Test expressions can be composed of parameter names, arithmetic operators, functions, and constants. Comparison operators (such as "=") and logical operators (such as “&”) cannot be used in TEST statement expressions. Parameters named in test expressions must be among the parameters estimated by the associated FIT statement.

If you specify only one expression in a test, that expression is tested against zero. For example, the following two TEST statements are equivalent:

```
test a + b;

test a + b = 0;
```

When you specify multiple tests on the same TEST statement, a joint test is performed. For example, the following TEST statement tests the joint hypothesis that both A and B are equal to zero.

```
test a, b;
```

To perform separate tests rather than a joint test, use separate TEST statements. For example, the following TEST statements test the two separate hypotheses that A is equal to zero and that B is equal to zero.

```
test a;
test b;
```

You can use the following options in the TEST statement.

WALD
specifies that a Wald test be computed. WALD is the default.

LM
RAO
LAGRANGE
specifies that a Lagrange multiplier test be computed.

LR
LIKE
specifies that a likelihood ratio test be computed.

ALL
requests all three types of tests.

OUT=
specifies the name of an output SAS data set that contains the test results. The format of the OUT= data set produced by the TEST statement is similar to that of the OUTEST= data set produced by the FIT statement.

VAR Statement

VAR *variables [initial_values] ... ;*

The VAR statement declares model variables and optionally provides initial values for the variables' lags. See the "Lag Logic" section for more information.

WEIGHT Statement

WEIGHT *variable;*

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used for the estimation. *variable* must be a numeric variable in the input data set.

An alternative weighting method is to use an assignment statement to give values to the special variable _WEIGHT_. The _WEIGHT_ variable must not depend on the parameters being estimated. If both weighting specifications are given, the weights are multiplied together.

Details: Estimation

Estimation Methods

Consider the general nonlinear model:

$$\begin{aligned} \epsilon_t &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \\ \mathbf{z}_t &= Z(\mathbf{x}_t) \end{aligned}$$

where $\mathbf{q} \in R^g$ is a real vector valued function, of $\mathbf{y}_t \in R^g$, $\mathbf{x}_t \in R^l$, $\theta \in R^p$, *g* is the number of equations, *l* is the number of exogenous variables (lagged endogenous variables are considered exogenous here), *p* is the number of parameters and *t* ranges from 1 to *n*. $\mathbf{z}_t \in R^k$ is a vector of instruments. ϵ_t is an unobservable disturbance vector with the following properties:

$$\begin{aligned} E(\epsilon_t) &= 0 \\ E(\epsilon_t \epsilon_t^{'}) &= \Sigma \end{aligned}$$

All of the methods implemented in PROC MODEL aim to minimize an *objective function*. The following table summarizes the objective functions defining the estimators and the corresponding estimator of the covariance of the parameter estimates for each method.

Table 20.1. Summary of PROC MODEL Estimation Methods

Method	Instruments	Objective Function	Covariance of θ
OLS	no	$\mathbf{r}'\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
ITOLS	no	$\mathbf{r}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{r}/\text{n}$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
SUR	no	$\mathbf{r}'(\mathbf{S}_{\text{OLS}}^{-1} \otimes \mathbf{I})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
ITSUR	no	$\mathbf{r}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{I})\mathbf{X})^{-1}$
N2SLS	yes	$\mathbf{r}'(\mathbf{I} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
IT2SLS	yes	$\mathbf{r}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{r}/\text{n}$	$(\mathbf{X}'(\text{diag}(\mathbf{S})^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
N3SLS	yes	$\mathbf{r}'(\mathbf{S}_{\text{N2SLS}}^{-1} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
IT3SLS	yes	$\mathbf{r}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{r}/n$	$(\mathbf{X}'(\mathbf{S}^{-1} \otimes \mathbf{W})\mathbf{X})^{-1}$
GMM	yes	$[n\mathbf{m}_n(\theta)]'\hat{\mathbf{V}}_{\text{N2SLS}}^{-1}[n\mathbf{m}_n(\theta)]/n$	$[(\mathbf{YX})'\hat{\mathbf{V}}^{-1}(\mathbf{YX})]^{-1}$
ITGMM	yes	$[n\mathbf{m}_n(\theta)]'\hat{\mathbf{V}}^{-1}[n\mathbf{m}_n(\theta)]/n$	$[(\mathbf{YX})'\hat{\mathbf{V}}^{-1}(\mathbf{YX})]^{-1}$
FIML	no	$constant + \frac{n}{2}\ln(\det(\mathbf{S}))$ $- \sum_1^n \ln\vert(\mathbf{J}_t)\vert$	$[\hat{\mathbf{Z}}'(\mathbf{S}^{-1} \otimes \mathbf{I})\hat{\mathbf{Z}}]^{-1}$

The column labeled "Instruments" identifies the estimation methods that require instruments. The variables used in this table and the remainder of this chapter are defined as follows:

$n =$ is the number of nonmissing observations.

$g =$ is the number of equations.

$k =$ is the number of instrumental variables.

$\mathbf{r} = \begin{bmatrix} r_1 \\ r_2 \\ \vdots \\ r_g \end{bmatrix}$ is the $ng \times 1$ vector of residuals for the *g* equations stacked together.

$\mathbf{r}_i = \begin{bmatrix} q_i(\mathbf{y}_1, \mathbf{x}_1, \theta) \\ q_i(\mathbf{y}_2, \mathbf{x}_2, \theta) \\ \vdots \\ q_i(\mathbf{y}_n, \mathbf{x}_n, \theta) \end{bmatrix}$ is the $n \times 1$ column vector of residuals for the *i*th equation.

S	is a $g \times g$ matrix that estimates Σ, the covariances of the errors across equations (referred to as the **S** matrix).
X	is an $ng \times p$ matrix of partial derivatives of the residual with respect to the parameters.
W	is an $n \times n$ matrix, $\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$.
Z	is an $n \times k$ matrix of instruments.
Y	is a $gk \times ng$ matrix of instruments. $\mathbf{Y} = \mathbf{I}_g \otimes \mathbf{Z}'$.
$\hat{\mathbf{Z}}$	$\hat{\mathbf{Z}} = (\hat{Z}_1, \hat{Z}_2, \ldots, \hat{Z}_p)$ is an $ng \times p$ matrix. $\hat{Z}_i$ is a $ng \times 1$ column vector obtained from stacking the columns of

$$\mathbf{U}\frac{1}{n}\sum_{t=1}^{n}\left(\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'}{\partial y_t}\right)^{-1}\frac{\partial^2 \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'}{\partial y_t \partial \theta_i} - \mathbf{Q}_i$$

U	is an $n \times g$ matrix of residual errors. $\mathbf{U} = \epsilon_1, \epsilon_2, \ldots, \epsilon_n{}'$
Q	is the $n \times g$ matrix $\mathbf{q}(\mathbf{y}_1, \mathbf{x}_1, \theta), \mathbf{q}(\mathbf{y}_2, \mathbf{x}_2, \theta), \ldots, \mathbf{q}(\mathbf{y}_n, n, \theta)$.
$\mathbf{Q}_i$	is an $n \times g$ matrix $\frac{\partial \mathbf{Q}}{\partial \theta_i}$.
I	is an $n \times n$ identity matrix.
$\mathbf{J}_t$	is $\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t'}$ which is a $g \times g$ Jacobian matrix.
$\mathbf{m}_n$	is first moment of the crossproduct $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t$. $m_n = \frac{1}{n}\sum_{t=1}^{n} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t$
$\mathbf{z}_t$	is a k column vector of instruments for observation t. $\mathbf{z}_t'$ is also the tth row of **Z**.

$\hat{\mathbf{V}}$	is the $gk \times gk$ matrix representing the variance of the moment functions.
k	is the number of instrumental variables used.
constant	is the constant $\frac{ng}{2}(1 + \ln(2\pi))$.
$\otimes$	is the notation for a Kronecker product.

All vectors are column vectors unless otherwise noted. Other estimates of the covariance matrix for FIML are also available.

Dependent Regressors and Two-Stage Least Squares

Ordinary regression analysis is based on several assumptions. A key assumption is that the independent variables are in fact statistically independent of the unobserved error component of the model. If this assumption is not true–if the regressor varies systematically with the error–then ordinary regression produces inconsistent results. The parameter estimates are *biased*.

Regressors might fail to be independent variables because they are dependent variables in a larger simultaneous system. For this reason, the problem of dependent regressors is often called *simultaneous equation bias*. For example, consider the following two-equation system.

$$y_1 = a_1 + b_1 y_2 + c_1 x_1 + \epsilon_1$$

$$y_2 = a_2 + b_2 y_1 + c_2 x_2 + \epsilon_2$$

In the first equation, y$_2$ is a dependent, or *endogenous,* variable. As shown by the second equation, y$_2$ is a function of y$_1$, which by the first equation is a function of ϵ_1, and therefore y$_2$ depends on ϵ_1. Likewise, y$_1$ depends on ϵ_2 and is a dependent regressor in the second equation. This is an example of a *simultaneous equation* system; y$_1$ and y$_2$ are a function of all the variables in the system.

Using the ordinary least squares (OLS) estimation method to estimate these equations produces biased estimates. One solution to this problem is to replace y$_1$ and y$_2$ on the right-hand side of the equations with predicted values, thus changing the regression problem to the following:

$$y_1 = a_1 + b_1 \hat{y}_2 + c_1 x_1 + \epsilon_1$$

$$y_2 = a_2 + b_2 \hat{y}_1 + c_2 x_2 + \epsilon_2$$

This method requires estimating the predicted values $\hat{y}_1$ and $\hat{y}_2$ through a preliminary, or "first stage," *instrumental regression*. An instrumental regression is a regression of the dependent regressors on a set of *instrumental variables*, which can be any independent variables useful for predicting the dependent regressors. In this example, the equations are linear and the exogenous variables for the whole system are known.

Thus, the best choice for instruments (of the variables in the model) are the variables x_1 and x_2.

This method is known as *two-stage least squares* or 2SLS, or more generally as the *instrumental variables method*. The 2SLS method for linear models is discussed in Pindyck (1981, p. 191-192). For nonlinear models this situation is more complex, but the idea is the same. In nonlinear 2SLS, the derivatives of the model with respect to the parameters are replaced with predicted values. See the section "Choice of Instruments" for further discussion of the use of instrumental variables in nonlinear regression.

To perform nonlinear 2SLS estimation with PROC MODEL, specify the instrumental variables with an INSTRUMENTS statement and specify the 2SLS or N2SLS option on the FIT statement. The following statements show how to estimate the first equation in the preceding example with PROC MODEL.

```
proc model data=in;
   y1 = a1 + b1 * y2 + c1 * x1;
   fit y1 / 2sls;
   instruments x1 x2;
run;
```

The 2SLS or instrumental variables estimator can be computed using a first-stage regression on the instrumental variables as described previously. However, PROC MODEL actually uses the equivalent but computationally more appropriate technique of projecting the regression problem into the linear space defined by the instruments. Thus PROC MODEL does not produce any "first stage" results when you use 2SLS. If you specify the FSRSQ option on the FIT statement, PROC MODEL prints "first-stage R^2" statistic for each parameter estimate.

Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n}\left(\sum_{t=1}^{n}(\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta)\otimes\mathbf{z}_t)\right)'\left(\sum_{t=1}^{n}I\otimes\mathbf{z}_t\mathbf{z}_t'\right)^{-1}\left(\sum_{t=1}^{n}(\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta)\otimes\mathbf{z}_t)\right)$$

is the N2SLS estimator of the parameters. The estimate of Σ at the final iteration is used in the covariance of the parameters given in Table 20.1. Refer to Amemiya (1985, p. 250) for details on the properties of nonlinear two-stage least squares.

Seemingly Unrelated Regression

If the regression equations are not simultaneous, so there are no dependent regressors, *seemingly unrelated regression* (SUR) can be used to estimate systems of equations with correlated random errors. The large-sample efficiency of an estimation can be improved if these cross-equation correlations are taken into account. SUR is also known as *joint generalized least squares* or *Zellner regression*. Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n}\sum_{t=1}^{n} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'\hat{\Sigma}^{-1}\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)$$

is the SUR estimator of the parameters.

The SUR method requires an estimate of the cross-equation covariance matrix, Σ. PROC MODEL first performs an OLS estimation, computes an estimate, $\hat{\Sigma}$, from the OLS residuals, and then performs the SUR estimation based on $\hat{\Sigma}$. The OLS results are not printed unless you specify the OLS option in addition to the SUR option.

You can specify the $\hat{\Sigma}$ to use for SUR by storing the matrix in a SAS data set and naming that data set in the SDATA= option. You can also feed the $\hat{\Sigma}$ computed from the SUR residuals back into the SUR estimation process by specifying the ITSUR option. You can print the estimated covariance matrix $\hat{\Sigma}$ using the COVS option on the FIT statement.

The SUR method requires estimation of the Σ matrix, and this increases the sampling variability of the estimator for small sample sizes. The efficiency gain SUR has over OLS is a large sample property, and you must have a reasonable amount of data to realize this gain. For a more detailed discussion of SUR, refer to Pindyck (1981, p. 331-333).

Three-Stage Least-Squares Estimation

If the equation system is simultaneous, you can combine the 2SLS and SUR methods to take into account both dependent regressors and cross-equation correlation of the errors. This is called *three-stage least squares* (3SLS).

Formally, the $\hat{\theta}$ that minimizes

$$\hat{S}_n = \frac{1}{n}\left(\sum_{t=1}^{n}(\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)\otimes\mathbf{z}_t)\right)'\left(\sum_{t=1}^{n}(\hat{\Sigma}\otimes\mathbf{z}_t\mathbf{z}_t')\right)^{-1}\left(\sum_{t=1}^{n}(\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)\otimes\mathbf{z}_t)\right)$$

is the 3SLS estimator of the parameters. For more details on 3SLS, refer to Gallant (1987, p. 435).

Residuals from the 2SLS method are used to estimate the Σ matrix required for 3SLS. The results of the preliminary 2SLS step are not printed unless the 2SLS option is also specified.

To use the three-stage least-squares method, specify an INSTRUMENTS statement and use the 3SLS or N3SLS option on either the PROC MODEL statement or a FIT statement.

Generalized Method of Moments - GMM

For systems of equations with heteroscedastic errors, generalized method of moments (GMM) can be used to obtain efficient estimates of the parameters. See the "Heteroscedasticity" section for alternatives to GMM.

Consider the nonlinear model

$$\begin{aligned} \boldsymbol{\epsilon}_t &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \\ \mathbf{z}_t &= Z(\mathbf{x}_t) \end{aligned}$$

where $\mathbf{z}_t$ is a vector of instruments and ϵ_t is an unobservable disturbance vector that can be serially correlated and nonstationary.

In general, the following orthogonality condition is desired:

$$E(\boldsymbol{\epsilon}_t \otimes \mathbf{z}_t) = 0$$

which states that the expected crossproducts of the unobservable disturbances, $\boldsymbol{\epsilon}_t$, and functions of the observable variables are set to 0. The first moment of the crossproducts is

$$\begin{aligned} \mathbf{m}_n &= \frac{1}{n}\sum_{t=1}^{n} \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) \\ \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t \end{aligned}$$

where $\mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) \in R^{gk}$.

The case where $gk > p$ is considered here, where *p* is the number of parameters.

Estimate the true parameter vector θ^0 by the value of $\hat{\theta}$ that minimizes

$$S(\theta, V) = [n\mathbf{m}_n(\theta)]' V^{-1} [n\mathbf{m}_n(\theta)]/n$$

where

$$V = \mathrm{Cov}\left([\mathrm{n}\mathbf{m}_{\mathrm{n}}(\theta^0)], [\mathrm{n}\mathbf{m}_{\mathrm{n}}(\theta^0)]'\right)$$

The parameter vector that minimizes this objective function is the GMM estimator. GMM estimation is requested on the FIT statement with the GMM option.

The variance of the moment functions, V, can be expressed as

$$\begin{aligned} V &= E\left(\sum_{t=1}^{n}\epsilon_t\otimes\mathbf{z}_t\right)\left(\sum_{s=1}^{n}\epsilon_s\otimes\mathbf{z}_s\right)' \\ &= \sum_{t=1}^{n}\sum_{s=1}^{n}E\left[(\epsilon_t\otimes\mathbf{z}_t)(\epsilon_s\otimes\mathbf{z}_s)'\right] \\ &= nS_n^0 \end{aligned}$$

where S_n^0 is estimated as

$$\hat{S}_n = \frac{1}{n}\sum_{t=1}^{n}\sum_{s=1}^{n}(\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta)\otimes\mathbf{z}_t)(\mathbf{q}(\mathbf{y}_s,\mathbf{x}_s,\theta)\otimes\mathbf{z}_s)'$$

Note that $\hat{S}_n$ is a $gk\times gk$ matrix. Because Var $(\hat{S}_n)$ will not decrease with increasing *n* we consider estimators of S_n^0 of the form:

$$\begin{aligned} \hat{S}_n(l(n)) &= \sum_{\tau=-n+1}^{n-1} w\left(\frac{\tau}{l(n)}\right)D\hat{S}_{n,\tau}D \\ \hat{S}_{n,\tau} &= \begin{cases} \sum_{t=1+\tau}^{n}[\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta^{\#})\otimes\mathbf{z}_t][\mathbf{q}(\mathbf{y}_{t-\tau},\mathbf{x}_{t-\tau},\theta^{\#})\otimes\mathbf{z}_{t-\tau}]' & \tau\geq 0 \\ (\hat{S}_{n,-\tau})' & \tau<0 \end{cases} \end{aligned}$$

where $l(n)$ is a scalar function that computes the bandwidth parameter, $w(\cdot)$ is a scalar valued kernel, and the diagonal matrix D is used for a small sample degrees of freedom correction (Gallant 1987). The initial $\theta^{\#}$ used for the estimation of $\hat{S}_n$ is obtained from a 2SLS estimation of the system. The degrees of freedom correction is handled by the VARDEF= option as for the **S** matrix estimation.

The following kernels are supported by PROC MODEL. They are listed with their default bandwidth functions.

Bartlett: KERNEL=BART

$$\begin{aligned} w(x) &= \begin{cases} 1-|x| & |x| <= 1 \\ 0 & \text{otherwise} \end{cases} \\ l(n) &= \frac{1}{2}n^{1/3} \end{aligned}$$

Parzen: KERNEL=PARZEN

$$
\begin{aligned}
w(x) &= \begin{cases} 1-6|x|^2+6|x|^3 & 0 <= |x| <= \frac{1}{2} \\ 2(1-|x|)^3 & \frac{1}{2} <= |x| <= 1 \\ 0 & \text{otherwise} \end{cases} \\
l(n) &= n^{1/5}
\end{aligned}
$$

Quadratic Spectral: KERNEL=QS

$$
\begin{aligned}
w(x) &= \frac{25}{12\pi^2 x^2}\left(\frac{sin(6\pi x/5)}{6\pi x/5} - cos(6\pi x/5)\right) \\
l(n) &= \frac{1}{2}n^{1/5}
\end{aligned}
$$

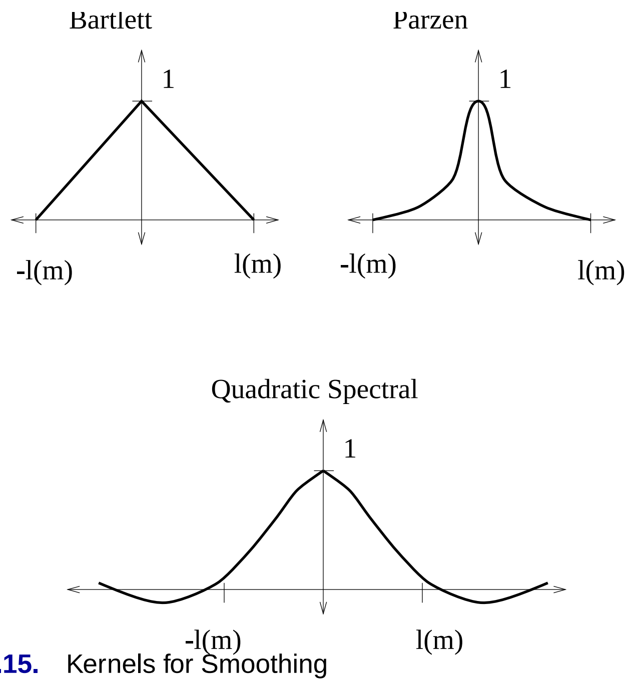

Figure 20.15. Kernels for Smoothing

Details of the properties of these and other kernels are given in Andrews (1991). Kernels are selected with the KERNEL= option; KERNEL=PARZEN is the default. The general form of the KERNEL= option is

```
KERNEL=( PARZEN | QS | BART, c, e )
```

where the $e \geq 0$ and $c \geq 0$ are used to compute the bandwidth parameter as

$$l(n) = cn^e$$

The bias of the standard error estimates increases for large bandwidth parameters. A warning message is produced for bandwidth parameters greater than $n^{\frac{1}{3}}$. For a discussion of the computation of the optimal $l(n)$, refer to Andrews (1991).

The "Newey-West" kernel (Newey (1987)) corresponds to the Bartlett kernel with bandwidth parameter $l(n) = L + 1$. That is, if the "lag length" for the Newey-West kernel is L then the corresponding Model procedure syntax is KERNEL=(bart, L+1, 0).

Andrews (1992) has shown that using prewhitening in combination with GMM can improve confidence interval coverage and reduce over rejection of *t*-statistics at the cost of inflating the variance and MSE of the estimator. Prewhitening can be performed using the %AR macros.

For the special case that the errors are not serially correlated, that is

$$E(e_t \otimes \mathbf{z}_t)(e_s \otimes \mathbf{z}_s) = 0 \qquad t \neq s$$

the estimate for S_n^0 reduces to

$$\hat{S}_n = \frac{1}{n} \sum_{t=1}^{n} [\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t][\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t]'$$

The option KERNEL=(*kernel*,0,) is used to select this type of estimation when using GMM.

Covariance of GMM estimators

The Covariance of GMM estimators given general weighting matrix $\mathbf{V}_{\mathrm{G}}^{-1}$ is

$$[(\mathbf{YX})'\mathbf{V}_{\mathrm{G}}^{-1}(\mathbf{YX})]^{-1}(\mathbf{YX})'\mathbf{V}_{\mathrm{G}}^{-1}\hat{\mathbf{V}}\mathbf{V}_{\mathrm{G}}^{-1}(\mathbf{YX})[(\mathbf{YX})'\mathbf{V}_{\mathrm{G}}^{-1}(\mathbf{YX})]^{-1}$$

By default or when GENGMMV is specified, this is the covariance of GMM estimators.

If the weighting matrix is the same as $\hat{\mathbf{V}}$, then the covariance of GMM estimators becomes

$$[(\mathbf{YX})'\hat{\mathbf{V}}^{-1}(\mathbf{YX})]^{-1}$$

If NOGENGMMV is specified, this is used as the covariance estimators.

Testing Over-Identifying Restrictions

Let *r* be the number of unique instruments times the number of equations. The value *r* represents the number of orthogonality conditions imposed by the GMM method. Under the assumptions of the GMM method, $r - p$ linearly independent combinations of the orthogonality should be close to zero. The GMM estimates are computed by setting these combinations to zero. When *r* exceeds the number of parameters to be estimated, the OBJECTIVE*N, reported at the end of the estimation, is an asymptoticly valid statistic to test the null hypothesis that the over-identifying restrictions of the model are valid. The OBJECTIVE*N is distributed as a chi-square with $r - p$ degrees of freedom (Hansen 1982, p. 1049).

Iterated Generalized Method of Moments - ITGMM

Iterated generalized method of moments is similar to the iterated versions of 2SLS, SUR, and 3SLS. The variance matrix for GMM estimation is re-estimated at each iteration with the parameters determined by the GMM estimation. The iteration terminates when the variance matrix for the equation errors change less than the CONVERGE= value. Iterated generalized method of moments is selected by the ITGMM option on the FIT statement. For some indication of the small sample properties of ITGMM, refer to Ferson and Foerster (1993).

Simulated Method of Moments - SMM

The SMM method uses simulation techniques in model inference and estimation. It is appropriate for estimating models in which integrals appear in the objective function and these integrals can be approximated by simulation. There may be various reasons for integrals to appear in an objective function, for example, transformation of a latent model into an observable model, missing data, random coefficients, heterogeneity, etc.

This simulation method can be used with all the estimation methods except Full Information Maximum Likelihood (FIML) in PROC MODEL. SMM, also known as Simulated Generalized Method of Moments (SGMM), is the default estimation method because of its nice properties.

Estimation Details

A general nonlinear model can be described as

$$\epsilon_t = \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)$$

where $\mathbf{q} \in R^g$ is a real vector valued function of $\mathbf{y}_t \in R^g$, $\mathbf{x}_t \in R^l$, $\theta \in R^p$, *g* is the number of equations, *l* is the number of exogenous variables (lagged endogenous variables are considered exogenous here), *p* is the number of parameters, and *t* ranges from 1 to *n*. ϵ_t is an unobservable disturbance vector with the following properties:

$$\begin{aligned} E(\epsilon_t) &= 0 \\ E(\epsilon_t \epsilon_t') &= \Sigma \end{aligned}$$

In many cases it is not possible to write $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)$ in a closed form. Instead $\mathbf{q}$ is expressed as an integral of a function $\mathbf{f}$, that is,

$$\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) = \int \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \theta, \mathbf{u}_t) \, dP(\mathbf{u})$$

where $\mathbf{f} \in R^g$ is a real vector valued function of $\mathbf{y}_t \in R^g$, $\mathbf{x}_t \in R^l$, $\theta \in R^p$, and $\mathbf{u}_t \in R^m$, m is the number of stochastic variables with a known distribution $P(\mathbf{u})$. Since the distribution of $\mathbf{u}$ is completely known, it is possible to simulate artificial draws from this distribution. Using such independent draws $\mathbf{u}_{ht}$, $h = 1, \ldots, H$, and the strong law of large numbers, $\mathbf{q}$ can be approximated by

$$\frac{1}{H} \sum_{h=1}^{H} \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \theta, \mathbf{u}_{ht}).$$

Simulated Generalized Method of Moments - SGMM

Generalized Method of Moments (GMM) is widely used to obtain efficient estimates for general model systems. When the moment conditions are not readily available in closed forms but can be approximated by simulation, Simulated Generalized Method of Moments (SGMM) can be used. The SGMM estimators have the nice property of being asymptotically consistent and normally distributed even if the number of draws H is fixed (see McFadden 1989, Pakes and Pollard 1989).

Consider the nonlinear model

$$\begin{aligned} \boldsymbol{\epsilon}_t &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) = \frac{1}{H} \sum_{h=1}^{H} \mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \theta, \mathbf{u}_{ht}) \\ \mathbf{z}_t &= Z(\mathbf{x}_t) \end{aligned}$$

where $\mathbf{z}_t \in R^k$ is a vector of k instruments and ϵ_t is an unobservable disturbance vector that can be serially correlated and nonstationary. In case of no instrumental variables, $\mathbf{z}_t$ is 1. $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)$ is the vector of moment conditions, and it is approximated by simulation.

In general, theory suggests the following orthogonality condition

$$E(\boldsymbol{\epsilon}_t \otimes \mathbf{z}_t) = 0$$

which states that the expected crossproducts of the unobservable disturbances, $\boldsymbol{\epsilon}_t$, and functions of the observable variables are set to 0. The sample means of the crossproducts are

$$\begin{aligned} \mathbf{m}_n &= \frac{1}{n} \sum_{t=1}^{n} \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) \\ \mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \otimes \mathbf{z}_t \end{aligned}$$

where $\mathbf{m}(\mathbf{y}_t, \mathbf{x}_t, \theta) \in R^{gk}$. The case where $gk > p$, where p is the number of parameters, is considered here. An estimate of the true parameter vector θ^0 is the value of $\hat{\theta}$ that minimizes

$$S(\theta, V) = [n\mathbf{m}_n(\theta)]' V^{-1} [n\mathbf{m}_n(\theta)]/n$$

where

$$V = \mathrm{Cov}\left(\mathbf{m}(\theta^0), \mathbf{m}(\theta^0)'\right).$$

The steps for SGMM are as follows:

1. Start with a positive definite $\hat{V}$ matrix. This $\hat{V}$ matrix can be estimated from a consistent estimator of θ. If $\hat{\theta}$ is a consistent estimator, then $\mathbf{u}_t$ for $t = 1, ..., n$ can be simulated H' number of times. A consistent estimator of V is obtained as

$$\hat{V} = \frac{1}{n}\sum_{t=1}^{n}[\frac{1}{H'}\sum_{h=1}^{H'}\mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \hat{\theta}, \mathbf{u}_{ht})\otimes\mathbf{z}_t][\frac{1}{H'}\sum_{h=1}^{H'}\mathbf{f}(\mathbf{y}_t, \mathbf{x}_t, \hat{\theta}, \mathbf{u}_{ht})\otimes\mathbf{z}_t]'$$

H' must be large so that this is an consistent estimator of V.

2. Simulate H number of $\mathbf{u}_t$ for $t = 1, ..., n$. As shown by Gourieroux and Monfort (1993), the number of simulations H does not need to be very large. For $H = 10$, the SGMM estimator achieves 90% of the efficiency of the corresponding GMM estimator. Find $\hat{\theta}$ that minimizes the quadratic product of the moment conditions again with the weight matrix being $\hat{V}^{-1}$.

$$\min_{\theta}[n\mathbf{m}_n(\theta)]'\hat{V}^{-1}[n\mathbf{m}_n(\theta)]/n$$

3. The covariance matrix of $\sqrt{n}\theta$ is given as (Gourieroux and Monfont 1993)

$$\Sigma_1^{-1}D\hat{V}^{-1}V(\hat{\theta})\hat{V}^{-1}D'\Sigma_1^{-1} + \frac{1}{H}\Sigma_1^{-1}D\hat{V}^{-1}E[\mathbf{z}\otimes Var(\mathbf{f}|\mathbf{x})\otimes\mathbf{z}]\hat{V}^{-1}D'\Sigma_1^{-1}$$

where $\Sigma_1 = D\hat{V}^{-1}D$, D is the matrix of partial derivatives of the residuals with respect to the parameters, $V(\hat{\theta})$ is the covariance of moments from estimated parameters $\hat{\theta}$, and $Var(\mathbf{f}|\mathbf{x})$ is the covarince of moments for each observation from simulation. The first term is the variance-covariance matrix of the exact GMM estimator, and the second term accounts for the variation contributed by simulating the moments.

Implementation in PROC MODEL

In PROC MODEL, if the user specifies the GMM and NDRAW options on the FIT statement, PROC MODEL first fits the model using N2SLS and computes $\hat{V}$ using the estimates from N2SLS and H' simulation. If NO2SLS is specified on the FIT statement, $\hat{V}$ is read from VDATA= data set. If the user does not provide a $\hat{V}$ matrix, the initial starting value of θ is used as the estimator for computing the $\hat{V}$ matrix in step 1. If ITGMM option is specified instead of GMM, then PROC MODEL iterates from step 1 to step 3 until the V matrix converges.

The consistency of the parameter estimates is not affected by the variance correction shown in the second term in step 3. The correction on the variance of parameter estimates is not computed by default. To add the adjustment, use ADJSMMV option on the FIT statement. This correction is of the order of $\frac{1}{H}$ and is small even for moderate H.

The following example illustrates how to use SMM to estimate a simple regression model. Suppose the model is

$$y = a + bx + u, u \sim iid\, N(0, s^2).$$

First, consider the problem in GMM context. The first two moments of y are easily derived:

$$\begin{aligned} E(y) &= a + bx \\ E(y^2) &= (a+bx)^2 + s^2 \end{aligned}$$

Rewrite the moment conditions in the form similar to the discussion above:

$$\begin{aligned} \epsilon_{1t} &= y_t - (a + bx_t) \\ \epsilon_{2t} &= y_t^2 - (a+bx_t)^2 - s^2 \end{aligned}$$

Then you can estimate this model using GMM with following code:

```
proc model data=a;
  parms a b s;
  instrument x;
  eq.m1 = y-(a+b*x);
  eq.m2 = y*y - (a+b*x)**2 - s*s;
  bound s > 0;
  fit m1 m2 / gmm;
run;
```

Now suppose you do not have the closed form for the moment conditions. Instead you can simulate the moment conditions by generating H number of simulated samples based on the parameters. Then the simulated moment conditions are

$$\begin{aligned} \epsilon_{1t} &= \frac{1}{H}\sum_{h=1}^{H}\{y_t - (a + bx_t + su_{t,h})\} \\ \epsilon_{2t} &= \frac{1}{H}\sum_{h=1}^{H}\{y_t^2 - (a + bx_t + su_{t,h})^2\} \end{aligned}$$

This model can be estimated using SGMM with the following code:

```
   proc model data=_tmpdata;
          parms a b s;
          instrument x;
          ysim = (a+b*x) + s * rannor( 98711 );
          eq.m1 = y-ysim;
          eq.m2 = y*y - ysim*ysim;
          bound s > 0;
          fit m1 m2 / gmm ndraw=10;
   run;
```

Note that the NDRAW= option tells PROC MODEL that this is a simulation-based estimation. Thus the random number function RANNOR returns random numbers in estimation process. During the simulation, 10 draws of $m1$ and $m2$ are generated for each observation, and the averages enter the objective functions just as the equations specified previously.

Other Estimation Methods

The simulation method can be used not only with GMM and ITGMM, but also with OLS, ITOLS, SUR, ITSUR, N2SLS, IT2SLS, N3SLS, and IT3SLS. These simulation-based methods are similar to the corresponding methods in PROC MODEL; however, the only difference is that the objective functions include the average of the H simulations.

Full Information Maximum Likelihood Estimation - FIML

A different approach to the simultaneous equation bias problem is the full information maximum likelihood (FIML) estimation method (Amemiya 1977).

Compared to the instrumental variables methods (2SLS and 3SLS), the FIML method has these advantages and disadvantages:

- FIML does not require instrumental variables.
- FIML requires that the model include the full equation system, with as many equations as there are endogenous variables. With 2SLS or 3SLS you can estimate some of the equations without specifying the complete system.
- FIML assumes that the equations errors have a multivariate normal distribution. If the errors are not normally distributed, the FIML method may produce poor results. 2SLS and 3SLS do not assume a specific distribution for the errors.
- The FIML method is computationally expensive.

The full information maximum likelihood estimators of θ and σ are the $\hat{\theta}$ and $\hat{\sigma}$ that minimize the negative log likelihood function:

$$\begin{aligned}\mathbf{l}_n(\theta,\sigma) = \; & \tfrac{ng}{2} \ln(2\pi) - \sum_{t=1}^{n} \ln\left(\left|\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t^{'}}\right|\right) + \frac{n}{2}\ln\left(|\Sigma(\sigma)|\right) \\ + \; & \frac{1}{2}\mathrm{tr}\left(\Sigma(\sigma)^{-1}\sum_{\mathrm{t=1}}^{\mathrm{n}} \mathbf{q}(\mathbf{y}_{\mathrm{t}}, \mathbf{x}_{\mathrm{t}}, \theta)\mathbf{q}'(\mathbf{y}_{\mathrm{t}}, \mathbf{x}_{\mathrm{t}}, \theta)\right)\end{aligned}$$

The option FIML requests full information maximum likelihood estimation. If the errors are distributed normally, FIML produces efficient estimators of the parameters. If instrumental variables are not provided the starting values for the estimation are obtained from a SUR estimation. If instrumental variables are provided, then the starting values are obtained from a 3SLS estimation. The negative log likelihood value and the l_2 norm of the gradient of the negative log likelihood function are shown in the estimation summary.

