Mathematically, cross entropy is written as

$$\textbf{Minimize} \quad \sum_{i=1}^{n} p_i \ln(\,p_i \,/\, q_i)$$

$$\textit{subject to:} \quad \sum_{i=1}^{n} p_i \;=\; 1,$$

where q_i is the probability associated with the *i*th point in the distribution from which the discrepancy is measured. The q_i (in conjunction with the support) are often referred to as the prior distribution. The measure is nonnegative and is equal to zero when p_i equals q_i. The properties of the cross entropy measure are examined by Kapur and Kesavan (1992).

The Principle of Minimum Cross Entropy (Kullback 1959; Good 1963) states that one should choose probabilities that are as close as possible to the prior probabilities.

That is, out of all probability distributions satisfying a given set of constraints reflecting known information about the distribution, choose the distribution that is closest (as measured by $p(\ln(p) - \ln(q))$refgce1) to the prior distribution. When the prior distribution is uniform, maximum entropy and minimum cross entropy produce the same results (Kapur and Kesavan 1992), with higher values for entropy corresponding exactly with the lower values for cross entropy.

If the prior distributions are nonuniform, the problem can be stated as a Generalized Cross Entropy (GCE) formulation. The cross entropy terminology specifies weights, q_i and u_i, for the points Z and V, respectively. Given informative prior distributions on Z and V, the GCE problem is

$$\begin{aligned} \textbf{Minimize} \quad I(p,q,w,u) \;&=\; \frac{p'\,\ln(p/q)}{w'\,\ln(w/u)} \\ \textit{subject to:} \quad y \;&=\; X\,Z\,p \;+\; V\,w \\ 1_K \;&=\; (I_K \otimes 1'_L)\,p \\ 1_T \;&=\; (I_T \otimes 1'_L)\,w \end{aligned}$$

where *y* denotes the *T* column vector of observations of the dependent variables; *X* denotes the $(T \times K)$ matrix of observations of the independent variables; *q* and *p* denote *LK* column vectors of prior and posterior weights, respectively, associated with the points in *Z*; *u* and *w* denote the *LT* column vectors of prior and posterior weights, respectively, associated with the points in *V*; 1_K, 1_L, and 1_T are *K*- , *L*-, and *T*-dimensional column vectors, respectively, of ones; and I_K and I_T are ($K \times K$) and ($T \times T$) dimensional identity matrices.

The optimization problem can be rewritten using set notation.

$$\textbf{Minimize} \quad I(p,q,w,u) \;=\; \sum_{l=1}^{L}\sum_{k=1}^{K} p_{kl}\,\ln(p_{kl}/q_{kl}) \;+\; \sum_{l=1}^{L}\sum_{t=1}^{T} w_{tl}\,\ln(w_{tl}/u_{tl})$$

$$\textit{subject to:} \quad y_t \;=\; \sum_{l=1}^{L}\left[\sum_{k=1}^{K}\left(X_{kt}\,Z_{kl}\,p_{kl}\right) \;+\; V_{tl}\,w_{tl}\right]$$

$$\sum_{l=1}^{L} p_{kl} \;=\; 1 \;\text{ and }\; \sum_{l=1}^{L} w_{tl} \;=\; 1$$

The subscript *l* denotes the support point (l=1,2,..,L), *k* denotes the parameter (k=1,2,..K), and *t* denotes the observation (t=1,2,..,T).

The objective function is strictly convex; therefore, there is a unique global minimum for the problem (Golan, Judge, and Miller 1996). The optimal estimated weights, *p* and *w*, and the prior supports, *Z* and *V*, can be used to form the point estimates of the unknown parameters, β, and the unknown errors, *e* using

$$\beta = Z p = \begin{bmatrix} z_{11} & \cdots & z_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & z_{12} & \cdots & z_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1K} & \cdots & z_{LK} \end{bmatrix} \begin{bmatrix} p_{11} \\ \vdots \\ p_{L1} \\ p_{12} \\ \vdots \\ p_{L2} \\ \vdots \\ p_{1K} \\ \vdots \\ p_{LK} \end{bmatrix}$$

$$e = V w = \begin{bmatrix} v_{11} & \cdots & v_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & v_{12} & \cdots & v_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{1T} & \cdots & v_{LT} \end{bmatrix} \begin{bmatrix} w_{11} \\ \vdots \\ w_{L1} \\ w_{12} \\ \vdots \\ w_{L2} \\ \vdots \\ w_{1T} \\ \vdots \\ w_{LT} \end{bmatrix}$$

Computational Details

This constrained estimation problem can either be solved directly (Primal) or by using the dual form. Either way, it is prudent to factor out one probability for each parameter and each observation as the sum of the other probabilities. This factoring reduces the computational complexity significantly. If the primal formalization is used and two support points are used for the parameters and the errors, the resulting GME problem is O($(nparms + nobs)^3$). For the dual form the problem is O($(nobs)^3$). Therefore for large data sets, GME-NM should be used instead of GME.

Normed Moment Generalized Maximum Entropy

The default estimation technique is Normed Moment Generalized Maximum Entropy (GME-NM). This is simply GME with the data constraints modified by multiplying both sides by X'. GME-NM then becomes

$$\textbf{Maximize} \quad H(p, w) = -p' \ln(p) - w' \ln(w)$$

$$\begin{aligned} \textit{subject to:} \quad X'y &= X'X\,Z\,p + X'V\,w \\ 1_K &= (I_K \otimes 1'_L)\,p \\ 1_T &= (I_T \otimes 1'_L)\,w \end{aligned}$$

There is also the Cross Entropy version of GME-NM, which has the same form as GCE but with the normed constraints.

GME versus GME-NM

GME-NM is more computationally attractive than GME for large data sets because the computational complexity of estimation problem primarily depends on the number of parameters and not on the number of observations. GME-NM is based on the first moment of the data whereas GME is based on the data itself. If the distribution of the residuals is well defined by its first moment, then GME-NM is a good choice. So if the residuals are normally distributed or exponentially distributed, then GME-NM should be used. On the other hand if the distribution is Cauchy, lognormal, or other distribution, where the first moment does not describe the distribution, then use GME. See Example 15.1 for an illustration of this point.

Maximum Entropy-based Seemingly Unrelated Regression

In a multivariate regression model, the errors in different equations may be correlated. In this case, the efficiency of the estimation may be improved by taking these cross-equation correlations into account. Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems.

Like SUR in the least squares setting, the Maximum Entropy SUR (GME-SUR) method assumes that all the regressors are independent variables, and uses the correlations among the errors in different equations to improve the regression estimates. The GME-SUR method requires an initial entropy regression to compute residuals. The entropy residuals are used to estimate the cross-equation covariance matrix.

In the iterative GME-SUR (ITGME-SUR) case, the preceding process is repeated using the residuals from the GME-SUR estimation to estimate a new cross-equation covariance matrix. ITGME-SUR method alternates between estimating the system coefficients and estimating the cross-equation covariance matrix until the estimated coefficients and covariance matrix converge.

The estimation problem becomes the Generalized Maximum Entropy system adapted for multi-equations.

$$\begin{aligned} \textbf{Maximize} \quad H(p,w) &= -p'\ln(p) - w'\ln(w) \\ \textit{subject to:} \quad y &= X\,Z\,p + V\,w \\ 1_{KM} &= (I_{KM} \otimes 1'_L)\,p \\ 1_{MT} &= (I_{MT} \otimes 1'_L)\,w \end{aligned}$$

where

$$\beta \ = \ Z\,p$$

$$Z \ = \ \begin{bmatrix} z_{11}^{1} & \cdots & z_{L1}^{1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & z_{11}^{K} & \cdots & z_{L1}^{K} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1M}^{1} & \cdots & z_{LM}^{1} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1M}^{K} & \cdots & z_{LM}^{K} \end{bmatrix}$$

$$p \ = \ \left[\ p_{11}^{1} \ \cdot \ p_{L1}^{1} \ \cdot \ p_{11}^{K} \ \cdot \ p_{L1}^{K} \ \cdot \ p_{1M}^{1} \ \cdot \ p_{LM}^{1} \ \cdot \ p_{1M}^{K} \ \cdot \ p_{LM}^{K}\ \right]'$$

$$e \ = \ V\,w$$

$$V \ = \ \begin{bmatrix} v_{11}^{1} & \cdots & v_{11}^{L} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & v_{1T}^{1} & \cdots & v_{1T}^{L} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{M1}^{1} & \cdots & v_{M1}^{L} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{MT}^{1} & \cdots & v_{MT}^{L} \end{bmatrix}$$

$$w \ = \ \left[\ w_{11}^{1} \ \cdot \ w_{11}^{L} \ \cdot \ w_{1T}^{1} \ \cdot \ w_{1T}^{L} \ \cdot \ w_{M1}^{1} \ \cdot \ w_{M1}^{L} \ \cdot \ w_{MT}^{1} \ \cdot \ w_{MT}^{L}\ \right]'$$

y denotes the *MT* column vector of observations of the dependent variables; *X* denotes the (*MT* x *KM*) matrix of observations for the independent variables; *p* denotes the *LKM* column vector of weights associated with the points in *Z*; *w* denotes the *LMT* column vector of weights associated with the points in *V*; 1_L, 1_{KM}, and 1_{MT} are *L*-, *KM*-, and *MT*-dimensional column vectors, respectively, of ones; and I_{KM} and I_{MT} are (*KM* x *KM*) and (*MT* x *MT*) dimensional identity matrices. The subscript *l* denotes the support point (l=1,2,..,L), *k* denotes the parameter (k=1,2,..K), *m* denotes the equation (m=1,2,...,M), and *t* denotes the observation (t=1,2,..,T).

Using this notation, the Maximum Entropy problem that is analogous to the OLS problem used as the initial step of the traditional SUR approach is:

Maximize $H(p,w) \ = \ -p' \ln(p) \ - \ w' \ln(w)$

subject to: $(y \ - \ X\,Z\,p) \ = \sqrt{\Sigma}\,V\,w$

$$1_{KM} \ = \ (I_{KM} \otimes 1_L')\,p$$

$$1_{MT} \ = \ (I_{MT} \otimes 1_L')\,w$$

The results are GME-SUR estimates with independent errors, the analog of OLS. The covariance matrix $\hat{\Sigma}$ is computed based on the residual of the equations, $Vw = e$. An $L'L$ factorization of the $\hat{\Sigma}$ is used to compute the square root of the matrix.

After solving this problem, these entropy-based estimates are analogous to Aitken 2-step. For iterative GME-SUR, the covariance matrix of the errors is recomputed, and a new $\hat{\Sigma}$ is computed and factored. As in traditional ITSUR, this process repeats until the covariance matrix and the parameter estimates converge.

The estimation of the parameters for the normed-moment version of SUR, GME-SUR-NM, uses an identical process. The constraints for the normed-moment version of SUR, GME-SUR-NM, is defined as:

$$X'y \;=\; X'(\mathbf{S}^{-1}\otimes\mathbf{I})X\,Z\,p \;+\; X'(\mathbf{S}^{-1}\otimes\mathbf{I})V\,w$$

The estimation of the parameters for GME-SUR-NM uses an identical process as outlined previously for GME-SUR.

Generalized Maximum Entropy for Multinomial Discrete Choice Models

Multinomial discrete choice models take the form of an experiment consisting of n trials. On each trial, one of k alternatives is observed. If y_{ij} is the random variable that takes on the value 1 when alternative j is selected for the ith trial and 0 otherwise, then the probability that y_{ij} is 1 conditional on a vector of regressors X_i and unknown parameter vector β_j is

$$\Pr(y_{ij} = 1|X_i, \beta_j) = G(X_i'\beta_j)$$

where $G()$ is a link function. For noisy data the model becomes

$$y_{ij} = G(X_i'\beta_j) + \epsilon_{ij} = p_{ij} + \epsilon_{ij}$$

The standard maximum likelihood approach for multinomial logit is equivalent to the maximum entropy solution for discrete choice models. The generalized maximum entropy approach avoids an assumption of the form of the link function $G()$.

The generalized maximum entropy for discrete choice models (GME-D) is written in primal form as

$$\begin{array}{lll}
\textbf{Maximize} & H(p,w) & = -p'\ \ln(p)\ -\ w'\ \ln(w) \\
\textit{subject to:} & (I_j \otimes X'y) & = (I_j \otimes X')p\ +\ (I_j \otimes X')V\,w \\
 & \sum_j^k p_{ij} & = 1 \quad \text{for } i = 1 \text{ to } N \\
 & \sum_m^L w_{ijm} & = 1 \quad \text{for } i = 1 \text{ to } N \text{ and } j = 1 \text{ to } k
\end{array}$$

The parameters β_j are the Lagrange multipliers of the constraints. The covariance matrix of the parameter estimates is computed as the inverse of the Hessian of the dual form of the objective function.

Information Measures

Normalized entropy, NE, measures the relative informational content of both the signal and noise components through *p* and *w*, respectively (Golan, Judge, and Miller 1996). Let *S* denote the normalized entropy of the signal, $X\beta$, defined as

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{-q' \ln(q)}$$

where $S(\tilde{p}) \, \epsilon \, [0,1]$. In the case of GME, where uniform priors are assumed, *S* may be written as

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{\sum_i \ln(M_i)}$$

where M_i is the number of support points for parameter i. A value of 0 for *S* implies there is no uncertainty regarding the parameters, hence, it is a degenerate situation. However, a value of 1 implies that the posterior distributions equal the priors, which indicates total uncertainty if the priors are uniform.

Since NE is relative, it may be used for comparing various situations. Consider adding a data point to the model. If $S_{T+1} = S_T$ then there is no additional information contained within that data constraint. However, if $S_{T+1} < S_T$, then the data point will give a more informed set of parameter estimates.

NE can be used for determining the importance of particular variables in regard to the reduction of the uncertainty they bring to the model. Each of the k parameters being estimated has an associated NE defined as

$$S(\tilde{p_k}) = \frac{-\tilde{p}_k' \ln(\tilde{p}_k)}{-\ln(q_k)}$$

or if in the GME case,

$$S(\tilde{p_k}) = \frac{-\tilde{p}_k' \ln(\tilde{p}_k)}{\ln(M)}$$

where p_k is the vector of supports for parameter β_k and m is the corresponding number of support points. Since a value of 1 implies no relative information for that particular sample, Golan, Judge, and Miller (1996) suggest an exclusion criteria of $S(\tilde{p_k}) > 0.99$ as an acceptable means of selecting noninformative variables. See Golan, Judge, and Miller (1996) for some simulation results.

Parameter Covariance For GCE

For the data-constrained cross-entropy problem, the estimate of the asymptotic variance of the signal parameter is given by

$$V\hat{a}r(\hat{\beta}) = \frac{\hat{\sigma_\gamma^2}(\hat{\beta})}{\hat{\psi}^2(\hat{\beta})}(X'X)^{-1}$$

where

$$\hat{\sigma_\gamma^2}(\hat{\beta}) = \frac{1}{N}\sum_{i=1}^{N}\gamma_i^2$$

and γ_i is the Lagrange multiplier associated with the *i*th row of the Vw constraint matrix. Also,

$$\hat{\psi}^2(\hat{\beta}) = \left[\frac{1}{N}\sum_{i=1}^{N}\left(\sum_{j=1}^{J}v_{ij}^2 w_{ij} - (\sum_{j=1}^{J}v_{ij}w_{ij})^2\right)^{-1}\right]^2$$

Parameter Covariance For GCE-NM

Golan, Judge, and Miller (1996) give the finite approximation to the asymptotic variance matrix of the Normed Moment formulation as

$$V\hat{a}r(\hat{\beta}) = \Sigma_z X'XC^{-1}DC^{-1}X'X\Sigma_z$$

where

$$C = X'X\Sigma_z X'X + \Sigma_v$$

and

$$D = X'\Sigma_e X$$

Recall that in the Normed Moment formulation, V is the support of $\frac{X'e}{T}$, which implies Σ_v is a K-dimensional variance matrix. Σ_z and Σ_v are both diagonal matrices with the form

$$\Sigma_z = \begin{bmatrix} \sum_{l=1}^{L} z_{1l}^2 p_{1l} - (\sum_{l=1}^{L} z_{1l}p_{1l})^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{l=1}^{L} z_{Kl}^2 p_{Kl} - (\sum_{l=1}^{L} z_{Kl}p_{Kl})^2 \end{bmatrix}$$

and

$$\Sigma_v = \begin{bmatrix} \sum_{j=1}^{J} v_{1j}^2 w_{jl} - (\sum_{j=1}^{J} v_{1j} w_{1j})^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{j=1}^{J} v_{Kl}^2 w_{Kl} - (\sum_{j=1}^{J} v_{Kl} w_{Kl})^2 \end{bmatrix}$$

Statistical Tests

Since the GME estimates have been shown to be asymptotically normally distributed, the classical Wald, Score, and Likelihood statistics may be used for testing linear restrictions on the parameters.

Wald Tests

Let $H_0 : L\beta = m$, where L is a set of linearly independent combinations of the elements of β. Then under the null hypothesis, the Wald test statistic,

$$T_W = (L\beta - m)' \left(L(\hat{Var}(\hat{\beta}))L' \right)^{-1} (L\beta - m)$$

has a central χ^2 limiting distribution with degrees of freedom equal to the rank of L.

Pseudo-likelihood Ratio Tests

Using the conditionally maximized entropy function as a pseudo-likelihood, F, Mittelhammer and Cardell (2000) state that

$$\frac{2\hat{\psi}(\hat{\beta})}{\hat{\sigma_\gamma^2}(\hat{\beta})} \left(F(\hat{\beta}) - F(\tilde{\beta}) \right)$$

has the limiting distribution of the Wald statistic when testing the same hypothesis. Note that $F(\hat{\beta})$ and $F(\tilde{\beta})$ are the maximum values of the entropy objective function over the full and restricted parameter spaces, respectively.

Score Tests

Again using the GME function as a pseudo-likelihood, Mittelhammer and Cardell (2000) define the Score statistic as

$$\frac{1}{\hat{\sigma_\gamma^2}(\tilde{\beta})} G(\tilde{\beta})'(X'X)^{-1} G(\tilde{\beta})$$

where G is the gradient of F, which is being evaluated at the optimum point for the restricted parameters. This of course shares the same limiting distribution as the Wald and pseudo-likelihood ratio tests.

Missing Values

If an observation the input data set contains missing value for any of the regressors or dependent values, that observation is dropped.

Output Data Sets

OUT= Data Set

The OUT= data set specified on the ENTROPY statement contains residuals of the dependent variables computed from the parameter estimates. The ID and BY variables are also added to this data set.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- _NAME_, a character variable of length 32, blank for observations containing parameter estimates or a parameter name for observations containing covariances
- _TYPE_, a character variable of length 8 identifying the estimation method: GME or GMENM
- the parameters estimated

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the _NAME_ values containing the parameter names for the rows.

OUTP= Data Set

The OUTP= data set specified on the ENTROPY statement contains the probabilities estimated for each support point, as well as the support points and prior probabilities used in the estimation.

The variables in the data set are as follows:

- BY variables
- _TYPE_, a character variable of length 8 identifying the estimation method: GME or GMENM
- Variable, a character variable of length 32 indicating the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- _OBS_, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The _OBS_ and the equation name identify which residual the probability is associated with

- Equation, a character variable of length 32 indicating the name of the dependent variable
- NSupport, a numeric variable indicating the number of support points for each basis. This number is needed for the PDATA= data set.
- Support, a numeric variable that is the support value the probability is associated with
- Prior, a numeric variable that is the prior probability associated with the probability
- Prb, a numeric variable that is the estimated probability

OUTL= Data Set

The OUTL= data set specified on the ENTROPY statement contains the Lagrange multiplier values for the underlying maximum entropy problem.

The variables in the data set are as follows:

- BY variables
- Equation, a character variable of length 32 indicating the name of the dependent variable
- Variable, a character variable of length 32 indicating the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- _OBS_, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The _OBS_ and the equation name identify which residual the Lagrange multiplier is associated with
- LagrangeMult, a numeric variable containing the Lagrange multipliers

ODS Table Names

PROC ENTROPY assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 15.1. ODS Tables Produced in PROC ENTROPY

ODS Table Name	**Description**	**Option**
ConvCrit	Convergence criteria for estimation	default
ConvergenceStatus	Convergence status	default
DatasetOptions	Data sets used	default
MinSummary	Number of parameters, estimation kind	default
ObsUsed	Observations read, used, and missing.	default
ParameterEstimates	Parameter Estimates	default
ResidSummary	Summary of the SSE, MSE for the equations	default
TestResults	Test statement table	

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the ENTROPY procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

ODS Graph Names

PROC ENTROPY assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 15.2.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 15.2. ODS Graphics Produced by PROC ENTROPY

ODS Graph Name	Plot Description
ActualByPredicted	Predicted vs actual plot
CooksD	Cook's D plot
StudentResidualPlot	Studentized residual plot

Examples

Example 15.1. Nonnormal Error Estimation

This example illustrates the difference between GME-NM and GME. One of the basic assumptions of OLS estimation is that the errors in the estimation are normally distributed. If this assumption is violated, the estimated parameters are biased. For GME-NM the story is similar. If the first moment of the distribution of the errors and a scale factor cannot be used to describe the distribution, then the parameter estimates from GME-MN will be more biased. GME is much less sensitive to the underlying distribution of the errors than GME-NM.

Consider the following model

$$y = a * x_1 + b * x_2 + \epsilon$$

where ϵ is distributed first normally, then chi-squared with six degrees of freedom, and finally distributed Cauchy.

Here 100 samples of 10 observations each were drawn from each population. The data for the Cauchy errors is generated using the following SAS code:

```
data one;
    call streaminit(156789);
    do by = 1 to 100;
```

```
        do x2 = 1 to 10;
           x1 = 10 * ranuni( 512);
           y = x1 + 2*x2 + rand('cauchy');
           output;
        end;
    end;
run;
```

The code for the other distributions is identical except for the argument to the RAND() function.

The parameters to the model were estimated using data-constrained maximum entropy using the following statements:

```
proc entropy data = one gme outest=parm1;
   model y = x1 x2;
   by by;
run;
```

The estimation using moment-constrained maximum entropy was performed by changing the GME option to GMENM. For comparison the same model was estimated using OLS with the following SAS statements.

```
proc reg data = one outest=parm3;
   model y = x1 x2;
   by by;
run;
```

The 100 estimations of the coefficient on variable `x1` are then summarized using the following SAS statements.

```
proc univariate data=parm1 ;
var x1;
run;
```

The following table summarizes the results from the estimations. The true value for the coefficient on `x1` is 1.0.

Estimation	Normal		Chi-Squared		Cauchy	
Method	Mean	Std Deviation	Mean	Std Deviation	Mean	Std Deviation
GME	0.418	0.117	0.626	.330	0.818	3.36
GME-NM	0.878	0.116	0.948	0.427	3.03	13.62
OLS	0.973	0.142	1.023	0.467	5.54	26.83

Note that for normal or nearly normal data moment-constrained maximum entropy is a good choice. For distributions not well described by a normal distribution, data-constrained maximum entropy is a good choice.

Example 15.2. Unreplicated Factorial Experiments

Overview

Factorial experiments are useful for studying the effects of various factors on a response. For the practitioner constrained to the use of OLS regression, there must be replication to estimate all of the possible main and interaction effects in a factorial experiment. Using OLS regression to analyze unreplicated experimental data will result in no degrees of freedom for error in the ANOVA table, i.e. there are as many parameters as observations. This situation leaves the experimenter unable to compute confidence intervals or perform hypothesis testing on the parameter estimates.

Several options are available when replication is impossible. The higher-order interactions may be assumed to have negligible effects and have their degrees of freedom pooled to create the error degrees of freedom that will be used to perform inference on the lower-order estimates. Or, if a preliminary experiment is being run, a normal probability plot of all effects may give a clue as to which effects are significant and should be focused upon in a later, more complete experiment. The following example illustrates the probability plot methodology and an alternative using PROC ENTROPY. Consider a 2^4 factorial model with no replication. The data are taken from Myers and Montgomery(1995).

```
data rate;
   do a=-1,1; do b=-1,1; do c=-1,1; do d=-1,1;
      input y @@;
      ab=a*b; ac=a*c; ad=a*d; bc=b*c; bd=b*d; cd=c*d;
      abc=a*b*c; abd=a*b*d; acd=a*c*d; bcd=b*c*d;
      abcd=a*b*c*d;
      output;
   end; end; end; end;
   datalines;
   45 71 48 65 68 60 80 65 43 100 45 104 75 86 70 96
   ;
run;
```

Analyze the data using PROC REG, then output the resulting estimates.

```
proc reg data=rate outest=regout;
   model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;

proc transpose data=regout out=ploteff name=effect prefix=est;
   var a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
```

Now the normal scores for the estimates must be computed.

```
proc rank data=ploteff normal=blom out=qqplot;
   var est1;
   ranks normalq;
```

To create the probability plot, simply plot the estimates versus their normal scores.

```
proc gplot data=qqplot;
   plot normalq*est1=effect;
```

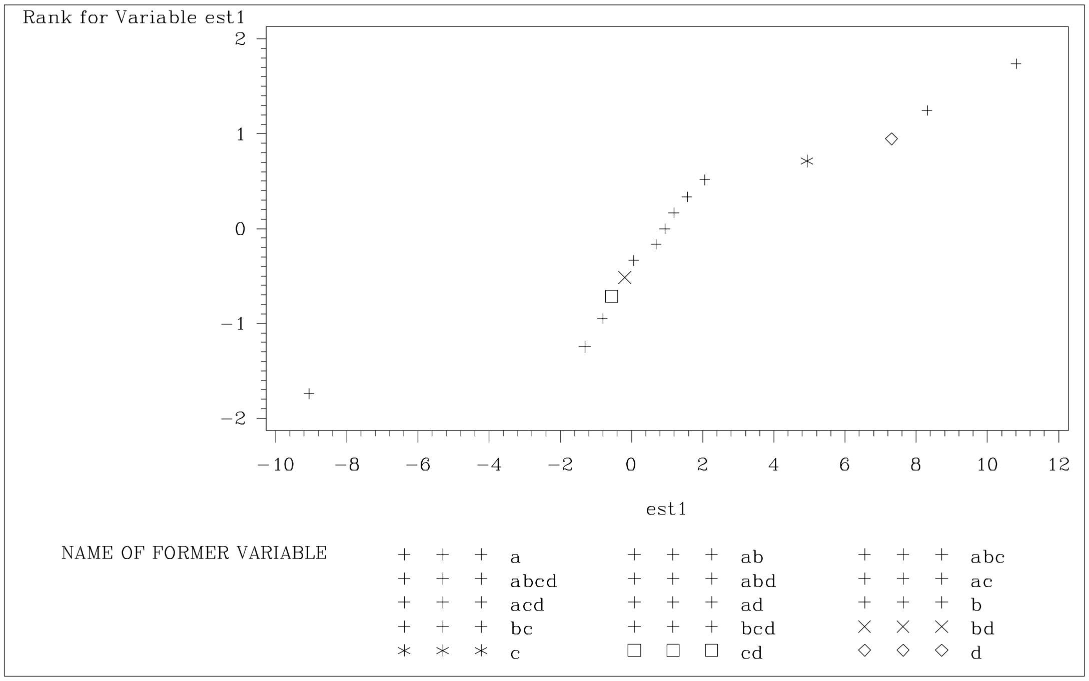

Figure 15.22. Normal Probability Plot of Effects

The plot shown in Figure 15.22 displays evidence that the a, c, d, ac and ad estimates do not fit into the purely random normal model, which suggests that they may have some significant effect on the response variable. To verify this, fit a reduced model that contains only these effects.

```
proc reg data=rate;
   model y=a c d ad ac;
```

The estimates for the reduced model are shown in Output 15.2.1.

Output 15.2.1. Reduced Model OLS Estimates

```
                              The REG Procedure
                                Model: MODEL1
                            Dependent Variable: y

                             Parameter Estimates

                            Parameter       Standard
   Variable      DF          Estimate          Error    t Value    Pr > |t|

   Intercept      1          70.06250        3.40920      20.55      <.0001
   a              1           7.31250        3.40920       2.14      0.0576
   c              1           1.56250        3.40920       0.46      0.6565
   d              1          10.81250        3.40920       3.17      0.0100
   ad             1           8.31250        3.40920       2.44      0.0350
   ac             1          -0.18750        3.40920      -0.05      0.9572
```

These results certainly support the probability plot methodology. However, PROC ENTROPY can directly estimate the full model without having to rely upon the probability plot for clues to which effects may be significant. A simple ENTROPY run using default parameter and error supports is shown.

```
proc entropy data=rate ;
   model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
```

Proc ENTROPY immediately picks out a, c, d, ac and ad as significant. The GME estimates are shown in Output 15.2.2.

Output 15.2.2. Full Model Entropy Results

```

       bcd             0.059594         0.0654       0.91         0.3755
       abcd             0.02476         0.0387       0.64         0.5317
       Intercept       69.87685         1.1404      61.28         <.0001
```

Example 15.3. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. This is a continuation of the "Simple Regression Analysis" in the section "Getting Started" on page 735. These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the ENTROPY procedure, see the "ODS Graphics" section on page 774.

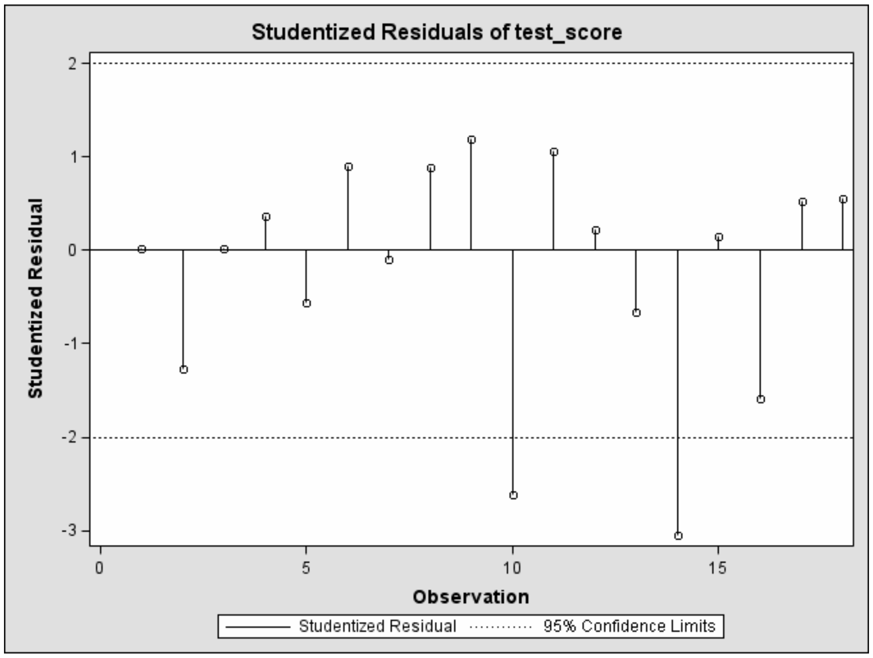
The following statements show how to generate ODS graphics plots with the ENTROPY procedure. The plots are displayed in Output 15.3.1 through Output 15.3.3.

```
ods html;
ods graphics on;

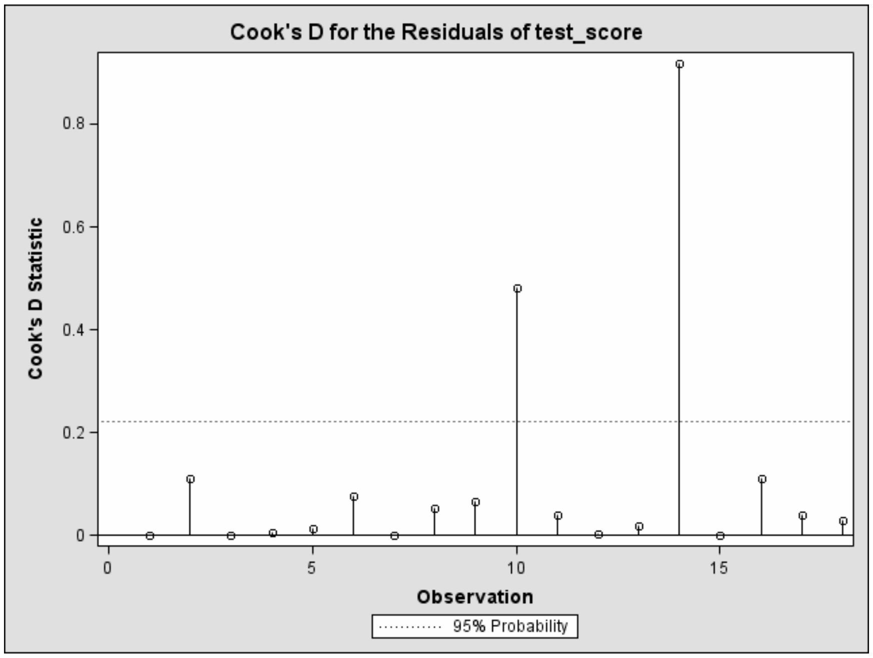
proc entropy data=coleman;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;

ods graphics off;
ods html close;
```

Output 15.3.1. Studentized Residuals Plot (Experimental)



Output 15.3.2. Cook's D Plot (Experimental)



Output 15.3.3. Predicted vs Actual Plot (Experimental)

Chapter 16
The EXPAND Procedure

Chapter Contents

Chapter 16
The EXPAND Procedure

Overview

The EXPAND procedure converts time series from one sampling interval or frequency to another and interpolates missing values in time series. A wide array of data transformation is also supported. Using PROC EXPAND, you can collapse time series data from higher frequency intervals to lower frequency intervals, or expand data from lower frequency intervals to higher frequency intervals. For example, quarterly estimates can be interpolated from an annual series, or quarterly values can be aggregated to produce an annual series.

Time series frequency conversion is useful when you need to combine series with different sampling intervals into a single data set. For example, if you need as input to a monthly model a series that is only available quarterly, you might use PROC EXPAND to interpolate the needed monthly values.

You can also interpolate missing values in time series, either without changing series frequency or in conjunction with expanding or collapsing the series.

You can convert between any combination of input and output frequencies that can be specified by SAS time interval names. (See Chapter 3, “Date Intervals, Formats, and Functions,” for a complete description of SAS interval names.) When the “from” and “to” intervals are specified, PROC EXPAND automatically accounts for calendar effects such as the differing number of days in each month and leap years.

The EXPAND procedure also handles conversions of frequencies that cannot be defined by standard interval names. Using the FACTOR= option, you can interpolate any number of output observations for each group of a specified number of input observations. For example, if you specify the option FACTOR=(13:2), 13 equally spaced output observations are interpolated from each pair of input observations.

You can also convert aperiodic series, observed at arbitrary points in time, into periodic estimates. For example, a series of randomly timed quality control spot-check results might be interpolated to form estimates of monthly average defect rates.

The EXPAND procedure can also change the observation characteristics of time series. Time series observations can measure beginning-of-period values, end-of-period values, midpoint values, or period averages or totals. PROC EXPAND can convert between these cases. You can construct estimates of interval averages from end-of-period values of a variable, estimate beginning-of-period or midpoint values from interval averages, or compute averages from interval totals, and so forth.

By default, the EXPAND procedure fits cubic spline curves to the nonmissing values of variables to form continuous-time approximations of the input series. Output series are then generated from the spline approximations. Several alternate conversion methods are described in the section “Conversion Methods” on page 802. You can also interpolate estimates of the rate of change of time series by differentiating the interpolating spline curve.

Various transformations can be applied to the input series prior to interpolation and to the interpolated output series. For example, the interpolation process can be modified by transforming the input series, interpolating the transformed series, and applying the inverse of the input transformation to the output series. PROC EXPAND can also be used to apply transformations to time series without interpolation or frequency conversion.

The results of the EXPAND procedure are stored in a SAS data set. No printed output is produced.

Experimental graphics are now available with the EXPAND procedure. For more information, see the "ODS Graphics" section on page 820.

Getting Started

Converting to Higher Frequency Series

To create higher frequency estimates, specify the input and output intervals with the FROM= and TO= options, and list the variables to be converted in a CONVERT statement. For example, suppose variables X, Y, and Z in the data set ANNUAL are annual time series, and you want monthly estimates. You can interpolate monthly estimates by using the following statements:

```
proc expand data=annual out=monthly from=year to=month;
   convert x y z;
run;
```

Note that interpolating values of a time series does not add any real information to the data as the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series containing interpolated values.

Aggregating to Lower Frequency Series

PROC EXPAND provides two ways to convert from a higher frequency to a lower frequency. When a curve fitting method is used, converting to a lower frequency is no different than converting to a higher frequency–you just specify the desired output frequency with the TO= option. This provides for interpolation of missing values and allows conversion from nonnested intervals, such as converting from weekly to monthly values.

Alternatively, you can specify simple aggregation or selection without interpolation of missing values. This might be useful, for example, if you wanted to add up monthly values to produce annual totals but wanted the annual output data set to contain values only for complete years.

To perform simple aggregation, use the METHOD=AGGREGATE option in the CONVERT statement. For example, the following statements aggregate monthly values to yearly values:

```
proc expand data=monthly out=annual from=month to=year;
   convert x y z / method=aggregate;
   convert a b c / observed=total method=aggregate;
   id date;
run;
```

Note that the AGGREGATE method can be used only if the input intervals are nested within the output intervals, as when converting from daily to monthly or from monthly to yearly frequency.

Combining Time Series with Different Frequencies

One important use of PROC EXPAND is to combine time series measured at different sampling frequencies. For example, suppose you have data on monthly money stocks (M1), quarterly gross domestic product (GDP), and weekly interest rates (INTEREST), and you want to perform an analysis of a model that uses all these variables. To perform the analysis, you first need to convert the series to a common frequency and combine the variables into one data set.

The following statements illustrate this process for the three data sets QUARTER, MONTHLY, and WEEKLY. The data sets QUARTER and WEEKLY are converted to monthly frequency using two PROC EXPAND steps, and the three data sets are then merged using a DATA step MERGE statement to produce the data set COMBINED.

```
proc expand data=quarter out=temp1 from=qtr to=month;
   id date;
   convert gdp / observed=total;
run;

proc expand data=weekly out=temp2 from=week to=month;
   id date;
   convert interest / observed=average;
run;

data combined;
   merge monthly temp1 temp2;
   by date;
run;
```

See Chapter 2, "Working with Time Series Data," for further discussion of time series periodicity, time series dating, and time series interpolation.

Interpolating Missing Values

To interpolate missing values in time series without converting the observation frequency, leave off the TO= option. For example, the following statements interpolate any missing values in the time series in the data set ANNUAL.

```
proc expand data=annual out=new from=year;
   id date;
   convert x y z;
   convert a b c / observed=total;
run;
```

To interpolate missing values in variables observed at specific points in time, omit both the FROM= and TO= options and use the ID statement to supply time values for the observations. The observations do not need to be periodic or form regular time series, but the data set must be sorted by the ID variable. For example, the following statements interpolate any missing values in the numeric variables in the data set A.

```
proc expand data=a out=b;
   id date;
run;
```

If the observations are equally spaced in time, and all the series are observed as beginning-of-period values, only the input and output data sets need to be specified. For example, the following statements interpolate any missing values in the numeric variables in the data set A, assuming that the observations are at equally spaced points in time.

```
proc expand data=a out=b;
run;
```

Refer to the section “Missing Values” on page 811 for further information.

Requesting Different Interpolation Methods

By default, a cubic spline curve is fit to the input series, and the output is computed from this interpolating curve. Other interpolation methods can be specified with the METHOD= option on the CONVERT statement. The section “Conversion Methods” on page 802 explains the available methods.

For example, the following statements convert annual series to monthly series using linear interpolation instead of cubic spline interpolation.

```
proc expand data=annual out=monthly from=year to=month;
   id date;
   convert x y z / method=join;
run;
```

Using the ID Statement

An ID statement is normally used with PROC EXPAND to specify a SAS date or datetime variable to identify the time of each input observation. An ID variable allows PROC EXPAND to do the following:

- identify the observations in the output data set
- determine the time span between observations and detect gaps in the input series caused by omitted observations
- account for calendar effects such as the number of days in each month and leap years

If you do not specify an ID variable with SAS date or datetime values, PROC EXPAND makes default assumptions that may not be what you want. See the section "ID Statement" for details.

Specifying Observation Characteristics

It is important to distinguish between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series "U.S. Gross Domestic Product" represents the total value of production over the year and also the yearly average rate of production in dollars per year. However, a monthly variable *inventory* may represent the cost of a stock of goods as of the end of the month.

When the data represent periodic totals or averages, the process of interpolation to a higher frequency is sometimes called *distribution*, and the total values of the larger intervals are said to be *distributed* to the smaller intervals. The process of interpolating periodic total or average values to lower frequency estimates is sometimes called *aggregation*.

By default, PROC EXPAND assumes that all time series represent beginning-of-period point-in-time values. If a series does not measure beginning of period point-in-time values, interpolation of the data values using this assumption is not appropriate, and you should specify the correct observation characteristics of the series. The observation characteristics of series are specified with the OBSERVED= option on the CONVERT statement.

For example, suppose that the data set ANNUAL contains variables A, B, and C that measure yearly totals, while the variables X, Y, and Z measure first-of-year values. The following statements estimate the contribution of each month to the annual totals in A, B, and C, and interpolate first-of-month estimates of X, Y, and Z.

```
proc expand data=annual out=monthly from=year to=month;
   id date;
   convert x y z;
   convert a b c / observed=total;
run;
```

The EXPAND procedure supports five different observation characteristics. The OBSERVED= option values for these five observation characteristics are:

BEGINNING	beginning-of-period values
MIDDLE	period midpoint values
END	end-of-period values
TOTAL	period totals
AVERAGE	period averages

The interpolation of each series is adjusted appropriately for its observation characteristics. When OBSERVED=TOTAL or AVERAGE is specified, the interpolating curve is fit to the data values so that the area under the curve within each input interval equals the value of the series. For OBSERVED=MIDDLE or END, the curve is fit through the data points, with the time position of each data value placed at the specified offset from the start of the interval.

See the section “The OBSERVED= Option” on page 794 for details.

Converting Observation Characteristics

The EXPAND procedure can be used to interpolate values for output series with different observation characteristics than the input series. To change observation characteristics, specify two values in the OBSERVED= option. The first value specifies the observation characteristics of the input series; the second value specifies the observation characteristics of the output series.

For example, the following statements convert the period total variable A in the data set ANNUAL to yearly midpoint estimates. This example does not change the series frequency, and the other variables in the data set are copied to the output data set unchanged.

```
proc expand data=annual out=new from=year;
   id date;
   convert a / observed=(total,middle);
run;
```

Creating New Variables

You can use the CONVERT statement to name a new variable to contain the results of the conversion. Using this feature, you can create several different versions of a series in a single PROC EXPAND step. Specify the new name after the input variable name and an equal sign:

```
convert variable=newname ... ;
```

For example, suppose you are converting quarterly data to monthly and you want both first-of-month and midmonth estimates for a beginning-of-period variable X. The following statements perform this task:

```
proc expand data=a out=b from=qtr to=month;
   id date;
   convert x=x_begin  / observed=beginning;
   convert x=x_mid    / observed=(beginning,middle);
run;
```

Transforming Series

The interpolation methods used by PROC EXPAND assume that there are no restrictions on the range of values that series can have. This assumption can sometimes cause problems if the series must be within a certain range.

For example, suppose you are converting monthly sales figures to weekly estimates. Sales estimates should never be less than zero, but since the spline curve ignores this restriction some interpolated values may be negative. One way to deal with this problem is to transform the input series before fitting the interpolating spline and then reverse transform the output series.

You can apply various transformations to the input series using the TRANSFORMIN= option on the CONVERT statement. (The TRANSFORMIN= option can be abbreviated as TRANSFORM= or TIN=.) You can apply transformations to the output series using the TRANSFORMOUT= option. (The TRANSFORMOUT= option can be abbreviated as TOUT=.)

For example, you might use a logarithmic transformation of the input sales series and exponentiate the interpolated output series. The following statements fit a spline curve to the log of SALES and then exponentiate the output series.

```
proc expand data=a out=b from=month to=week;
   id date;
   convert sales / observed=total
                   transformin=(log) transformout=(exp);
run;
```

As another example, suppose you are interpolating missing values in a series of market share estimates. Market shares must be between 0% and 100%, but applying a spline interpolation to the raw series can produce estimates outside of this range.

The following statements use the logistic transformation to transform proportions in the range 0 to 1 to values in the range $-\infty$ to $+\infty$. The TIN= option first divides the market shares by 100 to rescale percent values to proportions and then applies the LOGIT function. The TOUT= option applies the inverse logistic function ILOGIT to the interpolated values to convert back to proportions and then multiplies by 100 to rescale back to percentages.

```
proc expand data=a out=b;
   id date;
   convert mshare / tin=( / 100 logit ) tout=( ilogit * 100 );
run;
```

You can also use the TRANSFORM= (or TRANSFORMOUT=) option as a convenient way to do calculations normally performed with the SAS DATA step. For example, the following statements add the lead of X to the data set A. The METHOD=NONE option is used to suppress interpolation.

```
proc expand data=a method=none;
   id date;
   convert x=xlead / transform=(lead);
run;
```

Any number of operations can be listed in the TRANSFORMIN= and TRANSFORMOUT= options. See Table 16.1 for a list of the operations supported.

Syntax

The EXPAND procedure uses the following statements:

PROC EXPAND *options* **;**
  BY *variables* **;**
  CONVERT *variables / options* **;**
  ID *variable* **;**

Functional Summary

The statements and options controlling the EXPAND procedure are summarized in the following table.

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify conversion options	CONVERT	
specify the ID variable	ID	
Data Set Options		
specify the input data set	PROC EXPAND	DATA=
specify the output data set	PROC EXPAND	OUT=
write interpolating functions to a data set	PROC EXPAND	OUTEST=
extrapolate values before or after input series	PROC EXPAND	EXTRAPOLATE

Description	Statement	Option
Input and Output Frequencies		
specify input frequency	PROC EXPAND	FROM=
specify output frequency	PROC EXPAND	TO=
specify frequency conversion factor	PROC EXPAND	FACTOR=
control the alignment of SAS Date values	PROC EXPAND	ALIGN=
Interpolation Control Options		
specify interpolation method	PROC EXPAND CONVERT	METHOD=
specify observation characteristics	CONVERT	OBSERVED=
specify transformations of the input series	CONVERT	TRANSIN=
specify transformations of the output series	CONVERT	TRANSOUT=

PROC EXPAND Statement

PROC EXPAND *options;*

The following options can be used with the PROC EXPAND statement.

Data Set Options

DATA=*SAS-data-set*
names the input data set. If the DATA= option is omitted, the most recently created SAS data set is used.

OUT=*SAS-data-set*
names the output data set containing the result time series. If OUT= is not specified, the data set is named using the DATA*n* convention. See the section "OUT= Data Set" on page 818 for details.

OUTEST=*SAS-data-set*
names an output data set containing the coefficients of the spline curves fit to the input series. If the OUTEST= option is not specified, the spline coefficients are not output. See the section "OUTEST= Data Set" on page 819 for details.

Options That Define Input and Output Frequencies

FACTOR=*n*
FACTOR=*(n:m)*
FACTOR=*(n,m)*
specifies the number of output observations to be created from the input observations. FACTOR=(*n*:*m*) specifies that *n* output observations are to be produced for each group of *m* input observations. FACTOR=*n* is the same as FACTOR=(*n*:1).

The FACTOR= option cannot be used if the TO= option is used. The default value is FACTOR=(1:1). For more information, see the "Frequency Conversion" section (page 797).

FROM=*interval*
specifies the time interval between observations in the input data set. Examples of FROM= values are YEAR, QTR, MONTH, DAY, and HOUR. See Chapter 3, "Date Intervals, Formats, and Functions," for a complete description and examples of interval specification.

TO=*interval*
specifies the time interval between observations in the output data set. By default, the TO= interval is generated from the combination of the FROM= and the FACTOR= values or is set to be the same as the FROM= value if FACTOR= is not specified. See Chapter 3, "Date Intervals, Formats, and Functions," for a description of interval specifications.

ALIGN=*option*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

Options to Control the Interpolation

METHOD=*option*
METHOD=SPLINE(*constraint* **[,** *constraint***])**
specifies the method used to convert the data series. The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified on the PROC EXPAND statement can be overridden for particular series by the METHOD= option on the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. See the "Conversion Methods" section on page 802 for more information about these methods.

OBSERVED=*value*
OBSERVED=*(from-value, to-value)*
indicates the observation characteristics of the input time series and of the output series. Specifying the OBSERVED= option on the PROC EXPAND statement sets the default OBSERVED= value for subsequent CONVERT statements. See the sections "CONVERT Statement" and "The OBSERVED= Option" later in this chapter for details. The default is OBSERVED=BEGINNING.

EXTRAPOLATE
specifies that missing values at the beginning or end of input series be replaced with values produced by a linear extrapolation of the interpolating curve fit to the input series. See the section "Extrapolation" later in this chapter for details.

By default, PROC EXPAND avoids extrapolating values beyond the first or last input value for a series and only interpolates values within the range of the nonmissing input values. Note that the extrapolated values are often not very accurate, and for the SPLINE method the EXTRAPOLATE option results may be very unreasonable. The EXTRAPOLATE option is not normally used.

BY Statement

BY *variables;*

A BY statement can be used with PROC EXPAND to obtain separate analyses on observations in groups defined by the BY variables. The input data set must be sorted by the BY variables and be sorted by the ID variable within each BY group.

Use a BY statement when you want to interpolate or convert time series within levels of a cross-sectional variable. For example, suppose you have a data set STATE containing annual estimates of average disposable personal income per capita (DPI) by state and you want quarterly estimates by state. These statements convert the DPI series within each state:

```
proc sort data=state;
   by state date;
run;

proc expand data=state out=stateqtr from=year to=qtr;
   convert dpi;
   by state;
   id date;
run;
```

CONVERT Statement

CONVERT *variable=newname ... / options;*

The CONVERT statement lists the variables to be processed. Only numeric variables can be processed.

For each of the variables listed, a new variable name can be specified after an equal sign to name the variable in the output data set that contains the converted values. If a name for the output series is not given, the variable in the output data set has the same name as the input variable. Variable lists may be used only when no name is given for the output series.

For example, variable lists can be specified as follows:

```
convert y1-y25 / observed=(beginning,end);
convert x--a /observed=average;
convert x-numeric-a/observed=average;
```

Any number of CONVERT statements can be used. If no CONVERT statement is used, all the numeric variables in the input data set except those appearing in the BY and ID statements are processed.

The following options can be used with the CONVERT statement.

METHOD=*option*
METHOD=SPLINE(*constraint* **[,** *constraint***])**

specifies the method used to convert the data series. The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified on the PROC EXPAND statement can be overridden for particular series by the METHOD= option on the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. See the "Conversion Methods" section on page 802 for more information about these methods.

OBSERVED=*value*
OBSERVED=*(from-value, to-value)*

indicates the observation characteristics of the input time series and of the output series. The values supported are TOTAL, AVERAGE, BEGINNING, MIDDLE, and END. In addition, DERIVATIVE can be specified as the *to-value* when the SPLINE method is used. See the section "The OBSERVED= Option" later in this chapter for details.

The default is the value specified for the OBSERVED= option on the PROC EXPAND statement, if any, or else the default value is OBSERVED=BEGINNING.

TRANSFORMIN=*(operation ...)*

specifies a list of transformations to be applied to the input series before the interpolating function is fit. The operations are applied in the order listed. See the section "Transformation Operations" later in this chapter for the operations that can be specified. The TRANSFORMIN= option can be abbreviated as TRANSIN=, TIN=, or TRANSFORM=.

TRANSFORMOUT=*(operation ...)*

specifies a list of transformations to be applied to the output series. The operations are applied in the order listed. See the section "Transformation Operations" later in this chapter for the operations that can be specified. The TRANSFORMOUT= option can be abbreviated as TRANSOUT=, or TOUT=.

ID Statement

ID *variable;*

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values.

The input data must form time series. This means that the observations in the input data set must be sorted by the ID variable (within the BY variables, if any). Moreover, there should be no duplicate observations, and no two observations should have ID values within the same time interval as defined by the FROM= option.

If the ID statement is omitted, SAS date or datetime values are generated to label the input observations. These ID values are generated by assuming that the input data set starts at a SAS date value of 0, that is, 1 January 1960. This default starting date is then incremented for each observation by the FROM= interval (using the INTNX function). If the FROM= option is not specified, the ID values are generated as the observation count minus 1. When the ID statement is not used, an ID variable is added to the output data set named either DATE or DATETIME, depending on the value specified in the TO= option. If neither the TO= option nor the FROM= option is given, the ID variable in the output data set is named TIME.

Details

Frequency Conversion

Frequency conversion is controlled by the FROM=, TO=, and FACTOR= options. The possible combinations of these options are explained in the following:

None Used
If FROM=, TO=, and FACTOR= are not specified, no frequency conversion is done. The data are processed to interpolate any missing values and perform any specified transformations. Each input observation produces one output observation.

FACTOR=(n:m)
FACTOR=(*n*:*m*) specifies that *n* output observations are produced for each group of *m* input observations. The fraction *m*/*n* is reduced first: thus FACTOR=(10:6) is equivalent to FACTOR=(5:3). Note that if *m*/*n*=1, the result is the same as the case given previously under “None Used”.

FROM=interval
The FROM= option used alone establishes the frequency and interval widths of the input observations. Missing values are interpolated, and any specified transformations are performed, but no frequency conversion is done.

TO=interval
When the TO= option is used without the FROM= option, output observations with the TO= frequency are generated over the range of input ID values. The first output observation is for the TO= interval containing the ID value of the first input observation; the last output observation is for the TO= interval containing the ID value of the last input observation. The input observations are not assumed to form regular time series and may represent aperiodic points in time. An ID variable is required to give the date or datetime of the input observations.

FROM=interval TO=interval
When both the FROM= and TO= options are used, the input observations have the frequency given by the FROM= interval, and the output observations have the frequency given by the TO= interval.

FROM=interval FACTOR=(n:m)
When both the FROM= and FACTOR= options are used, a TO= interval is inferred from the combination of the FROM=*interval* and the FACTOR=(*n*:*m*) values specified. For example, FROM=YEAR FACTOR=4 is the same as FROM=YEAR TO=QTR. Also, FROM=YEAR FACTOR=(3:2) is the same as FROM=YEAR used with TO=MONTH8. Once the implied TO= interval is determined, this combination

operates the same as if FROM= and TO= had been specified. If no valid TO= interval can be constructed from the combination of the FROM= and FACTOR= options, an error is produced.

TO=interval FACTOR=(n:m)
The combination of the TO= option and the FACTOR= option is not allowed and produces an error.

ALIGN= option
Controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

Converting to a Lower Frequency

When converting to a lower frequency, the results are either exact or approximate, depending on whether or not the input intervals nest within the output intervals and depending on the need to interpolate missing values within the series. If the TO= interval is nested within the FROM= interval (as when converting monthly to yearly), and if there are no missing input values or partial periods, the results are exact.

When values are missing or the FROM= intervals are not nested within the TO= intervals (as when aggregating weekly to monthly), the results depend on an interpolation. The METHOD=AGGREGATE option always produces exact results, never an interpolation. However, this method cannot be used unless the FROM= interval is nested within the TO= interval.

Identifying Observations

The variable specified in the ID statement is used to identify the observations. Usually, SAS date or datetime values are used for this variable. PROC EXPAND uses the ID variable to do the following:

- identify the time interval of the input values
- validate the input data set observations
- compute the ID values for the observations in the output data set

Identifying the Input Time Intervals

When the FROM= option is specified, observations are understood to refer to the whole time interval and not to a single time point. The ID values are interpreted as identifying the FROM= time interval containing the value. In addition, the widths of these input intervals are used by the OBSERVED= cases TOTAL, AVERAGE, MIDDLE, and END.

For example, if FROM=MONTH is specified, then each observation is for the whole calendar month containing the ID value for the observation, and the width of the time interval covered by the observation is the number of days in that month. Therefore, if FROM=MONTH, the ID value ’31MAR92’D is equivalent to the ID value ’1MAR92’D–both of these ID values identify the same interval, March of 1992.

Widths of Input Time Intervals

When the FROM= option is not specified, the ID variable values are usually interpreted as referring to points in time. However, if an OBSERVED= option is specified that assumes the observations refer to whole intervals and also requires interval widths, then, in the absence of the FROM= specification, interval widths are assumed to be the time span between ID values. For the last observation, the interval width is assumed to be the same as for the next to last observation. (If neither the FROM= option nor the ID statement are specified, interval widths are assumed to be 1.0.) A note is printed in the SAS log warning that this assumption is made.

Validating the Input Data Set Observations

The ID variable is used to verify that successive observations read from the input data set correspond to sequential FROM= intervals. When the FROM= option is not used, PROC EXPAND verifies that the ID values are nonmissing and in ascending order. An error message is produced and the observation is ignored when an invalid ID value is found in the input data set.

ID values for Observations in the Output Data Set

The time unit used for the ID variable in the output data set is controlled by the interval value specified by the TO= option. If you specify a date interval for the TO= value, the ID variable values in the output data set are SAS date values. If you specify a datetime interval for the TO= value, the ID variable values in the output data set are SAS datetime values.

Range of Output Observations

If no frequency conversion is done, the range of output observations is the same as in the input data set.

When frequency conversion is done, the observations in the output data set range from the earliest start of any result series to the latest end of any result series. Observations at the beginning or end of the input range for which all result values are missing are not written to the OUT= data set.

When the EXTRAPOLATE option is not used, the range of the nonmissing output results for each series is as follows. The first result value is for the TO= interval that contains the ID value of the start of the FROM= interval containing the ID value of the first nonmissing input observation for the series. The last result value is for the TO= interval that contains the end of the FROM= interval containing the ID value of the last nonmissing input observation for the series.

When the EXTRAPOLATE option is used, result values for all series are computed for the full time range covered by the input data set.