FIML Details

To compute the minimum of $\mathbf{l}_n(\theta, \sigma)$, this function is *concentrated* using the relation

$$\Sigma(\theta) = \frac{1}{n} \sum_{t=1}^{n} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)\mathbf{q}'(\mathbf{y}_t, \mathbf{x}_t, \theta)$$

This results in the concentrated negative log likelihood function:

$$\mathbf{l}_n(\theta) = \frac{ng}{2}(1 + \ln(2\pi)) - \sum_{t=1}^{n} \ln \left| \frac{\partial}{\partial \mathbf{y}_t'} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \right| + \frac{n}{2} \ln |\Sigma(\theta|)$$

The gradient of the negative log likelihood function is

$$\frac{\partial}{\partial \theta_i} \mathbf{l}_n(\theta) = \sum_{t=1}^{n} \nabla_i(t)$$

$$\begin{aligned}
\nabla_i(t) \quad = & \quad -\mathrm{tr}\left(\left(\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t'} \right)^{-1} \frac{\partial^2 \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t' \partial \theta_i} \right) \\
+ & \quad \frac{1}{2} \mathrm{tr}\left(\Sigma(\theta)^{-1} \frac{\partial \Sigma(\theta)}{\partial \theta_i} \right. \\
& \quad \left. \left[I - \Sigma(\theta)^{-1} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)' \right] \right) \\
+ & \quad \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta')\Sigma(\theta)^{-1} \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \theta_i}
\end{aligned}$$

where

$$\frac{\partial \Sigma(\theta)}{\partial \theta_i} = \frac{2}{n} \sum_{t=1}^{n} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) \frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'}{\partial \theta_i}$$

The estimator of the variance-covariance of $\hat{\theta}$ (COVB) for FIML can be selected with the COVBEST= option with the following arguments:

CROSS selects the crossproducts estimator of the covariance matrix (default) (Gallant 1987, p. 473):

$$C = \left(\frac{1}{n} \sum_{t=1}^{n} \nabla(t) \nabla'(t) \right)^{-1}$$

where $\nabla(t) = [\nabla_1(t), \nabla_2(t), \ldots, \nabla_p(t)]'$

GLS	selects the generalized least-squares estimator of the covariance matrix. This is computed as (Dagenais 1978) $$C = [\hat{Z}'(\Sigma(\theta)^{-1} \otimes I)\hat{Z}]^{-1}$$ where $\hat{Z} = (\hat{Z}_1, \hat{Z}_2, \ldots, \hat{Z}_p)$ is $ng \times p$ and each $\hat{Z}_i$ column vector is obtained from stacking the columns of $$U \frac{1}{n} \sum_{t=1}^{n} \left(\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'}{\partial y} \right)^{-1} \frac{\partial^2 \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)'}{\partial \mathbf{y}'_n \partial \theta_i} - Q_i$$ U is an $n \times g$ matrix of residuals and q_i is an $n \times g$ matrix $\frac{\partial \mathbf{Q}}{\partial \theta_i}$.
FDA	selects the inverse of concentrated likelihood Hessian as an estimator of the covariance matrix. The Hessian is computed numerically, so for a large problem this is computationally expensive.

The HESSIAN= option controls which approximation to the Hessian is used in the minimization procedure. Alternate approximations are used to improve convergence and execution time. The choices are as follows.

CROSS	The crossproducts approximation is used.
GLS	The generalized least-squares approximation is used (default).
FDA	The Hessian is computed numerically by finite differences.

HESSIAN=GLS has better convergence properties in general, but COVBEST=CROSS produces the most pessimistic standard error bounds. When the HESSIAN= option is used, the default estimator of the variance-covariance of $\hat{\theta}$ is the inverse of the Hessian selected.

Multivariate t-Distribution Estimation

The multivariate *t*-distribution is specified using the ERRORMODEL statement with the T option. Other method specifications (FIML and OLS, for example) are ignored when the ERRORMODEL statement is used for a distribution other than normal.

The probability density function for the multivariate *t*-distribution is

$$P_q = \frac{\Gamma(\frac{df+m}{2})}{(\pi * df)^{\frac{m}{2}} * \Gamma(\frac{df}{2}) \, |\Sigma(\sigma)|^{\frac{1}{2}}} * \left(1 + \frac{\mathbf{q}'(\mathbf{y}_t, \mathbf{x}_t, \theta)\Sigma(\sigma)^{-1}\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{df} \right)^{-\frac{df+m}{2}}$$

where m is the number of equations and df is the degrees of freedom.

The maximum likelihood estimators of θ and σ are the $\hat{\theta}$ and $\hat{\sigma}$ that minimize the negative log-likelihood function:

$$\begin{aligned}\mathbf{l}_n(\theta,\sigma) &= -\sum_{t=1}^{n}\ln\left(\frac{\Gamma(\frac{df+m}{2})}{(\pi * df)^{\frac{m}{2}} * \Gamma(\frac{df}{2})} * \left(1+\frac{q_t'\Sigma^{-1}q_t}{df}\right)^{-\frac{df+m}{2}}\right)\\ &+\frac{n}{2} * \ln\left(|\Sigma|\right) - \sum_{t=1}^{n}\ln\left(\left|\frac{\partial q_t}{\partial y_t'}\right|\right)\end{aligned}$$

The ERRORMODEL statement is used to request the *t*-distribution maximum likelihood estimation. An OLS estimation is done to obtain initial parameter estimates and MSE.*var* estimates. Use NOOLS to turn off this initial estimation. If the errors are distributed normally, *t*-distribution estimation will produce results similar to FIML.

The multivariate model has a single shared degrees of freedom parameter, which is estimated. The degrees of freedom parameter can also be set to a fixed value. The negative log-likelihood value and the l_2 norm of the gradient of the negative log-likelihood function are shown in the estimation summary.

t-Distribution Details

Since a variance term is explicitly specified using the ERRORMODEL statement, $\Sigma(\theta)$ is estimated as a correlation matrix and $\mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)$ is normalized by the variance. The gradient of the negative log-likelihood function with respect to the degrees of freedom is

$$\begin{aligned}\frac{\partial l_n}{\partial df} &= \frac{nm}{2\,df} - \frac{n}{2}\frac{\Gamma'(\frac{df+m}{2})}{\Gamma(\frac{df+m}{2})} + \frac{n}{2}\frac{\Gamma'(\frac{df}{2})}{\Gamma(\frac{df}{2})} + \\ & 0.5\log(1+\frac{\mathbf{q}'\Sigma^{-1}\mathbf{q}}{df}) - \frac{0.5(df+m)}{(1+\frac{\mathbf{q}'\Sigma^{-1}\mathbf{q}}{df})}\frac{\mathbf{q}'\Sigma^{-1}\mathbf{q}}{df^2}\end{aligned}$$

The gradient of the negative log-likelihood function with respect to the parameters is

$$\frac{\partial l_n}{\partial \theta_i} = \frac{0.5(df+m)}{(1+\mathbf{q}'\Sigma^{-1}\mathbf{q}/df)}\left[\frac{(2\,\mathbf{q}'\Sigma^{-1}\frac{\partial \mathbf{q}}{\partial \theta_i})}{df} + \mathbf{q}'\Sigma^{-1}\frac{\partial\Sigma}{\partial\theta_i}\Sigma^{-1}\mathbf{q}\right] - \frac{n}{2}\text{trace}(\Sigma^{-1}\frac{\partial \Sigma}{\partial \theta_i})$$

where

$$\frac{\partial\Sigma(\theta)}{\partial\theta_i} = \frac{2}{n}\sum_{t=1}^{n}\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta)\frac{\partial\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta)'}{\partial\theta_i}$$

and

$$\mathbf{q}(\mathbf{y}_t,\mathbf{x}_t,\theta) = \frac{\epsilon(\theta)}{\sqrt{h(\theta)}} \in R^{m\times n}$$

The estimator of the variance-covariance of $\hat{\theta}$ (COVB) for the *t*-distribution is the inverse of the likelihood Hessian. The gradient is computed analytically and the Hessian is computed numerically.

Empirical Distribution Estimation and Simulation

The following SAS statements fit a model using least squares as the likelihood function, but represent the distribution of the residuals with an empirical CDF. The plot of the empirical probability distribution is shown in the following output.

```
data t;  /* Sum of two normals  */
   format date monyy.;
   do t=0 to 3 by 0.1;
      date = intnx( 'month', '1jun90'd,(t*10)-1);
      y =  0.1 * (rannor(123)-10) +
             .5 *(rannor(456)+10);
      output;
   end;
run;

proc model data=t time=t itprint;
   dependent y;
   parm a 5 ;
   y = a;
   obj = resid.y * resid.y;
   errormodel y ~ general( obj )
      cdf=(empirical=( tails=( t(15) percent= 5)));

   fit y / outns=s out=r;
   id  date;
   solve y / data=t(where=(date='1jun95'd ))
      residdata=r sdata=s random=200 seed=6789 out=monte;
run;

    /*--- Generate the pdf ---*/
proc kde data =monte out=density;
   var y;
run;

symbol1 value=none interpol=join;
proc gplot data=density;
   plot density*y;
run;
```

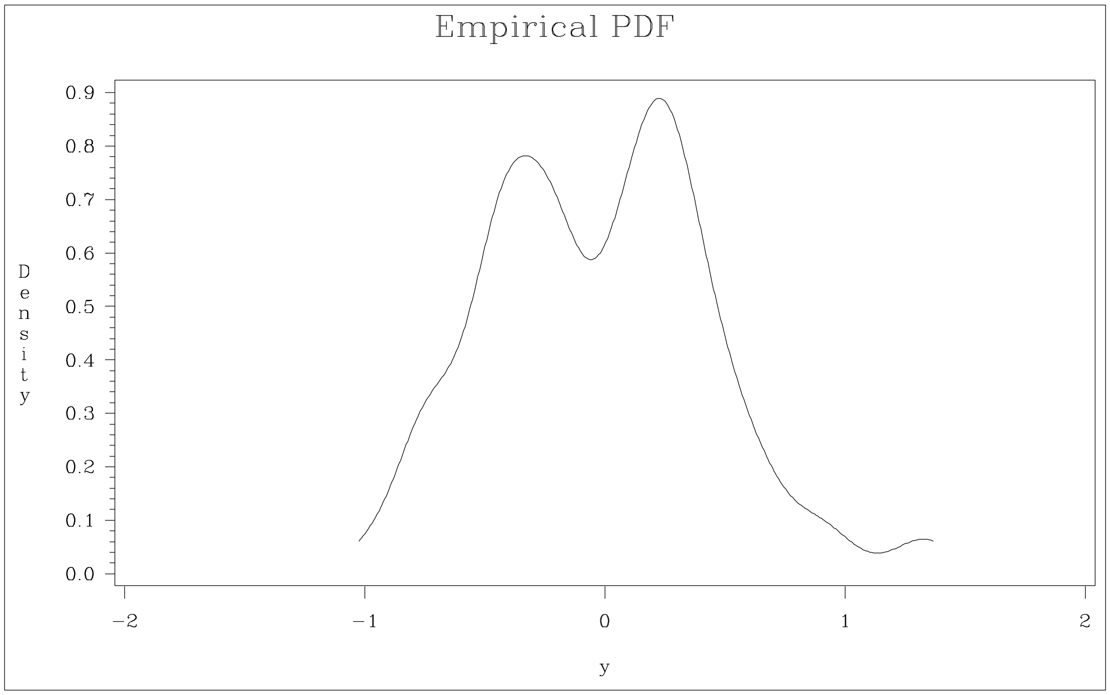

Figure 20.16. Empirical PDF Plot

For simulation, if the CDF for the model is not built in to the procedure, you can use the CDF=EMPIRICAL() option. This uses the sorted residual data to create an empirical CDF. For computing the inverse CDF the program needs to know how to handle the tails. For continuous data, the tail distribution is generally poorly determined. To counter this, the PERCENT= option specifies the percent of the observations to use in constructing each tail. The default for the PERCENT= option is 10.

A normal distribution or a *t*-distribution is used to extrapolate the tails to infinity. The standard errors for this extrapolation are obtained from the data so that the empirical CDF is continuous.

Properties of the Estimates

All of the methods are consistent. Small sample properties may not be good for nonlinear models. The tests and standard errors reported are based on the convergence of the distribution of the estimates to a normal distribution in large samples.

These nonlinear estimation methods reduce to the corresponding linear systems regression methods if the model is linear. If this is the case, PROC MODEL produces the same estimates as PROC SYSLIN.

Except for GMM, the estimation methods assume that the equation errors for each observation are identically and independently distributed with a 0 mean vector and positive definite covariance matrix Σ consistently estimated by **S**. For FIML, the errors need to be normally distributed. There are no other assumptions concerning the distribution of the errors for the other estimation methods.

The consistency of the parameter estimates relies on the assumption that the **S** matrix is a consistent estimate of Σ. These standard error estimates are asymptotically valid, but for nonlinear models they may not be reliable for small samples.

The **S** matrix used for the calculation of the covariance of the parameter estimates is the best estimate available for the estimation method selected. For **S**-iterated methods this is the most recent estimation of Σ. For OLS and 2SLS, an estimate of the **S** matrix is computed from OLS or 2SLS residuals and used for the calculation of the covariance matrix. For a complete list of the **S** matrix used for the calculation of the covariance of the parameter estimates, see Table 20.1.

Missing Values

An observation is excluded from the estimation if any variable used for FIT tasks is missing, if the weight for the observation is not greater than 0 when weights are used, or if a DELETE statement is executed by the model program. Variables used for FIT tasks include the equation errors for each equation, the instruments, if any, and the derivatives of the equation errors with respect to the parameters estimated. Note that variables can become missing as a result of computational errors or calculations with missing values.

The number of usable observations can change when different parameter values are used; some parameter values can be invalid and cause execution errors for some observations. PROC MODEL keeps track of the number of usable and missing observations at each pass through the data, and if the number of missing observations counted during a pass exceeds the number that was obtained using the previous parameter vector, the pass is terminated and the new parameter vector is considered infeasible. PROC MODEL never takes a step that produces more missing observations than the current estimate does.

The values used to compute the Durbin-Watson, R^2, and other statistics of fit are from the observations used in calculating the objective function and do not include any observation for which any needed variable was missing (residuals, derivatives, and instruments).

Details on the Covariance of Equation Errors

There are several **S** matrices that can be involved in the various estimation methods and in forming the estimate of the covariance of parameter estimates. These **S** matrices are estimates of Σ, the true covariance of the equation errors. Apart from the choice of instrumental or noninstrumental methods, many of the methods provided by PROC MODEL differ in the way the various **S** matrices are formed and used.

All of the estimation methods result in a final estimate of Σ, which is included in the output if the COVS option is specified. The final **S** matrix of each method provides the initial **S** matrix for any subsequent estimation.

This estimate of the covariance of equation errors is defined as

$$\mathbf{S} = \mathbf{D}(\mathbf{R}'\mathbf{R})\mathbf{D}$$

where $\mathbf{R} = (\mathbf{r}_1, \ldots, \mathbf{r}_g)$ is composed of the equation residuals computed from the current parameter estimates in an $n \times g$ matrix and **D** is a diagonal matrix that depends on the VARDEF= option.

For VARDEF=N, the diagonal elements of **D** are $1/\sqrt{n}$, where *n* is the number of nonmissing observations. For VARDEF=WGT, *n* is replaced with the sum of the weights. For VARDEF=WDF, *n* is replaced with the sum of the weights minus the model degrees of freedom. For the default VARDEF=DF, the *i*th diagonal element of **D** is $1/\sqrt{n - df_i}$, where df_i is the degrees of freedom (number of parameters) for the *i*th equation. Binkley and Nelson (1984) show the importance of using a degrees-of-freedom correction in estimating Σ. Their results indicate that the DF method produces more accurate confidence intervals for N3SLS parameter estimates in the linear case than the alternative approach they tested. VARDEF=N is always used for the computation of the FIML estimates.

For the fixed **S** methods, the OUTSUSED= option writes the **S** matrix used in the estimation to a data set. This **S** matrix is either the estimate of the covariance of equation errors matrix from the preceding estimation, or a prior Σ estimate read in from a data set when the SDATA= option is specified. For the diagonal **S** methods, all of the off-diagonal elements of the **S** matrix are set to 0 for the estimation of the parameters and for the OUTSUSED= data set, but the output data set produced by the OUTS= option will contain the off-diagonal elements. For the OLS and N2SLS methods, there is no previous estimate of the covariance of equation errors matrix, and the option OUTSUSED= will save an identity matrix unless a prior Σ estimate is supplied by the SDATA= option. For FIML the OUTSUSED= data set contains the **S** matrix computed with VARDEF=N. The OUTS= data set contains the **S** matrix computed with the selected VARDEF= option.

If the COVS option is used, the method is not **S**-iterated, and **S** is not an identity, the OUTSUSED= matrix is included in the printed output.

For the methods that iterate the covariance of equation errors matrix, the **S** matrix is iteratively re-estimated from the residuals produced by the current parameter estimates. This **S** matrix estimate iteratively replaces the previous estimate until both the parameter estimates and the estimate of the covariance of equation errors matrix converge. The final OUTS= matrix and OUTSUSED= matrix are thus identical for the **S**-iterated methods.

Nested Iterations

By default, for **S**-iterated methods, the **S** matrix is held constant until the parameters converge once. Then the **S** matrix is re-estimated. One iteration of the parameter estimation algorithm is performed, and the **S** matrix is again re-estimated. This latter process is repeated until convergence of both the parameters and the **S** matrix. Since the objective of the minimization depends on the **S** matrix, this has the effect of chasing a moving target.

When the NESTIT option is specified, iterations are performed to convergence for the structural parameters with a fixed **S** matrix. The **S** matrix is then re-estimated, the parameter iterations are repeated to convergence, and so on until both the parameters and the **S** matrix converge. This has the effect of fixing the objective function for the inner parameter iterations. It is more reliable, but usually more expensive, to nest the iterations.

R^2

For unrestricted linear models with an intercept successfully estimated by OLS, R^2 is always between 0 and 1. However, nonlinear models do not necessarily encompass the dependent mean as a special case and can produce negative R^2 statistics. Negative R^2's can also be produced even for linear models when an estimation method other than OLS is used and no intercept term is in the model.

R^2 is defined for normalized equations as

$$R^2 = 1 - \frac{SSE}{SSA - \bar{y}^2 \times n}$$

where SSA is the sum of the squares of the actual y's and $\bar{y}$ are the actual means. R^2 cannot be computed for models in general form because of the need for an actual Y.

Minimization Methods

PROC MODEL currently supports two methods for minimizing the objective function. These methods are described in the following sections.

GAUSS

The Gauss-Newton parameter-change vector for a system with *g* equations, *n* nonmissing observations, and *p* unknown parameters is

$$\mathbf{\Delta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}$$

where Δ is the change vector, **X** is the stacked $ng \times p$ Jacobian matrix of partial derivatives of the residuals with respect to the parameters, and **r** is an $ng \times 1$vector of the stacked residuals. The components of **X** and **r** are weighted by the $\mathbf{S}^{-1}$ matrix. When instrumental methods are used, **X** and **r** are the projections of the Jacobian matrix and residuals vector in the instruments space and not the Jacobian and residuals themselves. In the preceding formula, **S** and W are suppressed. If instrumental variables are used, then the change vector becomes:

$$\mathbf{\Delta} = (\mathbf{X}'(\mathbf{S}^{-1}\otimes\mathbf{W})\mathbf{X})^{-1}\mathbf{X}'(\mathbf{S}^{-1}\otimes\mathbf{W})\mathbf{r}$$

This vector is computed at the end of each iteration. The objective function is then computed at the changed parameter values at the start of the next iteration. If the objective function is not improved by the change, the Δ vector is reduced by one-half and the objective function is re-evaluated. The change vector will be halved up to MAXSUBITER= times until the objective function is improved.

For FIML the $\mathbf{X}'\mathbf{X}$ matrix is substituted with one of three choices for approximations to the Hessian. See the "FIML Estimation" section in this chapter.

MARQUARDT

The Marquardt-Levenberg parameter change vector is

$$\mathbf{\Delta} = (\mathbf{X}'\mathbf{X} + \lambda \mathrm{diag}(\mathbf{X}'\mathbf{X}))^{-1}\mathbf{X}'\mathbf{r}$$

where Δ is the change vector, and **X** and **r** are the same as for the Gauss-Newton method, described in the preceding section. Before the iterations start, λ is set to a small value (1E-6). At each iteration, the objective function is evaluated at the parameters changed by Δ. If the objective function is not improved, λ is increased to 10λ and the step is tried again. λ can be increased up to MAXSUBITER= times to a maximum of 1E15 (whichever comes first) until the objective function is improved. For the start of the next iteration, λ is reduced to max(λ/10,1E-10).

Convergence Criteria

There are a number of measures that could be used as convergence or stopping criteria. PROC MODEL computes five convergence measures labeled R, S, PPC, RPC, and OBJECT.

When an estimation technique that iterates estimates of Σ is used (that is, IT3SLS), two convergence criteria are used. The termination values can be specified with the CONVERGE=(*p*,*s*) option on the FIT statement. If the second value, *s*, is not specified, it defaults to *p*. The criterion labeled S (given in the following) controls the convergence of the **S** matrix. When S is less than *s*, the **S** matrix has converged. The criterion labeled R is compared to the *p* value to test convergence of the parameters.

The R convergence measure cannot be computed accurately in the special case of singular residuals (when all the residuals are close to 0) or in the case of a 0 objective value. When either the trace of the **S** matrix computed from the current residuals (trace(S)) or the objective value is less than the value of the SINGULAR= option, convergence is assumed.

The various convergence measures are explained in the following:

R is the primary convergence measure for the parameters. It measures the degree to which the residuals are orthogonal to the Jacobian columns, and it approaches 0 as the gradient of the objective function becomes small. R is defined as the square root of

$$\frac{(r'(S^{-1}{\otimes}W)X(X'(S^{-1}{\otimes}W)X)^{-1}X'(S^{-1}{\otimes}W)r)}{(r'(S^{-1}{\otimes}W)r)}$$

where **X** is the Jacobian matrix and **r** is the residuals vector. R is similar to the relative offset orthogonality convergence criterion proposed by Bates and Watts (1981).

In the univariate case, the R measure has several equivalent interpretations:

- the cosine of the angle between the residuals vector and the column space of the Jacobian matrix. When this cosine is 0, the residuals are orthogonal to the partial derivatives of the predicted values with respect to the parameters, and the gradient of the objective function is 0.
- the square root of the R^2 for the current linear pseudo-model in the residuals.
- a norm of the gradient of the objective function, where the norming matrix is proportional to the current estimate of the covariance of the parameter estimates. Thus, using R, convergence is judged when the gradient becomes small in this norm.
- the prospective relative change in the objective function value expected from the next GAUSS step, assuming that the current linearization of the model is a good local approximation.

In the multivariate case, R is somewhat more complicated but is designed to go to 0 as the gradient of the objective becomes small and can still be given the previous interpretations for the aggregation of the equations weighted by $\mathbf{S}^{-1}$.

PPC is the prospective parameter change measure. PPC measures the maximum relative change in the parameters implied by the parameter-change vector computed for the next iteration. At the *k*th iteration, PPC is the maximum over the parameters

$$\frac{|\theta_i^{k+1} - \theta_i^k|}{|\theta|_i^k + 1.0e^{-6}}$$

where θ_i^k is the current value of the *i*th parameter and θ_i^{k+1} is the prospective value of this parameter after adding the change vector computed for the next iteration. The parameter with the maximum prospective relative change is printed with the value of PPC, unless the PPC is nearly 0.

RPC is the retrospective parameter change measure. RPC measures the maximum relative change in the parameters from the previous iteration. At the *k*th iteration, RPC is the maximum over *i* of

$$\frac{|\theta_i^k - \theta_i^{k-1}|}{|\theta_i^{k-1} + 1.0e^{-6}|}$$

where θ_i^k is the current value of the *i*th parameter and θ_i^{k-1} is the previous value of this parameter. The name of the parameter with the maximum retrospective relative change is printed with the value of RPC, unless the RPC is nearly 0.

OBJECT measures the relative change in the objective function value between iterations:

$$\frac{|(O^k - O^{k-1}|}{|O^{k-1} + 1.0e^{-6}|}$$

where O^{k-1} is the value of the objective function (O^k) from the previous iteration.

S measures the relative change in the **S** matrix. S is computed as the maximum over *i*, *j* of

$$\frac{|S_{ij}^k - S_{ij}^{k-1}|}{|S_{ij}^{k-1} + 1.0e^{-6}|}$$

where S^{k-1} is the previous **S** matrix. The S measure is relevant only for estimation methods that iterate the **S** matrix.

An example of the convergence criteria output is as follows:

```

```

Figure 20.17. Convergence Criteria Output

This output indicates the total number of iterations required by the Gauss minimization for all the **S** matrices was 35. The "Trace(S)" is the trace (the sum of the diagonal elements) of the **S** matrix computed from the current residuals. This row is labeled MSE if there is only one equation.

Troubleshooting Convergence Problems

As with any nonlinear estimation routine, there is no guarantee that the estimation will be successful for a given model and data. If the equations are linear with respect to the parameters, the parameter estimates always converge in one iteration. The methods that iterate the **S** matrix must iterate further for the **S** matrix to converge. Nonlinear models may not necessarily converge.

Convergence can be expected only with fully identified parameters, adequate data, and starting values sufficiently close to solution estimates.

Convergence and the rate of convergence may depend primarily on the choice of starting values for the estimates. This does not mean that a great deal of effort should be invested in choosing starting values. First, try the default values. If the estimation fails with these starting values, examine the model and data and re-run the estimation using reasonable starting values. It is usually not necessary that the starting values be very good, just that they not be very bad; choose values that seem plausible for the model and data.

An Example of Requiring Starting Values

Suppose you want to regress a variable Y on a variable X assuming that the variables are related by the following nonlinear equation:

$$y = a + bx^c + \epsilon$$

In this equation, Y is linearly related to a power transformation of X. The unknown parameters are *a*, *b*, and *c*. ϵ is an unobserved random error. Some simulated data was generated using the following SAS statements. In this simulation, $a = 10$, $b = 2$, and the use of the SQRT function corresponds to $c = .5$.

```
data test;
  do i = 1 to 20;
     x = 5 * ranuni(1234);
     y = 10 + 2 * sqrt(x) + .5 * rannor(2345);
     output;
     end;
run;
```

The following statements specify the model and give descriptive labels to the model parameters. Then the FIT statement attempts to estimate *a*, *b*, and *c* using the default starting value .0001.

```
proc model data=test;
   y = a + b * x ** c;
   label a = "Intercept"
         b = "Coefficient of Transformed X"
         c = "Power Transformation Parameter";
   fit y;
run;
```

PROC MODEL prints model summary and estimation problem summary reports and then prints the output shown in Figure 20.18.

```

      parameter estimation using different starting values for the parameter
      estimates.
PROC MODEL continues as if the parameter estimates had converged.
```

Figure 20.18. Diagnostics for Convergence Failure

By using the default starting values, PROC MODEL was unable to take even the first step in iterating to the solution. The change in the parameters that the Gauss-Newton method computes is very extreme and makes the objective values worse instead of better. Even when this step is shortened by a factor of a million, the objective function is still worse, and PROC MODEL is unable to estimate the model parameters.

The problem is caused by the starting value of C. Using the default starting value C=.0001, the first iteration attempts to compute better values of A and B by what is, in effect, a linear regression of Y on the 10,000th root of X, which is almost the same as the constant 1. Thus the matrix that is inverted to compute the changes is nearly singular and affects the accuracy of the computed parameter changes.

This is also illustrated by the next part of the output, which displays collinearity diagnostics for the crossproducts matrix of the partial derivatives with respect to the parameters, shown in Figure 20.19.

```
                          The MODEL Procedure
                            OLS Estimation

                       Collinearity Diagnostics

```

Figure 20.19. Collinearity Diagnostics

This output shows that the matrix is singular and that the partials of A, B, and C with respect to the residual are collinear at the point $(0.0001, 0.0001, 0.0001)$ in the parameter space. See the section "Linear Dependencies" for a full explanation of the collinearity diagnostics.

The MODEL procedure next prints the note shown in Figure 20.20, which suggests that you try different starting values.

```
                          The MODEL Procedure
                            OLS Estimation

NOTE: The parameter estimation is abandoned. Check your model and data. If the
      model is correct and the input data are appropriate, try rerunning the
      parameter estimation using different starting values for the parameter
      estimates.
PROC MODEL continues as if the parameter estimates had converged.
```

Figure 20.20. Estimation Failure Note

PROC MODEL then produces the usual printout of results for the nonconverged parameter values. The estimation summary is shown in Figure 20.21. The heading includes the reminder "(Not Converged)."

```

Figure 20.22. Nonconverged Results

Note that the R^2 statistic is negative. An $R^2 < 0$ results when the residual mean square error for the model is larger than the variance of the dependent variable. Negative R^2 statistics may be produced when either the parameter estimates fail to converge correctly, as in this case, or when the correctly estimated model fits the data very poorly.

Controlling Starting Values

To fit the preceding model you must specify a better starting value for C. Avoid starting values of C that are either very large or close to 0. For starting values of A and B, you can either specify values, use the default, or have PROC MODEL fit starting values for them conditional on the starting value for C.

Starting values are specified with the START= option of the FIT statement or on a PARMS statement. For example, the following statements estimate the model parameters using the starting values A=.0001, B=.0001, and C=5.

```
proc model data=test;
   y = a + b * x ** c;
   label a = "Intercept"
         b = "Coefficient of Transformed X"
         c = "Power Transformation Parameter";
   fit y start=(c=5);
run;
```

Using these starting values, the estimates converge in 16 iterations. The results are shown in Figure 20.23. Note that since the START= option explicitly declares parameters, the parameter C is placed first in the table.

```

Figure 20.23. Converged Results

Using the STARTITER Option

PROC MODEL can compute starting values for some parameters conditional on starting values you specify for the other parameters. You supply starting values for some parameters and specify the STARTITER option on the FIT statement.

For example, the following statements set C to 1 and compute starting values for A and B by estimating these parameters conditional on the fixed value of C. With C=1 this is equivalent to computing A and B by linear regression on X. A PARMS statement is used to declare the parameters in alphabetical order. The ITPRINT option is used to print the parameter values at each iteration.

```
proc model data=test;
   parms a b c;
   y = a + b * x ** c;
   label a = "Intercept"
         b = "Coefficient of Transformed X"
         c = "Power Transformation Parameter";
   fit y start=(c=1) / startiter itprint;
run;
```

With better starting values, the estimates converge in only 5 iterations. Counting the 2 iterations required to compute the starting values for A and B, this is 5 fewer than the 12 iterations required without the STARTITER option. The iteration history listing is shown in Figure 20.24.

Figure 20.24. ITPRINT Listing

The results produced in this case are almost the same as the results shown in Figure 20.23, except that the PARMS statement causes the Parameter Estimates table to be ordered A, B, C instead of C, A, B. They are not exactly the same because the different starting values caused the iterations to converge at a slightly different place. This effect is controlled by changing the convergence criterion with the CONVERGE= option.

By default, the STARTITER option performs one iteration to find starting values for the parameters not given values. In this case the model is linear in A and B, so only one iteration is needed. If A or B were nonlinear, you could specify more than one "starting values" iteration by specifying a number for the STARTITER= option.

Finding Starting Values by Grid Search

PROC MODEL can try various combinations of parameter values and use the combination producing the smallest objective function value as starting values. (For OLS the objective function is the residual mean square.) This is known as a preliminary *grid search*. You can combine the STARTITER option with a grid search.

For example, the following statements try 5 different starting values for C: 10, 5, 2.5, -2.5, -5. For each value of C, values for A and B are estimated. The combination of A, B, and C values producing the smallest residual mean square is then used to start the iterative process.

```
proc model data=test;
   parms a b c;
   y = a + b * x ** c;
   label a = "Intercept"
         b = "Coefficient of Transformed X"
         c = "Power Transformation Parameter";
   fit y start=(c=10 5 2.5 -2.5 -5) / startiter itprint;
run;
```

The iteration history listing is shown in Figure 20.25. Using the best starting values found by the grid search, the OLS estimation only requires 2 iterations. However, since the grid search required 10 iterations, the total iterations in this case is 12.

Figure 20.25. ITPRINT Listing

Because no initial values for A or B were provided in the PARAMETERS statement or were read in with a PARMSDATA= or ESTDATA= option, A and B were given the default value of 0.0001 for the first iteration. At the second grid point, C=5, the values of A and B obtained from the previous iterations are used for the initial iteration. If initial values are provided for parameters, the parameters start at those initial values at each grid point.

Guessing Starting Values from the Logic of the Model

Example 20.1, which uses a logistic growth curve model of the U.S. population, illustrates the need for reasonable starting values. This model can be written

$$pop = \frac{a}{1 + \exp(b - c(t - 1790))}$$

where *t* is time in years. The model is estimated using decennial census data of the U.S. population in millions. If this simple but highly nonlinear model is estimated using the default starting values, the estimation fails to converge.

To find reasonable starting values, first consider the meaning of *a* and *c*. Taking the limit as time increases, *a* is the limiting or maximum possible population. So, as a starting value for *a*, several times the most recent population known can be used, for example, one billion (1000 million).

Dividing the time derivative by the function to find the growth rate and taking the limit as *t* moves into the past, you can determine that *c* is the initial growth rate. You can examine the data and compute an estimate of the growth rate for the first few decades, or you can pick a number that sounds like a plausible population growth rate figure, such as 2%.

To find a starting value for *b*, let *t* equal the base year used, 1790, which causes *c* to drop out of the formula for that year, and then solve for the value of *b* that is consistent with the known population in 1790 and with the starting value of *a*. This yields $b = \ln(a/3.9 - 1)$ or about 5.5, where *a* is 1000 and 3.9 is roughly the population for 1790 given in the data. The estimates converge using these starting values.

Convergence Problems

When estimating nonlinear models, you may encounter some of the following convergence problems.

Unable to Improve

The optimization algorithm may be unable to find a step that improves the objective function. If this happens in the Gauss-Newton method, the step size is halved to find a change vector for which the objective improves. In the Marquardt method, λ will be increased to find a change vector for which the objective improves. If, after MAXSUBITER= step-size halvings or increases in λ, the change vector still does not produce a better objective value, the iterations are stopped and an error message is printed.

Failure of the algorithm to improve the objective value can be caused by a CONVERGE= value that is too small. Look at the convergence measures reported at the point of failure. If the estimates appear to be approximately converged, you can accept the NOT CONVERGED results reported, or you can try re-running the FIT task with a larger CONVERGE= value.

If the procedure fails to converge because it is unable to find a change vector that improves the objective value, check your model and data to ensure that all parameters are identified and data values are reasonably scaled. Then, re-run the model with different starting values. Also, consider using the Marquardt method if Gauss-Newton fails; the Gauss-Newton method can get into trouble if the Jacobian matrix is nearly singular or ill-conditioned. Keep in mind that a nonlinear model may be well-identified and well-conditioned for parameter values close to the solution values but unidentified or numerically ill-conditioned for other parameter values. The choice of starting values can make a big difference.

Nonconvergence

The estimates may diverge into areas where the program overflows or the estimates may go into areas where function values are illegal or too badly scaled for accurate calculation. The estimation may also take steps that are too small or that make only marginal improvement in the objective function and, thus, fail to converge within the iteration limit.

When the estimates fail to converge, collinearity diagnostics for the Jacobian crossproducts matrix are printed if there are 20 or fewer parameters estimated. See "Linear Dependencies" later in this section for an explanation of these diagnostics.

Inadequate Convergence Criterion

If convergence is obtained, the resulting estimates will only approximate a minimum point of the objective function. The statistical validity of the results is based on the exact minimization of the objective function, and for nonlinear models the quality of the results depends on the accuracy of the approximation of the minimum. This is controlled by the convergence criterion used.

There are many nonlinear functions for which the objective function is quite flat in a large region around the minimum point so that many quite different parameter vectors may satisfy a weak convergence criterion. By using different starting values, different convergence criteria, or different minimization methods, you can produce very different estimates for such models.

You can guard against this by running the estimation with different starting values and different convergence criteria and checking that the estimates produced are essentially the same. If they are not, use a smaller CONVERGE= value.

Local Minimum

You may have converged to a local minimum rather than a global one. This problem is difficult to detect because the procedure will appear to have succeeded. You can guard against this by running the estimation with different starting values or with a different minimization technique. The START= option can be used to automatically perform a grid search to aid in the search for a global minimum.

Discontinuities

The computational methods assume that the model is a continuous and smooth function of the parameters. If this is not the case, the methods may not work.

If the model equations or their derivatives contain discontinuities, the estimation will usually succeed, provided that the final parameter estimates lie in a continuous interval and that the iterations do not produce parameter values at points of discontinuity or parameter values that try to cross asymptotes.

One common case of discontinuities causing estimation failure is that of an asymptotic discontinuity between the final estimates and the initial values. For example, consider the following model, which is basically linear but is written with one parameter in reciprocal form:

```
   y = a + b * x1 + x2 / c;
```

By placing the parameter C in the denominator, a singularity is introduced into the parameter space at C=0. This is not necessarily a problem, but if the correct estimate of C is negative while the starting value is positive (or vice versa), the asymptotic discontinuity at 0 will lie between the estimate and the starting value. This means that the iterations have to pass through the singularity to get to the correct estimates. The situation is shown in Figure 20.26.

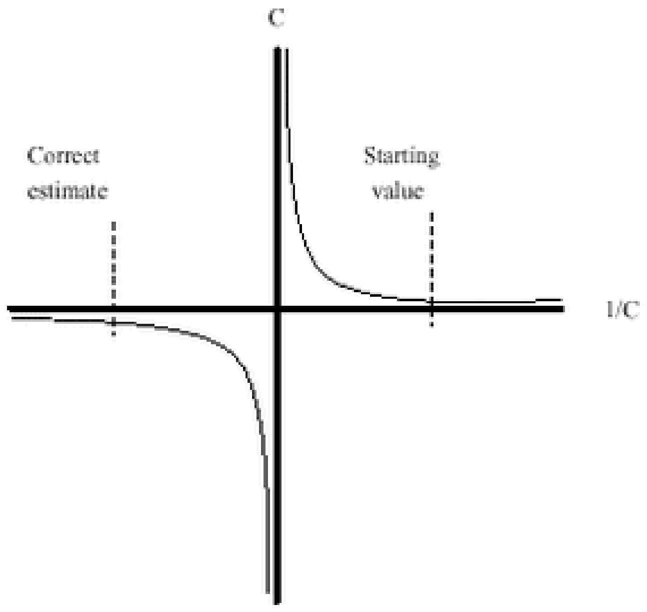

Figure 20.26. Asymptotic Discontinuity

Because of the incorrect sign of the starting value, the C estimate goes off towards positive infinity in a vain effort to get past the asymptote and onto the correct arm of the hyperbola. As the computer is required to work with ever closer approximations to infinity, the numerical calculations break down and an "objective function was not improved" convergence failure message is printed. At this point, the iterations terminate with an extremely large positive value for C. When the sign of the starting value for C is changed, the estimates converge quickly to the correct values.

Linear Dependencies

In some cases, the Jacobian matrix may not be of full rank; parameters may not be fully identified for the current parameter values with the current data. When linear dependencies occur among the derivatives of the model, some parameters appear with a standard error of 0 and with the word BIASED printed in place of the *t* statistic. When this happens, collinearity diagnostics for the Jacobian crossproducts matrix are printed if the DETAILS option is specified and there are twenty or fewer parameters estimated. Collinearity diagnostics are also printed out automatically when a minimization method fails, or when the COLLIN option is specified.

For each parameter, the proportion of the variance of the estimate accounted for by each *principal component* is printed. The principal components are constructed from the eigenvalues and eigenvectors of the correlation matrix (scaled covariance matrix). When collinearity exists, a principal component is associated with proportion of the variance of more than one parameter. The numbers reported are proportions so they will remain between 0 and 1. If two or more parameters have large proportion values associated with the same principle component, then two problems can occur: the computation of the parameter estimates are slow or nonconvergent; and the parameter estimates have inflated variances (Belsley 1980, p. 105-117).

For example, the following cubic model is fit to a quadratic data set:

```
proc model data=test3;
   exogenous x1 ;
   parms b1 a1 c1 ;
   y1 = a1 * x1 + b1 * x1 * x1  + c1 * x1 * x1 *x1;
   fit y1/ collin ;
run;
```

The collinearity diagnostics are shown in Figure 20.27.

```
                                The MODEL Procedure

```

Figure 20.27. Collinearity Diagnostics

Notice that the proportions associated with the smallest eigenvalue are almost 1. For this model, removing any of the parameters will decrease the variances of the remaining parameters.

In many models the collinearity might not be clear cut. Collinearity is not necessarily something you remove. A model may need to be reformulated to remove the redundant parameterization or the limitations on the estimatability of the model can be accepted. The GINV=G4 option can be helpful to avoid problems with convergence for models containing collinearities.

Collinearity diagnostics are also useful when an estimation does not converge. The diagnostics provide insight into the numerical problems and can suggest which parameters need better starting values. These diagnostics are based on the approach of Belsley, Kuh, and Welsch (1980).

Iteration History

The options ITPRINT, ITDETAILS, XPX, I, and ITALL specify a detailed listing of each iteration of the minimization process.

ITPRINT Option

The ITPRINT information is selected whenever any iteration information is requested.

The following information is displayed for each iteration:

N	the number of usable observations
Objective	the corrected objective function value
Trace(S)	the trace of the **S** matrix
subit	the number of subiterations required to find a λ or a damping factor that reduces the objective function
R	the R convergence measure

The estimates for the parameters at each iteration are also printed.

ITDETAILS Option

The additional values printed for the ITDETAILS option are:

Theta	is the angle in degrees between Δ, the parameter change vector, and the negative gradient of the objective function.
Phi	is the directional derivative of the objective function in the Δ direction scaled by the objective function.
Stepsize	is the value of the damping factor used to reduce Δ if the Gauss-Newton method is used.
Lambda	is the value of λ if the Marquardt method is used.
Rank(XPX)	If the projected Jacobian crossproducts matrix is singular, the rank of the $\mathbf{X'X}$ matrix is output.

The definitions of PPC and R are explained in the section "Convergence Criteria." When the values of PPC are large, the parameter associated with the criteria is displayed in parentheses after the value.

XPX and I Options

The XPX and the I options select the printing of the augmented $\mathbf{X'X}$ matrix and the augmented $\mathbf{X'X}$ matrix after a *sweep* operation (Goodnight 1979) has been performed on it. An example of the output from the following statements is shown in Figure 20.28.

```
proc model data=test2 ;
   y1 = a1 * x2 * x2 - exp( d1*x1);
   y2 = a2 * x1 * x1 + b2 * exp( d2*x2);
   fit y1 y2 / XPX I ;
run;
```

```

Figure 20.28. XPX and I Options Output

The first matrix, labeled "Cross Products," for OLS estimation is

$$\begin{bmatrix} \mathbf{X'X} & \mathbf{X'r} \\ \mathbf{r'X} & \mathbf{r'r} \end{bmatrix}$$

The column labeled "Residual" in the output is the vector $\mathbf{X'r}$, which is the gradient of the objective function. The diagonal scalar value $\mathbf{r'r}$ is the objective function uncorrected for degrees of freedom. The second matrix, labeled "XPX Inverse," is created through a sweep operation on the augmented $\mathbf{X'X}$ matrix to get:

$$\begin{bmatrix} (\mathbf{X'X})^{-1} & (\mathbf{X'X})^{-1}\mathbf{X'r} \\ (\mathbf{X'r})'(\mathbf{X'X})^{-1} & \mathbf{r'r} - (\mathbf{X'r})'(\mathbf{X'X})^{-1}\mathbf{X'r} \end{bmatrix}$$

Note that the residual column is the change vector used to update the parameter estimates at each iteration. The corner scalar element is used to compute the R convergence criteria.

ITALL Option

The ITALL option, in addition to causing the output of all of the preceding options, outputs the **S** matrix, the inverse of the **S** matrix, the CROSS matrix, and the swept CROSS matrix. An example of a portion of the CROSS matrix for the preceding example is shown in Figure 20.29.

Figure 20.29. ITALL Option Cross-Products Matrix Output

Computer Resource Requirements

If you are estimating large systems, you need to be aware of how PROC MODEL uses computer resources such as memory and the CPU so they can be used most efficiently.

Saving Time with Large Data Sets

If your input data set has many observations, the FIT statement does a large number of model program executions. A pass through the data is made at least once for each iteration and the model program is executed once for each observation in each pass. If you refine the starting estimates by using a smaller data set, the final estimation with the full data set may require fewer iterations.

For example, you could use

```
proc model;
   /* Model goes here */
   fit / data=a(obs=25);
   fit / data=a;
```

where OBS=25 selects the first 25 observations in A. The second FIT statement produces the final estimates using the full data set and starting values from the first run.

Fitting the Model in Sections to Save Space and Time

If you have a very large model (with several hundred parameters, for example), the procedure uses considerable space and time. You may be able to save resources by breaking the estimation process into several steps and estimating the parameters in subsets.

You can use the FIT statement to select for estimation only the parameters for selected equations. Do not break the estimation into too many small steps; the total computer time required is minimized by compromising between the number of FIT statements that are executed and the size of the crossproducts matrices that must be processed.

When the parameters are estimated for selected equations, the entire model program must be executed even though only a part of the model program may be needed to compute the residuals for the equations selected for estimation. If the model itself can be broken into sections for estimation (and later combined for simulation and forecasting), then more resources can be saved.

For example, to estimate the following four equation model in two steps, you could use

```
proc model data=a outmodel=part1;
   parms a0-a2 b0-b2 c0-c3 d0-d3;
   y1 = a0 + a1*y2 + a2*x1;
   y2 = b0 + b1*y1 + b2*x2;
   y3 = c0 + c1*y1 + c2*y4 + c3*x3;
   y4 = d0 + d1*y1 + d2*y3 + d3*x4;
   fit y1 y2;
   fit y3 y4;
   fit y1 y2 y3 y4;
run;
```

You should try estimating the model in pieces to save time only if there are more than 14 parameters; the preceding example takes more time, not less, and the difference in memory required is trivial.

Memory Requirements for Parameter Estimation

PROC MODEL is a large program, and it requires much memory. Memory is also required for the SAS System, various data areas, the model program and associated tables and data vectors, and a few crossproducts matrices. For most models, the memory required for PROC MODEL itself is much larger than that required for the model program, and the memory required for the model program is larger than that required for the crossproducts matrices.

The number of bytes needed for two crossproducts matrices, four **S** matrices, and three parameter covariance matrices is

$$8 \times (2 + k + m + g)^2 + 16 \times g^2 + 12 \times (p + 1)^2$$

plus lower-order terms. *m* is the number of unique nonzero derivatives of each residual with respect to each parameter, *g* is the number of equations, *k* is the number of instruments, and *p* is the number of parameters. This formula is for the memory required for 3SLS. If you are using OLS, a reasonable estimate of the memory required for large problems (greater than 100 parameters) is to divide the value obtained from the formula in half.

Consider the following model program.

```
proc model data=test2 details;
   exogenous x1 x2;
   parms b1 100 a1 a2 b2 2.5 c2 55;
   y1 = a1 * y2 + b1 * x1 * x1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2;
   fit y1 y2 / n3sls;
   inst b1 b2 c2 x1 ;
run;
```

The DETAILS option prints the storage requirements information shown in Figure 20.30.

```

                    Order of S Matrix                   2
                    Order of Cross Matrix              13
                    Total Nonzero Derivatives           5
                    Distinct Variable Derivatives       5
                    Size of Cross matrix              728
```

Figure 20.30. Storage Requirements Information

The matrix $\mathbf{X}'\mathbf{X}$ augmented by the residual vector is called the XPX matrix in the output, and it has the size $m + 1$. The order of the **S** matrix, 2 for this example, is the value of *g*. The CROSS matrix is made up of the *k* unique instruments, a constant column representing the intercept terms, followed by the *m* unique Jacobian variables plus a constant column representing the parameters with constant derivatives, followed by the *g* residuals.

The size of two CROSS matrices in bytes is

$$8 \times (2 + k + m + g)^2 + 2 + k + m + g$$

Note that the CROSS matrix is symmetric, so only the diagonal and the upper triangular part of the matrix is stored. For examples of the CROSS and XPX matrices see "Iteration History" in this section.

The MEMORYUSE Option

The MEMORYUSE option on the FIT, SOLVE, MODEL, or RESET statement may be used to request a comprehensive memory usage summary.

Figure 20.31 shows an example of the output produced by the MEMORYUSE option.

```
                              The MODEL Procedure

```

Figure 20.31. MEMORYUSE Option Output for SOLVE Task

Definitions of the memory components follows:

symbols	memory used to store information about variables in the model
strings	memory used to store the variable names and labels
lists	space used to hold lists of variables
arrays	memory used by ARRAY statements
statements	memory used for the list of programming statements in the model
opcodes	memory used to store the code compiled to evaluate the expression in the model program
parsing	memory used in parsing the SAS statements
executable	the compiled model program size (not correct yet)
block option	memory used by the BLOCK option
cross ref.	memory used by the XREF option
flow analysis	memory used to compute the interdependencies of the variables
derivatives	memory used to compute and store the analytical derivatives
data vector	memory used for the program data vector
cross matrix	memory used for one or more copies of the Cross matrix
$\mathbf{X}'\mathbf{X}$ matrix	memory used for one or more copies of the $\mathbf{X}'\mathbf{X}$ matrix
S matrix	memory used for the covariance matrix
GMM memory	additional memory used for the GMM and ITGMM methods
Jacobian	memory used for the Jacobian matrix for SOLVE and FIML
work vectors	memory used for miscellaneous work vectors
overhead	other miscellaneous memory

Testing for Normality

The NORMAL option on the FIT statement performs multivariate and univariate tests of normality.

The three multivariate tests provided are Mardia's skewness test and kurtosis test (Mardia 1980) and the Henze-Zirkler $T_{n,\beta}$ test (Henze and Zirkler 1990). The two univariate tests provided are the Shapiro-Wilk W test and the Kolmogorov-Smirnov test. (For details on the univariate tests, refer to "Tests for Normality" in "The UNIVARIATE Procedure" chapter in the *SAS Procedures Guide*.) The null hypothesis for all these tests is that the residuals are normally distributed.

For a random sample $X_1, \ldots, X_n$, $X_i \in \mathrm{R}^{\mathrm{d}}$, where *d* is the dimension of X_i and *n* is the number of observations, a measure of multivariate skewness is

$$b_{1,d} = \frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} [(X_i - \mu)' S^{-1} (X_j - \mu)]^3$$

where **S** is the sample covariance matrix of **X**. For weighted regression, both **S** and $(X_i - \mu)$ are computed using the weights supplied by the WEIGHT statement or the _WEIGHT_ variable.

Mardia showed that under the null hypothesis $\frac{n}{6} b_{1,d}$ is asymptotically distributed as $\chi^2(d(d+1)(d+2)/6)$.

A measure of multivariate kurtosis is given by

$$b_{2,d} = \frac{1}{n}\sum_{i=1}^{n}[(X_i - \mu)' S^{-1}(X_i - \mu)]^2$$

Mardia showed that under the null hypothesis $b_{2,d}$is asymptotically normally distributed with mean $d(d+2)$ and variance $8d(d+2)/n$.

The Henze-Zirkler test is based on a nonnegative functional $D(.,.)$that measures the distance between two distribution functions and has the property that

$$D(\mathrm{N_d}(0, \mathrm{I_d}), \mathrm{Q}) = 0$$

if and only if

$$Q = \mathrm{N_d}(0, \mathrm{I_d})$$

where $\mathrm{N_d}(\mu, \Sigma_\mathrm{d})$ is a *d*-dimensional normal distribution.

The distance measure $D(.,.)$ can be written as

$$D_\beta(P,Q) = \int_{\mathrm{R^d}} |\hat{P}(t) - \hat{Q}(t)|^2 \varphi_\beta(t)dt$$

where $\hat{P}(t)$ and $\hat{Q}(t)$ are the Fourier transforms of P and Q, and $\varphi_\beta(t)$ is a weight or a kernel function. The density of the normal distribution $\mathrm{N_d}(0, \beta^2\mathrm{I_d})$ is used as $\varphi_\beta(t)$

$$\varphi_\beta(t) = (2\pi\beta^2)^{\frac{-d}{2}}\exp(\frac{-|\mathrm{t}|^2}{2\beta^2}), \quad \mathrm{t} \in \mathrm{R^d}$$

where $|t| = (t' t)^{0.5}$.

The parameter β depends on n as

$$\beta_d(n) = \frac{1}{\sqrt{2}}(\frac{2d+1}{4})^{1/(d+4)}n^{1/(d+4)}$$

The test statistic computed is called $T_\beta(d)$ and is approximately distributed as a log normal. The log normal distribution is used to compute the null hypothesis probability.

$$T_\beta(d) = \frac{1}{n^2} \sum_{j=1}^{n}\sum_{k=1}^{n}\exp(-\frac{\beta^2}{2}|Y_j - Y_k|^2)$$

$$- \quad 2(1+\beta^2)^{-d/2}\frac{1}{n}\sum_{j=1}^{n}\exp(-\frac{\beta^2}{2(1+\beta^2)}|Y_j|^2) + (1+2\beta^2)^{-d/2}$$

where

$$|Y_j - Y_k|^2 = (X_j - X_k)'S^{-1}(X_j - X_k)$$

$$|Y_j|^2 = (X_j - \bar{X})'S^{-1}(X_j - \bar{X})$$

Monte Carlo simulations suggest that $T_\beta(d)$ has good power against distributions with heavy tails.

The Shapiro-Wilk W test is computed only when the number of observations (*n*) is less than 2000.

The following is an example of the output produced by the NORMAL option.

```
                              The MODEL Procedure

                                 Normality Test
              Equation        Test Statistic       Value       Prob

              y1              Shapiro-Wilk W        0.37    <.0001

                              Mardia Kurtosis      31.28    <.0001
                              Henze-Zirkler T       7.09    <.0001
```

Figure 20.32. Normality Test Output

Heteroscedasticity

One of the key assumptions of regression is that the variance of the errors is constant across observations. If the errors have constant variance, the errors are called *homoscedastic*. Typically, residuals are plotted to assess this assumption. Standard estimation methods are inefficient when the errors are *heteroscedastic* or have non-constant variance.

Heteroscedasticity Tests

The MODEL procedure provides two tests for heteroscedasticity of the errors: White's test and the modified Breusch-Pagan test.

Both White's test and the Breusch-Pagan are based on the residuals of the fitted model. For systems of equations, these tests are computed separately for the residuals of each equation.

The residuals of an estimation are used to investigate the heteroscedasticity of the true disturbances.

The WHITE option tests the null hypothesis

$$H_0 : \sigma_i^2 = \sigma^2 \quad \text{for all i}$$

White's test is general because it makes no assumptions about the form of the heteroscedasticity (White 1980). Because of its generality, White's test may identify specification errors other than heteroscedasticity (Thursby 1982). Thus White's test may be significant when the errors are homoscedastic but the model is misspecified in other ways.

White's test is equivalent to obtaining the error sum of squares for the regression of the squared residuals on a constant and all the unique variables in $\mathbf{J}\otimes\mathbf{J}$, where the matrix **J** is composed of the partial derivatives of the equation residual with respect to the estimated parameters.

Note that White's test in the MODEL procedure is different than White's test in the REG procedure requested by the SPEC option. The SPEC option produces the test from Theorem 2 on page 823 of White (1980). The WHITE option, on the other hand, produces the statistic from Corollary 1 on page 825 of White (1980).

The null hypothesis for the modified Breusch-Pagan test is homosedasticity. The alternate hyposthesis is that the error variance varies with a set of regressors, which are listed in the BREUSCH= option.

Define the matrix Z to be composed of the values of the variables listed in the BREUSCH= option, such that $z_{i,j}$ is the value of the *j*th variable in the BREUSCH= option for the *i*th observation. The null hypothesis of the Breusch-Pagan test is

$$\begin{aligned} \sigma_i^2 &= \sigma^2(\alpha_0 + \boldsymbol{\alpha}'\mathbf{z_i}) \\ H_0 : & \quad \boldsymbol{\alpha} = \mathbf{0} \end{aligned}$$

where σ_i^2 is the error variance for the *i*th observation, and α_0 and $\boldsymbol{\alpha}$ are regression coefficients.

The test statistic for the Breusch-Pagan test is

$$bp = \frac{1}{v}(\mathbf{u} - \bar{u}\mathbf{i})'Z(Z'Z)^{-1}Z'(\mathbf{u} - \bar{u}\mathbf{i})$$

where $\mathbf{u} = (e_1^2, e_2^2, \ldots, e_n^2)$, $\mathbf{i}$ is a $n \times 1$ vector of ones, and

$$v = \frac{1}{n}\sum_{i=1}^{n}(e_i^2 - \frac{\mathbf{e}'\mathbf{e}}{n})^2$$

This is a modified version of the Breusch-Pagan test, which is less sensitive to the assumption of normality than the original test (Greene 1993, p. 395).

The statements in the following example produce the output in Figure 20.33:

```
proc model data=schools;
   parms const inc inc2;

   exp = const + inc * income + inc2 * income * income;
   incsq = income * income;

   fit exp / white breusch=(1 income incsq);
run;
```

```
                              The MODEL Procedure

Figure 20.33. Output for Heteroscedasticity Tests

Correcting for Heteroscedasticity

There are two methods for improving the efficiency of the parameter estimation in the presence of heteroscedastic errors. If the error variance relationships are known, weighted regression can be used or an error model can be estimated. For details on error model estimation see section “Error Covariance Structure Specification”. If the error variance relationship is unknown, GMM estimation can be used.

Weighted Regression

The WEIGHT statement can be used to correct for the heteroscedasticity. Consider the following model, which has a heteroscedastic error term:

$$y_t = 250(e^{-0.2t} - e^{-0.8t}) + \sqrt{(9/t)}\epsilon_t$$

The data for this model is generated with the following SAS statements.

```
data test;
   do t=1 to 25;
      y = 250 * (exp( -0.2 * t ) - exp( -0.8 * t )) +
          sqrt( 9 / t ) * rannor(1);
      output;
   end;
run;
```

If this model is estimated with OLS,

```
proc model data=test;
   parms b1 0.1 b2 0.9;
   y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
   fit y;
run;
```

the estimates shown in Figure 20.34 are obtained for the parameters.

```
                              The MODEL Procedure

                       Nonlinear OLS Parameter Estimates

                                         Approx                     Approx
          Parameter        Estimate     Std Err    t Value     Pr > |t|

          b1               0.200977     0.00101     198.60       <.0001
          b2               0.826236     0.00853      96.82       <.0001
```

Figure 20.34. Unweighted OLS Estimates

If both sides of the model equation are multiplied by $\sqrt{t}$, the model will have a homoscedastic error term. This multiplication or weighting is done through the WEIGHT statement. The WEIGHT statement variable operates on the squared residuals as

$$\epsilon_t^{'}\epsilon_t = weight \times \mathbf{q}_t^{'}\mathbf{q}_t$$

so that the WEIGHT statement variable represents the square of the model multiplier. The following PROC MODEL statements corrects the heteroscedasticity with a WEIGHT statement

```
proc model data=test;
   parms b1 0.1 b2 0.9;
   y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
   fit y;
   weight t;
run;
```

Note that the WEIGHT statement follows the FIT statement. The weighted estimates are shown in Figure 20.35.

```
                              The MODEL Procedure

                       Nonlinear OLS Parameter Estimates

                                         Approx                     Approx
          Parameter        Estimate     Std Err    t Value     Pr > |t|

          b1               0.200503    0.000844     237.53       <.0001
          b2               0.816701      0.0139      58.71       <.0001
```

Figure 20.35. Weighted OLS Estimates

The weighted OLS estimates are identical to the output produced by the following PROC MODEL example:

```
proc model data=test;
   parms b1 0.1 b2 0.9;
```

```
      y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
      _weight_ = t;
      fit y;
   run;
```

If the WEIGHT statement is used in conjunction with the _WEIGHT_ variable, the two values are multiplied together to obtain the weight used.

The WEIGHT statement and the _WEIGHT_ variable operate on all the residuals in a system of equations. If a subset of the equations needs to be weighted, the residuals for each equation can be modified through the RESID. variable for each equation. The following example demonstrates the use of the RESID. variable to make a homoscedastic error term:

```
   proc model data=test;
      parms b1 0.1 b2 0.9;
      y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
      resid.y = resid.y * sqrt(t);
      fit y;
   run;
```

These statements produce estimates of the parameters and standard errors that are identical to the weighted OLS estimates. The reassignment of the RESID.Y variable must be done after Y is assigned, otherwise it would have no effect. Also, note that the residual (RESID.Y) is multiplied by $\sqrt{t}$. Here the multiplier is acting on the residual before it is squared.

GMM Estimation

If the form of the heteroscedasticity is unknown, generalized method of moments estimation (GMM) can be used. The following PROC MODEL statements use GMM to estimate the example model used in the preceding section:

```
   proc model data=test;
      parms b1 0.1 b2 0.9;
      y = 250 * ( exp( -b1 * t ) - exp( -b2 * t ) );
      fit y / gmm;
      instruments b1 b2;
   run;
```

GMM is an instrumental method, so instrument variables must be provided.

GMM estimation generates estimates for the parameters shown in Figure 20.36.

```
                              The MODEL Procedure

                        Nonlinear GMM Parameter Estimates

                                           Approx                       Approx
          Parameter       Estimate        Std Err     t Value        Pr > |t|

          b1              0.200487       0.000807      248.38          <.0001
          b2              0.822148         0.0142       57.95          <.0001
```

Figure 20.36. GMM Estimation for Heteroscedasticity

Heteroscedasticity-Consistent Covariance Matrix Estimation

Homoscedasticity is required for ordinary least-squares regression estimates to be efficient. A nonconstant error variance, heteroscedasticity, causes the OLS estimates to be inefficient, and the usual OLS covariance matrix, $\hat{\Sigma}$, is generally invalid.

$$\hat{\Sigma} = \sigma^2(X'X)^{-1}$$

When the variance of the errors of a classical linear model

$$Y = X\beta + \epsilon$$

is not constant across observations (heteroscedastic), so that $\sigma_i^2 \neq \sigma_j^2$ for some $j > 1$, the OLS estimator

$$\hat{\beta}_{OLS} = (X'X)^{-1}X'Y$$

is unbiased but it is inefficient. Models that take into account the changing variance can make more efficient use of the data. When the variances, σ_t^2, are known, generalized least squares (GLS) can be used and the estimator

$$\hat{\beta}_{GLS} = (X'\Omega X)^{-1}X'\Omega^{-1}Y$$

where

$$\Omega = \begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \sigma_T^2 \end{bmatrix}$$

is unbiased and efficient. However, GLS is unavailable when the variances, σ_t^2, are unknown.

To solve this problem White (1980) proposed a heteroscedastic consistent-covariance matrix estimator (HCCME)

$$\hat{\Sigma} = (X'X)^{-1}X'\hat{\Omega}X(X'X)^{-1}$$

that is consistent as well as unbiased, where

$$\hat{\Omega}_0 = \begin{bmatrix} \epsilon_1^2 & 0 & 0 & 0 \\ 0 & \epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \epsilon_T^2 \end{bmatrix}$$

and $\epsilon_t = Y_t - X_t \hat{\beta_{OLS}}$.

This estimator is considered somewhat unreliable in finite samples. Therefore, Davidson and MacKinnon (1993) propose three different modifications to estimating $\hat{\Omega}$. The first solution is to simply multiply ϵ_t^2 by $\frac{n}{n-df}$, where *n* is the number of observations and *df* is the number of explanatory variables, so that

$$\hat{\Omega}_1 = \begin{bmatrix} \frac{n}{n-df}\,\epsilon_1^2 & 0 & 0 & 0 \\ 0 & \frac{n}{n-df}\,\epsilon_2^2 & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{n}{n-df}\,\epsilon_n^2 \end{bmatrix}$$

The second solution is to define

$$\hat{\Omega}_2 = \begin{bmatrix} \frac{\epsilon_1^2}{1-\hat{h}_1} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{1-\hat{h}_2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{1-\hat{h}_n} \end{bmatrix}$$

where $\hat{h}_t = X_t(X'X)^{-1}X_t'$.

The third solution, called the "jackknife," is to define

$$\hat{\Omega}_3 = \begin{bmatrix} \frac{\epsilon_1^2}{(1-\hat{h}_1)^2} & 0 & 0 & 0 \\ 0 & \frac{\epsilon_2^2}{(1-\hat{h}_2)^2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \frac{\epsilon_n^2}{(1-\hat{h}_T)^2} \end{bmatrix}$$

MacKinnon and White (1985) investigated these three modified HCCMEs, including the original HCCME, based on finite-sample performance of pseudo-t statistics. The original HCCME performed the worst. The first modification performed better. The second modification performed even better than the first, and the third modification performed the best. They concluded that the original HCCME should never be used in finite sample estimation, and that the second and third modifications should be used over the first modification if the diagonals of $\hat{\Omega}$ are available.

Seemingly Unrelated Regression HCCME

Extending the discussion to systems of g equations, the HCCME for SUR estimation is

$$(\tilde{X}'\tilde{X})^{-1}\tilde{X}'\hat{\Omega}\tilde{X}(\tilde{X}'\tilde{X})^{-1}$$

where $\tilde{X}$ is a $n\,g \times k$ matrix with the first g rows representing the first observation, the next g rows representing the second observation, and so on. $\hat{\Omega}$ is now a $n\,g \times n\,g$ block diagonal matrix with typical block $g \times g$

$$\hat{\Omega}_i = \begin{bmatrix} \psi_{1,i}\,\psi_{1,i} & \psi_{1,i}\,\psi_{2,i} & \ldots & \psi_{1,i}\,\psi_{g,i} \\ \psi_{2,i}\,\psi_{1,i} & \psi_{2,i}\,\psi_{2,i} & \ldots & \psi_{2,i}\,\psi_{g,i} \\ \vdots & \vdots & \vdots & \vdots \\ \psi_{g,i}\,\psi_{1,i} & \psi_{g,i}\,\psi_{2,i} & \ldots & \psi_{g,i}\,\psi_{g,i} \end{bmatrix}$$

where

$$\psi_{j,i} = \epsilon_{j,i} \quad HC_0$$

or

$$\psi_{j,i} = \sqrt{\frac{n}{n - df}}\epsilon_{j,i} \quad HC_1$$

or

$$\psi_{j,i} = \epsilon_{j,i}/\sqrt{1 - \hat{h}_i} \quad HC_2$$

or

$$\psi_{j,i} = \epsilon_{j,i}/(1 - \hat{h}_i) \quad HC_3$$

Two- and Three-Stage Least Squares HCCME

For two- and three-stage least squares, the HCCME for a g equation system is

$$CovF(\hat{\Omega})Cov$$

where

$$Cov = \left(\frac{1}{n}X'(I \otimes Z(Z'Z)^{-1}Z')X\right)^{-1}$$

is the normal covariance matrix without the S matrix and

$$F(\Omega) = \frac{1}{n}\sum_{i}^{g}\sum_{j}^{g} X_i'Z(Z'Z)^{-1}Z'\hat{\Omega}_{ij}Z(Z'Z)^{-1}Z'X_j$$

where X_j is a $n \times p$ matrix with the jth equations regressors in the appropriate columns and zeros everywhere else.

$$\hat{\Omega}_{ij} = \begin{bmatrix} \psi_{i,1}\psi_{j,1} & 0 & 0 & 0 \\ 0 & \psi_{i,2}\psi_{j,2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \psi_{i,n}\psi_{j,n} \end{bmatrix}$$

For 2SLS $\hat{\Omega}_{ij} = 0$ when $i \neq j$. The ϵ_t used in $\hat{\Omega}$ is computed using the parameter estimates obtained from the instrumental variables estimation.

The leverage value for the ith equation used in the HCCME=2 and HCCME=3 methods is computed as conditional on the first stage as

$$h_{ti} = Z_t(Z'Z)^{-1}X_i(X'(I \otimes Z(Z`*Z)^{-1}Z`)X)^{-1}X_i'Z(Z'Z)^{-1}Z_t'$$

for 2SLS and

$$h_{ti} = Z_t(Z'Z)^{-1}X_i(X'(S^{-1} \otimes Z(Z`*Z)^{-1}Z`)X)^{-1}X_i'Z(Z'Z)^{-1}Z_t'/S_{ii}$$

for 3SLS.

Testing for Autocorrelation

The GODFREY= option on the FIT statement produces the Godfrey Lagrange multiplier test for serially correlated residuals for each equation (Godfrey 1978a and 1978b). n is the maximum autoregressive order, and specifies that Godfrey's tests be computed for lags 1 through n. The default number of lags is four.

The tests are performed separately for each equation estimated by the FIT statement. When a nonlinear model is estimated, the test is computed using a linearized model.

The following is an example of the output produced by the GODFREY=3 option:

```
                          Godfrey Test Output

                          The MODEL Procedure

                   Godfrey's Serial Correlation Test

           Equation        Alternative        LM     Pr > LM

           y                    1            6.63     0.0100
                                2            6.89     0.0319
                                3            6.96     0.0732
```

Figure 20.37. Autocorrelation Test Output

The three variations of the test reported by the GODFREY=3 option are designed to have power against different alternative hypothesis. Thus, if the residuals in fact have only first-order autocorrelation, the lag 1 test will have the most power for rejecting the null hypothesis of uncorrelated residuals. If the residuals have second- but not higher-order autocorrelation, the lag 2 test may be more likely to reject; the same is true for third-order autocorrelation and the lag 3 test.

The null hypothesis of Godfrey's tests is that the equation residuals are white noise. However, if the equation includes autoregressive error model of order p (AR(p),) then the lag i test, when considered in terms of the structural error, is for the null hypothesis that the structural errors are from an AR(p) process versus the alternative hypothesis that the errors are from an AR($p + i$) process.

The alternative ARMA(p, i) process is locally equivalent to the alternative AR($p + i$) process with respect to the null model AR(p). Thus, the GODFREY= option results are also a test of AR(p) errors against the alternative hypothesis of ARMA(p, i) errors. Refer to Godfrey (1978a and 1978b) for more detailed information.

Transformation of Error Terms

In PROC MODEL you can control the form of the error term. By default the error term is assumed to be additive. This section demonstrates how to specify nonadditive error terms and discusses the effects of these transformations.

Models with Nonadditive Errors

The estimation methods used by PROC MODEL assume that the error terms of the equations are independently and identically distributed with zero means and finite variances. Furthermore, the methods assume that the RESID.*name* equation variable for normalized form equations or the EQ.*name* equation variable for general form equations contains an estimate of the error term of the true stochastic model whose parameters are being estimated. Details on RESID.*name* and EQ.*name* equation variables are in the section "Model Translations."

To illustrate these points, consider the common loglinear model

$$y = \alpha x^{\beta} \tag{1}$$

$$\ln y = a + b\ln(x) \tag{2}$$

where *a*=log(α) and *b*=β. Equation (2) is called the *log form* of the equation in contrast to equation (1), which is called the *level form* of the equation. Using the SYSLIN procedure, you can estimate equation (2) by specifying

```
proc syslin data=in;
   model logy=logx;
run;
```

where LOGY and LOGX are the logs of Y and X computed in a preceding DATA step. The resulting values for INTERCEPT and LOGX correspond to *a* and *b* in equation (2).

Using the MODEL procedure, you can try to estimate the parameters in the level form (and avoid the DATA step) by specifying

```
proc model data=in;
   parms alpha beta;
   y = alpha * x ** beta;
   fit y;
run;
```

where ALPHA and BETA are the parameters in equation (1).