Extrapolation

The spline functions fit by the EXPAND procedure are very good at approximating continuous curves within the time range of the input data but poor at extrapolating beyond the range of the data. The accuracy of the results produced by PROC EXPAND may be somewhat less at the ends of the output series than at time periods for which there are several input values at both earlier and later times. The curves fit by PROC EXPAND should not be used for forecasting.

PROC EXPAND normally avoids extrapolation of values beyond the time range of the nonmissing input data for a series, unless the EXTRAPOLATE option is used. However, if the start or end of the input series does not correspond to the start or end of an output interval, some output values may depend in part on an extrapolation.

For example, if FROM=YEAR, TO=WEEK, and OBSERVED=BEGINNING, the first observation output for a series is for the week of 1 January of the first nonmissing input year. If 1 January of that year is not a Sunday, the beginning of this week falls before the date of the first input value, and therefore a beginning-of-period output value for this week is extrapolated.

This extrapolation is made only to the extent needed to complete the terminal output intervals that overlap the endpoints of the input series and is limited to no more than the width of one FROM= interval or one TO= interval, whichever is less. This restriction of the extrapolation to complete terminal output intervals is applied to each series separately, and it takes into account the OBSERVED= option for the input and output series.

When the EXTRAPOLATE option is used, the normal restriction on extrapolation is overridden. Output values are computed for the full time range covered by the input data set.

For the SPLINE method, extrapolation is performed by a linear projection of the trend of the cubic spline curve fit to the input data, not by extrapolation of the first and last cubic segments.

The OBSERVED= Option

The values of the CONVERT statement OBSERVED= option are as follows:

BEGINNING	indicates that the data are beginning-of-period values. OBSERVED=BEGINNING is the default.
MIDDLE	indicates that the data are period midpoint values.
ENDING	indicates that the data represent end-of-period values.
TOTAL	indicates that the data values represent period totals for the time interval corresponding to the observation.
AVERAGE	indicates that the data values represent period averages.
DERIVATIVE	requests that the output series be the derivatives of the cubic spline curve fit to the input data by the SPLINE method.

If only one value is specified in the OBSERVED= option, that value applies to both the input and the output series. For example, OBSERVED=TOTAL is the same as OBSERVED=(TOTAL,TOTAL), which indicates both that the input values represent totals over the time intervals corresponding to the input observations and that the converted output values also represent period totals. The value DERIVATIVE can be used only as the second OBSERVED= option value, and it can be used only when METHOD=SPLINE is specified or is the default method.

Since the TOTAL, AVERAGE, MIDDLE, and END cases require that the width of each input interval be known, both the FROM= option and an ID statement are normally required if one of these observation characteristics is specified for any series. However, if the FROM= option is not specified, each input interval is assumed to extend from the ID value for the observation to the ID value of the next observation, and the width of the interval for the last observation is assumed to be the same as the width for the next to last observation.

Scale of OBSERVED=AVERAGE Values

The average values are assumed to be expressed in the time units defined by the FROM= or TO= option. That is, the product of the average value for an interval and the width of the interval is assumed to equal the total value for the interval. For purposes of interpolation, OBSERVED=AVERAGE values are first converted to OBSERVED=TOTAL values using this assumption, and then the interpolated totals are converted back to averages by dividing by the widths of the output intervals. For example, suppose the options FROM=MONTH, TO=HOUR, and OBSERVED=AVERAGE are specified.

Since FROM=MONTH in this example, each input value is assumed to represent an average rate per day such that the product of the value and the number of days in the month is equal to the total for the month. The input values are assumed to represent a per-day rate because FROM=MONTH implies SAS date ID values that measure time in days, and therefore the widths of MONTH intervals are measured in days. If FROM=DTMONTH is used instead, the values are assumed to represent a per-second rate, because the widths of DTMONTH intervals are measured in seconds.

Since TO=HOUR in this example, the output values are scaled as an average rate per second such that the product of each output value and the number of seconds in an hour (3600) is equal to the interpolated hourly total. A per-second rate is used because TO=HOUR implies SAS datetime ID values that measure time in seconds, and therefore the widths of HOUR intervals are measured in seconds.

Note that the scale assumed for OBSERVED=AVERAGE data is important only when converting between AVERAGE and another OBSERVED= option, or when converting between SAS date and SAS datetime ID values. When both the input and the output series are AVERAGE values, and the units for the ID values are not changed, the scale assumed does not matter.

For example, suppose you are converting a series gross domestic product (GDP) from quarterly to monthly. The GDP values are quarterly averages measured at annual rates. If you want the interpolated monthly values to also be measured at annual rates, then the option OBSERVED=AVERAGE works fine. Since there is no change of scale involved in this problem, it makes no difference that PROC EXPAND assumes daily rates instead of annual rates.

However, suppose you want to convert GDP from quarterly to monthly and also convert from annual rates to monthly rates, so that the result is total gross domestic product for the month. Using the option OBSERVED=(AVERAGE,TOTAL) would fail, because PROC EXPAND assumes the average is scaled to daily, not annual, rates.

One solution is to rescale to quarterly totals and treat the data as totals. You could use the options TRANSFORMIN=(/ 4) OBSERVED=TOTAL. Alternatively, you could treat the data as averages but first convert to daily rates. In this case you would use the options TRANSFORMIN=(/ 365.25) OBSERVED=AVERAGE.

Results of the OBSERVED=DERIVATIVE Option

If the first value of the OBSERVED= option is BEGINNING, TOTAL, or AVERAGE, the result is the derivative of the spline curve evaluated at first-of-period ID values for the output observation. For OBSERVED=(MIDDLE,DERIVATIVE), the derivative of the function is evaluated at output interval midpoints. For OBSERVED=(END,DERIVATIVE), the derivative is evaluated at end-of-period ID values.

Conversion Methods

The SPLINE Method

The SPLINE method fits a cubic spline curve to the input values. A cubic spline is a segmented function consisting of third-degree (cubic) polynomial functions joined together so that the whole curve and its first and second derivatives are continuous.

For point-in-time input data, the spline curve is constrained to pass through the given data points. For interval total or average data, the definite integrals of the spline over the input intervals are constrained to equal the given interval totals.

For boundary constraints, the *not-a-knot* condition is used by default. This means that the first two spline pieces are constrained to be part of the same cubic curve, as are the last two pieces. Thus the spline used by PROC EXPAND by default is not the same as the commonly used natural spline, which uses zero second-derivative endpoint constraints. While DeBoor (1981) recommends the *not-a-knot* constraint for cubic spline interpolation, using this constraint can sometimes produce anomalous results at the ends of the interpolated series. PROC EXPAND provides options to specify other endpoint constraints for spline curves.

To specify endpoint constraints, use the following form of the METHOD= option.

METHOD=SPLINE(*constraint* **[,** *constraint***])**

The first constraint specification applies to the lower endpoint, and the second constraint specification applies to the upper endpoint. If only one constraint is specified, it applies to both the lower and upper endpoints.

The *constraint* specifications can have the following values:

NOTANOT
specifies the not-a-knot constraint. This is the default.

NATURAL
specifies the *natural spline* constraint. The second derivative of the spline curve is constrained to be zero at the endpoint.

SLOPE= value
specifies the first derivative of the spline curve at the endpoint.

CURVATURE= value
specifies the second derivative of the spline curve at the endpoint. Specifying CURVATURE=0 is equivalent to specifying the NATURAL option.

For example, to specify natural spline interpolation, use the following option in the CONVERT or PROC EXPAND statement:

```
method=spline(natural)
```

For OBSERVED=BEGINNING, MIDDLE, and END series, the spline knots are placed at the beginning, middle, and end of each input interval, respectively. For total or averaged series, the spline knots are set at the start of the first interval, at the end of the last interval, and at the interval midpoints, except that there are no knots for the first two and last two midpoints.

Once the cubic spline curve is fit to the data, the spline is extended by adding linear segments at the beginning and end. These linear segments are used for extrapolating values beyond the range of the input data.

For point-in-time output series, the spline function is evaluated at the appropriate points. For interval total or average output series, the spline function is integrated over the output intervals.

The JOIN Method

The JOIN method fits a continuous curve to the data by connecting successive straight line segments. (This produces a linear spline.) For point-in-time data, the JOIN method connects successive nonmissing input values with straight lines. For interval total or average data, interval midpoints are used as the break points, and ordinates are chosen so that the integrals of the piecewise linear curve agree with the input totals.

For point-in-time output series, the JOIN function is evaluated at the appropriate points. For interval total or average output series, the JOIN function is integrated over the output intervals.

The STEP Method

The STEP method fits a discontinuous piecewise constant curve. For point-in-time input data, the resulting step function is equal to the most recent input value. For interval total or average data, the step function is equal to the average value for the interval.

For point-in-time output series, the step function is evaluated at the appropriate points. For interval total or average output series, the step function is integrated over the output intervals.

The AGGREGATE Method

The AGGREGATE method performs simple aggregation of time series without interpolation of missing values.

If the input data are totals or averages, the results are the sums or averages, respectively, of the input values for observations corresponding to the output observations. That is, if either TOTAL or AVERAGE is specified for the OBSERVED= option, the METHOD=AGGREGATE result is the sum or mean of the input values corresponding to the output observation. For example, suppose METHOD=AGGREGATE, FROM=MONTH, and TO=YEAR. For OBSERVED=TOTAL series, the result for each output year is the sum of the input values over the months of that year. If any input value is missing, the corresponding sum or mean is also a missing value.

If the input data are point-in-time values, the result value of each output observation equals the input value for a selected input observation determined by the OBSERVED= attribute. For example, suppose METHOD=AGGREGATE, FROM=MONTH, and TO=YEAR. For OBSERVED=BEGINNING series, January observations are selected as the annual values. For OBSERVED=MIDDLE series, July observations are selected as the annual values. For OBSERVED=END series, December observations are selected as the annual values. If the selected value is missing, the output annual value is missing.

The AGGREGATE method can be used only when the FROM= intervals are nested within the TO= intervals. For example, you can use METHOD=AGGREGATE when FROM=MONTH and TO=QTR because months are nested within quarters. You cannot use METHOD=AGGREGATE when FROM=WEEK and TO=QTR because weeks are not nested within quarters.

In addition, the AGGREGATE method cannot convert between point-in-time data and interval total or average data. Conversions between TOTAL and AVERAGE data are allowed, but conversions between BEGINNING, MIDDLE, and END are not.

Missing input values produce missing result values for METHOD=AGGREGATE. However, gaps in the sequence of input observations are not allowed. For example, if FROM=MONTH, you may have a missing value for a variable in an observation for a given February. But if an observation for January is followed by an observation for March, there is a gap in the data, and METHOD=AGGREGATE cannot be used.

When the AGGREGATE method is used, there is no interpolating curve, and therefore the EXTRAPOLATE option is not allowed.

METHOD=NONE

The option METHOD=NONE specifies that no interpolation be performed. This option is normally used in conjunction with the TRANSFORMIN= or TRANSFORMOUT= option.

When METHOD=NONE is specified, there is no difference between the TRANSFORMIN= and TRANSFORMOUT= options; if both are specified, the TRANSFORMIN= operations are performed first, followed by the

TRANSFORMOUT= operations. TRANSFORM= can be used as an abbreviation for TRANSFORMIN=. METHOD=NONE cannot be used when frequency conversion is specified.

Transformation Operations

The operations that can be used in the TRANSFORMIN= and TRANSFORMOUT= options are shown in Table 16.1. Operations are applied to each value of the series. Each value of the series is replaced by the result of the operation.

In Table 16.1, x_t or *x* represents the value of the series at a particular time period *t* before the transformation is applied, y_t represents the value of the result series, and N represents the total number of observations.

The notation [*n*] indicates that the argument *n* is optional; the default is 1. The notation *window* is used as the argument for the moving statistics operators, and it indicates that you can specify either an integer number of periods *n* or a list of *n* weights in parentheses. The notation *sequence* is used as the argument for the sequence operators, and it indicates that you must specify a sequence of numbers. The notation *s* indicates the length of seasonality, and it is a required argument.

Table 16.1. Transformation Operations

Syntax	**Result**
+ *number*	adds the specified *number*: $x + number$
- *number*	subtracts the specified *number*: $x - number$
* *number*	multiplies by the specified *number*: $x * number$
& *number*	divides by the specified *number*: $x \& number$
ADJUST	indicates that the following moving window summation or product operator should be adjusted for window width
ABS	absolute value: $\lvert x \rvert$
CD_I *s*	classical decomposition irregular component
CD_S *s*	classical decomposition seasonal component
CD_SA *s*	classical decomposition seasonally adjusted series
CD_TC *s*	classical decomposition trend-cycle component
CDA_I *s*	classical decomposition (additive) irregular component
CDA_S *s*	classical decomposition (additive) seasonal component
CDA_SA *s*	classical decomposition (additive) seasonally adjusted series
CEIL	smallest integer greater than or equal to *x*: $\mathrm{ceil(x)}$
CMOVAVE *window*	centered moving average
CMOVCSS *window*	centered moving corrected sum of squares
CMOVGMEAN *window*	centered moving geometric mean
CMOVMAX *n*	centered moving maximum
CMOVMED *n*	centered moving median
CMOVMIN *n*	centered moving minimum
CMOVPROD *window*	centered moving product
CMOVRANGE *n*	centered moving range
CMOVRANK n	centered moving rank

Table 16.1. (continued)

Syntax	**Result**
CMOVSTD *window*	centered moving standard deviation
CMOVSUM *n*	centered moving sum
CMOVTVALUE *window*	centered moving *t*-value
CMOVUSS *window*	centered moving uncorrected sum of squares
CMOVVAR *window*	centered moving variance
CUAVE [*n*]	cumulative average
CUCSS [*n*]	cumulative corrected sum of squares
CUGMEAN	cumulative geometric mean
CUMAX [*n*]	cumulative maximum
CUMED [*n*]	cumulative median
CUMIN [*n*]	cumulative minimum
CUPROD	cumulative product
CURANK	cumulative rank
CURANGE [*n*]	cumulative range
CUSTD [*n*]	cumulative standard deviation
CUSUM [*n*]	cumulative sum
CUTVALUE	cumulative *t*-value
CUUSS [*n*]	cumulative uncorrected sum of squares
CUVAR [*n*]	cumulative variance
DIF [*n*]	lag *n* difference: $x_t - x_{t-n}$
EWMA *number*	exponentially weighted moving average of x with smoothing weight *number*, where $0 < number < 1$: $y_t = number\ \ x_t + (1 - number)y_{t-1}$. This operation is also called simple exponential smoothing.
EXP	exponential function: $\exp(x)$
FDIF *d*	fractional difference with difference order d where $0 < d < 0.5$
FLOOR	largest integer less than or equal to *x*: $\mathrm{floor(x)}$
FSUM d	fractional summation with summation order d where $0 < d < 0.5$
HP_T *lambda*	Hodrick-Prescott Filter trend component where *lambda* is the non-negative filter parameter
HP_C *lambda*	Hodrick-Prescott Filter cycle component where *lambda* is the non-negative filter parameter
ILOGIT	inverse logistic function: $\frac{\exp(x)}{1+\exp(x)}$
LAG [*n*]	value of the series *n* periods earlier: x_{t-n}
LEAD [*n*]	value of the series *n* periods later: x_{t+n}
LOG	natural logarithm: $\log(x)$
LOGIT	logistic function: $\log(\frac{x}{1-x})$
MAX *number*	maximum of *x* and *number*: $\max(x, number)$
MIN *number*	minimum of *x* and *number*: $\min(x, number)$
> *number*	missing value if $x <= number$, else *x*
>= *number*	missing value if $x < number$, else *x*
= *number*	missing value if $x \neq number$, else *x*

Table 16.1. (continued)

Syntax	**Result**
∧= *number*	missing value if $x = number$, else *x*
< *number*	missing value if $x >= number$, else *x*
<= *number*	missing value if $x > number$, else *x*
MOVAVE *n*	moving average of *n* neighboring values: $\frac{1}{n}\sum_{j=0}^{n-1} x_{t-j}$
MOVAVE($w_1 \ldots w_n$)	weighted moving average of neighboring values: $(\sum_{j=1}^{n} w_j x_{t-j+1})/(\sum_{j=1}^{n} w_j)$
MOVAVE *window*	backward moving average
MOVCSS *window*	backward moving corrected sum of squares
MOVMAX *n*	backward moving maximum
MOVGMEAN *window*	backward moving geometric mean
MOVMED *n*	backward moving median
MOVMIN *n*	backward moving minimum
MOVPROD *window*	backward moving product
MOVRANK n	backward moving rank
MOVRANGE *n*	backward moving range
MOVSTD *window*	backward moving standard deviation
MOVSUM *n*	backward moving sum
MOVTVALUE *window*	backward moving *t*-value
MOVUSS *window*	backward moving uncorrected sum of squares
MOVVAR *window*	backward moving variance
MISSONLY <MEAN>	indicates that the following moving time window statistic operator should replace only missing values with the moving statistic and should leave nonmissing values unchanged. If the option MEAN is specified, then missing values are replaced by the overall mean of the series.
NEG	changes the sign: $-x$
NOMISS	indicates that the following moving time window statistic operator should not allow missing values
PCTDIF n	percent difference of the current value and lag n
PCTSUM n	percent summation of the current value and cumulative sum n-lag periods
RATIO n	ratio of current value to lag n
RECIPROCAL	reciprocal: $1/x$
REVERSE	reverse the series: x_{N-t}
SCALE n_1 n_2	scale series between n_1 and n_2
SEQADD *sequence*	add sequence values to series
SEQDIV *sequence*	divide series by sequence values
SEQMINUS *sequence*	subtract sequence values to series
SEQMULT *sequence*	multiply series by sequence values
SET n_1 n_2	set all values of n_1 to n_2
SETEMBEDDED n_1 n_2	set embedded values of n_1 to n_2
SETLEFT n_1 n_2	set beginning values of n_1 to n_2
SETMISS *number*	replaces missing values in the series with the number specified

Table 16.1. (continued)

Syntax	**Result**
SETRIGHT n_1 n_2	set ending values of n_1 to n_2
SIGN	-1, 0, or 1 as *x* is < 0, equals 0, or > 0 respectively
SQRT	square root: $\sqrt{x}$
SQUARE	square: x^2
SUM	cumulative sum: $\sum_{j=1}^{t} x_j$
SUM *n*	cumulative sum of *n*-period lags: $x_t + x_{t-n} + x_{t-2n} + \ldots$
TRIM *n*	sets x_t to missing a value if $t \leq n$ or $t \geq N - n + 1$
TRIMLEFT *n*	sets x_t to missing a value if $t \leq n$
TRIMRIGHT *n*	sets x_t to missing a value if $t \geq N - n + 1$

Moving Time Window Operators

Some operators compute statistics for a set of values within a moving time window; these are called *moving time window operators*. There are backward and centered versions of these operators.

The centered moving time window operators are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVMAX, CMOVMED, CMOVMIN, CMOVPROD, CMOVRANGE, CMOVRANK, CMOVSTD, CMOVTVALUE, CMOVSUM, CMOVUSS, and CMOVVAR. These operators compute statistics of the n values x_i for observations $t-(n-1)/2 \ \leq \ i \ \leq \ t+(n-1)/2$.

The backward moving time window operators are MOVAVE, MOVCSS, MOVGMEAN, MOVMAX, MOVMED, MOVMIN, MOVPROD, MOVRANGE, MOVRANK, MOVSTD, MOVTVALUE, MOVSUM, MOVUSS, and MOVVAR. These operators compute statistics of the n values $x_t, x_{t-1}, \ldots, x_{t-n+1}$.

All the moving time window operators accept an argument n specifying the number of periods to include in the time window. For example, the following statement computes a five-period backward moving average of *X*.

```
convert x=y / transformout=( movave 5 );
```

In this example, the resulting transformation is
$y_t = (x_t + x_{t-1} + x_{t-2} + x_{t-3} + x_{t-4})/5$.

The following statement computes a five-period centered moving average of *X*.

```
convert x=y / transformout=( cmovave 5 );
```

In this example, the resulting transformation is
$y_t = (x_{t-2} + x_{t-1} + x_t + x_{t+1} + x_{t+2})/5$.

If the window with a centered moving time window operator is not an odd number, one more lagged value than lead value is included in the time window. For example,

the result of the CMOVAVE 4 operator is
$y_t = (x_{t-1} + x_t + x_{t+1} + x_{t+2})/4$.

You can compute a forward moving time window operation by combining a backward moving time window operator with the REVERSE operator. For example, the following statement computes a five-period forward moving average of *X*.

```
convert x=y / transformout=( reverse movave 5 reverse );
```

In this example, the resulting transformation is
$y_t = (x_t + x_{t+1} + x_{t+2} + x_{t+3} + x_{t+4})/5$.

Some of the moving time window operators enable you to specify a list of weight values to compute weighted statistics. These are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVPROD, CMOVSTD, CMOVTVALUE, CMOVUSS, CMOVVAR, MOVAVE, MOVCSS, MOVGMEAN, MOVPROD, MOVSTD, MOVTVALUE, MOVUSS, and MOVVAR.

To specify a weighted moving time window operator, enter the weight values in parentheses after the operator name. The window width n is equal to the number of weights that you specify; do not specify n.

For example, the following statement computes a weighted five-period centered moving average of *X*.

```
convert x=y / transformout=( cmovave( .1 .2 .4 .2 .1 ) );
```

In this example, the resulting transformation is
$y_t = .1x_{t-2} + .2x_{t-1} + .4x_t + .2x_{t+1} + .1x_{t+2}$.

The weight values must be greater than zero. If the weights do not sum to 1, the weights specified are divided by their sum to produce the weights used to compute the statistic.

At the beginning of the series, and at the end of the series for the centered operators, a complete time window is not available. The computation of the moving time window operators is adjusted for these boundary conditions as follows.

For backward moving window operators, the width of the time window is shortened at the beginning of the series. For example, the results of the MOVSUM 3 operator are

$$\begin{aligned}
y_1 &= x_1 \\
y_2 &= x_1 + x_2 \\
y_3 &= x_1 + x_2 + x_3 \\
y_4 &= x_2 + x_3 + x_4 \\
y_5 &= x_3 + x_4 + x_5 \\
&\dots
\end{aligned}$$

For centered moving window operators, the width of the time window is shortened at the beginning and the end of the series due to unavailable observations. For example, the results of the CMOVSUM 5 operator are

$$\begin{aligned}
y_1 &= x_1 + x_2 + x_3 \\
y_2 &= x_1 + x_2 + x_3 + x_4 \\
y_3 &= x_1 + x_2 + x_3 + x_4 + x_5 \\
y_4 &= x_2 + x_3 + x_4 + x_5 + x_6 \\
&\ldots \\
y_{N-2} &= x_{N-4} + x_{N-3} + x_{N-2} + x_{N-1} + x_N \\
y_{N-1} &= x_{N-3} + x_{N-2} + x_{N-1} + x_N \\
y_N &= x_{N-2} + x_{N-1} + x_N
\end{aligned}$$

For weighted moving time window operators, the weights for the unavailable or unused observations are ignored and the remaining weights renormalized to sum to 1.

Cumulative Statistics Operators

Some operators compute cumulative statistics for a set of current and previous values of the series. The cumulative statistics operators are CUAVE, CUCSS, CUMAX, CUMED, CUMIN, CURANGE, CUSTD, CUSUM, CUUSS, and CUVAR. These operators compute statistics of the values $x_t, x_{t-n}, x_{t-2n}, \ldots, x_{t-in}$ for $t - in > 0$.

By default, the cumulative statistics operators compute the statistics from all previous values of the series, so that y_t is based on the set of values $x_1, x_2, \ldots, x_t$. For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for $i \le t$.

```
convert x=y / transformout=( cusum );
```

You can also specify a lag increment argument n for the cumulative statistics operators. In this case, the statistic is computed from the current and every n^{th} previous value. For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for odd i when t is odd and for even i when t is even.

```
convert x=y / transformout=( cusum 2 );
```

The results of this example are

$$\begin{aligned}
y_1 &= x_1 \\
y_2 &= x_2 \\
y_3 &= x_1 + x_3 \\
y_4 &= x_2 + x_4 \\
y_5 &= x_1 + x_3 + x_5
\end{aligned}$$

$$
\begin{aligned}
y_6 &= x_2 + x_4 + x_6 \\
&\dots
\end{aligned}
$$

Missing Values

You can truncate the length of the result series by using the TRIM, TRIMLEFT, and TRIMRIGHT operators to set values to missing at the beginning or end of the series.

You can use these functions to trim the results of moving time window operators so that the result series contains only values computed from a full width time window. For example, the following statements compute a centered five-period moving average of *X*, and they set to missing values at the ends of the series that are averages of fewer than five values.

```
convert x=y / transformout=( cmovave 5 trim 2 );
```

Normally, the moving time window and cumulative statistics operators ignore missing values and compute their results for the nonmissing values. When preceded by the NOMISS operator, these functions produce a missing result if any value within the time window is missing.

The NOMISS operator does not perform any calculations, but serves to modify the operation of the moving time window operator that follows it. The NOMISS operator has no effect unless it is followed by a moving time window operator.

For example, the following statement computes a five-period moving average of the variable *X* but produces a missing value when any of the five values are missing.

```
convert x=y / transformout=( nomiss movave 5 );
```

The following statement computes the cumulative sum of the variable *X* but produces a missing value for all periods after the first missing X value.

```
convert x=y / transformout=( nomiss cusum );
```

Similar to the NOMISS operator, the MISSONLY operator does not perform any calculations (unless followed by the MEAN option), but it serves to modify the operation of the moving time window operator that follows it. When preceded by the MISSONLY operator, these moving time window operators replace any missing values with the moving statistic and leave nonmissing values unchanged.

For example, the following statement replaces any missing values of the variable *X* with an exponentially weighted moving average of the past values of *X* and leaves nonmissing values unchanged. The missing values are then interpolated using an exponentially weighted moving average or simple exponential smoothing.

```
convert x=y / transformout=( missonly ewma 0.3 );
```

For example, the following statement replaces any missing values of the variable *X* with the overall mean of *X*.

```
convert x=y / transformout=( missonly mean );
```

You can use the SETMISS operator to replace missing values with a specified number. For example, the following statement replaces any missing values of the variable *X* with the number 8.77.

```
convert x=y / transformout=( setmiss 8.77 );
```

Classical Decomposition Operators

If y_t is a seasonal time series with s observations per season, *classical decomposition* methods "break down" a time series into four components: trend, cycle, seasonal, and irregular components. The trend and cycle components are often combined to form the trend-cycle component. There are two forms of decomposition: multiplicative and additive.

$$\begin{aligned} y_t &= TC_t S_t I_t \\ y_t &= TC_t + S_t + I_t \end{aligned}$$

where

TC_t	is the trend-cycle component
S_t	is the seasonal component or seasonal factors that are periodic with period s and with mean one (multiplicative) or zero (additive)
I_t	is the irregular or random component that is assumed to have mean one (multiplicative) or zero (additive)

The CD_TC operator computes the trend-cycle component for both the multiplicative and additive models. When s is odd, this operator computes an s-period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k}/s$$

In the case $s = 5$, the CD_TC *s* operator is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=( cmovave 5 trim 2 );
```

When s is even, the CD_TC *s* operator computes the average of two adjacent s-period centered moving averages as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor - 1} (y_{t+k} + y_{t+1+k})/2s$$

In the case $s = 12$, the CD_TC *s* operator is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=(cmovave 12 movave 2 trim 6);
```

The CD_S and CDA_S operators compute the seasonal components for the multiplicative and additive models, respectively. First, the trend-cycle component is computed as shown previously. Second, the seasonal-irregular component is computed by $SI_t = y_t/TC_t$ for the multiplicative model and by $SI_t = y_t - TC_t$ for the additive model. The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{n/s}$$

where $0 \le j \le n/s$ and $1 \le k \le s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

The CD_I and CDA_I operators compute the irregular component for the multiplicative and additive models respectively. First, the seasonal component is computed as shown previously. Next, the irregular component is determined from the seasonal-irregular and seasonal components as appropriate.

$$\begin{aligned} I_t &= SI_t/S_t \\ I_t &= SI_t - S_t \end{aligned}$$

The CD_SA and CDA_SA operators compute the seasonally adjusted time series for the multiplicative and additive models, respectively. After decomposition, the original time series can be seasonally adjusted as appropriate.

$$\begin{aligned} \tilde{y}_t &= y_t/S_t = TC_t I_t \\ \tilde{y}_t &= y_t - S_t = TC_t + I_t \end{aligned}$$

The following statements compute all the multiplicative classical decomposition components for the variable *X* for s=12.

```
convert x=tc / transformout=( cd_tc 12 );
convert x=s  / transformout=( cd_s  12 );
convert x=i  / transformout=( cd_i  12 );
convert x=sa / transformout=( cd_sa 12 );
```

The following statements compute all the additive classical decomposition components for the variable *X* for s=4.

```
convert x=tc / transformout=( cd_tc  4 );
convert x=s  / transformout=( cda_s  4 );
convert x=i  / transformout=( cda_i  4 );
convert x=sa / transformout=( cda_sa 4 );
```

Fractional Operators

For fractional operators, the parameter, *d*, represents the order of fractional differencing. Fractional summation is the inverse operation of fractional differencing.

Examples of Usage

Suppose that *Y* is a fractionally integrated time series variable of order d=0.25. Fractionally differencing *Y* forms a time series variable *X* which is not integrated.

```
convert y=x / transformout=(fdif 0.25);
```

Suppose that *Z* is a nonintegrated time series variable. Fractionally summing *Z* forms a time series W which is fractionally integrated of order $d = 0.25$.

```
convert z=w / transformout=(fsum 0.25);
```

Moving Rank Operators

For the rank operators, the ranks are computed based on the current value with respect to the cumulative, centered, or moving window values. If the current value is missing, the transformed current value is set to missing. If the NOMISS option was previously specified and if any missing values are present in the moving window, the transformed current value is set to missing. Otherwise, redundant values from the moving window are removed and the rank of the current value is computed among the unique values of the moving window.

Examples of Usage

The trades of a particular security are recorded for each weekday in a variable named PRICE. Given the historical daily trades, what is the ranking of the price of this security for each trading day considering its entire past history?

```
convert price=history / transformout=( curank );
```

What is the ranking of the price of this security for each trading day considering the previous week's history?

```
convert price=lastweek / transformout=( movrank 5 );
```

What is the ranking of the price of this security for each trading day considering the previous two week's history?

```
convert price=twoweek / transformout=( movrank 10 );
```

Moving Product Operators

For the product operators, the current transformed value is computed based on the (weighted) product of the cumulative, centered, or moving window values. If missing values are present in the moving window and the NOMISS operator is previously specified, the current transformed value is set to missing. Otherwise, the current transformed value is set to the (weighted) product of the nonmissing values of the moving window. If the geometric mean is desired, the exponents of each product are normalized to one.

Examples of Usage

The interest rates for a savings account are recorded for each month in the data set variable RATES. What is the cumulative interest rate for each month considering the entire account past history?

```
convert rates=history / transformout=( + 1 cuprod - 1);
```

What is the interest rate for each quarter considering the previous quarter history?

```
convert rates=lastqtr / transformout=( + 1 movprod 3 - 1);
```

Sequence Operators

For the sequence operators, the sequence values are used to compute the transformed values from the original values in a sequential fashion. You can add to or subtract from the original series or you can multiply or divide by the sequence values. The first sequence value is applied to the first observation of the series, the second sequence value is applied to the second observation of the series, and so on until the end of the sequence is reached. At this point, the first sequence value is applied to the next observation of the series and the second sequence value on the next observation and so on.

Let $v_1, \ldots, v_m$ be the sequence values and let x_t, $t = 1, \ldots N$, be the original time series. The transformed series, y_t, is computed as follows:

$$\begin{aligned} y_1 &= x_1 \; op \; v_1 \\ y_2 &= x_2 \; op \; v_2 \\ &\ldots \end{aligned}$$

$$\begin{aligned}
y_m &= x_m \; op \; v_m \\
y_{m+1} &= x_{m+1} \; op \; v_1 \\
y_{m+2} &= x_{m+2} \; op \; v_2 \\
&\ldots \\
y_{2m} &= x_{2m} \; op \; v_m \\
y_{2m+1} &= x_{2m+1} \; op \; v1 \\
y_{2m+2} &= x_{2m+2} \; op \; v2 \\
&\ldots
\end{aligned}$$

where $op = +, -, *, \text{ or } /$.

Examples of Usage

The multiplicative seasonal indices are 0.9, 1.3. 0.8, and 1.1 for the four quarters. Let ADJUST be a quarterly time series variable that has been seasonally adjusted in a multiplicative fashion. To restore the seasonality to ADJUST use the following transformation:

```
   convert adjust=seasonal / transformout=(seqmult (0.9 1.3 0.8 1.1));
```

The additive seasonal indices are 4.4, -1.1, -2.1, and -1.2 for the four quarters. Let ADJUST be a quarterly time series variable that has been seasonally adjusted in additive fashion. To restore the seasonality to ADJUST use the following transformation:

```
   convert adjust=seasonal / transformout=(seqadd (4.4 -1.1 -2.1 -1.2));
```

Set Operators

For the set operators, the first parameter, n_1, represents the value to be replaced and the second parameter, n_2, represents the replacement value. The replacement can be localized to the beginning, middle, or end of the series.

Examples of Usage

Suppose that a store opened recently and that the sales history is stored in a database that does not recognize missing values. Even though demand may have existed prior to the stores opening, this database assigns the value of zero. Modeling the sales history may be problematic because the sales history is mostly zero. To compensate for this deficiency, the leading zero values should be to missing with the remaining zero values unchanged (representing no demand).

```
   convert sales=demand / transformout=(setleft 0 .);
```

Likewise, suppose a store is closed recently. The demand may still be present and hence a recorded value of zero does not accurately reflect actual demand.

```
   convert sales=demand / transformout=(setright 0 .);
```

Scale Operator

For the scale operator, the first parameter, n_1, represents the value associated with the minimum value (y_{min}) and the second parameter, n_2, represents the value associated with the maximum value (y_{max}) of the original series (y_t). The scale operator scales the data between the parameters n_1 and n_2 as follows:

$$x_t = ((n_2 - n_1)/(y_{max} - y_{min}))(y_t - y_{min}) + n_1$$

Examples of Usage

Suppose that two new product sales histories are stored in variables X and Y and you wish to determine their adoption rates. In order to compare their adoption histories the variables must be scaled for comparison.

```
convert x=w / transformout=(scale 0 1);
convert y=z / transformout=(scale 0 1);
```

Adjust Operator

For the moving summation and product window operators, the window widths at the beginning and end of the series are smaller than those in the middle of the series. Likewise, if there are embedded missing values, the window width will be smaller than specified. When preceded by the ADJUST operator, the moving summation (MOVSUM CMOVSUM) and moving product operators (MOVPROD CMOVPROD) are adjusted by the window width.

For example, suppose the variable X has 10 values and the moving summation operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movsum 3);
convert x=z / transformout=(movsum 3);
```

The above transformation result in the following: $y_1 = 3z_1$, $y_2 = \frac{3}{2}z_2$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

For example, suppose the variable X has 10 values and the moving multiplicative operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movprod 3);
convert x=z / transformout=(movprod 3);
```

The above transformation result in the following: $y_1 = z_1^3$, $y_2 = z_2^{3/2}$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

Moving T-Value Operators

The moving *t*-value operators (CUTVALUE, MOVTVALUE, CMOVTVALUE) compute the *t*-value of the cumulative series or moving window. They can be viewed as combinations of the moving average (CUAVE, MOVAVE, CMOVAVE) and the moving standard deviation (CUSTD, MOVSTD, CMOVSTD), respectively.

Percent Operators

The percentage operators compute the percent summation and the percent difference of the current value and the $\text{lag}(n)$. The percent summation operator (PCTSUM) computes $y_t = 100x_t/\text{cusum}(x_{t-n})$. If any of the values of the preceding equation are missing or the cumulative summation is zero, the result is set to missing. The percent difference operator (PCTDIF) computes $y_t = 100(x_t - x_{t-n})/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose variable X contains the series. The percent summation of lag 4 is applied to X to create the variable Y. The percent difference of lag 4 is applied to X to create the variable Z.

```
convert x=y / transformout=(pctsum 4);
convert x=z / transformout=(pctdif 4);
```

Ratio Operators

The ratio operator computes the ratio of the current value and the $\text{lag}(n)$. The ratio operator (RATIO) computes $y_t = x_t/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose variable X contains the series. The ratio of lag 4 is applied to X to create the variable Y. The percent ratio of lag 4 is applied to X to create the variable Z.

```
convert x=y / transformout=(ratio 4);
convert x=z / transformout=(ratio 4 * 100);
```

OUT= Data Set

The OUT= output data set contains the following variables:

- the BY variables, if any
- an ID variable that identifies the time period for each output observation
- the result variables
- if no frequency conversion is performed (so that there is one output observation corresponding to each input observation), all the other variables in the input data set are copied to the output data set

The ID variable in the output data set is named as follows:

- If an ID statement is used, the new ID variable has the same name as the variable used in the ID statement.
- If no ID statement is used, but the FROM= option is used, then the name of the ID variable is either DATE or DATETIME, depending on whether the TO= option indicates SAS date or SAS datetime values.
- If neither an ID statement nor the TO= option is used, the ID variable is named TIME.

OUTEST= Data Set

The OUTEST= data set contains the coefficients of the spline curves fit to the input series. The OUTEST= data set is of interest if you want to verify the interpolating curve PROC EXPAND uses, or if you want to use this function in another context, (for example, in a SAS/IML program).

The OUTEST= data set contains the following variables:

- the BY variables, if any
- VARNAME, a character variable containing the name of the input variable to which the coefficients apply
- METHOD, a character variable containing the value of the METHOD= option used to fit the series
- OBSERVED, a character variable containing the first letter of the OBSERVED= option name for the input series
- the ID variable that contains the lower breakpoint (or “knot”) of the spline segment to which the coefficients apply. The ID variable has the same name as the variable used in the ID statement. If an ID statement is not used, but the FROM= option is used, then the name of the ID variable is DATE or DATETIME, depending on whether the FROM= option indicates SAS date or SAS datetime values. If neither an ID statement nor the FROM= option is used, the ID variable is named TIME.
- CONSTANT, the constant coefficient for the spline segment
- LINEAR, the linear coefficient for the spline segment
- QUAD, the quadratic coefficient for the spline segment
- CUBIC, the cubic coefficient for the spline segment

For each BY group, the OUTEST= data set contains observations for each polynomial segment of the spline curve fit to each input series. To obtain the observations defining the spline curve used for a series, select the observations where the value of VARNAME equals the name of the series.

The observations for a series in the OUTEST= data set encode the spline function fit to the series as follows. Let $a_i, b_i, c_i,$ and d_i be the values of the variables CUBIC, QUAD, LINEAR, and CONSTANT, respectively, for the *i*th observation for the series. Let x_i be the value of the ID variable for the *i*th observation for the series. Let *n* be the number of observations in the OUTEST= data set for the series. The value of the spline function evaluated at a point *x* is

$$f(x) = a_i(x - x_i)^3 + b_i(x - x_i)^2 + c_i(x - x_i) + d_i$$

where the segment number *i* is selected as follows:

$$i = \begin{cases} i & \text{such that } x_i \le x < x_{i+1}, 1 \le i < n \\ 1 & \text{if } x < x_1 \\ n & \text{if } x \ge x_n \end{cases}$$

In other words, if *x* is between the first and last ID values ($x_1 \le x < x_n$), use the observation from the OUTEST= data set with the largest ID value less than or equal to *x*. If *x* is less than the first ID value x_1, then $i = 1$. If *x* is greater than or equal to the last ID value ($x \ge x_n$), then $i = n$.

For METHOD=JOIN, the curve is a linear spline, and the values of CUBIC and QUAD are 0. For METHOD=STEP, the curve is a constant spline, and the values of CUBIC, QUAD, and LINEAR are 0. For METHOD=AGGREGATE, no coefficients are output.

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the EXPAND procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement and the PLOT= option in the EXPAND statement according to the following syntax. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

PLOT= *option* **|** **(***options***)**

specifies the graphical output desired. If the PLOT= option is used, the specified graphical output is produced for each output variable specified by a CONVERT statement. By default, the EXPAND procedure produces no graphical output. The following PLOT= options are available:

INPUT	plots the input series.
TRANSFORMIN	plots the transformed input series. (TRANSFORMIN= option)
CROSSINPUT	plots both the input series and the transformed input series. (TRANSFORMIN= option must be specified.)
JOINTINPUT	plots both the input series and the transformed input series. (TRANSFORMIN= option must be specified.)
CONVERTED|METHOD	plots the converted series. (METHOD= option)

TRANSFORMOUT	plots the transformed output series. (TRANSFORMOUT= option)
CROSSOUTPUT	plots both the converted series and the transformed output series. (TRANSFORMOUT= option must be specified.)
JOINTOUTPUT	plots both the converted series and the transformed output series. (TRANSFORMOUT= option must be specified.)
SERIES|OUTPUT	plots the series stored in the OUT= data set. (combination of TRANSFORMIN=, METHOD=, and/or TRANFORMOUT= options)
ALL	Same as PLOT=(INPUT TRANFORMIN CONVERTED TRANSFORMOUT).

The PLOT= option produces results associated with each CONVERT statement output variable and the options listed next to the above PLOT= options in parenthesis. The PLOT= option produces output for these results utilizing the Output Delivery System (ODS).

The PLOT=TRANSFORMIN plots the series after the input transformation (TRANSFORMIN= option) is applied. If the TRANFORMIN= option is not specified in the CONVERT statement for an output variable, the input transformation plot is not produced.

The PLOT=CROSSINPUT plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. The left side vertical axis refers to the input series, while the right side vertical axis refers to the series after the transformation. If the TRANFORMIN= option is not specified in the CONVERT statement for an output variable, the cross input plot is not produced.

The PLOT=JOINTINPUT jointly plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. If the TRANFORMIN= option is not specified in the CONVERT statement for an output variable, the joint input plot is not produced.

The PLOT=CONVERT plots the series after the input transformation (TRANSFORMIN= option) is applied and after frequency conversion (METHOD= option). If there is no frequency conversion for an output variable, the converted series plot is not produced.

The PLOT=TRANSFORMOUT plots the series after the output transformation (TRANSFORMOUT= option) is applied. If the TRANFORMOUT= option is not specified in the CONVERT statement for an output variable, the output transformation plot is not produced.

The PLOT=CROSSOUTPUT plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. The left side vertical axis refers to the input series, while the right side vertical axis refers to the series after the transformation. If the TRANFORMOUT= option is not specified in the CONVERT statement for an output variable, the cross output plot is not produced.

The PLOT=JOINTOUTPUT jointly plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. If the TRANFORMOUT= option is not specified in the CONVERT statement for an output variable, the joint output plot is not produced.

The PLOT=SERIES option plots the series after it has undergone input transformation (TRANSFORMIN= option), frequency conversion (METHOD= option), and output transformation (TRANSFORMOUT= option) if these CONVERT statement options were specified.

The PLOT=(ALL SERIES) option plots the series in the same way as the previous example as well as the intermediate series associated with the CONVERT statement options (TRANSFORMIN=, METHOD=, and/or TRANFORMOUT= options if specified).

The PLOT=(ALL SERIES JOINTINPUT JOINTOUTPUT CROSSINPUT CROSSOUTPUT) option plots the series in the same way as the previous example as well as the joint and cross plots series associated with the CONVERT statement options (TRANSFORMIN=, METHOD=, and/or TRANFORMOUT= options if specified).

Note: The joint graphics options (PLOT=JOINTINPUT or PLOT=JOINTOUTPUT) plot the (input or converted) series and the transformed series on the same scale. If the transformation changes the range of the (input or converted) series, these plots may be hard to visualize.

ODS Graph Names

PROC EXPAND assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 16.2.

To request these graphs, you must specify the ODS GRAPHICS statement and the PLOT= option in the EXPAND statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 16.2. ODS Graphics Produced by PROC EXPAND

ODS Graph Name	Plot Description	PLOT= Option Argument
ConvertedSeriesPlot	Converted Series Plot	CONVERTED|METHOD|SERIES|OUTPUT|ALL
CrossInputSeriesPlot	Cross Input Series Plot	CROSSINPUT
CrossOutputSeriesPlot	Cross Output Series Plot	CROSSOUTPUT
InputSeriesPlot	Input Series Plot	INPUT|JOINTINPUT|ALL
JointInputSeriesPlot	Joint Input Series Plot	JOINTINPUT
JointOutputSeriesPlot	Joint Output Series Plot	JOINTOUTPUT
OutputSeriesPlot	Output Series Plot	SERIES|OUTPUT

Table 16.2. (continued)

ODS Graph Name	Plot Description	PLOT= Option Argument
TransformedInputSeriesPlot	Transformed Input Series Plot	TRANSFORMIN|SERIES|OUTPUT|ALL
TransformedOutputSeriesPlot	Transformed Output Series Plot	TRANSFORMOUT|SERIES|OUTPUT|ALL

Examples

Example 16.1. Combining Monthly and Quarterly Data

This example combines monthly and quarterly data sets by interpolating monthly values for the quarterly series. The series are extracted from two small sample data sets stored in the SASHELP library. These data sets were contributed by Citicorp Data Base services and contain selected U.S. macro economic series.

The quarterly series gross domestic product (GDP) and implicit price deflator (GD) are extracted from SASHELP.CITIQTR. The monthly series industrial production index (IP) and unemployment rate (LHUR) are extracted from SASHELP.CITIMON. Only observations for the years 1990 and 1991 are selected. PROC EXPAND is then used to interpolate monthly estimates for the quarterly series, and the interpolated series are merged with the monthly data.

The following statements extract and print the quarterly data, shown in Output 16.1.1.

```
data qtrly;
   set sashelp.citiqtr;
   where date >= '1jan1990'd &
         date <  '1jan1992'd ;
   keep date gdp gd;
run;

title "Quarterly Data";
proc print data=qtrly;
run;
```

Output 16.1.1. Quarterly Data Set

```
                                  Quarterly Data

                     Obs      DATE        GD          GDP

          24     DEC1991     107.800     7.10000     5737.75        .
```

Example 16.2. Interpolating Irregular Observations

This example shows the interpolation of a series of values measured at irregular points in time. The data are hypothetical. Assume that a series of randomly timed quality control inspections are made and defect rates for a process are measured. The problem is to produce two reports: estimates of monthly average defect rates for the months within the period covered by the samples, and a plot of the interpolated defect rate curve over time.

The following statements read and print the input data, as shown in Output 16.2.1.

```
data samples;
  input date : date9. defects @@;
  label defects = "Defects per 1000 units";
  format date date9.;
datalines;

                      12    11JUL1992       97
                      13    15AUG1992      112
                      14    29AUG1992       89
                      15    10SEP1992       77
                      16    27SEP1992       82
```

To compute the monthly estimates, use PROC EXPAND with the TO=MONTH option and specify OBSERVED=(BEGINNING,AVERAGE). The following statements interpolate the monthly estimates.

```
proc expand data=samples out=monthly to=month;
  id date;
  convert defects / observed=(beginning,average);
run;

title "Estimated Monthly Average Defect Rates";
proc print data=monthly;
run;
```

The results are printed in Output 16.2.2.

Output 16.2.2. Monthly Average Estimates

```
                 Estimated Monthly Average Defect Rates

                      Obs       date    defects

                        1     JAN1992     59.323
                        2     FEB1992     82.000
                        3     MAR1992     66.909
                        4     APR1992     70.205
                        5     MAY1992     82.762
                        6     JUN1992     99.701
                        7     JUL1992    101.564
                        8     AUG1992    105.491
                        9     SEP1992     79.206
```

To produce the plot, first use PROC EXPAND with TO=DAY to interpolate a full set of daily values, naming the interpolated series INTERPOL. Then merge this data set with the samples so you can plot both the measured and the interpolated values on the same graph. PROC GPLOT is used to plot the curve. The actual sample points are plotted with asterisks. The following statements interpolate and plot the defects rate curve.

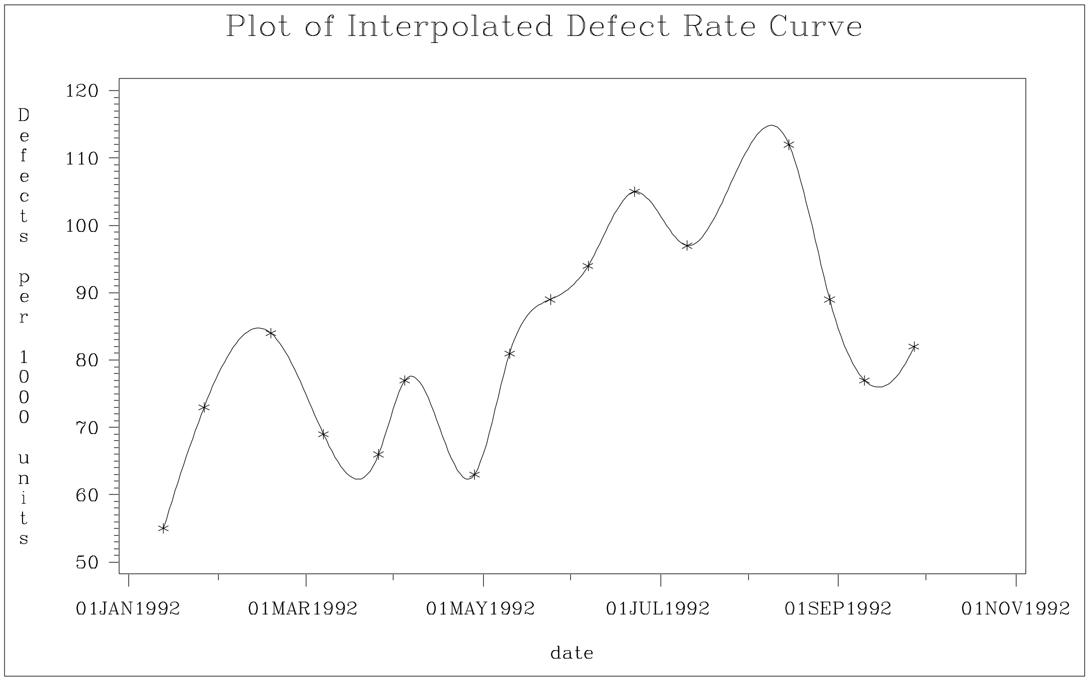
```
proc expand data=samples out=daily to=day;
  id date;
  convert defects = interpol;
run;

data daily;
  merge daily samples;
  by date;
run;

title "Plot of Interpolated Defect Rate Curve";
proc gplot data=daily;
   axis2 label=(a=-90 r=90 );
   symbol1 v=none i=join;
   symbol2 v=star i=none;
   plot interpol * date = 1 defects * date = 2  /
        vaxis=axis2 overlay;
run;
quit;
```

The plot is shown in Output 16.2.3.

Output 16.2.3. Interpolated Defects Rate Curve



Example 16.3. Using Transformations

This example shows the use of PROC EXPAND to perform various transformations of time series. The following statements read in monthly values for a variable X.

```
data test;
   input year qtr x;
   date = yyq( year, qtr );
   format date yyqc.;
datalines;
1989 3 5238
1989 4 5289
1990 1 5375
1990 2 5443
1990 3 5514
1990 4 5527
1991 1 5557
1991 2 5615
;
```

The following statements use PROC EXPAND to compute lags and leads and a 3-period moving average of the X series.

```
proc expand data=test out=out method=none;
   id date;
   convert x = x_lag2   / transformout=(lag 2);
   convert x = x_lag1   / transformout=(lag 1);
   convert x;
   convert x = x_lead1  / transformout=(lead 1);
   convert x = x_lead2  / transformout=(lead 2);
   convert x = x_movave / transformout=(movave 3);
run;

title "Transformed Series";
proc print data=out;
run;
```

Because there are no missing values to interpolate and no frequency conversion, the METHOD=NONE option is used to prevent PROC EXPAND from performing unnecessary computations. Because no frequency conversion is done, all variables in the input data set are copied to the output data set. The CONVERT X; statement is included to control the position of X in the output data set. This statement can be omitted, in which case X is copied to the output data set following the new variables computed by PROC EXPAND.

The results are shown in Output 16.3.1.

Output 16.3.1. Output Data Set with Transformed Variables

```
                                Transformed Series

```

Example 16.4. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics.

The graphical displays are requested by specifying the experimental ODS GRAPHICS statement and the experimental PLOT= option in the PROC EXPAND statement. For general information about ODS graphics, see Chapter 9, “Statistical Graphics Using ODS.” For specific information about the graphics available in the EXPAND procedure, see the “ODS Graphics” section on page 820.

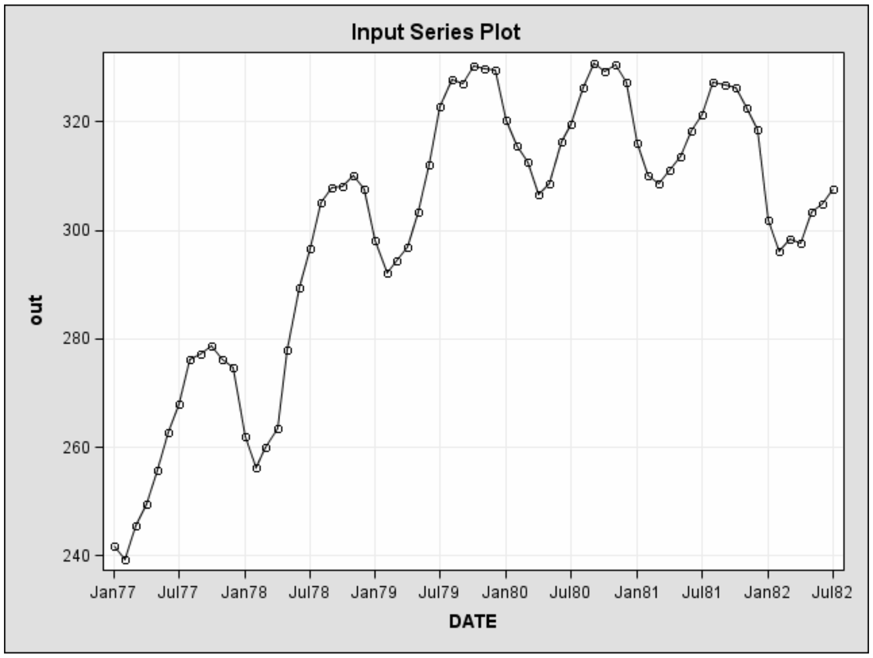
The following statements utilize the SASHELP.WORKERS data set to convert the time series of electrical workers from monthly to quarterly frequency, and display ODS graphics plots. The PLOT=ALL option is specified to request the plots of the input series, the transformed input series, the converted series, and the transformed output series. Output 16.4.1 through Output 16.4.4 show these plots.

```
ods html;
ods graphics on;

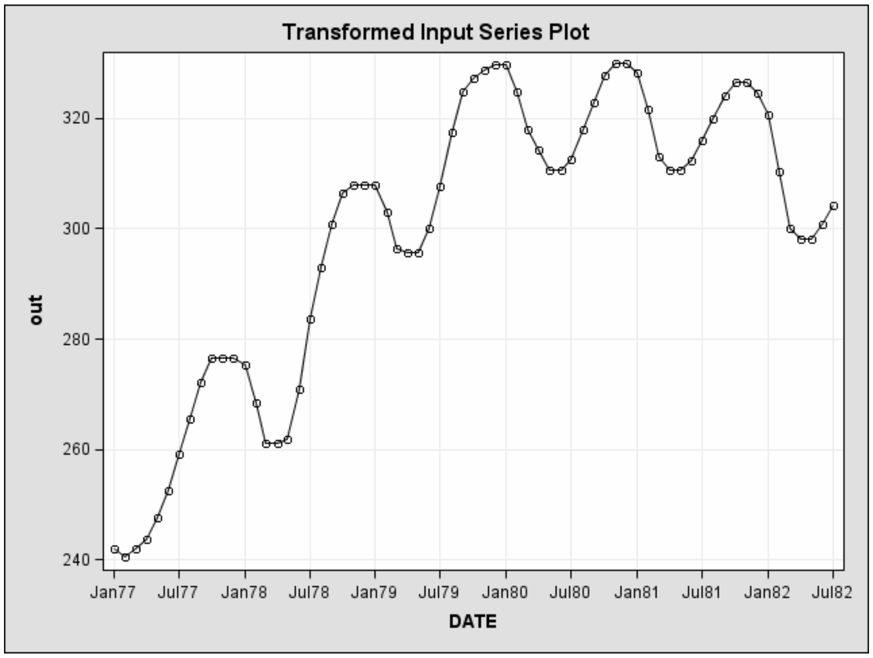
proc expand data=sashelp.workers out=out from=month to=qtr plot=all;
   id date;
   convert electric=out / transformin=(movmed 4) method=spline
                          transformout=(movave 3);
run;

ods graphics off;
ods html close;
```

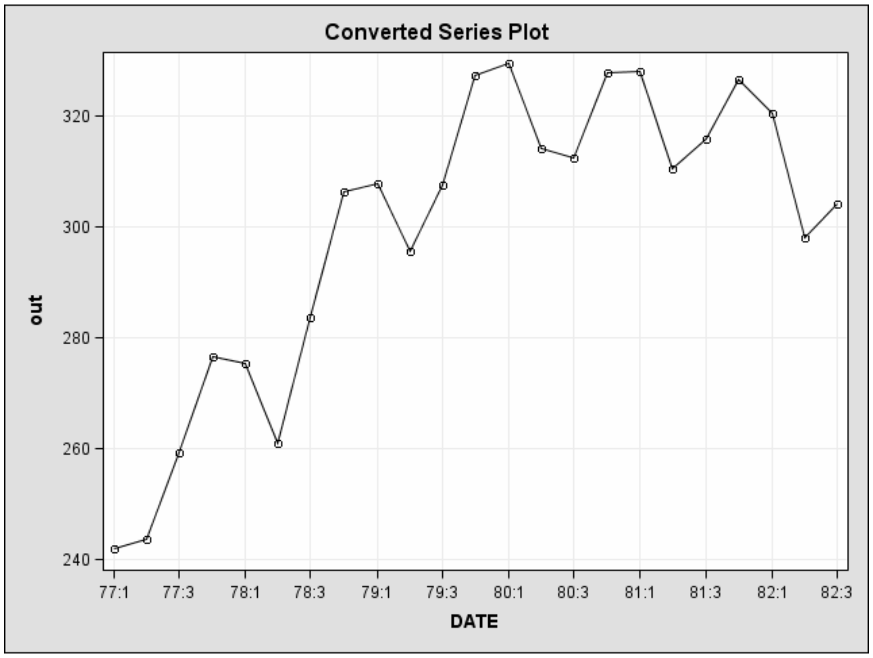
Output 16.4.1. Input Series Plot (Experimental)



Output 16.4.2. Transformed Input Series Plot (Experimental)



Output 16.4.3. Converted Series Plot (Experimental)



Output 16.4.4. Transformed Output Series Plot (Experimental)

The FORECAST Procedure

Chapter Contents

Chapter 17
The FORECAST Procedure

Overview

The FORECAST procedure provides a quick and automatic way to generate forecasts for many time series in one step. The procedure can forecast hundreds of series at a time, with the series organized into separate variables or across BY groups. PROC FORECAST uses extrapolative forecasting methods where the forecasts for a series are functions only of time and past values of the series, not of other variables.

You can use the following forecasting methods. For each of these methods, you can specify linear, quadratic, or no trend.

- The stepwise autoregressive method is used by default. This method combines time trend regression with an autoregressive model and uses a stepwise method to select the lags to use for the autoregressive process.
- The exponential smoothing method produces a time trend forecast, but in fitting the trend, the parameters are allowed to change gradually over time, and earlier observations are given exponentially declining weights. Single, double, and triple exponential smoothing are supported, depending on whether no trend, linear trend, or quadratic trend is specified. Holt two-parameter linear exponential smoothing is supported as a special case of the Holt-Winters method without seasons.
- The Winters method (also called Holt-Winters) combines a time trend with multiplicative seasonal factors to account for regular seasonal fluctuations in a series. Like the exponential smoothing method, the Winters method allows the parameters to change gradually over time, with earlier observations given exponentially declining weights. You can also specify the additive version of the Winters method, which uses additive instead of multiplicative seasonal factors. When seasonal factors are omitted, the Winters method reduces to the Holt two-parameter version of double exponential smoothing.

The FORECAST procedure writes the forecasts and confidence limits to an output data set, and can write parameter estimates and fit statistics to an output data set. The FORECAST procedure does not produce printed output.

PROC FORECAST is an extrapolation procedure useful for producing practical results efficiently. However, in the interest of speed, PROC FORECAST uses some shortcuts that cause some statistical results (such as confidence limits) to be only approximate. For many time series, the FORECAST procedure, with appropriately chosen methods and weights, can yield satisfactory results. Other SAS/ETS procedures can produce better forecasts but at greater computational expense.

You can perform the stepwise autoregressive forecasting method with the AUTOREG procedure. You can perform exponential smoothing with statistically optimal weights as an ARIMA model using the ARIMA procedure. Seasonal ARIMA models can be used for forecasting seasonal series for which the Winters and additive Winters methods might be used.

Additionally, the Time Series Forecasting System can be used to develop forecasting models, estimate the model parameters, evaluate the models' ability to forecast and display the results graphically. See Chapter 34, "Getting Started with Time Series Forecasting," for more details.

Getting Started

To use PROC FORECAST, specify the input and output data sets and the number of periods to forecast in the PROC FORECAST statement, then list the variables to forecast in a VAR statement.

For example, suppose you have monthly data on the sales of some product, in a data set, named PAST, as shown in Figure 17.1, and you want to forecast sales for the next 10 months.

```
                                 Obs     date      sales

                                   1    JUL89     9.5161
                                   2    AUG89     9.6994
                                   3    SEP89     9.2644
                                   4    OCT89     9.6837
                                   5    NOV89    10.0784
                                   6    DEC89     9.9005
                                   7    JAN90    10.2375

                                   9    MAR90    10.6290
                                  10    APR90    11.0332
                                  11    MAY90    11.0270
                                  12    JUN90    11.4165
                                  13    JUL90    11.2918
                                  14    AUG90    11.3475
                                  15    SEP90    11.2913
                                  16    OCT90    11.3771
                                  17    NOV90    11.5457
                                  18    DEC90    11.6433
                                  19    JAN91    11.9293
                                  20    FEB91    11.9752
                                  21    MAR91    11.9283
                                  22    APR91    11.8985
                                  23    MAY91    12.0419
                                  24    JUN91    12.3537
                                  25    JUL91    12.4546
```

Figure 17.1. Example Data Set PAST

The following statements forecast 10 observations for the variable SALES using the default STEPAR method and write the results to the output data set PRED:

```
   proc forecast data=past lead=10 out=pred;
```

```
      var sales;
   run;
```

The following statements use the PRINT procedure to print the data set PRED:

```
   proc print data=pred;
   run;
```

The PROC PRINT listing of the forecast data set PRED is shown in Figure 17.2.

```
                    Obs     _TYPE_      _LEAD_      sales

                      1    FORECAST        1       12.6205
                      2    FORECAST        2       12.7665
                      3    FORECAST        3       12.9020
                      4    FORECAST        4       13.0322
                      5    FORECAST        5       13.1595
                      6    FORECAST        6       13.2854
                      7    FORECAST        7       13.4105
                      8    FORECAST        8       13.5351
                      9    FORECAST        9       13.6596
                     10    FORECAST       10       13.7840
```

Figure 17.2. Forecast Data Set PRED

Giving Dates to Forecast Values

Normally, your input data set has an ID variable that gives dates to the observations, and you want the forecast observations to have dates also. Usually, the ID variable has SAS date values. (See Chapter 2, “Working with Time Series Data,” for information on using SAS date values.) The ID statement specifies the identifying variable.

If the ID variable contains SAS date values, the INTERVAL= option should be used on the PROC FORECAST statement to specify the time interval between observations. (See Chapter 3, “Date Intervals, Formats, and Functions,” for more information on time intervals.) The FORECAST procedure uses the INTERVAL= option to generate correct dates for forecast observations.

The data set PAST, shown in Figure 17.1, has monthly observations and contains an ID variable DATE with SAS date values identifying each observation. The following statements produce the same forecast as the preceding example and also include the ID variable DATE in the output data set. Monthly SAS date values are extrapolated for the forecast observations.

```
   proc forecast data=past interval=month lead=10 out=pred;
      var sales;
      id date;
   run;
```

Computing Confidence Limits

Depending on the output options specified, multiple observations are written to the OUT= data set for each time period. The different parts of the results are contained in the VAR statement variables in observations identified by the character variable _TYPE_ and by the ID variable.

For example, the following statements use the OUTLIMIT option to write forecasts and 95% confidence limits for the variable SALES to the output data set PRED. This data set is printed with the PRINT procedure.

```
proc forecast data=past interval=month lead=10
              out=pred outlimit;
   var sales;
   id date;
run;

proc print data=pred;
run;
```

The output data set PRED is shown in Figure 17.3.

```
             Obs    date     _TYPE_      _LEAD_     sales

Figure 17.3. Output Data Set

Form of the OUT= Data Set

The OUT= data set PRED, shown in Figure 17.3, contains three observations for each of the 10 forecast periods. Each of these three observations has the same value of the ID variable DATE, the SAS date value for the month and year of the forecast.

The three observations for each forecast period have different values of the variable _TYPE_. For the _TYPE_=FORECAST observation, the value of the variable SALES is the forecast value for the period indicated by the DATE value. For the _TYPE_=L95 observation, the value of the variable SALES is the lower limit of the 95% confidence interval for the forecast. For the _TYPE_=U95 observation, the value of the variable SALES is the upper limit of the 95% confidence interval.

You can control the types of observations written to the OUT= data set with the PROC FORECAST statement options OUTLIMIT, OUTRESID, OUTACTUAL, OUT1STEP, OUTSTD, OUTFULL, and OUTALL. For example, the OUTFULL option outputs the confidence limit values, the one-step-ahead predictions, and the actual data, in addition to the forecast values. See the sections "Syntax" and "OUT= Data Set" later in this chapter for more information.

Plotting Forecasts

The forecasts, confidence limits, and actual values can be plotted on the same graph with the GPLOT procedure. Use the appropriate output control options on the PROC FORECAST statement to include in the OUT= data set the series you want to plot. Use the _TYPE_ variable in the GPLOT procedure PLOT statement to separate the observations for the different plots.

In this example, the OUTFULL option is used, and the resulting output data set contains the actual and predicted values, as well as the upper and lower 95

```
proc forecast data=past interval=month lead=10
              out=pred outfull;
   id date;
   var sales;
run;

proc gplot data=pred;
   plot sales * date = _type_ /
        haxis= '1jan90'd to '1jan93'd by qtr
        href='15jul91'd;
   symbol1 i=none   v=star; /* for _type_=ACTUAL */
   symbol2 i=spline v=circle;   /* for _type_=FORECAST */
   symbol3 i=spline l=3;        /* for _type_=L95 */
   symbol4 i=spline l=3;        /* for _type_=U95 */
   where date >= '1jan90'd;
run;
```

The _TYPE_ variable is used in the GPLOT procedure's PLOT statement to make separate plots over time for each type of value. A reference line marks the start of the forecast period. (Refer to *SAS/GRAPH Software: Reference, Volume 2, Version 7, First Edition* for more information on using PROC GPLOT.) The WHERE statement restricts the range of the actual data shown in the plot. In this example, the variable SALES has monthly data from July 1989 through July 1991, but only the data for 1990 and 1991 are shown in the plot.

The plot is shown in Figure 17.4.

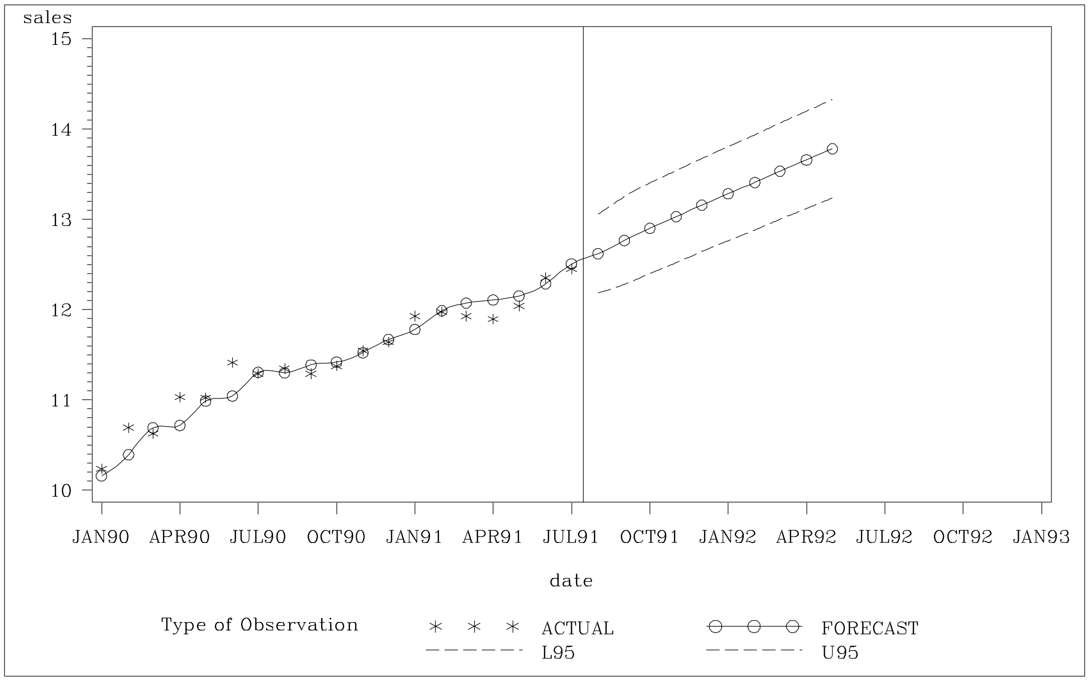

Figure 17.4. Plot of Forecast with Confidence Limits

Plotting Residuals

You can plot the residuals from the forecasting model using PROC GPLOT and a WHERE statement.

1. Use the OUTRESID option or the OUTALL option in the PROC FORECAST statement to include the residuals in the output data set.
2. Use a WHERE statement to specify the observation type of ’RESIDUAL’ in the PROC GPLOT code.

The following example adds the OUTRESID option to the preceding example and plots the residuals:

```
proc forecast data=past interval=month lead=10
              out=pred outfull outresid;
   id date;
   var sales;
run;

proc gplot data=pred;
```

```
      where _type_='RESIDUAL';
      plot sales * date /
           haxis= '1jan89'd to '1oct91'd by qtr;
      symbol1 i=needle v=circle;
   run;
```

The plot of residuals is shown in Figure 17.5.

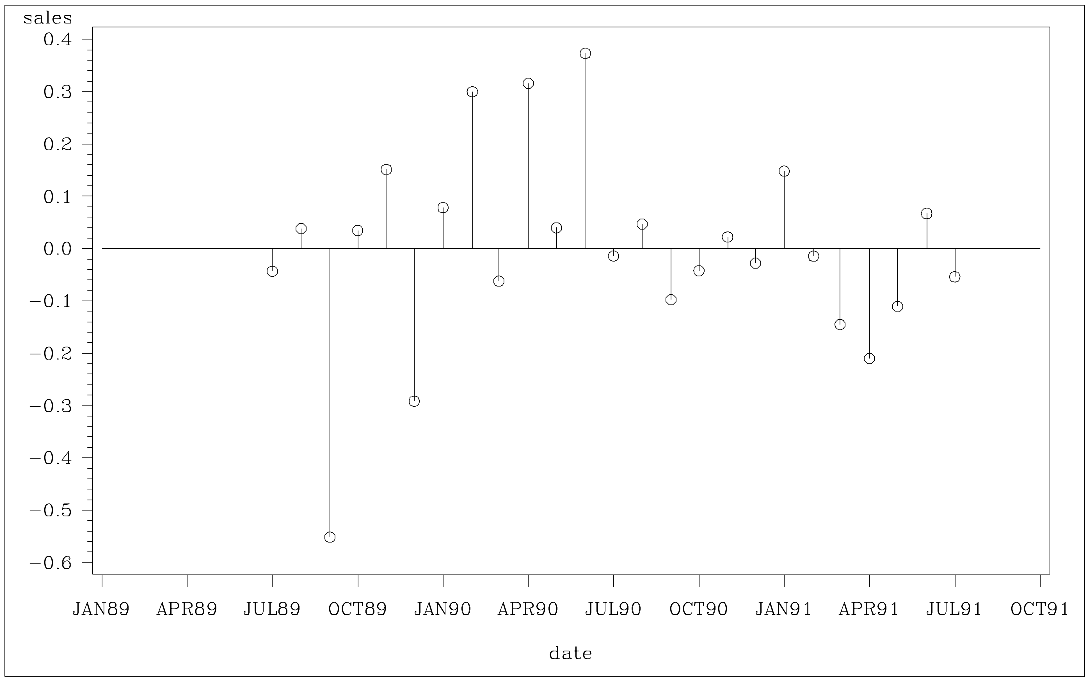

Figure 17.5. Plot of Residuals

Model Parameters and Goodness-of-Fit Statistics

You can write the parameters of the forecasting models used, as well as statistics measuring how well the forecasting models fit the data, to an output SAS data set using the OUTEST= option. The options OUTFITSTATS, OUTESTTHEIL, and OUTESTALL control what goodness-of-fit statistics are added to the OUTEST= data set.

For example, the following statements add the OUTEST= and OUTFITSTATS options to the previous example to create the output statistics data set EST for the results of the default stepwise autoregressive forecasting method:

```
   proc forecast data=past interval=month lead=10
                 out=pred outfull outresid
                 outest=est outfitstats;
      id date;
      var sales;
   run;
```

```
proc print data=est;
run;
```

The PRINT procedure prints the OUTEST= data set, as shown in Figure 17.6.

```
                      Obs    _TYPE_       date        sales

Figure 17.6. The OUTEST= Data Set for STEPAR Method

In the OUTEST= data set, the DATE variable contains the ID value of the last observation in the data set used to fit the forecasting model. The variable SALES contains the statistic indicated by the value of the _TYPE_ variable. The _TYPE_=N, NRESID, and DF observations contain, respectively, the number of observations read from the data set, the number of nonmissing residuals used to compute the goodness-of-fit statistics, and the number of nonmissing observations minus the number of parameters used in the forecasting model.

The observation having _TYPE_=SIGMA contains the estimate of the standard deviation of the one-step prediction error computed from the residuals. The _TYPE_=CONSTANT and _TYPE_=LINEAR contain the coefficients of the time trend regression. The _TYPE_=AR1, AR2, ..., AR8 observations contain the estimated autoregressive parameters. A missing autoregressive parameter indicates that the autoregressive term at that lag was not included in the model by the stepwise model selection method. (See the section "STEPAR Method" later in this chapter for more information.)

The other observations in the OUTEST= data set contain various goodness-of-fit statistics that measure how well the forecasting model used fits the given data. See "OUTEST= Data Set" later in this chapter for details.

Controlling the Forecasting Method

The METHOD= option controls which forecasting method is used. The TREND= option controls the degree of the time trend model used. For example, the following statements produce forecasts of SALES as in the preceding example but use the double exponential smoothing method instead of the default STEPAR method:

```
proc forecast data=past interval=month lead=10
              method=expo trend=2
              out=pred outfull outresid
              outest=est outfitstats;
   var sales;
   id date;
run;

proc print data=est;
run;
```

The PRINT procedure prints the OUTEST= data set for the EXPO method, as shown in Figure 17.7.

```
                     Obs    _TYPE_       date        sales

                       1    N           JUL91           25

                      29    CORR        JUL91    0.9772418
```

Figure 17.7. The OUTEST= Data Set for METHOD=EXPO

See the "Syntax" section later in this chapter for other options that control the forecasting method. See "Introduction to Forecasting Methods" and "Forecasting Methods" later in this chapter for an explanation of the different forecasting methods.

Introduction to Forecasting Methods

This section briefly introduces the forecasting methods used by the FORECAST procedure. Refer to textbooks on forecasting and see "Forecasting Methods" later in this chapter for more detailed discussions of forecasting methods.

The FORECAST procedure combines three basic models to fit time series:

- time trend models for long-term, deterministic change
- autoregressive models for short-term fluctuations
- seasonal models for regular seasonal fluctuations

Two approaches to time series modeling and forecasting are *time trend models* and *time series methods*.

Time Trend Models

Time trend models assume that there is some permanent deterministic pattern across time. These models are best suited to data that are not dominated by random fluctuations.

Examining a graphical plot of the time series you want to forecast is often very useful in choosing an appropriate model. The simplest case of a time trend model is one in which you assume the series is a constant plus purely random fluctuations that are independent from one time period to the next. Figure 17.8 shows how such a time series might look.

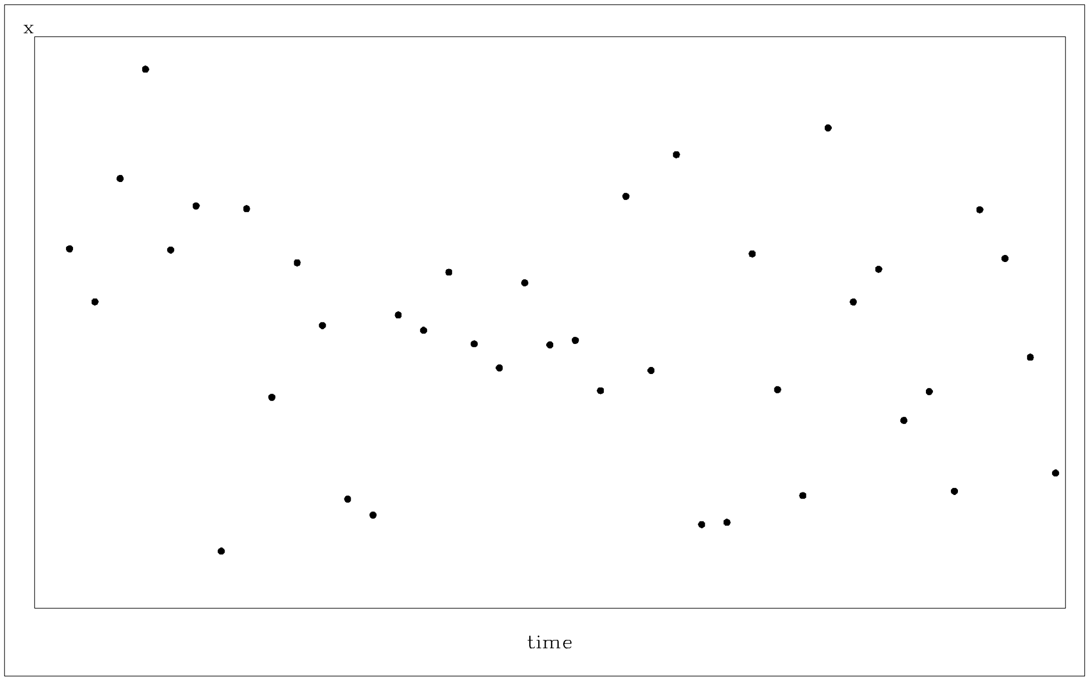

Figure 17.8. Time Series without Trend

The x_t values are generated according to the equation

$$x_t = b_0 + \epsilon_t$$

where ϵ_t is an independent, zero-mean, random error, and b_0 is the true series mean.

Suppose that the series exhibits growth over time, as shown in Figure 17.9.

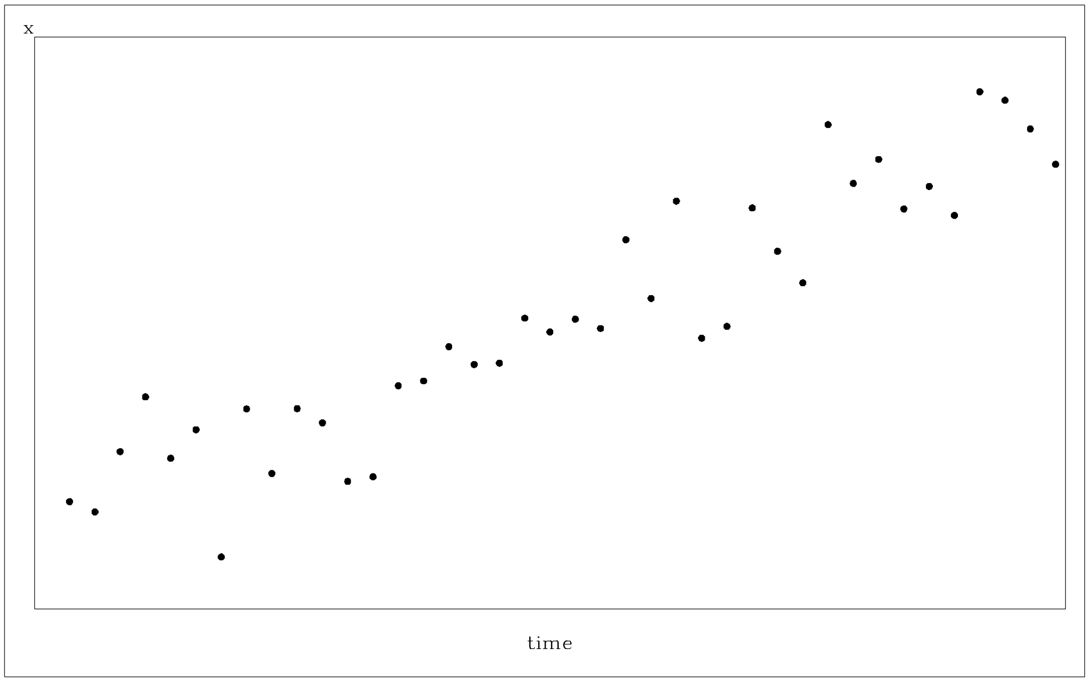

Figure 17.9. Time Series with Linear Trend

A linear model is appropriate for this data. For the linear model, assume the x_t values are generated according to the equation

$$x_t = b_0 + b_1 t + \epsilon_t$$

The linear model has two parameters. The predicted values for the future are the points on the estimated line. The extension of the polynomial model to three parameters is the quadratic (which forms a parabola). This allows for a constantly changing slope, where the x_t values are generated according to the equation

$$x_t = b_0 + b_1 t + b_2 t^2 + \epsilon_t$$

PROC FORECAST can fit three types of time trend models: constant, linear, and quadratic. For other kinds of trend models, other SAS procedures can be used.

Exponential smoothing fits a time trend model using a smoothing scheme in which the weights decline geometrically as you go backward in time. The forecasts from exponential smoothing are a time trend, but the trend is based mostly on the recent observations instead of on all the observations equally. How well exponential smoothing works as a forecasting method depends on choosing a good smoothing weight for the series.

To specify the exponential smoothing method, use the METHOD=EXPO option. Single exponential smoothing produces forecasts with a constant trend (that is, no trend). Double exponential smoothing produces forecasts with a linear trend, and triple exponential smoothing produces a quadratic trend. Use the TREND= option with the METHOD=EXPO option to select single, double, or triple exponential smoothing.

The time trend model can be modified to account for regular seasonal fluctuations of the series about the trend. To capture seasonality, the trend model includes a seasonal parameter for each season. Seasonal models can be additive or multiplicative.

$$x_t = b_0 + b_1 t + s(t) + \epsilon_t \qquad \text{(Additive)}$$

$$x_t = (b_0 + b_1 t)s(t) + \epsilon_t \qquad \text{(Multiplicative)}$$

where *s(t)* is the seasonal parameter for the season corresponding to time *t*.

The Winters method is similar to exponential smoothing, but includes seasonal factors. The Winters method can use either additive or multiplicative seasonal factors. Like exponential smoothing, good results with the Winters method depend on choosing good smoothing weights for the series to be forecast.

To specify the multiplicative or additive versions of the Winters method, use the METHOD=WINTERS or METHOD=ADDWINTERS options, respectively. To specify seasonal factors to include in the model, use the SEASONS= option.

Many observed time series do not behave like constant, linear, or quadratic time trends. However, you can partially compensate for the inadequacies of the trend models by fitting time series models to the departures from the time trend, as described in the following sections.

Time Series Methods

Time series models assume the future value of a variable to be a linear function of past values. If the model is a function of past values for a finite number of periods, it is an *autoregressive model* and is written as follows:

$$x_t = a_0 + a_1 x_{t-1} + a_2 x_{t-2} + \ldots + a_p x_{t-p} + \epsilon_t$$

The coefficients a_i are *autoregressive parameters*. One of the simplest cases of this model is the random walk, where the series dances around in purely random jumps. This is illustrated in Figure 17.10.

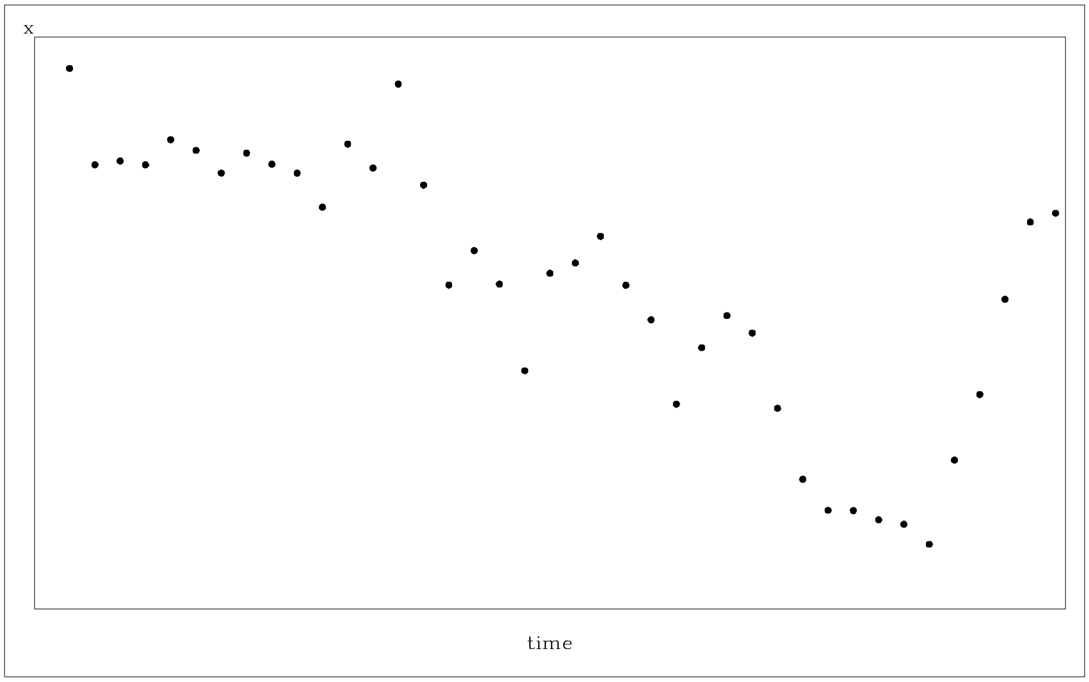

Figure 17.10. Random Walk Series

The x_t values are generated by the equation

$$x_t = x_{t-1} + \epsilon_t$$

In this type of model, the best forecast of a future value is the present value. However, with other autoregressive models, the best forecast is a weighted sum of recent values. Pure autoregressive forecasts always damp down to a constant (assuming the process is stationary).

Autoregressive time series models can also be used to predict seasonal fluctuations.

Combining Time Trend with Autoregressive Models

Trend models are suitable for capturing long-term behavior, whereas autoregressive models are more appropriate for capturing short-term fluctuations. One approach to forecasting is to combine a deterministic time trend model with an autoregressive model.

The *stepwise autoregressive method* (STEPAR method) combines a time-trend regression with an autoregressive model for departures from trend. The combined time-trend and autoregressive model is written as follows:

$$x_t = b_0 + b_1 t + b_2 t^2 + u_t$$

$$u_t = a_1 u_{t-1} + a_2 u_{t-2} + \ldots + a_p u_{t-p} + \epsilon_t$$

The autoregressive parameters included in the model for each series are selected by a stepwise regression procedure, so that autoregressive parameters are only included at those lags at which they are statistically significant.

The stepwise autoregressive method is fully automatic and, unlike the exponential smoothing and Winters methods, does not depend on choosing smoothing weights. However, the STEPAR method assumes that the long-term trend is stable; that is, the time trend regression is fit to the whole series with equal weights for the observations.

The stepwise autoregressive model is used when you specify the METHOD=STEPAR option or do not specify any METHOD= option. To select a constant, linear, or quadratic trend for the time-trend part of the model, use the TREND= option.

Syntax

The following statements are used with PROC FORECAST:

```
PROC FORECAST options;
   BY variables;
   ID variables;
   VAR variables;
```

Functional Summary

The statements and options controlling the FORECAST procedure are summarized in the following table:

Description	Statement	Option
Statements		
specify BY-group processing	BY	
identify observations	ID	
specify the variables to forecast	VAR	
Input Data Set Options		
specify the input SAS data set	PROC FORECAST	DATA=
specify frequency of the input time series	PROC FORECAST	INTERVAL=
specify increment between observations	PROC FORECAST	INTPER=
specify seasonality	PROC FORECAST	SEASONS=
specify number of periods in a season	PROC FORECAST	SINTPER=
treat zeros at beginning of series as missing	PROC FORECAST	ZEROMISS
Output Data Set Options		
specify the number of periods ahead to forecast	PROC FORECAST	LEAD=

Description	**Statement**	**Option**
name output data set containing the forecasts	PROC FORECAST	OUT=
write actual values to the OUT= data set	PROC FORECAST	OUTACTUAL
write confidence limits to the OUT= data set	PROC FORECAST	OUTLIMIT
write residuals to the OUT= data set	PROC FORECAST	OUTRESID
write standard errors of the forecasts to the OUT= data set	PROC FORECAST	OUTSTD
write one-step-ahead predicted values to the OUT= data set	PROC FORECAST	OUT1STEP
write predicted, actual, and confidence limit values to the OUT= data set	PROC FORECAST	OUTFULL
write all available results to the OUT= data set	PROC FORECAST	OUTALL
specify significance level for confidence limits	PROC FORECAST	ALPHA=
control the alignment of SAS Date values	PROC FORECAST	ALIGN=
Parameters and Statistics Output Data Set Options		
write parameter estimates and goodness-of-fit statistics to an output data set	PROC FORECAST	OUTEST=
write additional statistics to OUTEST= data set	PROC FORECAST	OUTESTALL
write Theil statistics to OUTEST= data set	PROC FORECAST	OUTESTTHEIL
write forecast accuracy statistics to OUTEST= data set	PROC FORECAST	OUTFITSTATS
Forecasting Method Options		
specify the forecasting method	PROC FORECAST	METHOD=
specify degree of the time trend model	PROC FORECAST	TREND=
specify smoothing weights	PROC FORECAST	WEIGHT=
specify order of the autoregressive model	PROC FORECAST	AR=
specify significance level for adding AR lags	PROC FORECAST	SLENTRY=
specify significance level for keeping AR lags	PROC FORECAST	SLSTAY=
start forecasting before the end of data	PROC FORECAST	START=
specify criterion for judging singularity	PROC FORECAST	SINGULAR=
Initializing Smoothed Values		
specify number of beginning values to use in calculating starting values	PROC FORECAST	NSTART=
specify number of beginning values to use in calculating initial seasonal parameters	PROC FORECAST	NSSTART=
specify starting values for constant term	PROC FORECAST	ASTART=
specify starting values for linear trend	PROC FORECAST	BSTART=
specify starting values for the quadratic trend	PROC FORECAST	CSTART=

PROC FORECAST Statement

PROC FORECAST *options;*

The following options can be specified in the PROC FORECAST statement:

ALIGN= *option*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

ALPHA= *value*
specifies the significance level to use in computing the confidence limits of the forecast. The value of the ALPHA= option must be between .01 and .99. You should use only two digits for the ALPHA= option because PROC FORECAST rounds the value to the nearest percent (ALPHA=.101 is the same as ALPHA=.10). The default is ALPHA=.05, which produces 95% confidence limits.

AR= *n*
NLAGS= *n*
specifies the maximum order of the autoregressive model. The AR= option is only valid for METHOD=STEPAR. The default value of *n* depends on the INTERVAL= option and on the number of observations in the DATA= data set. See "STEPAR Method" later in this chapter for details.

ASTART= *value*
ASTART= *(value ...)*
specifies starting values for the constant term for the exponential smoothing, Winters, and additive Winters methods. This option is ignored if METHOD=STEPAR. See "Starting Values for EXPO, WINTERS, and ADDWINTERS Methods" later in this chapter for details.

BSTART= *value*
BSTART= *(value ...)*
specifies starting values for the linear trend for the exponential smoothing, Winters, and additive Winters methods. This option is ignored if METHOD=STEPAR or TREND=1. See "Starting Values for EXPO, WINTERS, and ADDWINTERS Methods" later in this chapter for details.

CSTART= *value*
CSTART= *(value ...)*
specifies starting values for the quadratic trend for the exponential smoothing, Winters, and additive Winters methods. This option is ignored if METHOD=STEPAR or TREND=1 or 2. See "Starting Values for EXPO, WINTERS, and ADDWINTERS Methods" later in this chapter for details.

DATA= *SAS-data-set*
names the SAS data set containing the input time series for the procedure to forecast. If the DATA= option is not specified, the most recently created SAS data set is used.

INTERVAL= *interval*

specifies the frequency of the input time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. See Chapter 3, “Date Intervals, Formats, and Functions,” for more details on the intervals available.

INTPER= *n*

when the INTERVAL= option is not used, INTPER= specifies an increment (other than 1) to use in generating the values of the ID variable for the forecast observations in the output data set.

LEAD= *n*

specifies the number of periods ahead to forecast. The default is LEAD=12.

The LEAD= value is relative to the last observation in the input data set and not to the end of a particular series. Thus, if a series has missing values at the end, the actual number of forecasts computed for that series will be greater than the LEAD= value.

MAXERRORS= *n*

limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50.

This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

METHOD= *method-name*

specifies the method to use to model the series and generate the forecasts.

METHOD=STEPAR specifies the stepwise autoregressive method.

METHOD=EXPO specifies the exponential smoothing method.

METHOD=WINTERS specifies the Holt-Winters exponentially smoothed trend-seasonal method.

METHOD=ADDWINTERS specifies the additive seasonal factors variant of the Winters method.

For more information, see the section "Forecasting Methods" later in this chapter. The default is METHOD=STEPAR.

NSTART= *n*
NSTART= MAX

specifies the number of beginning values of the series to use in calculating starting values for the trend parameters in the exponential smoothing, Winters, and additive Winters methods. This option is ignored if METHOD=STEPAR.

For METHOD=EXPO, *n* beginning values of the series are used in forming the exponentially smoothed values S1, S2, and S3, where *n* is the value of the NSTART= option. The parameters are initialized by fitting a time trend regression to the first *n* nonmissing values of the series.

For METHOD=WINTERS or METHOD=ADDWINTERS, *n* beginning complete seasonal cycles are used to compute starting values for the trend parameters. For example, for monthly data the seasonal cycle is one year, and NSTART=2 specifies that the first 24 observations at the beginning of each series are used for the time trend regression used to calculate starting values.

When NSTART=MAX is specified, all the observations are used. The default for METHOD=EXPO is NSTART=8; the default for METHOD=WINTERS or METHOD=ADDWINTERS is NSTART=2. See "Starting Values for EXPO, WINTERS, and ADDWINTERS Methods" later in this chapter for details.

NSSTART= *n*
NSSTART= MAX

specifies the number of beginning values of the series to use in calculating starting values for seasonal parameters for METHOD=WINTERS or METHOD=ADDWINTERS. The seasonal parameters are initialized by averaging over the first *n* values of the series for each season, where *n* is the value of the NSSTART= option. When NSSTART=MAX is specified, all the observations are used.

If NSTART= is specified, but NSSTART= is not, NSSTART= defaults to the value specified for NSTART=. If neither NSTART= nor NSSTART= is specified, then the default is NSSTART=2. This option is ignored if METHOD=STEPAR or METHOD=EXPO. See "Starting Values for EXPO, WINTERS, and ADDWINTERS Methods" later in this chapter for details.

OUT= *SAS-data-set*

names the output data set to contain the forecasts. If the OUT= option is not specified, the data set is named using the DATA*n* convention. See "OUT= Data Set" later in this chapter for details.

OUTACTUAL

writes the actual values to the OUT= data set.

OUTALL

provides all the output control options (OUTLIMIT, OUT1STEP, OUTACTUAL, OUTRESID, and OUTSTD).

OUTEST= *SAS-data-set*

names an output data set to contain the parameter estimates and goodness-of-fit statistics. When the OUTEST= option is not specified, the parameters and goodness-of-fit statistics are not stored. See "OUTEST= Data Set" later in this chapter for details.

OUTESTALL

writes additional statistics to the OUTEST= data set. This option is the same as specifying both OUTESTTHEIL and OUTFITSTATS.

OUTESTTHEIL

writes Theil forecast accuracy statistics to the OUTEST= data set.

OUTFITSTATS

writes various R^2-type forecast accuracy statistics to the OUTEST= data set.

OUTFULL
provides OUTACTUAL, OUT1STEP, and OUTLIMIT output control options in addition to the forecast values.

OUTLIMIT
writes the forecast confidence limits to the OUT= data set.

OUTRESID
writes the residuals (when available) to the OUT= data set.

OUTSTD
writes the standard errors of the forecasts to the OUT= data set.

OUT1STEP
writes the one-step-ahead predicted values to the OUT= data set.

SEASONS= *interval*
SEASONS= (*interval1 [interval2 [interval3]]* **)**
SEASONS= *n*
SEASONS= (*n1 [n2 [n3]]* **)**
specifies the seasonality for seasonal models. The *interval* can be QTR, MONTH, DAY, or HOUR, or multiples of these (QTR2, MONTH2, MONTH3, MONTH4, MONTH6, HOUR2, HOUR3, HOUR4, HOUR6, HOUR8, HOUR12).

Alternatively, seasonality can be specified by giving the length of the seasonal cycles. For example, SEASONS=3 means that every group of three observations forms a seasonal cycle. The SEASONS= option is valid only for METHOD=WINTERS or METHOD=ADDWINTERS. See "Specifying Seasonality" later in this chapter for details.

SINGULAR= *value*
gives the criterion for judging singularity. The default depends on the precision of the computer that you run SAS programs on.

SINTPER= *m*
SINTPER= (*m1 [m2 [m3]]* **)**
specifies the number of periods to combine in forming a season. For example, SEASONS=3 SINTPER=2 specifies that each group of two observations forms a season and that the seasonal cycle repeats every six observations. The SINTPER= option is valid only when the SEASONS= option is used. See "Specifying Seasonality" later in this chapter for details.

SLENTRY= *value*
controls the significance levels for entry of autoregressive parameters in the STEPAR method. The value of the SLENTRY= option must be between 0 and 1. The default is SLENTRY=0.2. See "STEPAR Method" later in this chapter for details.

SLSTAY= *value*
controls the significance levels for removal of autoregressive parameters in the STEPAR method. The value of the SLSTAY= option must be between 0 and 1. The default is SLSTAY=0.05. See "STEPAR Method" later in this chapter for details.

START= *n*

uses the first *n* observations to fit the model and begins forecasting with the *n*+1 observation.

TREND= *n*

specifies the degree of the time trend model. The value of the TREND= option must be 1, 2, or 3. TREND=1 selects the constant trend model; TREND=2 selects the linear trend model; and TREND=3 selects the quadratic trend model. The default is TREND=2, except for METHOD=EXPO, for which the default is TREND=3.

WEIGHT= *w*

WEIGHT= (*w1 [w2 [w3]]* **)**

specifies the smoothing weights for the EXPO, WINTERS, and ADDWINTERS methods. For the EXPO method, only one weight can be specified. For the WINTERS or ADDWINTERS method, *w1* gives the weight for updating the constant component, *w2* gives the weight for updating the linear and quadratic trend components, and *w3* gives the weight for updating the seasonal component. The *w2* and *w3* values are optional. Each value in the WEIGHT= option must be between 0 and 1. For default values, see "EXPO Method" and "WINTERS Method" later in this chapter.

ZEROMISS

treats zeros at the beginning of a series as missing values. For example, a product may be introduced at a date after the date of the first observation in the data set, and the sales variable for the product may be recorded as zero for the observations prior to the introduction date. The ZEROMISS option says to treat these initial zeros as missing values.

BY Statement

BY *variables;*

A BY statement can be used with PROC FORECAST to obtain separate analyses on observations in groups defined by the BY variables.

ID Statement

ID *variables;*

The first variable listed in the ID statement identifies observations in the input and output data sets. Usually, the first ID variable is a SAS date or datetime variable. Its values are interpreted and extrapolated according to the values of the INTERVAL= option. See "Data Periodicity and Time Intervals" later in this chapter for details.

If more than one ID variable is specified in the ID statement, only the first is used to identify the observations; the rest are just copied to the OUT= data set and will have missing values for forecast observations.

VAR Statement

VAR *variables;*

The VAR statement specifies the variables in the input data set that you want to forecast. If no VAR statement is specified, the procedure forecasts all numeric variables except the ID and BY variables.

Details

Missing Values

The treatment of missing values varies by method. For METHOD=STEPAR, missing values are tolerated in the series; the autocorrelations are estimated from the available data and tapered, if necessary. For the EXPO, WINTERS, and ADDWINTERS methods, missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted values are applied to the smoothing equations. For the WINTERS method, negative or zero values are treated as missing.

Data Periodicity and Time Intervals

The INTERVAL= option is used to establish the frequency of the time series. For example, INTERVAL=MONTH specifies that each observation in the input data set represents one month. If INTERVAL=MONTH2, each observation represents two months. Thus, there is a two-month time interval between each pair of successive observations, and the data frequency is bimonthly.

See Chapter 3, “Date Intervals, Formats, and Functions,” for details on the interval values supported.

The INTERVAL= option is used together with the ID statement to fully describe the observations that make up the time series. The first variable specified in the ID statement is used to identify the observations. Usually, SAS date or datetime values are used for this variable. PROC FORECAST uses the ID variable in the following ways:

- to validate the data periodicity. When the INTERVAL= option is specified, the ID variable is used to check the data and verify that successive observations have valid ID values corresponding to successive time intervals. When the INTERVAL= option is not used, PROC FORECAST verifies that the ID values are nonmissing and in ascending order. A warning message is printed when an invalid ID value is found in the input data set.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for January 1970 is followed by an observation for April 1970, there is a gap in the input data, with two observations omitted. When a gap in the input data is found, a warning message is printed, and PROC FORECAST processes missing values for each omitted input observation.

- to label the forecast observations in the output data set. The values of the ID variable for the forecast observations after the end of the input data set are extrapolated according to the frequency specifications of the INTERVAL= option. If the INTERVAL= option is not specified, the ID variable is extrapolated by incrementing the ID variable value for the last observation in the input data set by the INTPER= value, if specified, or by one.

The ALIGN= option controls the alignment of SAS dates. See Chapter 3, "Date Intervals, Formats, and Functions," for more information.

Forecasting Methods

This section explains the forecasting methods used by PROC FORECAST.

STEPAR Method

In the STEPAR method, PROC FORECAST first fits a time trend model to the series and takes the difference between each value and the estimated trend. (This process is called *detrending*.) Then, the remaining variation is fit using an autoregressive model.

The STEPAR method fits the autoregressive process to the residuals of the trend model using a backwards-stepping method to select parameters. Since the trend and autoregressive parameters are fit in sequence rather than simultaneously, the parameter estimates are not optimal in a statistical sense; however, the estimates are usually close to optimal, and the method is computationally inexpensive.

The STEPAR Algorithm

The STEPAR method consists of the following computational steps:

1. Fit the trend model as specified by the TREND= option using ordinary least-squares regression. This step detrends the data. The default trend model for the STEPAR method is TREND=2, a linear trend model.
2. Take the residuals from step 1 and compute the autocovariances to the number of lags specified by the NLAGS= option.
3. Regress the current values against the lags, using the autocovariances from step 2 in a Yule-Walker framework. Do not bring in any autoregressive parameter that is not significant at the level specified by the SLENTRY= option. (The default is SLENTRY=0.20.) Do not bring in any autoregressive parameter which results in a nonpositive-definite Toeplitz matrix.
4. Find the autoregressive parameter that is least significant. If the significance level is greater than the SLSTAY= value, remove the parameter from the model. (The default is SLSTAY=0.05.) Continue this process until only significant autoregressive parameters remain. If the OUTEST= option is specified, write the estimates to the OUTEST= data set.
5. Generate the forecasts using the estimated model and output to the OUT= data set. Form the confidence limits by combining the trend variances with the autoregressive variances.

Missing values are tolerated in the series; the autocorrelations are estimated from the available data and tapered if necessary.

This method requires at least three passes through the data: two passes to fit the model and a third pass to initialize the autoregressive process and write to the output data set.

Default Value of the NLAGS= Option

If the NLAGS= option is not specified, the default value of the NLAGS= option is chosen based on the data frequency specified by the INTERVAL= option and on the number of observations in the input data set, if this can be determined in advance. (PROC FORECAST cannot determine the number of input observations before reading the data when a BY statement or a WHERE statement is used or if the data are from a tape format SAS data set or external database. The NLAGS= value must be fixed before the data are processed.)

If the INTERVAL= option is specified, the default NLAGS= value includes lags for up to three years plus one, subject to the maximum of 13 lags or one third of the number of observations in your data set, whichever is less. If the number of observations in the input data set cannot be determined, the maximum NLAGS= default value is 13. If the INTERVAL= option is not specified, the default is NLAGS=13 or one-third the number of input observations, whichever is less.

If the Toeplitz matrix formed by the autocovariance matrix at a given step is not positive definite, the maximal number of autoregressive lags is reduced.

For example, for INTERVAL=QTR, the default is NLAGS=13 (that is, $4{\times}3+1$) provided that there are at least 39 observations. The NLAGS= option default is always at least 3.

EXPO Method

Exponential smoothing is used when the METHOD=EXPO option is specified. The term *exponential smoothing* is derived from the computational scheme developed by Brown and others (Brown and Meyers 1961; Brown 1962). Estimates are computed with updating formulas that are developed across time series in a manner similar to smoothing.

The EXPO method fits a trend model such that the most recent data are weighted more heavily than data in the early part of the series. The weight of an observation is a geometric (exponential) function of the number of periods that the observation extends into the past relative to the current period. The weight function is

$$w_\tau = \omega(1-\omega)^{t-\tau}$$

where τ is the observation number of the past observation, *t* is the current observation number, and ω is the weighting constant specified with the WEIGHT= option.

You specify the model with the TREND= option as follows:

- TREND=1 specifies single exponential smoothing (a constant model)

- TREND=2 specifies double exponential smoothing (a linear trend model)
- TREND=3 specifies triple exponential smoothing (a quadratic trend model)

Updating Equations

The single exponential smoothing operation is expressed by the formula

$$S_t = \omega x_t + (1 - \omega)S_{t-1}$$

where S_t is the smoothed value at the current period, *t* is the time index of the current period, and x_t is the current actual value of the series. The smoothed value S_t is the forecast of x_{t+1} and is calculated as the smoothing constant ω times the value of the series, x_t, in the current period plus $(1 - \omega)$ times the previous smoothed value S_{t-1}, which is the forecast of x_t computed at time $t - 1$.

Double and triple exponential smoothing are derived by applying exponential smoothing to the smoothed series, obtaining smoothed values as follows:

$$S_t^{[2]} = \omega S_t + (1 - \omega)S_{t-1}^{[2]}$$

$$S_t^{[3]} = \omega S_t^{[2]} + (1 - \omega)S_{t-1}^{[3]}$$

Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted value is then applied to the smoothing equations.

The polynomial time trend parameters CONSTANT, LINEAR, and QUAD in the OUTEST= data set are computed from S_T, $S_T^{[2]}$, and $S_T^{[3]}$, the final smoothed values at observation *T*, the last observation used to fit the model. In the OUTEST= data set, the values of S_T, $S_T^{[2]}$, and $S_T^{[3]}$ are identified by _TYPE_=S1, _TYPE_=S2, and _TYPE_=S3, respectively.

Smoothing Weights

Exponential smoothing forecasts are forecasts for an integrated moving-average process; however, the weighting parameter is specified by the user rather than estimated from the data. Experience has shown that good values for the WEIGHT= option are between 0.05 and 0.3. As a general rule, smaller smoothing weights are appropriate for series with a slowly changing trend, while larger weights are appropriate for volatile series with a rapidly changing trend. If unspecified, the weight defaults to $(1 - .8^{1/trend})$, where *trend* is the value of the TREND= option. This produces defaults of WEIGHT=0.2 for TREND=1, WEIGHT=0.10557 for TREND=2, and WEIGHT=0.07168 for TREND=3.

Confidence Limits

The confidence limits for exponential smoothing forecasts are calculated as they would be for an exponentially weighted time-trend regression, using the simplifying assumption of an infinite number of observations. The variance estimate is computed using the mean square of the unweighted one-step-ahead forecast residuals.

More detailed descriptions of the forecast computations can be found in Montgomery and Johnson (1976) and Brown (1962).

Exponential Smoothing as an ARIMA Model

The traditional description of exponential smoothing given in the preceding section is standard in most books on forecasting, and so this traditional version is employed by PROC FORECAST.

However, the standard exponential smoothing model is, in fact, a special case of an ARIMA model (McKenzie 1984). Single exponential smoothing corresponds to an ARIMA(0,1,1) model; double exponential smoothing corresponds to an ARIMA(0,2,2) model; and triple exponential smoothing corresponds to an ARIMA(0,3,3) model.

The traditional exponential smoothing calculations can be viewed as a simple and computationally inexpensive method of forecasting the equivalent ARIMA model. The exponential smoothing technique was developed in the 1960s before computers were widely available and before ARIMA modeling methods were developed.

If you use exponential smoothing as a forecasting method, you might consider using the ARIMA procedure to forecast the equivalent ARIMA model as an alternative to the traditional version of exponential smoothing used by PROC FORECAST. The advantages of the ARIMA form are:

- The optimal smoothing weight is automatically computed as the estimate of the moving average parameter of the ARIMA model.
- For double exponential smoothing, the optimal pair of two smoothing weights are computed. For triple exponential smoothing, the optimal three smoothing weights are computed by the ARIMA method. Most implementations of the traditional exponential smoothing method (including PROC FORECAST) use the same smoothing weight for each stage of smoothing.
- The problem of setting the starting smoothed value is automatically handled by the ARIMA method. This is done in a statistically optimal way when the maximum likelihood method is used.
- The statistical estimates of the forecast confidence limits have a sounder theoretical basis.

See Chapter 11, "The ARIMA Procedure," for information on forecasting with ARIMA models.

The Time Series Forecasting System provides for exponential smoothing models and allows you to either specify or optimize the smoothing weights. See Chapter 34, "Getting Started with Time Series Forecasting," for details.

WINTERS Method

The WINTERS method uses updating equations similar to exponential smoothing to fit parameters for the model

$$x_t = (a + bt)s(t) + \epsilon_t$$

where *a* and *b* are the trend parameters, and the function *s*(*t*) selects the seasonal parameter for the season corresponding to time *t*.

The WINTERS method assumes that the series values are positive. If negative or zero values are found in the series, a warning is printed and the values are treated as missing.

The preceding standard WINTERS model uses a linear trend. However, PROC FORECAST can also fit a version of the WINTERS method that uses a quadratic trend. When TREND=3 is specified for METHOD=WINTERS, PROC FORECAST fits the following model:

$$x_t = (a + bt + ct^2)s(t) + \epsilon_t$$

The quadratic trend version of the Winters method is often unstable, and its use is not recommended.

When TREND=1 is specified, the following constant trend version is fit:

$$x_t = as(t) + \epsilon_t$$

The default for the WINTERS method is TREND=2, which produces the standard linear trend model.

Seasonal Factors

The notation *s*(*t*) represents the selection of the seasonal factor used for different time periods. For example, if INTERVAL=DAY and SEASONS=MONTH, there are 12 seasonal factors, one for each month in the year, and the time index *t* is measured in days. For any observation, *t* is determined by the ID variable and *s*(*t*) selects the seasonal factor for the month that *t* falls in. For example, if *t* is 9 February 1993 then *s*(*t*) is the seasonal parameter for February.

When there are multiple seasons specified, *s*(*t*) is the product of the parameters for the seasons. For example, if SEASONS=(MONTH DAY), then *s*(*t*) is the product of the seasonal parameter for the month corresponding to the period *t*, and the seasonal parameter for the day of the week corresponding to period *t*. When the SEASONS= option is not specified, the seasonal factors *s*(*t*) are not included in the model. See the section "Specifying Seasonality" later in this chapter for more information on specifying multiple seasonal factors.

Updating Equations

This section shows the updating equations for the Winters method. In the following formula, x_t is the actual value of the series at time *t*; a_t is the smoothed value of the series at time *t*; b_t is the smoothed trend at time *t*; c_t is the smoothed quadratic trend at time *t*; $s_{t-1}(t)$ selects the old value of the seasonal factor corresponding to time *t* before the seasonal factors are updated.

The estimates of the constant, linear, and quadratic trend parameters are updated using the following equations:

For TREND=3,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1-\omega_1)(a_{t-1} + b_{t-1} + c_{t-1})$$

$$b_t = \omega_2(a_t - a_{t-1} + c_{t-1}) + (1-\omega_2)(b_{t-1} + 2c_{t-1})$$

$$c_t = \omega_2 \frac{1}{2}(b_t - b_{t-1}) + (1-\omega_2)c_{t-1}$$

For TREND=2,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1-\omega_1)(a_{t-1} + b_{t-1})$$

$$b_t = \omega_2(a_t - a_{t-1}) + (1-\omega_2)b_{t-1}$$

For TREND=1,

$$a_t = \omega_1 \frac{x_t}{s_{t-1}(t)} + (1-\omega_1)a_{t-1}$$

In this updating system, the trend polynomial is always centered at the current period so that the intercept parameter of the trend polynomial for predicted values at times after *t* is always the updated intercept parameter a_t. The predicted value for τ periods ahead is

$$x_{t+\tau} = (a_t + b_t\tau)s_t(t+\tau)$$

The seasonal parameters are updated when the season changes in the data, using the mean of the ratios of the actual to the predicted values for the season. For example, if SEASONS=MONTH and INTERVAL=DAY, then when the observation for the first of February is encountered, the seasonal parameter for January is updated using the formula

$$s_t(t-1) = \omega_3 \frac{1}{31} \sum_{i=t-31}^{t-1} \frac{x_i}{a_i} + (1-\omega_3)s_{t-1}(t-1)$$

where *t* is February 1 of the current year, $s_t(t-1)$ is the seasonal parameter for January updated with the data available at time *t*, and $s_{t-1}(t-1)$ is the seasonal parameter for January of the previous year.

When multiple seasons are used, $s_t(t)$ is a product of seasonal factors. For example, if SEASONS=(MONTH DAY) then $s_t(t)$ is the product of the seasonal factors for the month and for the day of the week: $s_t(t) = s_t^m(t)s_t^d(t)$.

The factor $s_t^m(t)$ is updated at the start of each month using a modification of the preceding formula that adjusts for the presence of the other seasonal by dividing the summands $\frac{x_i}{a_i}$ by the corresponding day of the week effect $s_i^d(i)$.

Similarly, the factor $s_t^d(t)$ is updated using the following formula:

$$s_t^d(t) = \omega_3 \frac{x_t}{a_t s_t^m(t)} + (1 - \omega_3) s_{t-1}^d(t)$$

where $s_{t-1}^d(t)$ is the seasonal factor for the same day of the previous week.

Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted value is substituted for x_i and applied to the updating equations.

Normalization

The parameters are normalized so that the seasonal factors for each cycle have a mean of 1.0. This normalization is performed after each complete cycle and at the end of the data. Thus, if INTERVAL=MONTH and SEASONS=MONTH are specified, and a series begins with a July value, then the seasonal factors for the series are normalized at each observation for July and at the last observation in the data set. The normalization is performed by dividing each of the seasonal parameters, and multiplying each of the trend parameters, by the mean of the unnormalized seasonal parameters.