Unfortunately, at least one of the preceding is wrong; an ambiguity results because equations (1) and (2) contain no explicit error term. The SYSLIN and MODEL procedures both deal with additive errors; the residual used (the estimate of the error term in the equation) is the difference between the predicted and actual values (of LOGY for PROC SYSLIN and of Y for PROC MODEL in this example). If you perform the regressions discussed previously, PROC SYSLIN estimates equation (3) while PROC MODEL estimates equation (4).

$$\ln y = a + b\ln(x) + \epsilon \qquad (3)$$

$$y = \alpha x^{\beta} + \xi \qquad (4)$$

These are different statistical models. Equation (3) is the log form of equation (5)

$$y = \alpha x^{\beta}\mu \qquad (5)$$

where μ=e$^{\epsilon}$. Equation (4), on the other hand, cannot be linearized because the error term ξ (different from μ) is additive in the level form.

You must decide whether your model is equation (4) or (5). If the model is equation (4), you should use PROC MODEL. If you linearize equation (1) without considering the error term and apply SYSLIN to MODEL LOGY=LOGX, the results will be wrong. On the other hand, if your model is equation (5) (in practice it usually is), and you want to use PROC MODEL to estimate the parameters in the *level* form, you must do something to account for the multiplicative error.

PROC MODEL estimates parameters by minimizing an objective function. The objective function is computed using either the RESID.-prefixed equation variable or the EQ.-prefixed equation variable. You must make sure that these prefixed equation variables are assigned an appropriate error term. If the model has additive errors that satisfy the assumptions, nothing needs to be done. In the case of equation (5), the error is nonadditive and the equation is in normalized form, so you must alter the value of RESID.Y.

The following assigns a valid estimate of μ to RESID.Y:

```
y = alpha * x ** beta;
resid.y = actual.y / pred.y;
```

However, μ=e$^{\epsilon}$ and, therefore, μ cannot have a mean of zero and you cannot consistently estimate α and β by minimizing the sum of squares of an estimate of μ. Instead, you use $\epsilon = \ln\mu$.

```
proc model data=in;
   parms alpha beta;
   y = alpha * x ** beta;
   resid.y = log( actual.y / pred.y );
   fit y;
run;
```

If the model was expressed in general form, this transformation becomes

```
proc model data=in;
   parms alpha beta;
   EQ.trans = log( y / (alpha * x ** beta));
   fit trans;
run;
```

Both examples produce estimates of α and β of the level form that match the estimates of *a* and *b* of the log form. That is, ALPHA=exp(INTERCEPT) and BETA=LOGX, where INTERCEPT and LOGX are the PROC SYSLIN parameter estimates from the MODEL LOGY=LOGX. The standard error reported for ALPHA is different from that for the INTERCEPT in the log form.

The preceding example is not intended to suggest that loglinear models should be estimated in level form but, rather, to make the following points:

- Nonlinear transformations of equations involve the error term of the equation, and this should be taken into account when transforming models.
- The RESID.-prefixed and the EQ.-prefixed equation variables for models estimated by the MODEL procedure must represent additive errors with zero means.
- You can use assignments to RESID.-prefixed and EQ.-prefixed equation variables to transform error terms.
- Some models do not have additive errors or zero means, and many such models can be estimated using the MODEL procedure. The preceding approach applies not only to multiplicative models but to any model that can be manipulated to isolate the error term.

Predicted Values of Transformed Models

Nonadditive or transformed errors affect the distribution of the predicted values, as well as the estimates. For the preceding loglinear example, the MODEL procedure produces consistent parameter estimates. However, the predicted values for Y computed by PROC MODEL are not unbiased estimates of the expected values of Y, although they do estimate the conditional median Y values.

In general, the predicted values produced for a model with nonadditive errors are not unbiased estimates of the conditional means of the endogenous value. If the model can be transformed to a model with additive errors by using a *monotonic* transformation, the predicted values estimate the conditional medians of the endogenous variable.

For transformed models in which the biasing factor is known, you can use programming statements to correct for the bias in the predicted values as estimates of the endogenous means. In the preceding loglinear case, the predicted values will be biased by the factor exp(σ^2/2). You can produce approximately unbiased predicted values in this case by writing the model as

```
proc model data=in;
   parms alpha beta;
   y=alpha * x ** beta;
   resid.y = log( actual.y / pred.y );

   fit y;
run;
```

Refer to Miller (1984) for a discussion of bias factors for predicted values of transformed models.

Note that models with transformed errors are not appropriate for Monte Carlo simulation using the SDATA= option. PROC MODEL computes the OUTS= matrix from the transformed RESID.-prefixed equation variables, while it uses the SDATA= matrix to generate multivariate normal errors, which are added to the predicted values. This method of computing errors is inconsistent when the equation variables have been transformed.

Error Covariance Structure Specification

One of the key assumptions of regression is that the variance of the errors is constant across observations. Correcting for heteroscedasticity improves the efficiency of the estimates.

Consider the following general form for models:

$$\begin{aligned} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \varepsilon_{\mathbf{t}} \\ \varepsilon_{\mathbf{t}} &= H_t * \epsilon_{\mathbf{t}} \end{aligned}$$

$$
\begin{aligned}
H_t &= \begin{bmatrix} \sqrt{h_{t,1}} & 0 & \dots & 0 \\ 0 & \sqrt{h_{t,2}} & \dots & 0 \\ & & \ddots & \\ 0 & 0 & \dots & \sqrt{h_{t,g}} \end{bmatrix} \\
\mathbf{h_t} &= \mathbf{g}(\mathbf{y}_t, \mathbf{x}_t, \phi)
\end{aligned}
$$

where $\epsilon_{\mathbf{t}} \sim N(0, \Sigma)$.

For models that are homoscedastic,

$$h_t = 1$$

If you had a model which was heteroscedastic with known form you can improve the efficiency of the estimates by performing a weighted regression. The weight variable, using this notation, would be $1/\sqrt{h_t}$.

If the errors for a model are heteroscedastic and the functional form of the variance is known, the model for the variance can be estimated along with the regression function.

To specify a functional form for the variance, assign the function to an H.*var* variable where *var* is the equation variable. For example, if you wanted to estimate the scale parameter for the variance of a simple regression model

$$y = a * x + b$$

you can specify

```
proc model data=s;
   y = a * x + b;
   h.y = sigma**2;
fit y;
```

Consider the same model with the following functional form for the variance:

$$h_t = \sigma^2 * x^{2*\alpha}$$

This would be written as

```
proc model data=s;
   y = a * x + b;
   h.y = sigma**2 * x**(2*alpha);
fit y;
```

There are three ways to model the variance in the MODEL procedure; Feasible generalized least squares; Generalized method of moments; and Full information maximum likelihood.

Feasible GLS

A simple approach to estimating a variance function is to estimate the mean parameters θ using some auxiliary method, such as OLS, and then use the residuals of that estimation to estimate the parameters ϕ of the variance function. This scheme is called *feasible GLS*. It is possible to use the residuals from an auxiliary method for the purpose of estimating ϕ because in many cases the residuals consistently estimate the error terms.

For all estimation methods except GMM and FIML, using the H.var syntax specifies that feasible GLS will be used in the estimation. For feasible GLS the mean function is estimated by the usual method. The variance function is then estimated using pseudolikelihood (PL) function of the generated residuals. The objective function for the PL estimation is

$$p_n(\sigma, \theta) = \sum_{i=1}^{n} \left(\frac{(y_i - f(x_i, \hat{\beta}))^2}{\sigma^2 h(z_i, \theta)} + \log[\sigma^2 h(z_i, \theta)] \right)$$

Once the variance function has been estimated the mean function is re-estimated using the variance function as weights. If an S-iterated method is selected, this process is repeated until convergence (iterated feasible GLS).

Note, feasible GLS will not yield consistent estimates when one of the following is true:

- The variance is unbounded.
- There is too much serial dependence in the errors (the dependence does not fade with time).
- A combination of serial dependence and lag dependent variables.

The first two cases are unusual but the third is much more common. Whether iterated feasible GLS avoids consistency problems with the last case is an unanswered research question. For more information see (Davidson and MacKinnon 1993) pages 298-301 or (Gallant 1987) pages 124-125 and (Amemiya 1985) pages 202-203.

One limitation is that parameters can not be shared between the mean equation and the variance equation. This implies that certain GARCH models, cross equation restrictions of parameters, or testing of combinations of parameters in the mean and variance component are not allowed.

Generalized Method of Moments

In GMM, normally the first moment of the mean function is used in the objective function.

$$\begin{aligned} \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta) &= \epsilon_t \\ \mathbf{E}(\epsilon_t) &= 0 \end{aligned}$$

To add the second moment conditions to the estimation, add the equation

$$\mathbf{E}(\varepsilon_t * \varepsilon_t - h_t) = 0$$

to the model. For example if you wanted to estimate σ for linear example above, you can write

```
proc model data=s;
   y = a * x + b;
   eq.two = resid.y**2 - sigma**2;
fit y two/ gmm;
instruments x;
run;
```

This is a popular way to estimate a continuous-time interest rate processes (see (Chan, et al 1992)). The H.var syntax will automatically generate this system of equations.

To further take advantage of the information obtained about the variance, the moment equations can be modified to

$$\begin{aligned}\mathbf{E}(\varepsilon_t/\sqrt{h_t}) &= 0 \\ \mathbf{E}(\varepsilon_t * \varepsilon_t - h_t) &= 0\end{aligned}$$

For the above example, this can be written as

```
proc model data=s;
   y = a * x + b;
   eq.two = resid.y**2 - sigma**2;
   resid.y = resid.y / sigma;
fit y two/ gmm;
instruments x;
run;
```

Note that, if the error model is misspecified in this form of the GMM model, the parameter estimates may be inconsistent.

Full Information Maximum Likelihood

For FIML estimation of variance functions, the concentrated likelihood below is used as the objective function. That is, the mean function will be coupled with the variance function and the system will be solved simultaneously.

$$\begin{aligned}l_n(\phi) &= \frac{ng}{2}(1+\ln(2\pi)) - \sum_{t=1}^{n} \ln\left(\left|\frac{\partial \mathbf{q}(\mathbf{y}_t, \mathbf{x}_t, \theta)}{\partial \mathbf{y}_t}\right|\right) \\ &\quad + \frac{1}{2}\sum_{t=1}^{n}\sum_{i=1}^{g}\left(\ln(h_{t,i}) + \mathbf{q}_i(\mathbf{y}_t, \mathbf{x}_t, \theta)^2/h_{t,i}\right)\end{aligned}$$

where g is the number of equations in the system.

The HESSIAN=GLS option is not available for FIML estimation involving variance functions. The matrix used when HESSIAN=CROSS is specified is a cross products matrix which has been enhanced by the dual quasi-newton approximation.

Examples

You can specify a GARCH(1,1) model as follows:

```
proc model data=modloc.usd_jpy;

             /* Mean model --------*/
   jpyret = intercept ;

             /* Variance model ----------------*/
   h.jpyret = arch0 + arch1 * xlag( resid.jpyret ** 2, mse.jpyret  )
              + garch1 * xlag(h.jpyret, mse.jpyret) ;

   bounds arch0 arch1 garch1 >= 0;

fit jpyret/method=marquardt fiml;
run;
```

Note that the BOUNDS statement was used to ensure that the parameters were positive, a requirement for GARCH models.

EGARCH models are used because there is no restrictions on the parameters. You can specify a EGARCH(1,1) model as follows:

```
proc model data=sasuser.usd_dem ;

        /* Mean model ----------*/
  demret = intercept ;

           /* Variance model ----------------*/
  if ( _OBS_ =1 )  then
    h.demret = exp( earch0/ (1. - egarch1)  );
  else
    h.demret = exp( earch0 + earch1 * zlag( g)
                       + egarch1 * log(zlag(h.demret)));
  g = theta * nresid.demret + abs( nresid.demret ) - sqrt(2/3.1415);

                     /* Fit and save the model */
fit demret/method=marquardt fiml  maxiter=100
run;
```

Ordinary Differential Equations

Ordinary differential equations (ODEs) are also called *initial value problems* because a time zero value for each first-order differential equation is needed. The following is an example of a first-order system of ODEs:

$$y' = -0.1y + 2.5z^2$$

$$\begin{aligned} z' &= -z \\ y_0 &= 0 \\ z_0 &= 1 \end{aligned}$$

Note that you must provide an initial value for each ODE.

As a reminder, any *n*-order differential equation can be modeled as a system of first-order differential equations. For example, consider the differential equation

$$\begin{aligned} y^{''} &= by^{'} + cy \\ y_0 &= 0 \\ y_0^{'} &= 1 \end{aligned}$$

which can be written as the system of differential equations

$$\begin{aligned} y^{'} &= z \\ z^{'} &= by^{'} + cy \\ y_0 &= 0 \\ z_0 &= 1 \end{aligned}$$

This differential system can be simulated as follows:

```
data t;
   time=0; output;
   time=1; output;
   time=2; output;
run;

proc model data=t ;
   dependent y 0 z 1;
   parm b -2 c -4;
      /* Solve  y’’=b y’ + c y --------------*/

   dert.y = z;
   dert.z = b * dert.y + c * y;

   solve y z / dynamic solveprint;
run;
```

The preceding statements produce the following output. These statements produce additional output, which is not shown.

```
                           The MODEL Procedure
                         Simultaneous Simulation

```

The differential variables are distinguished by the derivative with respect to time (DERT.) prefix. Once you define the DERT. variable, you can use it on the right-hand side of another equation. The differential equations must be expressed in normal form; implicit differential equations are not allowed, and other terms on the left-hand side are not allowed.

The TIME variable is the *implied with respect to* variable for all DERT. variables. The TIME variable is also the only variable that must be in the input data set.

You can provide initial values for the differential equations in the data set, in the declaration statement (as in the previous example), or in statements in the code. Using the previous example, you can specify the initial values as

```
proc model data=t ;
   dependent y z ;
   parm b -2 c -4;
      /* Solve  y’’=b y’ + c y -------------*/
   if ( time=0 ) then
      do;
         y=0;
         z=1;
      end;
   else
```

```
            do;
               dert.y = z;
               dert.z = b * dert.y + c * y;
            end;
         end;
         solve y z / dynamic solveprint;
      run;
```

If you do not provide an initial value, 0 is used.

DYNAMIC and STATIC Simulation

Note that, in the previous example, the DYNAMIC option was specified in the SOLVE statement. The DYNAMIC and STATIC options work the same for differential equations as they do for dynamic systems. In the differential equation case, the DYNAMIC option makes the initial value needed at each observation the computed value from the previous iteration. For a static simulation, the data set must contain values for the integrated variables. For example, if DERT.Y and DERT.Z are the differential variables, you must include Y and Z in the input data set in order to do a static simulation of the model.

If the simulation is dynamic, the initial values for the differential equations are obtained from the data set, if they are available. If the variable is not in the data set, you can specify the initial value in a declaration statement. If you do not specify an initial value, the value of 0.0 is used.

A dynamic solution is obtained by solving one initial value problem for all the data. A graph of a simple dynamic simulation is shown in Figure 20.38. If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted from this point. This allows for multiple samples in one data file.

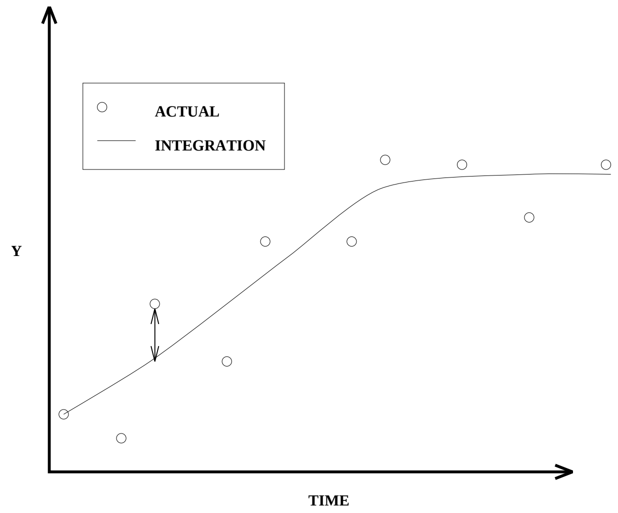

Figure 20.38. Dynamic Solution

In a static solution, n-1 initial value problems are solved using the first n-1 data values as initial values. The equations are integrated using the ith data value as an initial value to the i+1 data value. Figure 20.39 displays a static simulation of noisy data from a simple differential equation. The static solution does not propagate errors in initial values as the dynamic solution does.

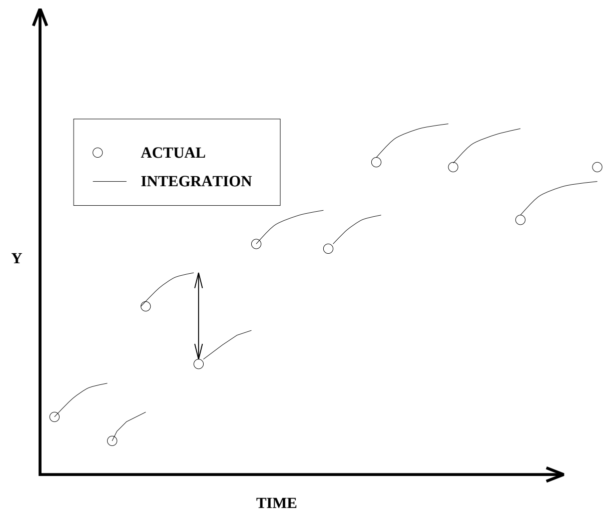

Figure 20.39. Static Solution

For estimation, the DYNAMIC and STATIC options in the FIT statement perform the same functions as they do in the SOLVE statement. Components of differential systems that have missing values or are not in the data set are simulated dynamically. For example, often in multiple compartment kinetic models, only one compartment is monitored. The differential equations describing the unmonitored compartments are simulated dynamically.

For estimation, it is important to have accurate initial values for ODEs that are not in the data set. If an accurate initial value is not known, the initial value can be made an unknown parameter and estimated. This allows for errors in the initial values but increases the number of parameters to estimate by the number of equations.

Estimation of Differential Equations

Consider the kinetic model for the accumulation of mercury (Hg) in mosquito fish (Matis, Miller, and Allen 1991, p. 177). The model for this process is the one-compartment constant infusion model shown in Figure 20.40.

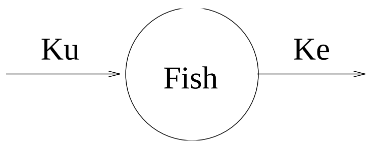

Figure 20.40. One-Compartment Constant Infusion Model

The differential equation that models this process is

$$\begin{aligned} \frac{dconc}{dt} &= k_u - k_e conc \\ conc_0 &= 0 \end{aligned}$$

The analytical solution to the model is

$$conc = (k_u/k_e)(1 - \exp(-\mathrm{k_e t}))$$

The data for the model are

```
data fish;
   input day conc;
   datalines;
0.0    0.0
1.0    0.15
2.0    0.2
3.0    0.26
4.0    0.32
6.0    0.33
;
run;
```

To fit this model in differential form, use the following statements:

```
proc model data=fish;
   parm ku ke;

   dert.conc = ku - ke * conc;

   fit conc / time=day;
run;
```

The results from this estimation are shown in Figure 20.41.

```
                              The MODEL Procedure

                        Nonlinear OLS Parameter Estimates

                                        Approx                      Approx
          Parameter       Estimate     Std Err     t Value       Pr > |t|

          ku              0.180159      0.0312        5.78         0.0044
          ke              0.524661      0.1181        4.44         0.0113
```

Figure 20.41. Static Estimation Results for Fish Model

To perform a dynamic estimation of the differential equation, add the DYNAMIC option to the FIT statement.

```
proc model data=fish;
   parm ku .3 ke .3;

   dert.conc = ku - ke * conc;

   fit conc / time = day dynamic;
run;
```

The equation DERT.CONC is integrated from $conc(0) = 0$. The results from this estimation are shown in Figure 20.42.

```
                          The MODEL Procedure

                   Nonlinear OLS Parameter Estimates

                                      Approx                  Approx
         Parameter       Estimate    Std Err    t Value     Pr > |t|

         ku              0.167109     0.0170       9.84       0.0006
         ke              0.469033     0.0731       6.42       0.0030
```

Figure 20.42. Dynamic Estimation Results for Fish Model

To perform a dynamic estimation of the differential equation and estimate the initial value, use the following statements:

```
proc model data=fish;
   parm ku .3 ke .3 conc0 0;

   dert.conc = ku - ke * conc;

   fit conc initial=(conc = conc0) / time = day dynamic;
run;
```

The INITIAL= option in the FIT statement is used to associate the initial value of a differential equation with a parameter. The results from this estimation are shown in Figure 20.43.

```

         Parameter       Estimate    Std Err    t Value     Pr > |t|

         ku              0.164408     0.0230       7.14       0.0057
         ke               0.45949     0.0943       4.87       0.0165
         conc0           0.003798     0.0174       0.22       0.8414
```

Figure 20.43. Dynamic Estimation with Initial Value for Fish Model

Finally, to estimate the fish model using the analytical solution, use the following statements:

```
proc model data=fish;
   parm ku .3  ke .3;

   conc = (ku/ ke)*( 1 -exp(-ke * day));

   fit conc;
run;
```

The results from this estimation are shown in Figure 20.44.

```
                              The MODEL Procedure

                      Nonlinear OLS Parameter Estimates

                                        Approx                      Approx
          Parameter       Estimate     Std Err     t Value     Pr > |t|

          ku              0.167109      0.0170        9.84       0.0006
          ke              0.469033      0.0731        6.42       0.0030
```

Figure 20.44. Analytical Estimation Results for Fish Model

A comparison of the results among the four estimations reveals that the two dynamic estimations and the analytical estimation give nearly identical results (identical to the default precision). The two dynamic estimations are identical because the estimated initial value (0.00013071) is very close to the initial value used in the first dynamic estimation (0). Note also that the static model did not require an initial guess for the parameter values. Static estimation, in general, is more forgiving of bad initial values.

The form of the estimation that is preferred depends mostly on the model and data. If a very accurate initial value is known, then a dynamic estimation makes sense. If, additionally, the model can be written analytically, then the analytical estimation is computationally simpler. If only an approximate initial value is known and not modeled as an unknown parameter, the static estimation is less sensitive to errors in the initial value.

The form of the error in the model is also an important factor in choosing the form of the estimation. If the error term is additive and independent of previous error, then the dynamic mode is appropriate. If, on the other hand, the errors are cumulative, a static estimation is more appropriate. See the section "Monte Carlo Simulation" for an example.

Auxiliary Equations

Auxiliary equations can be used with differential equations. These are equations that need to be satisfied with the differential equations at each point between each data value. They are automatically added to the system, so you do not need to specify them in the SOLVE or FIT statement.

Consider the following example.

The Michaelis-Menten Equations describe the kinetics of an enzyme-catalyzed reaction. The enzyme is E, and S is called the *substrate*. The enzyme first reacts with the substrate to form the enzyme-substrate complex ES, which then breaks down in a second step to form enzyme and products P.

The reaction rates are described by the following system of differential equations:

$$\frac{d[ES]}{dt} = k_1([E]-[ES])[S]-k_2[ES]-k_3[ES]$$

$$\begin{aligned}\frac{d[S]}{dt} &= -k_1([E]-[ES])[S]+k_2[ES] \\ [E] &= [E]_{tot}-[ES]\end{aligned}$$

The first equation describes the rate of formation of ES from E + S. The rate of formation of ES from E + P is very small and can be ignored. The enzyme is in either the complexed or the uncomplexed form. So if the total ($[E]_{tot}$) concentration of enzyme and the amount bound to the substrate is known, $[E]$ can be obtained by conservation.

In this example, the conservation equation is an auxiliary equation and is coupled with the differential equations for integration.

Time Variable

You must provide a time variable in the data set. The name of the time variable defaults to TIME. You can use other variables as the time variable by specifying the TIME= option in the FIT or SOLVE statement. The time intervals need not be evenly spaced. If the time variable for the current observation is less than the time variable for the previous observation, the integration is restarted.

Differential Equations and Goal Seeking

Consider the following differential equation

$$y^{'} = a*x$$

and the data set

```
data t2;
   y=0; time=0; output;
   y=2; time=1; output;
   y=3; time=2; output;
run;
```

The problem is to find values for X that satisfy the differential equation and the data in the data set. Problems of this kind are sometimes referred to as *goal seeking problems* because they require you to search for values of X that will satisfy the goal of Y.

This problem is solved with the following statements:

```
proc model data=t2 ;
   dependent x 0;
   independent y;
   parm a 5;
   dert.y = a * x;
   solve x / out=foo;
run;

proc print data=foo; run;
```

The output from the PROC PRINT statement is shown in Figure 20.45.

```
    Obs     _TYPE_       _MODE_      _ERRORS_         x           y        time

     1      PREDICT     SIMULATE         0        0.00000     0.00000       0
     2      PREDICT     SIMULATE         0        0.80000     2.00000       1
     3      PREDICT     SIMULATE         0       -0.40000     3.00000       2
```

Figure 20.45. Dynamic Solution

Note that an initial value of 0 is provided for the X variable because it is undetermined at TIME = 0.

In the preceding goal seeking example, X is treated as a linear function between each set of data points (see Figure 20.46).

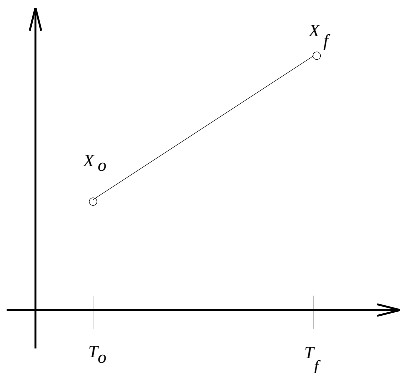

Figure 20.46. Form of X Used for Integration in Goal Seeking

If you integrate $y^{'} = ax$ manually, you have

$$\begin{aligned} x(t) &= \frac{t_f - t}{t_f - t_0} x_0 + \frac{-T_0}{t_f - t_0} x_f \\ y &= \int_{t_o}^{t_f} a x(t) dt \\ &= a \frac{1}{t_f - t_0} (t(t_f x_0 - t_0 x_f) + \frac{1}{2} t^2 (x_f - x_0))|_{t_0}^{t_f} \end{aligned}$$

For observation 2, this reduces to

$$y = \frac{1}{2} a * x_f$$

$$2 \quad = \quad 2.5{*}x_f$$

So $x = 0.8$ for this observation.

Goal seeking for the TIME variable is not allowed.

Restrictions and Bounds on Parameters

Using the BOUNDS and RESTRICT statements, PROC MODEL can compute optimal estimates subject to equality or inequality constraints on the parameter estimates.

Equality restrictions can be written as a vector function

$$\mathbf{h}(\theta) = 0$$

Inequality restrictions are either active or inactive. When an inequality restriction is active, it is treated as an equality restriction. All inactive inequality restrictions can be written as a vector function

$$F(\theta) \geq 0$$

Strict inequalities, such as $(f(\theta) > 0)$, are transformed into inequalities as $f(\theta) \times (1 - \epsilon) - \epsilon \geq 0$, where the tolerance ϵ is controlled by the EPSILON= option on the FIT statement and defaults to 10^{-8}. The *i*th inequality restriction becomes active if $F_i < 0$ and remains active until its Lagrange multiplier becomes negative. Lagrange multipliers are computed for all the nonredundant equality restrictions and all the active inequality restrictions.

For the following, assume the vector $\mathbf{h}(\theta)$ contains all the current active restrictions. The constraint matrix A is

$$A(\hat{\theta}) = \frac{\partial \mathbf{h}(\hat{\theta})}{\partial \hat{\theta}}$$

The covariance matrix for the restricted parameter estimates is computed as

$$Z(Z'HZ)^{-1}Z'$$

where H is Hessian or approximation to the Hessian of the objective function $((X'(\mathrm{diag}(\mathrm{S})^{-1}{\otimes}\mathrm{I})\mathrm{X})$ for OLS), and Z is the last $(np - nc)$ columns of Q. Q is from an LQ factorization of the constraint matrix, *nc* is the number of active constraints, and *np* is the number of parameters. Refer to Gill, Murray, and Wright (1981) for more details on LQ factorization. The covariance column in Table 20.1 summarizes the Hessian approximation used for each estimation method.

The covariance matrix for the Lagrange multipliers is computed as

$$(AH^{-1}A')^{-1}$$

The *p*-value reported for a restriction is computed from a beta distribution rather than a *t*-distribution because the numerator and the denominator of the *t*-ratio for an estimated Lagrange multiplier are not independent.

The Lagrange multipliers for the active restrictions are printed with the parameter estimates. The Lagrange multiplier estimates are computed using the relationship

$$A^{'}\lambda = \mathrm{g}$$

where the dimension of the constraint matrix *A* is the number of constraints by the number of parameters, λ is the vector of Lagrange multipliers, and *g* is the gradient of the objective function at the final estimates.

The final gradient includes the effects of the estimated S matrix. For example, for OLS the final gradient would be:

$$\mathrm{g} = X'(\mathrm{diag(S)}^{-1} \otimes \mathrm{I})\mathrm{r}$$

where *r* is the residual vector. Note that when nonlinear restrictions are imposed, the convergence measure R may have values greater than one for some iterations.

Tests on Parameters

In general, the hypothesis tested can be written as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is a vector valued function of the parameters θ given by the *r* expressions specified on the TEST statement.

Let $\hat{V}$ be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ and $\tilde{\theta}$ be the constrained estimate of θ such that $h(\tilde{\theta}) = 0$. Let

$$A(\theta) = \partial h(\theta)/\partial\theta \mid_{\hat{\theta}}$$

Let *r* be the dimension of $h(\theta)$ and *n* be the number of observations. Using this notation, the test statistics for the three kinds of tests are computed as follows.

The Wald test statistic is defined as

$$W = h^{'}(\hat{\theta}) \left(A(\hat{\theta})\hat{V}A^{'}(\hat{\theta}) \right)^{-1} h(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory 1985, Gallant 1987, p. 219). For more information on the theoretical properties of the Wald test see Phillips and Park 1988.

The Lagrange multiplier test statistic is

$$R = \lambda' A(\tilde{\theta}) \tilde{V}^{-1} A'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

The Lagrange multiplier test statistic is equivalent to Rao's efficient score test statistic:

$$R = (\partial L(\tilde{\theta}) / \partial \theta)' \tilde{V}^{-1} (\partial L(\tilde{\theta}) / \partial \theta)$$

where L is the log likelihood function for the estimation method used. For SUR, 3SLS, GMM, and iterated versions of these methods, the likelihood function is computed as

$$L = Objective \times Nobs/2$$

For OLS and 2SLS the Lagrange multiplier test statistic is computed as:

$$R = [(\partial \hat{S}(\tilde{\theta}) / \partial \theta)' \tilde{V}^{-1} (\partial \hat{S}(\tilde{\theta}) / \partial \theta)] / \hat{S}(\tilde{\theta})$$

where $\hat{S}(\tilde{\theta})$ is the corresponding objective function value at the constrained estimate.

The likelihood ratio test statistic is

$$T = 2 \left(L(\tilde{\theta}) - L(\hat{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log likelihood value.

For OLS and 2SLS, the likelihood ratio test statistic is computed as:

$$T = (n - nparms) \times (\hat{S}(\tilde{\theta}) - \hat{S}(\hat{\theta})) / \hat{S}(\hat{\theta})$$

where df is the difference in degrees of freedom for the full and restricted models, and $nparms$ is the number of parameters in the full system.

The Likelihood ratio test is not appropriate for models with nonstationary serially correlated errors (Gallant 1987, p. 139). The likelihood ratio test should not be used for dynamic systems, for systems with lagged dependent variables, or with the FIML estimation method unless certain conditions are met (see Gallant 1987, p. 479).

For each kind of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with *r* degrees of freedom, where *r* is the number of expressions on the TEST statement. The *p*-values reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation to its small sample distribution than the other two tests. However, the Wald test has the least computational cost, since it does not require computation of the constrained estimate $\tilde{\theta}$.

The following is an example of using the TEST statement to perform a likelihood ratio test for a compound hypothesis.

```
   test a*exp(-k) = 1-k, d = 0 ,/ lr;
```

It is important to keep in mind that although individual *t* tests for each parameter are printed by default into the parameter estimates table, they are only asymptotically valid for nonlinear models. You should be cautious in drawing any inferences from these *t* tests for small samples.

Hausman Specification Test

Hausman's specification test, or *m*-statistic, can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu (1973). Hausman's *m*-statistic is as follows.

Given two estimators, $\hat{\beta}_0$ and $\hat{\beta}_1$, where under the null hypothesis both estimators are consistent but only $\hat{\beta}_0$ is asymptotically efficient and under the alternative hypothesis only $\hat{\beta}_1$ is consistent, the *m*-statistic is

$$m = \hat{q}'(\hat{V}_1 - \hat{V}_0)^{-}\hat{q}$$

where $\hat{V}_1$ and $\hat{V}_0$ represent consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_1$ and $\hat{\beta}_0$, and

$$q = \hat{\beta}_1 - \hat{\beta}_0$$

The *m*-statistic is then distributed χ^2 with k degrees of freedom, where k is the rank of the matrix $(\hat{V}_1 - \hat{V}_0)$. A generalized inverse is used, as recommended by Hausman (1982).

In the MODEL procedure, Hausman's *m*-statistic can be used to determine if it is necessary to use an instrumental variables method rather than a more efficient OLS estimation. Hausman's *m*-statistic can also be used to compare 2SLS with 3SLS for a class of estimators for which 3SLS is asymptotically efficient (similarly for OLS and SUR).

Hausman's *m*-statistic can also be used, in principle, to test the null hypothesis of normality when comparing 3SLS to FIML. Because of the poor performance of this form of the test, it is not offered in the MODEL procedure. Refer to R.C. Fair (1984, pp. 246-247) for a discussion of why Hausman's test fails for common econometric models.

To perform a Hausman's specification test, specify the HAUSMAN option in the FIT statement. The selected estimation methods are compared using Hausman's *m*-statistic.

In the following example, OLS, SUR, 2SLS, 3SLS, and FIML are used to estimate a model, and Hausman's test is requested.

```
proc model data=one out=fiml2;
   endogenous y1 y2;

   y1 = py2 * y2 + px1 * x1 + interc;
   y2 = py1* y1 + pz1 * z1 + d2;

   fit y1 y2 / ols sur 2sls 3sls fiml hausman;
   instruments x1 z1;
run;
```

The output specified by the HAUSMAN option produces the following results.

```
                         The MODEL Procedure

                  Hausman's Specification Test Results
     Comparing    To            DF    Statistic    Pr > ChiSq

     SUR          OLS            6        17.77        0.0068
     OLS          2SLS           6        13.86        0.0313
     3SLS         OLS            6         0.27        0.9996
     3SLS         2SLS           6        -0.00         .
```

Figure 20.47. Hausman's Specification Test Results

Figure 20.47 indicates that 2SLS, a system estimation method, is preferred over OLS. The model needs an IV estimator but not a full error covariance matrix. Note that the FIML estimation results are not compared.

Chow Tests

The Chow test is used to test for break points or structural changes in a model. The problem is posed as a partitioning of the data into two parts of size n_1 and n_2. The null hypothesis to be tested is

$$H_o : \quad \beta_1 = \beta_2 = \beta$$

where β_1 is estimated using the first part of the data and β_2 is estimated using the second part.

The test is performed as follows (refer to Davidson and MacKinnon 1993, p. 380).