Smoothing Weights

The weight for updating the seasonal factors, ω_3, is given by the third value specified in the WEIGHT= option. If the WEIGHT= option is not used, then ω_3 defaults to 0.25; if the WEIGHT= option is used but does not specify a third value, then ω_3 defaults to ω_2. The weight for updating the linear and quadratic trend parameters, ω_2, is given by the second value specified in the WEIGHT= option; if the WEIGHT= option does not specify a second value, then ω_2 defaults to ω_1. The updating weight for the constant parameter, ω_1, is given by the first value specified in the WEIGHT= option. As a general rule, smaller smoothing weights are appropriate for series with a slowly changing trend, while larger weights are appropriate for volatile series with a rapidly changing trend.

If the WEIGHT= option is not used, then ω_1 defaults to $(1 - .8^{1/trend})$, where *trend* is the value of the TREND= option. This produces defaults of WEIGHT=0.2 for TREND=1, WEIGHT=0.10557 for TREND=2, and WEIGHT=0.07168 for TREND=3.

The Time Series Forecasting System provides for generating forecast models using Winters Method and allows you to specify or optimize the weights. See Chapter 34, "Getting Started with Time Series Forecasting," for details.

Confidence Limits

A method for calculating exact forecast confidence limits for the WINTERS method is not available. Therefore, the approach taken in PROC FORECAST is to assume that the true seasonal factors have small variability about a set of fixed seasonal factors and that the remaining variation of the series is small relative to the mean level of the series. The equations are written

$$s_t(t) = \mathrm{I(t)}(1 + \delta_{\mathrm{t}})$$

$$x_t = \mu \mathrm{I(t)}(1 + \gamma_{\mathrm{t}})$$

$$a_t = \xi(1 + \alpha_t)$$

where μ is the mean level and I(*t*) are the fixed seasonal factors. Assuming that α_t and δ_t are small, the forecast equations can be linearized and only first-order terms in δ_t and α_t kept. In terms of forecasts for γ_t, this linearized system is equivalent to a seasonal ARIMA model. Confidence limits for γ_t are based on this ARIMA model and converted into confidence limits for x_t using $s_t(t)$ as estimates of I(*t*).

The exponential smoothing confidence limits are based on an approximation to a weighted regression model, whereas the preceding Winters confidence limits are based on an approximation to an ARIMA model. You can use METHOD=WINTERS without the SEASONS= option to do exponential smoothing and get confidence limits for the EXPO forecasts based on the ARIMA model approximation. These are generally more pessimistic than the weighted regression confidence limits produced by METHOD=EXPO.

ADDWINTERS Method

The ADDWINTERS method is like the WINTERS method except that the seasonal parameters are added to the trend instead of multiplied with the trend. The default TREND=2 model is as follows:

$$x_t = a + bt + s(t) + \epsilon_t$$

The WINTERS method for updating equation and confidence limits calculations described in the preceding section are modified accordingly for the additive version.

Holt Two-Parameter Exponential Smoothing

If the seasonal factors are omitted (that is, if the SEASONS= option is not specified), the WINTERS (and ADDWINTERS) method reduces to the Holt two-parameter version of exponential smoothing. Thus, the WINTERS method is often referred to as the Holt-Winters method.

Double exponential smoothing is a special case of the Holt two-parameter smoother. The double exponential smoothing results can be duplicated with METHOD=WINTERS by omitting the SEASONS= option and appropriately setting the WEIGHT= option. Letting $\alpha = \omega(2 - \omega)$ and $\beta = \omega/(2 - \omega)$, the following statements produce the same forecasts:

```
   proc forecast method=expo trend=2 weight=ω ...  ;
   proc forecast method=winters trend=2
                 weight=(α,β) ...  ;
```

Although the forecasts are the same, the confidence limits are computed differently.

Choice of Weights for EXPO, WINTERS, and ADDWINTERS Methods

For the EXPO, WINTERS, and ADDWINTERS methods, properly chosen smoothing weights are of critical importance in generating reasonable results. There are several factors to consider in choosing the weights.

The noisier the data, the lower should be the weight given to the most recent observation. Another factor to consider is how quickly the mean of the time series is changing. If the mean of the series is changing rapidly, relatively more weight should be given to the most recent observation. The more stable the series over time, the lower should be the weight given to the most recent observation.

Note that the smoothing weights should be set separately for each series; weights that produce good results for one series may be poor for another series. Since PROC FORECAST does not have a feature to use different weights for different series, when forecasting multiple series with the EXPO, WINTERS, or ADDWINTERS method it may be desirable to use different PROC FORECAST steps with different WEIGHT= options.

For the Winters method, many combinations of weight values may produce unstable *noninvertible* models, even though all three weights are between 0 and 1. When the model is noninvertible, the forecasts depend strongly on values in the distant past, and predictions are determined largely by the starting values. Unstable models usually produce poor forecasts. The Winters model may be unstable even if the weights are optimally chosen to minimize the in-sample MSE. Refer to Archibald (1990) for a detailed discussion of the unstable region of the parameter space of the Winters model.

Optimal weights and forecasts for exponential smoothing models can be computed using the ARIMA procedure. For more information, see "Exponential Smoothing as an ARIMA Model" earlier in this chapter.

The ARIMA procedure can also be used to compute optimal weights and forecasts for seasonal ARIMA models similar to the Winters type methods. In particular, an ARIMA(0,1,1)$\times$(0,1,1)S model may be a good alternative to the additive version of the Winters method. The ARIMA(0,1,1)$\times$(0,1,1)S model fit to the logarithms of the series may be a good alternative to the multiplicative Winters method. See Chapter 11, “The ARIMA Procedure,” for information on forecasting with ARIMA models.

The Time Series Forecasting System can be used to automatically select an appropriate smoothing method as well as to optimize the smoothing weights. See Chapter 34, “Getting Started with Time Series Forecasting,” for more information.

Starting Values for EXPO, WINTERS, and ADDWINTERS Methods

The exponential smoothing method requires starting values for the smoothed values S_0, $S_0^{[2]}$, and $S_0^{[3]}$. The Winters and additive Winters methods require starting values for the trend coefficients and seasonal factors.

By default, starting values for the trend parameters are computed by a time-trend regression over the first few observations for the series. Alternatively, you can specify the starting value for the trend parameters with the ASTART=, BSTART=, and CSTART= options.

The number of observations used in the time-trend regression for starting values depends on the NSTART= option. For METHOD=EXPO, NSTART= beginning values of the series are used, and the coefficients of the time-trend regression are then used to form the initial smoothed values S_0, $S_0^{[2]}$, and $S_0^{[3]}$.

For METHOD=WINTERS or METHOD=ADDWINTERS, *n* complete seasonal cycles are used to compute starting values for the trend parameter, where *n* is the value of the NSTART= option. For example, for monthly data the seasonal cycle is one year, so NSTART=2 specifies that the first 24 observations at the beginning of each series are used for the time trend regression used to calculate starting values.

The starting values for the seasonal factors for the WINTERS and ADDWINTERS methods are computed from seasonal averages over the first few complete seasonal cycles at the beginning of the series. The number of seasonal cycles averaged to compute starting seasonal factors is controlled by the NSSTART= option. For example, for monthly data with SEASONS=12 or SEASONS=MONTH, the first *n* January values are averaged to get the starting value for the January seasonal parameter, where *n* is the value of the NSSTART= option.

The $s_0(i)$ seasonal parameters are set to the ratio (for WINTERS) or difference (for ADDWINTERS) of the mean for the season to the overall mean for the observations used to compute seasonal starting values.

For example, if METHOD=WINTERS, INTERVAL=DAY, SEASON=(MONTH DAY), and NSTART=2 (the default), the initial seasonal parameter for January is the ratio of the mean value over days in the first two Januarys after the start of the series (that is, after the first nonmissing value), to the mean value for all days read for initialization of the seasonal factors. Likewise, the initial factor for Sundays is the ratio of the mean value for Sundays to the mean of all days read.

For the ASTART=, BSTART=, and CSTART= options, the values specified are associated with the variables in the VAR statement in the order in which the variables are listed (the first value with the first variable, the second value with the second variable, and so on). If there are fewer values than variables, default starting values are used for the later variables. If there are more values than variables, the extra values are ignored.

Specifying Seasonality

Seasonality of a time series is a regular fluctuation about a trend. This is called seasonality because the time of year is the most common source of periodic variation. For example, sales of home heating oil are regularly greater in winter than during other times of the year.

Seasonality can be caused by many things other than weather. In the United States, sales of nondurable goods are greater in December than in other months because of the Christmas shopping season. The term seasonality is also used for cyclical fluctuation at periods other than a year. Often, certain days of the week cause regular fluctuation in daily time series, such as increased spending on leisure activities during weekends.

Three kinds of seasonality are supported in PROC FORECAST: time-of-year, day-of-week, and time-of-day. The seasonal part of the model is specified using the SEASONS= option. The values for the SEASONS= option are listed in Table 17.1.

Table 17.1. The SEASONS= Option

SEASONS= Value	Cycle Length	Type of Seasonality
QTR	yearly	time of year
MONTH	yearly	time of year
DAY	weekly	day of week
HOUR	daily	time of day

The three kinds of seasonality can be combined. For example, SEASONS=(MONTH DAY HOUR) specifies that 24 hour-of-day seasons are nested within 7 day-of-week seasons, which in turn are nested within 12 month-of-year seasons. The different kinds of intervals can be listed in the SEASONS= option in any order. Thus, SEASONS=(HOUR DAY MONTH) is the same as SEASONS=(MONTH DAY HOUR). Note that the Winters method smoothing equations may be less stable when multiple seasonal factors are used.

Multiple period seasons can also be used. For example, SEASONS=QTR2 specifies two semiannual time-of-year seasons. The grouping of observations into multiple period seasons starts with the first interval in the seasonal cycle. Thus, MONTH2 seasons are January-February, March-April, and so on. (There is no provision for shifting seasonal intervals; thus, there is no way to specify December-January, February-March, April-May, and so on seasons.)

For multiple period seasons, the number of intervals combined to form the seasons must evenly divide and be less than the basic cycle length. For example, with SEASONS=MONTH*n*, the basic cycle length is 12, so MONTH2, MONTH3, MONTH4, and MONTH6 are valid SEASONS= values (since 2, 3, 4, and 6 evenly divide 12 and are less than 12), but MONTH5 and MONTH12 are not valid SEASONS= values.

The frequency of the seasons must not be greater than the frequency of the input data. For example, you cannot specify SEASONS=MONTH if INTERVAL=QTR or SEASONS=MONTH if INTERVAL=MONTH2. You also cannot specify two seasons of the same basic cycle. For example, SEASONS=(MONTH QTR) or SEASONS=(MONTH2 MONTH4) is not allowed.

Alternatively, the seasonality can be specified by giving the number of seasons in the SEASONS= option. SEASONS=*n* specifies that there are *n* seasons, with observations 1, *n*+1, 2*n*+1, and so on in the first season, observations 2, *n*+2, 2*n*+2, and so on in the second season, and so forth.

The options SEASONS=*n* and SINTPER=*m* cause PROC FORECAST to group the input observations into *n* seasons, with *m* observations to a season, which repeat every

nm observations. The options SEASONS=(n_1 n_2) and SINTPER=(m_1 m_2) produce n_1 seasons with m_1 observations to a season nested within n_2 seasons with $n_1 m_1 m_2$ observations to a season.

If the SINTPER=m option is used with the SEASONS= option, the SEASONS= interval is multiplied by the SINTPER= value. For example, specifying both SEASONS=(QTR HOUR) and SINTPER=(2 3) is the same as specifying SEASONS=(QTR2 HOUR3) and also the same as specifying SEASONS=(HOUR3 QTR2).

Data Requirements

You should have ample data for the series that you forecast using PROC FORECAST. However, the results may be poor unless you have a good deal more than the minimum amount of data the procedure allows. The minimum number of observations required for the different methods is as follows:

- If METHOD=STEPAR is used, the minimum number of nonmissing observations required for each series forecast is the TREND= option value plus the value of the NLAGS= option. For example, using NLAGS=13 and TREND=2, at least 15 nonmissing observations are needed.
- If METHOD=EXPO is used, the minimum is the TREND= option value.
- If METHOD=WINTERS or ADDWINTERS is used, the minimum number of observations is either the number of observations in a complete seasonal cycle or the TREND= option value, whichever is greater. (However, there should be data for several complete seasonal cycles, or the seasonal factor estimates may be poor.) For example, for the seasonal specifications SEASONS=MONTH, SEASONS=(QTR DAY), or SEASONS=(MONTH DAY HOUR), the longest cycle length is one year, so at least one year of data is required.

OUT= Data Set

The FORECAST procedure writes the forecast to the output data set named by the OUT= option. The OUT= data set contains the following variables:

- the BY variables
- _TYPE_, a character variable that identifies the type of observation
- _LEAD_, a numeric variable that indicates the number of steps ahead in the forecast. The value of _LEAD_ is 0 for the one-step-ahead forecasts before the start of the forecast period.
- the ID statement variables
- the VAR statement variables, which contain the result values as indicated by the _TYPE_ variable value for the observation

The FORECAST procedure processes each of the input variables listed in the VAR statement and writes several observations for each forecast period to the OUT= data set. The observations are identified by the value of the _TYPE_ variable. The options OUTACTUAL, OUTALL, OUTLIMIT, OUTRESID, OUT1STEP, OUTFULL, and OUTSTD control which types of observations are included in the OUT= data set.

The values of the variable _TYPE_ are as follows:

ACTUAL	The VAR statement variables contain actual values from the input data set. The OUTACTUAL option writes the actual values. By default, only the observations for the forecast period are output.
FORECAST	The VAR statement variables contain forecast values. The OUT1STEP option writes the one-step-ahead predicted values for the observations used to fit the model.
RESIDUAL	The VAR statement variables contain residuals. The residuals are computed by subtracting the forecast value from the actual value ($residual = actual - forecast$). The OUTRESID option writes observations for the residuals.
L*nn*	The VAR statement variables contain lower *nn*% confidence limits for the forecast values. The value of *nn* depends on the ALPHA= option; with the default ALPHA=0.05, the _TYPE_ value is L95 for the lower confidence limit observations. The OUTLIMIT option writes observations for the upper and lower confidence limits.
U*nn*	The VAR statement variables contain upper *nn*% confidence limits for the forecast values. The value of *nn* depends on the ALPHA= option; with the default ALPHA=0.05, the _TYPE_ value is U95 for the upper confidence limit observations. The OUTLIMIT option writes observations for the upper and lower confidence limits.
STD	The VAR statement variables contain standard errors of the forecast values. The OUTSTD option writes observations for the standard errors of the forecast.

If no output control options are specified, PROC FORECAST outputs only the forecast values for the forecast periods.

The _TYPE_ variable can be used to subset the OUT= data set. For example, the following data step splits the OUT= data set into two data sets, one containing the forecast series and the other containing the residual series. For example

```
proc forecast out=out outresid ...;
   ...
run;

data fore resid;
   set out;
   if _TYPE_='FORECAST' then output fore;
   if _TYPE_='RESIDUAL' then output resid;
run;
```

See Chapter 2, “Working with Time Series Data,” for more information on processing time series data sets in this format.

OUTEST= Data Set

The FORECAST procedure writes the parameter estimates and goodness-of-fit statistics to an output data set when the OUTEST= option is specified. The OUTEST= data set contains the following variables:

- the BY variables
- the first ID variable, which contains the value of the ID variable for the last observation in the input data set used to fit the model
- _TYPE_, a character variable that identifies the type of each observation
- the VAR statement variables, which contain statistics and parameter estimates for the input series. The values contained in the VAR statement variables depend on the _TYPE_ variable value for the observation.

The observations contained in the OUTEST= data set are identified by the _TYPE_ variable. The OUTEST= data set may contain observations with the following _TYPE_ values:

AR1–AR*n*	The observation contains estimates of the autoregressive parameters for the series. Two-digit lag numbers are used if the value of the NLAGS= option is 10 or more; in that case these _TYPE_ values are AR01–AR*n*. These observations are output for the STEPAR method only.
CONSTANT	The observation contains the estimate of the constant or intercept parameter for the time-trend model for the series. For the exponential smoothing and the Winters’ methods, the trend model is centered (that is, t=0) at the last observation used for the fit.
LINEAR	The observation contains the estimate of the linear or slope parameter for the time-trend model for the series. This observation is output only if you specify TREND=2 or TREND=3.
N	The observation contains the number of nonmissing observations used to fit the model for the series.
QUAD	The observation contains the estimate of the quadratic parameter for the time-trend model for the series. This observation is output only if you specify TREND=3.
SIGMA	The observation contains the estimate of the standard deviation of the error term for the series.
S1–S3	The observations contain exponentially smoothed values at the last observation. _TYPE_=S1 is the final smoothed value of the single exponential smooth. _TYPE_=S2 is the final smoothed value of the double exponential smooth. _TYPE_=S3 is the final smoothed

	value of the triple exponential smooth. These observations are output for METHOD=EXPO only.
S_*name*	The observation contains estimates of the seasonal parameters. For example, if SEASONS=MONTH, the OUTEST= data set will contain observations with _TYPE_=S_JAN, _TYPE_=S_FEB, _TYPE_=S_MAR, and so forth. For multiple-period seasons, the names of the first and last interval of the season are concatenated to form the season name. Thus, for SEASONS=MONTH4, the OUTEST= data set will contain observations with _TYPE_=S_JANAPR, _TYPE_=S_MAYAUG, and _TYPE_=S_SEPDEC. When the SEASONS= option specifies numbers, the seasonal factors are labeled _TYPE_=S_*i*_*j*. For example, SEASONS=(2 3) produces observations with _TYPE_ values of S_1_1, S_1_2, S_2_1, S_2_2, and S_2_3. The observation with _TYPE_=S_*i*_*j* contains the seasonal parameters for the *j*th season of the *i*th seasonal cycle. These observations are output only for METHOD=WINTERS or METHOD=ADDWINTERS.
WEIGHT	The observation contains the smoothing weight used for exponential smoothing. This is the value of the WEIGHT= option. This observation is output for METHOD=EXPO only.
WEIGHT1	
WEIGHT2	
WEIGHT3	The observations contain the weights used for smoothing the WINTERS or ADDWINTERS method parameters (specified by the WEIGHT= option). _TYPE_=WEIGHT1 is the weight used to smooth the CONSTANT parameter. _TYPE_=WEIGHT2 is the weight used to smooth the LINEAR and QUAD parameters. _TYPE_=WEIGHT3 is the weight used to smooth the seasonal parameters. These observations are output only for the WINTERS and ADDWINTERS methods.
NRESID	The observation contains the number of nonmissing residuals, *n*, used to compute the goodness-of-fit statistics. The residuals are obtained by subtracting the one-step-ahead predicted values from the observed values.
SST	The observation contains the total sum of squares for the series, corrected for the mean. $SST = \sum_{t=0}^{n} (y_t - \overline{y})^2$, where $\overline{y}$ is the series mean.
SSE	The observation contains the sum of the squared residuals, uncorrected for the mean. $SSE = \sum_{t=0}^{n} (y_t - \hat{y}_t)^2$, where $\hat{y}$ is the one-step predicted value for the series.

MSE	The observation contains the mean squared error, calculated from one-step-ahead forecasts. $MSE = \frac{1}{n-k} SSE$, where *k* is the number of parameters in the model.
RMSE	The observation contains the root mean square error. $RMSE = \sqrt{MSE}$.
MAPE	The observation contains the mean absolute percent error. $MAPE = \frac{100}{n} \sum_{t=0}^{n} \lvert (y_t - \hat{y}_t)/y_t \rvert$.
MPE	The observation contains the mean percent error. $MPE = \frac{100}{n} \sum_{t=0}^{n} (y_t - \hat{y}_t)/y_t$.
MAE	The observation contains the mean absolute error. $MAE = \frac{1}{n} \sum_{t=0}^{n} \lvert y_t - \hat{y}_t \rvert$.
ME	The observation contains the mean error. $MAE = \frac{1}{n} \sum_{t=0}^{n} (y_t - \hat{y}_t)$.
MAXE	The observation contains the maximum error (the largest residual).
MINE	The observation contains the minimum error (the smallest residual).
MAXPE	The observation contains the maximum percent error.
MINPE	The observation contains the minimum percent error.
RSQUARE	The observation contains the R^2 statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares *SSE* may be larger than *SST* and the R^2 statistic will be negative.
ADJRSQ	The observation contains the adjusted R^2 statistic. $ADJRSQ = 1 - (\frac{n-1}{n-k})(1 - R^2)$.
ARSQ	The observation contains Amemiya's adjusted R^2 statistic. $ARSQ = 1 - (\frac{n+k}{n-k})(1 - R^2)$.
RW_RSQ	The observation contains the random walk R^2 statistic (Harvey's R_{D}^2 statistic using the random walk model for comparison). $RW\_RSQ = 1 - (\frac{n-1}{n}) SSE/RWSSE$, where $RWSSE = \sum_{t=2}^{n} (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^{n} (y_t - y_{t-1})$.
AIC	The observation contains Akaike's information criterion. $AIC = n\ln(SSE/n) + 2k$.
SBC	The observation contains Schwarz's Bayesian criterion. $SBC = n\ln(SSE/n) + k\ln(n)$.
APC	The observation contains Amemiya's prediction criterion. $APC = \frac{1}{n} SST(\frac{n+k}{n-k})(1 - R^2) = (\frac{n+k}{n-k})\frac{1}{n} SSE$.

CORR	The observation contains the correlation coefficient between the actual values and the one-step-ahead predicted values.
THEILU	The observation contains Theil's U statistic using original units. Refer to Maddala (1977, pp. 344-345), and Pindyck and Rubinfeld (1981, pp. 364-365) for more information on Theil statistics.
RTHEILU	The observation contains Theil's U statistic calculated using relative changes.
THEILUM	The observation contains the bias proportion of Theil's U statistic.
THEILUS	The observation contains the variance proportion of Theil's U statistic.
THEILUC	The observation contains the covariance proportion of Theil's U statistic.
THEILUR	The observation contains the regression proportion of Theil's U statistic.
THEILUD	The observation contains the disturbance proportion of Theil's U statistic.
RTHEILUM	The observation contains the bias proportion of Theil's U statistic, calculated using relative changes.
RTHEILUS	The observation contains the variance proportion of Theil's U statistic, calculated using relative changes.
RTHEILUC	The observation contains the covariance proportion of Theil's U statistic, calculated using relative changes.
RTHEILUR	The observation contains the regression proportion of Theil's U statistic, calculated using relative changes.
RTHEILUD	The observation contains the disturbance proportion of Theil's U statistic, calculated using relative changes.

Examples

Example 17.1. Forecasting Auto Sales

This example uses the Winters method to forecast the monthly U.S. sales of passenger cars series (VEHICLES) from the data set SASHELP.USECON. These data are taken from *Business Statistics*, published by the U.S. Bureau of Economic Analysis.

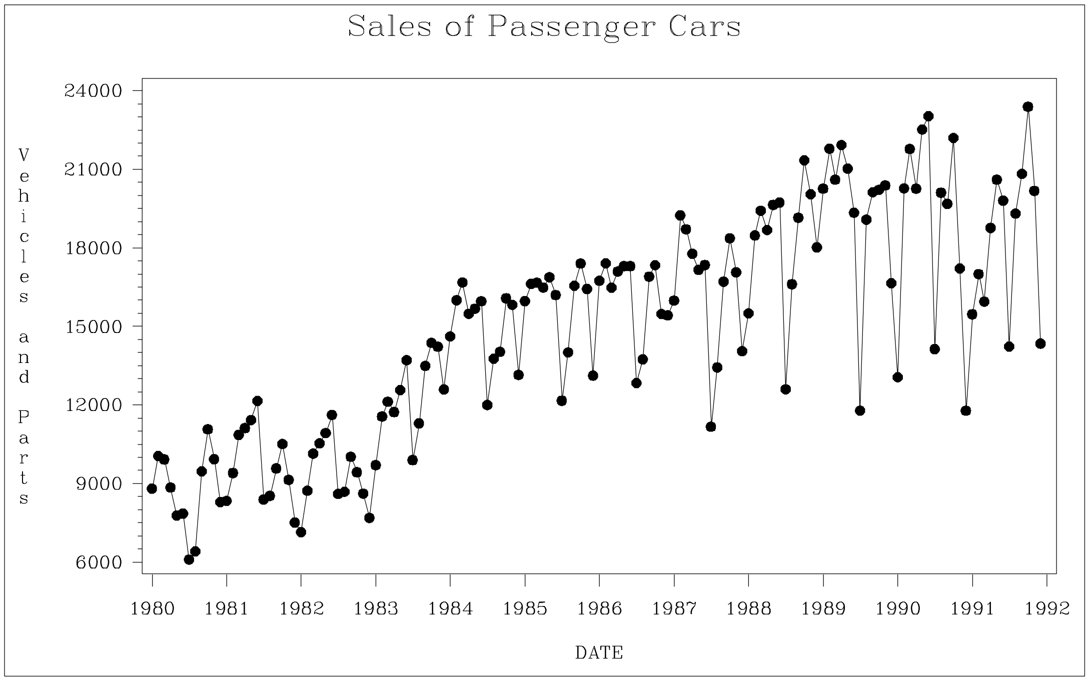
The following statements plot the series; the plot is shown in Output 17.1.1:

```
title1 "Sales of Passenger Cars";

symbol1 i=spline v=dot;
axis2 label=(a=-90 r=90 "Vehicles and Parts" )
      order=(6000 to 24000 by 3000) ;
proc gplot data=sashelp.usecon;
   plot vehicles * date = 1 /
```

```
          haxis= '1jan80'd to '1jan92'd by year
          vaxis=axis2;
     where date >= '1jan80'd;
     format date year4.;
  run;
```

Output 17.1.1. Monthly Passenger Car Sales



The following statements produce the forecast:

```
  proc forecast data=sashelp.usecon interval=month
                method=winters seasons=month lead=12
                out=out outfull outresid outest=est;
     id date;
     var vehicles;
     where date >= '1jan80'd;
  run;
```

The INTERVAL=MONTH option indicates that the data are monthly, and the ID DATE statement gives the dating variable. The METHOD=WINTERS specifies the Winters smoothing method. The LEAD=12 option forecasts 12 months ahead. The OUT=OUT option specifies the output data set, while the OUTFULL and OUTRESID options include in the OUT= data set the predicted and residual values for the historical period and the confidence limits for the forecast period. The OUTEST= option stores various statistics in an output data set. The WHERE statement is used to include only data from 1980 on.

The following statements print the OUT= data set:

```
title2 'The OUT= Data Set';
proc print data=out;
run;
```

The listing of the output data set produced by PROC PRINT is shown in part in Output 17.1.2.

Output 17.1.2. The OUT= Data Set Produced by PROC FORECAST

```
                        Sales of Passenger Cars
                           The OUT= Data Set

run;
```

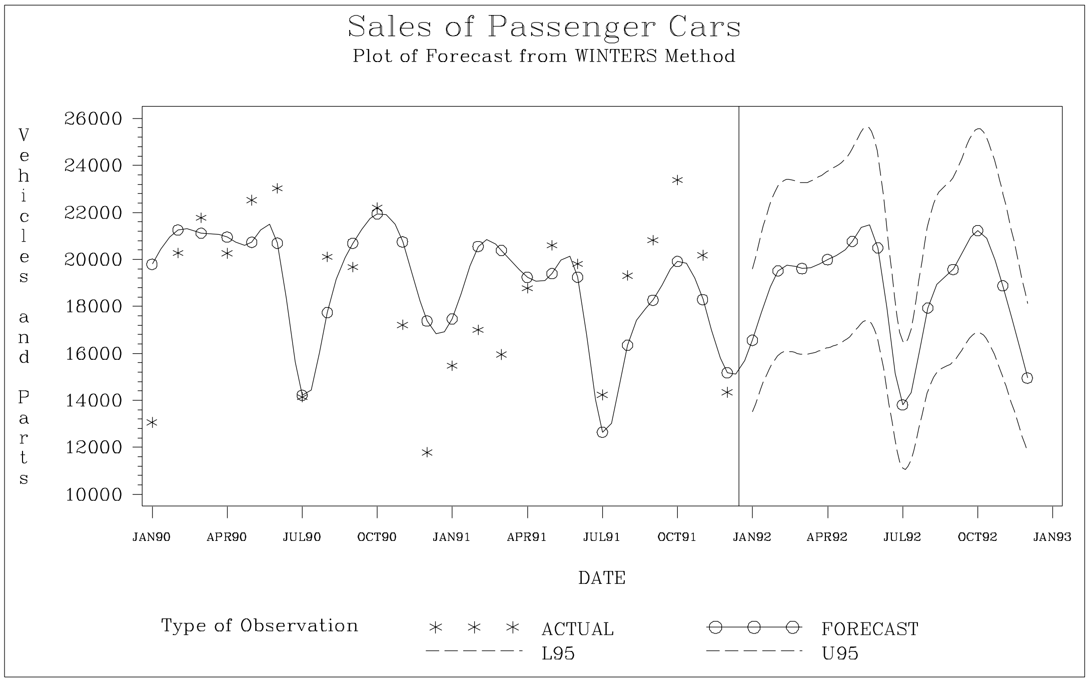
The plot is shown in Output 17.1.5.

Output 17.1.5. Forecast of Passenger Car Sales



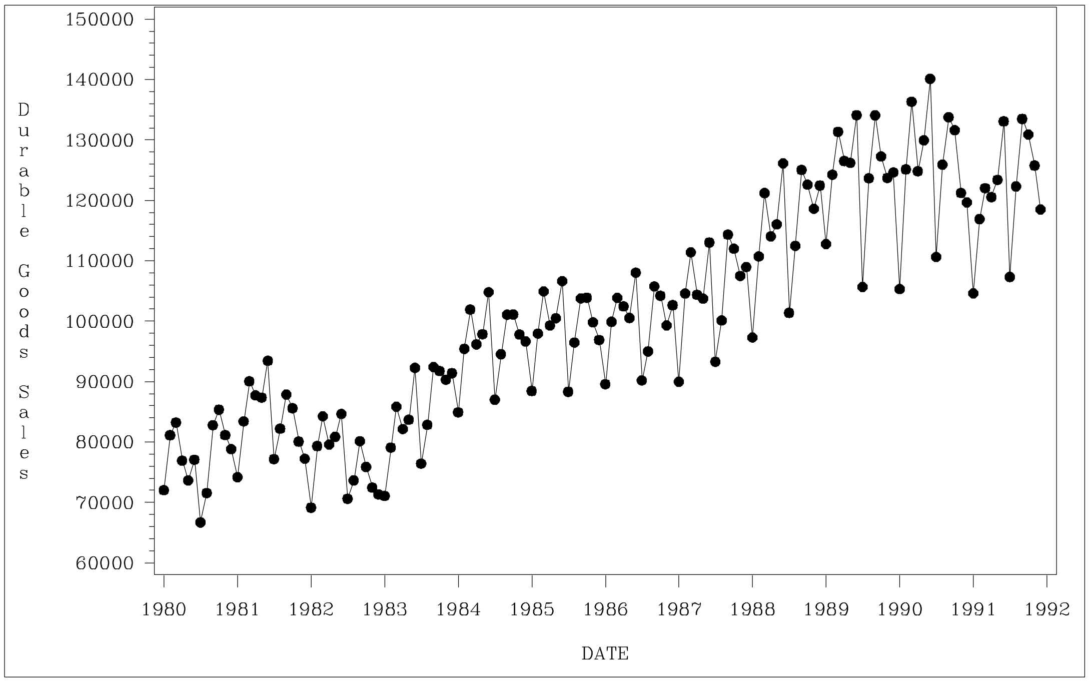
Example 17.2. Forecasting Retail Sales

This example uses the stepwise autoregressive method to forecast the monthly U.S. sales of durable goods (DURABLES) and nondurable goods (NONDUR) from the SASHELP.USECON data set. The data are from *Business Statistics* published by the U.S. Bureau of Economic Analysis. The following statements plot the series:

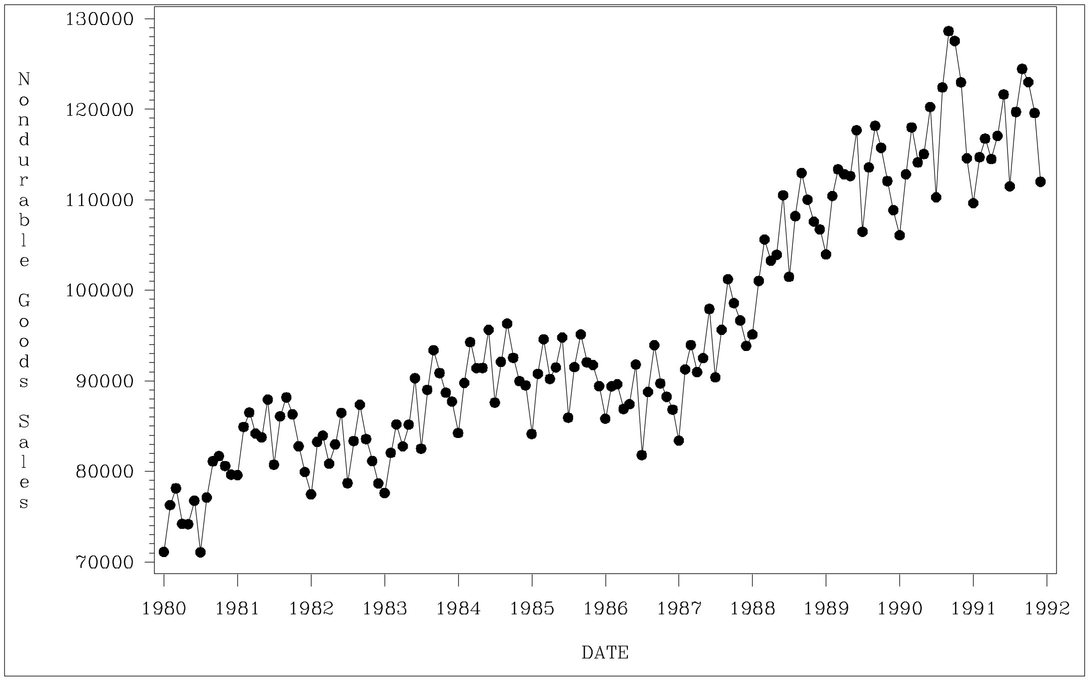
```
symbol1 i=spline v=dot;
proc gplot data=sashelp.usecon;
   plot ( durables nondur ) * date = 1 /
        haxis= '1jan80'd to '1jan92'd by year;
   where date >= '1jan80'd;
   format date year4.;
run;
```

The plots are shown in Output 17.2.1 and Output 17.2.2.

Output 17.2.1. Durable Goods Sales



Output 17.2.2. Nondurable Goods Sales



The following statements produce the forecast:

```
title1 "Forecasting Sales of Durable and Nondurable Goods";

proc forecast data=sashelp.usecon interval=month
              method=stepar trend=2 lead=12
              out=out outfull outest=est;
   id date;
   var durables nondur;
   where date >= '1jan80'd;
run;
```

The following statements print the OUTEST= data set.

```
title2 'OUTEST= Data Set: STEPAR Method';
proc print data=est;
run;
```

The PROC PRINT listing of the OUTEST= data set is shown in Output 17.2.3.

Output 17.2.3. The OUTEST= Data Set Produced by PROC FORECAST

```
                Forecasting Sales of Durable and Nondurable Goods

The LOAN Procedure

Chapter Contents

Chapter 18
The LOAN Procedure

Overview

The LOAN procedure analyzes and compares fixed rate, adjustable rate, buydown, and balloon payment loans. The LOAN procedure computes the loan parameters and outputs the loan summary information for each loan.

Multiple loans can be processed and compared in terms of economic criteria such as after-tax or before-tax present worth of cost and true interest rate, breakeven of periodic payment and of interest paid, and outstanding balance at different periods in time. PROC LOAN selects the best alternative in terms of the specified economic criterion for each loan comparison period.

The LOAN procedure allows various payment and compounding intervals (including continuous compounding) and uniform or lump sum prepayments for each loan. Down payments, discount points, and other initialization costs can be included in the loan analysis and comparison.

Getting Started

PROC LOAN supports four types of loans. You specify each type of loan using the corresponding statement: FIXED, BALLOON, ARM, and BUYDOWN.

- FIXED - Fixed rate loans have a constant interest rate and periodic payment throughout the life of the loan.
- BALLOON - Balloon payment loans are fixed rate loans with lump sum payments in certain payment periods in addition to the constant periodic payment.
- ARM - Adjustable rate loans are those in which the interest rate and periodic payment vary over the life of the loan. The future interest rates of an adjustable rate loan are not known with certainty, but they will vary within specified limits according to terms stated in the loan agreement. In practice, the rate adjustment terms vary. PROC LOAN offers a flexible set of options to capture a wide variety of rate adjustment terms.
- BUYDOWN - Buydown rate loans are similar to adjustable rate loans, but the interest rate adjustments are predetermined at the initialization of the loan, usually by paying interest points at the time of loan initialization.

Analyzing Fixed Rate Loans

The most common loan analysis is the calculation of the periodic payment when the loan amount, life, and interest rate are known. The following PROC LOAN statements analyze a 15-year (180 monthly payments) fixed rate loan for $100,000 with an annual nominal interest rate of 7.5%:

```
proc loan;
   fixed amount=100000 rate=7.5 life=180;
run;
```

Another parameter PROC LOAN can compute is the maximum amount you can borrow given the periodic payment you can afford and the rates available in the market. The following SAS statements analyze a loan for 180 monthly payments of $900, with a nominal annual rate of 7.5%:

```
proc loan;
   fixed payment=900 rate=7.5 life=180;
run;
```

Assume that you want to borrow $100,000 and can pay $900 a month. You know that the lender charges a 7.5% nominal interest rate compounded monthly. To determine how long it will take you to pay off your debt, use the following statements:

```
proc loan;
   fixed amount=100000 payment=900 rate=7.5;
run;
```

Sometimes, a loan is expressed in terms of the amount borrowed and the amount and number of periodic payments. In this case, you want to calculate the annual nominal rate charged on the loan to compare it to other alternatives. The following statements analyze a loan of $100,000 paid in 180 monthly payments of $800:

```
proc loan;
   fixed amount=100000 payment=800 life=180;
run;
```

There are four basic parameters that define a loan: life (number of periodic payments), principal amount, interest rate, and the periodic payment amount. PROC LOAN calculates the missing parameter among these four. Loan analysis output includes a loan summary table and an amortization schedule.

You can use the START= and LABEL= options to enhance your output. The START= option specifies the date of loan initialization and dates all the output accordingly. The LABEL= specification is used to label all output corresponding to a particular loan and is especially useful when multiple loans are analyzed. For example, the preceding statements for the first fixed rate loan are revised to include the START= and LABEL= options as follows:

```
proc loan start=1998:12;
   fixed amount=100000 rate=7.5 life=180
         label='BANK1, Fixed Rate';
run;
```

Loan Summary Table

The loan summary table is produced by default and contains loan analysis information. It shows the principal amount, the costs at the time of loan initialization (downpayment, discount points, and other loan initialization costs), the total payment and interest, the initial nominal and effective interest rates, payment and compounding intervals, the length of the loan in the time units specified, the start and end dates (if specified), a list of nominal and effective interest rates, and periodic payments throughout the life of the loan.

Figure 18.1 shows the loan summary table for the fixed rate loan labeled "BANK1, Fixed Rate."

```
                                 The LOAN Procedure

                             Fixed Rate Loan Summary

                                  BANK1, Fixed Rate

   Downpayment                  0.00    Principal Amount           100000.00
   Initialization               0.00    Points                          0.00
   Total Interest           66862.61    Nominal Rate                 7.5000%
   Total Payment           166862.61    Effective Rate               7.7633%

   Start Date                DEC1998    End Date                     DEC2013

                    Rates and Payments for BANK1, Fixed Rate
        Date            Nominal Rate     Effective Rate         Payment

        DEC1998            7.5000%            7.7633%            927.01
```

Figure 18.1. Fixed Rate Loan Summary

The loan is initialized in December 1998 and paid off in December 2013. The monthly payment is calculated to be $927.01, and the effective interest rate is 7.7633%. Over the 15 years, $66,862.61 is paid for interest charges on the loan.

Analyzing Balloon Payment Loans

You specify balloon payment loans like fixed rate loans, with the additional specification of the balloon payments. Assume you have an alternative to finance the $100,000 investment with a 15-year balloon payment loan. The annual nominal rate is 7.5%, as in the fixed rate loan. The terms of the loan require two balloon payments of $2000 and $1000 at the 15th and 48th payment periods, respectively. These balloon payments keep the periodic payment lower than that of the fixed rate loan. The balloon payment loan is defined by the following BALLOON statement:

```
proc loan start=1998:12;
   balloon amount=100000 rate=7.5 life=180
           balloonpayment=(15=2000 48=1000)
           label = 'BANK2, with Balloon Payment';
run;
```

List of Balloon Payments

In addition to the information for the fixed rate loan, the “Loan Summary Table” for the balloon payment loan includes a list of balloon payments in the “List of Rates and Payments.” For example, the balloon payment loan described previously includes two balloon payments, as shown in Figure 18.2.

```
                                The LOAN Procedure

                  Rates and Payments for BANK2, with Balloon Payment
             Date           Nominal Rate      Effective Rate          Payment

             DEC1998            7.5000%            7.7633%            903.25

                            Balloon Period          Payment

                            MAR2000                 2000.00
                            DEC2002                 1000.00
```

Figure 18.2. List of Rates and Payments for a Balloon Payment Loan

The periodic payment for the balloon payment loan is $23.76 less than that of the fixed rate loan.

Analyzing Adjustable Rate Loans

In addition to specifying the basic loan parameters, you need to specify the terms of the rate adjustments for an adjustable rate loan. There are many ways of stating the rate adjustment terms, and PROC LOAN facilitates all of them. For details, see the “Rate Adjustment Terms Options” in the “ARM Statement” section later in this chapter.

Assume that you have an alternative to finance the $100,000 investment with a 15-year adjustable rate loan with an initial annual nominal interest rate of 5.5%. The rate adjustment terms specify a 0.5% annual cap, a 2.5% life cap, and a rate adjustment every 12 months. *Annual cap* refers to the maximum increase in interest rate per adjustment period, and *life cap* refers to the maximum increase over the life of the loan. The following ARM statement specifies this adjustable rate loan assuming the interest rate adjustments will always increase by the maximum allowed by the terms of the loan. These assumptions are specified by the WORSTCASE and CAPS= options, as shown in the following statements:

```
proc loan start=1998:12;
   arm amount=100000 rate=5.5 life=180 worstcase
       caps=(0.5, 2.5)
       label='BANK3, Adjustable Rate';
run;
```

List of Rates and Payments for Adjustable Rate Loans

The “List of Rates and Payments” in the loan summary table for the adjustable rate loans reflects the changes in the interest rates and payments, as well as the dates these changes become effective. For the adjustable rate loan described previously, Figure 18.3 shows the “List of Rates and Payments” indicating five annual rate adjustments in addition to the initial rate and payment.

```
                              The LOAN Procedure

                  Rates and Payments for BANK3, Adjustable Rate
      Date            Nominal Rate      Effective Rate          Payment

      DEC1998             5.5000%             5.6408%            817.08
      JAN2000             6.0000%             6.1678%            842.33
      JAN2001             6.5000%             6.6972%            866.44
      JAN2002             7.0000%             7.2290%            889.32
      JAN2003             7.5000%             7.7633%            910.88
      JAN2004             8.0000%             8.3000%            931.03
```

Figure 18.3. List of Rates and Payments for an Adjustable Rate Loan

Notice that the periodic payment of the adjustable rate loan as of January 2004 ($931.03) exceeds that of the fixed rate loan ($927.01).

Analyzing Buydown Rate Loans

A 15-year buydown rate loan is another alternative to finance the $100,000 investment. The nominal annual interest rate is 6.5% initially and will increase to 8% and 9% as of the 24th and 48th payment periods, respectively. The nominal annual interest rate is lower than that of the fixed rate alternative, at the cost of a 1% discount point ($1000) paid at the initialization of the loan. The following BUYDOWN statement represents this loan alternative:

```
proc loan start=1998:12;
   buydown amount=100000 rate=6.5 life=180
           buydownrates=(24=8 48=9) pointpct=1
           label='BANK4, Buydown';
run;
```

List of Rates and Payments for Buydown Rate Loans

Figure 18.4 shows the “List of Rates and Payments” in the loan summary table. It reflects the two rate adjustments and the corresponding monthly payments as well as the initial values for these parameters. As of December 2000, the periodic payment of the buydown loan exceeds the periodic payment for any of the other alternatives.

```
                              The LOAN Procedure

                      Rates and Payments for BANK4, Buydown
      Date            Nominal Rate      Effective Rate          Payment

      DEC1998             6.5000%             6.6972%            871.11
      DEC2000             8.0000%             8.3000%            946.50
      DEC2002             9.0000%             9.3807%            992.01
```

Figure 18.4. List of Rates and Payments for a Buydown Rate Loan

Loan Repayment Schedule

In addition to the loan summary, you can print a loan repayment (amortization) schedule for each loan. For each payment period, this schedule contains the year and period within the year (or date, if the START= option is specified), the principal balance at the beginning of the period, the total payment, interest payment, principal repayment for the period, and the principal balance at the end of the period.

To print the first year of the amortization schedule for the fixed rate loan shown in Figure 18.5, use the following statements:

```
proc loan start=1998:12;
   fixed amount=100000 rate=7.5 life=180
         schedule=1
         label='BANK1, Fixed Rate';
run;
```

```
                                The LOAN Procedure

                             Loan Repayment Schedule

                                BANK1, Fixed Rate

               Beginning                       Interest      Principal         Ending
Date         Outstanding         Payment        Payment      Repayment    Outstanding

AUG1999         97845.87          927.01         611.54         315.47       97530.40
SEP1999         97530.40          927.01         609.57         317.44       97212.96
OCT1999         97212.96          927.01         607.58         319.43       96893.53
NOV1999         96893.53          927.01         605.58         321.43       96572.10
DEC1999         96572.10          927.01         603.58         323.43       96248.67

DEC1999        100000.00        11124.12        7372.79        3751.33       96248.67
```

Figure 18.5. Loan Repayment Schedule for the First Year

The principal balance at the end of one year is $96,248.67. The total payment for the year is $11,124.12 of which $3,751.33 went toward principal repayment.

You can also print the amortization schedule with annual summary information or for a specified number of years. The SCHEDULE=YEARLY option produces an annual summary loan amortization schedule, which is useful for loans with long life. For example, to print the annual summary loan repayment schedule for the buydown loan shown in Figure 18.6, use the following statements.

```
proc loan start=1998:12;
   buydown amount=100000 rate=6.5 life=180
           buydownrates=(24=8 48=9) pointpct=1
           schedule=yearly
           label='BANK4, Buydown';
run;
```

```
                                  The LOAN Procedure

                                Loan Repayment Schedule

```

Figure 18.6. Annual Summary Loan Repayment Schedule

Loan Comparison

The LOAN procedure can compare alternative loans on the basis of different economic criteria and help select the most desirable loan. You can compare alternative loans through different points in time. The economic criteria offered by PROC LOAN are

- outstanding principal balance, that is, the unpaid balance of the loan
- present worth of cost, that is, before-tax or after-tax net value of the loan cash flow through the comparison period. The cash flow includes all payments, discount points, initialization costs, down payment, and the outstanding principal balance at the comparison period.
- true interest rate, that is, before-tax or after-tax effective annual interest rate charged on the loan. The cash flow includes all payments, discount points, initialization costs, and the outstanding principal balance at the specified comparison period.
- periodic payment
- the total interest paid on the loan

The figures for present worth of cost, true interest rate, and interest paid are reported on the cash flow through the comparison period. The reported outstanding principal balance and the periodic payment are the values as of the comparison period.

The COMPARE statement specifies the type of comparison and the periods of comparison. For each period specified in the COMPARE statement, a loan comparison report is printed that also indicates the best alternative. Different criteria may lead to selection of different alternatives. Also, the period of comparison may change the desirable alternative. See the section "Loan Comparison Details" later in this chapter for further information.

Comparison of 15-Year versus 30-Year Loan Alternatives

An issue that arises in the purchase of a house is the length of the loan life. In the U.S., residential home loans are usually for 15 or 30 years. Ordinarily, 15-year loans have a lower interest rate but higher periodic payments than 30-year loans. A comparison of both loans might identify the better loan for your means and needs. The following SAS statements compare two such loans:

```
proc loan start=1998:12 amount=120000;
   fixed rate=7.5 life=360 label='30 year loan';
   fixed rate=6.5 life=180 label='15 year loan';
   compare;
run;
```

Default Loan Comparison Report

The default loan comparison report in Figure 18.7 shows the ending outstanding balance, periodic payment, interest paid, and before-tax true rate at the end of 30 years. In the case of the default loan comparison, the selection of the best alternative is based on minimization of the true rate.

```
                              The LOAN Procedure

                            Loan Comparison Report

                          Analysis through DEC2028

                               Ending                      Interest       True
  Loan Label              Outstanding        Payment          Paid        Rate

  30 year loan                   0.00         835.48     182058.02        7.76
  15 year loan                   0.00        1044.95      68159.02        6.70

NOTE: "15 year loan" is the best alternative based on true rate analysis through DEC2028.
```

Figure 18.7. Default Loan Comparison Report

Based on true rate, the best alternative is the 15-year loan. However, if the objective were to minimize the periodic payment, the 30-year loan would be the more desirable.

Comparison of Fixed Rate and Adjustable Rate Loans

Suppose you want to compare a fixed rate loan to an adjustable rate alternative. The nominal interest rate on the adjustable rate loan is initially 1.5% lower than the fixed rate loan. The future rates of the adjustable rate loan are calculated using the worst case scenario.

According to current U.S. tax laws, the loan for a family home qualifies the interest paid on the loan as a tax deduction. The TAXRATE=28 (income tax rate) option on the COMPARE statement bases the calculations of true interest rate on the after-tax cash flow. Assume, also, that you are uncertain as to how long you will keep this property. The AT=(60 120) option, as shown in the following example, produces two loan comparison reports through the end of the 5th and the 10th years, respectively:

```
proc loan start=1998:12 amount=120000 life=360;
   fixed rate=7.5 label='BANK1, Fixed Rate';
   arm   rate=6.0 worstcase caps=(0.5 2.5)
         label='BANK3, Adjustable Rate';
   compare taxrate=28 at=(60 120);
run;
```

After-Tax Loan Comparison Reports

The two loan comparison reports in Figure 18.8 and Figure 18.9 show the ending outstanding balance, periodic payment, interest paid, and after-tax true rate at the end of five years and ten years, respectively.