1. The p parameters of the model are estimated.
2. A second linear regression is performed on the residuals, $\hat{u}$, from the nonlinear estimation in step one.

   $$\hat{u} = \hat{X}b + \text{residuals}$$

   where $\hat{X}$ is Jacobian columns that are evaluated at the parameter estimates. If the estimation is an instrumental variables estimation with matrix of instruments W, then the following regression is performed:

   $$\hat{u} = P_{W^*}\hat{X}b + \text{residuals}$$

   where P_{W^*} is the projection matrix.
3. The restricted SSE (RSSE) from this regression is obtained. An SSE for each subsample is then obtained using the same linear regression.
4. The *F* statistic is then

   $$f = \frac{(RSSE - SSE_1 - SSE_2)/p}{(SSE_1 + SSE_2)/(n-2p)}$$

   This test has p and $n - 2p$ degrees of freedom.

Chow's test is not applicable if $\min(n_1, n_2) < p$, since one of the two subsamples does not contain enough data to estimate β. In this instance, the *predictive Chow test* can be used. The predictive Chow test is defined as

$$f = \frac{(RSSE - SSE_1) \times (n_1 - p)}{SSE_1 * n_2}$$

where $n_1 > p$. This test can be derived from the Chow test by noting that the $SSE_2 = 0$ when $n_2 <= p$ and by adjusting the degrees of freedom appropriately.

You can select the Chow test and the predictive Chow test by specifying the CHOW=*arg* and the PCHOW=*arg* options in the FIT statement, where *arg* is either the number of observations in the first sample or a parenthesized list of first sample sizes. If the size of the one of the two groups in which the sample is partitioned is less than the number of parameters, then a Predictive Chow test is automatically used. These tests statistics are not produced for GMM and FIML estimations.

The following is an example of the use of the Chow test.

```
data exp;
   x=0;
   do time=1 to 100;
      if time=50 then x=1;
      y = 35 * exp( 0.01 * time ) + rannor( 123 ) + x * 5;
      output;
   end;
run;
```

```
proc model data=exp;
   parm zo 35 b;
      dert.z = b * z;
      y=z;
   fit y init=(z=zo) / chow =(40 50 60) pchow=90;
run;
```

The data set introduced an artificial structural change into the model (the structural change effects the intercept parameter). The output from the requested Chow tests are shown in Figure 20.48.

```

```

Figure 20.48. Chow's Test Results

Profile Likelihood Confidence Intervals

Wald-based and likelihood ratio-based confidence intervals are available in the MODEL procedure for computing a confidence interval on an estimated parameter. A confidence interval on a parameter θ can be constructed by inverting a Wald-based or a likelihood ratio-based test.

The approximate $100(1-\alpha)$ % Wald confidence interval for a parameter θ is

$$\hat{\theta} \pm z_{1-\alpha/2}\hat{\sigma}$$

where z_p is the $100p$th percentile of the standard normal distribution, $\hat{\theta}$ is the maximum likelihood estimate of θ, and $\hat{\sigma}$ is the standard error estimate of $\hat{\theta}$.

A likelihood ratio-based confidence interval is derived from the χ^2 distribution of the generalized likelihood ratio test. The approximate $1-\alpha$ confidence interval for a parameter θ is

$$\theta : 2[l(\hat{\theta}) - l(\theta)] \leq q_{1,1-\alpha} = 2l^*$$

where $q_{1,1-\alpha}$ is the $(1-\alpha)$ quantile of the χ^2 with one degree of freedom, and $l(\theta)$ is the log likelihood as a function of one parameter. The endpoints of a confidence interval are the zeros of the function $l(\theta) - l^*$. Computing a likelihood ratio-based confidence interval is an iterative process. This process must be performed twice for each parameter, so the computational cost is considerable. Using a modified form of the algorithm recommended by Venzon and Moolgavkar (1988), you can determine that the cost of each endpoint computation is approximately the cost of estimating the original system.

To request confidence intervals on estimated parameters, specify the following option in the FIT statement:

PRL= WALD | LR | BOTH

By default the PRL option produces 95% likelihood ratio confidence limits. The coverage of the confidence interval is controlled by the ALPHA= option in the FIT statement.

The following is an example of the use of the confidence interval options.

```
data exp;
   do time = 1 to 20;
      y = 35 * exp( 0.01 * time ) + 5*rannor( 123 );
   output;
   end;
run;

proc model data=exp;
   parm zo 35 b;
      dert.z = b * z;
      y=z;
   fit y init=(z=zo) / prl=both;
   test zo = 40.475437 ,/lr;
run;
```

The output from the requested confidence intervals and the TEST statement are shown in Figure 20.49

```

```

Figure 20.49. Confidence Interval Estimation

Note that the likelihood ratio test reported the probability that $zo = 40.47543$ is 5% but $zo = 40.47543$ is the upper bound of a 95% confidence interval. To understand this conundrum, note that the TEST statement is using the likelihood ratio statistic to test the null hypothesis $H_0 : zo = 40.47543$ with the alternate that $H_a : zo \neq 40.47543$. The upper confidence interval can be viewed as a test with the null hypothesis $H_0 : zo <= 40.47543$.

Choice of Instruments

Several of the estimation methods supported by PROC MODEL are instrumental variables methods. There is no standard method for choosing instruments for nonlinear regression. Few econometric textbooks discuss the selection of instruments for nonlinear models. Refer to Bowden, R.J. and Turkington, D.A. (1984, p. 180-182) for more information.

The purpose of the instrumental projection is to purge the regressors of their correlation with the residual. For nonlinear systems, the regressors are the partials of the residuals with respect to the parameters.

Possible instrumental variables include

- any variable in the model that is independent of the errors

- lags of variables in the system
- derivatives with respect to the parameters, if the derivatives are independent of the errors
- low degree polynomials in the exogenous variables
- variables from the data set or functions of variables from the data set.

Selected instruments must not

- depend on any variable endogenous with respect to the equations estimated
- depend on any of the parameters estimated
- be lags of endogenous variables if there is serial correlation of the errors.

If the preceding rules are satisfied and there are enough observations to support the number of instruments used, the results should be consistent and the efficiency loss held to a minimum.

You need at least as many instruments as the maximum number of parameters in any equation, or some of the parameters cannot be estimated. Note that *number of instruments* means linearly independent instruments. If you add an instrument that is a linear combination of other instruments, it has no effect and does not increase the effective number of instruments.

You can, however, use too many instruments. In order to get the benefit of instrumental variables, you must have more observations than instruments. Thus, there is a trade-off; the instrumental variables technique completely eliminates the simultaneous equation bias only in large samples. In finite samples, the larger the excess of observations over instruments, the more the bias is reduced. Adding more instruments may improve the efficiency, but after some point efficiency declines as the excess of observations over instruments becomes smaller and the bias grows.

The instruments used in an estimation are printed out at the beginning of the estimation. For example, the following statements produce the instruments list shown in Figure 20.50.

```
proc model data=test2;
   exogenous x1 x2;
   parms b1 a1 a2 b2 2.5 c2 55;
   y1 = a1 * y2 + b1 * exp(x1);
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2;
   fit y1 y2 / n2sls;
   inst b1 b2 c2 x1 ;
run;
```

```
                              The MODEL Procedure

                          The 2 Equations to Estimate

                          y1 =  F(b1, a1(y2))
                          y2 =  F(a2(y1), b2, c2)
                 Instruments  1 x1 @y1/@b1 @y2/@b2 @y2/@c2
```

Figure 20.50. Instruments Used Message

This states that an intercept term, the exogenous variable X1, and the partial derivatives of the equations with respect to B1, B2, and C2, were used as instruments for the estimation.

Examples

Suppose that Y1 and Y2 are endogenous variables, that X1 and X2 are exogenous variables, and that A, B, C, D, E, F, and G are parameters. Consider the following model:

```
   y1 = a + b * x1 + c * y2 + d * lag(y1);
   y2 = e + f * x2 + g * y1;
   fit y1 y2;
   instruments exclude=(c g);
```

The INSTRUMENTS statement produces X1, X2, LAG(Y1), and an intercept as instruments.

In order to estimate the Y1 equation by itself, it is necessary to include X2 explicitly in the instruments since F, in this case, is not included in the estimation

```
   y1 = a + b * x1 + c * y2 + d * lag(y1);
   y2 = e + f * x2 + g * y1;
   fit y1;
   instruments x2 exclude=(c);
```

This produces the same instruments as before. You can list the parameter associated with the lagged variable as an instrument instead of using the EXCLUDE= option. Thus, the following is equivalent to the previous example:

```
   y1 = a + b * x1 + c * y2 + d * lag(y1);
   y2 = e + f * x2 + g * y1;
   fit y1;
   instruments x1 x2 d;
```

For an example of declaring instruments when estimating a model involving identities, consider Klein's Model I

```
proc model data=klien;
   endogenous c p w i x wsum k y;
   exogenous  wp g t year;
   parms c0-c3 i0-i3 w0-w3;
   a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
   b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
   c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
   x = c + i + g;
   y = c + i + g-t;
   p = x-w-t;
   k = lag(k) + i;
   wsum = w + wp;
```

The three equations to estimate are identified by the labels A, B, and C. The parameters associated with the predetermined terms are C2, I2, I3, W2, and W3 (and the intercepts, which are automatically added to the instruments). In addition, the system includes five identities that contain the predetermined variables G, T, LAG(K), and WP. Thus, the INSTRUMENTS statement can be written as

```
lagk = lag(k);
instruments c2 i2 i3 w2 w3 g t wp lagk;
```

where LAGK is a program variable used to hold LAG(K). However, this is more complicated than it needs to be. Except for LAG(K), all the predetermined terms in the identities are exogenous variables, and LAG(K) is already included as the coefficient of I3. There are also more parameters for predetermined terms than for endogenous terms, so you might prefer to use the EXCLUDE= option. Thus, you can specify the same instruments list with the simpler statement

```
instruments _exog_ exclude=(c1 c3 i1 w1);
```

To illustrate the use of polynomial terms as instrumental variables, consider the following model:

```
y1 = a + b * exp( c * x1 ) + d * log( x2 ) + e * exp( f * y2 );
```

The parameters are A, B, C, D, E, and F, and the right-hand-side variables are X1, X2, and Y2. Assume that X1 and X2 are exogenous (independent of the error), while Y2 is endogenous. The equation for Y2 is not specified, but assume that it includes the variables X1, X3, and Y1, with X3 exogenous, so the exogenous variables of the full system are X1, X2, and X3. Using as instruments quadratic terms in the exogenous variables, the model is specified to PROC MODEL as follows.

```
proc model;
   parms a b c d e f;
   y1 = a + b * exp( c * x1 ) + d * log( x2 ) + e * exp( f * y2 );
   instruments inst1-inst9;
```

```
      inst1 = x1; inst2 = x2; inst3 = x3;
      inst4 = x1 * x1; inst5 = x1 * x2; inst6 = x1 * x3;
      inst7 = x2 * x2; inst8 = x2 * x3; inst9 = x3 * x3;
      fit y1 / 2sls;
   run;
```

It is not clear what degree polynomial should be used. There is no way to know how good the approximation is for any degree chosen, although the first-stage R^2s may help the assessment.

First-Stage R^2s

When the FSRSQ option is used on the FIT statement, the MODEL procedure prints a column of first-stage R^2 (FSRSQ) statistics along with the parameter estimates. The FSRSQ measures the fraction of the variation of the derivative column associated with the parameter that remains after projection through the instruments.

Ideally, the FSRSQ should be very close to 1.00 for exogenous derivatives. If the FSRSQ is small for an endogenous derivative, it is unclear whether this reflects a poor choice of instruments or a large influence of the errors in the endogenous right-hand-side variables. When the FSRSQ for one or more parameters is small, the standard errors of the parameter estimates are likely to be large.

Note that you can make all the FSRSQs larger (or 1.00) by including more instruments, because of the disadvantage discussed previously. The FSRSQ statistics reported are unadjusted R^2s and do not include a degrees-of-freedom correction.

Autoregressive Moving Average Error Processes

Autoregressive moving average error processes (ARMA errors) and other models involving lags of error terms can be estimated using FIT statements and simulated or forecast using SOLVE statements. ARMA models for the error process are often used for models with autocorrelated residuals. The %AR macro can be used to specify models with autoregressive error processes. The %MA macro can be used to specify models with moving average error processes.

Autoregressive Errors

A model with first-order autoregressive errors, AR(1), has the form

$$y_t = f(x_t, \theta) + \mu_t$$

$$\mu_t = \phi\mu_{t-1} + \epsilon_t$$

while an AR(2) error process has the form

$$\mu_t = \phi_1\mu_{t-1} + \phi_2\mu_{t-2} + \epsilon_t$$

and so forth for higher-order processes. Note that the ϵ_t's are independent and identically distributed and have an expected value of 0.

An example of a model with an AR(2) component is

$$y = \alpha + \beta x_1 + \mu_t$$

$$\mu_t = \phi_1 \mu_{t-1} + \phi_2 \mu_{t-2} + \epsilon_t$$

You would write this model as follows:

```
proc model data=in;
   parms a b p1 p2;
   y = a + b * x1 + p1 * zlag1(y - (a + b * x1)) +
         p2 * zlag2(y - (a + b * x1));
   fit y;
run;
```

or equivalently using the %AR macro as

```
proc model data=in;
   parms a b;
   y = a + b * x1;
   %ar( y, 2 );
   fit y;
run;
```

Moving Average Models

A model with first-order moving average errors, MA(1), has the form

$$y_t = f(x_t) + \mu_t$$

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1}$$

where ϵ_t is identically and independently distributed with mean zero. An MA(2) error process has the form

$$\mu_t = \epsilon_t - \theta_1 \epsilon_{t-1} - \theta_2 \epsilon_{t-2}$$

and so forth for higher-order processes.

For example, you can write a simple linear regression model with MA(2) moving average errors as

```
proc model data=inma2;
   parms a b ma1 ma2;
   y = a + b * x + ma1 * zlag1( resid.y ) +
       ma2 * zlag2( resid.y );
   fit;
run;
```

where MA1 and MA2 are the moving average parameters.

Note that RESID.Y is automatically defined by PROC MODEL as

```
pred.y = a + b * x + ma1 * zlag1( resid.y ) +
       ma2 * zlag2( resid.y );
resid.y = pred.y - actual.y;
```

Note that RESID.Y is ϵ_t.

The ZLAG function must be used for MA models to truncate the recursion of the lags. This ensures that the lagged errors start at zero in the lag-priming phase and do not propagate missing values when lag-priming period variables are missing, and ensures that the future errors are zero rather than missing during simulation or forecasting. For details on the lag functions, see the section "Lag Logic."

This model written using the %MA macro is

```
proc model data=inma2;
   parms a b;
   y =  a + b * x;
   %ma(y, 2);
   fit;
run;
```

General Form for ARMA Models

The general ARMA(*p*,*q*) process has the following form

$$\mu_t = \phi_1 \mu_{t-1} + \ldots + \phi_p \mu_{t-p} + \epsilon_t - \theta_1 \epsilon_{t-1} - \ldots - \theta_q \epsilon_{t-q}$$

An ARMA(*p*,*q*) model can be specified as follows

```
yhat =  ... compute structural predicted value here ... ;
yarma = ar1 * zlag1( y - yhat ) + ...  /* ar part */
                                + ar(p) * zlag(p)( y - yhat )
     + ma1 * zlag1( resid.y )   + ...  /* ma part */
                                + ma(q) * zlag(q)( resid.y );
y = yhat + yarma;
```

where AR*i* and MA*j* represent the autoregressive and moving average parameters for the various lags. You can use any names you want for these variables, and there are many equivalent ways that the specification could be written.

Vector ARMA processes can also be estimated with PROC MODEL. For example, a two-variable AR(1) process for the errors of the two endogenous variables Y1 and Y2 can be specified as follows

```
y1hat =  ... compute structural predicted value here ... ;

y1    = y1hat + ar1_1 * zlag1( y1 - y1hat )   /* ar part y1,y1 */
              + ar1_2 * zlag1( y2 - y2hat );  /* ar part y1,y2 */

y21hat =  ... compute structural predicted value here ... ;

y2     = y2hat + ar2_2 * zlag1( y2 - y2hat )   /* ar part y2,y2 */
               + ar2_1 * zlag1( y1 - y1hat );  /* ar part y2,y1 */
```

Convergence Problems with ARMA Models

ARMA models can be difficult to estimate. If the parameter estimates are not within the appropriate range, a moving average model's residual terms will grow exponentially. The calculated residuals for later observations can be very large or can overflow. This can happen either because improper starting values were used or because the iterations moved away from reasonable values.

Care should be used in choosing starting values for ARMA parameters. Starting values of .001 for ARMA parameters usually work if the model fits the data well and the problem is well-conditioned. Note that an MA model can often be approximated by a high order AR model, and vice versa. This may result in high collinearity in mixed ARMA models, which in turn can cause serious ill-conditioning in the calculations and instability of the parameter estimates.

If you have convergence problems while estimating a model with ARMA error processes, try to estimate in steps. First, use a FIT statement to estimate only the structural parameters with the ARMA parameters held to zero (or to reasonable prior estimates if available). Next, use another FIT statement to estimate the ARMA parameters only, using the structural parameter values from the first run. Since the values of the structural parameters are likely to be close to their final estimates, the ARMA parameter estimates may now converge. Finally, use another FIT statement to produce simultaneous estimates of all the parameters. Since the initial values of the parameters are now likely to be quite close to their final joint estimates, the estimates should converge quickly if the model is appropriate for the data.

AR Initial Conditions

The initial lags of the error terms of AR(p) models can be modeled in different ways. The autoregressive error startup methods supported by SAS/ETS procedures are the following:

CLS	conditional least squares (ARIMA and MODEL procedures)
ULS	unconditional least squares (AUTOREG, ARIMA, and MODEL procedures)
ML	maximum likelihood (AUTOREG, ARIMA, and MODEL procedures)
YW	Yule-Walker (AUTOREG procedure only)
HL	Hildreth-Lu, which deletes the first p observations (MODEL procedure only)

See Chapter 12, for an explanation and discussion of the merits of various AR(p) startup methods.

The CLS, ULS, ML, and HL initializations can be performed by PROC MODEL. For AR(1) errors, these initializations can be produced as shown in Table 20.2. These methods are equivalent in large samples.

Table 20.2. Initializations Performed by PROC MODEL: AR(1) ERRORS

Method	**Formula**
conditional least squares	Y=YHAT+AR1*ZLAG1(Y-YHAT);

unconditional least squares	Y=YHAT+AR1*ZLAG1(Y-YHAT);
	IF _OBS_=1 THEN
	RESID.Y=SQRT(1-AR1**2)*RESID.Y;

maximum likelihood	Y=YHAT+AR1*ZLAG1(Y-YHAT);
	W=(1-AR1**2)**(-1/(2*_NUSED_));
	IF _OBS_=1 THEN W=W*SQRT(1-AR1**2);
	RESID.Y=W*RESID.Y;

Hildreth-Lu	Y=YHAT+AR1*LAG1(Y-YHAT);

MA Initial Conditions

The initial lags of the error terms of MA(q) models can also be modeled in different ways. The following moving average error startup paradigms are supported by the ARIMA and MODEL procedures:

ULS	unconditional least squares
CLS	conditional least squares
ML	maximum likelihood

The conditional least-squares method of estimating moving average error terms is not optimal because it ignores the startup problem. This reduces the efficiency of the estimates, although they remain unbiased. The initial lagged residuals, extending before the start of the data, are assumed to be 0, their unconditional expected value. This introduces a difference between these residuals and the generalized least-squares residuals for the moving average covariance, which, unlike the autoregressive model, persists through the data set. Usually this difference converges quickly to 0, but for nearly noninvertible moving average processes the convergence is quite slow. To minimize this problem, you should have plenty of data, and the moving average parameter estimates should be well within the invertible range.

This problem can be corrected at the expense of writing a more complex program. Unconditional least-squares estimates for the MA(1) process can be produced by specifying the model as follows:

```
yhat =  ... compute structural predicted value here ... ;
if _obs_ = 1 then do;
   h = sqrt( 1 + ma1 ** 2 );
   y = yhat;
```

```
      resid.y = ( y - yhat ) / h;
      end;
   else do;
      g = ma1 / zlag1( h );
      h = sqrt( 1 + ma1 ** 2 - g ** 2 );
      y = yhat + g * zlag1( resid.y );
      resid.y = ( ( y - yhat) - g * zlag1( resid.y ) ) / h;
      end;
```

Moving-average errors can be difficult to estimate. You should consider using an AR(*p*) approximation to the moving average process. A moving average process can usually be well-approximated by an autoregressive process if the data have not been smoothed or differenced.

The %AR Macro

The SAS macro %AR generates programming statements for PROC MODEL for autoregressive models. The %AR macro is part of SAS/ETS software and no special options need to be set to use the macro. The autoregressive process can be applied to the structural equation errors or to the endogenous series themselves.

The %AR macro can be used for

- univariate autoregression
- unrestricted vector autoregression
- restricted vector autoregression.

Univariate Autoregression

To model the error term of an equation as an autoregressive process, use the following statement after the equation:

```
   %ar( varname, nlags )
```

For example, suppose that Y is a linear function of X1 and X2, and an AR(2) error. You would write this model as follows:

```
   proc model data=in;
      parms a b c;
      y = a + b * x1 + c * x2;
      %ar( y, 2 )
      fit y / list;
   run;
```

The calls to %AR must come *after* all of the equations that the process applies to.

The preceding macro invocation, %AR(y,2), produces the statements shown in the LIST output in Figure 20.51.

```
                          The MODEL Procedure

                        Listing of Compiled Program Code
          Stmt     Line:Col      Statement as Parsed

             1     5738:50       PRED.y = a + b * x1 + c * x2;
             1     5738:50       RESID.y = PRED.y - ACTUAL.y;
             1     5738:50       ERROR.y = PRED.y - y;
             2     7987:23       _PRED__y = PRED.y;
             3     8003:15       #OLD_PRED.y = PRED.y + y_l1
                                 * ZLAG1( y - _PRED__y ) + y_l2
                                 * ZLAG2( y - _PRED__y );
             3     8003:15       PRED.y = #OLD_PRED.y;
             3     8003:15       RESID.y = PRED.y - ACTUAL.y;
             3     8003:15       ERROR.y = PRED.y - y;
```

Figure 20.51. LIST Option Output for an AR(2) Model

The _PRED__ prefixed variables are temporary program variables used so that the lags of the residuals are the correct residuals and not the ones redefined by this equation. Note that this is equivalent to the statements explicitly written in the "General Form for ARMA Models" earlier in this section.

You can also restrict the autoregressive parameters to zero at selected lags. For example, if you wanted autoregressive parameters at lags 1, 12, and 13, you can use the following statements:

```
proc model data=in;
   parms a b c;
   y = a + b * x1 + c * x2;
   %ar( y, 13, , 1 12 13 )
   fit y / list;
run;
```

These statements generate the output shown in Figure 20.52.

```
                          The MODEL Procedure

                        Listing of Compiled Program Code
          Stmt     Line:Col      Statement as Parsed

             1     8182:50       PRED.y = a + b * x1 + c * x2;
             1     8182:50       RESID.y = PRED.y - ACTUAL.y;
             1     8182:50       ERROR.y = PRED.y - y;
             2     8631:23       _PRED__y = PRED.y;
             3     8647:15       #OLD_PRED.y = PRED.y + y_l1 * ZLAG1( y -
                                 _PRED__y ) + y_l12 * ZLAG12( y -
                                 _PRED__y ) + y_l13 * ZLAG13(
                                 y - _PRED__y );
             3     8647:15       PRED.y = #OLD_PRED.y;
             3     8647:15       RESID.y = PRED.y - ACTUAL.y;
             3     8647:15       ERROR.y = PRED.y - y;
```

Figure 20.52. LIST Option Output for an AR Model with Lags at 1, 12, and 13

There are variations on the conditional least-squares method, depending on whether observations at the start of the series are used to "warm up" the AR process. By default, the %AR conditional least-squares method uses all the observations and assumes zeros for the initial lags of autoregressive terms. By using the M= option, you can request that %AR use the unconditional least-squares (ULS) or maximum-likelihood (ML) method instead. For example,

```
proc model data=in;
   y = a + b * x1 + c * x2;
   %ar( y, 2, m=uls )
   fit y;
run;
```

Discussions of these methods is provided in the "AR Initial Conditions" earlier in this section.

By using the M=CLS*n* option, you can request that the first *n* observations be used to compute estimates of the initial autoregressive lags. In this case, the analysis starts with observation *n*+1. For example:

```
proc model data=in;
   y = a + b * x1 + c * x2;
   %ar( y, 2, m=cls2 )
   fit y;
run;
```

You can use the %AR macro to apply an autoregressive model to the endogenous variable, instead of to the error term, by using the TYPE=V option. For example, if you want to add the five past lags of Y to the equation in the previous example, you could use %AR to generate the parameters and lags using the following statements:

```
proc model data=in;
   parms a b c;
   y = a + b * x1 + c * x2;
   %ar( y, 5, type=v )
   fit y / list;
run;
```

The preceding statements generate the output shown in Figure 20.53.

```
                              The MODEL Procedure

                        Listing of Compiled Program Code
     Stmt    Line:Col      Statement as Parsed

        1    8892:50       PRED.y = a + b * x1 + c * x2;
        1    8892:50       RESID.y = PRED.y - ACTUAL.y;
        1    8892:50       ERROR.y = PRED.y - y;
        2    9301:15       #OLD_PRED.y = PRED.y + y_l1 * ZLAG1( y )
                           + y_l2 * ZLAG2( y ) + y_l3 * ZLAG3( y )
                           + y_l4 * ZLAG4( y ) + y_l5 * ZLAG5( y );
        2    9301:15       PRED.y = #OLD_PRED.y;
        2    9301:15       RESID.y = PRED.y - ACTUAL.y;
        2    9301:15       ERROR.y = PRED.y - y;
```

Figure 20.53. LIST Option Output for an AR model of Y

This model predicts Y as a linear combination of X1, X2, an intercept, and the values of Y in the most recent five periods.

Unrestricted Vector Autoregression

To model the error terms of a set of equations as a vector autoregressive process, use the following form of the %AR macro after the equations:

```
%ar( process_name, nlags, variable_list )
```

The *process_name* value is any name that you supply for %AR to use in making names for the autoregressive parameters. You can use the %AR macro to model several different AR processes for different sets of equations by using different process names for each set. The process name ensures that the variable names used are unique. Use a short *process_name* value for the process if parameter estimates are to be written to an output data set. The %AR macro tries to construct parameter names less than or equal to eight characters, but this is limited by the length of *name*, which is used as a prefix for the AR parameter names.

The *variable_list* value is the list of endogenous variables for the equations.

For example, suppose that errors for equations Y1, Y2, and Y3 are generated by a second-order vector autoregressive process. You can use the following statements:

```
proc model data=in;
   y1 = ... equation for y1 ...;
   y2 = ... equation for y2 ...;
   y3 = ... equation for y3 ...;
   %ar( name, 2, y1 y2 y3 )
   fit y1 y2 y3;
run;
```

which generates the following for Y1 and similar code for Y2 and Y3:

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
     name1_1_2*zlag1(y2-name_y2) +
     name1_1_3*zlag1(y3-name_y3) +
     name2_1_1*zlag2(y1-name_y1) +
     name2_1_2*zlag2(y2-name_y2) +
     name2_1_3*zlag2(y3-name_y3) ;
```

Only the conditional least-squares (M=CLS or M=CLS*n*) method can be used for vector processes.

You can also use the same form with restrictions that the coefficient matrix be 0 at selected lags. For example, the statements

```
proc model data=in;
   y1 = ... equation for y1 ...;
```

```
      y2 = ... equation for y2 ...;
      y3 = ... equation for y3 ...;
      %ar( name, 3, y1 y2 y3, 1 3 )
      fit y1 y2 y3;
```

apply a third-order vector process to the equation errors with all the coefficients at lag 2 restricted to 0 and with the coefficients at lags 1 and 3 unrestricted.

You can model the three series Y1-Y3 as a vector autoregressive process in the variables instead of in the errors by using the TYPE=V option. If you want to model Y1-Y3 as a function of past values of Y1-Y3 and some exogenous variables or constants, you can use %AR to generate the statements for the lag terms. Write an equation for each variable for the nonautoregressive part of the model, and then call %AR with the TYPE=V option. For example,

```
   proc model data=in;
      parms a1-a3 b1-b3;
      y1 = a1 + b1 * x;
      y2 = a2 + b2 * x;
      y3 = a3 + b3 * x;
      %ar( name, 2, y1 y2 y3, type=v )
      fit y1 y2 y3;
   run;
```

The nonautoregressive part of the model can be a function of exogenous variables, or it may be intercept parameters. If there are no exogenous components to the vector autoregression model, including no intercepts, then assign zero to each of the variables. There must be an assignment to each of the variables before %AR is called.

```
   proc model data=in;
      y1=0;
      y2=0;
      y3=0;
      %ar( name, 2, y1 y2 y3, type=v )
      fit y1 y2 y3;
```

This example models the vector Y=(Y1 Y2 Y3)′ as a linear function only of its value in the previous two periods and a white noise error vector. The model has 18=(3 × 3 + 3 × 3) parameters.

Syntax of the %AR Macro

There are two cases of the syntax of the %AR macro. The first has the general form

%AR *(name, nlag [,endolist [***,***laglist]] [***,M=***method] [***,TYPE=***V])*

where

name specifies a prefix for %AR to use in constructing names of variables needed to define the AR process. If the *endolist* is not specified, the

	endogenous list defaults to *name*, which must be the name of the equation to which the AR error process is to be applied. The *name* value cannot exceed 32 characters.
nlag	is the order of the AR process.
endolist	specifies the list of equations to which the AR process is to be applied. If more than one name is given, an unrestricted vector process is created with the structural residuals of all the equations included as regressors in each of the equations. If not specified, *endolist* defaults to *name*.
laglist	specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to *nlag*, and there must be no duplicates. If not specified, the *laglist* defaults to all lags 1 through *nlag*.
M=*method*	specifies the estimation method to implement. Valid values of M= are CLS (conditional least-squares estimates), ULS (unconditional least-squares estimates), and ML (maximum-likelihood estimates). M=CLS is the default. Only M=CLS is allowed when more than one equation is specified. The ULS and ML methods are not supported for vector AR models by %AR.
TYPE=V	specifies that the AR process is to be applied to the endogenous variables themselves instead of to the structural residuals of the equations.

Restricted Vector Autoregression

You can control which parameters are included in the process, restricting those parameters that you do not include to 0. First, use %AR with the DEFER option to declare the variable list and define the dimension of the process. Then, use additional %AR calls to generate terms for selected equations with selected variables at selected lags. For example,

```
proc model data=d;
   y1 = ... equation for y1 ...;
   y2 = ... equation for y2 ...;
   y3 = ... equation for y3 ...;
   %ar( name, 2, y1 y2 y3, defer )
   %ar( name, y1, y1 y2 )
   %ar( name, y2 y3, , 1 )
   fit y1 y2 y3;
run;
```

The error equations produced are

```
y1 = pred.y1 + name1_1_1*zlag1(y1-name_y1) +
     name1_1_2*zlag1(y2-name_y2) + name2_1_1*zlag2(y1-name_y1) +
     name2_1_2*zlag2(y2-name_y2) ;
```

```
   y2 = pred.y2 + name1_2_1*zlag1(y1-name_y1) +
        name1_2_2*zlag1(y2-name_y2) + name1_2_3*zlag1(y3-name_y3) ;
   y3 = pred.y3 + name1_3_1*zlag1(y1-name_y1) +
        name1_3_2*zlag1(y2-name_y2) + name1_3_3*zlag1(y3-name_y3) ;
```

This model states that the errors for Y1 depend on the errors of both Y1 and Y2 (but not Y3) at both lags 1 and 2, and that the errors for Y2 and Y3 depend on the previous errors for all three variables, but only at lag 1.

%AR Macro Syntax for Restricted Vector AR

An alternative use of %AR is allowed to impose restrictions on a vector AR process by calling %AR several times to specify different AR terms and lags for different equations.

The first call has the general form

%AR(*name, nlag, endolist, DEFER)*

where

name	specifies a prefix for %AR to use in constructing names of variables needed to define the vector AR process.
nlag	specifies the order of the AR process.
endolist	specifies the list of equations to which the AR process is to be applied.
DEFER	specifies that %AR is not to generate the AR process but is to wait for further information specified in later %AR calls for the same *name* value.

The subsequent calls have the general form

```
   %AR( name, eqlist, varlist, laglist,TYPE= )
```

where

name	is the same as in the first call.
eqlist	specifies the list of equations to which the specifications in this %AR call are to be applied. Only names specified in the *endolist* value of the first call for the *name* value can appear in the list of equations in *eqlist*.
varlist	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in *eqlist*. Only names in the *endolist* of the first call for the *name* value can appear in *varlist*. If not specified, *varlist* defaults to *endolist*.

laglist	specifies the list of lags at which the AR terms are to be added. The coefficients of the terms at lags not listed are set to 0. All of the listed lags must be less than or equal to the value of *nlag*, and there must be no duplicates. If not specified, *laglist* defaults to all lags 1 through *nlag*.

The %MA Macro

The SAS macro %MA generates programming statements for PROC MODEL for moving average models. The %MA macro is part of SAS/ETS software and no special options are needed to use the macro. The moving average error process can be applied to the structural equation errors. The syntax of the %MA macro is the same as the %AR macro except there is no TYPE= argument.

When you are using the %MA and %AR macros combined, the %MA macro must follow the %AR macro. The following SAS/IML statements produce an ARMA(1, (1 3)) error process and save it in the data set MADAT2.

```
 /* use IML module to simulate a MA process  */
proc iml;
   phi={1 .2};
   theta={ 1 .3 0 .5};
   y=armasim(phi, theta, 0,.1, 200,32565);
   create madat2 from y[colname='y'];
   append to y;
quit;
```

The following PROC MODEL statements are used to estimate the parameters of this model using maximum likelihood error structure:

```
title1 'Maximum Likelihood ARMA(1, (1 3))';
proc model data=madat2;
   y=0;
   %ar(y,1,,  M=ml)
   %ma(y,3,,1 3,  M=ml)  /* %MA always after %AR */
   fit y;
run;
```

The estimates of the parameters produced by this run are shown in Figure 20.54.