```

NOTE: "BANK1, Fixed Rate" is the best alternative based on true rate analysis through DEC2008.
```

Figure 18.9. Loan Comparison Report as of December 2008

The loan comparison report through December 2003 picks the adjustable rate loan as the best alternative, whereas the report through December 2008 shows the fixed rate loan as the better alternative. This implies that if you intend to keep the loan for 10 years or longer, the best alternative is the fixed rate alternative. Otherwise, the adjustable rate loan is the better alternative in spite of the worst-case scenario. Further analysis shows that the actual breakeven of true interest rate occurs at August 2008. That is, the desirable alternative switches from the adjustable rate loan to the fixed rate loan in August 2008.

Note that, under the assumption of worst-case scenario for the rate adjustments, the periodic payment for the adjustable rate loan already exceeds that of the fixed rate loan on December 2003 (as of the rate adjustment on January 2003 to be exact). If the objective were to minimize the periodic payment, the fixed rate loan would have been more desirable as of December 2003. However, all of the other criteria at that point still favor the adjustable rate loan.

Syntax

The following statements are used with PROC LOAN:

PROC LOAN *options* **;**
  FIXED *options* **;**
  BALLOON *options* **;**
  ARM *options* **;**
  BUYDOWN *options* **;**
  COMPARE *options* **;**

Functional Summary

The statements and options controlling the LOAN procedure are summarized in the following table. Many of the loan specification options can be used on all of the statements except the COMPARE statement. For these options, the statement column will be left blank. Options specific to a type of loan will indicate the statement name.

Description	Statement	Option
Statements		
specify an adjustable rate loan	ARM	
specify a balloon payment loan	BALLOON	
specify a buydown rate loan	BUYDOWN	
specify loan comparisons	COMPARE	
specify a fixed rate loan	FIXED	

Description	Statement	Option
Data Set Options		
specify output data set for loan summary	PROC LOAN	OUTSUM=
specify output data set for repayment schedule		OUT=
specify output data set for loan comparison	COMPARE	OUTCOMP=
Printing Control Options		
suppress printing of loan summary report		NOSUMMARYPRINT
suppress all printed output		NOPRINT
print amortization schedule		SCHEDULE=

specify true interest rate analysis	COMPARE	TRUEINTEREST

PROC LOAN Statement

PROC LOAN *options ;*

The following output opton can be used in the PROC LOAN statement. In addition, the following loan specification options can be specified in the PROC LOAN statement to be used as defaults for all loans unless otherwise specified for a given loan:

AMOUNT=	INTERVAL=	POINTPCT=
AMOUNTPCT=	LABEL=	PREPAYMENTS=
COMPOUND=	LIFE=	PRICE=
DOWNPAYMENT=	NOSUMMARYPRINT	RATE=
DOWNPAYPCT=	NOPRINT	ROUND=
INITIAL=	PAYMENT=	START=
INITIALPCT=	POINTS=	SCHEDULE=.

Output Option

OUTSUM= *SAS-data-set*
: creates an output data set containing loan summary information for all loans other than those for which a different OUTSUM= output data set is specified.

FIXED Statement

FIXED *options ;*

The FIXED statement specifies a fixed rate and periodic payment loan. It can be specified using the options that are common to all loan statements. The FIXED statement options are listed in this section.

You must specify three of the following options in each loan statement: AMOUNT=, LIFE=, RATE=, and PAYMENT=. The LOAN procedure calculates the fourth parameter based on the values you give the other three. If you specify all four of the options, the PAYMENT= specification is ignored, and the periodic payment is recalculated for consistency.

As an alternative to specifying the AMOUNT= option, you can specify the PRICE= option along with one of the following options to facilitate the calculation of the loan amount: AMOUNTPCT=, DOWNPAYMENT=, or DOWNPAYPCT=.

Required Specifications

AMOUNT= *amount*
A= *amount*
: specifies the loan amount (the outstanding principal balance at the initialization of the loan).

LIFE= *n*
L= *n*
: gives the life of the loan in number of payments. (The payment frequency is specified by the INTERVAL= option.) For example, if the life of the loan is 10 years with monthly payments, use LIFE=120 and INTERVAL=MONTH (default) to indicate a 10-year loan in which 120 monthly payments are made.

PAYMENT= *amount*
P= *amount*
: specifies the periodic payment. For ARM and BUYDOWN loans where the periodic payment might change, the PAYMENT= option specifies the initial amount of the periodic payment.

RATE= *rate*
R= *rate*
: specifies the initial annual (nominal) interest rate in percent notation. The rate specified must be in the range 0% to 120%. For example, use RATE=12.75 for a 12.75% loan. For ARM and BUYDOWN loans, where the rate might change over the life of the loan, the RATE= option specifies the initial annual interest rate.

Specification Options

AMOUNTPCT= *value*
APCT= *value*

specifies the loan amount as a percentage of the purchase price (PRICE= option). The AMOUNTPCT= specification is used to calculate the loan amount if the AMOUNT= option is not specified. The value specified must be in the range 1% to 100%.

If both the AMOUNTPCT= and DOWNPAYPCT= options are specified and the sum of their values is not equal to 100, the value of the downpayment percentage is set equal to 100 minus the value of the amount percentage.

COMPOUND= *time-unit*

specifies the time interval between compoundings. The default is the time unit given by the INTERVAL= option. If the INTERVAL= option is not used, then the default is COMPOUND=MONTH. The following time units are valid COMPOUND= values: CONTINUOUS, DAY, SEMIMONTH, MONTH, QUARTER, SEMIYEAR, and YEAR. The compounding interval is used to calculate the simple interest rate per payment period from the nominal annual interest rate or vice versa.

DOWNPAYMENT= *amount*
DP= *amount*

specifies the down payment at the initialization of the loan. The down payment is included in the calculation of the present worth of cost but not in the calculation of the true interest rate. The after-tax analysis assumes that the down payment is not tax-deductible. (Specify after-tax analysis with the TAXRATE= option in the COMPARE statement.)

DOWNPAYPCT= *value*
DPCT= *value*

specifies the down payment as a percentage of the purchase price (PRICE= option). The DOWNPAYPCT= specification is used to calculate the down payment amount if you do not specify the DOWNPAYMENT= option. The value you specify must be in the range 0% to 99%.

If you specified both the AMOUNTPCT= and DOWNPAYPCT= options, and the sum of their values is not equal to 100, the value of the downpayment percentage is set equal to 100 minus the value of the amount percentage.

INITIAL= *amount*
INIT= *amount*

specifies the amount paid for loan initialization other than the discount points and down payment. This amount is included in the calculation of the present worth of cost and the true interest rate. The after-tax analysis assumes that the initial amount is not tax-deductible. (After-tax analysis is specified by the TAXRATE= option in the COMPARE statement.)

INITIALPCT= *value*
INITPCT= *value*

specifies the initialization costs as a percentage of the loan amount (AMOUNT= option). The INITIALPCT= specification is used to calculate the amount paid for loan initialization if you do not specify the INITIAL= option. The value you specify must be in the range of 0% to 100%.

INTERVAL= *time-unit*
gives the time interval between periodic payments. The default is INTERVAL=MONTH. The following time units are valid INTERVAL values: SEMIMONTH, MONTH, QUARTER, SEMIYEAR, and YEAR.

LABEL= *'loan-label'*
specifies a label for the loan. If you specify the LABEL= option, all output related to the loan is labeled accordingly. If you do not specify the LABEL= option, the loan is labeled by sequence number.

POINTS= *amount*
PNT= *amount*
specifies the amount paid for discount points at the initialization of the loan. This amount is included in the calculation of the present worth of cost and true interest rate. The amount paid for discount points is assumed to be tax-deductible in after-tax analysis (that is, if the TAXRATE= option is specified in the COMPARE statement).

POINTPCT= *value*
PNTPCT= *value*
specifies the discount points as a percentage of the loan amount (AMOUNT= option). The POINTPCT= specification is used to calculate the amount paid for discount points if you do not specify the POINTS= option. The value you specify must be in the range of 0% to 100%.

PREPAYMENTS= *amount*
PREPAYMENTS= *(date1=prepayment1 date2=prepayment2 ...)*
PREPAYMENTS= *(period1=prepayment1 period2=prepayment2 ...)*
PREP=
specifies either a uniform prepayment p throughout the life of the loan or lump sum prepayments. A uniform prepayment, p, is assumed to be paid with each periodic payment. Specify lump sum prepayments by pairs of periods (or dates) and respective prepayment amounts.

You can specify the prepayment periods as dates if you specify the START= option. Prepayment periods or dates and the respective prepayment amounts must be in time sequence. The prepayments are treated as principal payments, and the outstanding principal balance is adjusted accordingly. In the adjustable rate and buydown rate loans, if there is a rate adjustment after prepayments, the adjusted periodic payment is calculated based on the outstanding principal balance. The prepayments do not result in periodic payment amount adjustments in fixed rate and balloon payment loans.

PRICE= *amount*
PRC= *amount*
specifies the purchase price, which is the loan amount plus the down payment. If you specify the PRICE= option along with the loan amount (AMOUNT= option) or the down payment (DOWNPAYMENT= option), the value of the other one is calculated.

If you specify the PRICE= option with the AMOUNTPCT= or DOWNPAYPCT= options, the loan amount and the downpayment are calculated.

ROUND= *n*
ROUND= NONE
specifies the number of decimal places to which the monetary amounts are rounded for the loan. Valid values for *n* are integers from 0 to 6. If you specify ROUND=NONE, the values are not rounded off internally, but the printed output is rounded off to two decimal places. The default is ROUND=2.

START= *SAS-date*
START= *yyyy:per*
S=
gives the date of loan initialization. The first payment is assumed to be one payment interval after the start date. For example, you can specify the START= option as '1APR1990'd or as 1990:3 where 3 is the third payment interval. If INTERVAL=QUARTER, 3 refers to the third quarter. If you specify the START= option, all output involving the particular loan is dated accordingly.

Output Options

NOSUMMARYPRINT
NOSUMPR
suppresses the printing of the loan summary report. The NOSUMMARYPRINT option is usually used when an OUTSUM= data set is created to store loan summary information.

NOPRINT
NOP
suppresses all printed output for the loan.

OUT= *SAS-data-set*
writes the loan amortization schedule to an output data set.

OUTSUM= *SAS-data-set*
writes the loan summary for the individual loan to an output data set.

SCHEDULE
SCHEDULE= *nyears*
SCHEDULE= YEARLY
SCHED
prints the amortization schedule for the loan. SCHEDULE=*nyears* specifies the number of years the printed amortization table covers. If you omit the number of years or specify a period longer than the loan life, the schedule is printed for the full term of the loan. SCHEDULE=YEARLY prints yearly summary information in the amortization schedule rather than the full amortization schedule. SCHEDULE=YEARLY is useful for long-term loans.

BALLOON Statement

BALLOON *options;*

The BALLOON statement specifies a fixed rate loan with scheduled balloon payments in addition to the periodic payment. The following option is used in the BALLOON statement, in addition to the required options listed under the FIXED statement;

BALLOONPAYMENT= *(date1=payment1 date2=payment2 ...)*
BALLOONPAYMENT= *(period1=payment1 period2=payment2 ...)*
BPAY=

specifies pairs of periods and amounts of balloon (lump sum) payments in excess of the periodic payment during the life of the loan. You can also specify the balloon periods as dates if you specify the START= option.

If you do not specify this option, the calculations are identical to a loan specified in a FIXED statement. Balloon periods (or dates) and the respective balloon payments must be in time sequence.

ARM Statement

ARM *options;*

The ARM statement specifies an adjustable rate loan where the future interest rates are not known with certainty but will vary within specified limits according to the terms stated in the loan agreement. In practice, the adjustment terms vary. Adjustments in the interest rate can be captured using the ARM statement options.

In addition to the required specifications and options listed under the FIXED statement, you can use the following options with the ARM statement:

Rate Adjustment Terms Options

ADJUSTFREQ= *n*
ADF= *n*

specifies the number of periods, in terms of the INTERVAL= specification, between rate adjustments. INTERVAL=MONTH ADJUSTFREQ=6 indicates that the nominal interest rate can be adjusted every six months until the life cap or maximum rate (whichever is specified) is reached. The default is ADJUSTFREQ=12. The periodic payment is adjusted every adjustment period even if there is no rate change; therefore, if prepayments are made (as specified with the PREPAYMENTS= option), the periodic payment might change even if the nominal rate does not.

CAPS= *(periodic-cap, life-cap* **)**

specifies the maximum interest rate adjustment, in percent notation, allowed by the loan agreement. The *periodic cap* specifies the maximum adjustment allowed at each adjustment period. The *life cap* specifies the maximum total adjustment over the life of the loan. For example, a loan specified with CAPS=(0.5, 2) indicates that the nominal interest rate can change by 0.5% each adjustment period, and the annual nominal interest rate throughout the life of the loan will be within a 2% range of the initial annual nominal rate.

MAXADJUST= *rate*
MAXAD= *rate*

specifies the maximum rate adjustment, in percent notation, allowed at each adjustment period. Use the MAXADJUST= option with the MAXRATE= and MINRATE= options. The initial nominal rate plus the maximum adjustment should not exceed the specified MAXRATE= value. The initial nominal rate minus the maximum adjustment should not be less than the specified MINRATE= value.

MAXRATE= *rate*
MAXR= *rate*

specifies the maximum annual nominal rate, in percent notation, that might be charged on the loan. The maximum annual nominal rate should be greater than or equal to the initial annual nominal rate specified with the RATE= option.

MINRATE= *rate*
MINR= *rate*

specifies the minimum annual nominal rate, in percent notation, that might be charged on the loan. The minimum annual nominal rate should be less than or equal to the initial annual nominal rate specified with the RATE= option.

Rate Adjustment Case Options

PROC LOAN supports four rate adjustment scenarios for analysis of adjustable rate loans: pessimistic (WORSTCASE), optimistic (BESTCASE), no-change (FIXEDCASE), and estimated (ESTIMATEDCASE). The estimated case enables you to analyze the adjustable rate loan using your predictions of future interest rates. The default is worst-case analysis. If more than one case is specified, worst-case analysis is performed. You can specify options for adjustable rate loans as follows:

BESTCASE
B

specifies a best-case analysis. The best-case analysis assumes the interest rate charged on the loan will reach its minimum allowed limits at each adjustment period and over the life of the loan. If you use the BESTCASE option, you must specify either the CAPS= option or the MINRATE= and MAXADJUST= options.

ESTIMATEDCASE= *(date1=rate1 date2=rate2 ...)*
ESTIMATEDCASE= *(period1=rate1 period2=rate2 ...)*
ESTC=

specifies an estimated case analysis that indicates the rate adjustments will follow the rates you predict. This option specifies pairs of periods and estimated nominal interest rates.

The ESTIMATEDCASE= option can specify adjustments that cannot fit into the BESTCASE, WORSTCASE, or FIXEDCASE specifications, or “what-if” type analysis. If you specify the START= option, you can also specify the estimation periods as dates. Estimated rates and the respective periods must be in time sequence.

If the estimated period falls between two adjustment periods (determined by ADJUSTFREQ= option), the rate is adjusted in the next adjustment period. The nominal interest rate charged on the loan is constant between two adjustment periods.

If any of the MAXRATE=, MINRATE=, CAPS=, and MAXADJUST= options are specified to indicate the rate adjustment terms of the loan agreement, these specifications are used to bound the rate adjustments. By using the ESTIMATEDCASE= option, you are predicting what the annual nominal rates in the market will be at different points in time, not necessarily the interest rate on your particular loan. For example, if the initial nominal rate (RATE= option) is 6.0, ADJUSTFREQ=6, MAXADJUST=0.5, and the ESTIMATEDCASE=(6=6.5, 12=7.5), the actual nominal rates charged on the loan would be 6.0% initially, 6.5% for the sixth through the eleventh periods, and 7.5% for the twelfth period onward.

FIXEDCASE
FIXCASE

specifies a fixed case analysis that assumes the rate will stay constant. The FIXEDCASE option calculates the ARM loan values similar to a fixed rate loan, but the payments are updated every adjustment period even if the rate does not change, leading to minor differences between the two methods. One such difference is in the way prepayments are handled. In a fixed rate loan, the rate and the payments are never adjusted; therefore, the payment stays the same over the life of the loan even when prepayments are made (instead, the life of the loan is shortened). In an ARM loan with the FIXEDCASE option, on the other hand, if prepayments are made, the payment is adjusted in the following adjustment period, leaving the life of the loan constant.

WORSTCASE
W

specifies a worst-case analysis. The worst-case analysis assumes the interest rate charged on the loan will reach its maximum allowed limits at each rate adjustment period and over the life of the loan. If the WORSTCASE option is used, either the CAPS= option or the MAXRATE= and MAXADJUST= options must be specified.

BUYDOWN Statement

BUYDOWN *options;*

The BUYDOWN statement specifies a buydown rate loan. The buydown rate loans are similar to ARM loans, but the interest rate adjustments are predetermined at the initialization of the loan, usually by paying interest points at the time of loan initialization.

You can use all the required specifications and options listed under the FIXED statement with the BUYDOWN statement. The following option is specific to the BUYDOWN statement and is required:

BUYDOWNRATES= *(date1=rate1 date2=rate2 ...)*
BUYDOWNRATES= *(period1=rate1 period2=rate2 ...)*
BDR=

specifies pairs of periods and the predetermined nominal interest rates that will be charged on the loan starting at the corresponding time periods.

You can also specify the buydown periods as dates if you specify the START=option. Buydown periods (or dates) and the respective buydown rates must be in time sequence.

COMPARE Statement

COMPARE *options ;*

The COMPARE statement compares multiple loans and it can be used with a single loan. You can use only one COMPARE statement. COMPARE statement options specify the periods and desired types of analysis for loan comparison. The default analysis reports the outstanding principal balance, breakeven of payment, breakeven of interest paid, and before-tax true interest rate. The default comparison period corresponds to the first LIFE= option specification. If the LIFE= option is not specified for any loan, the loan comparison period defaults to the first calculated life.

You can use the following options with the COMPARE statement. For more detailed information on loan comparison, see the section "Loan Comparison Details" later in this chapter.

Analysis Options

ALL
is equivalent to specifying the BREAKINTEREST, BREAKPAYMENT, PWOFCOST, and TRUEINTEREST options. The loan comparison report includes all the criteria. You need to specify the MARR= option for present worth of cost calculation.

AT= *(date1 date2 ...)*
AT= *(period1 period2 ...)*
specifies the periods for loan comparison reports. If you specify the START= option in the PROC LOAN statement, you can specify the AT= option as a list of dates instead of periods. The comparison periods do not need to be in time sequence. If you do not specify the AT= option, the comparison period defaults to the first LIFE= option specification. If you do not specify the LIFE= option for any of the loans, the loan comparison period defaults to the first calculated life.

BREAKINTEREST
BI
specifies breakeven analysis of the interest paid. The loan comparison report includes the interest paid for each loan through the specified comparison period (AT= option).

BREAKPAYMENT
BP
specifies breakeven analysis of payment. The periodic payment for each loan is reported for every comparison period specified in the AT=option.

MARR= *rate*
specifies the MARR (**M**inimum **A**ttractive **R**ate of **R**eturn) in percent notation. MARR reflects the cost of capital or the opportunity cost of money. The MARR= option is used in calculating the present worth of cost.

PWOFCOST
PWC

calculates the present worth of cost (net present value of costs) for each loan based on the cash flow through the specified comparison periods. The calculations account for down payment, initialization costs, and discount points, as well as the payments and outstanding principal balance at the comparison period. If you specify the TAXRATE= option, the present worth of cost is based on after-tax cash flow. Otherwise, before-tax present worth of cost is calculated. You need to specify the MARR= option for present worth of cost calculations.

TAXRATE= *rate*
TAX= *rate*

specifies income tax rate in percent notation for the after-tax calculations of the true interest rate and present worth of cost for those assets that qualify for tax deduction. If you specify this option, the amount specified in the POINTS= option and the interest paid on the loan are assumed to be tax-deductible. Otherwise, it is assumed that the asset does not qualify for tax deductions, and the cash flow is not adjusted for tax savings.

TRUEINTEREST
TI

calculates the true interest rate (effective interest rate based on the cash flow of all payments, initialization costs, discount points, and the outstanding principal balance at the comparison period) for all the specified loans through each comparison period. If you specify the TAXRATE= option, the true interest rate is based on after-tax cash flow. Otherwise, the before-tax true interest rate is calculated.

Output Options

NOCOMPRINT
NOCP

suppresses the printing of the loan comparison report. The NOCOMPRINT option is usually used when an OUTCOMP= data set is created to store loan comparison information.

OUTCOMP= *SAS-data-set*

writes the loan comparison report to an output data set.

Details

Computational Details

These terms are used in the formulas that follow:

p	periodic payment
a	principal amount
r_a	nominal annual rate
f	compounding frequency (per year)
f'	payment frequency (per year)
r	periodic rate
r_e	effective interest rate
n	total number of payments

The periodic rate, or the simple interest applied during a payment period, is given by

$$r = \left(1 + \frac{r_a}{f}\right)^{f/f'} - 1$$

Note that the interest calculation is performed at each payment period rather than at the compound period. This is done by adjusting the nominal rate. Refer to Muksian (1984) for details.

Note that when $f = f'$, that is, when the payment and compounding frequency coincide, the preceding expression reduces to the familiar form:

$$r = \frac{r_a}{f}$$

The periodic rate for continuous compounding can be obtained from this general expression by taking the limit as the compounding frequency *f* goes to infinity. The resulting expression is

$$r = \exp\left(\frac{\mathrm{r_a}}{\mathrm{f'}}\right) - 1$$

The effective interest rate, or annualized percentage rate (APR), is that rate which, if compounded once per year, is equivalent to the nominal annual rate compounded *f* times per year. Thus,

$$(1 + r_e) = (1 + r)^f = \left(1 + \frac{r_a}{f}\right)^f$$

or

$$r_e = \left(1 + \frac{r_a}{f}\right)^f - 1$$

For continuous compounding, the effective interest rate is given by

$$r_e = \exp\left(\mathrm{r_a}\right) - 1$$

Refer to Muksian (1984) for details.

The payment is calculated as

$$p = \frac{ar}{1 - \frac{1}{(1+r)^n}}$$

The amount is calculated as

$$a = \frac{p}{r}\left(1 - \frac{1}{(1+r)^n}\right)$$

Both the payment and amount are rounded to the nearest hundredth (cent) unless the ROUND= specification is different than the default, 2.

The total number of payments *n* is calculated as

$$n = \frac{-\ln\left(1 - \frac{ar}{p}\right)}{\ln(1+r)}$$

The total number of payments is rounded up to the nearest integer.

The nominal annual rate is calculated using the bisection method, with *a* as the objective and *r* starting in the interval between $8 * 10^{-6}$ and .1 with an initial midpoint .01 and successive midpoints bisecting.

Loan Comparison Details

In order to compare the costs of different alternatives, the input cash flow for the alternatives must be represented in equivalent values. The equivalent value of a cash flow accounts for the time-value of money. That is, it is preferable to pay the same amount of money later than to pay it now, since the money can earn interest while you keep it. The MARR (**M**inimum **A**ttractive **R**ate of **R**eturn) reflects the cost of capital or the opportunity cost of money, that is, the interest that would have been earned on the savings that is foregone by making the investment. The MARR is used to discount the cash flow of alternatives into equivalent values at a fixed point in time. The MARR can vary for each investor and for each investment. Therefore, the MARR= option must be specified in the COMPARE statement if present worth of cost (PWOFCOST option) comparison is specified.

Present worth of cost reflects the equivalent amount at loan initialization of the loan cash flow discounted at MARR, not accounting for inflation. Present worth of cost accounts for the down payment, initialization costs, discount points, periodic payments, and the principal balance at the end of the report period. Therefore, it reflects the present worth of cost of the asset, not the loan. It is only meaningful to use minimization of present worth of cost as a selection criterion if the assets (down payment plus loan amount) are of the same value.

Another economic selection criterion is the rate of return (internal rate of return) of the alternatives. If interest is being earned by an alternative, the objective would be to maximize the rate of return. If interest is being paid, as in loan alternatives, the best alternative is the one that minimizes the rate of return. The true interest rate reflects the effective annual rate charged on the loan based on the cash flow, including the initialization cost and the discount points.

The effects of taxes on different alternatives must be accounted for when these vary among different alternatives. Since interest costs on certain loans are tax-deductible, the comparisons for those loans are made based on the after-tax cash flows. The cost of the loan is reduced by the tax benefits it offers through the loan life if the TAXRATE= option is specified. The present worth of cost and true interest rate are calculated based on the after-tax cash flow of the loan. The down payment on the loan and initialization costs are assumed to be not tax-deductible in after-tax analysis. Discount points and the interest paid in each periodic payment are assumed to be tax-deductible if the TAXRATE= option is specified. If the TAXRATE= option is not specified, the present worth of cost and the true interest rate are based on before-tax cash flow, assuming that the interest paid on the specified loan does not qualify for tax benefits.

The other two selection criteria are breakeven analysis of periodic payment and interest paid. If the objective is to minimize the periodic payment, the best alternative would be the one with the minimum periodic payment. If the objective is to minimize the interest paid on the principal, then the best alternative is the one with the least interest paid.

Another criterion might be the minimization of the outstanding balance of the loan at a particular point in time. For example, if you plan to sell a house before the end of the loan life (which is often the case), you might want to select the loan with the minimum principal balance at the time of the sale, since this balance must be paid at that time. The outstanding balance of the alternative loans is calculated for each loan comparison period by default.

If you specified the START= option in the PROC LOAN statement, the present worth of cost reflects the equivalent amount for each loan at that point in time. Any loan that has a START= specification different from the one in the PROC LOAN statement is not processed in the loan comparison.

The loan comparison report for each comparison period contains for each loan the loan label, outstanding balance, and any of the following measures if requested in the COMPARE statement: periodic payment (BREAKPAYMENT option), total interest paid to date (BREAKINTEREST option), present worth of cost (PWOFCOST option), and true interest rate (TRUEINTEREST option). The best loan is selected on the basis of present worth of cost or true interest rate. If both PWOFCOST and TRUEINTEREST options are specified, present worth of cost is the basis for the selection of the best loan.

You can use the OUTCOMP= option in the COMPARE statement to write the loan comparison report to a data set. The NOCOMPRINT option suppresses the printing of a loan comparison report.

OUT= Data Set

The OUT= option writes the loan amortization schedule to an output data set. The OUT= data set contains one observation for each payment period (or one observation for each year if you specified the SCHEDULE=YEARLY option). If you specified the START= option, the DATE variable denotes the date of the payment. Otherwise, YEAR and period variable (SEMIMONTH, MONTH, QUARTER, or SEMIYEAR) denote the payment year and period within the year.

The OUT= data set contains the following variables:

- DATE, date of the payment. DATE is included in the OUT= data set only when you specify the START= option.
- YEAR, year of the payment period. YEAR is included in the OUT= data set only when you do not specify the START= option.
- PERIOD, period within the year of the payment period. The name of the period variable matches the INTERVAL= specification (SEMIMONTH, MONTH, QUARTER, or SEMIYEAR.) The PERIOD variable is included in the OUT= data set only when you do not specify the START= option.
- BEGPRIN, beginning principal balance
- PAYMENT, payment
- INTEREST, interest payment
- PRIN, principal repayment
- ENDPRIN, ending principal balance

OUTCOMP= Data Set

The OUTCOMP= option in the COMPARE statement writes the loan comparison analysis results to an output data set. If you specified the START= option, the DATE variable identifies the date of the loan comparison. Otherwise, the PERIOD variable identifies the comparison period.

The OUTCOMP= data set contains one observation for each loan for each loan comparison period. The OUTCOMP= data set contains the following variables.

- DATE, date of loan comparison report. The DATE variable is included in the OUTCOMP= data set only when you specify the START= option.
- PERIOD, period of the loan comparison for the observation. The PERIOD variable is included in the OUTCOMP= data set only when you do not specify the START= option.
- LABEL, label string for the loan
- TYPE, type of the loan
- PAYMENT, periodic payment at the time of report. The PAYMENT is included in the OUTCOMP= data set if you specified the BREAKPAYMENT or ALL option or if you used default criteria.
- INTPAY, interest paid through the time of report. The INTPAY variable is included in the OUTCOMP= data set if you specified the BREAKINTEREST or ALL option or if you used default criteria.
- TRUERATE, true interest rate charged on the loan. The TRUERATE variable is included in the OUTCOMP= data set if you specified the TRUERATE or ALL option or if you used default criteria.
- PWOFCOST, present worth of cost. The PWOFCOST variable is included in the OUTCOMP= data set only if you specified the PWOFCOST or ALL option.
- BALANCE, outstanding principal balance at the time of report

OUTSUM= Data Set

The OUTSUM= option writes the loan summary to an output data set. If you specified this option in the PROC LOAN statement, the loan summary information for all loans will be written to the specified data set, except for those loans for which you specified a different OUTSUM= data set on the ARM, BALLOON, BUYDOWN, or FIXED statement.

The OUTSUM= data set contains one observation for each loan and contains the following variables:

- TYPE, type of loan
- LABEL, loan label
- PAYMENT, periodic payment
- AMOUNT, loan principal
- DOWNPAY, down payment. DOWNPAY is included in the OUTSUM= data set only when you specify a down payment.
- INITIAL, loan initialization costs. INITIAL is included in the OUTSUM= data set only when you specify initialization costs.
- POINTS, discount points. POINTS is included in the OUTSUM= data set only when you specify discount points.
- TOTAL, total payment

- INTEREST, total interest paid
- RATE, nominal annual interest rate
- EFFRATE, effective interest rate
- INTERVAL, payment interval
- COMPOUND, compounding interval
- LIFE, loan life (that is, the number of payment intervals)
- NCOMPND, number of compounding intervals
- COMPUTE, computed loan parameter: life, amount, payment, or rate

If you specified the START= option either in the PROC LOAN statement or for the individual loan, the OUTSUM= data set also contains the following variables:

- BEGIN, start date
- END, loan termination date

Printed Output

The output from PROC LOAN consists of the loan summary table, loan amortization schedule, and loan comparison report.

Loan Summary Table

The loan summary table shows the total payment and interest, the initial nominal annual and effective interest rates, payment and compounding intervals, the length of the loan in the time units specified, the start and end dates if specified, a list of nominal and effective interest rates, and periodic payments throughout the life of the loan.

A list of balloon payments for balloon payment loans and a list of prepayments if specified are printed with their respective periods or dates.

The loan summary table is printed for each loan by default. The NOSUMMARYPRINT option specified in the PROC LOAN statement will suppress the printing of the loan summary table for all loans. The NOSUMMARYPRINT option can be specified in individual loan statements to selectively suppress the printing of the loan summary table.

Loan Repayment Schedule

The amortization schedule contains for each payment period, the year and period within the year (or date, if you specified the START= option), principal balance at the beginning of the period, total payment, interest payment and principal payment for the period, and the principal balance at the end of the period. If you specified the SCHEDULE=YEARLY option, the amortization will contain a summary for each year instead of for each payment period.

The amortization schedule is not printed by default. The SCHEDULE option in the PROC LOAN statement requests the printing of amortization tables for all loans. You can specify the SCHEDULE option in individual loan statements to selectively request the printing of the amortization schedule.

Loan Comparison Report

The loan comparison report is processed for each report period and contains the results of economic analysis of the loans. The quantities reported can include the outstanding principal balance, after-tax or before-tax present worth of cost and true interest rate, periodic payment, and the interest paid through the report period for each loan. The best alternative is identified if the asset value (down payment plus loan amount) is the same for each alternative.

The loan comparison report is printed by default. The NOCOMPRINT option specified in the COMPARE statement suppresses the printing of the loan comparison report.

ODS Table Names

PROC LOAN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 18.1. ODS Tables Produced in PROC LOAN

ODS Table Name	Description	Option
ODS Tables Created by the PROC LOAN, FIXED, ARM, BALLOON, and BUYDOWN Statements		
Repayment	Loan Repayment Schedule	SCHEDULE
ODS Tables Created by the FIXED, ARM, BALLOON, and BUYDOWN Statements		
LoanSummary	Loan Summary	default
RateList	Rates and Payments	default
PrepayList	Prepayments and Periods	PREPAYMENTS=
ODS Tables Created by the BALLOON Statement		
BalloonList	Balloon Payments and Periods	default
ODS Tables Created by the COMPARE Statement		
Comparison	Loan Comparison Report	default

Examples

Example 18.1. Discount Points for Lower Interest Rates

This example illustrates the comparison of two $100,000 loans. The major difference between the two loans is that the nominal interest rate in the second one is lower than the first with the added expense of paying discount points at the time of initialization.

Both alternatives are 30-year loans. The first loan is labeled “8.25% - no discount points” and the second one is labeled “8% - 1 discount point.”

Assume that the interest paid qualifies for a tax deduction, and you are in the 33% tax bracket. Also, your Minimum Attractive Rate of Return (MARR) for an alternative investment is 4% (adjusted for tax rate.)

You use the following statements to find the breakeven point in the life of the loan for your preference between the loans:

```
proc loan start=1992:1 nosummaryprint amount=100000 life=360;
   fixed rate=8.25 label='8.25% - no discount points';
   fixed rate=8 points=1000 label='8% - 1 discount point';
   compare at=(48 54 60) all taxrate=33 marr=4;
run;
```

Output 18.1.1 shows the loan comparison reports as of January 1996 (48th period), July 1996 (54th period), and January 1997 (60th period).

Output 18.1.1. Loan Comparison Reports for Discount Point Breakeven

                                     Loan Comparison Report

                                   Analysis through JAN1996

                                     Ending    Present Worth                         Interest       True
Loan Label                      Outstanding          of Cost          Payment            Paid       Rate

8.25% - no discount                96388.09        105546.17           751.27        32449.05       5.67
points
8% - 1 discount point              96219.32        105604.05           733.76        31439.80       5.69

NOTE: "8.25 - no discount points" is the best alternative based on present worth of cost analysis
                                         through JAN1996.

                                     Loan Comparison Report

                                   Analysis through JUL1996

                                     Ending    Present Worth                         Interest       True
Loan Label                      Outstanding          of Cost          Payment            Paid       Rate

8.25% - no discount                95847.27        106164.97           751.27        36415.85       5.67
points
8% - 1 discount point              95656.22        106153.97           733.76        35279.26       5.67

  NOTE: "8 - 1 discount point" is the best alternative based on present worth of cost analysis
                                         through JUL1996.
```

```
                                    The LOAN Procedure

                                  Loan Comparison Report

                                Analysis through JAN1997

                                    Ending    Present Worth                    Interest      True
Loan Label                     Outstanding          of Cost        Payment         Paid      Rate

8.25% - no discount               95283.74        106768.07         751.27     40359.94      5.67
points
8% - 1 discount point             95070.21        106689.80         733.76     39095.81      5.66

  NOTE: "8 - 1 discount point" is the best alternative based on present worth of cost analysis
                                     through JAN1997.
```

Notice that the breakeven point for present worth of cost and true rate both happen on July 1996. This indicates that if you intend to keep the loan for 4.5 years or more, it is better to pay the discount points for the lower rate. If your objective is to minimize the interest paid or the periodic payment, the “8% - 1 discount point” loan is the preferred choice.

Example 18.2. Refinancing a Loan

Assume that you obtained a fixed rate 15-year loan in June 1995 for $78,500 with a nominal annual rate of 9%. By early 1998, the market offers a 6.5% interest rate, and you are considering whether to refinance your loan.

Use the following statements to find out the status of the loan on February 1998. Output 18.2.1 shows the results:

```
proc loan start=1995:6;
   fixed life=180 rate=9 amount=78500 noprint
         label='Original Loan';
   compare at=('10FEB1998'd);
run;
```

Output 18.2.1. Loan Comparison Report for Original Loan

```
                                    The LOAN Procedure

                                  Loan Comparison Report

                                Analysis through FEB1998

                                       Ending                      Interest       True
     Loan Label                   Outstanding         Payment          Paid       Rate

     Original Loan                   71028.75          796.20      18007.15       9.38
```

The monthly payment on the original loan is $796.20. The ending outstanding principal balance as of February is $71,028.75. At this point, you might want to refinance your loan with another 15-year loan. The alternate loan has a 6.5% nominal annual rate. The initialization costs are $1,419.00. Use the following statements to compare your alternatives:

```
proc loan start=1998:2 amount=71028.75;
   fixed rate=9 payment=796.20
```

```
         label='Keep the original loan' noprint;
   fixed life=180 rate=6.5 init=1419
         label='Refinance at 6.5%' noprint;
   compare at=(15 16) taxrate=33 marr=4 all;
run;
```

The comparison reports of May 1999 and June 1999 in Output 18.2.2 illustrate the breakeven between the two alternatives. If you intend to keep the loan through June 1999 or longer, your initialization costs for the refinancing are justified. The periodic payment of the refinanced loan is $618.74.

Output 18.2.2. Loan Comparison Report for Refinancing Decision

```
                                            The LOAN Procedure

NOTE: "With Prepayments" is the best alternative based on present worth of cost analysis through
                                   DEC2002.
```

Output 18.3.1 illustrates the Loan Summary Reports and the Loan Comparison report. Notice that with prepayments you pay off the loan in slightly more than 15 years. Also, the total payments and total interest are considerably lower with the prepayments. If you can afford the prepayments of $500 each month, another alternative you should consider is using a 15-year loan, which is generally offered at a lower nominal interest rate.

Example 18.4. Output Data Sets

This example shows the analysis and comparison of five alternative loans. Initialization cost, discount points, and both lump sum and periodic payments are included in the specification of these loans. Although no printed output is produced, the loan summary and loan comparison information is stored in the OUTSUM= and OUTCOMP= data sets.

```
proc loan start=1998:12 noprint outsum=loans
   amount=150000 life=360;

Example 18.5. Piggyback Loans

The *piggyback* loan is becoming a widely available alternative. Borrowers would like to avoid the PMI (Private Mortgage Insurance) required with loans where the borrower has a downpayment of less than 20% of the price. The piggyback allows a secondary home equity loan to be packaged with a primary loan with less than 20% downpayment. The secondary loan usually has a shorter life and higher interest rate. The interest paid on both loans are tax-deductible whereas PMI does not qualify for a tax deduction.

The following example compares a conventional fixed rate loan with 20% down as opposed to a piggyback loan: one primary fixed rate with 10% downpayment and a secondary, home equity loan for 10% of the original price. All loans have monthly payments.

The conventional loan alternative is a 30 year loan with a fixed annual rate of 7.5%. The primary loan in the piggyback loan setup is also a 30 year loan with a fixed annual rate of 7.75%. The secondary loan is a 15 year loan with a fixed annual interest rate of 8.25%.

The comparison output for the two loans comprising the piggyback loan is aggregated using the TIMESERIES procedure with a minimum of specified options:

- The INTERVAL= option requests that the data be aggregated into periods of length 5 years beginning on the 25th month, resulting in appropriately date identified periods.
- The ACC=TOTAL option specifies that the output should reflect accumulated totals as opposed to, say, averages.
- The NOTSORTED option indicates that the input data set has not been sorted by the ID variable.

See Chapter 28, “The TIMESERIES Procedure,” for more information on this procedure.

Use the following statements to analyze the conventional loan, as well as the piggyback alternative, and compare them on the basis of their present value of cost, outstanding balance, and interest payment amounts at the end of 5, 10, and 15 years into the loan life.

```
TITLE1 'LOAN: Piggyback loan example';

TITLE2 'LOAN: Conventional loan';

proc loan start=2002:1 noprint;

     fixed price=200000 dp=40000 rate=7.5 life=360
           label='20 percent down: Conventional Fixed Rate' ;

     compare at=(60 120 180) pwofcost taxrate=30 marr=12
            breakpay breakint outcomp=comploans;

run;

TITLE2 'LOAN: Piggyback: Primary Loan';

proc loan start=2002:1 noprint;

     fixed amount=160000 dp=20000 rate=7.75 life=360
           label='Piggyback: Primary loan' out=loan1;

     compare at=(60 120 180 ) pwofcost taxrate=30 marr=12
            breakpay breakint outcomp=cloan1;

run;

TITLE2 'LOAN: Piggyback: Secondary (Home Equity) Loan';

proc loan start=2002:1 noprint;

     fixed amount=20000  rate=8.25 life=180
           label='Piggyback: Secondary (Home Equity) Loan' out=loan2;

     compare at=(60 120 180 ) pwofcost taxrate=30 marr=12
            breakpay breakint  outcomp=cloan2;

run;

data cloan12;

set cloan1  cloan2;

run;

proc timeseries data=cloan12 out= totcomp ;
id date interval=year5.25 acc=total notsorted;
var payment interest pwofcost balance ;
run;

TITLE2 'LOAN: Piggyback loan';
proc print data=totcomp;
format date monyy7.;
run;
```

```
data comploans;
set comploans;
drop type label;
run;

TITLE2 'LOAN: Conventional Loan';

proc print data=comploans; run;
```

The loan comparisons in Output 18.5.1 illustrate the aftertax comparison of the loans. The after tax present value of cost for the piggyback loan is lower than the 20% down conventional fixed rate loan.

Chapter 19
The MDC Procedure

Overview

The MDC (Multinomial Discrete Choice) procedure analyzes models where the choice set consists of multiple alternatives. This procedure supports conditional logit, mixed logit, heteroscedastic extreme value, nested logit, and multinomial probit models. The MDC procedure uses the maximum likelihood (ML) or simulated maximum likelihood method for model estimation. The term *multinomial logit* is often used in the econometrics literature to refer to the *conditional logit* model of McFadden (1974). Here, the term *conditional logit* refers to McFadden's conditional logit model, and the term *multinomial logit* refers to a model that differs slightly. Schmidt and Strauss (1975) and Theil (1969) are early applications of the multinomial logit model in the econometrics literature. The main difference between McFadden's conditional logit model and the multinomial logit model is that the multinomial logit model makes the choice probabilities depend on the characteristics of the individuals only, whereas the conditional logit model considers the effects of choice attributes on choice probabilities as well.

Unordered multiple choices are observed in many settings in different areas of application. For example, choices of housing location, occupation, political party affiliation, type of automobile, and mode of transportation are all unordered multiple choices. Economics and psychology models often explain observed choices using the *random utility* function. The utility of a specific choice can be interpreted as the relative pleasure or happiness that the decision maker derives from that choice with respect to other alternatives in a finite choice set. It is assumed that the individual chooses the alternative for which the associated utility is highest. However, the utilities are not known to the analyst with certainty and are therefore treated by the analyst as random variables. When the utility function contains a random component, the individual choice behavior becomes a probabilistic process.

The random utility function of individual i for choice j can be decomposed into deterministic and stochastic components.

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where V_{ij} is a deterministic utility function, assumed to be linear in the explanatory variables, and ϵ_{ij} is an unobserved random variable that captures the factors that affect utility that are not included in V_{ij}. Different assumptions on the distribution of the errors, ϵ_{ij}, give rise to different classes of models.

The features of discrete choice models available in the MDC procedure are summarized in Table 19.1.

Table 19.1. Summary of Models Supported by PROC MDC

Model Type	**Utility Function**	**Distribution of ϵ_{ij}**
Conditional Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	IEV independent and identical
HEV	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	HEV independent and nonidentical
Nested Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	GEV correlated and identical
Mixed Logit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \xi_{ij} + \epsilon_{ij}$	IEV independent and identical
Multinomial Probit	$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$	MVN correlated and nonidentical

IEV stands for type I Extreme Value (or Gumbel) distribution with the probability density function and the cumulative distribution function of the random error given by $f(\epsilon_{ij}) = \exp(-\epsilon_{ij})\exp(-\exp(-\epsilon_{ij}))$ and $F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}))$; HEV stands for Heteroscedastic Extreme Value distribution with the probability density function and the cumulative distribution function of the random error given by $f(\epsilon_{ij}) = \frac{1}{\theta_j}\exp(\frac{\epsilon_{ij}}{\theta_j})\exp[-\exp(-\frac{\epsilon_{ij}}{\theta_j})]$ and $F(\epsilon_{ij}) = \exp[-\exp(-\frac{\epsilon_{ij}}{\theta_j})]$ where θ_j is a scale parameter for the random component of the jth alternative; GEV stands for Generalized Extreme Value distribution; MVN represents Multivariate Normal distribution; and ξ_{ij} is an error component. See the "Mixed Logit Model" section on page 961 for more information on ξ_{ij}.

Getting Started

Conditional Logit: Estimation and Prediction

The MDC procedure is similar in use to the other regression model procedures in the SAS System. However, the MDC procedure requires identification and choice variables. For example, consider a random utility function

$$U_{ij} = x_{1,ij}\beta_1 + x_{2,ij}\beta_2 + \epsilon_{ij} \quad j = 1, \ldots, 3$$

where the cumulative distribution function of the stochastic component is type I extreme value, $F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}))$. You can estimate this conditional logit model with the following statements:

```
proc mdc;
   model decision = x1 x2 / type=clogit
      choice=(mode 1 2 3);
   id pid;
run;
```

Note that the MDC procedure does not include the intercept term automatically like other regression procedures. The dependent variable decision takes the value 1 when a specific alternative is chosen; otherwise it takes the value 0. Each individual is allowed to choose one and only one of the possible alternatives. In other words, the variable decision takes the value 1 one time only for each individual. If each individual has three elements (1, 2, and 3) in the choice set, the NCHOICE=3 option can be specified instead of CHOICE=(mode 1 2 3).

Consider the following trinomial data from Daganzo (1979). The original data (origdata) contains travel time (ttime1-ttime3) and choice (choice) variables. ttime1-ttime3 are the travel times for three different modes of transportation, and choice indicates which one of the three modes is chosen. The choice variable must have integer values.

```
data origdata;

7.822   18.949  16.904  1  12.824  5.697   19.183  2
11.852  12.147  15.672  2  15.557  8.307   22.286  2
;
```

A new data set (newdata) is created since PROC MDC requires that each individual decision maker has one case for each alternative in his choice set. Note that the ID statement is required for all MDC models. In the following example, there are two public transportation modes, 1 and 2, and one private transportation mode, 3, and all individuals share the same choice set.

```
data newdata(keep=pid decision mode ttime);
   set origdata;
   array tvec{3} ttime1 - ttime3;
   retain pid 0;
   pid + 1;
```

```
      do i = 1 to 3;
         mode = i;
         ttime = tvec{i};
         decision = ( choice = i );
         output;
      end;
   run;
```

The first nine observations of the transformed data set are as follows:

```
                    Obs     pid     mode      ttime     decision

                      1       1        1     16.481         0
                      2       1        2     16.196         1
                      3       1        3     23.890         0
                      4       2        1     15.123         0
                      5       2        2     11.373         1
                      6       2        3     14.182         0
                      7       3        1     19.469         0
                      8       3        2      8.822         1
                      9       3        3     20.819         0
```

Figure 19.1. Transformed Modal Choice Data

The decision variable, decision, must have one nonzero value for each decision maker corresponding to the actual choice. When the RANK option is specified, the decision variable may contain rank data. For more details, see the "MODEL Statement" section on page 946. The following SAS statements estimate the conditional logit model using maximum likelihood:

```
   proc mdc data=newdata;
      model decision = ttime / type=clogit nchoice=3
         optmethod=qn covest=hess;
      id pid;
   run;
```

When all individuals have the same choice set, the NCHOICE= option can be used instead of the CHOICE= option. However, the NCHOICE= option is not allowed when a nested logit model is estimated. When the NCHOICE=$number$ option is specified, the choices are generated as $1, \ldots, number$. For more flexible alternatives (e.g., 1 3 6 8), you need to use the CHOICE= option. The choice variable must have integer values.

The OPTMETHOD=QN option specifies the quasi-Newton optimization technique. The covariance matrix of the parameter estimates is obtained from the Hessian matrix since COVEST=HESS is specified. You may also specify COVEST=OP or COVEST=QML. See the "MODEL Statement" section on page 946 for more details.

The MDC procedure produces a summary of model estimation displayed in Figure 19.2. Since there are multiple observations for each individual, the "Number of Cases" (150) is larger than the number of individuals, "Number of Observations"

(50). Figure 19.3 shows the frequency distribution of the three choice alternatives. In this example, mode 2 is most frequently chosen.

Figure 19.3. Choice Frequency

The MDC procedure computes nine goodness-of-fit measures for the discrete choice model. Seven of them are pseudo-R^2 measures based on the null hypothesis that all coefficients except for an intercept term are zero (Figure 19.4). McFadden's likelihood ratio index (LRI) is the smallest in value.

```

Figure 19.5. Parameter Estimate of Conditional Logit

The predicted choice probabilities are produced using the OUTPUT statement.

```
output out=probdata pred=p;
```

The parameter estimates can be used to forecast the choice probability of individuals that are not in the input data set. To do so, you need to append to the input data set extra observations whose values of the dependent variable decision are missing, since these extra observations are not supposed to be used in the estimation stage. The identification variable pid must have values that are not used in the existing observations. The output data set, probdata, contains a new variable, p, in addition to input variables in the data set, extdata.

```
data extra;
   input pid mode decision ttime;
   datalines;
51  1  .   5.0
51  2  .  15.0
51  3  .  14.0
;
data extdata;
   set newdata extra;
run;

proc mdc data=extdata;
   model decision = ttime /
         type=clogit covest=hess
         nchoice=3;
   id pid;
   output out=probdata pred=p;
run;

proc print data=probdata( where=( pid >= 49 ) );
   var mode decision p ttime;
   id pid;
run;
```

The last nine observations from the forecast data set (probdata) are displayed in Figure 19.6. It is expected that the decision maker will choose mode "1" based on predicted probabilities for all modes.

```
               pid     mode     decision        p         ttime

                49       1          0       0.46393     11.852
                49       2          1       0.41753     12.147

```

Figure 19.6. Out-Of-Sample Mode Choice Forecast

Nested Logit Modeling

A more general model can be specified using the nested logit model. Since the public transportation modes, 1 and 2, tend to be correlated, these two choices can be grouped together. The decision tree displayed in Figure 19.7 is constructed.

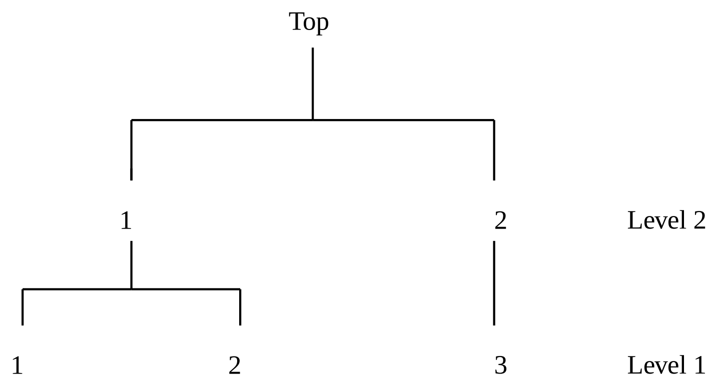

Figure 19.7. Decision Tree for Modal Choice

The two-level decision tree is specified in the NEST statement. The NCHOICE= option is not allowed for nested logit estimation. Instead, the CHOICE= option needs to be specified.

```
   proc mdc data=newdata;
      model decision = ttime / type=nlogit choice=(mode 1 2 3)
                               covest=hess;
      id pid;
      utility u(1,) = ttime;
      nest level(1) = (1 2 @ 1, 3 @ 2),
           level(2) = (1 2 @ 1);
   run;
```

In Figure 19.8, estimates of the inclusive value parameters, INC_L2G1C1 and INC_L2G1C2, are indicative of a nested model structure. See the section "Nested Logit" on page 965 and the section "Decision Tree and Nested Logit" on page 967 for more details on inclusive values.

```

```

Figure 19.9. Nested Logit Estimates with One Dissimilarity Parameter

The nested logit model is equivalent to the conditional logit model if INC_L2G1C1 = INC_L2G1C2 = 1. You can verify this relationship by estimating a constrained nested logit model. (See the "RESTRICT Statement" section on page 956 for details on imposing linear restrictions on parameter estimates.) The parameter estimates and the active linear constraints for the following constrained nested logit model are displayed in Figure 19.10.

```
   proc mdc data=newdata;
      model decision = ttime / type=nlogit
         choice=(mode 1 2 3) covest=hess;
      id pid;
      utility u(1,) = ttime;
      nest level(1) = (1 2 @ 1, 3 @ 2),
           level(2) = (1 2 @ 1);
      restrict INC_L2G1C1 = 1, INC_L2G1C2 =1;
   run;
```

```

Figure 19.10. Constrained Nested Logit Estimates

Multivariate Normal Utility Function

Consider the following random utility function:

$$U_{ij} = \text{ttime}_{ij}\beta + \epsilon_{ij}, \quad j = 1, 2, 3$$

where

$$\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \\ \epsilon_{i3} \end{bmatrix} \sim N\left(\mathbf{0}, \begin{bmatrix} 1 & \rho_{21} & 0 \\ \rho_{21} & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)$$

The correlation coefficient (ρ_{21}) between U_{i1} and U_{i2} represents common neglected attributes of public transportation modes, 1 and 2. The following SAS statements estimate this trinomial probit model:

```
proc mdc data=newdata;
   model decision = ttime / type=mprobit nchoice=3
      unitvariance=(1 2 3) covest=hess;
   id pid;
run;
```

The UNITVARIANCE=(1 2 3) option specifies that the random component of utility for each of these choices has unit variance. If the UNITVARIANCE= option is specified, it needs to include at least two choices. The results of this constrained multinomial probit model estimation are displayed in Figure 19.11 and Figure 19.12. The test for ttime = 0 is rejected at the 1% significance level.

```

Figure 19.12. Multinomial Probit Estimates with Unit Variances

HEV and Multinomial Probit: Heteroscedastic Utility Function

When the stochastic components of utility are heteroscedastic and independent, you can model the data using an HEV or a multinomial probit model. The HEV model assumes that the utility of alternative j for each individual i has heteroscedastic random components.

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where the cumulative distribution function of the Gumbel distributed ϵ_{ij} is

$$F(\epsilon_{ij}) = \exp(-\exp(-\epsilon_{ij}/\theta_j))$$

Note that the variance of ϵ_{ij} is $\frac{1}{6}\pi^2\theta_j^2$. Therefore, the error variance is proportional to the square of the scale parameter θ_j. For model identification, at least one of the scale parameters must be normalized to 1. The following SAS statements estimate an HEV model under a unit scale restriction for mode "1" ($\theta_1 = 1$):

```
proc mdc data=newdata;
   model decision = ttime / type=hev nchoice=3
      hev=(unitscale=1, integrate=laguerre)
      covest=hess;
   id pid;
run;
```

```

Figure 19.14. HEV Parameter Estimates

Note that the estimate of the HEV model is not always stable since computation of the log-likelihood function requires numerical integration. Bhat (1995) proposed the Gauss-Laguerre method. In general, the log-likelihood function value of HEV should be larger than that of conditional logit since HEV models include the conditional logit as a special case, but in this example the reverse is true (-33.414 for the HEV model, which is less than -33.321 for the conditional logit model). See Figure 19.13 and Figure 19.2. This indicates that the Gauss-Laguerre approximation to the true probability is too coarse. You can see how well the Gauss-Laguerre method works by specifying a unit scale restriction for all modes, since the HEV model with the unit variance for all modes reduces to the conditional logit model.

```
proc mdc data=newdata;
   model decision = ttime / type=hev nchoice=3
         hev=(unitscale=1 2 3, integrate=laguerre) covest=hess;
   id pid;
run;
```

Figure 19.15 shows that the ttime coefficient is not close to that of the conditional logit model.

    ttime          1      -0.2926          0.0438      -6.68      <.0001
```

Figure 19.15. HEV Estimates with All Unit Scale Parameters

There is another option of specifying the integration method. The INTEGRATE=HARDY option uses the adaptive Romberg-type integration method. The adaptive integration produces much more accurate probability and log-likelihood function values, but often, it is not practical to use this method for analysis of the HEV model since it requires excessive CPU time. The following SAS statements produce the HEV estimates using the adaptive Romberg-type integration method. The results are displayed in Figure 19.16 and Figure 19.17.

```
proc mdc data=newdata;
   model decision = ttime / type=hev nchoice=3
      hev=(unitscale=1, integrate=hardy) covest=hess;
   id pid;
run;
```

```

Figure 19.18. Alternative HEV Estimates with Unit Scale Restrictions

For comparison, we estimate a heteroscedastic multinomial probit model by imposing a zero restriction on the correlation parameter, $\rho_{31} = 0$. The MDC procedure requires normalization of at least two of the error variances in the multinomial probit model. Also, for identification, the correlation parameters associated with a unit normalized variance are restricted to be zero. When the UNITVARIANCE= option is specified, the zero restriction on correlation coefficients applies to the last choice of the list. In the following example, the variances of the first and second choices are normalized. The UNITVARIANCE=(1 2) option imposes additional restrictions that $\rho_{32} = \rho_{21} = 0$. The default for the UNITVARIANCE= option is the last two choices (which would have been equivalent to UNITVARIANCE=(2 3) for this example).

The utility function can be defined as

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where

$$\boldsymbol{\epsilon}_i \sim N\left(\mathbf{0}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \sigma_3^2 \end{bmatrix}\right)$$

```
proc mdc data=newdata;
   model decision = ttime / type=mprobit nchoice=3
                            unitvariance=(1 2) covest=hess;
   id pid;
   restrict RHO_31 = 0;
run;
```

Figure 19.19. Heteroscedastic Multinomial Probit Estimates

Parameter Heterogeneity: Mixed Logit

One way of modeling unobserved heterogeneity across individuals in their sensitivity to observed exogenous variables is to use the mixed logit model with a random parameters or random coefficients specification. The probability of choosing alternative j is written

$$P_i(j) = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k=1}^{J} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}$$

where $\boldsymbol{\beta}$ is a vector of coefficients that varies across individuals, and $\mathbf{x}_{ij}$ is a vector of exogenous attributes.

For example, you can specify the distribution of the parameter β to be the normal distribution.

The mixed logit model uses a Monte Carlo simulation method to estimate the probabilities of choice. There are two simulation methods available. When the RANDNUM=PSEUDO option is given in the MODEL statement, pseudo-random numbers are generated, while the RANDNUM=HALTON option uses Halton quasi-random sequences. The default value is RANDNUM=HALTON.

You can estimate the model with normally distributed random coefficients of ttime with the following SAS statements:

```
proc mdc data=newdata type=mixedlogit;
   model decision = ttime / nchoice=3
         mixed=(normalparm=ttime);
   id pid;
run;
```

Let β^m and β^s be mean and scale parameters for the random coefficient, β. The relevant utility function is

$$U_{ij} = \text{ttime}_{ij}\beta + \epsilon_{ij}$$

where $\beta = \beta^m + \beta^s\eta$. β^m and β^s are fixed mean and scale parameters. The stochastic component, η, is assumed to be standard normal since the NORMALPARM= option is given. Alternatively, the UNIFORMPARM= or LOGNORMALPARM= option can be specified. The LOGNORMALPARM= option is useful when nonnegative parameters are being estimated. The NORMALPARM=, UNIFORMPARM=, and LOGNORMALPARM= variables must be included on the right-hand-side of the MODEL statement. See the "Mixed Logit Model" section on page 961 for more details. To estimate a mixed logit model using the transportation mode choice data, the MDC procedure requires the MIXED= option for random components. Results of the mixed logit estimation are displayed in Figure 19.20.

```

Syntax

The MDC procedure is controlled by the following statements:

PROC MDC *options* **;**
  BOUNDS *bound1 [, bound2 . . .]* **;**
  BY *variables* **;**
  ID *variable* **;**
  MODEL *dependent variables = regressors / options* **;**
  NEST *LEVEL(value) = ((values)@(value),. . ., (values)@(value))* **;**
  NLOPTIONS *options* **;**
  OUTPUT *options* **;**
  RESTRICT *restriction1 [, restriction2 . . .]* **;**
  UTILITY *U() = variables, . . ., U() = variables* **;**

Functional Summary

The statements and options used with the MDC procedure are summarized in the following table:

Description	Statement	Option
Data Set Options		
specify the input data set	MDC	DATA=
write parameter estimates to an output data set	MDC	OUTEST=
include covariances in the OUTEST= data set	MDC	COVOUT
write linear predictors and predicted probabilities to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify the ID variable	ID	
specify BY-group processing variables	BY	

Description	**Statement**	**Option**
Printing Control Options		
request all printing options	MODEL	ALL
display correlation matrix of the estimates	MODEL	CORRB
display covariance matrix of the estimates	MODEL	COVB
Model Estimation Options		
specify the choice variables	MODEL	CHOICE=()
specify the convergence criterion	MODEL	CONVERGE=
specify the type of covariance matrix	MODEL	COVEST=
specify the starting point of the Halton sequence	MODEL	HALTONSTART=
specify options specific to the HEV model	MODEL	HEV=()
set the initial values of parameters used by the iterative optimization algorithm	MODEL	INITIAL=()
specify the maximum number of iterations	MODEL	MAXITER=
specify the options specific to mixed logit	MODEL	MIXED=()
specify the number of choices for each person	MODEL	NCHOICE=
specify the number of simulations	MODEL	NSIMUL=
specify the optimization technique	MODEL	OPTMETHOD=
specify the type of random number generators	MODEL	RANDNUM=
specify that initial values are generated using random numbers	MODEL	RANDINIT
specify the rank dependent variable	MODEL	RANK
specify optimization restart options	MODEL	RESTART=()
specify a restriction on inclusive parameters	MODEL	SAMESCALE
specify a seed for pseudo-random number generation	MODEL	SEED=
specify a stated preference data restriction on inclusive parameters	MODEL	SPSCALE
specify the type of the model	MODEL	TYPE=
specify normalization restrictions on multinomial probit error variances	MODEL	UNITVARIANCE=()
NESTED Logit Related Options		
specify the tree structure	NEST	LEVEL()=
specify the type of utility function	UTILITY	U()=
Output Control Options		
output predicted values	OUTPUT	P=
output estimated linear predictor	OUTPUT	XBETA=

PROC MDC Statement

PROC MDC *options* **;**

The following options can be used in the PROC MDC statement.

DATA= *SAS-data-set*

specifies the input SAS data set. If the DATA= option is not specified, PROC MDC uses the most recently created SAS data set.

OUTEST= *SAS-data-set*

names the SAS data set that the parameter estimates are written to. See “OUTEST= Data Set” later in this chapter for information on the contents of this data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

In addition, any of the following MODEL statement options can be specified in the PROC MDC statement, which is equivalent to specifying the option for the MODEL statement: ALL, CONVERGE=, CORRB, COVB, COVEST=, HALTONSTART=, ITPRINT, MAXITER=, NOPRINT, NSIMUL=, OPTMETHOD=, RANDINIT, RANK, RESTART=, SAMESCALE, SEED=, SPSCALE, TYPE=, and UNITVARIANCE=.

BOUNDS Statement

BOUNDS *bound1 [, bound2 ...]* **;**

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the MDC procedure. You can specify any number of BOUNDS statements.

Each *bound* is composed of variables, constants, and inequality operators:

item operator item [operator item [operator item . . .]]

Each *item* is a constant, the name of a regressor variable, or a list of regressor names. Each *operator* is ’<’, ’>’, ’<=’, or ’>=’.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the “RESTRICT Statement” section on page 956 as well.

Lagrange multipliers are reported for all the active boundary constraints. In the displayed output, the Lagrange multiplier estimates are identified with the names Restrict1, Restrict2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive, or nonbinding, bounds have no effect on the estimation results and are not noted in the output.

The following BOUNDS statement constrains the estimates of the coefficient of ttime to be negative and the coefficients of x1 through x10 to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds ttime < 0,
       0 < x1-x10 < 1;
```

BY Statement

BY *variables* **;**

A BY statement can be used with PROC MDC to obtain separate analyses on observations in groups defined by the BY variables.

ID Statement

ID *variable* **;**

The ID statement must be used with PROC MDC to specify the identification variable that controls multiple choice-specific cases. The MDC procedure requires only one ID statement even with multiple MODEL statements.

MODEL Statement

MODEL *dependent = regressors / options ;*

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. When the nested logit model is estimated, regressors in the UTILITY statement are used for estimation.

The following options can be used in the MODEL statement after a slash (/).

CHOICE= (*variables***)**
CHOICE=(*variable numbers***)**
specifies the variables that contain possible choices for each individual. Choice variables must have integer values. Multiple choice variables are only allowed for nested logit models. If all possible alternatives are written with the variable name, the MDC procedure checks all values of the choice variable. The CHOICE=(X 1 2 3) specification implies that the value of X should be 1, 2, or 3. On the other hand, the CHOICE=(X) specification considers all distinctive nonmissing values of X as elements of the choice set.

CONVERGE= *number*
specifies the convergence criterion. The CONVERGE= option is the same as the ABSGCONV= option in the NLOPTIONS statement. The ABSGCONV= option in the NLOPTIONS statement overrides the CONVERGE= option. The default value is 1E-5.

HALTONSTART= *number*

specifies the starting point of the Halton sequence. The specified number must be a positive integer. The default is HALTONSTART=11.

HEV= (*option-list***)**

specifies options that are used to estimate the HEV model. The HEV model with a unit scale for the alternative 1 is estimated using the following SAS statements:

```
model y = x1 x2 x3 / hev=(unitscale=1);
```

The following options can be used in the HEV=() option. These options are listed within parentheses and separated by commas.

INTORDER= *number*

specifies the number of summation terms for Gaussian quadrature integration. The default is INTORDER=40. The maximum order is limited to 45. This option applies only to the INTEGRATION=LAGUERRE method.

UNITSCALE= *number-list*

specifies restrictions on scale parameters of stochastic utility components.

INTEGRATE= LAGUERRE | HARDY

specifies the integration method. The INTEGRATE=HARDY option specifies an adaptive integration method, while the INTEGRATE=LAGUERRE option specifies the Gauss-Laguerre approximation method. The default is INTEGRATE=LAGUERRE.

MIXED= (*option-list***)**

specifies options that are used for mixed logit estimation. The mixed logit model with normally distributed random parameters is specified as follows:

```
model y = x1 x2 x3 / mixed=(normalparm=x1);
```

The following options can be used in the MIXED=() option. The options are listed within parentheses and separated by commas.

LOGNORMALPARM= *variables*

specifies the variables whose random coefficients are log-normally distributed. LOGNORMALPARM= variables must be included on the right-hand side of the MODEL statement.

NORMALEC= *variables*

specifies the error component variables whose coefficients have a normal distribution $N(0, \sigma^2)$.

NORMALPARM= *variables*

specifies the variables whose random coefficients are normally distributed. NORMALPARM= variables must be included on the right-hand side of the MODEL statement.

UNIFORMEC= *variables*

specifies the error component variables whose coefficients have a uniform distribution $U(-\sqrt{3}\sigma, \sqrt{3}\sigma)$.

UNIFORMPARM= *variables*

specifies the variables whose random coefficients are uniformly distributed. UNIFORMPARM= variables must be included on the right-hand side of the MODEL statement.

NCHOICE= *number*

specifies the number of choices for multinomial choice models when all individuals have the same choice set. The NCHOICE= and CHOICE= options must not be used simultaneously, and the NCHOICE= option cannot be used for nested logit models.

NSIMUL= *number*

specifies the number of simulations when the mixed logit or multinomial probit model is estimated. The default is NSIMUL=100. In general, you need a smaller number of simulations with RANDNUM=HALTON than with RANDNUM=PSEUDO.

RANDNUM= *value*

specifies the type of the random number generator used for simulation. RANDNUM=HALTON is the default. The following option values are allowed:

PSEUDO	specifies pseudo-random number generation
HALTON	specifies Halton sequence generation

RANDINIT
RANDINIT= *number*

specifies that initial parameter values are perturbed by uniform pseudo-random numbers for numerical optimization of the objective function. The default is $U(-1, 1)$. When the RANDINIT=r option is specified, $U(-r, r)$ pseudo-random numbers are generated. The value r should be positive. With a RANDINIT or RANDINIT= option, there are pure random searches for a given number of trials (1000 for conditional or nested logit, and 500 for other models) to get a maximum (or minimum) value of the objective function. For example, when there is a parameter estimate with an initial value of 1, the RANDINIT option will add a generated random number u to the initial value and compute an objective function value using $1 + u$. This option is helpful in finding the initial value automatically if there is no guidance in setting the initial estimate.

RANK

specifies that the dependent variable contains ranks. The numbers must be positive integers starting from 1. When the dependent variable has value 1, the corresponding alternative is chosen. This option is provided only as a convenience to the user: the extra information contained in the ranks is not currently used for estimation purposes.

RESTART=(*option-list*)

specifies options that are used for reiteration of the optimization problem. When the ADDRANDOM option is specified, the initial value of reiteration is computed using random grid searches around the initial solution.

```
   model y = x1 x2 / type=clogit
      restart=(addvalue=(.01 .01));
```

The preceding SAS statement reestimates a conditional logit model by adding ADDVALUE= values. If the ADDVALUE= option contains missing values, the restart option uses the corresponding estimate from the initial stage. If no ADDVALUE= value is specified for an estimate, a default value equal to (|estimate| * 1e-3) is added to the corresponding estimate from the initial stage. If both the ADDVALUE= and ADDRANDOM(=) options are specified, ADDVALUE= is ignored.

The following options can be used in the RESTART=() option. The options are listed within parentheses.

ADDMAXIT= *number*

specifies the maximum number of iterations for the second stage of the estimation. The default is ADDMAXIT=100.

ADDRANDOM

ADDRANDOM= *value*

specifies random added values to the estimates from the initial stage. With the ADDRANDOM option, $U(-1, 1)$ random numbers are created and added to the estimates obtained in the initial stage. When the ADDRANDOM=r option is specified, $U(-r, r)$ random numbers are generated. The restart initial value is determined based on the given number of random searches (1000 for conditional or nested logit, and 500 for other models).

ADDVALUE= (*value-list*)

specifies values added to the estimates from the initial stage. A missing value in the list is considered as a zero value for the corresponding estimate. When the ADDVALUE= option is not specified, default values equal to (|estimate| * 1e-3) are added.

SAMESCALE

specifies that the parameters of the inclusive values are the same within a group at each level when nested logit is estimated.

SEED= *number*

specifies an initial seed for pseudo-random number generation. The SEED= value must be less than $2^{31} - 1$. If the SEED= value is negative or zero, the time of day from the computer's clock is used to obtain the initial seed. The default is SEED=0.

SPSCALE

specifies that the parameters of the inclusive values are the same for any choice with only one nested choice within a group, for each level in a nested logit model. This option is useful in analyzing stated preference data.

TYPE= *value*

specifies the type of model to be analyzed. The supported model types are

CONDITIONLOGIT | CLOGIT | CL	specifies a conditional logit model
HEV	specifies a heteroscedastic extreme value model
MIXEDLOGIT | MXL	specifies a mixed logit model
MULTINOMPROBIT | MPROBIT | MP	specifies a multinomial probit model
NESTEDLOGIT | NLOGIT | NL	specifies a nested logit model

UNITVARIANCE= (*number-list***)**

specifies normalization restrictions on error variances of multinomial probit for the choices whose numbers are given in the list. If the UNITVARIANCE= option is specified, it must include at least two choices. Also, for identification, additional zero restrictions are placed on the correlation coefficients for the last choice in the list.

Printing Options

ALL

requests all printing options.

COVB

displays the estimated covariances of the parameter estimates.

CORRB

displays the estimated correlation matrix of the parameter estimates.

COVEST= *value*

The COVEST= option specifies the type of covariance matrix. Possible values are OP, HESSIAN, and QML. When COVEST=OP is specified, the outer product matrix is used to compute the covariance matrix of the parameter estimates. The COVEST=HESSIAN option produces the covariance matrix using the inverse Hessian matrix. The quasi-maximum likelihood estimates are computed with COVEST=QML. The default is COVEST=HESSIAN when the Newton-Raphson method is used. COVEST=OP is the default when the OPTMETHOD=QN option is specified. The supported covariance types are

OP	specifies the covariance from the outer product matrix
HESSIAN	specifies the covariance from the Hessian matrix
QML	specifies the covariance from the outer product and Hessian matrices

ITPRINT
displays the initial parameter estimates, convergence criteria, and constraints of the optimization. At each iteration, objective function value, maximum absolute gradient element, step size, and slope of search direction are printed as well. The objective function is the full negative log-likelihood function for the maximum likelihood method. When the ITPRINT option is specified in the presence of the NLOPTIONS statement, all printing options in the NLOPTIONS statement are ignored.

NOPRINT
suppresses all displayed output.

Estimation Control Options

You can also specify detailed optimization options in the NLOPTIONS statement. The OPTMETHOD= option overrides the TECHNIQUE= option in the NLOPTIONS statement. Note that the NLOPTIONS statement is ignored if the OPTMETHOD= option is specified.

INITIAL= *(initial-values)*
START= *(initial-values)*
specifies initial values for some or all of the parameter estimates. The values specified are assigned to model parameters in the same order as the parameter estimates are displayed in the MDC procedure output.

When you use the INITIAL= option, the initial values in the INITIAL= option must satisfy the restrictions specified for the parameter estimates. If they do not, the initial values you specify are adjusted to satisfy the restrictions.

MAXITER= *number*
sets the maximum number of iterations allowed. The MAXITER= option overrides the MAXITER= option in the NLOPTIONS statement. The default is MAXITER=100.

OPTMETHOD= *value*
The OPTMETHOD= option specifies the optimization technique when the estimation method uses nonlinear optimization.

QN	specifies the quasi-Newton method
NR	specifies the Newton-Raphson method
TR	specifies the trust region method

The OPTMETHOD=NR option is the same as the TECHNIQUE=NEWRAP option in the NLOPTIONS statement. For the conditional and nested logit models the default is OPTMETHOD=NR. For other models OPTMETHOD=QN is the default.

NEST Statement

NEST *LEVEL(level number)= (choices@choice, . . .)* **;**

The NEST statement is used when one choice variable contains all possible alternatives and the TYPE=NLOGIT option is specified. The decision tree is constructed based on the NEST statement. When the choice set is specified using multiple CHOICE= variables in the MODEL statement, the NEST statement is ignored.

Consider the following eight choices that are nested in a three-level tree structure.

```
Level 1     Level 2     Level 3    top
   1           1           1        1
   2           1           1        1
   3           1           1        1
   4           2           1        1
   5           2           1        1
   6           2           1        1
   7           3           2        1
   8           3           2        1
```

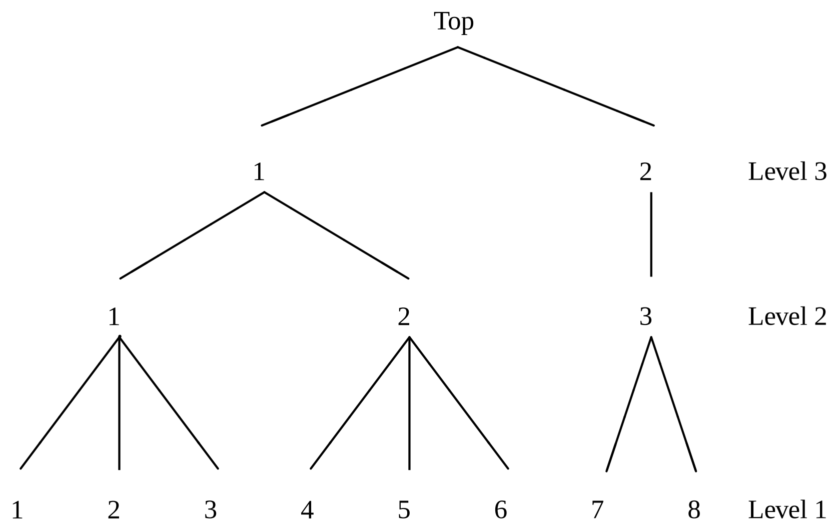

Figure 19.21. Three-Level Tree

You can use the NEST statement to specify the tree structure displayed in Figure 19.21.

```
nest level(1) = (1 2 3 @ 1, 4 5 6 @ 2, 7 8 @ 3),
     level(2) = (1 2 @ 1, 3 @ 2),
     level(3) = (1 2 @ 1);
```

Note that the decision tree is constructed based on the sequence of first-level choice set specification. Therefore, specifying another order at Level 1 builds a different tree. The following NEST statement builds the tree displayed in Figure 19.22.

```
nest level(1) = (4 5 6 @ 2, 1 2 3 @ 1, 7 8 @ 3),
     level(2) = (1 2 @ 1, 3 @ 2),
     level(3) = (1 2 @ 1);
```

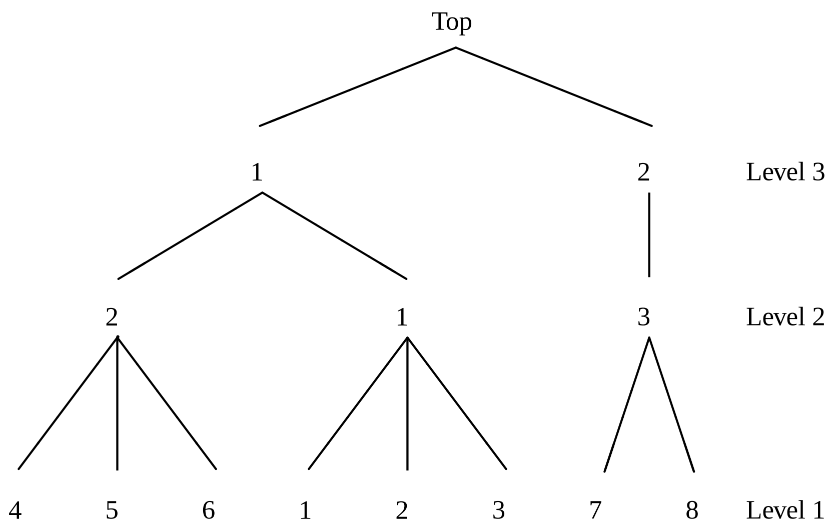

Figure 19.22. Alternative Three-Level Tree

However, the SAS statement with a different sequence of choice specification at higher levels builds the same tree as displayed in Figure 19.21 if the sequence at the first level is the same.

```
   nest level(1) = (1 2 3 @ 1, 4 5 6 @ 2, 7 8 @ 3),
        level(2) = (3 @ 2, 1 2 @ 1),
        level(3) = (1 2 @ 1);
```

The following specifications are equivalent:

```
   nest level(2) = (3 @ 2, 1 2 @ 1)

   nest level(2) = (3 @ 2, 1 @ 1, 2 @ 1)

   nest level(2) = (1 @ 1, 2 @ 1, 3 @ 2)
```

Since the MDC procedure contains multiple cases for each individual, it is important to keep data sequence in proper order. Consider the four-choice multinomial model with one explanatory variable cost.

```
   pid   choice  y   cost
    1      1     1    10
    1      2     0    25
    1      3     0    20
    1      4     0    30
    2      1     0    15
    2      2     0    22
    2      3     1    16
    2      4     0    25
```

The order of data needs to correspond to the value of choice. Therefore, the following data set is equivalent to the preceding data.

```
pid   choice  y   cost
 1      2     0    25
 1      3     0    20
 1      1     1    10
 1      4     0    30
 2      3     1    16
 2      4     0    25
 2      1     0    15
 2      2     0    22
```

The two-level nested model is estimated with a NEST statement.

```
proc mdc data=one type=nlogit;
     model y = cost / choice=(choice);
     id pid;
     utility(1,) = cost;
     nest level(1) = (1 2 3 @ 1, 4 @ 2),
          level(2) = (1 2 @ 1);
```

The tree is constructed as in Figure 19.23.

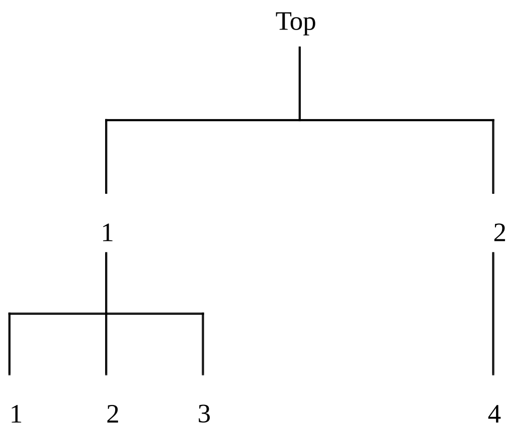

Figure 19.23. Two-Level Tree

Of course, another model is estimated if you specify the decision tree as in Figure 19.24. The different nested tree structure is specified in the following SAS statement:

```
proc mdc data=one type=nlogit;
     model y = cost / choice=(choice);
     id pid;
     utility u(1,) = cost;
     nest level(1) = (1 @ 1, 2 3 4 @ 2),
          level(2) = (1 2 @ 1);
```

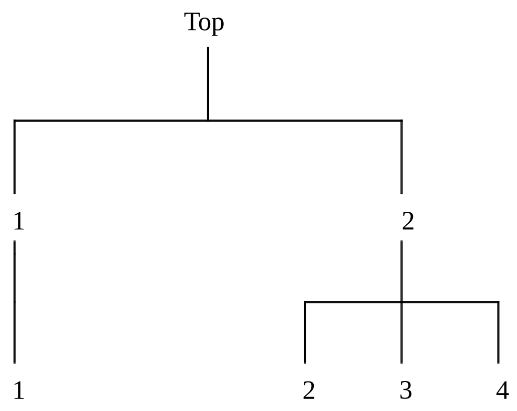

Figure 19.24. Two-Level Tree

NLOPTIONS Statement

NLOPTIONS *options* **;**

PROC MDC uses the NonLinear Optimization (NLO) subsystem to perform nonlinear optimization tasks. The NLOPTIONS statement specifies nonlinear optimization options. The NLOPTIONS statement must follow the MODEL statement. For a list of all the options of the NLOPTIONS statement, see Chapter 10, "Nonlinear Optimization Methods."

OUTPUT Statement

OUTPUT *options* **;**

The MDC procedure supports the OUTPUT statement. The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors (XBETA) and predicted probabilities (P). The input data set must be sorted by the choice variable(s) within each ID.

OUT= *SAS-data-set*
specifies the name of the output data set.

PRED= *variable name*
P= *variable name*
requests the predicted probabilities by naming the variable that contains the predicted probabilities in the output data set.

XBETA= *variable name*
names the variable that contains the linear predictor ($\mathbf{x}'\boldsymbol{\beta}$) values. However, the XBETA= option is not supported in the nested logit model.

RESTRICT Statement

RESTRICT *restriction1 [, restriction2 ...]* **;**

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <= , or >=.

Restriction expressions can be composed of variable names, times ($*$) and plus ($+$) operators, and constants. Variables named in restriction expressions must be among the variables estimated by the model. The restriction expressions must be a linear function of the variables.

Lagrange multipliers are reported for all the active linear constraints. In the displayed output, the Lagrange multiplier estimates are identified with the names Restrict1, Restrict2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994).

The following is an example of the use of the RESTRICT statement:

```
proc mdc data=one;
model y = x1-x10 /  type=clogit
   choice=(mode 1 2 3);
id pid;
restrict x1*2 <= x2 + x3;
run;
```

UTILITY Statement

UTILITY *U(level, <choices>)= variables ;*

The UTILITY statement can be used in estimating a nested logit model. The U()= option can have two arguments. The first argument contains level information while the second argument is related to choice information. The second argument can be omitted for the first level when all the choices at the first level share the same variables. The UTILITY statement specifies a utility function while the NEST statement constructs the decision tree.

Consider a two-level nested logit model that has one explanatory variable at level 1. This model can be specified as

```
proc mdc data=one type=nlogit;
     model y = cost / choice=(choice);
     id pid;
     utility u(1,2 3 4) = cost;
     nest level(1) = (1 @ 1, 2 3 4 @ 2),
          level(2) = (1 2 @ 1);
```

Of course, you also can specify

```
   utility u(1,) = cost;
```

since all the variables at the first level share the same explanatory variable, cost. The variable, cost, should be listed in the MODEL statement. When the additional explanatory variable, dummy, is included at level 2, another U()= option needs to be specified. Note that the U()= option must specify choices within any level above the first. Thus, it is specified as U(2, 1 2) below.

```
   proc mdc data=one type=nlogit;
        model y = cost dummy/ choice=(choice);
        id pid;
        utility u(1,) = cost,
                u(2,1 2) = dummy;
        nest level(1) = (1 @ 1, 2 3 4 @ 2),
             level(2) = (1 2 @ 1);
```

Details

Multinomial Discrete Choice Modeling

When the dependent variable takes multiple discrete values, you can use multinomial discrete choice modeling to analyze the data. We consider models for unordered multinomial data. Let the random utility function be defined by

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where the subscript i is an index for the individual, the subscript j is an index for the alternative, V_{ij} is a nonstochastic utility function, and ϵ_{ij} is a random component, or error, which captures unobserved characteristics of alternatives and/or individuals. In multinomial discrete choice models, the utility function is assumed to be linear, so that $V_{ij} = \mathbf{x}_{ij}'\boldsymbol{\beta}$. In the conditional logit model, each ϵ_{ij} for all $j \in C_i$ is distributed independently and identically (iid) with the type I extreme value distribution, $\exp(-\exp(-\epsilon_{ij}))$, also known as the Gumbel distribution. The iid assumption on the random components of the utilities of the different alternatives can be relaxed to overcome the well-known and restrictive *Independence from Irrelevant Alternatives* (IIA) property of the conditional logit model. This allows for more flexible substitution patterns among alternatives than the one imposed by the conditional logit model. See the section "Independence from Irrelevant Alternatives (IIA)" on page 960. The nested logit model is derived by allowing the random components to be identical but nonindependent. Instead of independent type I extreme value errors, the errors are assumed to have a generalized extreme value distribution. This model generalizes the conditional logit model to allow for particular patterns of correlation in unobserved utility (McFadden 1978). Another generalization of the conditional logit model, the heteroscedastic extreme value (HEV) model, is obtained by allowing independent but nonidentical errors distributed with a type I extreme value distribution (Bhat 1995). It permits different variances on the random components of utility across the alternatives. Mixed logit models are also generalizations of the conditional logit model that can represent very general patterns of substitution among alternatives. See the “Mixed Logit Model” section on page 961 for details. The multinomial probit (MNP) model is derived when the errors, $(\epsilon_{i1}, \epsilon_{i2}, \cdots, \epsilon_{iJ})$, have a multivariate normal (MVN) distribution. Thus, this model accommodates a very general error structure.

The multinomial probit model requires burdensome computation compared to a family of multinomial choice models derived from the Gumbel distributed utility function, since it involves multi-dimensional integration (with dimension $J - 1$) in the estimation process. In addition, the multinomial probit model requires more parameters than other multinomial choice models. As a result, conditional and nested logit models are used more frequently, even though they are derived from a utility function whose random component is more restrictively defined than the multinomial probit model.

The event of a choice being made, $\{y_i = j\}$, can be expressed using a random utility function as follows:

$$U_{ij} \geq \mathbf{max}_{k \in C_i, k \neq j} U_{ik}$$

where C_i is the choice set of individual i. Individual i chooses alternative j if and only if it provides a level of utility that is greater than or equal to that of any other alternative in his choice set. Then, the probability that individual i chooses alternative j (from among the n_i choices in his choice set C_i) is

$$P_i(j) = P_{ij} = P[\mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij} \geq \mathbf{max}_{k \in C_i}(\mathbf{x}'_{ik}\boldsymbol{\beta} + \epsilon_{ik})] \tag{19.1}$$

Multinomial Logit and Conditional Logit

When explanatory variables contain only individual characteristics, the multinomial logit model is defined as

$$P(y_i = j) = P_{ij} = \frac{\exp(\mathbf{x}'_i\boldsymbol{\beta}_j)}{\sum_{k=0}^{J} \exp(\mathbf{x}'_i\boldsymbol{\beta}_k)} \quad \text{for } j = 0, \cdots, J$$

where y_i is a random variable that indicates the choice made, x_i is a vector of characteristics specific to the ith individual, and $\boldsymbol{\beta}_j$ is a vector of coefficients specific to the jth alternative. Thus, this model involves choice specific coefficients and only individual specific regressors. For model identification, one often assumes that $\boldsymbol{\beta}_0 = 0$. The multinomial logit model reduces to the binary logit model if $J = 1$.

The ratio of the choice probabilities for alternatives j and l, or the *odds ratio* of alternatives j and l, is

$$\frac{P_{ij}}{P_{il}} = \frac{\exp(\mathbf{x}'_i\boldsymbol{\beta}_j)/\sum_{k=0}^{J}\exp(\mathbf{x}'_i\boldsymbol{\beta}_k)}{\exp(\mathbf{x}'_i\boldsymbol{\beta}_l)/\sum_{k=0}^{J}\exp(\mathbf{x}'_i\boldsymbol{\beta}_k)} = \exp[\mathbf{x}'_i(\boldsymbol{\beta}_j - \boldsymbol{\beta}_l)]$$

Note that the odds ratio of alternatives j and l does not depend on any alternatives other than j and l. For more on this, see the section "Independence from Irrelevant Alternatives (IIA)" on page 960.

The log-likelihood function of the multinomial logit model is

$$\mathcal{L} = \sum_{i=1}^{N} \sum_{j=0}^{J} d_{ij} \ln P(y_i = j)$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

This type of multinomial choice modeling has a couple of weaknesses: it has too many parameters (the number of individual characteristics times J) and it is difficult to interpret. The multinomial logit model can be used to predict the choice probabilities, among a given set of $J+1$ alternatives, of an individual with known vector of characteristics $\mathbf{x}_i$.

The parameters of the multinomial logit model can be estimated with the TYPE=CLOGIT option in the MODEL statement; however, this requires modification of the conditional logit model to allow individual specific effects.

The conditional logit model, sometimes also called the multinomial logit model, is similarly defined when choice specific data are available. Using properties of type I extreme value (or Gumbel) distribution, the probability that individual i chooses alternative j from among the choices in his choice set C_i is

$$P(y_i = j) = P_{ij} = P[\mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij} \geq \max_{k \in C_i, k \neq j}(\mathbf{x}'_{ik}\boldsymbol{\beta} + \epsilon_{ik})] = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k \in C_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}$$

where $\mathbf{x}_{ij}$ is a vector of attributes specific to the jth alternative as perceived by the ith individual. It is assumed that there are n_i choices in each individual's choice set, C_i.

The log-likelihood function of the conditional logit model is

$$\mathcal{L} = \sum_{i=1}^{N} \sum_{j \in C_i} d_{ij} \ln P(y_i = j)$$

The conditional logit model can be used to predict the probability that an individual will choose a previously unavailable alternative, given knowledge of $\boldsymbol{\beta}$ and the vector $\mathbf{x}_{ij}$ of choice specific characteristics.

Independence from Irrelevant Alternatives (IIA)

The problematic aspect of the conditional logit (and the multinomial logit) model lies in the property of independence from irrelevant alternatives (IIA). The IIA property can be derived from the probability ratio of any two choices. For the conditional logit model,

$$\frac{P_{ij}}{P_{il}} = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})/\sum_{k\in C_i}\exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}{\exp(\mathbf{x}'_{il}\boldsymbol{\beta})/\sum_{k\in C_i}\exp(\mathbf{x}'_{ik}\boldsymbol{\beta})} = \exp[(\mathbf{x}_{ij}-\mathbf{x}_{il})'\boldsymbol{\beta}]$$

It is evident that the ratio of the probabilities for alternatives j and l does not depend on any alternatives other than j and l. This was also shown to be the case for the multinomial logit model. Thus, for the conditional and multinomial logit models, the ratio of probabilities of any two alternatives is necessarily the same regardless of what other alternatives are in the choice set or what the characteristics of the other alternatives are. This is referred to as the IIA property.

The IIA property is useful from the point of view of estimation and forecasting. For example, it allows the prediction of demand for currently unavailable alternatives. If the IIA property is appropriate for the choice situation being considered, then estimation can be based on the set of currently available alternatives and then the estimated model can be used to calculate the probability that an individual would choose a new alternative not considered in the estimation procedure. However, the IIA property is restrictive from the point of view of choice behavior. Models that display the IIA property predict that a change in the attributes of one alternative changes the probabilities of the other alternatives proportionately such that the ratios of probabilities remain constant. Thus, cross elasticities due to a change in the attributes of an alternative j are equal for all alternatives $k \neq j$. This particular substitution pattern might be too restrictive in some choice settings.

The IIA property of the conditional logit model follows from the assumption that the random components of utility are identically and independently distributed. The other models in PROC MDC, namely, nested logit, HEV, mixed logit, and multinomial probit, relax the IIA property in different ways.

Heteroscedastic Extreme Value Model

The heteroscedastic extreme value (HEV) model (Bhat 1995) allows the random components of the utility function to be nonidentical. Specifically, the HEV model assumes independent but nonidentical error terms distributed with the type I extreme value distribution. The HEV model allows the variances of the random components of utility to differ across alternatives. Bhat (1995) argues that the HEV model does not have the IIA property. The HEV model contains the conditional logit model as a special case. The probability that an individual i will choose alternative j from the set C_i of available alternatives is

$$P_i(j) = \int_{-\infty}^{\infty} \prod_{k\in C_i, k\neq j} \Gamma\left[\frac{\mathbf{x}'_{ij}\boldsymbol{\beta} - \mathbf{x}'_{ik}\boldsymbol{\beta} + \theta_j w}{\theta_k}\right]\gamma(w)dw$$

where the choice set C_i has n_i elements and

$$\Gamma(x) = \exp(-\exp(-x))$$

$$\gamma(x) = \exp(-x)\Gamma(x)$$

are the cumulative distribution function and probability density function of the type I extreme value distribution. The variance of the error term for the jth alternative is $\frac{1}{6}\pi^2\theta_j^2$. If the scale parameters, θ_j, of the random components of utility of all alternatives are equal, then this choice probability is the same as that of the conditional logit model. The log-likelihood function of the HEV model can be written as

$$\mathcal{L} = \sum_{i=1}^{N} \sum_{j \in C_i} d_{ij} \ln[P_i(j)]$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

Since the log-likelihood function contains an improper integral function, it is computationally difficult to get a stable estimate. With the transformation $u = \exp(-w)$, the probability can be written

$$\begin{aligned} P_i(j) &= \int_0^\infty \Pi_{k \in C_i, k \neq j} \Gamma \left[\frac{\mathbf{x}'_{ij}\boldsymbol{\beta} - \mathbf{x}'_{ik}\boldsymbol{\beta} - \theta_j \ln(u)}{\theta_k} \right] \exp(-u)du \\ &= \int_0^\infty G_{ij}(u) \exp(-u)du \end{aligned}$$

Using the Gauss-Laguerre weight function, $W(x) = \exp(-u)$, the integration of the log-likelihood function can be replaced with a summation as follows:

$$\int_0^\infty G_{ij}(u) \exp(-u)du = \sum_{k=1}^{K} w_k G_{ij}(x_k)$$

Weights (w_k) and abscissas (x_k) are tabulated by Abramowitz and Stegun (1970).

Mixed Logit Model

In mixed logit models, an individual's utility from any alternative can be decomposed into a deterministic component, $\mathbf{x}'_{ij}\boldsymbol{\beta}$, which is a linear combination of observed variables, and a stochastic component, $\xi_{ij} + \epsilon_{ij}$.

$$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \xi_{ij} + \epsilon_{ij}$$

where $\mathbf{x}_{ij}$ is a vector of observed variables relating to individual i and alternative j, $\boldsymbol{\beta}$ is a vector of parameters, ξ_{ij} is an error component that can be correlated among alternatives and heteroscedastic for each individual, and ϵ_{ij} is a random term with zero mean that is independently and identically distributed over alternatives and individuals. The conditional logit model is derived if you assume ϵ_{ij} has an iid Gumbel distribution and $V(\xi_{ij}) = 0$.

The mixed logit model assumes a general distribution for ξ_{ij} and an iid Gumbel distribution for ϵ_{ij}. Denote the density function of the error component ξ_{ij} as $f(\xi_{ij}|\boldsymbol{\gamma})$, where $\boldsymbol{\gamma}$ is a parameter vector of the distribution of ξ_{ij}. The choice probability of alternative j for individual i is written as

$$P_i(j) = \int Q_i(j|\xi_{ij}) f(\xi_{ij}|\boldsymbol{\gamma}) d\xi_{ij}$$

where the conditional choice probability for a given value of ξ_{ij} is logit:

$$Q_i(j|\xi_{ij}) = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta} + \xi_{ij})}{\sum_{k \in C_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta} + \xi_{ik})}$$

Since ξ_{ij} is not given, the unconditional choice probability, $P_i(j)$, is the integral of the conditional choice probability, $Q_i(j|\xi_{ij})$, over the distribution of ξ_{ij}. This model is called "mixed logit" since the choice probability is a mixture of logits with $f(\xi_{ij}|\boldsymbol{\gamma})$ as the mixing distribution.

In general, the mixed logit model does not have an exact likelihood function since the probability $P_i(j)$ does not always have a closed form solution. Therefore, a simulation method is used for computing the approximate probability.

$$\tilde{P}_i(j) = 1/S \sum_{s=1}^{S} \tilde{Q}_i(j|\xi_{ij}^s)$$

where S is the number of simulation replications and $\tilde{P}_i(j)$ is a simulated probability. The simulated log-likelihood function is computed as

$$\tilde{\mathcal{L}} = \sum_{i=1}^{N} \sum_{j=1}^{n_i} d_{ij} \ln(\tilde{P}_i(j))$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

For simulation purposes, assume that the error component has a specific structure

$$\xi_{ij} = \mathbf{z}'_{ij}\boldsymbol{\mu} + \mathbf{w}'_{ij}\boldsymbol{\beta}^*$$

where $\mathbf{z}_{ij}$ is a vector of observed data and $\boldsymbol{\mu}$ is a random vector with zero mean and density function $\psi(\boldsymbol{\mu}|\boldsymbol{\gamma})$. The observed data vector ($\mathbf{z}_{ij}$) of the error component may contain some or all elements of $\mathbf{x}_{ij}$. The component $\mathbf{z}'_{ij}\boldsymbol{\mu}$ induces heteroscedasticity and correlation across unobserved utility components of the alternatives. This allows flexible substitution patterns among the alternatives. The kth element of vector $\boldsymbol{\mu}$ is distributed as

$$\mu_k \sim (0, \sigma_k^2)$$

Therefore, μ_k can be specified as

$$\mu_k = \sigma_k \epsilon_\mu$$

where

$$\epsilon_\mu \sim N(0,1)$$

or

$$\epsilon_\mu \sim U(-\sqrt{3}, \sqrt{3})$$

In addition, $\boldsymbol{\beta}^*$ is a vector of random parameters (or, random coefficients). Random coefficients allow heterogeneity across individuals in their sensitivity to observed exogenous variables. The observed data vector, $\mathbf{w}_{ij}$, is a subset of $\mathbf{x}_{ij}$. Three types of distributions for the random coefficients are supported. Denote the mth element of $\boldsymbol{\beta}^*$ as β^*_m.

- Normally distributed coefficient with the mean b_m and standard deviation s_m being estimated.

  $$\beta^*_m = b_m + s_m\epsilon_\beta \quad \text{and} \quad \epsilon_\beta \sim N(0,1)$$

- Uniformly distributed coefficient with the mean b_m and spread s_m being estimated. A uniform distribution with mean b and spread s is $U(b-s, b+s)$.

  $$\beta^*_m = b_m + s_m\epsilon_\beta \quad \text{and} \quad \epsilon_\beta \sim U(-1,1)$$

- Log-normally distributed coefficient with the mean b_m and standard deviation s_m being estimated. The coefficient is calculated as

  $$\beta^*_m = \exp(m + s\epsilon_\beta) \quad \text{and} \quad \epsilon_\beta \sim N(0,1)$$

  where m and s are parameters that are estimated. The mean and standard deviation of the log-normally distributed coefficient is then calculated as

  $$b_m = \exp[m + \frac{1}{2}s^2]$$

  and

  $$s_m = b_m[\exp(s^2) - 1]^{\frac{1}{2}}$$

A detailed description of mixed logit models can be found, for example, in Brownstone and Train (1999).

Multinomial Probit

The multinomial probit model allows the random components of the utility of the different alternatives to be nonindependent and nonidentical. Thus, it does not have the IIA property. The increase in the flexibility of the error structure comes at the expense of introducing several additional parameters in the covariance matrix of the errors.

Consider the random utility function

$$U_{ij} = \mathbf{x}'_{ij}\boldsymbol{\beta} + \epsilon_{ij}$$

where the joint distribution of $(\epsilon_{i1}, \epsilon_{i2}, \cdots, \epsilon_{iJ})$ is multivariate normal:

$$\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \\ \vdots \\ \epsilon_{iJ} \end{bmatrix} \sim N(\mathbf{0}, \boldsymbol{\Sigma})$$

$$\boldsymbol{\Sigma} = [\sigma_{jk}]_{j,k=1,\ldots,J}$$

The dimension of the error covariance matrix is determined by the number of alternatives J. Given $(\mathbf{x}_{i1}, \mathbf{x}_{i2}, \cdots, \mathbf{x}_{iJ})$, the jth alternative is chosen if and only if $U_{ij} \geq U_{ik}$ for all $k \neq j$. Thus, the probability that the jth alternative is chosen is

$$P(y_i = j) = P_{ij} = P[\epsilon_{i1} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{i1})'\boldsymbol{\beta}, \ldots, \epsilon_{iJ} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{iJ})'\boldsymbol{\beta}]$$

where y_i is a random variable that indicates the choice made. This is a cumulative probability from a $(J-1)$-variate normal distribution. Since evaluation of this probability involves multidimensional integration, it is practical to use a simulation method to estimate the model. Many studies have shown that the simulators proposed by Geweke (1989), Hajivassiliou (1993), and Keane (1994) (GHK) perform well. For example, Hajivassiliou et al. (1996) compare 13 simulators using 11 different simulation methods and conclude that the GHK simulation method is the most reliable. To compute the probability of the multivariate normal distribution, the recursive simulation method is used. Refer to Hajivassiliou (1993) for more details on GHK simulators.

The log-likelihood function for the multinomial probit model can be written as

$$\mathcal{L} = \sum_{i=1}^{N} \sum_{j=1}^{J} d_{ij} \ln P(y_i = j)$$

where

$$d_{ij} = \begin{cases} 1 & \text{if individual } i \text{ chooses alternative } j \\ 0 & \text{otherwise} \end{cases}$$

For identification of the multinomial probit model, two of the diagonal elements of Σ are normalized to 1 and it is assumed that for one of the choices whose error variance is normalized to 1, say k, it is also true that $\sigma_{jk} = \sigma_{kj} = 0$ for $j = 1, \cdots, J$ and $j \neq k$. Thus, a model with J alternatives has at most $J(J-1)/2 - 1$ covariance parameters after normalization.

Let D and R be defined as

$$D = \begin{bmatrix} \sigma_1 & 0 & \cdots & 0 \\ 0 & \sigma_2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & \sigma_J \end{bmatrix}$$

$$R = \begin{bmatrix} 1 & \rho_{12} & \cdots & \rho_{1J} \\ \rho_{21} & 1 & \cdots & \rho_{2J} \\ \vdots & \vdots & \vdots & \vdots \\ \rho_{J1} & \rho_{J2} & \cdots & 1 \end{bmatrix}$$

where $\sigma_j^2 = \sigma_{jj}$ and $\rho_{jk} = \frac{\sigma_{jk}}{\sigma_j \sigma_k}$. Then, for identification, $\sigma_{J-1} = \sigma_J = 1$ and $\rho_{kJ} = \rho_{Jk} = 0$, for all $k \neq J$ can be imposed, and the error covariance matrix is $\Sigma = DRD$.

In principle, the multinomial probit model is fully identified with the above normalizations, however, in practice, convergence in applications of the model with more than three alternatives often requires additional restrictions on the elements of $\mathbf{\Sigma}$.

It must also be noted that the unrestricted structure of the error covariance matrix makes it impossible to forecast demand for a new alternative without knowledge of the new $(J+1)$ by $(J+1)$ error covariance matrix.

Nested Logit

The nested logit model (McFadden 1978, 1981) allows partial relaxation of the assumption of independence of the stochastic components of utility of alternatives. In some choice situations, the IIA property holds for some pairs of alternatives but not all. In these situations, the nested logit model can be used if the set of alternatives faced by an individual can be partitioned into subsets such that the IIA property holds within subsets but not across subsets.

In the nested logit model, the joint distribution of the errors is generalized extreme value (GEV). This is a generalization of the type I extreme value distribution that gives rise to the conditional logit model. Note that all ϵ_{ij} within each subset are correlated with each other. Refer to McFadden (1978, 1981) for details.

Nested logit models can be described analytically following the notation of McFadden (1981). Assume that there are L levels, with 1 representing the lowest and L representing the highest level of the tree. The index of a node at level h in the tree is a pair (j_h, π_h), where $\pi_h = (j_{h+1}, \cdots, j_L)$ is the index of the adjacent node at level $h+1$. Thus, the primitive alternatives, at level 1 in the tree, are indexed by vectors $(j_1, \cdots, j_L)$, while the alternative nodes at level L are indexed by integers j_L. The choice set C_{π_h} is the set of primitive alternatives (at level 1) that belong to branches below the node π_h. The notation C_{π_h} is also used to denote a set of indices j_h such that (j_h, π_h) is a node immediately below π_h. Note that C_{π_0} is a set with a single element, while C_{π_L} represents a choice set containing all possible alternatives. As an example, consider the circled node at level 1 in Figure 19.25. Since it stems from node 11, $\pi_h = 11$, and, since it is the second node stemming from 11, $j_h = 2$, so that its index is $\pi_{h-1} = \pi_0 = (j_h, \pi_h) = 211$. Similarly, $C_{11} = \{111, 211, 311\}$ contains all the possible choices below 11.

Note that while this notation is useful for writing closed form solutions for probabilities, the MDC procedure allows a more flexible definition of indices. See the NEST statement in the "Syntax" section for more details on how to describe decision trees within the MDC procedure.

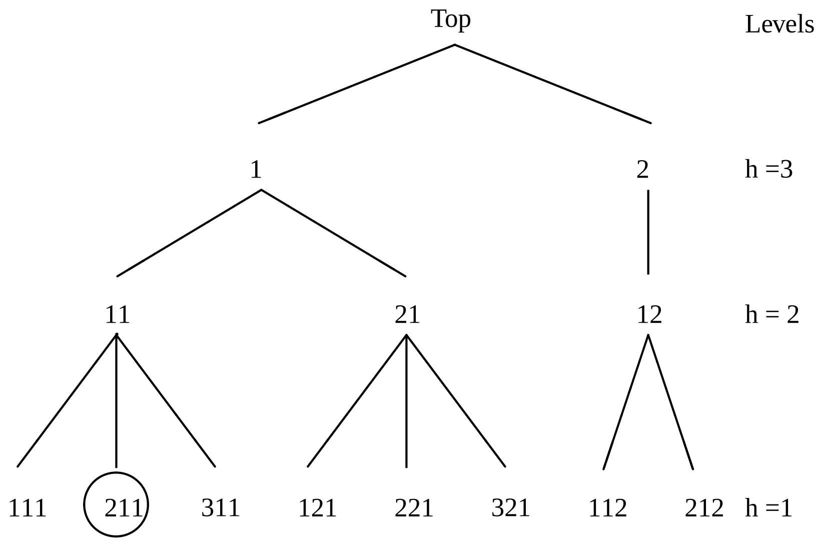

Figure 19.25. Node Indices for a Three-Level Tree

Let $\mathbf{x}^{(h)}_{i;j_h\pi_h}$ denote the vector of observed variables for individual i common to the alternatives below node $j_h\pi_h$. The probability of choice at level h has a closed form solution and is written

$$P_i(j_h|\pi_h) = \frac{\exp\left[\mathbf{x}^{(h)\prime}_{i;j_h\pi_h}\boldsymbol{\beta}^{(h)} + \sum_{k\in C_{i;j_h\pi_h}} I_{k,j_h\pi_h}\theta_{k,j_h\pi_h}\right]}{\sum_{j\in C_{i;\pi_h}} \exp\left[\mathbf{x}^{(h)\prime}_{i;j\pi_h}\boldsymbol{\beta}^{(h)} + \sum_{k\in C_{i;j\pi_h}} I_{k,j\pi_h}\theta_{k,j\pi_h}\right]}, \quad h = 2, \cdots, L$$

where I_{π_h} is the *inclusive value* (at level $h+1$) of the branch below node π_h and is defined recursively as follows:

$$I_{\pi_h} = \ln\left\{\sum_{j\in C_{i;\pi_h}} \exp\left[\mathbf{x}^{(h)\prime}_{i;j\pi_h}\boldsymbol{\beta}^{(h)} + \sum_{k\in C_{i;j\pi_h}} I_{k,j\pi_h}\theta_{k,j\pi_h}\right]\right\}$$

$$0 \le \theta_{k,\pi_1} \le \cdots \le \theta_{k,\pi_{L-1}}$$

The inclusive value I_{π_h} denotes the average utility that the individual can expect from the branch below π_h. The *dissimilarity parameters* or *inclusive value parameters* ($\theta_{k,j\pi_h}$) are the coefficients of the inclusive values and have values between 0 and 1 if nested logit is the correct model specification. When they all take value 1, the nested logit model is equivalent to the conditional logit model.

At decision level 1, there is no inclusive value, i.e. $I_{\pi_0} = 0$. Therefore, the conditional probability is

$$P_i(j_1|\pi_1) = \frac{\exp\left[\mathbf{x}_{i;j_1\pi_1}^{(1)\prime}\boldsymbol{\beta}^{(1)}\right]}{\sum_{j\in C_{i;\pi_1}}\exp\left[\mathbf{x}_{i;j\pi_1}^{(1)\prime}\boldsymbol{\beta}^{(1)}\right]}$$

The log-likelihood function at level h can then be written

$$\mathcal{L}^{(h)} = \sum_{i=1}^{N}\sum_{\pi_{h'}\in C_{i,\pi_{h+1}}}\sum_{j\in C_{i,\pi_{h'}}} y_{i,j\pi_{h'}}\ln P(C_{i,j\pi_{h'}}|C_{i,\pi_{h'}})$$

where $y_{i,j\pi_{h'}}$ is an indicator variable that has the value of 1 for the selected choice. The full log-likelihood function of the nested logit model is obtained by adding the conditional log-likelihood functions at each level:

$$\mathcal{L} = \sum_{h=1}^{L}\mathcal{L}^{(h)}$$

Note that the log-likelihood functions are computed from conditional probabilities when $h < L$. The nested logit model is estimated using the full information maximum likelihood method.

Decision Tree and Nested Logit

You can view choices as a decision tree and model the decision tree using the nested logit model. You need to use either the NEST statement or the CHOICE= option of the MODEL statement to specify the nested tree structure. Additionally, you need to identify which explanatory variables are used at each level of the decision tree. These explanatory variables are arguments for what is called a *utility function*. The utility function is specified using UTILITY statements. For example, consider a two-level decision tree. The tree structure is displayed in Figure 19.26.

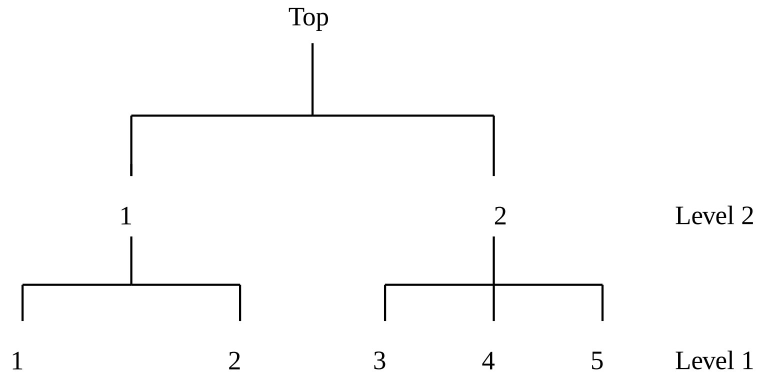

Figure 19.26. Two-Level Decision Tree

A nested logit model with two levels can be specified using the following SAS statements:

```
proc mdc data=one type=nlogit;
   model decision = x1 x2 x3 x4 x5 /
       choice=(upmode 1 2, mode 1 2 3 4 5);
   id pid;
   utility u(1, 3 4 5 @ 2) = x1 x2,
           u(1, 1 2 @ 1) = x3 x4,
           u(2, 1 2) = x5;
run;
```

The DATA=one data set should be arranged as

```
obs  pid  upmode   mode   x1  x2  x3  x4  x5  decision
 1    1     1       1     #   #   #   #   #      1
 2    1     1       2     #   #   #   #   #      0
 3    1     2       3     #   #   #   #   #      0
 4    1     2       4     #   #   #   #   #      0
 5    1     2       5     #   #   #   #   #      0
 6    2     1       1     #   #   #   #   #      0
 7    2     1       2     #   #   #   #   #      0
 8    2     2       3     #   #   #   #   #      0
 9    2     2       4     #   #   #   #   #      0
10    2     2       5     #   #   #   #   #      1
```

All model variables, x1 through x5, are specified in the utility statement. It is required that entries denoted as # have values for model estimation and prediction. The values of the level 2 utility variable x5 should be the same for all the primitive (level 1) alternatives below node 1 at level 2 and, similarly, for all the primitive alternatives below node 2 at level 2. In other words, x5 should have the same value for primitive alternatives 1 and 2 and, similarly, it should have the same value for primitive alternatives 3, 4, and 5. More generally, the values of any level 2 or higher utility function variables should be constant across primitive alternatives under each node for which the utility function applies. Since PROC MDC expects this to be the case, it will only use the values of x5 for the primitive alternatives 1 and 3, ignoring the values for the primitive alternatives 2, 4, and 5. Thus, PROC MDC only uses the values of the utility function variable for the primitive alternatives that come first under each node for which the utility function applies. This behavior applies to any utility function variables that are specified above the first level. The choice variable for level 2 (upmode) should be placed before the first-level choice variable (mode) when the CHOICE= option is given. Alternatively, the NEST statement can be used to specify the decision tree. The following SAS statements fit the same nested logit model:

```
proc mdc data=a type=nlogit;
   model decision = x1 x2 x3 x4 x5 /
       choice=(mode 1 2 3 4 5);
   id pid;
```

```
      utility u(1, 3 4 5 @ 2) = x1 x2,
              u(1, 1 2 @ 1) = x3 x4,
              u(2, 1 2) = x5;
      nest level(1) = (1 2 @ 1, 3 4 5 @ 2),
           level(2) = (1 2 @ 1);
   run;
```

The U(1, 3 4 5 @ 2)= option specifies three choices, 3, 4, and 5, at level 1 of the decision tree. They are connected to the upper branch 2. The specified variables (x1 and x2) are used to model this utility function. The bottom level of the decision tree is level 1. All variables in the UTILITY statement must be included in the MODEL statement. When all choices at the first level share the same variables, you can omit the second argument of the U()= option for that level. However, U(1,) = x1 x2 is not equivalent to

```
   u(1, 3 4 5 @ 2) = x1 x2;
   u(1, 1 2 @ 1) = x1 x2;
```

The CHOICE= variables need to be specified from the top to the bottom level. To forecast demand for new products, stated preference data are widely used. Stated preference data are attractive for market researchers since attribute variations can be controlled. Hensher (1993) explores the advantage of combining revealed preference (market data) and stated preference data. The scale factor (V_{rp}/V_{sp}) can be estimated using the nested logit model with the decision tree structure displayed in Figure 19.27.

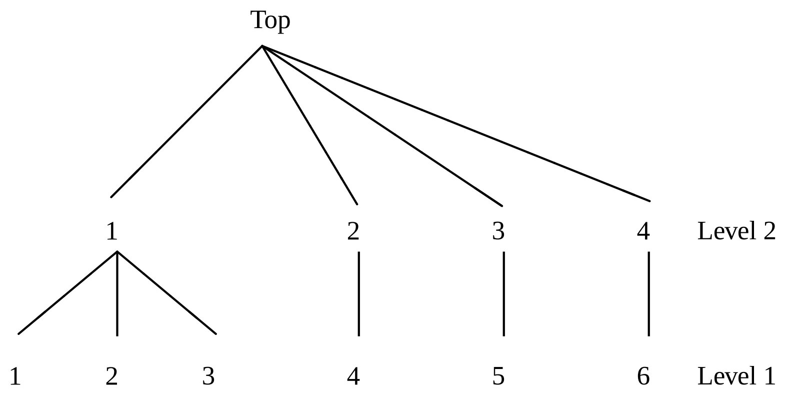

Figure 19.27. Decision Tree for Revealed and Stated Preference Data

Example SAS statements read

```
   proc mdc data=a type=nlogit;
      model decision = x1 x2 x3 / spscale
          choice=(mode 1 2 3 4 5 6);
      id pid;
      utility u(1,) = x1 x2 x3;
      nest level(1) = (1 2 3 @ 1, 4 @ 2, 5 @ 3, 6 @ 4),
           level(2) = (1 2 3 4 @ 1);
   run;
```

The SPSCALE option specifies that parameters of inclusive values for nodes 2, 3, and 4 at level 2 are the same. When you specify the SAMESCALE option, the MDC procedure imposes the same coefficient of inclusive values for choices 1 –4.

Goodness-of-Fit Measures

McFadden (1974) suggests a likelihood ratio index that is analogous to the R^2 in the linear regression model.

$$R_M^2 = 1 - \frac{\ln L}{\ln L_0}$$

where L is the maximum of the log-likelihood function and L_0 is the maximum of the log-likelihood function when all coefficients, except for an intercept term, are zero. McFadden's likelihood ratio index is bounded by 0 and 1.

Estrella (1998) proposes the following requirements for a goodness-of-fit measure to be desirable in discrete choice modeling:

- The measure must take values in $[0, 1]$, where 0 represents no fit and 1 corresponds to perfect fit.
- The measure should be directly related to the valid test statistic for the significance of all slope coefficients.
- The derivative of the measure with respect to the test statistic should comply with corresponding derivatives in a linear regression.

Estrella's measure is written

$$R_{E1}^2 = 1 - \left(\frac{\ln L}{\ln L_0}\right)^{-(2/N)\ln L_0}$$

Estrella suggests an alternative measure

$$R_{E2}^2 = 1 - [(\ln L - K)/\ln L_0]^{-(2/N)\ln L_0}$$

where $\ln L_0$ is computed with null parameter values, N is the number of observations used, and K represents the number of estimated parameters.

Other goodness-of-fit measures are summarized as follows:

$$\begin{aligned}
R_{CU1}^2 &= 1 - \left(\tfrac{L_0}{L}\right)^{\frac{2}{N}} && \text{(Cragg-Uhler 1)} \\
R_{CU2}^2 &= \frac{1-(L_0/L)^{\frac{2}{N}}}{1-L_0^{\frac{2}{N}}} && \text{(Cragg-Uhler 2)} \\
R_A^2 &= \frac{2(\ln L - \ln L_0)}{2(\ln L - \ln L_0)+N} && \text{(Aldrich-Nelson)} \\
R_{VZ}^2 &= R_A^2 \frac{2\ln L_0 - N}{2\ln L_0} && \text{(Veall-Zimmermann)}
\end{aligned}$$

OUTEST= Data Set

The OUTEST= data set contains all the parameters estimated in a MODEL statement. The OUTEST= option can be used when the PROC MDC call contains one MODEL statement. There are additional restrictions. For the HEV and multinomial probit models, you need to specify exactly all possible elements of the choice set, since additional parameters (e.g., SCALE1 or STD1) are generated automatically in the MDC procedure. Therefore, the following SAS statement is not valid when the OUTEST= option is given:

```
proc mdc data=a outest=e;
   model y = x / type=hev choice=(alter);
run;
```

You need to specify all possible choices in the CHOICE= option since the OUTEST= option is specified.

```
proc mdc data=a outest=e;
   model y = x / type=hev choice=(alter 1 2 3);
run;
```

When the NCHOICE= option is given, no additional information on possible choices is required. Therefore, the following is a correct SAS statement:

```
proc mdc data=a outest=e;
   model y = x / type=mprobit nchoice=3;
run;
```

The nested logit model does not produce the OUTEST= data set unless the NEST statement is specified.

Each parameter contains the estimate for the corresponding parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

DEPVAR	the name of the dependent variable
METHOD	the estimation method
MODEL	the label of the MODEL statement if one is given, or blank otherwise
STATUS	convergence status for optimization
NAME	the name of the row of the covariance matrix for the parameter estimate, if the COVOUT option is specified
LIKL	the log-likelihood value
STDERR	standard error of the parameter estimate, if the COVOUT option is specified
TYPE	PARMS for observations containing parameter estimates, or COV for observations containing covariance matrix elements

The OUTEST= data set contains one observation for the MODEL statement giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement giving the rows of the covariance matrix of parameter estimates. For covariance observations, the value of the _TYPE_ variable is COV, and the _NAME_ variable identifies the parameter associated with that row of the covariance matrix.

ODS Table Names

PROC MDC assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 19.2. ODS Tables Produced in PROC MDC

ODS Table Name	Description	Option
	ODS Tables Created by the Model Statement	
FitSummary	Summary of Nonlinear Estimation	default
ResponseProfile	Response Profile	default
GoodnessOfFit	Pseudo-R^2 Measures	default
ParameterEstimates	Parameter Estimates	default
ActiveLinConSol	Linearly Independent Active Linear Constraints	default
CovB	Covariance of Parameter Estimates	COVB
CorrB	Correlation of Parameter Estimates	CORRB

Examples

Example 19.1. Binary Data Modeling

The MDC procedure supports various multinomial choice models. However, binary choice models such as binary logit and probit can also be estimated using PROC MDC since these models are special cases of multinomial models.

Spector and Mazzeo (1980) studied the effectiveness of a new teaching method on students' performance in an economics course. They reported grade point average (gpa), previous knowledge of the material (tuce), a dummy variable for the new teaching method (psi), and the final course grade (grade). grade is recorded as 1 if a student earned the letter grade "A", and 0 otherwise.

The binary logit can be estimated using the conditional logit model. In order to use the MDC procedure, the data are converted so that each possible choice corresponds to one observation.

           2        0          1        2.89      22        0
           3        1          0        0.00       0        0
           3        0          1        3.28      24        0
           4        1          0        0.00       0        0
           4        0          1        2.92      12        0
           5        0          0        0.00       0        0
           5        1          1        4.00      21        0
```

Consider the choice probability of the conditional logit model for binary choice:

$$P_i(j) = \frac{\exp(\mathbf{x}'_{ij}\boldsymbol{\beta})}{\sum_{k=1}^{2}\exp(\mathbf{x}'_{ik}\boldsymbol{\beta})}, \quad j = 1, 2$$

The choice probability of the binary logit model is computed based on normalization. The preceding conditional logit model can be converted as

$$P_i(1) = \frac{1}{1 + \exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}$$

$$P_i(2) = \frac{\exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}{1 + \exp((\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta})}$$

Therefore, you can interpret the binary choice data as the difference between the first and second choice characteristics. In this example, it is assumed that $\mathbf{x}_{i1} = \mathbf{0}$. The binary logit model is estimated and displayed in Output 19.1.2.

```
   proc mdc data=smdata1;
      model decision = choice2 gpa_2 tuce_2 psi_2 /
            type=clogit nchoice=2 covest=hess;
      id id;
   run;
```

       choice2         1      -13.0213          4.9313       -2.64      0.0083
       gpa_2           1        2.8261          1.2629        2.24      0.0252
       tuce_2          1        0.0952          0.1416        0.67      0.5014
       psi_2           1        2.3787          1.0646        2.23      0.0255
```

Consider the choice probability of the multinomial probit model:

$$P_i(j) = P[\epsilon_{i1} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{i1})'\boldsymbol{\beta}, \ldots, \epsilon_{iJ} - \epsilon_{ij} < (\mathbf{x}_{ij} - \mathbf{x}_{iJ})'\boldsymbol{\beta}]$$

The probabilities of choice of the two alternatives can be written as

$$P_i(1) = P[\epsilon_{i2} - \epsilon_{i1} < (\mathbf{x}_{i1} - \mathbf{x}_{i2})'\boldsymbol{\beta}]$$

$$P_i(2) = P[\epsilon_{i1} - \epsilon_{i2} < (\mathbf{x}_{i2} - \mathbf{x}_{i1})'\boldsymbol{\beta}]$$

where $\begin{bmatrix} \epsilon_{i1} \\ \epsilon_{i2} \end{bmatrix} \sim N\left(\mathbf{0}, \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{12} & \sigma_2^2 \end{bmatrix}\right)$. Assume that $\mathbf{x}_{i1} = 0$ and $\sigma_{12} = 0$. The binary probit model is estimated and displayed in Output 19.1.3. You do not get the same estimates as that of the usual binary probit model. The probabilities of choice in the binary probit model are

$$P_i(2) = P[\epsilon_i < \mathbf{x}_i'\boldsymbol{\beta}]$$

$$P_i(1) = 1 - P[\epsilon_i < \mathbf{x}_i'\boldsymbol{\beta}]$$

where $\epsilon_i \sim N(0, 1)$. However, the multinomial probit model has the error variance $\text{Var}(\epsilon_{i2} - \epsilon_{i1}) = \sigma_1^2 + \sigma_2^2$ if ϵ_{i1} and ϵ_{i2} are independent ($\sigma_{12} = 0$). In this example, unit variance restrictions are imposed on choices 1 and 2 ($\sigma_1^2 = \sigma_2^2 = 1$). Therefore, the usual binary probit estimates (and standard errors) can be obtained by multiplying the multinomial probit estimates (and standard errors) in Output 19.1.3 by $1/\sqrt{2}$.