```
                       Maximum Likelihood ARMA(1, (1 3))

```

Figure 20.54. Estimates from an ARMA(1, (1 3)) Process

Syntax of the %MA Macro

There are two cases of the syntax for the %MA macro. The first has the general form

%MA *(name, nlag [,endolist [,laglist]] [,***M=***method])*

where

name	specifies a prefix for %MA to use in constructing names of variables needed to define the MA process and is the default *endolist*.
nlag	is the order of the MA process.
endolist	specifies the equations to which the MA process is to be applied. If more than one name is given, CLS estimation is used for the vector process.
laglist	specifies the lags at which the MA terms are to be added. All of the listed lags must be less than or equal to *nlag*, and there must be no duplicates. If not specified, the *laglist* defaults to all lags 1 through *nlag*.
M=*method*	specifies the estimation method to implement. Valid values of M= are CLS (conditional least-squares estimates), ULS (unconditional least-squares estimates), and ML (maximum-likelihood estimates). M=CLS is the default. Only M=CLS is allowed when more than one equation is specified on the *endolist*.

%MA Macro Syntax for Restricted Vector Moving Average

An alternative use of %MA is allowed to impose restrictions on a vector MA process by calling %MA several times to specify different MA terms and lags for different equations.

The first call has the general form

%MA(*name, nlag, endolist,* **DEFER** *)*

where

name	specifies a prefix for %MA to use in constructing names of variables needed to define the vector MA process.
nlag	specifies the order of the MA process.
endolist	specifies the list of equations to which the MA process is to be applied.
DEFER	specifies that %MA is not to generate the MA process but is to wait for further information specified in later %MA calls for the same *name* value.

The subsequent calls have the general form

```
%MA( name, eqlist, varlist, laglist )
```

where

name	is the same as in the first call.
eqlist	specifies the list of equations to which the specifications in this %MA call are to be applied.
varlist	specifies the list of equations whose lagged structural residuals are to be included as regressors in the equations in *eqlist*.
laglist	specifies the list of lags at which the MA terms are to be added.

Distributed Lag Models and the %PDL Macro

In the following example, the variable *y* is modeled as a linear function of *x*, the first lag of *x*, the second lag of *x*, and so forth:

$$y_t = a + b_0 x_t + b_1 x_{t-1} + b_2 x_{t-2} + b_3 x_{t-3} + \ldots + b_n x_{t-l}$$

Models of this sort can introduce a great many parameters for the lags, and there may not be enough data to compute accurate independent estimates for them all. Often, the number of parameters is reduced by assuming that the lag coefficients follow some pattern. One common assumption is that the lag coefficients follow a polynomial in the lag length

$$b_i = \sum_{j=0}^{d} \alpha_j (i)^j$$

where *d* is the degree of the polynomial used. Models of this kind are called *Almon lag models*, *polynomial distributed lag models*, or *PDLs* for short. For example, Figure 20.55 shows the lag distribution that can be modeled with a low order polynomial. Endpoint restrictions can be imposed on a PDL to require that the lag coefficients be 0 at the 0th lag, or at the final lag, or at both.

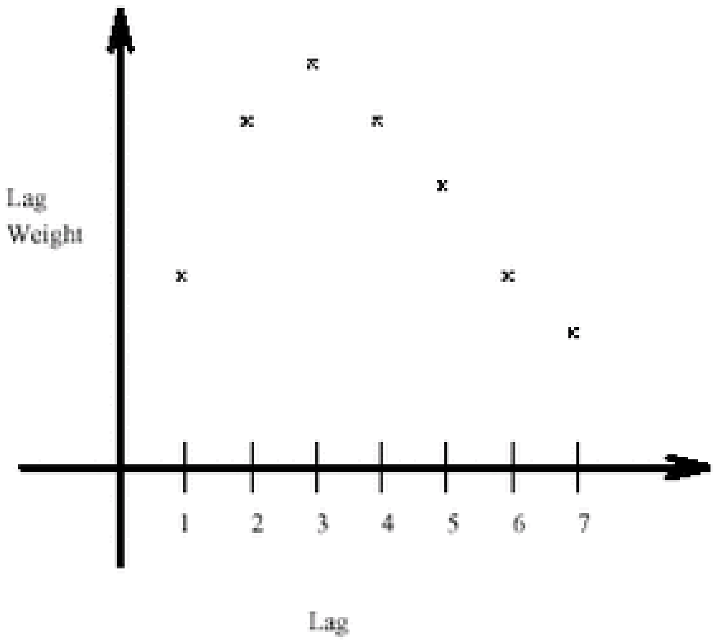

Figure 20.55. Polynomial Distributed Lags

For linear single-equation models, SAS/ETS software includes the PDLREG procedure for estimating PDL models. See Chapter 21, "The PDLREG Procedure," for a more detailed discussion of polynomial distributed lags and an explanation of endpoint restrictions.

Polynomial and other distributed lag models can be estimated and simulated or forecast with PROC MODEL. For polynomial distributed lags, the %PDL macro can generate the needed programming statements automatically.

The %PDL Macro

The SAS macro %PDL generates the programming statements to compute the lag coefficients of polynomial distributed lag models and to apply them to the lags of variables or expressions.

To use the %PDL macro in a model program, you first call it to declare the lag distribution; later, you call it again to apply the PDL to a variable or expression. The first call generates a PARMS statement for the polynomial parameters and assignment statements to compute the lag coefficients. The second call generates an expression that applies the lag coefficients to the lags of the specified variable or expression. A PDL can be declared only once, but it can be used any number of times (that is, the second call can be repeated).

The initial declaratory call has the general form

%PDL *(pdlname, nlags, degree, R=code, OUTEST=dataset)*

where *pdlname* is a name (up to 32 characters) that you give to identify the PDL, *nlags* is the lag length, and *degree* is the degree of the polynomial for the distribution. The R=*code* is optional for endpoint restrictions. The value of *code* can be FIRST (for upper), LAST (for lower), or BOTH (for both upper and lower endpoints). See chapter pdlreg, "The PDLREG Procedure," for a discussion of endpoint restrictions. The option OUTEST=*dataset* creates a data set containing the estimates of the parameters and their covariance matrix.

The later calls to apply the PDL have the general form

```
%PDL( pdlname, expression )
```

where *pdlname* is the name of the PDL and *expression* is the variable or expression to which the PDL is to be applied. The *pdlname* given must be the same as the name used to declare the PDL.

The following statements produce the output in Figure 20.56:

```
proc model data=in list;
   parms int pz;
   %pdl(xpdl,5,2);
   y = int + pz * z + %pdl(xpdl,x);
   %ar(y,2,M=ULS);
   id i;
fit y / out=model1 outresid converge=1e-6;
run;
```

```

                                                                   coefficient for lag5
```

Figure 20.56. %PDL Macro ESTIMATE Statement Output

This second example models two variables, Y1 and Y2, and uses two PDLs:

```
proc model data=in;
   parms int1 int2;
   %pdl( logxpdl, 5, 3 )
   %pdl( zpdl, 6, 4 )
   y1 = int1 + %pdl( logxpdl, log(x) ) + %pdl( zpdl, z );
   y2 = int2 + %pdl( zpdl, z );
   fit y1 y2;
run;
```

A (5,3) PDL of the log of X is used in the equation for Y1. A (6,4) PDL of Z is used in the equations for both Y1 and Y2. Since the same ZPDL is used in both equations, the lag coefficients for Z are the same for the Y1 and Y2 equations, and the polynomial parameters for ZPDL are shared by the two equations. See Example 20.5 for a complete example and comparison with PDLREG.

Input Data Sets

DATA= Input Data Set

For FIT tasks, the DATA= option specifies which input data set to use in estimating parameters. Variables in the model program are looked up in the DATA= data set and, if found, their attributes (type, length, label, and format) are set to be the same as those in the DATA= data set (if not defined otherwise within PROC MODEL), and values for the variables in the program are read from the data set.

ESTDATA= Input Data Set

The ESTDATA= option specifies an input data set that contains an observation giving values for some or all of the model parameters. The data set can also contain observations giving the rows of a covariance matrix for the parameters.

Parameter values read from the ESTDATA= data set provide initial starting values for parameters estimated. Observations providing covariance values, if any are present in the ESTDATA= data set, are ignored.

The ESTDATA= data set is usually created by the OUTEST= option in a previous FIT statement. You can also create an ESTDATA= data set with a SAS DATA step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the ESTDATA= data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an ESTDATA= data set. The data set must also contain a character variable _NAME_ of length 32. _NAME_ has a blank value for the observation that gives values to the parameters. _NAME_ contains the name of a parameter for observations defining rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the ESTDATA= data set if the observations for the different estimates are identified by the variable _TYPE_. _TYPE_ must be a character variable of length 8. The TYPE= option is used to select for input the part of the ESTDATA= data set for which the _TYPE_ value matches the value of the TYPE= option.

The following SAS statements generate the ESTDATA= data set shown in Figure 20.57. The second FIT statement uses the TYPE= option to select the estimates from the GMM estimation as starting values for the FIML estimation.

```
         /* Generate test data */
data gmm2;
    do t=1 to 50;
       x1 = sqrt(t) ;
       x2 = rannor(10) * 10;
       y1 = -.002 * x2 * x2 - .05 / x2 - 0.001 * x1 * x1;
       y2 = 0.002* y1 + 2 * x2 * x2 + 50 / x2 + 5 * rannor(1);
       y1 = y1 + 5 * rannor(1);
       z1 = 1; z2 = x1 * x1; z3 = x2 * x2; z4 = 1.0/x2;
       output;
    end;
run;

proc model data=gmm2 ;
   exogenous x1 x2;
   parms a1 a2 b1 2.5 b2 c2 55 d1;
   inst b1 b2 c2 x1 x2;
   y1 = a1 * y2 + b1 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / 3sls gmm kernel=(qs,1,0.2) outest=gmmest;

   fit y1 y2 / fiml type=gmm estdata=gmmest;
run;

proc print data=gmmest;
run;
```

```

```

Figure 20.57. ESTDATA= Data Set

MISSING= PAIRWISE | DELETE

When missing values are encountered for any one of the equations in a system of equations, the default action is to drop that observation for all of the equations. The new MISSING=PAIRWISE option on the FIT statement provides a different method of handling missing values that avoids losing data for nonmissing equations for the observation. This is especially useful for SUR estimation on equations with unequal numbers of observations.

The option MISSING=PAIRWISE specifies that missing values are tracked on an equation-by-equation basis. The MISSING=DELETE option specifies that the entire observation is omitted from the analysis when any equation has a missing predicted or actual value for the equation. The default is MISSING=DELETE.

When you specify the MISSING=PAIRWISE option, the S matrix is computed as

$$S = D(R'R)D$$

where D is a diagonal matrix that depends on the VARDEF= option, the matrix R is $(\mathbf{r}_1, \ldots, \mathbf{r}_g)$, and $\mathbf{r}_i$ is the vector of residuals for the *i*th equation with r_{ij} replaced with zero when r_{ij} is missing.

For MISSING=PAIRWISE, the calculation of the diagonal element $d_{i,i}$ of **D** is based on n_i, the number of nonmissing observations for the *i*th equation, instead of on *n* or, for VARDEF=WGT or WDF, on the sum of the weights for the nonmissing observations for the *i*th equation instead of on the sum of the weights for all observations. Refer to the description of the VARDEF= option for the definition of **D**.

The degrees of freedom correction for a shared parameter is computed using the average number of observations used in its estimation.

The MISSING=PAIRWISE option is not valid for the GMM and FIML estimation methods.

For the instrumental variables estimation methods (2SLS, 3SLS), when an instrument is missing for an observation, that observation is dropped for all equations,

regardless of the MISSING= option.

PARMSDATA= Input Data Set

The option PARMSDATA= reads values for all parameters whose names match the names of variables in the PARMSDATA= data set. Values for any or all of the parameters in the model can be reset using the PARMSDATA= option. The PARMSDATA= option goes on the PROC MODEL statement, and the data set is read before any FIT or SOLVE statements are executed.

Together, the OUTPARMS= and PARMSDATA= options allow you to change part of a model and recompile the new model program without the need to reestimate equations that were not changed.

Suppose you have a large model with parameters estimated and you now want to replace one equation, Y, with a new specification. Although the model program must be recompiled with the new equation, you don't need to reestimate all the equations, just the one that changed.

Using the OUTPARMS= and PARMSDATA= options, you could do the following:

```
proc model model=oldmod outparms=temp; run;
proc model outmodel=newmod parmsdata=temp data=in;
   ...  include new model definition with changed y eq. here ...
   fit y;
run;
```

The model file NEWMOD will then contain the new model and its estimated parameters plus the old models with their original parameter values.

SDATA= Input Data Set

The SDATA= option allows a cross-equation covariance matrix to be input from a data set. The **S** matrix read from the SDATA= data set, specified in the FIT statement, is used to define the objective function for the OLS, N2SLS, SUR, and N3SLS estimation methods and is used as the initial **S** for the methods that iterate the **S** matrix.

Most often, the SDATA= data set has been created by the OUTS= or OUTSUSED= option on a previous FIT statement. The OUTS= and OUTSUSED= data sets from a FIT statement can be read back in by a FIT statement in the same PROC MODEL step.

You can create an input SDATA= data set using the DATA step. PROC MODEL expects to find a character variable _NAME_ in the SDATA= data set as well as variables for the equations in the estimation or solution. For each observation with a _NAME_ value matching the name of an equation, PROC MODEL fills the corresponding row of the **S** matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, a 1 is placed on the diagonal for the row or column. Missing values are ignored, and since the **S** matrix is symmetric, you can include only a triangular part of the **S** matrix in the SDATA= data set with the omitted part indicated by missing values. If the SDATA= data set contains multiple observations with the same _NAME_, the last values supplied for the _NAME_ are used. The structure of the expected data set is further described in the "OUTS=Data Set" section.

Use the TYPE= option on the PROC MODEL or FIT statement to specify the type of estimation method used to produce the **S** matrix you want to input.

The following SAS statements are used to generate an **S** matrix from a GMM and a 3SLS estimation and to store that estimate in the data set GMMS:

```
proc model data=gmm2 ;
   exogenous x1 x2;
   parms a1 a2 b1 2.5 b2 c2 55 d1;
   inst b1 b2 c2 x1 x2;
   y1 = a1 * y2 + b1 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / 3sls gmm kernel=(qs,1,0.2) outest=gmmest outs=gmms;
run;
```

The data set GMMS is shown in Figure 20.58.

```
          Obs     _NAME_     _TYPE_     _NUSED_        y1          y2

            1       y1       3SLS          50      27.1032     38.1599
            2       y2       3SLS          50      38.1599     74.6253

            4       y2       GMM           50      46.4028     99.4656
```

Figure 20.58. SDATA= Data Set

VDATA= Input data set

The VDATA= option allows a variance matrix for GMM estimation to be input from a data set. When the VDATA= option is used on the PROC MODEL or FIT statement, the matrix that is input is used to define the objective function and is used as the initial V for the methods that iterate the V matrix.

Normally the VDATA= matrix is created from the OUTV= option on a previous FIT statement. Alternately an input VDATA= data set can be created using the DATA step. Each row and column of the V matrix is associated with an equation and an instrument. The position of each element in the V matrix can then be indicated by an equation name and an instrument name for the row of the element and an equation name and an instrument name for the column. Each observation in the VDATA= data set is an element in the V matrix. The row and column of the element are indicated by four variables EQ_ROW, INST_ROW, EQ_COL, and INST_COL which contain the equation name or instrument name. The variable name for an element is VALUE. Missing values are set to 0. Because the variance matrix is symmetric, only a triangular part of the matrix needs to be input.

The following SAS statements are used to generate a **V** matrix estimation from GMM and to store that estimate in the data set GMMV:

```
proc model data=gmm2 ;
   exogenous x1 x2;
   parms a1 a2 b2 b1 2.5 c2 55 d1;
   inst b1 b2 c2 x1 x2;
   y1 = a1 * y2 + b1 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / gmm outv=gmmv;
run;
```

The data set GMM2 was generated by the example in the preceding ESTDATA= section. The **V** matrix stored in GMMV is selected for use in an additional GMM estimation by the following FIT statement:

```
fit y1 y2 / gmm vdata=gmmv;
run;

proc print data=gmmv(obs=15);
run;
```

A partial listing of the GMMV data set is shown in Figure 20.59. There are a total of 78 observations in this data set. The **V** matrix is 12 by 12 for this example.

```

Figure 20.59. The First 15 Observations in the VDATA= Data Set

Output Data Sets

OUT= Data Set

For normalized form equations, the OUT= data set specified on the FIT statement contains residuals, actuals, and predicted values of the dependent variables computed from the parameter estimates. For general form equations, actual values of the endogenous variables are copied for the residual and predicted values.

The variables in the data set are as follows:

- BY variables
- RANGE variable
- ID variables
- _ESTYPE_, a character variable of length 8 identifying the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- _TYPE_, a character variable of length 8 identifying the type of observation: RESIDUAL, PREDICT, or ACTUAL
- _WEIGHT_, the weight of the observation in the estimation. The _WEIGHT_ value is 0 if the observation was not used. It is equal to the product of the _WEIGHT_ model program variable and the variable named in the WEIGHT statement, if any, or 1 if weights were not used.
- the WEIGHT statement variable if used
- the model variables. The dependent variables for the normalized-form equations in the estimation contain residuals, actuals, or predicted values, depending on the _TYPE_ variable, whereas the model variables that are not associated with estimated equations always contain actual values from the input data set.
- any other variables named in the OUTVARS statement. These can be program variables computed by the model program, CONTROL variables, parameters, or special variables in the model program.

The following SAS statements are used to generate and print an OUT= data set:

```
proc model data=gmm2;
   exogenous x1 x2;
   parms a1 a2 b2 b1 2.5 c2 55 d1;
   inst b1 b2 c2 x1 x2;
   y1 = a1 * y2 + b1 * x1 * x1 + d1;
   y2 = a2 * y1 + b2 * x2 * x2 + c2 / x2 + d1;

   fit y1 y2 / 3sls gmm out=resid outall ;
run;

proc print data=resid(obs=20);
run;
```

The data set GMM2 was generated by the example in the preceding ESTDATA= section above. A partial listing of the RESID data set is shown in Figure 20.60.

```

Figure 20.60. The OUT= Data Set

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- _NAME_, a character variable of length 32, blank for observations containing parameter estimates or a parameter name for observations containing covariances
- _TYPE_, a character variable of length 8 identifying the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- the parameters estimated.

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the _NAME_ values containing the parameter names for the rows. Parameter names longer than 32 characters are truncated.

OUTPARMS= Data Set

The option OUTPARMS= writes all the parameter estimates to an output data set. This output data set contains one observation and is similar to the OUTEST= data set, but it contains all the parameters, is not associated with any FIT task, and contains no covariances. The OUTPARMS= option is used on the PROC MODEL statement, and the data set is written at the end, after any FIT or SOLVE steps have been performed.

OUTS= Data Set

The OUTS= SAS data set contains the estimate of the covariance matrix of the residuals across equations. This matrix is formed from the residuals that are computed using the parameter estimates.

The variables in the OUTS= data set are as follows:

- BY variables
- _NAME_, a character variable containing the name of the equation
- _TYPE_, a character variable of length 8 identifying the estimation method: OLS, SUR, N2SLS, N3SLS, ITOLS, ITSUR, IT2SLS, IT3SLS, GMM, ITGMM, or FIML
- variables with the names of the equations in the estimation.

Each observation contains a row of the covariance matrix. The data set is suitable for use with the SDATA= option on a subsequent FIT or SOLVE statement. (See "Tests on Parameters" in this chapter for an example of the SDATA= option.)

OUTSUSED= Data Set

The OUTSUSED= SAS data set contains the covariance matrix of the residuals across equations that is used to define the objective function. The form of the OUTSUSED= data set is the same as that for the OUTS= data set.

Note that OUTSUSED= is the same as OUTS= for the estimation methods that iterate the **S** matrix (ITOLS, IT2SLS, ITSUR, and IT3SLS). If the SDATA= option is specified in the FIT statement, OUTSUSED= is the same as the SDATA= matrix read in for the methods that do not iterate the **S** matrix (OLS, SUR, N2SLS, and N3SLS).

OUTV= Data Set

The OUTV= data set contains the estimate of the variance matrix, V. This matrix is formed from the instruments and the residuals that are computed using the parameter estimates obtained from the initial 2SLS estimation when GMM estimation is selected. If an estimation method other than GMM or ITGMM is requested and OUTV= is specified, a V matrix is created using computed estimates. In the case that a VDATA= data set is used, this becomes the OUTV= data set. For ITGMM, the OUTV= data set is the matrix formed from the instruments and the residuals computed using the final parameter estimates.

ODS Table Names

PROC MODEL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, “Using the Output Delivery System.”

Table 20.3. ODS Tables Produced in PROC MODEL

ODS Table Name	Description	Option
ODS Tables Created by the FIT Statement		
AugGMMCovariance	Cross products matrix	GMM
ChowTest	Structural change test	CHOW=
CollinDiagnostics	Collinearity Diagnostics	
ConfInterval	Profile likelihood Confidence Intervals	PRL=

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the MODEL procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

ODS Graph Names

PROC MODEL assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 20.4.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 20.4. ODS Graphics Produced by PROC MODEL

ODS Graph Name	Plot Description
ACFPlot	Autocorrelation of residuals
ActualByPredicted	Predicted vs actual plot
CooksD	Cook's D plot
IACFPlot	Inverse autocorrelation of residuals
QQPlot	QQ plot of residuals
PACFPlot	Partial autocorrelation of residuals
ResidualHistogram	Histogram of the residuals
StudentResidualPlot	Studentized residual plot

Details: Simulation

The *solution* given the vector **k**, of the following nonlinear system of equations is the vector **u** which satisfies this equation:

$$\mathbf{q}(\mathbf{u}, \mathbf{k}, \theta) = 0$$

A *simulation* is a set of solutions $\mathbf{u}_t$ for a specific sequence of vectors $\mathbf{k}_t$.

Model simulation can be performed to

- check how well the model predicts the actual values over the historical period
- investigate the sensitivity of the solution to changes in the input values or parameters
- examine the dynamic characteristics of the model
- check the stability of the simultaneous solution
- estimate the statistical distribution of the predicted values of the nonlinear model using Monte Carlo methods

By combining the various solution modes with different input data sets, model simulation can answer many different questions about the model. This section presents details of model simulation and solution.

Solution Modes

The following solution modes are commonly used:

- *Dynamic simultaneous forecast* mode is used for forecasting with the model. Collect the historical data on the model variables, the future assumptions of the exogenous variables, and any prior information on the future endogenous values, and combine them in a SAS data set. Use the FORECAST option on the SOLVE statement.
- *Dynamic simultaneous simulation* mode is often called *ex-post simulation*, *historical simulation*, or *ex-post forecasting*. Use the DYNAMIC option. This mode is the default.
- *Static simultaneous simulation* mode can be used to examine the within-period performance of the model without the complications of previous period errors. Use the STATIC option.
- *NAHEAD=n dynamic simultaneous simulation* mode can be used to see how well *n*-period-ahead forecasting would have performed over the historical period. Use the NAHEAD=*n* option.

The different solution modes are explained in detail in the following sections.

Dynamic and Static Simulations

In model simulation, either solved values or actual values from the data set can be used to supply lagged values of an endogenous variable. A *dynamic* solution refers to a solution obtained by using only solved values for the lagged values. Dynamic mode is used both for forecasting and for simulating the dynamic properties of the model.

A *static* solution refers to a solution obtained by using the actual values when available for the lagged endogenous values. Static mode is used to simulate the behavior of the model without the complication of previous period errors. Dynamic simulation is the default.

If you wish to use static values for lags only for the first *n* observations, and dynamic values thereafter, specify the START=*n* option. For example, if you want a dynamic simulation to start after observation twenty-four, specify START=24 on the SOLVE statement. If the model being simulated had a value lagged for four time periods, then this value would start using dynamic values when the simulation reached observation number 28.

n-Period-Ahead Forecasting

Suppose you want to regularly forecast 12 months ahead and produce a new forecast each month as more data becomes available. *n*-period-ahead forecasting allows you to test how well you would have done over time had you been using your model to forecast 1 year ahead.

To see how well a model predicts *n* time periods in the future, perform an *n*-period-ahead forecast on real data and compare the forecast values with the actual values.

n-period-ahead forecasting refers to using dynamic values for the lagged endogenous variables only for lags *1* through *n-1*. For example, 1-period-ahead forecasting, specified by the NAHEAD=1 option on the SOLVE statement, is the same as if a static solution had been requested. Specifying NAHEAD=2 produces a solution that uses dynamic values for lag one and static, actual, values for longer lags.

The following example is a 2-year-ahead dynamic simulation. The output is shown in Figure 20.61.

```
data yearly;
   input year x1 x2 x3 y1 y2 y3;
   datalines;

```

Figure 20.62. C Data Set

The preceding 2-year-ahead simulation can be emulated without using the NAHEAD= option by the following PROC MODEL statements:

```
proc model data=test model=foo;
  range year = 87 to 88;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 88 to 89;
  solve y1 y2 y3 / dynamic solveprint;
run;

  range year = 89 to 90;
  solve y1 y2 y3 / dynamic solveprint;
run;
```

```
range year = 90 to 91;
solve y1 y2 y3 / dynamic solveprint;
```

The totals shown under "Observations Processed" in Figure 20.61 are equal to the sum of the four individual runs.

Simulation and Forecasting

You can perform a simulation of your model or use the model to produce forecasts. *Simulation* refers to the determination of the endogenous or dependent variables as a function of the input values of the other variables, even when actual data for some of the solution variables are available in the input data set. The simulation mode is useful for verifying the fit of the model parameters. Simulation is selected by the SIMULATE option on the SOLVE statement. Simulation mode is the default.

In forecast mode, PROC MODEL solves only for those endogenous variables that are missing in the data set. The actual value of an endogenous variable is used as the solution value whenever nonmissing data for it are available in the input data set. Forecasting is selected by the FORECAST option on the SOLVE statement.

For example, an econometric forecasting model can contain an equation to predict future tax rates, but tax rates are usually set in advance by law. Thus, for the first year or so of the forecast, the predicted tax rate should really be exogenous. Or, you may want to use a prior forecast of a certain variable from a short-run forecasting model to provide the predicted values for the earlier periods of a longer-range forecast of a long-run model. A common situation in forecasting is when historical data needed to fill the initial lags of a dynamic model are available for some of the variables but have not yet been obtained for others. In this case, the forecast must start in the past to supply the missing initial lags. Clearly, you should use the actual data that are available for the lags. In all the preceding cases, the forecast should be produced by running the model in the FORECAST mode; simulating the model over the future periods would not be appropriate.

Monte Carlo Simulation

The accuracy of the forecasts produced by PROC MODEL depends on four sources of error (Pindyck 1981, 405-406):

- The system of equations contains an implicit random error term ϵ

  $$\mathbf{g}(\mathbf{y}, \mathbf{x}, \hat{\theta}) = \epsilon$$

  where **y**, **x**, **g**, $\hat{\theta}$, and ϵ are vector valued.
- The estimated values of the parameters, $\hat{\theta}$, are themselves random variables.
- The exogenous variables may have been forecast themselves and therefore may contain errors.
- The system of equations may be incorrectly specified; the model only approximates the process modeled.

The RANDOM= option is used to request Monte Carlo (or stochastic) simulations to generate confidence intervals for errors arising from the first two sources. The Monte Carlo simulations can be performed with ϵ, θ, or both vectors represented as random variables. The SEED= option is used to control the random number generator for the simulations. SEED=0 forces the random number generator to use the system clock as its seed value.

In Monte Carlo simulations, repeated simulations are performed on the model for random perturbations of the parameters and the additive error term. The random perturbations follow a multivariate normal distribution with expected value of 0 and covariance described by a covariance matrix of the parameter estimates in the case of θ, or a covariance matrix of the equation residuals for the case of ϵ. PROC MODEL can generate both covariance matrices or you can provide them.

The ESTDATA= option specifies a data set containing an estimate of the covariance matrix of the parameter estimates to use for computing perturbations of the parameters. The ESTDATA= data set is usually created by the FIT statement with the OUTEST= and OUTCOV options. When the ESTDATA= option is specified, the matrix read from the ESTDATA= data set is used to compute vectors of random shocks or perturbations for the parameters. These random perturbations are computed at the start of each repetition of the solution and added to the parameter values. The perturbed parameters are fixed throughout the solution range. If the covariance matrix of the parameter estimates is not provided, the parameters are not perturbed.

The SDATA= option specifies a data set containing the covariance matrix of the residuals to use for computing perturbations of the equations. The SDATA= data set is usually created by the FIT statement with the OUTS= option. When SDATA= is specified, the matrix read from the SDATA= data set is used to compute vectors of random shocks or perturbations for the equations. These random perturbations are computed at each observation. The simultaneous solution satisfies the model equations plus the random shocks. That is, the solution is not a perturbation of a simultaneous solution of the structural equations; rather, it is a simultaneous solution of the stochastic equations using the simulated errors. If the SDATA= option is not specified, the random shocks are not used.

The different random solutions are identified by the _REP_ variable in the OUT= data set. An unperturbed solution with _REP_=0 is also computed when the RANDOM= option is used. RANDOM=*n* produces *n*+1 solution observations for each input observation in the solution range. If the RANDOM= option is not specified, the SDATA= and ESTDATA= options are ignored, and no Monte Carlo simulation is performed.

PROC MODEL does not have an automatic way of modeling the exogenous variables as random variables for Monte Carlo simulation. If the exogenous variables have been forecast, the error bounds for these variables should be included in the error bounds generated for the endogenous variables. If the models for the exogenous variables are included in PROC MODEL, then the error bounds created from a Monte Carlo simulation will contain the uncertainty due to the exogenous variables.

Alternatively, if the distribution of the exogenous variables is known, the built-in random number generator functions can be used to perturb these variables appropriately for the Monte Carlo simulation. For example, if you knew the forecast of an exogenous variable, X, had a standard error of 5.2 and the error was normally distributed, then the following statements could be used to generate random values for X:

```
   x_new = x + 5.2 * rannor(456);
```

During a Monte Carlo simulation the random number generator functions produce one value at each observation. It is important to use a different seed value for all the random number generator functions in the model program; otherwise, the perturbations will be correlated. For the unperturbed solution, _REP_=0, the random number generator functions return 0.

PROC UNIVARIATE can be used to create confidence intervals for the simulation (see the Monte Carlo simulation example in the "Getting Started" section).

Multivariate t-Distribution Simulation

To perform a Monte Carlo analysis of models that have residuals distributed as a multivariate *t*, use the ERRORMODEL statement with either the $\sim$ t(*variance*, *df*) option or with the CDF=t(*variance*, *df*) option. The CDF= option specifies the distribution that is used for simulation so that the estimation can be done for one set of distributional assumptions and the simulation for another.

The following is an example of estimating and simulating a system of equations with *t*-distributed errors using the ERRORMODEL statement:

```
       /* generate simulation data set */
data five;
set xfrate end=last;
if last then do;
```

```
    todate = date +5;
    do date = date to todate;
       output;
    end;
 end;
```

The preceding DATA step generates the data set to request a five-days-ahead forecast. The following statements estimate and forecast the three forward-rate models of the following form.

$$\begin{aligned} rate_t &= rate_{t-1} + \mu * rate_{t-1} + \nu \\ \nu &= \sigma * rate_{t-1} * \epsilon \\ \epsilon &\sim \mathrm{N}(0,1) \end{aligned}$$

```
Title "Daily Multivariate Geometric Brownian Motion Model "
         "of D-Mark/USDollar Forward Rates";

proc model data=xfrate;

   parms df 15;       /* Give initial value to df */

   demusd1m = lag(demusd1m) + mu1m * lag(demusd1m);
   var_demusd1m = sigma1m ** 2 * lag(demusd1m **2);
   demusd3m = lag(demusd3m) + mu3m * lag(demusd3m);
   var_demusd3m = sigma3m ** 2 * lag(demusd3m ** 2);
   demusd6m = lag(demusd6m) + mu6m * lag(demusd6m);
   var_demusd6m = sigma6m ** 2 * lag(demusd6m ** 2);

      /* Specify the error distribution */
   errormodel demusd1m demusd3m demusd6m
        ~ t( var_demusd1m var_demusd3m var_demusd6m, df );

      /* output normalized S matrix */
   fit demusd1m demusd3m demusd6m / outsn=s;
run;
      /* forecast five days in advance */
   solve demusd1m demusd3m demusd6m /
         data=five sdata=s random=1500 out=monte;
   id date;
run;

   /* select out the last date ---*/
data monte; set monte;
   if date = ’10dec95’d then output;
run;

title "Distribution of demusd1m Five Days Ahead";
proc univariate data=monte noprint;
     var demusd1m;
     histogram demusd1m / normal(noprint color=red)
```

```
          kernel(noprint color=blue) cfill=ligr;
run;
```

The Monte Carlo simulation specified in the preceding example draws from a multivariate *t*-distribution with constant degrees of freedom and forecasted variance and computes future states of DEMUSD1M, DEMUSD3M, and DEMUSD6M. The OUTSN= option on the FIT statement is used to specify the data set for the normalized Σ matrix. That is the Σ matrix is created by crossing the normally distributed residuals. The normally distributed residuals are created from the *t*-distributed residuals using the normal inverse CDF and the *t* CDF. This matrix is a correlation matrix.

The distribution of DEMUSD1M on the fifth day is shown in the following output. The two curves overlayed on the graph are a kernel density estimation and a normal distribution fit to the results.

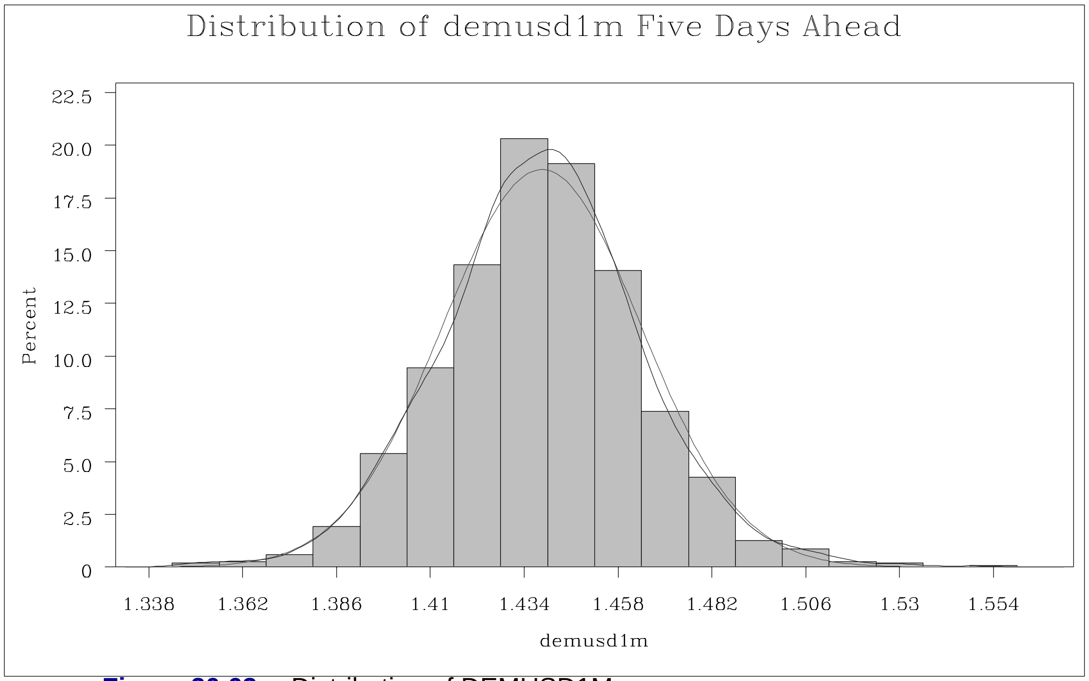

Figure 20.63. Distribution of DEMUSD1M

Alternate Distribution Simulation

As an alternate to the normal distribution, the ERRORMODEL statement can be used in a simulation to specify other distributions. The distributions available for simulation are Cauchy, Chi-squared, *F*, Poisson, *t*, and Uniform. An empirical distribution can also be used if the residuals are specified using the RESIDDATA= option on the SOLVE statement.

Except for the *t*, all of these alternate distributions are univariate but can be used together in a multivariate simulation. The ERRORMODEL statement applies to solved for equations only. That is, the normal form or general form equation referred to by the ERRORMODEL statement must be one of the equations you have selected in the SOLVE statement.

In the following example, two Poisson distributed variables are used to simulate the calls arriving and leaving a call center.