```
proc mdc data=smdata1;
   model decision = choice2 gpa_2 tuce_2 psi_2 /
         type=mprobit nchoice=2 covest=hess
         unitvariance=(1 2);
   id id;
run;
```

Output 19.1.3. Binary Probit Estimates

```

```

Example 19.2. Conditional Logit and Data Conversion

In this example, a data preparation macro is introduced. Sometimes, choice-specific information is stored in multiple variables. Since the MDC procedure requires multiple observations for each decision maker, you need to arrange the data so that there is an observation for each subject-alternative (or individual-choice) combination. Simple binary choice data are obtained from Ben-Akiva and Lerman (1985).

```
data travel;
   input auto transit mode $;
   datalines;
52.9   4.4 Transit
4.1   28.5 Transit
4.1   86.9 Auto
56.2  31.6 Transit
51.8  20.2 Transit
0.2   91.2 Auto
27.6  79.7 Auto
89.9  2.2  Transit
41.5  24.5 Transit
95.0  43.5 Transit
99.1  8.4  Transit
18.5  84.0 Auto
82.0  38.0 Auto
 8.6  1.6  Transit
22.5  74.1 Auto
51.4  83.8 Auto
81.0  19.2 Transit
51.0  85.0 Auto
62.2  90.1 Auto
95.1  22.2 Transit
41.6  91.5 Auto
;
run;
```

The travel time is stored in two variables, auto and transit. In addition, the chosen alternatives are stored in a character variable, mode. The choice variable, mode, is converted to a numeric variable, decision, since the MDC procedure only supports numeric variables. The following statements convert the original data set, travel, and estimate the binary logit model. The first 10 observations of a relevant subset of the new data set and the parameter estimates are displayed in Output 19.2.1 and Output 19.2.2, respectively.

```
data new;
   set travel;
   retain id 0;
   id+1;
   /*-- create auto variable --*/
   decision = (upcase(mode) = 'AUTO');
   ttime = auto;
   autodum = 1;
   trandum = 0;
   output;
   /*-- create transit variable --*/
   decision = (upcase(mode) = 'TRANSIT');
   ttime = transit;
   autodum = 0;
   trandum = 1;
   output;
run;

proc print data=new(obs=10);
   var decision autodum trandum ttime;
   id id;
run;

proc mdc data=new;
   model decision = autodum ttime /
         type=clogit nchoice=2;
   id id;
run;
```

Output 19.2.1. Converted Data

```
id    decision    autodum    trandum    ttime

 1        0          1          0        52.9

```

In order to handle more general cases, you can use the data conversion macro program, %mdcdata. The %mdcdata macro generates choice specific dummy variables and creates multiple observations for each individual. The %mdcdata macro arguments are described below followed by the macro itself.

INDATA=	The name of the input data set.
OUTDATA=	The name of the output data set.
NCHOICE=	Number of alternatives for the choice variable.
ALTSET=	Names the alternatives using characters separated by spaces. There should be a total of nchoice alternatives listed.
DUMLIST=	Names the new dummy variables in the output data set which correspond to the alternatives. Thus, there should be nchoice variables listed here. If not specified, dummy variables will be created as dum_1, ..., dum_J.
VARLIST=	The list of variables from the input data set that will be interleaved in order to reduce the number of variables while expanding the number of observations. This list has a total of NCHOICE times NVAR variables. These variables should be in groups of NCHOICE. For example, if NCHOICE=3, there should be groups of three variables, with each of the three associated with a different alternative.
NVAR=	Number of groups of NCHOICE variables listed in VARLIST=. The %mdcdata macro takes the VARLIST= input variables and reduces them down to only NVAR variables in the output. However, these variables have NCHOICE times as many observations as the input data set variables. The variables are named as x_1, ..., x_n.
SELECT=	Character variable found in the input data set. The values of this variable store the alternatives that were chosen for each subject/individual. The values of this variable must precisely match those listed as ALTSET= values.
ID=	Names the new subject ID variable in the output data set. If not specified, the ID variable will be named id_var.

CHOICE=	Names the new output variable that will identify the alternative value associated with each observation in the output data set. If not specified, the variable will be named alt_var.
DECISION=	Names the new output binary variable that identifies which alternative was chosen. If not specified, the variable will be named dec_var.

```
/*--------------------------------------------------------------
 * name: %mdcdata
 * note: original data contains one observation for each
 *       decision maker (or id).  The choice specific data are
 *       stored in multiple variables.  The created variables are
 *       x_1, ..., x_n.  Choice dummy variables are created as
 *       dum_1, ..., dum_J.  In addition, id_var, alt_var,
 *       and dec_var variables are created.
 * purpose: prepare data for use in the mdc procedure

   run;
   %end_macro:
%mend mdcdata;
```

The following macro invocation shows another way of converting the original data set, travel, for analysis by PROC MDC.

```
%mdcdata(indata=travel,outdata=new,
         varlist=auto transit,
         dumlist=autodum trandum,nchoice=2,nvar=1,
         altset=%str(auto transit),
         select=mode)
```

The first 10 observations of the new data set are displayed in Output 19.2.3.

```
proc print data=new(obs=10);
   var alt_var dec_var autodum trandum x_1;
   id id_var;
run;
```

Output 19.2.3. Converted Data Using %MDCDATA Macro

```
         id_var    alt_var    dec_var    autodum    trandum      x_1

            1         1          0          1          0        52.9
            1         2          1          0          1         4.4
            2         1          0          1          0         4.1
            2         2          1          0          1        28.5
            3         1          1          1          0         4.1
            3         2          0          0          1        86.9
            4         1          0          1          0        56.2
            4         2          1          0          1        31.6
            5         1          0          1          0        51.8
            5         2          1          0          1        20.2
```

The converted explanatory variables are created as x_1, . . ., x_n. In this example, the values of the two variables, auto and transit, are interleaved to produce one variable, x_1, with twice as many observations as the original variables. Additionally, dummy variables (autodum and trandum) listed in the DUMLIST= macro argument are created. When any of the ID=, CHOICE=, or DECISION= macro arguments are not specified, the corresponding variable is automatically produced as id_var, alt_var, or dec_var.

Finally, the binary logit model is estimated. The estimates displayed in Output 19.2.4 are the same as those in Output 19.2.2.

```
proc mdc data=new type=clogit;
   model dec_var = autodum x_1 / nchoice=2;
   id id_var;
run;
```

Output 19.2.4. Conditional Logit Estimates

```

```

Example 19.3. Correlated Choice Modeling

It is not realistic to assume that the random components of utility for all choices are independent. To analyze correlated data, trinomial choice data (1000 observations) is created using a pseudo-random number generator. The random utility function is

$$U_{ij} = V_{ij} + \epsilon_{ij}, \quad j = 1, 2, 3$$

where

$$\epsilon_{ij} \sim N\left(0, \begin{bmatrix} 2 & .6 & 0 \\ .6 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)$$

```
%let ndim = 3;
%let nobs = 1000;

/*-- generate simulated series --*/
data one;
   array error{&ndim} e1-e3;
   array vtemp{&ndim} _temporary_;
   array lm{6} _temporary_ (1.4142136 0.4242641 0.9055385 0 0 1);
   retain nseed 345678 useed 223344;

   do id = 1 to &nobs;
      index = 0;
      /* generate independent normal variate */
      do i = 1 to &ndim;
         /* index of diagonal element */
         vtemp{i} = rannor(nseed);
      end;
      /* get multivariate normal variate */
      index = 0;
      do i = 1 to &ndim;
         error{i} = 0;
         do j = 1 to i;
            error{i} = error{i} + lm{index+j}*vtemp{j};
         end;
         index = index + i;
      end;
      x1 = 1.0 + 2.0 * ranuni(useed);
      x2 = 1.2 + 2.0 * ranuni(useed);
      x3 = 1.5 + 1.2 * ranuni(useed);
      util1 = 2.0 * x1 + e1;
      util2 = 2.0 * x2 + e2;
      util3 = 2.0 * x3 + e3;
      do i = 1 to &ndim;
         vtemp{i} = 0;
      end;
      if ( util1 > util2 & util1 > util3 ) then
         vtemp{1} = 1;
      else if ( util2 > util1 & util2 > util3 ) then
         vtemp{2} = 1;
      else if ( util3 > util1 & util3 > util2 ) then
         vtemp{3} = 1;
      else continue;
       /*-- first choice --*/
      x = x1;
      mode = 1;
      decision = vtemp{1};
      output;
       /*-- second choice --*/
      x = x2;
      mode = 2;
      decision = vtemp{2};
      output;
       /*-- third choice --*/
      x = x3;
      mode = 3;
      decision = vtemp{3};
      output;
   end;
run;
```

First, the multinomial probit model is estimated. Results show that standard deviation, correlation, and slope estimates are close to the parameter values. Note that $\rho_{12} = \frac{\sigma_{12}}{\sqrt{(\sigma_1^2)(\sigma_2^2)}} = \frac{.6}{\sqrt{(2)(1)}} = .42$, $\sigma_1 = \sqrt{2} = 1.41$, $\sigma_2 = \sqrt{1} = 1$, and the parameter value for the variable x is 2.0. See Output 19.3.1.

```
   proc mdc data=one randnum=halton nsimul=100;
      model decision = x / type=mprobit
            choice=(mode 1 2 3) covest=op optmethod=qn;
      id id;
   run;
```

Output 19.3.1. Trinomial Probit Model Estimation

```
                                The MDC Procedure

                            Multinomial Probit Estimates

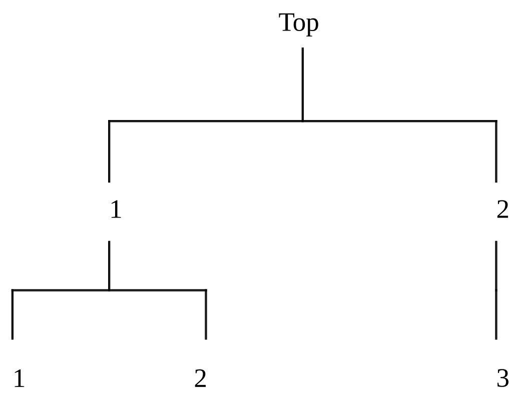
                               Parameter Estimates

                                             Standard                 Approx
        Parameter      DF      Estimate         Error    t Value    Pr > |t|

        x               1        1.7987        0.1202      14.97      <.0001
        STD_1           1        1.2824        0.1468       8.74      <.0001
        RHO_21          1        0.4233        0.1041       4.06      <.0001
```

The nested model is also estimated based on a two-level decision tree. See Output 19.3.2. The estimated result shows that the data supports the nested tree model since the estimates of the inclusive value parameters are significant and are less than 1.

Output 19.3.2. Nested Tree Structure



```
proc mdc data=one;
   model decision = x / type=nlogit
      choice=(mode 1 2 3) covest=op optmethod=qn;
   id id;
   utility u(1,) = x;
   nest level(1) = (1 2 @ 1, 3 @ 2),
        level(2) = (1 2 @ 1);
run;
```

```

Example 19.4. Testing for Homoscedasticity of the Utility Function

The “Getting Started” section analyzes an HEV model using Daganzo’s trinomial choice data and displays the HEV parameter estimates in Figure 19.14. The inverted scale estimates for mode “2” and mode “3” suggest that the conditional logit model (which imposes equal variances on random components of utility of all alternatives) might be misleading. The HEV estimation summary from that analysis is repeated in Output 19.4.1.

Output 19.4.1. HEV Estimation Summary ($\theta_1 = 1$)

```
                                 The MDC Procedure

                  Heteroscedastic Extreme Value Model Estimates

                                 Model Fit Summary

                  Dependent Variable                      decision
                  Number of Observations                        50
                  Number of Cases                              150
                  Log Likelihood                         -33.41383
                  Maximum Absolute Gradient              0.0000218
                  Number of Iterations                          11
                  Optimization Method             Dual Quasi-Newton
                  AIC                                     72.82765
                  Schwarz Criterion                       78.56372
```

You can estimate the HEV model with unit scale restrictions on all three alternatives ($\theta_1 = \theta_2 = \theta_3 = 1$) with the following statements. Output 19.4.2 displays the estimation summary.

```
proc mdc data=newdata;
   model decision = ttime / type=hev nchoice=3
         hev=(unitscale=1 2 3, integrate=laguerre) covest=hess;
   id pid;
run;
```

Output 19.4.2. HEV Estimation Summary ($\theta_1 = \theta_2 = \theta_3 = 1$)

```
                                The MDC Procedure

                   Heteroscedastic Extreme Value Model Estimates

                                Model Fit Summary

                   Dependent Variable                        decision
                   Number of Observations                          50
                   Number of Cases                                150
                   Log Likelihood                           -34.12756
                   Maximum Absolute Gradient               6.79511E-9
                   Number of Iterations                             5
                   Optimization Method              Dual Quasi-Newton
                   AIC                                       70.25512
                   Schwarz Criterion                         72.16714
```

The test for scale equivalence (SCALE2=SCALE3=1) is performed using a likelihood ratio test statistic. The following SAS statements compute the test statistic (1.4276) and its p-value (.4898) from the log-likelihood values in Output 19.4.1 and Output 19.4.2:

```
data _null_;
   /*-- test for H0: scale2 = scale3 = 1 --*/
   /*   ln L(max) = -34.1276                */
   /*   ln L(0)   = -33.4138                */
   stat = -2 * ( - 34.1276 + 33.4138 );
   df = 2;
   p_value = 1 - probchi(stat, df);
   put stat p_value;
run;
```

The test statistic fails to reject the null hypothesis of equal scale parameters, which implies that the random utility function is homoscedastic.

A multinomial probit model also allows heteroscedasticity of the random components of utility for different alternatives. Consider the following utility function:

$$U_{ij} = V_{ij} + \epsilon_{ij}$$

where

$$\boldsymbol{\epsilon}_i \sim N\left(\mathbf{0}, \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \sigma_3^2 \end{bmatrix}\right)$$

This multinomial probit model is estimated and the estimation summary is displayed in Output 19.4.3.

```
proc mdc data=newdata;
   model decision = ttime / type=mprobit nchoice=3
```

```
            unitvariance=(1 2) covest=hess;
      id pid;
      restrict RHO_31 = 0;
   run;
```

Output 19.4.3. Heteroscedastic Multinomial Probit Estimation Summary

```
                              The MDC Procedure

                        Multinomial Probit Estimates

                              Model Fit Summary

                  Dependent Variable                      decision
                  Number of Observations                        50
                  Number of Cases                              150
                  Log Likelihood                         -33.88604
                  Maximum Absolute Gradient                1.18537
                  Number of Iterations                           8
                  Optimization Method             Dual Quasi-Newton
                  AIC                                     71.77209
                  Schwarz Criterion                       75.59613
```

Next, the multinomial probit model with unit variances ($\sigma_1 = \sigma_2 = \sigma_3 = 1$) is estimated and the estimation summary is displayed in Output 19.4.4.

```
   proc mdc data=newdata;
      model decision = ttime / type=mprobit nchoice=3
            unitvariance=(1 2 3) covest=hess;
      id pid;
   restrict RHO_21 = 0;
   run;
```

Output 19.4.4. Homoscedastic Multinomial Probit Estimation Summary

```
                              The MDC Procedure

                        Multinomial Probit Estimates

                              Model Fit Summary

                  Dependent Variable                      decision
                  Number of Observations                        50
                  Number of Cases                              150
                  Log Likelihood                         -34.54252
                  Maximum Absolute Gradient                2.13340
                  Number of Iterations                           5
                  Optimization Method             Dual Quasi-Newton
                  AIC                                     71.08505
                  Schwarz Criterion                       72.99707
```

The test for homoscedasticity (σ_3 = 1) under $\sigma_1 = \sigma_2 = 1$ shows that the error variance is not heteroscedastic since the test statistic (1.313) is less than $\chi^2_{.05,1} = 3.84$. The marginal probability or p-value computed from the PROBCHI function is $.2519$.

```
data _null_;
   /*-- test for H0: sigma3 = 1 --*/
   /*   ln L(max) = -33.8860      */
   /*   ln L(0)   = -34.5425      */
   stat = -2 * ( -34.5425 + 33.8860 );
   df = 1;
   p_value = 1 - probchi(stat, df);
   put stat p_value;
run;
```

Example 19.5. Choice of Time for Work Trips: Nested Logit Analysis

A sample data of 527 automobile commuters in San Francisco Bay Area has been analyzed by Small (1982) and Brownstone and Small (1989). The regular time of arrival is recorded as between 42.5 minutes early and 17.5 minutes late, and indexed by 12 alternatives using five-minute interval groups. Refer to Small (1982) for more details on this data.

Brownstone and Small (1989) analyzed a two-level nested logit model displayed in Output 19.5.1. The probability of choosing j at level 2 is written

$$P_i(j) = \frac{\exp(\tau_j I_j)}{\sum_{j'=1}^{3} \exp(\tau_{j'} I_{j'})}$$

where $I_{j'}$ is an inclusive value and is computed as

$$I_{j'} = \ln \left[\sum_{k' \in C_{j'}} \exp(\mathbf{x}'_{ik'} \boldsymbol{\beta}) \right]$$

The probability of choosing an alternative k is denoted as

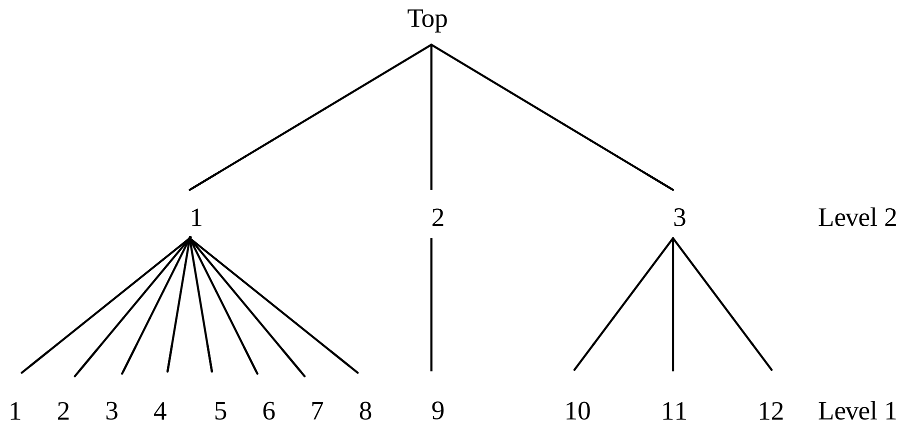
$$P_i(k|j) = \frac{\exp(\mathbf{x}'_{ik} \boldsymbol{\beta})}{\sum_{k' \in C_j} \exp(\mathbf{x}'_{ik'} \boldsymbol{\beta})}$$

The full information maximum likelihood (FIML) method maximizes the following log-likelihood function:

$$\mathcal{L} = \sum_{i=1}^{N} \sum_{j=1}^{J} d_{ij} \left[\ln(P_i(k|j)) + \ln(P_i(j)) \right]$$

where $d_{ij} = 1$ if a decision maker i chooses j, and 0 otherwise.

Output 19.5.1. Decision Tree for Two-Level Nested Logit



The following statements estimate the two-level nested logit model.

```
proc mdc data=mylib.small maxit=200 outest=a;
   model decision = r15 r10 ttime ttime_cp sde sde_cp
      sdl sdlx d2l / type=nlogit choice=(alt);
   id id;
   utility u(1, ) = r15 r10 ttime ttime_cp sde sde_cp
                    sdl sdlx d2l;
   nest level(1) = (1 2 3 4 5 6 7 8 @ 1, 9 @ 2, 10 11 12 @ 3),
        level(2) = (1 2 3 @ 1);
run;
```

The estimation summary, discrete response profile, and the FIML estimates are displayed in Output 19.5.2 through Output 19.5.4.

Output 19.5.2. Nested Logit Estimation Summary

```

Brownstone and Small (1989) also estimate the two-level nested logit model with equal scale parameter constraints, $\tau_1 = \tau_2 = \tau_3$. Replication of their model results is displayed in Output 19.5.5 and Output 19.5.6. The parameter estimates and standard errors are almost identical to those in Brownstone and Small (1989, p. 69).

      stat = -2 * ( -994.3940 + 990.8191 );
      df = 2;
      p_value = 1 - probchi(stat, df);
      put stat p_value;
   run;
```

Acknowledgments

Professor Kenneth Small has provided the work trip data that is used in the "Examples" section. This data was collected for the urban travel demand forecasting project, which was carried out by McFadden et al. (1977). The project was supported by the National Science Foundation, Research Applied to National Needs Program through grants GI-43740 and APR74-20392, and the Alfred P. Sloan Foundation, through grant 74-21-8.

Chapter 20
The MODEL Procedure

Overview

The MODEL procedure analyzes models in which the relationships among the variables comprise a system of one or more nonlinear equations. Primary uses of the MODEL procedure are estimation, simulation, and forecasting of nonlinear simultaneous equation models.

PROC MODEL features include

- SAS programming statements to define simultaneous systems of nonlinear equations
- tools to analyze the structure of the simultaneous equation system
- ARIMA, PDL, and other dynamic modeling capabilities
- tools to specify and estimate the error covariance structure
- tools to estimate and solve ordinary differential equations
- the following methods for parameter estimation:
  - Ordinary Least Squares (OLS)
  - Two-Stage Least Squares (2SLS)
  - Seemingly Unrelated Regression (SUR) and iterative SUR (ITSUR)
  - Three-Stage Least Squares (3SLS) and iterative 3SLS (IT3SLS)
  - Generalized Method of Moments (GMM)
  - Simulated Method of Moments (SMM)
  - Full Information Maximum Likelihood (FIML)
  - General Log-Likelihood maximization
- simulation and forecasting capabilities
- Monte Carlo simulation
- goal seeking solutions

Experimental graphics are now available with the MODEL procedure. For more information, see the "ODS Graphics" section on page 1166.

A system of equations can be nonlinear in the parameters, nonlinear in the observed variables, or nonlinear in both the parameters and the variables. *Nonlinear* in the parameters means that the mathematical relationship between the variables and parameters is not required to have a linear form. (A linear model is a special case of a nonlinear model.) A general nonlinear system of equations can be written as

$$\begin{aligned}
q_1(y_{1,t}, y_{2,t}, \ldots, y_{g,t}, x_{1,t}, x_{2,t}, \ldots, x_{m,t}, \theta_1, \theta_2, \ldots, \theta_p) &= \epsilon_{1,t} \\
q_2(y_{1,t}, y_{2,t}, \ldots, y_{g,t}, x_{1,t}, x_{2,t}, \ldots, x_{m,t}, \theta_1, \theta_2, \ldots, \theta_p) &= \epsilon_{2,t} \\
&\vdots \\
q_g(y_{1,t}, y_{2,t}, \ldots, y_{g,t}, x_{1,t}, x_{2,t}, \ldots, x_{m,t}, \theta_1, \theta_2, \ldots, \theta_p) &= \epsilon_{g,t}
\end{aligned}$$

where $y_{i,t}$ is an endogenous variable, $x_{i,t}$ is an exogenous variable, θ_i is a parameter, and ϵ_i is the unknown error. The subscript t represents time or some index to the data. In econometrics literature, the observed variables are either *endogenous* (dependent) variables or *exogenous* (independent) variables. This system can be written more succinctly in vector form as

$$\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) = \epsilon_t$$

This system of equations is in *general form* because the error term is by itself on one side of the equality. Systems can also be written in *normalized form* by placing the endogenous variable on one side of the equality, with each equation defining a predicted value for a unique endogenous variable. A normalized form equation system can be written in vector notation as

$$\mathbf{y}_t = \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \theta) + \epsilon_t.$$

PROC MODEL handles equations written in both forms.

Econometric models often explain the current values of the endogenous variables as functions of past values of exogenous and endogenous variables. These past values are referred to as *lagged* values, and the variable x_{t-i} is called lag *i* of the variable x_t. Using lagged variables, you can create a *dynamic*, or time dependent, model. In the preceding model systems, the lagged exogenous and endogenous variables are included as part of the exogenous variables.

If the data are time series, so that *t* indexes time (see Chapter 2, “Working with Time Series Data,” for more information on time series), it is possible that ϵ_t depends on ϵ_{t-i} or, more generally, the ϵ_t’s are not identically and independently distributed. If the errors of a model system are autocorrelated, the standard error of the estimates of the parameters of the system will be inflated.

Sometimes the ϵ_i’s are not identically distributed because the variance of ϵ is not constant. This is known as *heteroscedasticity*. Heteroscedasticity in an estimated model can also inflate the standard error of the estimates of the parameters. Using a weighted estimation can sometimes eliminate this problem. Alternately, a variance model such as GARCH or EGARCH can be estimated to correct for heteroscedasticity. If the proper weighting scheme and the form of the error model is difficult to determine, generalized methods of moments (GMM) estimation can be used to determine parameter estimates with very few assumptions about the form of the error process.

Other problems may also arise when estimating systems of equations. Consider the system of equations:

$$\begin{aligned} y_{1,t} &= \theta_1 + (\theta_2 + \theta_3\theta_4^t)^{-1} + \theta_5 y_{2,t} + \epsilon_{1,t} \\ y_{2,t} &= \theta_6 + (\theta_7 + \theta_8\theta_9^t)^{-1} + \theta_{10} y_{1,t} + \epsilon_{2,t} \end{aligned}$$

which is nonlinear in its parameters and cannot be estimated with linear regression. This system of equations represents a rudimentary predator-prey process with y_1 as the prey and y_2 as the predator (the second term in both equations is a logistics curve). The two equations must be estimated simultaneously because of the cross dependency of y's. This cross-dependency makes ϵ_1 and ϵ_2 violate the assumption of indpendence. Nonlinear ordinary least-squares estimation of these equations will produce biased and inconsistent parameter estimates. This is called *simultaneous equation bias*.

One method to remove simultaneous equation bias, in the linear case, is to replace the endogenous variables on the right-hand side of the equations with predicted values that are uncorrelated with the error terms. These predicted values can be obtained through a preliminary, or "first stage," *instrumental variable regression*. *Instrumental variables*, which are uncorrelated with the error term, are used as regressors to model the predicted values. The parameter estimates are obtained by a second regression using the predicted values of the regressors. This process is called *two-stage least squares*.

In the nonlinear case, nonlinear ordinary least-squares estimation is performed iteratively using a linearization of the model with respect to the parameters. The instrumental solution to simultaneous equation bias in the nonlinear case is the same as the linear case except the linearization of the model with respect to the parameters is predicted by the instrumental regression. Nonlinear two-stage least squares is one of several instrumental variables methods available in the MODEL procedure to handle simultaneous equation bias.

When you have a system of several regression equations, the random errors of the equations can be correlated. In this case, the large-sample efficiency of the estimation can be improved by using a joint generalized least-squares method that takes the cross-equation correlations into account. If the equations are not simultaneous (no dependent regressors), then *seemingly unrelated regression* (SUR) can be used. The SUR method requires an estimate of the cross-equation error covariance matrix, Σ. The usual approach is to first fit the equations using OLS, compute an estimate $\hat{\Sigma}$ from the OLS residuals, and then perform the SUR estimation based on $\hat{\Sigma}$. The MODEL procedure estimates Σ by default, or you can supply your own estimate of Σ.

If the equation system is simultaneous, you can combine the 2SLS and SUR methods to take into account both simultaneous equation bias and cross-equation correlation of the errors. This is called *three-stage least squares* or 3SLS.

A different approach to the simultaneous equation bias problem is the full information maximum likelihood, or FIML, estimation method. FIML does not require instrumental variables, but it assumes that the equation errors have a multivariate normal distribution. 2SLS and 3SLS estimation do not assume a particular distribution for the errors.

Other non-normal error distribution models can be estimated as well. The centered *t*-distribution with estimated degrees of freedom and non-constant variance is an additional built in likelihood function. If the distribution of the equation errors is not normal or *t* but known, then the log likelihood can be specified using the ERRORMODEL statement.

Once a nonlinear model has been estimated, it can be used to obtain forecasts. If the model is linear in the variables you want to forecast, a simple linear solve can generate the forecasts. If the system is nonlinear, an iterative procedure must be used. The preceding example system is linear in its endogenous variables. The MODEL procedure's SOLVE statement is used to forecast nonlinear models.

One of the main purposes of creating models is to obtain an understanding of the relationship among the variables. There are usually only a few variables in a model you can control (for example, the amount of money spent on advertising). Often you want to determine how to change the variables under your control to obtain some target goal. This process is called *goal seeking*. PROC MODEL allows you to solve for any subset of the variables in a system of equations given values for the remaining variables.

The nonlinearity of a model creates two problems with the forecasts: the forecast errors are not normally distributed with zero mean, and no formula exits to calculate the forecast confidence intervals. PROC MODEL provides Monte Carlo techniques, which, when used with the covariance of the parameters and error covariance matrix, can produce approximate error bounds on the forecasts. The following distributions on the errors are supported for multivariate Monte Carlo simulation:

- Cauchy
- Chi-squared
- Empirical
- *F*
- Poisson
- *t*
- Uniform

A transformation technique is used to create a covariance matrix for generating the correct innovations in a Monte Carlo simulation.

Getting Started

This section introduces the MODEL procedure and shows how to use PROC MODEL for several kinds of nonlinear regression analysis and nonlinear systems simulation problems.

Nonlinear Regression Analysis

One of the most important uses of PROC MODEL is to estimate unknown parameters in a nonlinear model. A simple nonlinear model has the form:

$$y = f(\mathbf{x}, \theta) + \epsilon$$

where $\mathbf{x}$ is a vector of exogenous variables. To estimate unknown parameters using PROC MODEL, do the following:

1. Use the DATA= option in a PROC MODEL statement to specify the input SAS data set containing $\mathbf{y}$ and $\mathbf{x}$, the observed values of the variables.
2. Write the equation for the model using SAS programming statements, including all parameters and arithmetic operators but leaving off the unobserved error component, ϵ.
3. Use a FIT statement to fit the model equation to the input data to determine the unknown parameters, θ.

An Example

The SASHELP library contains the data set CITIMON, which contains the variable LHUR, the monthly unemployment figures, and the variable IP, the monthly industrial production index. You suspect that the unemployment rates are inversely proportional to the industrial production index. Assume that these variables are related by the following nonlinear equation:

$$lhur = \frac{1}{a \cdot \mathrm{ip} + b} + c + \epsilon$$

In this equation *a*, *b*, and *c* are unknown coefficients and ϵ is an unobserved random error.

The following statements illustrate how to use PROC MODEL to estimate values for *a*, *b*, and *c* from the data in SASHELP.CITIMON.

```
proc model data=sashelp.citimon;
   lhur = 1/(a * ip + b) + c;
   fit lhur;
run;
```

Notice that the model equation is written as a SAS assignment statement. The variable LHUR is assumed to be the dependent variable because it is named in the FIT statement and is on the left-hand side of the assignment.

PROC MODEL determines that LHUR and IP are observed variables because they are in the input data set. A, B, and C are treated as unknown parameters to be estimated from the data because they are not in the input data set. If the data set contained a variable named A, B, or C, you would need to explicitly declare the parameters with a PARMS statement.

In response to the FIT statement, PROC MODEL estimates values for A, B, and C using nonlinear least squares and prints the results. The first part of the output is a “Model Summary table, shown in Figure 20.1.

```
                              The MODEL Procedure

                                 Model Summary

                           Model Variables         1
                           Parameters              3
                           Equations               1
                           Number of Statements    1

                             Model Variables  LHUR
                                  Parameters  a b c
                                   Equations  LHUR
```

Figure 20.1. Model Summary Report

This table details the size of the model, including the number of programming statements defining the model, and lists the dependent variables (LHUR in this case), the unknown parameters (A, B, and C), and the model equations. In this case the equation is named for the dependent variable, LHUR.

PROC MODEL then prints a summary of the estimation problem, as shown in Figure 20.2.

```
                              The MODEL Procedure

                          The Equation to Estimate is

                             LHUR =  F(a, b, c(1))
```

Figure 20.2. Estimation Problem Report

The notation used in the summary of the estimation problem indicates that LHUR is a function of A, B, and C, which are to be estimated by fitting the function to the data. If the partial derivative of the equation with respect to a parameter is a simple variable or constant, the derivative is shown in parentheses after the parameter name. In this case, the derivative with respect to the intercept C is 1. The derivatives with respect to A and B are complex expressions and so are not shown.

Next, PROC MODEL prints an estimation summary as shown in Figure 20.3.

```

Figure 20.3. Estimation Summary Report

The estimation summary provides information on the iterative process used to compute the estimates. The heading "OLS Estimation Summary" indicates that the nonlinear ordinary least-squares (OLS) estimation method is used. This table indicates that all 3 parameters were estimated successfully using 144 nonmissing observations from the data set SASHELP.CITIMON. Calculating the estimates required 10 iterations of the GAUSS method. Various measures of how well the iterative process converged are also shown. For example, the "RPC(B)" value 0.00968 means that on the final iteration the largest relative change in any estimate was for parameter B, which changed by .968 percent. See the section "Convergence Criteria" later in this chapter for details.

PROC MODEL then prints the estimation results. The first part of this table is the summary of residual errors, shown in Figure 20.4.

```

```

Figure 20.4. Summary of Residual Errors Report

This table lists the sum of squared errors (SSE), the mean square error (MSE), the root mean square error (Root MSE), and the R^2 and adjusted R^2 statistics. The R^2 value of .7472 means that the estimated model explains approximately 75 percent more of the variability in LHUR than a mean model explains.

Following the summary of residual errors is the parameter estimates table, shown in Figure 20.5.

```

```

Figure 20.5. Parameter Estimates

Because the model is nonlinear, the standard error of the estimate, the t value, and its significance level are only approximate. These values are computed using asymptotic formulas that are correct for large sample sizes but only approximately correct for smaller samples. Thus, you should use caution in interpreting these statistics for nonlinear models, especially for small sample sizes. For linear models, these results are exact and are the same as standard linear regression.

The last part of the output produced by the FIT statement is shown in Figure 20.6.

```

Figure 20.6. System Summary Statistics

This table lists the objective value for the estimation of the nonlinear system, which is a weighted system mean square error. This statistic can be used for testing cross-equation restrictions in multi-equation regression problems. See the section “Restrictions and Bounds on Parameters” for details. Since there is only a single equation in this case, the objective value is the same as the residual MSE for LHUR except that the objective value does not include a degrees of freedom correction. This can be seen in the fact that “Objective*N” equals the residual SSE, 75.1989. N is 144, the number of observations used.

Convergence and Starting Values

Computing parameter estimates for nonlinear equations requires an iterative process. Starting with an initial guess for the parameter values, PROC MODEL tries different parameter values until the objective function of the estimation method is minimized.

(The objective function of the estimation method is sometimes called the *fitting function*.) This process does not always succeed, and whether it does succeed depends greatly on the starting values used. By default, PROC MODEL uses the starting value .0001 for all parameters.

Consequently, in order to use PROC MODEL to achieve convergence of parameter estimates, you need to know two things: how to recognize convergence failure by interpreting diagnostic output, and how to specify reasonable starting values. The MODEL procedure includes alternate iterative techniques and grid search capabilities to aid in finding estimates. See the section "Troubleshooting Convergence Problems" for more details.

Nonlinear Systems Regression

If a model has more than one endogenous variable, several facts need to be considered in the choice of an estimation method. If the model has endogenous regressors, then an instrumental variables method such as 2SLS or 3SLS can be used to avoid simultaneous equation bias. Instrumental variables must be provided to use these methods. A discussion of possible choices for instrumental variables is provided in the the section "Choice of Instruments" on page 1135 in this chapter.

The following is an example of the use of 2SLS and the INSTRUMENTS statement:

```
proc model data=test2 ;
   exogenous x1 x2;
   parms a1 a2 b2 2.5 c2 55 d1;

   y1 = a1 * y2 + b2 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / 2sls;
   instruments b2 c2 _exog_;
run;
```

The estimation method selected is added after the slash (/) on the FIT statement. The INSTRUMENTS statement follows the FIT statement and in this case selects all the exogenous variables as instruments with the _EXOG_ keyword. The parameters B2 and C2 on the instruments list request that the derivatives with respect to B2 and C2 be additional instruments.

Full information maximum likelihood (FIML) can also be used to avoid simultaneous equation bias. FIML is computationally more expensive than an instrumental variables method and assumes that the errors are normally distributed. On the other hand, FIML does not require the specification of instruments. FIML is selected with the FIML option on the FIT statement.

The preceding example is estimated with FIML using the following statements:

```
proc model data=test2 ;
   exogenous x1 x2;
   parms a1 a2 b2 2.5 c2 55 d1;

   y1 = a1 * y2 + b2 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / fiml;
run;
```

General Form Models

The single equation example shown in the preceding section was written in normalized form and specified as an assignment of the regression function to the dependent variable LHUR. However, sometimes it is impossible or inconvenient to write a nonlinear model in normalized form.

To write a general form equation, give the equation a name with the prefix “EQ.” . This EQ.-prefixed variable represents the equation error. Write the equation as an assignment to this variable.

For example, suppose you have the following nonlinear model relating the variables *x* and *y*:

$$\epsilon = a + b\ln(cy + dx)$$

Naming this equation ‘one’, you can fit this model with the following statements:

```
proc model data=xydata;
   eq.one = a + b * log( c * y + d * x );
   fit one;
run;
```

The use of the EQ. prefix tells PROC MODEL that the variable is an error term and that it should not expect actual values for the variable ONE in the input data set.

Supply and Demand Models

General form specifications are often useful when you have several equations for the same dependent variable. This is common in supply and demand models, where both the supply equation and the demand equation are written as predictions for quantity as functions of price.

For example, consider the following supply and demand system:

$$\text{(supply)} \qquad \text{quantity} = \alpha_1 + \alpha_2\ \text{price} + \epsilon_1$$

$$\text{(demand)} \qquad \text{quantity} = \beta_1 + \beta_2 \text{ price} + \beta_3 \text{ income} + \epsilon_2$$

Assume the *quantity* of interest is the amount of energy consumed in the U.S.; the *price* is the price of gasoline, and the *income* variable is the consumer debt. When the market is at equilibrium, these equations determine the market price and the equilibrium quantity. These equations are written in general form as

$$\epsilon_1 = quantity - (\alpha_1 + \alpha_2\, price)$$

$$\epsilon_2 = quantity - (\beta_1 + \beta_2\, price + \beta_3\, income)$$

Note that the endogenous variables *quantity* and *price* depend on two error terms so that OLS should not be used. The following example uses three-stage least-squares estimation.

Data for this model is obtained from the SASHELP.CITIMON data set.

```
title1 'Supply-Demand Model using General-form Equations';
proc model data=sashelp.citimon;
   endogenous eegp eec;
   exogenous exvus cciutc;
   parameters a1 a2 b1 b2 b3 ;
   label eegp   = 'Gasoline Retail Price'
         eec    = 'Energy Consumption'
         cciutc = 'Consumer Debt';

   /* -------- Supply equation ------------- */
   eq.supply = eec - (a1 + a2 * eegp );

   /* -------- Demand equation ------------- */
   eq.demand = eec - (b1 + b2 * eegp + b3 * cciutc);

   /* -------- Instrumental variables -------*/
   lageegp = lag(eegp); lag2eegp=lag2(eegp);

   /* -------- Estimate parameters --------- */
   fit supply demand / n3sls fsrsq;
   instruments _EXOG_ lageegp lag2eegp;
run;
```

The FIT statement specifies the two equations to estimate and the method of estimation, N3SLS. Note that '3SLS' is an alias for N3SLS. The option FSRSQ is selected to get a report of the first stage R^2 to determine the acceptability of the selected instruments.

Since three-stage least squares is an instrumental variables method, instruments are specified with the INSTRUMENTS statement. The instruments selected are all the exogenous variables, selected with the _EXOG_ option, and two lags of the variable EEGP, LAGEEGP and LAG2EEGP.

The data set CITIMON has four observations that generate missing values because values for either EEGP, EEC, or CCIUTC are missing. This is revealed in the "Observations Processed" output shown in Figure 20.7. Missing values are also generated when the equations cannot be computed for a given observation. Missing observations are not used in the estimation.

```

                                Used        139
                                Missing       4
                                Lagged        2
```

Figure 20.7. Supply-Demand Observations Processed

The lags used to create the instruments also reduce the number of observations used. In this case, the first 2 observations were used to fill the lags of EEGP.

The data set has a total of 145 observations, of which 4 generated missing values and 2 were used to fill lags, which left 139 observations for the estimation. In the estimation summary, in Figure 20.8, the total degrees of freedom for the model and error is 139.

```

Figure 20.8. Supply-Demand Parameter Estimates

One disadvantage of specifying equations in general form is that there are no actual values associated with the equation, so the R^2 statistic cannot be computed.

Solving Simultaneous Nonlinear Equation Systems

You can use a SOLVE statement to solve the nonlinear equation system for some variables when the values of other variables are given.

Consider the demand and supply model shown in the preceding example. The following statement computes equilibrium price (EEGP) and quantity (EEC) values for given observed cost (CCIUTC) values and stores them in the output data set EQUILIB.

```
title1 'Supply-Demand Model using General-form Equations';
proc model data=sashelp.citimon;
   endogenous eegp eec;
   exogenous exvus cciutc;
   parameters a1 a2 a3 b1 b2 ;
   label eegp   = 'Gasoline Retail Price'
         eec    = 'Energy Consumption'
         cciutc = 'Consumer Debt';

   /* -------- Supply equation ------------- */
   eq.supply = eec - (a1 + a2 * eegp + a3 * cciutc);

   /* -------- Demand equation ------------- */
   eq.demand = eec - (b1 + b2 * eegp );

   /* -------- Instrumental variables -------*/
   lageegp = lag(eegp); lag2eegp=lag2(eegp);

   /* -------- Estimate parameters --------- */
   instruments _EXOG_ lageegp lag2eegp;
   fit supply demand / n3sls ;
   solve eegp eec / out=equilib;
run;
```

As a second example, suppose you want to compute points of intersection between the square root function and hyperbolas of the form $a + b/x$. That is, solve the system:

$$\text{(square root)} \qquad y = \sqrt{x}$$

$$\text{(hyperbola)} \qquad y = a + \frac{b}{x}$$

The following statements read parameters for several hyperbolas in the input data set TEST and solve the nonlinear equations. The SOLVEPRINT option on the SOLVE statement prints the solution values. The ID statement is used to include the values of A and B in the output of the SOLVEPRINT option.

```
data test;
  input a b @@;
  datalines;
  0 1   1 1   1 2
;

proc model data=test;
   eq.sqrt      = sqrt(x) - y;
   eq.hyperbola = a + b / x - y;
   solve x y / solveprint;
   id a b;
run;
```

The printed output produced by this example consists of a model summary report, a listing of the solution values for each observation, and a solution summary report. The model summary for this example is shown in Figure 20.9.

```

Figure 20.10. Solution Values for Each Observation

For each observation, a heading line is printed that lists the values of the ID variables for the observation and information on the iterative process used to compute the solution. Following the heading line for the observation, the solution values are printed.

The heading line shows the solution method used (Newton's method by default), the number of iterations required, and the convergence measure, labeled CC=. This convergence measure indicates the maximum error by which solution values fail to satisfy the equations. When this error is small enough (as determined by the CONVERGE= option), the iterations terminate. The equation with the largest error is indicated in parentheses. For example, for observation 3 the HYPERBOLA equation has an error of 4.42×10^{-13} while the error of the SQRT equation is even smaller.

The last part of the SOLVE statement output is the solution summary report shown in Figure 20.11. This report summarizes the iteration history and the model solved.

Monte Carlo Simulation

The RANDOM= option is used to request Monte Carlo (or stochastic) simulation to generate confidence intervals for a forecast. The confidence intervals are implied by the model's relationship to the the implicit random error term ϵ and the parameters.

The Monte Carlo simulation generates a random set of additive error values, one for each observation and each equation, and computes one set of perturbations of the parameters. These new parameters, along with the additive error terms, are then used to compute a new forecast that satisfies this new simultaneous system. Then a new set of additive error values and parameter perturbations is computed, and the process is repeated the requested number of times.

Consider the following exchange rate model for the U.S. dollar with the German mark and the Japanese yen:

$$rate\_jp = a_1 + b_1 im\_jp + c_1 di\_jp;$$

$$rate\_wg = a_2 + b_2 im\_wg + c_1 di\_wg;$$

where *rate_jp* and *rate_wg* are the exchange rate of the Japanese yen and the German mark versus the U.S. dollar respectively; *im_jp* and *im_wg* are the imports from Japan and Germany in 1984 dollars respectively; and *di_jp* and *di_wg* are the differences in inflation rate of Japan and the U.S., and Germany and the U.S. respectively. The

Monte Carlo capabilities of the MODEL procedure are used to generate error bounds on a forecast using this model.

```
proc model data=exchange;
   endo im_jp im_wg;
   exo di_jp di_wg;
   parms a1 a2 b1 b2 c1 c2;
   label rate_jp = 'Exchange Rate of Yen/$'
         rate_wg = 'Exchange Rate of Gm/$'
         im_jp = 'Imports to US from Japan in 1984 $'
         im_wg = 'Imports to US from WG in 1984 $'
         di_jp = 'Difference in Inflation Rates US-JP'
         di_wg = 'Difference in Inflation Rates US-WG';

   rate_jp = a1 + b1*im_jp + c1*di_jp;
   rate_wg = a2 + b2*im_wg + c2*di_wg;

            /* Fit the EXCHANGE data */
   fit rate_jp rate_wg / sur outest=xch_est outcov outs=s;

            /* Solve using the WHATIF data set */
   solve rate_jp rate_wg / data=whatif estdata=xch_est sdata=s
          random=100 seed=123 out=monte forecast;
   id yr;
   range yr=1986;
run;
```

Data for the EXCHANGE data set was obtained from the Department of Commerce and the yearly "Economic Report of the President."

First, the parameters are estimated using SUR selected by the SUR option on the FIT statement. The OUTEST= option is used to create the XCH_EST data set which contains the estimates of the parameters. The OUTCOV option adds the covariance matrix of the parameters to the XCH_EST data set. The OUTS= option is used to save the covariance of the equation error in the data set S.

Next, Monte Carlo simulation is requested using the RANDOM= option on the SOLVE statement. The data set WHATIF, shown below, is used to drive the forecasts. The ESTDATA= option reads in the XCH_EST data set which contains the parameter estimates and covariance matrix. Because the parameter covariance matrix is included, perturbations of the parameters are performed. The SDATA= option causes the Monte Carlo simulation to use the equation error covariance in the S data set to perturb the equation errors. The SEED= option selects the number 123 as seed value for the random number generator. The output of the Monte Carlo simulation is written to the data set MONTE selected by the OUT= option.

```

```

To generate a confidence interval plot for the forecast, use PROC UNIVARIATE to generate percentile bounds and use PROC GPLOT to plot the graph. The following SAS statements produce the graph in Figure 20.12.

```
     proc sort data=monte;
        by yr;
     run;

     proc univariate data=monte noprint;
        by yr;
        var rate_jp rate_wg;
        output out=bounds mean=mean p5=p5 p95=p95;
     run;

     title "Monte Carlo Generated Confidence
                Intervals on a Forecast";
     proc gplot data=bounds;
        plot mean*yr p5*yr p95*yr /overlay;
        symbol1 i=join value=triangle;
        symbol2 i=join value=square l=4;
        symbol3 i=join value=square l=4;
     run;
```

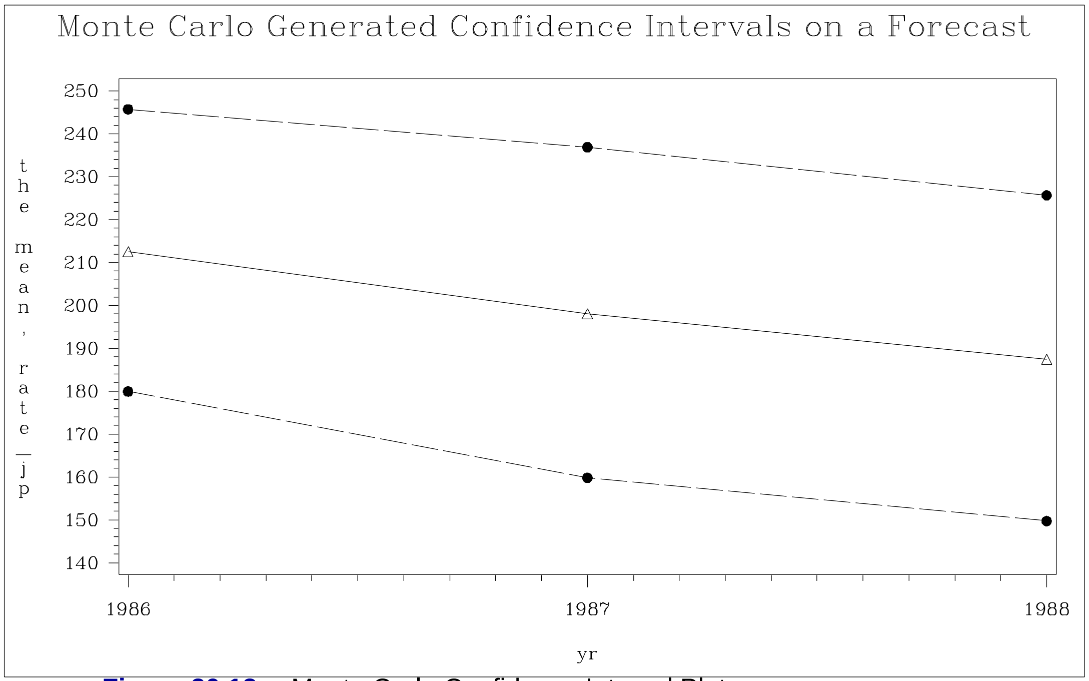

Figure 20.12. Monte Carlo Confidence Interval Plot

Syntax

The following statements can be used with the MODEL procedure:

PROC MODEL *options*;
  ABORT ;
  ARRAY *arrayname variables . . .* **;**
  ATTRIB *variable-list attribute-list [variable-list attribute-list]*;
  BOUNDS *bound1, bound2 . . .* **;**
  BY *variables*;
  CALL *name [(expression [, expression . . .])]* **;**
  CONTROL *variable [value] . . .* **;**
  DELETE ;
  DO *[variable = expression [TO expression] [BY expression]*
    [, expression **TO** *expression] [* **BY** *expression] . . .]*
   [**WHILE** *expression] [* **UNTIL** *expression]* **;**
  END ;
  DROP *variable . . .* **;**
  ENDOGENOUS *variable [initial values] . . .* **;**
  ERRORMODEL *equation-name ~ distribution*
    [**CDF=(** *CDF(options))]* **;**
  ESTIMATE *item [, item . . .] [,/ options]* **;**
  EXOGENOUS *variable [initial values] . . .* **;**
  FIT *equations [* **PARMS**=*(parameter values . . .)]*
    START=*(parameter values . . .)*
    [**DROP**=*(parameters)] [/ options]*;

FORMAT *variables [format] [* **DEFAULT** *= default-format]***;**
GOTO *statement_label* **;**
ID *variables***;**

Functional Summary

The statements and options in the MODEL procedure are summarized in the following table.