```
data s;    /* Covariance between arriving and leaving */
   arriving = 1; leaving = 0.7; _name_= "arriving";
   output;
   arriving = 0.7; leaving = 1.0; _name_= "leaving";
   output;
run;

data calls;
   date = '20mar2001'd;
   output;
run;
```

The first DATA step generates a data set containing a covariance matrix for the ARRIVING and LEAVING variables. The covariance is

$$\begin{vmatrix} 1 & .7 \\ .7 & 1 \end{vmatrix}$$

```
proc model data=calls;
   arriving = 10;
   errormodel arriving ~ poisson( 10 );

      /* Have four people answering the phone */
   leaving  = 4;
   errormodel leaving ~ poisson( 11 );

   waiting = arriving - leaving;

   solve arriving leaving / random=500 sdata=s out=sim;
run;

title "Distribution of Clients Waiting";
proc univariate data=sim noprint;
     var waiting ;
     histogram waiting / cfill=ligr;
run;
```

The distribution of number of waiting clients is shown in the following output.

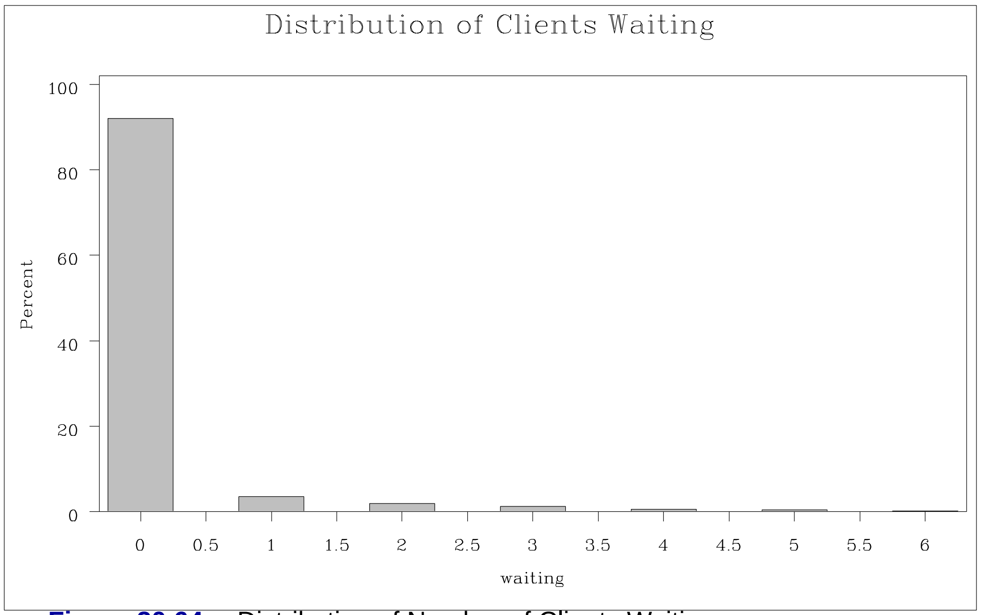

Figure 20.64. Distribution of Number of Clients Waiting

Mixtures of Distributions - Copulas

The theory of copulas is what enables the MODEL procedure to combine and simulate multivariate distributions with different marginals. This section provides a brief overview of copulas.

Modeling a system of variables accurately is a difficult task. The underlying, ideal, distributional assumptions for each variable are usually different from each other. An individual variable may be best modeled as a *t*-distribution or as a Poisson process. The correlation of the various variables are very important to estimate as well. A joint estimation of a set of variables would make it possible to estimate a correlation structure but would restrict the modeling to single, simple multivariate distribution (for example, the norma l). Even with a simple multivariate distribution, the joint estimation would be computationally difficult and would have to deal with issues of missing data.

Using the MODEL procedure ERRORMODEL statement you can combine and simulate from models of different distributions. The covariance matrix for the combined model is constructed using the copula induced by the multivariate normal distribution. A copula is a function that couples joint distributions to their marginal distributions.

The copula used by the model procedure is based on the multivariate normal. This particular multivariate normal has zero mean and covariance matrix R. The user provides R, which can be created using the following steps

1. Each model is estimated separately and their residuals saved.
2. The residuals for each model are converted to a normal distribution using their CDFs, $F_i(.)$, using the relationship $\Phi^{-1}(F(\epsilon_{it}))$.
3. Cross these normal residuals, to create a covariance matrix R.

If the model of interest can be estimated jointly, such as multivariate T, then the OUTSN= option can be used to generate the correct covariance matrix.

A draw from this mixture of distributions is created using the following steps that are performed automatically by the MODEL procedure.

1. Independent $N(0, 1)$ variables are generated.
2. These variables are transformed to a correlated set using the covariance matrix R.
3. These correlated normals are transformed to a uniform using $\Phi()$.
4. $F^{-1}()$ is used to compute the final sample value.

Quasi-Random Number Generators

Traditionally high discrepancy pseudo-random number generators are used to generate innovations in Monte Carlo simulations. Loosely translated, a high discrepancy pseudo-random number generator is one in which there is very little correlation between the current number generated and the past numbers generated. This property is ideal if indeed independence of the innovations is required. If, on the other hand, the efficient spanning of a multi-dimensional space is desired, a low discrepancy, quasi-random number generator can be used. A quasi-random number generator produces numbers which have no random component.

A simple one-dimensional quasi-random sequence is the van der Corput sequence. Given a prime number r ($r \geq 2$) any integer has a unique representation in terms of base r. A number in the interval [0,1) can be created by inverting the representation base power by base power. For example, consider r=3 and n=1. 1 in base 3 is

$$1_{10} = 1 \cdot 3^0 = 1_3$$

When the powers of 3 are inverted,

$$\phi(1) = \frac{1}{3}$$

Also 11 in base 3 is

$$11_{10} = 1 \cdot 3^2 + 2 \cdot 3^0 = 102_3$$

When the powers of 3 are inverted,

$$\phi(11) = \frac{1}{9} + 2 \cdot \frac{1}{3} = \frac{7}{9}$$

The first 10 numbers in this sequence $\phi(1) \ldots \phi(10)$ are provided below

$$0, \frac{1}{3}, \frac{2}{3}, \frac{1}{9}, \frac{4}{9}, \frac{7}{9}, \frac{2}{9}, \frac{5}{9}, \frac{8}{9}, \frac{1}{27}$$

As the sequence proceeds it fills in the gaps in a uniform fashion.

Several authors have expanded this idea to many dimensions. Two versions supported by the MODEL procedure are the Sobol sequence (QUASI=SOBOL) and the Faure sequence (QUASI=FAURE). The Sobol sequence is based on binary numbers an is generally computationally faster than the Faure sequence. The Faure sequence uses the dimensionality of the problem to determine the number base to use to generate the sequence. The Faure sequence has better distributional properties than the Sobol sequence for dimensions greater than 8.

As an example of the difference between a pseudo random number and a quasi random number consider simulating a bivariate normal with 100 draws.

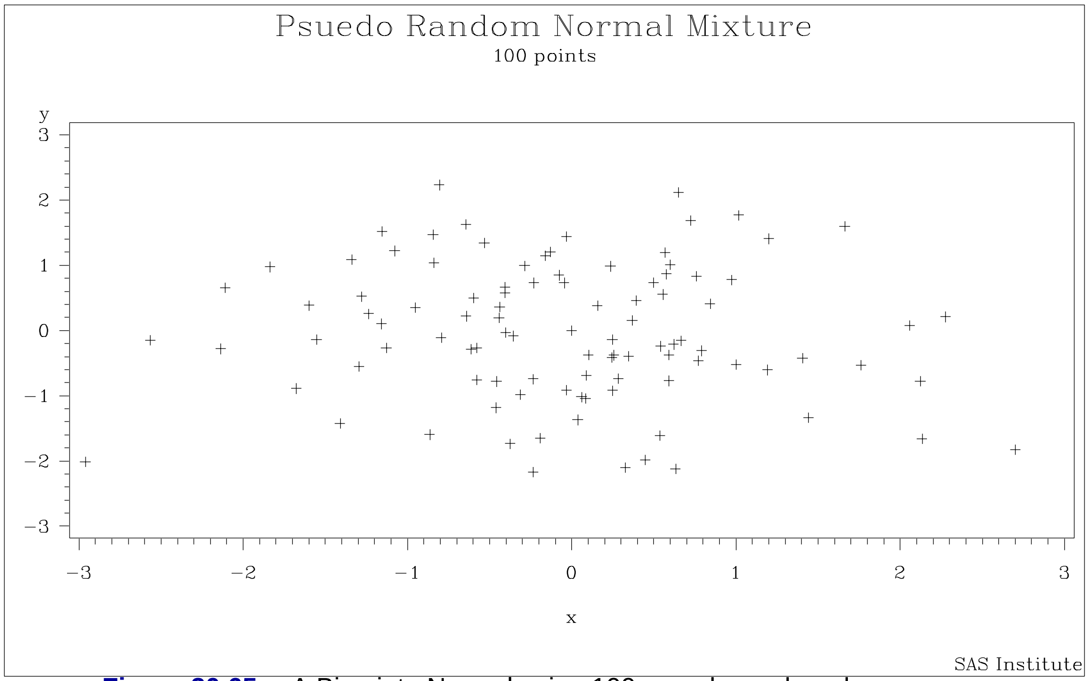

Figure 20.65. A Bivariate Normal using 100 pseudo random draws

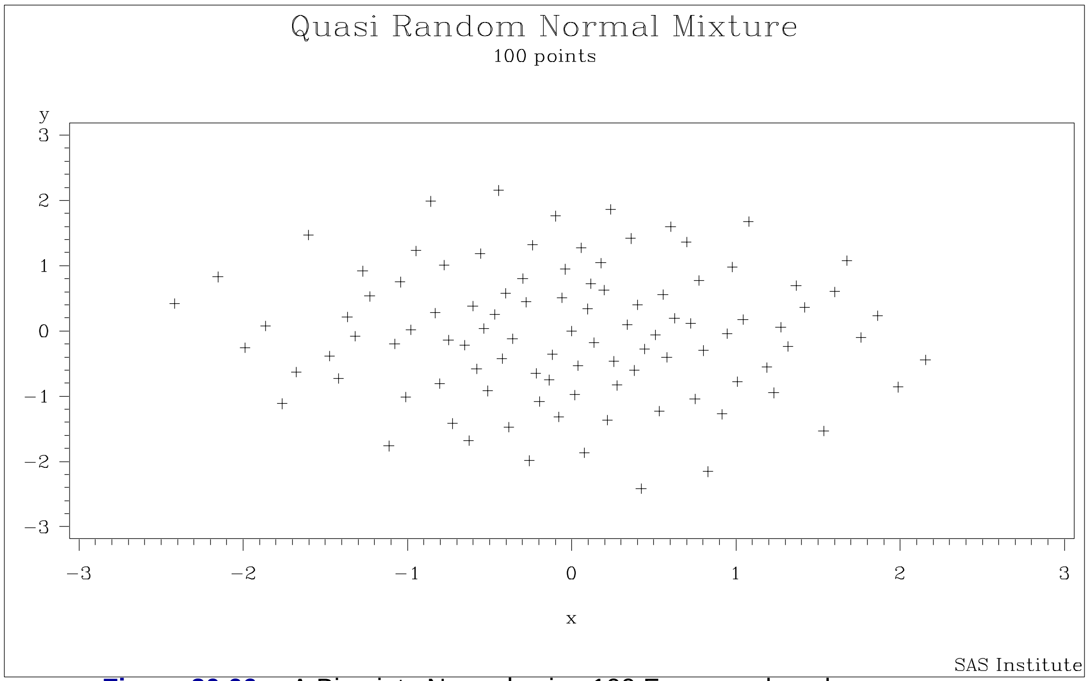

Figure 20.66. A Bivariate Normal using 100 Faure random draws

Solution Mode Output

The following SAS statements dynamically forecast the solution to a nonlinear equation:

```
proc model data=sashelp.citimon;
   parameters a 0.010708  b  -0.478849 c 0.929304;
   lhur = 1/(a * ip) + b + c * lag(lhur);
   solve lhur / out=sim forecast dynamic;
run;
```

The first page of output produced by the SOLVE step is shown in Figure 20.67. This is the summary description of the model. The error message states that the simulation was aborted at observation 144 because of missing input values.

```
                         The MODEL Procedure

Figure 20.69. Solution Summary Report

This solution summary table includes the names of the input data set and the output data set followed by a description of the model. The table also indicates the solution method defaulted to Newton's method. The remaining output is defined as follows.

Maximum CC	is the maximum convergence value accepted by the Newton procedure. This number is always less than the value for "CONVERGE=."
Maximum Iterations	is the maximum number of Newton iterations performed at each observation and each replication of Monte Carlo simulations.
Total Iterations	is the sum of the number of iterations required for each observation and each Monte Carlo simulation.
Average Iterations	is the average number of Newton iterations required to solve the system at each step.
Solved	is the number of observations used times the number of random replications selected plus one, for Monte Carlo simulations. The one additional simulation is the original unperturbed solution. For simulations not involving Monte Carlo, this number is the number of observations used.

Summary Statistics

The STATS and THEIL options are used to select goodness of fit statistics. Actual values must be provided in the input data set for these statistics to be printed. When the RANDOM= option is specified, the statistics do not include the unperturbed (_REP_=0) solution.

STATS Option Output

If the STATS and THEIL options are added to the model in the previous section

```
proc model data=sashelp.citimon;
   parameters a 0.010708  b  -0.478849 c 0.929304;
   lhur= 1/(a * ip) + b + c * lag(lhur) ;
   solve lhur / out=sim dynamic stats theil;
   range date to ’01nov91’d;
run;
```

the STATS output in Figure 20.70 and the THEIL output in Figure 20.71 are generated.

                                            16 YEARS
```

Figure 20.70. STATS Output

The number of observations (Nobs), the number of observations with both predicted and actual values nonmissing (N), and the mean and standard deviation of the actual and predicted values of the determined variables are printed first. The next set of columns in the output are defined as follows.

Mean Error	$\frac{1}{N}\sum_{j=1}^{N}(\hat{y}_j - y_j)$
Mean % Error	$\frac{100}{N}\sum_{j=1}^{N}(\hat{y}_j - y_j)/y_j$
Mean Abs Error	$\frac{1}{N}\sum_{j=1}^{N}\lvert\hat{y}_j - y_j\rvert$
Mean Abs % Error	$\frac{100}{N}\sum_{j=1}^{N}\lvert(\hat{y}_j - y_j)/y_j\rvert$
RMS Error	$\sqrt{\frac{1}{N}\sum_{j=1}^{N}(\hat{y}_j - y_j)^2}$
RMS % Error	$100\sqrt{\frac{1}{N}\sum_{j=1}^{N}((\hat{y}_j - y_j)/y_j)^2}$
R-square	$1 - SSE/CSSA$
SSE	$\sum_{j=1}^{N}(\hat{y}_j - y_j)^2$
SSA	$\sum_{j=1}^{N}(y_j)^2$
CSSA	$SSA - \left(\sum_{j=1}^{N} y_j\right)^2$
$\hat{y}$	predicted value
y	actual value

When the RANDOM= option is specified, the statistics do not include the unperturbed (_REP_=0) solution.

THEIL Option Output

The THEIL option specifies that Theil forecast error statistics be computed for the actual and predicted values and for the relative changes from lagged values. Mathematically, the quantities are

$$\hat{y}c = (\hat{y} - lag(y))/lag(y)$$

$$yc = (y - lag(y))/lag(y)$$

where $\hat{y}c$ is the relative change for the predicted value and *yc* is the relative change for the actual value.

```

Figure 20.71. THEIL Output

The columns have the following meaning:

Corr (R) is the correlation coefficient, ρ, between the actual and predicted values.

$$\rho = \frac{\mathrm{cov}(\mathrm{y}, \hat{\mathrm{y}})}{\sigma_a \sigma_p}$$

where σ_p and σ_a are the standard deviations of the predicted and actual values.

Bias (UM) is an indication of systematic error and measures the extent to which the average values of the actual and predicted deviate from each other.

$$\frac{(\mathrm{E}(\mathrm{y}) - \mathrm{E}(\hat{\mathrm{y}}))^2}{\frac{1}{N}\sum_{t=1}^{N}(y_t - \hat{y}_t)^2}$$

Reg (UR) is defined as $(\sigma_p - \rho * \sigma_a)^2/MSE$. Consider the regression

$$y = \alpha + \beta\hat{y}$$

If $\hat{\beta} = 1$, UR will equal zero.

Dist (UD) is defined as $(1 - \rho^2)\sigma_a\sigma_a/MSE$ and represents the variance of the residuals obtained by regressing *yc* on $\hat{y}c$.

Var (US) is the variance proportion. US indicates the ability of the model to replicate the degree of variability in the endogenous variable.

$$US = \frac{(\sigma_p - \sigma_a)^2}{MSE}$$

Covar (UC) represents the remaining error after deviations from average values and average variabilities have been accounted for.

$$UC = \frac{2(1-\rho)\sigma_p\sigma_a}{MSE}$$

U1 is a statistic measuring the accuracy of a forecast.

$$U1 = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N}\sum_{t=1}^{N}(y_t)^2}}$$

U is the Theil's inequality coefficient defined as follows:

$$U = \frac{\sqrt{MSE}}{\sqrt{\frac{1}{N}\sum_{t=1}^{N}(y_t)^2} + \sqrt{\frac{1}{N}\sum_{t=1}^{N}(\hat{y}_t)^2}}$$

MSE is the mean square error. In the case of the Relative Change Theil statistics, the MSE is computed as follows:

$$MSE = \frac{1}{N}\sum_{t=1}^{N}(\hat{y}c_t - yc_t)^2$$

More information on these statistics can be found in the references Maddala (1977, 344–347) and Pindyck and Rubinfeld (1981, 364–365).

Goal Seeking: Solving for Right-Hand-Side Variables

The process of computing input values needed to produce target results is often called *goal seeking*. To compute a goal-seeking solution, use a SOLVE statement that lists the variables you want to solve for and provide a data set containing values for the remaining variables.

Consider the following demand model for packaged rice

$$quantity\ demanded = \alpha_1 + \alpha_2 price^{2/3} + \alpha_3 income$$

where *price* is the price of the package and *income* is disposable personal income. The only variable the company has control over is the price it charges for rice. This model is estimated using the following simulated data and PROC MODEL statements:

```
data demand;
   do t=1 to 40;
       price = (rannor(10) +5) * 10;
       income = 8000 * t ** (1/8);
       demand = 7200 - 1054 * price ** (2/3) +
                7 * income + 100 * rannor(1);
       output;
   end;
run;

data goal;
    demand = 85000;
    income = 12686;
run;
```

The goal is to find the price the company would have to charge to meet a sales target of 85,000 units. To do this, a data set is created with a DEMAND variable set to 85000 and with an INCOME variable set to 12686, the last income value.

```
proc model data=demand ;
   demand = a1 - a2 * price ** (2/3) + a3 * income;
   fit demand / outest=demest;
run;
```

The desired price is then determined using the following PROC MODEL statement:

```
    solve price / estdata=demest data=goal solveprint;
run;
```

The SOLVEPRINT option prints the solution values, number of iterations, and final residuals at each observation. The SOLVEPRINT output from this solve is shown in Figure 20.72.

```
                        The MODEL Procedure
                     Single-Equation Simulation

Observation   1   Iterations   6   CC    0.000000   ERROR.demand    0.000000

                          Solution Values

                               price

                             33.59016
```

Figure 20.72. Goal Seeking, SOLVEPRINT Output

The output indicates that it took 6 Newton iterations to determine the PRICE of 33.5902, which makes the DEMAND value within 16E-11 of the goal of 85,000 units.

Consider a more ambitious goal of 100,000 units. The output shown in Figure 20.73 indicates that the sales target of 100,000 units is not attainable according to this model.

```
                                  The MODEL Procedure
                               Single-Equation Simulation

NOTE: 3 parameter estimates were read from the ESTDATA=DEMEST data set.

                                  The MODEL Procedure
                               Single-Equation Simulation

ERROR: Could not reduce norm of residuals in 10 subiterations.

ERROR: The solution failed because 1 equations are missing or have extreme
       values for observation 1 at NEWTON iteration 1.
NOTE: Additional information on the values of the variables at this
      observation, which may be helpful in determining the cause of the failure
      of the solution process, is printed below.

             Observation    1    Iteration    1    CC    -1.000000
                                 Missing      1
Iteration Errors - Missing.

             Observation    1    Iteration    1    CC    -1.000000
                                 Missing      1
ERROR: 2 execution errors for this observation
NOTE: Check for missing input data or uninitialized lags.
      (Note that the LAG and DIF functions return missing values for the
initial lag starting observations. This is a change from the 1982 and earlier
versions of SAS/ETS which returned zero for uninitialized lags.)
NOTE: Simulation aborted.
```

Figure 20.73. Goal Seeking, Convergence Failure

The program data vector indicates that even with PRICE nearly 0 (4.462312E-22) the demand is still 4,164 less than the goal. You may need to reformulate your model or collect more data to more accurately reflect the market response.

Numerical Solution Methods

If the SINGLE option is not used, PROC MODEL computes values that simultaneously satisfy the model equations for the variables named in the SOLVE statement. PROC MODEL provides three iterative methods, Newton, Jacobi, and Seidel, for computing a simultaneous solution of the system of nonlinear equations.

Single-Equation Solution

For normalized-form equation systems, the solution can either simultaneously satisfy all the equations or can be computed for each equation separately, using the actual values of the solution variables in the current period to compute each predicted value.

By default, PROC MODEL computes a simultaneous solution. The SINGLE option on the SOLVE statement selects single-equation solutions.

Single-equation simulations are often made to produce residuals (which estimate the random terms of the stochastic equations) rather than the predicted values themselves. If the input data and range are the same as that used for parameter estimation, a static single-equation simulation will reproduce the residuals of the estimation.

Newton's Method

The NEWTON option on the SOLVE statement requests Newton's method to simultaneously solve the equations for each observation. Newton's method is the default solution method. Newton's method is an iterative scheme that uses the derivatives of the equations with respect to the solution variables, *J*, to compute a change vector as

$$\Delta \mathbf{y}^i = J^{-1}\mathbf{q}(\mathbf{y}^i, \mathbf{x}, \theta)$$

PROC MODEL builds and solves *J* using efficient sparse matrix techniques. The solution variables $\mathbf{y}^i$ at the *i*th iteration are then updated as

$$\mathbf{y}^{i+1} = \mathbf{y}^i + d \times \Delta \mathbf{y}^i$$

d is a damping factor between 0 and 1 chosen iteratively so that

$$\|\mathbf{q}(\mathbf{y}^{i+1}, \mathbf{x}, \theta)\| < \|\mathbf{q}(\mathbf{y}^i, \mathbf{x}, \theta)\|$$

The number of subiterations allowed for finding a suitable *d* is controlled by the MAXSUBITER= option. The number of iterations of Newton's method allowed for each observation is controlled by MAXITER= option. Refer to Ortega and Rheinbolt (1970) for more details.

Jacobi Method

The JACOBI option on the SOLVE statement selects a matrix-free alternative to Newton's method. This method is the traditional nonlinear Jacobi method found in the literature. The Jacobi method as implemented in PROC MODEL substitutes predicted values for the endogenous variables and iterates until a fixed point is reached. Then necessary derivatives are computed only for the diagonal elements of the jacobian, **J**.

If the normalized-form equation is

$$\mathbf{y} = \mathbf{f}(\mathbf{y}, \mathbf{x}, \theta)$$

the Jacobi iteration has the form

$$\mathbf{y}^{i+1} = \mathbf{f}(\mathbf{y}^i, \mathbf{x}, \theta)$$

Seidel Method

The Seidel method is an order-dependent alternative to the Jacobi method. The Seidel method is selected by the SEIDEL option on the SOLVE statement. The Seidel method is like the Jacobi method except that in the Seidel method the model is further edited to substitute the predicted values into the solution variables immediately after they are computed. Seidel thus differs from the other methods in that the values of the solution variables are not fixed within an iteration. With the other methods, the order of the equations in the model program makes no difference, but the Seidel method may work much differently when the equations are specified in a different sequence. Note that this fixed point method is the traditional nonlinear Seidel method found in the literature.

The iteration has the form

$$\mathbf{y}_j^{i+1} = \mathbf{f}(\hat{\mathbf{y}}^i, \mathbf{x}, \theta)$$

where $\mathbf{y}_j^{i+1}$ is the *j*th equation variable at the *i*th iteration and

$$\hat{\mathbf{y}}^i = (y_1^{i+1}, y_2^{i+1}, y_3^{i+1}, \ldots, y_{j-1}^{i+1}, y_j^i, y_{j+1}^i, \ldots, y_g^i)'$$

If the model is recursive, and if the equations are in recursive order, the Seidel method will converge at once. If the model is block-recursive, the Seidel method may converge faster if the equations are grouped by block and the blocks are placed in block-recursive order. The BLOCK option can be used to determine the block-recursive form.

Jacobi and Seidel Methods with General Form Equations

Jacobi and Seidel solution methods support general form equations.

There are two cases where derivatives are (automatically) computed. The first case is for equations with the solution variable on the right-hand side and on the left-hand side of the equation

$$y^i = f(\mathbf{x}, y^i)$$

In this case the derivative of ERROR.y with respect to y is computed, and the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, y^i) - y^i}{\partial(f(\mathbf{x}, y^i) - y^i)/\partial y}$$

The second case is a system of equations containing one or more EQ.var equations. In this case, a heuristic algorithm is used to make the assignment of a unique solution variable to each general form equation. Use the DETAILS option on the SOLVE statement to print a listing of the assigned variables.

Once the assignment is made, the new y approximation is computed as

$$y^{i+1} = y^i - \frac{f(\mathbf{x}, \mathbf{y}^i) - y^i}{\partial(f(\mathbf{x}, \mathbf{y}^i) - y^i)/\partial y}$$

If k is the number of general form equations, then k derivatives are required.

The convergence properties of the Jacobi and Seidel solution methods remain significantly poorer than the default Newton's method.

Comparison of Methods

Newton's method is the default and should work better than the others for most small- to medium-sized models. The Seidel method is always faster than the Jacobi for recursive models with equations in recursive order. For very large models and some highly nonlinear smaller models, the Jacobi or Seidel methods can sometimes be faster. Newton's method uses more memory than the Jacobi or Seidel methods.

Both the Newton's method and the Jacobi method are order-invariant in the sense that the order in which equations are specified in the model program has no effect on the operation of the iterative solution process. In order-invariant methods, the values of the solution variables are fixed for the entire execution of the model program. Assignments to model variables are automatically changed to assignments to corresponding equation variables. Only after the model program has completed execution are the results used to compute the new solution values for the next iteration.

Troubleshooting Problems

In solving a simultaneous nonlinear dynamic model you may encounter some of the following problems.

Missing Values

For SOLVE tasks, there can be no missing parameter values. If there are missing right-hand-side variables, this will result in a missing left-hand-side variable for that observation.

Unstable Solutions

A solution may exist but be unstable. An unstable system can cause the Jacobi and Seidel methods to diverge.

Explosive Dynamic Systems

A model may have well-behaved solutions at each observation but be dynamically unstable. The solution may oscillate wildly or grow rapidly with time.

Propagation of Errors

During the solution process, solution variables can take on values that cause computational errors. For example, a solution variable that appears in a LOG function may be positive at the solution but may be given a negative value during one of the iterations. When computational errors occur, missing values are generated and propagated, and the solution process may collapse.

Convergence Problems

The following items can cause convergence problems:

- illegal function values (that is $\sqrt{-1}$)
- local minima in the model equation
- no solution exists
- multiple solutions exist
- initial values too far from the solution
- the CONVERGE= value too small.

When PROC MODEL fails to find a solution to the system, the current iteration information and the program data vector are printed. The simulation halts if actual values are not available for the simulation to proceed. Consider the following program:

```
data test1;
   do t=1 to 50;
      x1 = sqrt(t) ;
      y = .;
      output;
   end;

proc model data=test1;
   exogenous x1 ;
   control a1 -1 b1 -29 c1 -4 ;
   y = a1 * sqrt(y) + b1 * x1 * x1 + c1 * lag(x1);
   solve y / out=sim forecast dynamic ;
run;
```

which produces the output shown in Figure 20.74.

```

                                 Missing      1
ERROR: 1 execution errors for this observation
NOTE: Check for missing input data or uninitialized lags.
      (Note that the LAG and DIF functions return missing values for the
initial lag starting observations. This is a change from the 1982 and earlier
versions of SAS/ETS which returned zero for uninitialized lags.)
NOTE: Simulation aborted.
```

Figure 20.74. SOLVE Convergence Problems

At the first observation the following equation is attempted to be solved:

$$y = -\sqrt{y} - 62$$

There is no solution to this problem. The iterative solution process got as close as it could to making Y negative while still being able to evaluate the model. This problem can be avoided in this case by altering the equation.

In other models, the problem of missing values can be avoided by either altering the data set to provide better starting values for the solution variables or by altering the equations.

You should be aware that, in general, a nonlinear system can have any number of solutions, and the solution found may not be the one that you want. When multiple solutions exist, the solution that is found is usually determined by the starting values for the iterations. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at 0.

Iteration Output

The iteration output, produced by the ITPRINT option, is useful in determining the cause of a convergence problem. The ITPRINT option forces the printing of the solution approximation and equation errors at each iteration for each observation. A portion of the ITPRINT output from the following statement is shown in Figure 20.75.

```
proc model data=test1;
   exogenous x1 ;
   control a1 -1 b1 -29 c1 -4 ;
   y = a1 * sqrt(abs(y)) + b1 * x1 * x1 + c1 * lag(x1);
   solve y / out=sim forecast dynamic itprint;
run;
```

For each iteration, the equation with the largest error is listed in parentheses after the Newton convergence criteria measure. From this output you can determine which equation or equations in the system are not converging well.

```

Figure 20.75. SOLVE, ITPRINT Output

Numerical Integration

The differential equation system is numerically integrated to obtain a solution for the derivative variables at each data point. The integration is performed by evaluating the provided model at multiple points between each data point. The integration method used is a variable order, variable step-size backward difference scheme; for more detailed information, refer to Aiken (1985) and Byrne (1975). The step size or time step is chosen to satisfy a *local truncation error* requirement. The term *truncation error* comes from the fact that the integration scheme uses a truncated series expansion of the integrated function to do the integration. Because the series is truncated, the integration scheme is within the truncation error of the true value.

To further improve the accuracy of the integration, the total integration time is broken up into small intervals (time steps or step sizes), and the integration scheme is applied to those intervals. The integration at each time step uses the values computed at the previous time step so that the truncation error tends to accumulate. It is usually not possible to estimate the global error with much precision. The best that can be done is to monitor and to control the local truncation error, which is the truncation error committed at each time step relative to

$$d = \max_{0 \le t \le T} (\|y(t)\|_\infty, 1)$$

where $y(t)$ is the integrated variable. Furthermore, the $y(t)$s are dynamically scaled to within two orders of magnitude one to keep the error monitoring well behaved.

The local truncation error requirement defaults to $1.0E - 9$. You can specify the LTEBOUND= option to modify that requirement. The LTEBOUND= option is a relative measure of accuracy, so a value smaller than $1.0E - 10$ is usually not practical. A larger bound increases the speed of the simulation and estimation but decreases the accuracy of the results. If the LTEBOUND= option is set too small, the integrator is not able to take time steps small enough to satisfy the local truncation error requirement and still have enough machine precision to compute the results. Since the integrations are scaled to within $1.0E - 2$ of one, the simulated values should be correct to at least seven decimal places.

There is a default minimum time step of $1.0E - 14$. This minimum time step is controlled by the MINTIMESTEP= option and the machine epsilon. If the minimum time step is smaller than the machine epsilon times the final time value, the minimum time step is increased automatically.

For the points between each observation in the data set, the values for nonintegrated variables in the data set are obtained from a linear interpolation from the two closest points. Lagged variables can be used with integrations, but their values are discrete and are not interpolated between points. Lagging, therefore, can then be used to input step functions into the integration.

The derivatives necessary for estimation (the gradient with respect to the parameters) and goal seeking (the Jacobian) are computed by numerically integrating analytical derivatives. The accuracy of the derivatives is controlled by the same integration techniques mentioned previously.

Limitations

There are limitations to the types of differential equations that can be solved or estimated. One type is an explosive differential equation (finite escape velocity) for which the following differential equation is an example:

$$y^{'} = a{\times}y, \quad a > 0$$

If this differential equation is integrated too far in time, y exceeds the maximum value allowed on the computer, and the integration terminates.

Likewise, differential systems that are singular cannot be solved or estimated in general. For example, consider the following differential system:

$$\begin{aligned} x^{'} &= -y^{'} + 2x + 4y + \exp(\mathrm{t}) \\ y^{'} &= -x^{'} + y + \exp(4{*}\mathrm{t}) \end{aligned}$$

This system has an analytical solution, but an accurate numerical solution is very difficult to obtain. The reason is that $y^{'}$ and $x^{'}$ cannot be isolated on the left-hand side of the equation. If the equation is modified slightly to

$$\begin{aligned} x^{'} &= -y^{'} + 2x + 4y + \exp(\mathrm{t}) \\ y^{'} &= x^{'} + y + \exp(4\mathrm{t}) \end{aligned}$$

the system is nonsingular, but the integration process could still fail or be extremely slow. If the MODEL procedure encounters either system, a warning message is issued.

This system can be rewritten as the following recursive system,

$$\begin{aligned} x^{'} &= 0.5y + 0.5\exp(4t) + x + 1.5y - 0.5\exp(t) \\ y^{'} &= x^{'} + y + \exp(4\mathrm{t}) \end{aligned}$$

which can be estimated and simulated successfully with the MODEL procedure.

Petzold (1982) mentions a class of differential algebraic equations that, when integrated numerically, could produce incorrect or misleading results. An example of such a system mentioned in Petzold (1982) is

$$\begin{aligned} y_2^{'}(t) &= y_1(t) + g_1(t) \\ 0 &= y_2(t) + g_2(t) \end{aligned}$$

The analytical solution to this system depends on g and its derivatives at the current time only and not on its initial value or past history. You should avoid systems of this and other similar forms mentioned in Petzold (1982).

SOLVE Data Sets

SDATA= Input Data Set

The SDATA= option reads a cross-equation covariance matrix from a data set. The covariance matrix read from the SDATA= data set specified on the SOLVE statement is used to generate random equation errors when the RANDOM= option specifies Monte Carlo simulation.

Typically, the SDATA= data set is created by the OUTS= on a previous FIT statement. (The OUTS= data set from a FIT statement can be read back in by a SOLVE statement in the same PROC MODEL step.)

You can create an input SDATA= data set using the DATA step. PROC MODEL expects to find a character variable _NAME_ in the SDATA= data set as well as variables for the equations in the estimation or solution. For each observation with a _NAME_ value matching the name of an equation, PROC MODEL fills the corresponding row of the S matrix with the values of the names of equations found in the data set. If a row or column is omitted from the data set, an identity matrix row or column is assumed. Missing values are ignored. Since the S matrix is symmetric, you can include only a triangular part of the S matrix in the SDATA= data set with the omitted part indicated by missing values. If the SDATA= data set contains multiple observations with the same _NAME_, the last values supplied for the _NAME_ variable are used. The "OUTS= Data Set" section contains more details on the format of this data set.

Use the TYPE= option to specify the type of estimation method used to produce the S matrix you want to input.

ESTDATA= Input Data Set

The ESTDATA= option specifies an input data set that contains an observation with values for some or all of the model parameters. It can also contain observations with the rows of a covariance matrix for the parameters.

When the ESTDATA= option is used, parameter values are set from the first observation. If the RANDOM= option is used and the ESTDATA= data set contains a covariance matrix, the covariance matrix of the parameter estimates is read and used to generate pseudo-random shocks to the model parameters for Monte Carlo simulation. These random perturbations have a multivariate normal distribution with the covariance matrix read from the ESTDATA= data set.

The ESTDATA= data set is usually created by the OUTEST= option in a FIT statement. The OUTEST= data set contains the parameter estimates produced by the FIT statement and also contains the estimated covariance of the parameter estimates if the OUTCOV option is used. This OUTEST= data set can be read in by the ESTDATA= option in a SOLVE statement.

You can also create an ESTDATA= data set with a SAS DATA step program. The data set must contain a numeric variable for each parameter to be given a value or covariance column. The name of the variable in the ESTDATA= data set must match the name of the parameter in the model. Parameters with names longer than 32 characters cannot be set from an ESTDATA= data set. The data set must also contain a character variable _NAME_ of length 32. _NAME_ has a blank value for the observation that gives values to the parameters. _NAME_ contains the name of a parameter for observations defining rows of the covariance matrix.

More than one set of parameter estimates and covariances can be stored in the ESTDATA= data set if the observations for the different estimates are identified by the variable _TYPE_. _TYPE_ must be a character variable of length eight. The TYPE= option is used to select for input the part of the ESTDATA= data set for which the value of the _TYPE_ variable matches the value of the TYPE= option.

OUT= Data Set

The OUT= data set contains solution values, residual values, and actual values of the solution variables.

The OUT= data set contains the following variables:

- BY variables
- RANGE variable
- ID variables
- _TYPE_, a character variable of length eight identifying the type of observation. The _TYPE_ variable can be PREDICT, RESIDUAL, ACTUAL, or ERROR.
- _MODE_, a character variable of length eight identifying the solution mode. _MODE_ takes the value FORECAST or SIMULATE.
- if lags are used, a numeric variable, _LAG_, containing the number of dynamic lags that contribute to the solution. The value of _LAG_ is always zero for STATIC mode solutions. _LAG_ is set to a missing value for lag-starting observations.
- _REP_, a numeric variable containing the replication number, if the RANDOM= option is used. For example, if RANDOM=10, each input observation results in eleven output observations with _REP_ values 0 through 10. The observations with _REP_=0 are from the unperturbed solution. (The random-number generator functions are suppressed, and the parameter and endogenous perturbations are zero when _REP_=0.)
- _ERRORS_, a numeric variable containing the number of errors that occurred during the execution of the program for the last iteration for the observation. If the solution failed to converge, this is counted as one error, and the _ERRORS_ variable is made negative.
- solution and other variables. The solution variables contain solution or predicted values for _TYPE_=PREDICT observations, residuals for

TYPE=RESIDUAL observations, or actual values for _TYPE_=ACTUAL observations. The other model variables, and any other variables read from the input data set, are always actual values from the input data set.

- any other variables named in the OUTVARS statement. These can be program variables computed by the model program, CONTROL variables, parameters, or special variables in the model program. Compound variable names longer than 32 characters are truncated in the OUT= data set.

By default only the predicted values are written to the OUT= data set. The OUTRESID, OUTACTUAL, and OUTERROR options are used to add the residual, actual, and ERROR. values to the data set.

For examples of the OUT= data set, see Example 20.6 at the end of this chapter.

DATA= Input Data Set

The input data set should contain all of the exogenous variables and should supply nonmissing values for them for each period to be solved.

Solution variables can be supplied in the input data set and are used as follows:

- to supply initial lags. For example, if the lag length of the model is three, three observations are read in to feed the lags before any solutions are computed.
- to evaluate the goodness of fit. Goodness-of-fit measures are computed based on the difference between the solved values and the actual values supplied from the data set.
- to supply starting values for the iterative solution. If the value from the input data set for a solution variable is missing, the starting value for it is taken from the solution of the last period (if nonmissing) or else the solution estimate is started at zero.
- For STATIC mode solutions, actual values from the data set are used by the lagging functions for the solution variables.
- for FORECAST mode solutions, actual values from the data set are used as the solution values when nonmissing.

Programming Language Overview

Variables in the Model Program

Variable names are alphanumeric but must start with a letter. The length is limited to thirty-two characters.

PROC MODEL uses several classes of variables, and different variable classes are treated differently. Variable class is controlled by *declaration statements*. These are the VAR, ENDOGENOUS, and EXOGENOUS statements for model variables, the PARAMETERS statement for parameters, and the CONTROL statement for control class variables. These declaration statements have several valid abbreviations. Various *internal variables* are also made available to the model program to allow communication between the model program and the procedure. RANGE, ID, and BY variables are also available to the model program. Those variables not declared as any of the preceding classes are *program variables*.

Some classes of variables can be lagged; that is, their value at each observation is remembered, and previous values can be referred to by the lagging functions. Other classes have only a single value and are not affected by lagging functions. For example, parameters have only one value and are not affected by lagging functions; therefore, if P is a parameter, DIF*n*(P) is always 0, and LAG*n*(P) is always the same as P for all values of *n*.

The different variable classes and their roles in the model are described in the following.

Model Variables

Model variables are declared by VAR, ENDOGENOUS, or EXOGENOUS statements, or by FIT and SOLVE statements. The model variables are the variables that the model is intended to explain or predict.

PROC MODEL allows you to use expressions on the left-hand side of the equal sign to define model equations. For example, a log linear model for Y can be written as