Description	**Statement**	**Option**
Data Set Options		
specify the input data set for the variables	FIT, SOLVE	DATA=
specify the input data set for parameters	FIT, SOLVE	ESTDATA=
specify the method for handling missing values	FIT	MISSING=

Description	**Statement**	**Option**
specify the input data set for parameters	MODEL	PARMSDATA=
specify the output data set for residual, predicted, or actual values	FIT	OUT=
specify the output data set for solution mode results	SOLVE	OUT=
write the actual values to OUT= data set	FIT	OUTACTUAL
select all output options	FIT	OUTALL
write the covariance matrix of the estimates	FIT	OUTCOV
write the parameter estimates to a data set	FIT	OUTEST=
write the parameter estimates to a data set	MODEL	OUTPARMS=
write the observations used to start the lags	SOLVE	OUTLAGS
write the predicted values to the OUT= data set	FIT	OUTPREDICT
write the residual values to the OUT= data set	FIT	OUTRESID
write the covariance matrix of the equation errors to a data set	FIT	OUTS=
write the **S** matrix used in the objective function definition to a data set	FIT	OUTSUSED=
write the estimate of the variance matrix of the moment generating function	FIT	OUTV=
read the covariance matrix of the equation errors	FIT, SOLVE	SDATA=
read the covariance matrix for GMM and ITGMM	FIT	VDATA=
specify the name of the time variable	FIT, SOLVE, MODEL	TIME=
select the estimation type to read	FIT, SOLVE	TYPE=
General ESTIMATE Statement Options		
specify the name of the data set in which the estimate of the functions of the parameters are to be written	ESTIMATE	OUTEST=
write the covariance matrix of the functions of the parameters to the OUTEST= data set	ESTIMATE	OUTCOV
print the covariance matrix of the functions of the parameters	ESTIMATE	COVB
print the correlation matrix of the functions of the parameters	ESTIMATE	CORRB
Printing Options for FIT Tasks		
print the modified Breusch-Pagan test for heteroscedasticity	FIT	BREUSCH
print the Chow test for structural breaks	FIT	CHOW=
print collinearity diagnostics	FIT	COLLIN

Description	Statement	Option
print the correlation matrices	FIT	CORR
print the correlation matrix of the parameters	FIT	CORRB
print the correlation matrix of the residuals	FIT	CORRS
print the covariance matrices	FIT	COV
print the covariance matrix of the parameters	FIT	COVB
print the covariance matrix of the residuals	FIT	COVS
print Durbin-Watson *d* statistics	FIT	DW
print first-stage R^2 statistics	FIT	FSRSQ
print Godfrey's tests for autocorrelated residuals for each equation	FIT	GODFREY
print Hausman's specification test	FIT	HAUSMAN
print tests of normality of the model residuals	FIT	NORMAL
print the predictive Chow test for structural breaks	FIT	PCHOW=
specify all the printing options	FIT	PRINTALL
print White's test for heteroscedasticity	FIT	WHITE
Options to Control FIT Iteration Output		
print the inverse of the crossproducts Jacobian matrix	FIT	I
print a summary iteration listing	FIT	ITPRINT
print a detailed iteration listing	FIT	ITDETAILS
print the crossproduct Jacobian matrix	FIT	XPX
specify all the iteration printing-control options	FIT	ITALL
Options to Control the Minimization Process		
specify the convergence criteria	FIT	CONVERGE=
select the Hessian approximation used for FIML	FIT	HESSIAN=
specifies the local truncation error bound for the integration	FIT, SOLVE, MODEL	LTEBOUND=
specify the maximum number of iterations allowed	FIT	MAXITER=
specify the maximum number of subiterations allowed	FIT	MAXSUBITER=
select the iterative minimization method to use	FIT	METHOD=
specifies the smallest allowed time step to be used in the integration	FIT, SOLVE, MODEL	MINTIMESTEP=
modify the iterations for estimation methods that iterate the **S** matrix or the **V** matrix	FIT	NESTIT
specify the smallest pivot value	MODEL, FIT, SOLVE	SINGULAR

Description	Statement	Option
specify the number of minimization iterations to perform at each grid point	FIT	STARTITER=
specify a weight variable	WEIGHT	
Options to Read and Write Model Files		
read a model from one or more input model files	INCLUDE	MODEL=
suppress the default output of the model file	MODEL, RESET	NOSTORE
specify the name of an output model file	MODEL, RESET	OUTMODEL=
delete the current model	RESET	PURGE
Options to List or Analyze the Structure of the Model		
print a dependency structure of a model	MODEL	BLOCK
print a graph of the dependency structure of a model	MODEL	GRAPH
print the model program and variable lists	MODEL	LIST
print the derivative tables and compiled model program code	MODEL	LISTCODE
print a dependency list	MODEL	LISTDEP
print a table of derivatives	MODEL	LISTDER
print a cross-reference of the variables	MODEL	XREF
General Printing Control Options		
expand parts of the printed output	FIT, SOLVE	DETAILS
print a message for each statement as it is executed	FIT, SOLVE	FLOW
select the maximum number of execution errors that can be printed	FIT, SOLVE	MAXERRORS=
select the number of decimal places shown in the printed output	FIT, SOLVE	NDEC=
suppress the normal printed output	FIT, SOLVE	NOPRINT
specify all the noniteration printing options	FIT, SOLVE	PRINTALL
print the result of each operation as it is executed	FIT, SOLVE	TRACE
request a comprehensive memory usage summary	FIT, SOLVE, MODEL, RESET	MEMORYUSE
turns off the NOPRINT option	RESET	PRINT
Statements that Declare Variables		
associate a name with a list of variables and constants	ARRAY	
declare a variable to have a fixed value	CONTROL	

Description	Statement	Option
declare a variable to be a dependent or endogenous variable	ENDOGENOUS	
declare a variable to be an independent or exogenous variable	EXOGENOUS	
specify identifying variables	ID	
assign a label to a variable	LABEL	
select additional variables to be output	OUTVARS	
declare a variable to be a parameter	PARAMETERS	
force a variable to hold its value from a previous observation	RETAIN	
declare a model variable	VAR	
declare an instrumental variable	INSTRUMENTS	
omit the default intercept term in the instruments list	INSTRUMENTS	NOINT
General FIT Statement Options		
omit parameters from the estimation	FIT	DROP=
associate a *variable* with an initial value as a parameter or a constant	FIT	INITIAL=
bypass OLS to get initial parameter estimates for GMM, ITGMM, or FIML	FIT	NOOLS
bypass 2SLS to get initial parameter estimates for GMM, ITGMM, or FIML	FIT	NO2SLS
specify the parameters to estimate	FIT	PARMS=
request confidence intervals on estimated parameters	FIT	PRL=
select a grid search	FIT	START=
Options to Control the Estimation Method Used		
specify nonlinear ordinary least squares	FIT	OLS
specify iterated nonlinear ordinary least squares	FIT	ITOLS
specify seemingly unrelated regression	FIT	SUR
specify iterated seemingly unrelated regression	FIT	ITSUR
specify two-stage least squares	FIT	2SLS
specify iterated two-stage least squares	FIT	IT2SLS
specify three-stage least squares	FIT	3SLS
specify iterated three-stage least squares	FIT	IT3SLS
specify full information maximum likelihood	FIT	FIML
specify simulated method of moments	FIT	NDRAW
specify number of draws for the V matrix	FIT	NDRAWV

Description	Statement	Option
specify number of initial observations for SMM	FIT	NPREOBS
select the variance-covariance estimator used for FIML	FIT	COVBEST=
specify generalized method of moments	FIT	GMM
specify the kernel for GMM and ITGMM	FIT	KERNEL=
specify iterated generalized method of moments	FIT	ITGMM
specify the type of generalized inverse used for the covariance matrix	FIT	GINV=
specify the denominator for computing variances and covariances	FIT	VARDEF=
specify adding the variance adjustment for SMM	FIT	ADJSMMV
specify variance correction for heteroscedasticity	FIT	HCCME=
specify GMM variance under arbitrary weighting matrix	FIT	GENGMMV
specify GMM variance under optimal weighting matrix	FIT	NOGENGMMV
Solution Mode Options		
select a subset of the model equations	SOLVE	SATISFY=
solve only for missing variables	SOLVE	FORECAST
solve for all solution variables	SOLVE	SIMULATE
Solution Mode Options: Lag Processing		
use solved values in the lag functions	SOLVE	DYNAMIC
use actual values in the lag functions	SOLVE	STATIC
produce successive forecasts to a fixed forecast horizon	SOLVE	NAHEAD=
select the observation to start dynamic solutions	SOLVE	START=
Solution Mode Options: Numerical Methods		
specify the maximum number of iterations allowed	SOLVE	MAXITER=
specify the maximum number of subiterations allowed	SOLVE	MAXSUBITER=
specify the convergence criteria	SOLVE	CONVERGE=
compute a simultaneous solution using a Jacobi-like iteration	SOLVE	JACOBI

Description	Statement	Option
compute a simultaneous solution using a Gauss-Seidel-like iteration	SOLVE	SEIDEL
compute a simultaneous solution using Newton's method	SOLVE	NEWTON
compute a nonsimultaneous solution	SOLVE	SINGLE
Monte Carlo Simulation Options		
specify quasi-random number generator	SOLVE	QUASI=
specify pseudo-random number generator	SOLVE	PSUEDO=
repeat the solution multiple times	SOLVE	RANDOM=
initialize the pseudo-random number generator	SOLVE	SEED=
Solution Mode Printing Options		
print between data points integration values for the DERT. variables and the auxiliary variables	FIT, SOLVE, MODEL	INTGPRINT
print the solution approximation and equation errors	SOLVE	ITPRINT
print the solution values and residuals at each observation	SOLVE	SOLVEPRINT
print various summary statistics	SOLVE	STATS
print tables of Theil inequality coefficients	SOLVE	THEIL
specify all printing control options	SOLVE	PRINTALL
General TEST Statement Options		
specify that a Wald test be computed	TEST	WALD
specify that a Lagrange multiplier test be computed	TEST	LM
specify that a likelihood ratio test be computed	TEST	LR
requests all three types of tests	TEST	ALL
specify the name of an output SAS data set that contains the test results	TEST	OUT=
Miscellaneous Statements		
specify the range of observations to be used	RANGE	
subset the data set with *by* variables	BY	

PROC MODEL Statement

PROC MODEL *options;*

The following options can be specified in the PROC MODEL statement. All of the nonassignment options (the options that do not accept a value after an equal sign) can have NO prefixed to the option name in the RESET statement to turn the option off. The default case is not explicitly indicated in the discussion that follows. Thus, for example, the option DETAILS is documented in the following, but NODETAILS is not documented since it is the default. Also, the NOSTORE option is documented because STORE is the default.

Data Set Options

DATA= *SAS-data-set*

names the input data set. Variables in the model program are looked up in the DATA= data set and, if found, their attributes (type, length, label, format) are set to be the same as those in the input data set (if not previously defined otherwise). The values for the variables in the program are read from the input data set when the model is estimated or simulated by FIT and SOLVE statements.

OUTPARMS= *SAS-data-set*
writes the parameter estimates to a SAS data set. See "Output Data Sets" for details.

PARMSDATA= *SAS-data-set*
names the SAS data set that contains the parameter estimates. See "Input Data Sets" for details.

Options to Read and Write Model Files

MODEL= *model-name*
MODEL= *(model-list)*
reads the model from one or more input model files created by previous PROC MODEL executions. Model files are written by the OUTMODEL= option.

NOSTORE
suppresses the default output of the model file. This option is only applicable when FIT or SOLVE statements are not used, the MODEL= option is not used, and when a model is specified.

OUTMODEL= *model-name*
specifies the name of an output model file to which the model is to be written. Model files are stored as members of a SAS catalog, with the type MODEL.

V5MODEL= *model-name*
reads model files written by Version 5 of SAS/ETS software.

Options to List or Analyze the Structure of the Model

These options produce reports on the structure of the model or list the programming statements defining the models. These options are automatically reset (turned off) after the reports are printed. To turn these options back on after a RUN statement has been entered, use the RESET statement or specify the options on a FIT or SOLVE statement.

BLOCK
prints an analysis of the structure of the model given by the assignments to model variables appearing in the model program. This analysis includes a classification of model variables into endogenous (dependent) and exogenous (independent) groups based on the presence of the variable on the left-hand side of an assignment statement. The endogenous variables are grouped into simultaneously determined blocks. The dependency structure of the simultaneous blocks and exogenous variables is also printed. The BLOCK option cannot analyze dependencies implied by general form equations.

GRAPH
prints the graph of the dependency structure of the model. The GRAPH option also invokes the BLOCK option and produces a graphical display of the information listed by the BLOCK option.

LIST
prints the model program and variable lists, including the statements added by PROC MODEL and macros.

LISTALL
selects the LIST, LISTDEP, LISTDER, and LISTCODE options.

LISTCODE
prints the derivative tables and compiled model program code. LISTCODE is a debugging feature and is not normally needed.

LISTDEP
prints a report that lists for each variable in the model program the variables that depend on it and that it depends on. These lists are given separately for current-period values and for lagged values of the variables.

The information displayed is the same as that used to construct the BLOCK report but differs in that the information is listed for all variables (including parameters, control variables, and program variables), not just the model variables. Classification into endogenous and exogenous groups and analysis of simultaneous structure is not done by the LISTDEP report.

LISTDER
prints a table of derivatives for FIT and SOLVE tasks. (The LISTDER option is only applicable for the default NEWTON method for SOLVE tasks.) The derivatives table shows each nonzero derivative computed for the problem. The derivative listed can be a constant, a variable in the model program, or a special derivative variable created to hold the result of the derivative expression. This option is turned on by the LISTCODE and PRINTALL options.

XREF
prints a cross-reference of the variables in the model program showing where each variable was referenced or given a value. The XREF option is normally used in conjunction with the LIST option. A more detailed description is given in the "Diagnostics and Debugging" section.

General Printing Control Options

DETAILS
specifies the detailed printout. Parts of the printed output are expanded when the DETAILS option is specified. If ODS GRAPHICS=ON is selected the following additional graphs of the residuals are produced: ACF, PACF, IACF, white noise, and QQ plot versus the normal.

FLOW
prints a message for each statement in the model program as it is executed. This debugging option is needed very rarely and produces voluminous output.

MAXERRORS= *n*
specifies the maximum number of execution errors that can be printed. The default is MAXERRORS=50.

NDEC= *n*
specifies the precision of the format that PROC MODEL uses when printing various numbers. The default is NDEC=3, which means that PROC MODEL attempts to print values using the D format but ensures that at least three significant digits are shown. If the NDEC= value is greater than nine, the BEST. format is used. The smallest value allowed is NDEC=2.

The NDEC= option affects the format of most, but not all, of the floating point numbers that PROC MODEL can print. For some values (such as parameter estimates), a precision limit one or two digits greater than the NDEC= value is used. This option does not apply to the precision of the variables in the output data set.

NOPRINT
suppresses the normal printed output but does not suppress error listings. Using any other print option turns the NOPRINT option off. The PRINT option can be used with the RESET statement to turn off NOPRINT.

PRINTALL
turns on all the printing-control options. The options set by PRINTALL are DETAILS; the model information options LIST, LISTDEP, LISTDER, XREF, BLOCK, and GRAPH; the FIT task printing options FSRSQ, COVB, CORRB, COVS, CORRS, DW, and COLLIN; and the SOLVE task printing options STATS, THEIL, SOLVEPRINT, and ITPRINT.

TRACE
prints the result of each operation in each statement in the model program as it is executed, in addition to the information printed by the FLOW option. This debugging option is needed very rarely and produces voluminous output.

MEMORYUSE
prints a report of the memory required for the various parts of the analysis.

FIT Task Options

The following options are used in the FIT statement (parameter estimation) and can also be used in the PROC MODEL statement: COLLIN, CONVERGE=, CORR, CORRB, CORRS, COVB, COVBEST=, COVS, DW, FIML, FSRSQ, GMM, HESSIAN=, I, INTGPRINT, ITALL, ITDETAILS, ITGMM, ITPRINT, ITOLS, ITSUR, IT2SLS, IT3SLS, KERNEL=, LTEBOUND=, MAXITER=, MAXSUBITER=, METHOD=, MINTIMESTEP=, NESTIT, N2SLS, N3SLS, OLS, OUTPREDICT, OUTRESID, OUTACTUAL, OUTLAGS, OUTERRORS, OUTALL, OUTCOV, SINGULAR=, STARTITER=, SUR, TIME=, VARDEF, and XPX. See "FIT Statement Syntax" later in this chapter for a description of these options.

When used in the PROC MODEL or RESET statement, these are default options for subsequent FIT statements. For example, the statement

```
   proc model n2sls ... ;
```

makes two-stage least squares the default parameter estimation method for FIT statements that do not specify an estimation method.

SOLVE Task Options

The following options used in the SOLVE statement can also be used in the PROC MODEL statement: CONVERGE=, DYNAMIC, FORECAST, INTGPRINT, ITPRINT, JACOBI, LTEBOUND=, MAXITER=, MAXSUBITER=, MINTIMESTEP=, NAHEAD=, NEWTON, OUTPREDICT, OUTRESID, OUTACTUAL, OUTLAGS, OUTERRORS, OUTALL, SEED=, SEIDEL, SIMULATE, SINGLE, SINGULAR=, SOLVEPRINT, START=, STATIC, STATS, THEIL, TIME=, and TYPE=. See "SOLVE Statement Syntax" later in this chapter for a description of these options.

When used in the PROC MODEL or RESET statement, these options provide default values for subsequent SOLVE statements.

BOUNDS Statement

BOUNDS *bound1 [, bound2 ...] ;*

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the associated FIT statement (that is, to either the preceding FIT statement or, in the absence of a preceding FIT statement, to the following FIT statement). You can specify any number of BOUNDS statements.

Each *bound* is composed of parameters and constants and inequality operators:

item operator item [operator item [operator item . . .]]

Each *item* is a constant, the name of an estimated parameter, or a list of parameter names. Each *operator* is '<', '>', '<=', or '>='.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the "RESTRICT Statement" section on page 1048 for more information on the computational details of estimation with inequality restrictions.

Lagrange multipliers are reported for all the active boundary constraints. In the printed output and in the OUTEST= data set, the Lagrange multiplier estimates are identified with the names BOUND1, BOUND2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). To give the constraints more descriptive names, use the RESTRICT statement instead of the BOUNDS statement.

The following BOUNDS statement constrains the estimates of the parameters A and B and the ten parameters P1 through P10 to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < a b p1-p10 < 1;
```

The following is an example of the use of the BOUNDS statement:

```
title 'Holzman Function (1969), Himmelblau No. 21, N=3';
data zero;
   do i = 1 to 99;
      output;
   end;
run;

proc model data=zero ;
   parms x1= 100 x2= 12.5 x3=  3;
   bounds .1 <= x1 <= 100,
           0 <= x2 <=  25.6,
           0 <= x3 <=   5;

   t = 2 / 3;
   u = 25 + (-50 * log(0.01 * i )) ** t;
   v = (u - x2) ** x3;
   w = exp(-v / x1);
   eq.foo = -.01 * i + w;

   fit foo / method=marquardt;
run;
```

```

Figure 20.13. Output from Bounded Estimation

BY Statement

BY *variables;*

A BY statement is used with the FIT statement to obtain separate estimates for observations in groups defined by the BY variables. Note that if an output model file is written, using the OUTMODEL= option, the parameter values stored are those from the last BY group processed. To save parameter estimates for each BY group, use the OUTEST= option in the FIT statement.

A BY statement is used with the SOLVE statement to obtain solutions for observations in groups defined by the BY variables. If the BY variables are identical in the DATA= data set and the ESTDATA= data set, then the two data sets are synchronized and the simulations are performed using the data and parameters for each BY group. This holds for BY variables in the SDATA= data set as well. If, at some point, the BY variables don't match, BY processing is abandoned in either the ESTDATA= data set or the SDATA= data set, whichever has the missing BY value. If the DATA= data set does not contain BY variables and the ESTDATA= data set or the SDATA= data set does, then BY processing is performed for the ESTDATA= data set and the SDATA= data set by reusing the data in the DATA= data set for each BY group.

CONTROL Statement

CONTROL *variable [value] ... ;*

The CONTROL statement declares control variables and specifies their values. A control variable is like a parameter except that it has a fixed value and is not estimated from the data. You can use control variables for constants in model equations that you may want to change in different solution cases. You can use control variables to vary the program logic. Unlike the retained variables, these values are fixed across iterations.

ENDOGENOUS Statement

ENDOGENOUS *variable [initial-values] ... ;*

The ENDOGENOUS statement declares model variables and identifies them as endogenous. You can declare model variables with an ENDOGENOUS statement instead of with a VAR statement to help document the model or to indicate the default solution variables. The variables declared endogenous are solved when a SOLVE statement does not indicate which variables to solve. Valid abbreviations for the ENDOGENOUS statement are ENDOG and ENDO.

The DEPENDENT statement is equivalent to the ENDOGENOUS statement and is provided for the convenience of non-econometric practitioners.

The ENDOGENOUS statement optionally provides initial values for lagged dependent variables. See "Lag Logic" in the "Functions Across Time" section for more information.

ERRORMODEL Statement

ERRORMODEL *equation-name* $\sim$ *distribution* **[CDF=(** *CDF(options)* **)] ;**

The ERRORMODEL statement is the mechanism for specifying the distribution of the residuals. You must specify the dependent/endogenous variables or general form model name, a tilde ($\sim$), and then a distribution with its parameters. The following options are used in the ERRORMODEL statement:

Options to Specify the Distribution

CAUCHY(<*location, scale>* **)**
specifies the Cauchy distribution. This option is only supported for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

CHISQUARED (*df < , nc>* **)**
specifies the χ^2 distribution. This option is only supported for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

GENERAL(*Likelihood, <parm1, parm2, . . . parmn***>** **)**
specifies minus a general log likelihood function that you construct using SAS programming statements. $parm1, parm2, ...parmn$ are optional parameters for this distribution and are used for documentation purposes only.

F(*ndf, ddf < , nc>* **)**
specifies the F distribution. This option is only supported for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

NORMAL($v_1\ v_2\ \ldots\ v_n$ **)**
: specifies a multivariate normal (Gaussian) distribution with mean 0 and variances v_1 through v_n.

POISSON(*mean* **)**
: specifies the Poisson distribution. This option is only supported for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

T($v_1 v_2 \cdots v_n$, *df* **)**
: specifies a multivariate t distribution with noncentrality 0, variance v_1 through v_n, and common degrees of freedom df.

UNIFORM(*<left, right>* **)**
: specifies the uniform distribution. This option is only supported for simulation. The arguments correspond to the arguments of the SAS CDF function (ignoring the random variable argument).

Options to Specify the CDF for Simulation

CDF=(*CDF(options)* **)**
: specifies the univariate distribution that is used for simulation so that the estimation can be done for one set of distributional assumptions and the simulation for another. The CDF can be any of the distributions from the previous section with the exception of the General Likelihood. In addition, you can specify the empirical distribution of the residuals.

EMPIRICAL= (<TAILS=*(options)***>)**
: uses the sorted residual data to create an empirical CDF.

TAILS=(*tail options* **)**
: specifies how to handle the tails in computing the inverse CDF from an empirical distribution, where *Tail options* are:

NORMAL	specifies the normal distribution to extrapolate the tails.
T(*df*)	specifies the t distribution to extrapolate the tails.
PERCENT= *p*	specifies the percent of the observations to use in constructing each tail. The default for the PERCENT= option is 10. A normal distribution or a t distribution is used to extrapolate the tails to infinity. The variance for the tail distributions is are obtained from the data so that the empirical CDF is continuous.

ESTIMATE Statement

ESTIMATE *item [, item ...] [,/ options] ;*

The ESTIMATE statement computes estimates of functions of the parameters.

The ESTIMATE statement refers to the parameters estimated by the associated FIT statement (that is, to either the preceding FIT statement or, in the absence of a preceding FIT statement, to the following FIT statement). You can use any number of ESTIMATE statements.

If you specify options on the ESTIMATE statement, a comma is required before the "/" character separating the test expressions from the options, since the "/" character can also be used within test expressions to indicate division. Each *item* is written as an optional name followed by an expression,

["name"] expression

where *"name"* is a string used to identify the estimate in the printed output and in the OUTEST= data set.

Expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as "=" or "<") and logical operators (such as “&”) cannot be used in ESTIMATE statement expressions. Parameters named in ESTIMATE expressions must be among the parameters estimated by the associated FIT statement.

You can use the following options in the ESTIMATE statement:

OUTEST=
specifies the name of the data set in which the estimate of the functions of the parameters are to be written. The format for this data set is identical to the OUTEST= data set for the FIT statement.

If you specify a *name* in the ESTIMATE statement, that name is used as the parameter name for the estimate in the OUTEST= data set. If no *name* is provided and the expression is just a symbol, the symbol name is used; otherwise, the string "_Estimate #" is used, where "#" is the variable number in the OUTEST= data set.

OUTCOV
writes the covariance matrix of the functions of the parameters to the OUTEST= data set in addition to the parameter estimates.

COVB
prints the covariance matrix of the functions of the parameters.

CORRB
prints the correlation matrix of the functions of the parameters.

The following is an example of the use of the ESTIMATE statement in a segmented model:

```
data a;
   input y x @@;
   datalines;
   .46 1  .47  2 .57  3 .61  4 .62  5 .68  6 .69  7
   .78 8  .70  9 .74 10 .77 11 .78 12 .74 13 .80 13
   .80 15 .78 16
   ;

title 'Segmented Model -- Quadratic with Plateau';
proc model data=a;
```

```
      x0 = -.5 * b / c;

      if x < x0 then y = a + b*x + c*x*x;
      else           y = a + b*x0 + c*x0*x0;

      fit y start=( a .45 b .5 c -.0025 );

      estimate 'Join point' x0 ,
               'plateau' a + b*x0 + c*x0**2 ;
   run;
```

```
                      Segmented Model -- Quadratic with Plateau

                                 The MODEL Procedure

                              Nonlinear OLS  Estimates

                                  Approx                  Approx
Term              Estimate       Std Err    t Value     Pr > |t|    Label

Join point         12.7504        1.2785       9.97       <.0001    x0
plateau           0.777516        0.0123      63.10       <.0001    a + b*x0 + c*x0**2
```

Figure 20.14. ESTIMATE Statement Output

EXOGENOUS Statement

EXOGENOUS *variable [initial-values] ... ;*

The EXOGENOUS statement declares model variables and identifies them as exogenous. You can declare model variables with an EXOGENOUS statement instead of with a VAR statement to help document the model or to indicate the default instrumental variables. The variables declared exogenous are used as instruments when an instrumental variables estimation method is requested (such as N2SLS or N3SLS) and an INSTRUMENTS statement is not used. Valid abbreviations for the EXOGENOUS statement are EXOG and EXO.

The INDEPENDENT statement is equivalent to the ENDOGENOUS statement and is provided for the convenience of non-econometric practitioners.

The EXOGENOUS statement optionally provides initial values for lagged exogenous variables. See "Lag Logic" in the "Functions Across Time" section for more information.

FIT Statement

FIT *[equations] [* **PARMS=(** *parameter [values] ...)]*

[**START=(** *parameter values ...)]*
[**DROP=(** *parameter ...)]*
[**INITIAL=(** *variable = [parameter* | *constant] ...)*
[/ options] **;**

The FIT statement estimates model parameters by fitting the model equations to input data and optionally selects the equations to be fit. If the list of equations is omitted, all model equations containing parameters are fit.

The following options can be used in the FIT statement.

DROP= *(parameters ...)*
specifies that the named parameters not be estimated. All the parameters in the equations fit are estimated except those listed in the DROP= option. The dropped parameters retain their previous values and are not changed by the estimation.

INITIAL= *(variable = [parameter | constant] ...)*
associates a *variable* with an initial value as a *parameter* or a *constant*.

PARMS= *(parameters [values] ...)*
selects a subset of the parameters for estimation. When the PARMS= option is used, only the named parameters are estimated. Any parameters not specified in the PARMS= list retain their previous values and are not changed by the estimation.

PRL= WALD | LR | BOTH
requests confidence intervals on estimated parameters. By default the PRL option produces 95% likelihood ratio confidence limits. The coverage of the confidence interval is controlled by the ALPHA= option in the FIT statement.

START= *(parameter values ...)*
supplies starting values for the parameter estimates. If the START= option specifies more than one starting value for one or more parameters, a grid search is performed over all combinations of the values, and the best combination is used to start the iterations. For more information, see the STARTITER= option.

Options to Control the Estimation Method Used

ADJSMMV
specifies adding the variance adjustment from simulating the moments to the variance-covariance matrix of the parameter estimators. By default no adjustment is made.

COVBEST=GLS | CROSS | FDA
specifies the variance-covariance estimator used for FIML. COVBEST=GLS selects the generalized least-squares estimator. COVBEST=CROSS selects the crossproducts estimator. COVBEST=FDA selects the inverse of the finite difference approximation to the Hessian. The default is COVBEST=CROSS.

FIML
specifies full information maximum likelihood estimation.

GINV=G2 | G4
specifies the type of generalized inverse to be used when computing the covariance matrix. G4 selects the Moore Penrose generalized inverse. The default is GINV=G2.

Rather than deleting linearly related rows and columns of the covariance matrix, the Moore-Penrose generalized inverse averages the variance effects between collinear rows. When the option GINV=G4 is used, the Moore-Penrose generalized inverse is use to calculate standard errors and the covariance matrix of the parameters as well as the change vector for the optimization problem. For singular systems, a normal G2 inverse is used to determine the singular rows so that the parameters can be marked in the Parameter Estimates table. Whether or not you use a G4 inverse, if the covariance matrix is singular, the parameter estimates are not unique. Refer to Noble and Daniel (1977, pp. 337–340) for more details on generalized inverses.

GENGMMV

specify GMM variance under arbitrary weighting matrix. See the "Estimation Methods" section for more details.

The is the default method for GMM estimation.

GMM

specifies generalized method of moments estimation.

HCCME= 0 | 1 | 2 | 3 | NO

specifies the type of heteroscedasticity-consistent covariance matrix estimator to use for OLS, 2SLS, 3SLS, SUR, and the iterated versions of these estimation methods. The number corresponds to the type of covariance matrix estimator to use as

$$\begin{array}{ll} HC_0: & \hat{\epsilon}_t^2 \\ HC_1: & \frac{n}{n-df}\hat{\epsilon}_t^2 \\ HC_2: & \hat{\epsilon}_t^2/(1-\hat{h}_t) \\ HC_3: & \hat{\epsilon}_t^2/(1-\hat{h}_t)^2 \end{array}$$

The default is NO.

ITGMM

specifies iterated generalized method of moments estimation.

ITOLS

specifies iterated ordinary least-squares estimation. This is the same as OLS unless there are cross-equation parameter restrictions.

ITSUR

specifies iterated seemingly unrelated regression estimation

IT2SLS

specifies iterated two-stage least-squares estimation. This is the same as 2SLS unless there are cross-equation parameter restrictions.

IT3SLS

specifies iterated three-stage least-squares estimation.

KERNEL=(PARZEN | BART | QS, *[c]*, *[e]* **)**
KERNEL=PARZEN | BART | QS

specifies the kernel to be used for GMM and ITGMM. PARZEN selects the Parzen kernel, BART selects the Bartlett kernel, and QS selects the Quadratic Spectral kernel. $e \geq 0$ and $c \geq 0$ are used to compute the bandwidth parameter. The default is KERNEL=(PARZEN, 1, 0.2). See the "Estimation Methods" section for more details.

N2SLS | 2SLS
specifies nonlinear two-stage least-squares estimation. This is the default when an INSTRUMENTS statement is used.

N3SLS | 3SLS
specifies nonlinear three-stage least-squares estimation.

NDRAW <=*number of draws*>
requests the simulation method for estimation. H is the *number of draws*. If *number of draws* is not specified, the default H is set to 10.

NOOLS
NO2SLS
specifies bypassing OLS or 2SLS to get initial parameter estimates for GMM, ITGMM, or FIML. This is important for certain models that are poorly defined in OLS or 2SLS, or if good initial parameter values are already provided. Note that for GMM, the V matrix is created using the initial values specified and this may not be consistently estimated.

NO3SLS
specifies not to use 3SLS automatically for FIML initial parameter starting values.

NOGENGMMV
specify not to use GMM variance under arbitrary weighting matrix. Use GMM variance under optimal weighting matrix instead. See the "Estimation Methods" section for more details.

NPREOBS =*number of obs to initialize*
specifies the initial number of observations to run the simulation before the simulated values are compared to observed variables. This option is most useful in cases where the program statements involve lag operations. Use this option to avoid the effect of the starting point on the simulation.

NVDRAW =*number of draws for V matrix*
specifies H', the *number of draws for V matrix*. If this option is not specified, the default H' is set to 20.

OLS
specifies ordinary least-squares estimation. This is the default when no INSTRUMENTS statement is used.

SUR
specifies seemingly unrelated regression estimation.

VARDEF=N | WGT | DF | WDF
specifies the denominator to be used in computing variances and covariances. VARDEF=N specifies that the number of nonmissing observations be used. VARDEF=WGT specifies that the sum of the weights be used. VARDEF=DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used. VARDEF=WDF specifies that the sum of the weights minus the model degrees of freedom be used. The default is VARDEF=DF. VARDEF=N is used for FIML estimation.

Data Set Options

DATA= *SAS-data-set*

specifies the input data set. Values for the variables in the program are read from this data set. If the DATA= option is not specified on the FIT statement, the data set specified by the DATA= option on the PROC MODEL statement is used.

ESTDATA= *SAS-data-set*

specifies a data set whose first observation provides initial values for some or all of the parameters.

MISSING= PAIRWISE | DELETE

The option MISSING=PAIRWISE specifies that missing values are tracked on an equation-by-equation basis. The MISSING=DELETE option specifies that the entire observation is omitted from the analysis when any equation has a missing predicted or actual value for the equation. The default is MISSING=DELETE.

OUT= *SAS-data-set*

names the SAS data set to contain the residuals, predicted values, or actual values from each estimation. Only the residuals are output by default.

OUTACTUAL

writes the actual values of the endogenous variables of the estimation to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTALL

selects the OUTACTUAL, OUTERRORS, OUTLAGS, OUTPREDICT, and OUTRESID options.

OUTCOV
COVOUT

writes the covariance matrix of the estimates to the OUTEST= data set in addition to the parameter estimates. The OUTCOV option is applicable only if the OUTEST= option is also specified.

OUTEST= *SAS-data-set*

names the SAS data set to contain the parameter estimates and optionally the covariance of the estimates.

OUTLAGS

writes the observations used to start the lags to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTPREDICT

writes the predicted values to the OUT= data set. This option is applicable only if OUT= is specified.

OUTRESID

writes the residual values computed from the parameter estimates to the OUT= data set. The OUTRESID option is the default if neither OUTPREDICT nor OUTACTUAL is specified. This option is applicable only if the OUT= option is specified.

OUTS= *SAS-data-set*
names the SAS data set to contain the estimated covariance matrix of the equation errors. This is the covariance of the residuals computed from the parameter estimates.

OUTSN= *SAS-data-set*
names the SAS data set to contain the estimated normalized covariance matrix of the equation errors. This is valid for multivariate t-distribution estimation.

OUTSUSED= *SAS-data-set*
names the SAS data set to contain the S matrix used in the objective function definition. The OUTSUSED= data set is the same as the OUTS= data set for the methods that iterate the S matrix.

OUTUNWGTRESID
writes the unweighted residual values computed from the parameter estimates to the OUT= data set. These are residuals computed as $actual - predicted$ with no accounting for the WEIGHT statement, the _WEIGHT_ variable, or any variance expressions. This option is applicable only if the OUT= option is specified.

OUTV= *SAS-data-set*
names the SAS data set to contain the estimate of the variance matrix for GMM and ITGMM.

SDATA= *SAS-data-set*
specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation covariance matrix (S matrix) in the estimation. (The SDATA= S matrix is used to provide only the initial estimate of **S** for the methods that iterate the S matrix.)

TIME= *name*
specifies the name of the time variable. This variable must be in the data set.

TYPE= *name*
specifies the estimation type to read from the SDATA= and ESTDATA= data sets. The name specified in the TYPE= option is compared to the _TYPE_ variable in the ESTDATA= and SDATA= data sets to select observations to use in constructing the covariance matrices. When the TYPE= option is omitted, the last estimation type in the data set is used. Valid values are the estimation methods used in PROC MODEL.

VDATA= *SAS-data-set*
specifies a data set containing a variance matrix for GMM and ITGMM estimation.

Printing Options for FIT Tasks

BREUSCH= *(variable-list)*
specifies the modified Breusch-Pagan test, where *variable-list* is a list of variables used to model the error variance.

CHOW= *obs*
CHOW= *(obs1 obs2 ... obsn)*
prints the Chow test for break points or structural changes in a model. The argument is the number of observations in the first sample or a parenthesized list of first sample sizes. If the size of the one of the two groups in which the sample is partitioned is

less than the number of parameters, then a Predictive Chow test is automatically used. See the section "Chow Tests" on page 1131 for details.

COLLIN
prints collinearity diagnostics for the Jacobian crossproducts matrix (XPX) after the parameters have converged. Collinearity diagnostics are also automatically printed if the estimation fails to converge.

CORR
prints the correlation matrices of the residuals and parameters. Using CORR is the same as using both CORRB and CORRS.

CORRB
prints the correlation matrix of the parameter estimates.

CORRS
prints the correlation matrix of the residuals.

COV
prints the covariance matrices of the residuals and parameters. Specifying COV is the same as specifying both COVB and COVS.

COVB
prints the covariance matrix of the parameter estimates.

COVS
prints the covariance matrix of the residuals.

DW <=>
prints Durbin-Watson d statistics, which measure autocorrelation of the residuals. When the residual series is interrupted by missing observations, the Durbin-Watson statistic calculated is d' as suggested by Savin and White (1978). This is the usual Durbin-Watson computed by ignoring the gaps. Savin and White show that it has the same null distribution as the DW with no gaps in the series and can be used to test for autocorrelation using the standard tables. The Durbin-Watson statistic is not valid for models containing lagged endogenous variables.

You can use the DW= option to request higher order Durbin-Watson statistics. Since the ordinary Durbin-Watson statistic tests only for first-order autocorrelation, the Durbin-Watson statistics for higher-order autocorrelation are called *generalized Durbin-Watson* statistics.

DWPROB
Use the DWPROB option to print the significance level (p-values) for the Durbin-Watson tests. Since the Durbin-Watson p-values are computationally expensive, they are not reported by default. In the Durbin-Watson test, the null hypothesis is that there is autocorrelation at a specific lag.

See the section "Generalized Durbin-Watson Tests" in the Autoreg Chapter for limitations of the statistic.

FSRSQ
prints the first-stage R^2 statistics for instrumental estimation methods. These R^2s measure the proportion of the variance retained when the Jacobian columns associated with the parameters are projected through the instruments space.

GODFREY
GODFREY= *n*
performs Godfrey's tests for autocorrelated residuals for each equation, where *n* is the maximum autoregressive order, and specifies that Godfrey's tests be computed for lags 1 through *n*. The default number of lags is one.

HAUSMAN
performs Hausman's specification test, or m-statistics.

NORMAL
performs tests of normality of the model residuals.

PCHOW= *obs*
PCHOW= *(obs1 obs2 ... obsn)*
prints the Predictive Chow test for break points or structural changes in a model. The argument is the number of observations in the first sample or a parenthesized list of first sample sizes. See the section "Chow Tests" on page 1131 for details.

PRINTALL
specifies the printing options COLLIN, CORRB, CORRS, COVB, COVS, DETAILS, DW, and FSRSQ.

WHITE
specifies White's test.

Options to control iteration output

Details of the output produced are discussed in the section "Iteration History".

I
prints the inverse of the crossproducts Jacobian matrix at each iteration.

ITALL
specifies all iteration printing-control options (I, ITDETAILS, ITPRINT, and XPX). ITALL also prints the crossproducts matrix (labeled CROSS), the parameter change vector, and the estimate of the cross-equation covariance of residuals matrix at each iteration.

ITDETAILS
prints a detailed iteration listing. This includes the ITPRINT information and additional statistics.

ITPRINT
prints the parameter estimates, objective function value, and convergence criteria at each iteration.

XPX
prints the crossproducts Jacobian matrix at each iteration.

Options to Control the Minimization Process

The following options may be helpful when you experience a convergence problem:

CONVERGE= *value1*
CONVERGE= *(value1, value2)*
specifies the convergence criteria. The convergence measure must be less than *value1* before convergence is assumed. *value2* is the convergence criterion for the **S** and **V** matrices for **S** and **V** iterated methods. *value2* defaults to *value1*. See "The Convergence Criteria" for details. The default value is CONVERGE=.001.

HESSIAN= CROSS | GLS | FDA
specifies the Hessian approximation used for FIML. HESSIAN=CROSS selects the crossproducts approximation to the Hessian, HESSIAN=GLS selects the generalized least-squares approximation to the Hessian, and HESSIAN=FDA selects the finite difference approximation to the Hessian. HESSIAN=GLS is the default.

LTEBOUND= *n*
specifies the local truncation error bound for the integration. This option is ignored if no ODE's are specified.

MAXITER= *n*
specifies the maximum number of iterations allowed. The default is MAXITER=100.

MAXSUBITER= *n*
specifies the maximum number of subiterations allowed for an iteration. For the GAUSS method, the MAXSUBITER= option limits the number of step halvings. For the MARQUARDT method, the MAXSUBITER= option limits the number of times λ can be increased. The default is MAXSUBITER=30. See "Minimization Methods" for details.

METHOD= GAUSS | MARQUARDT
specifies the iterative minimization method to use. METHOD=GAUSS specifies the Gauss-Newton method, and METHOD=MARQUARDT specifies the Marquardt-Levenberg method. The default is METHOD=GAUSS. See "Minimization Methods" for details.

MINTIMESTEP= *n*
specifies the smallest allowed time step to be used in the integration. This option is ignored if no ODE's are specified.

NESTIT
changes the way the iterations are performed for estimation methods that iterate the estimate of the equation covariance (**S** matrix). The NESTIT option is relevant only for the methods that iterate the estimate of the covariance matrix (ITGMM, ITOLS, ITSUR, IT2SLS, IT3SLS). See "Details on the Covariance of Equation Errors" for an explanation of NESTIT.

SINGULAR= *value*
specifies the smallest pivot value allowed. The default 1.0E-12.

STARTITER= *n*
specifies the number of minimization iterations to perform at each grid point. The default is STARTITER=0, which implies that no minimization is performed at the grid points. See "Using the STARTITER option" for more details.

Other Options

Other options that can be used on the FIT statement include the following that list and analyze the model: BLOCK, GRAPH, LIST, LISTCODE, LISTDEP, LISTDER, and XREF. The following printing control options are also available: DETAILS, FLOW, INTGPRINT, MAXERRORS=, NOPRINT, PRINTALL, and TRACE. For complete descriptions of these options, see the discussion of the PROC MODEL statement options earlier in this chapter.

ID Statement

ID *variables;*

The ID statement specifies variables to identify observations in error messages or other listings and in the OUT= data set. The ID variables are normally SAS date or datetime variables. If more than one ID variable is used, the first variable is used to identify the observations; the remaining variables are added to the OUT= data set.

INCLUDE Statement

INCLUDE *model-names ... ;*

The INCLUDE statement reads model files and inserts their contents into the current model. However, instead of replacing the current model as the RESET MODEL= option does, the contents of included model files are inserted into the model program at the position that the INCLUDE statement appears.

INSTRUMENTS Statement

The INSTRUMENTS statement specifies the instrumental variables to be used in the N2SLS, N3SLS, IT2SLS, IT3SLS, GMM, and ITGMM estimation methods. There are three forms of the INSTRUMENTS statement:

INSTRUMENTS *variables [* **_EXOG_** *] ;*

INSTRUMENTS *[instruments] [* **_EXOG_** *]*
[**EXCLUDE**=*(parameters)] [/ options]* **;**

INSTRUMENTS *(equation, variables) (equation, variables) ... ;*

The first form of the INSTRUMENTS statement is used only before a FIT statement and defines the default instruments list. The items specified as instruments can be variables or the special keyword _EXOG_. _EXOG_ indicates that all the model variables declared EXOGENOUS are to be added to the instruments list.

The second form of the INSTRUMENTS statement is used only after the FIT statement and before the next RUN statement. The items specified as instruments for the second form can be variables, names of parameters to be estimated, or the special keyword _EXOG_. If you specify the name of a parameter in the instruments list, the partial derivatives of the equations with respect to the parameter (that is, the columns of the Jacobian matrix associated with the parameter) are used as instruments. The parameter itself is not used as an instrument. These partial derivatives should not depend on any of the parameters to be estimated. Only the names of parameters to be estimated can be specified.

EXCLUDE= _(parameters)_

specifies that the derivatives of the equations with respect to all of the parameters to be estimated, except the parameters listed in the EXCLUDE list, be used as instruments, in addition to the other instruments specified. If you use the EXCLUDE= option, you should be sure that the derivatives with respect to the nonexcluded parameters in the estimation are independent of the endogenous variables and not functions of the parameters estimated.

A third form of the INSTRUMENTS statement is used to specify instruments for each equation. There is no explicit intercept added, parameters cannot be specified to represent instruments, and the _EXOG_ keyword is not allowed. Equations not explicitly assigned instruments will use all the instruments specified for the other equations as well as instruments not assigned specific equations. In the following example, z1, z2, and z3 are instruments used with equation y1, and z2, z3, and z4 are instruments used with equation y2.

```
proc model data=data_sim;
   exogenous x1 x2;
   parms a b c d e f;

   y1 =a*x1**2 + b*x2**2 + c*x1*x2   ;
   y2 =d*x1**2 + e*x2**2 + f*x1*x2**2;

   fit y1 y2 / 3sls ;
   instruments (y1, z1 z2 z3) (y2,z2 z3 z4);
run;
```

The following option is specified on the INSTRUMENTS statement following a slash (/):

NOINTERCEPT
NOINT

excludes the constant of 1.0 (intercept) from the instruments list. An intercept is always included as an instrument unless NOINTERCEPT is specified.

When a FIT statement specifies an instrumental variables estimation method and no INSTRUMENTS statement accompanies the FIT statement, the default instruments are used. If no default instruments list has been specified, all the model variables declared EXOGENOUS are used as instruments. See the section "Choice of Instruments" on page 1135 for more details.

INTONLY

INTONLY

specifies that only the intercept be used as an instrument. This option is used for GMM estimation where the moments have been specified explicitly.

LABEL Statement

LABEL *variable='label' ... ;*

The LABEL statement specifies a label of up to 255 characters for parameters and other variables used in the model program. Labels are used to identify parts of the printout of FIT and SOLVE tasks. The labels will be displayed in the output if the LINESIZE= option is large enough.

MOMENT Statement

In many scenarios, endogenous variables are observed from data. From the models we can simulate these endogenous variables based on a fixed set of parameters. The goal of SMM is to find a set of parameters such that the moments of the simulated data match the moments of the observed variables. If there are many moments to match, the code may be tedious. The following MOMENT statement provides a way to generate some commonly used moments automatically. Multiple MOMENT statements can be used.

MOMENT *variables = moment specification ;*

variables can be one or more endogenous variables.

moment specification can have the following four types:

1. (*number list*) – the endogenous variable is raised to the power specified by each number in *number list.* For example,

```
moment y = (2 3);
```

adds the following two equations to be estimated:

```
eq._moment_1 = y**2 - pred.y**2;
eq._moment_2 = y**3 - pred.y**3;
```

2. ABS(*number list*) – the absolute value of the endogenous variable is raised to the power specified by each number in *number list.* For example,

```
moment y = ABS(3);
```

adds the following equation to be estimated:

```
eq._moment_2 = abs(y)**3 - abs(pred.y)**3;
```

3. LAG*num* (*number list*) – the endogenous variable is multiplied by the *num*th lag of the endogenous variable, and this product is raised to the power specified by each number in *number list.* For example,

```
moment y = LAG4(3);
```

adds the following equation to be estimated:

```
eq._moment_3 = (y*lag4(y))**3 - (pred.y*lag4(pred.y))**3;
```

4. ABS_LAG*num* (*number list*) – the endogenous variable is multiplied by the *num*th lag of the endogenous variable, and the absolute value of this product is raised to the power specified by each number in *number list.* For example,

```
moment y = ABS_LAG4(3);
```

adds the following equation to be estimated:

```
eq._moment_4 = abs(y*lag4(y))**3 - abs(pred.y*lag4(pred.y))**3;
```

The following PROC MODEL code utilizes the MOMENT statement to generate 24 moments and fit these moments using SMM.

```
 proc model data=_tmpdata list;
       parms a b .5 s 1;
       instrument _exog_ / intonly;

       u = rannor( 10091 );
       z = rannor( 97631 );

       lsigmasq = xlag(sigmasq,exp(a));

       lnsigmasq = a + b * log(lsigmasq) + s * u;
       sigmasq = exp( lnsigmasq );

       y = sqrt(sigmasq) * z;

       moment y = (2 4) abs(1 3) abs_lag1(1 2) abs_lag2(1 2);
       moment y = abs_lag3(1 2) abs_lag4(1 2)
                  abs_lag5(1 2) abs_lag6(1 2)
                  abs_lag7(1 2) abs_lag8(1 2)
                  abs_lag9(1 2) abs_lag10(1 2);

       fit y  / gmm npreobs=20 ndraw=10;
       bound s > 0, 1>b>0;

run;
```

OUTVARS Statement

OUTVARS *variables;*

The OUTVARS statement specifies additional variables defined in the model program to be output to the OUT= data sets. The OUTVARS statement is not needed unless the variables to be added to the output data set are not referred to by the model, or unless you wish to include parameters or other special variables in the OUT= data set. The OUTVARS statement includes additional variables, whereas the KEEP statement excludes variables.

PARAMETERS Statement

PARAMETERS *variable [value] [variable [value]] ... ;*

The PARAMETERS statement declares the parameters of a model and optionally sets their initial values. Valid abbreviations are PARMS and PARM.

Each parameter has a single value associated with it, which is the same for all observations. Lagging is not relevant for parameters. If a value is not specified in the PARMS statement (or by the PARMS= option of a FIT statement), the value defaults to 0.0001 for FIT tasks and to a missing value for SOLVE tasks.

RANGE Statement

RANGE *variable [= first] [***TO** *last];*

The RANGE statement specifies the range of observations to be read from the DATA= data set. For FIT tasks, the RANGE statement controls the period of fit for the estimation. For SOLVE tasks, the RANGE statement controls the simulation period or forecast horizon.

The RANGE variable must be a numeric variable in the DATA= data set that identifies the observations, and the data set must be sorted by the RANGE variable. The first observation in the range is identified by *first*, and the last observation is identified by *last*.

PROC MODEL uses the first *l* observations prior to *first* to initialize the lags, where *l* is the maximum number of lags needed to evaluate any of the equations to be fit or solved, or the maximum number of lags needed to compute any of the instruments when an instrumental variables estimation method is used. There should be at least *l* observations in the data set before *first*. If *last* is not specified, all the nonmissing observations starting with *first* are used.

If *first* is omitted, the first *l* observations are used to initialize the lags, and the rest of the data, until *last*, is used. If a RANGE statement is used but both *first* and *last* are omitted, the RANGE statement variable is used to report the range of observations processed.

The RANGE variable should be nonmissing for all observations. Observations containing missing RANGE values are deleted.

The following are examples of RANGE statements:

```
range year = 1971 to 1988;              /* yearly  data  */
range date = '1feb73'd to '1nov82'd;    /* monthly data  */
range time = 60.5;                      /* time in years */
range year to 1977;         /* use all years through 1977 */
range date; /* use values of date to report period-of-fit */
```

RESET Statement

RESET *options;*

All of the options of the PROC MODEL statement can be reset by the RESET statement. In addition, the RESET statement supports one additional option:

PURGE
deletes the current model so that a new model can be defined.

When the MODEL= option is used in the RESET statement, the current model is deleted before the new model is read.

RESTRICT Statement

RESTRICT *restriction1 [, restriction2 ...] ;*

The RESTRICT statement is used to impose linear and nonlinear restrictions on the parameter estimates.

RESTRICT statements refer to the parameters estimated by the associated FIT statement (that is, to either the preceding FIT statement or, in the absence of a preceding FIT statement, to the following FIT statement). You can specify any number of RESTRICT statements.

Each *restriction* is written as an optional name, followed by an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

["name"] expression operator expression

The optional *"name"* is a string used to identify the restriction in the printed output and in the OUTEST= data set. The *operator* can be =, <, >, <= , or >=. The operator and second expression are optional, as in the TEST statement (=0).

Restriction expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as "=" or "<") and logical operators (such as “&”) cannot be used in RESTRICT statement expressions. Parameters named in restriction expressions must be among the parameters estimated by the associated FIT statement. Expressions can refer to variables defined in the program.

The restriction expressions can be linear or nonlinear functions of the parameters.

The following is an example of the use of the RESTRICT statement:

```
proc model data=one;
   endogenous y1 y2;
   exogenous x1 x2;
   parms a b c;
   restrict b*(b+c) <= a;

   eq.one = -y1/c + a/x2 + b * x1**2 + c * x2**2;
   eq.two = -y2 * y1 + b * x2**2 - c/(2 * x1);

   fit one two / fiml;
run;
```

SOLVE Statement

SOLVE *[variables]* [**SATISFY=** *equations]* [**INITIAL=** *(variable=[parameter]]* *[/options];*

The SOLVE statement specifies that the model be simulated or forecast for input data values and, optionally, selects the variables to be solved. If the list of variables is omitted, all of the model variables declared ENDOGENOUS are solved. If no model variables are declared ENDOGENOUS, then all model variables are solved.

The following specification can be used in the SOLVE statement:

SATISFY= *equation*
SATISFY= *(equations)*
specifies a subset of the model equations that the solution values are to satisfy. If the SATISFY= option is not used, the solution is computed to satisfy all the model equations. Note that the number of equations must equal the number of variables solved.

Data Set Options

DATA= *SAS-data-set*
names the input data set. The model is solved for each observation read from the DATA= data set. If the DATA= option is not specified on the SOLVE statement, the data set specified by the DATA= option on the PROC MODEL statement is used.

ESTDATA= *SAS-data-set*
names a data set whose first observation provides values for some or all of the parameters and whose additional observations (if any) give the covariance matrix of the parameter estimates. The covariance matrix read from the ESTDATA= data set is used to generate multivariate normal pseudo-random shocks to the model parameters when the RANDOM= option requests Monte Carlo simulation.

OUT= *SAS-data-set*
outputs the predicted (solution) values, residual values, actual values, or equation errors from the solution to a data set. Only the solution values are output by default.

OUTACTUAL
outputs the actual values of the solved variables read from the input data set to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTALL
specifies the OUTACTUAL, OUTERRORS, OUTLAGS, OUTPREDICT, and OUTRESID options

OUTERRORS
writes the equation errors to the OUT= data set. These values are normally very close to zero when a simultaneous solution is computed; they can be used to double-check the accuracy of the solution process. It is applicable only if the OUT= option is specified.

OUTLAGS
writes the observations used to start the lags to the OUT= data set. This option is applicable only if the OUT= option is specified.

OUTPREDICT
writes the solution values to the OUT= data set. This option is relevant only if the OUT= option is specified.

The OUTPREDICT option is the default unless one of the other output options is used.

OUTRESID
writes the residual values computed as the difference of the solution values and the values for the solution variables read from the input data set to the OUT= data set. This option is applicable only if the OUT= option is specified.

PARMSDATA= *SAS-data-set*
specifies a data set that contains the parameter estimates. See the "Input Data Sets" section for more details.

RESIDDATA= *sas data-set*
specifies a data set that contains the residuals that are to be used in the empirical distribution. This data set can be created using the OUT= option on the Fit statement.

SDATA= *SAS-data-set*
specifies a data set that provides the covariance matrix of the equation errors. The covariance matrix read from the SDATA= data set is used to generate multivariate normal pseudo-random shocks to the equations when the RANDOM= option requests Monte Carlo simulation.

TYPE= *name*
specifies the estimation type. The name specified in the TYPE= option is compared to the _TYPE_ variable in the ESTDATA= and SDATA= data sets to select observations to use in constructing the covariance matrices. When TYPE= is omitted, the last estimation type in the data set is used.

Solution Mode Options: Lag Processing

DYNAMIC

specifies a dynamic solution. In the dynamic solution mode, solved values are used by the lagging functions. DYNAMIC is the default.

NAHEAD= *n*

specifies a simulation of *n*-period-ahead dynamic forecasting. The NAHEAD= option is used to simulate the process of using the model to produce successive forecasts to a fixed forecast horizon, with each forecast using the historical data available at the time the forecast is made.

Note that NAHEAD=1 produces a static (one-step-ahead) solution. NAHEAD=2 produces a solution using one-step-ahead solutions for the first lag (LAG1 functions return static predicted values) and actual values for longer lags. NAHEAD=3 produces a solution using NAHEAD=2 solutions for the first lags, NAHEAD=1 solutions for the second lags, and actual values for longer lags. In general, NAHEAD=*n* solutions use NAHEAD=*n*-1 solutions for LAG1, NAHEAD=*n*-2 solutions for LAG2, and so forth.

START= *s*

specifies static solutions until the *s*th observation and then changes to dynamic solutions. If the START=*s* option is specified, the first observation in the range in which LAG*n* delivers solved predicted values is *s*+*n*, while LAG*n* returns actual values for earlier observations.

STATIC

specifies a static solution. In static solution mode, actual values of the solved variables from the input data set are used by the lagging functions.

Solution Mode Options: Use of Available Data

FORECAST

specifies that the actual value of a solved variable is used as the solution value (instead of the predicted value from the model equations) whenever nonmissing data are available in the input data set. That is, in FORECAST mode, PROC MODEL solves only for those variables that are missing in the input data set.

SIMULATE

specifies that PROC MODEL always solves for all solution variables as a function of the input values of the other variables, even when actual data for some of the solution variables are available in the input data set. SIMULATE is the default.

Solution Mode Options: Numerical Solution Method

JACOBI

computes a simultaneous solution using a Jacobi iteration.

NEWTON

computes a simultaneous solution using Newton's method. When the NEWTON option is selected, the analytic derivatives of the equation errors with respect to the solution variables are computed and memory-efficient sparse matrix techniques are used for factoring the Jacobian matrix.

The NEWTON option can be used to solve both normalized-form and general-form equations and can compute goal-seeking solutions. NEWTON is the default.

SEIDEL
computes a simultaneous solution using a Gauss-Seidel method.

SINGLE
ONEPASS
specifies a single-equation (nonsimultaneous) solution. The model is executed once to compute predicted values for the variables from the actual values of the other endogenous variables. The SINGLE option can only be used for normalized-form equations and cannot be used for goal-seeking solutions.

For more information on these options, see the "Solution Modes" section later in this chapter.

Monte Carlo Simulation Options

PSEUDO= DEFAULT | TWISTER
specifies which pseudo number generator is too be use in generating draws for Monte Carlo simulation. The two pseudo-random number generators supported by the MODEL procedure are a default congruential generator which has period $2^{31} - 1$ and Mersenne-Twister pseudo-random number generator which has an extraordinarily long period $2^{19937} - 1$.

QUASI= NONE|SOBOL|FAURE
specifies a pseudo or quasi-random number generator. Two Quasi-random number generators supported by the MODEL procedure, the Sobol sequence (QUASI=SOBOL) and the Faure sequence (QUASI=FAURE). The default is QUASI=NONE which is the pseudo random number generator.

RANDOM= *n*
repeats the solution *n* times for each BY group, with different random perturbations of the equation errors if the SDATA= option is used; with different random perturbations of the parameters if the ESTDATA= option is used and the ESTDATA= data set contains a parameter covariance matrix; and with different values returned from the random-number generator functions, if any are used in the model program. If RANDOM=0, the random-number generator functions always return zero. See "Monte Carlo Simulation" for details. The default is RANDOM=0.

SEED= *n*
specifies an integer to use as the seed in generating pseudo-random numbers to shock the parameters and equations when the ESTDATA= or the SDATA= options are specified. If *n* is negative or zero, the time of day from the computer's clock is used as the seed. The SEED= option is only relevant if the RANDOM= option is used. The default is SEED=0.

WISHART= *df*
specifies that a Wishart distribution with degrees of freedom *df* be used in place of the normal error covariance matrix. This option is used to model the variance of the error covariance matrix when Monte Carlo simulation is selected.

Options for Controlling the Numerical Solution Process

The following options are useful when you have difficulty converging to the simultaneous solution.

CONVERGE= *value*

specifies the convergence criterion for the simultaneous solution. Convergence of the solution is judged by comparing the CONVERGE= value to the maximum over the equations of

$$\frac{|\epsilon_i|}{|y_i| + 1E-6}$$

if it is computable, otherwise

$$|\epsilon_i|$$

where ϵ_i represents the equation error and y_i represents the solution variable corresponding to the *i*th equation for normalized-form equations. The default is CONVERGE=1E-8.

MAXITER= *n*

specifies the maximum number of iterations allowed for computing the simultaneous solution for any observation. The default is MAXITER=50.

INITIAL= *(variable= [parameter])*

specifies starting values for the parameters

MAXSUBITER= *n*

specifies the maximum number of damping subiterations that are performed in solving a nonlinear system when using the NEWTON solution method. Damping is disabled by setting MAXSUBITER=0. The default is MAXSUBITER=10.

Printing Options

INTGPRINT

prints between data points integration values for the DERT. variables and the auxiliary variables. If you specify the DETAILS option, the integrated derivative variables are printed as well.

ITPRINT

prints the solution approximation and equation errors at each iteration for each observation. This option can produce voluminous output.

PRINTALL

specifies the printing control options DETAILS, ITPRINT, SOLVEPRINT, STATS, and THEIL.

SOLVEPRINT
prints the solution values and residuals at each observation

STATS
prints various summary statistics for the solution values

THEIL
prints tables of Theil inequality coefficients and Theil relative change forecast error measures for the solution values. See "Summary Statistics" in the "Details" section for more information.

Other Options

Other options that can be used on the SOLVE statement include the following that list and analyze the model: BLOCK, GRAPH, LIST, LISTCODE, LISTDEP, LISTDER, and XREF. The LTEBOUND= and MINTIMESTEP= options can be used to control the integration process. The following printing-control options are also available: DETAILS, FLOW, MAXERRORS=, NOPRINT, and TRACE. For complete descriptions of these options, see the PROC MODEL and FIT statement options described earlier in this chapter.

TEST Statement

TEST *["name"] test1 [, test2 ...] [,/ options] ;*

The TEST statement performs tests of nonlinear hypotheses on the model parameters.

The TEST statement applies to the parameters estimated by the associated FIT statement (that is, either the preceding FIT statement or, in the absence of a preceding FIT statement, the following FIT statement). You can specify any number of TEST statements.

If you specify options on the TEST statement, a comma is required before the "/" character separating the test expressions from the options, because the "/" character can also be used within test expressions to indicate division.

Each test is written as an expression optionally followed by an equal sign (=) and a second expression:

[expression] [= expression]