```
log( y ) = a + b * x;
```

Previously, only a variable name was allowed on the left-hand side of the equal sign.

The text on the left hand side of the equation serves as the equation name used to identify the equation in printed output, in the OUT= data sets, and in FIT or SOLVE statements. To refer to equations specified using left-hand side expressions (on the FIT statement, for example), place the left-hand side expression in quotes. For example, the following statements fit a log linear model to the dependent variable Y:

```
proc model data=in;
   log( y ) = a + b * x;
   fit "log(y)";
run;
```

The estimation and simulation is performed by transforming the models into general form equations. No actual or predicted value is available for general form equations so no R^2 or adjusted R^2 will be computed.

Equation Variables

An equation variable is one of several special variables used by PROC MODEL to control the evaluation of model equations. An equation variable name consists of one of the prefixes EQ, RESID, ERROR, PRED, or ACTUAL, followed by a period and the name of a model equation.

Equation variable names can appear on parts of the PROC MODEL printed output, and they can be used in the model program. For example, RESID-prefixed variables can be used in LAG functions to define equations with moving-average error terms. See the "Autoregressive Moving-Average Error Processes" section earlier in this chapter for details.

The meaning of these prefixes is detailed in the "Equation Translations" section.

Parameters

Parameters are variables that have the same value for each observation. Parameters can be given values or can be estimated by fitting the model to data. During the SOLVE stage, parameters are treated as constants. If no estimation is performed, the SOLVE stage uses the initial value provided in either the ESTDATA= data set, the MODEL= file, or on the PARAMETER statement, as the value of the parameter.

The PARAMETERS statement declares the parameters of the model. Parameters are not lagged, and they cannot be changed by the model program.

Control Variables

Control variables supply constant values to the model program that can be used to control the model in various ways. The CONTROL statement declares control variables and specifies their values. A control variable is like a parameter except that it has a fixed value and is not estimated from the data.

Control variables are not reinitialized before each pass through the data and can thus be used to retain values between passes. You can use control variables to vary the program logic. Control variables are not affected by lagging functions.

For example, if you have two versions of an equation for a variable Y, you could put both versions in the model and, using a CONTROL statement to select one of them, produce two different solutions to explore the effect the choice of equation has on the model:

```
      select (case);
         when (1) y =  ...first version of equation... ;
         when (2) y =  ...second version of equation... ;
      end;
      control case 1;
      solve / out=case1;
   run;
```

```
      control case 2;
      solve / out=case2;
   run;
```

RANGE, ID, and BY Variables

The RANGE statement controls the range of observations in the input data set that is processed by PROC MODEL. The ID statement lists variables in the input data set that are used to identify observations on the printout and in the output data set. The BY statement can be used to make PROC MODEL perform a separate analysis for each BY group. The variable in the RANGE statement, the ID variables, and the BY variables are available for the model program to examine, but their values should not be changed by the program. The BY variables are not affected by lagging functions.

Internal Variables

You can use several internal variables in the model program to communicate with the procedure. For example, if you wanted PROC MODEL to list the values of all the variables when more than 10 iterations are performed and the procedure is past the 20th observation, you can write

```
   if _obs_ > 20 then if _iter_ > 10 then _list_ = 1;
```

Internal variables are not affected by lagging functions, and they cannot be changed by the model program except as noted. The following internal variables are available. The variables are all numeric except where noted.

ERRORS	a flag that is set to 0 at the start of program execution and is set to a nonzero value whenever an error occurs. The program can also set the _ERRORS_ variable.
ITER	the iteration number. For FIT tasks, the value of _ITER_ is negative for preliminary grid-search passes. The iterative phase of the estimation starts with iteration 0. After the estimates have converged, a final pass is made to collect statistics with _ITER_ set to a missing value. Note that at least one pass, and perhaps several subiteration passes as well, is made for each iteration. For SOLVE tasks, _ITER_ counts the iterations used to compute the simultaneous solution of the system.
LAG	the number of dynamic lags that contribute to the solution at the current observation. _LAG_ is always 0 for FIT tasks and for STATIC solutions. _LAG_ is set to a missing value during the lag starting phase.
LIST	list flag that is set to 0 at the start of program execution. The program can set _LIST_ to a nonzero value to request a listing of the values of all the variables in the program after the program has finished executing.

METHOD	is the solution method in use for SOLVE tasks. _METHOD_ is set to a blank value for FIT tasks. _METHOD_ is a character-valued variable. Values are NEWTON, JACOBI, SIEDEL, or ONEPASS.
MODE	takes the value ESTIMATE for FIT tasks and the value SIMULATE or FORECAST for SOLVE tasks. _MODE_ is a character-valued variable.
NMISS	the number of missing or otherwise unusable observations during the model estimation. For FIT tasks, _NMISS_ is initially set to 0; at the start of each iteration, _NMISS_ is set to the number of unusable observations for the previous iteration. For SOLVE tasks, _NMISS_ is set to a missing value.
NUSED	the number of nonmissing observations used in the estimation. For FIT tasks, PROC MODEL initially sets _NUSED_ to the number of parameters; at the start of each iteration, _NUSED_ is reset to the number of observations used in the previous iteration. For SOLVE tasks, _NUSED_ is set to a missing value.
OBS	counts the observations being processed. _OBS_ is negative or 0 for observations in the lag starting phase.
REP	the replication number for Monte Carlo simulation when the RANDOM= option is specified in the SOLVE statement. _REP_ is 0 when the RANDOM= option is not used and for FIT tasks. When _REP_=0, the random-number generator functions always return 0.
WEIGHT	the weight of the observation. For FIT tasks, _WEIGHT_ provides a weight for the observation in the estimation. _WEIGHT_ is initialized to 1.0 at the start of execution for FIT tasks. For SOLVE tasks, _WEIGHT_ is ignored.

Program Variables

Variables not in any of the other classes are called program variables. Program variables are used to hold intermediate results of calculations. Program variables are reinitialized to missing values before each observation is processed. Program variables can be lagged. The RETAIN statement can be used to give program variables initial values and enable them to keep their values between observations.

Character Variables

PROC MODEL supports both numeric and character variables. Character variables are not involved in the model specification but can be used to label observations, to write debugging messages, or for documentation purposes. All variables are numeric unless they are the following.

- character variables in a DATA= SAS data set
- program variables assigned a character value
- declared to be character by a LENGTH or ATTRIB statement.

Equation Translations

Equations written in normalized form are always automatically converted to general form equations. For example, when a normalized-form equation such as

```
y = a + b*x;
```

is encountered, it is translated into the equations

```
PRED.y = a + b*x;
RESID.y = PRED.y - ACTUAL.y;
ERROR.y = PRED.y - y;
```

If the same system is expressed as the following general-form equation, then this equation is used unchanged.

```
EQ.y = y -  a + b*x;
```

This makes it easy to solve for arbitrary variables and to modify the error terms for autoregressive or moving average models.

Use the LIST option to see how this transformation is performed. For example, the following statements produce the listing shown in Figure 20.76.

```
proc model data=line list;
    y = a1 + b1*x1 + c1*x2;
    fit y;
run;
```

```
                              The MODEL Procedure

                        Listing of Compiled Program Code
   Stmt     Line:Col       Statement as Parsed

      1     15820:39       PRED.y = a1 + b1 * x1 + c1 * x2;
      1     15820:39       RESID.y = PRED.y - ACTUAL.y;
      1     15820:39       ERROR.y = PRED.y - y;
```

Figure 20.76. LIST Output

PRED.Y is the predicted value of Y, and ACTUAL.Y is the value of Y in the data set. The predicted value minus the actual value, RESID.Y, is then the error term, ϵ, for the original Y equation. ACTUAL.Y and Y have the same value for parameter estimation. For solve tasks, ACTUAL.Y is still the value of Y in the data set but Y becomes the solved value; the value that satisfies PRED.Y - Y = 0.

The following are the equation variable definitions.

EQ.	The value of an EQ-prefixed equation variable (normally used to define a general-form equation) represents the failure of the equation to hold. When the EQ.*name* variable is 0, the *name* equation is satisfied.
RESID.	The RESID.*name* variables represent the stochastic parts of the equations and are used to define the objective function for the estimation process. A RESID.-prefixed equation variable is like an EQ-prefixed variable but makes it possible to use or transform the stochastic part of the equation. The RESID. equation is used in place of the ERROR. equation for model solutions if it has been reassigned or used in the equation.
ERROR.	An ERROR.*name* variable is like an EQ-prefixed variable, except that it is used only for model solution and does not affect parameter estimation.
PRED.	For a normalized-form equation (specified by assignment to a model variable), the PRED.*name* equation variable holds the predicted value, where *name* is the name of both the model variable and the corresponding equation. (PRED-prefixed variables are not created for general-form equations.)
ACTUAL.	For a normalized-form equation (specified by assignment to a model variable), the ACTUAL.*name* equation variable holds the value of the *name* model variable read from the input data set.
DERT.	The DERT.*name* variable defines a differential equation. Once defined, it may be used on the right-hand side of another equation.
H.	The H.*name* variable specifies the functional form for the variance of the named equation.
GMM_H.	This is created for H.*vars* and is the moment equation for the variance for GMM. This variable is used only for GMM.

```
GMM_H.name = RESID.name**2 - H.name;
```

MSE.	The MSE.*y* variable contains the value of the mean square error for *y* at each iteration. An MSE. variable is created for each dependent/endogenous variable in the model. These variables can be used to specify the missing lagged values in the estimation and simulation of GARCH type models.

```
demret = intercept ;
h.demret = arch0 +
             arch1 * xlag( resid.demret ** 2, mse.demret) +
             garch1 * zlag(h.demret, mse.demret) ;
```

NRESID.	This is created for H.*vars* and is the normalized residual of the variable <*name*>. The formula is

```
NRESID.name = RESID.name/ sqrt(H.name);
```

The three equation variable prefixes, RESID., ERROR., and EQ. allow for control over the objective function for the FIT, the SOLVE, or both the FIT and the SOLVE stages. For FIT tasks, PROC MODEL looks first for a RESID.*name* variable for each equation. If defined, the RESID-prefixed equation variable is used to define the objective function for the parameter estimation process. Otherwise, PROC MODEL looks for an EQ-prefixed variable for the equation and uses it instead.

For SOLVE tasks, PROC MODEL looks first for an ERROR.*name* variable for each equation. If defined, the ERROR-prefixed equation variable is used for the solution process. Otherwise, PROC MODEL looks for an EQ-prefixed variable for the equation and uses it instead. To solve the simultaneous equation system, PROC MODEL computes values of the solution variables (the model variables being solved for) that make all of the ERROR.name and EQ.*name* variables close to 0.

Derivatives

Nonlinear modeling techniques require the calculation of derivatives of certain variables with respect to other variables. The MODEL procedure includes an analytic differentiator that determines the model derivatives and generates program code to compute these derivatives. When parameters are estimated, the MODEL procedure takes the derivatives of the equation with respect to the parameters. When the model is solved, Newton's method requires the derivatives of the equations with respect to the variables solved for.

PROC MODEL uses exact mathematical formulas for derivatives of non-user-defined functions. For other functions, numerical derivatives are computed and used.

The differentiator differentiates the entire model program, including conditional logic and flow of control statements. Delayed definitions, as when the LAG of a program variable is referred to before the variable is assigned a value, are also differentiated correctly.

The differentiator includes optimization features that produce efficient code for the calculation of derivatives. However, when flow of control statements such as GOTO statements are used, the optimization process is impeded, and less efficient code for derivatives may be produced. Optimization is also reduced by conditional statements, iterative DO loops, and multiple assignments to the same variable.

The table of derivatives is printed with the LISTDER option. The code generated for the computation of the derivatives is printed with the LISTCODE option.

Derivative Variables

When the differentiator needs to generate code to evaluate the expression for the derivative of a variable, the result is stored in a special derivative variable. Derivative variables are not created when the derivative expression reduces to a previously computed result, a variable, or a constant. The names of derivative variables, which may sometimes appear in the printed output, have the form *@obj*/*@wrt*, where *obj* is the variable whose derivative is being taken and *wrt* is the variable that the differentiation is with respect to. For example, the derivative variable for the derivative of *Y* with respect to *X* is named *@Y/@X*.

The derivative variables cannot be accessed or used as part of the model program.

Mathematical Functions

The following is a brief summary of SAS functions useful for defining models. Additional functions and details are in *SAS Language: Reference*. Information on creating new functions can be found in *SAS/TOOLKIT Software: Usage and Reference*, chapter 15, "Writing a SAS Function or Call Routine."

ABS(*x*)	the absolute value of *x*
ARCOS(*x*)	the arccosine in radians of *x*. *x* should be between -1 and 1.
ARSIN(*x*)	the arcsine in radians of *x*. *x* should be between -1 and 1.
ATAN(*x*)	the arctangent in radians of *x*
COS(*x*)	the cosine of *x*. *x* is in radians.
COSH(*x*)	the hyperbolic cosine of *x*
EXP(*x*)	e^{x}
LOG(*x*)	the natural logarithm of *x*
LOG10(*x*)	the log base ten of *x*
LOG2(*x*)	the log base two of *x*
SIN(*x*)	the sine of *x*. *x* is in radians.
SINH(*x*)	the hyperbolic sine of *x*
SQRT(*x*)	the square root of *x*
TAN(*x*)	the tangent of *x*. *x* is in radians and is not an odd multiple of $\pi/2$.
TANH(*x*)	the hyperbolic tangent of *x*

Random-Number Functions

The MODEL procedure provides several functions for generating random numbers for Monte Carlo simulation. These functions use the same generators as the corresponding SAS DATA step functions.

The following random-number functions are supported: RANBIN, RANCAU, RAND, RANEXP, RANGAM, RANNOR, RANPOI, RANTBL, RANTRI, and RANUNI. For more information, refer to *SAS Language: Reference*.

Each reference to a random-number function sets up a separate pseudo-random sequence. Note that this means that two calls to the same random function with the same seed produce identical results. This is different from the behavior of the random-number functions used in the SAS DATA step. For example, the statements

```
x=rannor(123);
y=rannor(123);
z=rannor(567);
q=rand('BETA', 1, 12 );
```

produce identical values for X and Y, but Z is from an independent pseudo-random sequence.

For FIT tasks, all random-number functions always return 0. For SOLVE tasks, when Monte Carlo simulation is requested, a random-number function computes a new random number on the first iteration for an observation (if it is executed on that iteration) and returns that same value for all later iterations of that observation. When Monte Carlo simulation is not requested, random-number functions always return 0.

Functions Across Time

PROC MODEL provides four types of special built-in functions that refer to the values of variables and expressions in previous time periods. These functions have the form

LAG*n*(**[** *i* **,]** *x*)	returns the *i*th lag of *x*, where *n* is the maximum lag;
DIF*n*(*x*)	difference of *x* at lag *n*
ZLAG*n*(**[** *i* **,]** *x*)	returns the *i*th lag of *x*, where *n* is the maximum lag, with missing lags replaced with zero;
XLAG*n*(*x* **,** *y*)	returns the *n*th lag of *x* if *x* is nonmissing, or *y* if x is missing;
ZDIF*n*(*x*)	difference with lag length truncated and missing values converted to zero;
MOVAVGn(*x*)	the width of the moving average is *n*, and *x* is the variable or expression to compute the moving average of. Missing values of *x* are omitted in computing the average.

where *n* represents the number of periods, and *x* is any expression. The argument *i* is a variable or expression giving the lag length ($0 <= i <= n$), if the index value *i* is omitted, the maximum lag length *n* is used.

If you do not specify *n*, the number of periods is assumed to be one. For example, LAG(X) is the same as LAG1(X). No more than four digits can be used with a lagging function; that is, LAG9999 is the greatest LAG function, ZDIF9999 is the greatest ZDIF function, and so on.

The LAG functions get values from previous observations and make them available to the program. For example, LAG(X) returns the value of the variable X as it was computed in the execution of the program for the preceding observation. The expression LAG2(X+2*Y) returns the value of the expression X+2*Y, computed using the values of the variables X and Y that were computed by the execution of the program for the observation two periods ago.

The DIF functions return the difference between the current value of a variable or expression and the value of its LAG. For example, DIF2(X) is a short way of writing X-LAG2(X), and DIF15(SQRT(2*Z)) is a short way of writing SQRT(2*Z)-LAG15(SQRT(2*Z)).

The ZLAG and ZDIF functions are like the LAG and DIF functions, but they are not counted in the determination of the program lag length, and they replace missing values with 0s. The ZLAG function returns the lagged value if the lagged value is nonmissing, or 0 if the lagged value is missing. The ZDIF function returns the differenced value if the differenced value is nonmissing, or 0 if the value of the differenced value is missing. The ZLAG function is especially useful for models with ARMA error processes. See "Lag Logic", which follows for details.

Lag Logic

The LAG and DIF lagging functions in the MODEL procedure are different from the queuing functions with the same names in the DATA step. Lags are determined by the final values that are set for the program variables by the execution of the model program for the observation. This can have upsetting consequences for programs that take lags of program variables that are given different values at various places in the program, for example,

```
   temp = x + w;
   t    = lag( temp );
   temp = q - r;
   s    = lag( temp );
```

The expression LAG(TEMP) always refers to LAG(Q-R), never to LAG(X+W), since Q-R is the final value assigned to the variable TEMP by the model program. If LAG(X+W) is wanted for T, it should be computed as T=LAG(X+W) and not T=LAG(TEMP), as in the preceding example.

Care should also be exercised in using the DIF functions with program variables that may be reassigned later in the program. For example, the program

```
   temp =  x ;
   s    = dif( temp );
   temp = 3 * y;
```

computes values for S equivalent to

```
   s =  x  - lag( 3 * y );
```

Note that in the preceding examples, TEMP is a program variable, *not* a model variable. If it were a model variable, the assignments to it would be changed to assignments to a corresponding equation variable.

Note that whereas LAG1(LAG1(X)) is the same as LAG2(X), DIF1(DIF1(X)) is *not* the same as DIF2(X). The DIF2 function is the difference between the current period value at the point in the program where the function is executed and the final value at the end of execution two periods ago; DIF2 is not the second difference. In contrast, DIF1(DIF1(X)) is equal to DIF1(X)-LAG1(DIF1(X)), which equals X-2*LAG1(X)+LAG2(X), which is the second difference of X.

More information on the differences between PROC MODEL and the DATA step LAG and DIF functions is found in Chapter 2, “Working with Time Series Data.” .

Lag Lengths

The lag length of the model program is the number of lags needed for any relevant equation. The program lag length controls the number of observations used to initialize the lags.

PROC MODEL keeps track of the use of lags in the model program and automatically determines the lag length of each equation and of the model as a whole. PROC MODEL sets the program lag length to the maximum number of lags needed to compute any equation to be estimated, solved, or needed to compute any instrument variable used.

In determining the lag length, the ZLAG and ZDIF functions are treated as always having a lag length of 0. For example, if Y is computed as

```
   y = lag2( x + zdif3( temp ) );
```

then Y has a lag length of 2 (regardless of how TEMP is defined). If Y is computed as

```
   y = zlag2( x + dif3( temp ) );
```

then Y has a lag length of 0.

This is so that ARMA errors can be specified without causing the loss of additional observations to the lag starting phase and so that recursive lag specifications, such as moving-average error terms, can be used. Recursive lags are not permitted unless the ZLAG or ZDIF functions are used to truncate the lag length. For example, the following statement produces an error message:

```
   t = a + b * lag( t );
```

The program variable T depends recursively on its own lag, and the lag length of T is therefore undefined.

In the following equation RESID.Y depends on the predicted value for the Y equation but the predicted value for the Y equation depends on the LAG of RESID.Y, and, thus, the predicted value for the Y equation depends recursively on its own lag.

```
   y = yhat + ma * lag( resid.y );
```

The lag length is infinite, and PROC MODEL prints an error message and stops. Since this kind of specification is allowed, the recursion must be truncated at some point. The ZLAG and ZDIF functions do this.

The following equation is legal and results in a lag length for the Y equation equal to the lag length of YHAT:

```
   y = yhat + ma * zlag( resid.y );
```

Initially, the lags of RESID.Y are missing, and the ZLAG function replaces the missing residuals with 0s, their unconditional expected values.

The ZLAG0 function can be used to zero out the lag length of an expression. ZLAG0(*x*) returns the current period value of the expression *x*, if nonmissing, or else returns 0, and prevents the lag length of *x* from contributing to the lag length of the current statement.

Initializing Lags

At the start of each pass through the data set or BY group, the lag variables are set to missing values and an initialization is performed to fill the lags. During this phase, observations are read from the data set, and the model variables are given values from the data. If necessary, the model is executed to assign values to program variables that are used in lagging functions. The results for variables used in lag functions are saved. These observations are not included in the estimation or solution.

If, during the execution of the program for the lag starting phase, a lag function refers to lags that are missing, the lag function returns missing. Execution errors that occur while starting the lags are not reported unless requested. The modeling system automatically determines whether the program needs to be executed during the lag starting phase.

If L is the maximum lag length of any equation being fit or solved, then the first L observations are used to prime the lags. If a BY statement is used, the first L observations in the BY group are used to prime the lags. If a RANGE statement is used, the first L observations prior to the first observation requested in the RANGE statement are used to prime the lags. Therefore, there should be at least L observations in the data set.

Initial values for the lags of model variables can also be supplied in VAR, ENDOGENOUS, and EXOGENOUS statements. This feature provides initial lags of solution variables for dynamic solution when initial values for the solution variable are not available in the input data set. For example, the statement

```
   var x 2 3 y 4 5 z 1;
```

feeds the initial lags exactly like these values in an input data set:

Lag	X	Y	Z
2	3	5	.
1	2	4	1

If initial values for lags are available in the input data set and initial lag values are also given in a declaration statement, the values in the VAR, ENDOGENOUS, or EXOGENOUS statements take priority.

The RANGE statement is used to control the range of observations in the input data set that are processed by PROC MODEL. In the statement

```
   range date = '01jan1924'd to '01dec1943'd;
```

'01jan1924' specifies the starting period of the range, and '01dec1943' specifies the ending period. The observations in the data set immediately prior to the start of the range are used to initialize the lags.

Language Differences

For the most part, PROC MODEL programming statements work the same as they do in the DATA step as documented in *SAS Language: Reference*. However, there are several differences that should be noted.

DO Statement Differences

The DO statement in PROC MODEL does not allow a character index variable. Thus, the following DO statement is not valid in PROC MODEL, although it is supported in the DATA step:

```
   do i = 'A', 'B', 'C';         /* invalid PROC MODEL code */
```

IF Statement Differences

The IF statement in PROC MODEL does not allow a character-valued condition. For example, the following IF statement is not supported by PROC MODEL:

```
   if 'this' then  statement;
```

Comparisons of character values are supported in IF statements, so the following IF statement is acceptable:

```
   if 'this' < 'that' then  statement};
```

PROC MODEL allows for embedded conditionals in expressions. For example the following two statements are equivalent:

```
   flag = if time = 1 or time = 2 then conc+30/5 + dose*time
                else if time > 5 then (0=1) else (patient * flag);

   if time = 1 or time = 2 then flag= conc+30/5 + dose*time;
          else if time > 5 then flag=(0=1); else flag=patient*flag;
```

Note that the ELSE operator only involves the first object or token after it so that the following assignments are not equivalent:

```
   total = if sum > 0 then sum else sum + reserve;
   total = if sum > 0 then sum else (sum + reserve);
```

The first assignment makes TOTAL always equal to SUM plus RESERVE.

PUT Statement Differences

The PUT statement, mostly used in PROC MODEL for program debugging, only supports some of the features of the DATA step PUT statement. It also has some new features that the DATA step PUT statement does not support.

The PROC MODEL PUT statement does not support line pointers, factored lists, iteration factors, overprinting, the _INFILE_ option, or the colon (:) format modifier.

The PROC MODEL PUT statement does support expressions but an expression must be enclosed in parentheses. For example, the following statement prints the square root of x:

```
   put (sqrt(x));
```

Subscripted array names must be enclosed in parentheses. For example, the following statement prints the *i*th element of the array A:

```
   put (a i);
```

However, the following statement is an error:

```
   put a i;
```

The PROC MODEL PUT statement supports the print item _PDV_ to print a formatted listing of all the variables in the program. For example, the following statement prints a much more readable listing of the variables than does the _ALL_ print item:

```
   put _pdv_;
```

To print all the elements of the array A, use the following statement:

```
   put a;
```

To print all the elements of A with each value labeled by the name of the element variable, use the statement

```
   put a=;
```

ABORT Statement Difference

In the MODEL procedure, the ABORT statement does not allow any arguments.

SELECT/WHEN/OTHERWISE Statement Differences

The WHEN and OTHERWISE statements allow more than one target statement. That is, DO groups are not necessary for multiple statement WHENs. For example in PROC MODEL, the following syntax is valid:

```
select;
   when(exp1)
      stmt1;
      stmt2;
   when(exp2)
      stmt3;
      stmt4;
end;
```

The ARRAY Statement

ARRAY *arrayname [{dimensions}] [$ [length]] [variables and constants];*

The ARRAY statement is used to associate a name with a list of variables and constants. The array name can then be used with subscripts in the model program to refer to the items in the list.

In PROC MODEL, the ARRAY statement does not support all the features of the DATA step ARRAY statement. Implicit indexing cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement supported by PROC MODEL does allow both variables and constants to be used as array elements. You cannot make assignments to constant array elements. Both dimension specification and the list of elements are optional, but at least one must be supplied. When the list of elements is not given or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

The following are valid PROC MODEL array statements:

```
array x[120];           /* array X of length 120           */
array q[2,2];           /* Two dimensional array Q         */
array b[4] va vb vc vd; /* B[2] = VB, B[4] = VD            */
array x x1-x30;         /* array X of length 30, X[7] = X7  */
array a[5] (1 2 3 4 5); /* array A initialized to 1,2,3,4,5 */
```

RETAIN Statement

RETAIN *variables initial-values ;*

The RETAIN statement causes a program variable to hold its value from a previous observation until the variable is reassigned. The RETAIN statement can be used to initialize program variables.

The RETAIN statement does not work for model variables, parameters, or control variables because the values of these variables are under the control of PROC MODEL and not programming statements. Use the PARMS and CONTROL statements to initialize parameters and control variables. Use the VAR, ENDOGENOUS, or EXOGENOUS statement to initialize model variables.

Storing Programs in Model Files

Models can be saved and recalled from SAS catalog files. SAS catalogs are special files that can store many kinds of data structures as separate units in one SAS file. Each separate unit is called an entry, and each entry has an entry type that identifies its structure to the SAS system.

In general, to save a model, use the OUTMODEL=*name* option on the PROC MODEL statement, where *name* is specified as *libref.catalog.entry*, *libref.entry*, or *entry*. The *libref*, *catalog*, and *entry* names must be valid SAS names no more than 32 characters long. The *catalog* name is restricted to seven characters on the CMS operating system. If not given, the *catalog* name defaults to MODELS, and the *libref* defaults to WORK. The entry type is always MODEL. Thus, OUTMODEL=X writes the model to the file WORK.MODELS.X.MODEL.

The MODEL= option is used to read in a model. A list of model files can be specified in the MODEL= option, and a range of names with numeric suffixes can be given, as in MODEL=(MODEL1-MODEL10). When more than one model file is given, the list must be placed in parentheses, as in MODEL=(A B C), except in the case of a single name. If more than one model file is specified, the files are combined in the order listed in the MODEL= option.

When the MODEL= option is specified in the PROC MODEL statement and model definition statements are also given later in the PROC MODEL step, the model files are read in first, in the order listed, and the model program specified in the PROC MODEL step is appended after the model program read from the MODEL= files. The class assigned to a variable, when multiple model files are used, is the last declaration of that variable. For example, if Y1 was declared endogenous in the model file M1 and exogenous in the model file M2, the following statement will cause Y1 to be declared exogenous.

```
   proc model model=(m1 m2);
```

The INCLUDE statement can be used to append model code to the current model code. In contrast, when the MODEL= option is used on the RESET statement, the current model is deleted before the new model is read.

No model file is output by default if the PROC MODEL step performs any FIT or SOLVE tasks, or if the MODEL= option or the NOSTORE option is used. However, to ensure compatibility with previous versions of SAS/ETS software, when the PROC MODEL step does nothing but compile the model program, no input model file is read, and the NOSTORE option is not used, a model file is written. This model file is the default input file for a later PROC SYSNLIN or PROC SIMNLIN step. The default output model filename in this case is WORK.MODELS._MODEL_.MODEL.

If FIT statements are used to estimate model parameters, the parameter estimates written to the output model file are the estimates from the last estimation performed for each parameter.

Diagnostics and Debugging

PROC MODEL provides several features to aid in finding errors in the model program. These debugging features are not usually needed; most models can be developed without them.

The example model program that follows will be used in the following sections to illustrate the diagnostic and debugging capabilities. This example is the estimation of a segmented model.

```
*---------Fitting a Segmented Model using MODEL----*

Program Listing

The LIST option produces a listing of the model program. The statements are printed one per line with the original line number and column position of the statement.

The program listing from the example program is shown in Figure 20.77.

```
                              QUADRATIC MODEL WITH PLATEAU

                                  The MODEL Procedure

                            Listing of Compiled Program Code
          Stmt    Line:Col      Statement as Parsed

             1    15888:74      x0 = (-0.5 * b) / c;
             2    15888:96      if x < x0 then
             3    15888:124     PRED.y = a + b * x + c * x * x;
             3    15888:124     RESID.y = PRED.y - ACTUAL.y;
             3    15888:124     ERROR.y = PRED.y - y;
             4    15888:148     else
             5    15888:176     PRED.y = a + b * x0 + c * x0 * x0;
             5    15888:176     RESID.y = PRED.y - ACTUAL.y;
             5    15888:176     ERROR.y = PRED.y - y;
```

Figure 20.77. LIST Output for Segmented Model

The LIST option also shows the model translations that PROC MODEL performs. LIST output is useful for understanding the code generated by the %AR and the %MA macros.

Cross-Reference

The XREF option produces a cross-reference listing of the variables in the model program. The XREF listing is usually used in conjunction with the LIST option. The XREF listing does not include derivative (@-prefixed) variables. The XREF listing does not include generated assignments to equation variables, PRED, RESID, and ERROR-prefixed variables, unless the DETAILS option is used.

The cross-reference from the example program is shown in Figure 20.78.

```
                                  The MODEL Procedure

                          Cross Reference Listing For Program

```

Figure 20.78. XREF Output for Segmented Model

Compiler Listing

The LISTCODE option lists the model code and derivatives tables produced by the compiler. This listing is useful only for debugging and should not normally be needed.

LISTCODE prints the operator and operands of each operation generated by the compiler for each model program statement. Many of the operands are temporary variables generated by the compiler and given names such as #temp1. When derivatives are taken, the code listing includes the operations generated for the derivatives calculations. The derivatives tables are also listed.

A LISTCODE option prints the transformed equations from the example shown in Figure 20.79 and Figure 20.80.

```

Figure 20.80. LISTCODE Output for Segmented Model - Compiled Code

Analyzing the Structure of Large Models

PROC MODEL provides several features to aid in analyzing the structure of the model program. These features summarize properties of the model in various forms.

The following Klein's model program is used to introduce the LISTDEP, BLOCK, and GRAPH options.

```
proc model  out=m data=klein listdep graph block;
   endogenous c p w i x wsum k y;
   exogenous  wp g t year;
   parms c0-c3 i0-i3 w0-w3;
   a: c = c0 + c1 * p + c2 * lag(p) + c3 * wsum;
   b: i = i0 + i1 * p + i2 * lag(p) + i3 * lag(k);
   c: w = w0 + w1 * x + w2 * lag(x) + w3 * year;
   x = c + i + g;
   y = c + i + g-t;
   p = x-w-t;
   k = lag(k) + i;
   wsum = w + wp;
   id year;
run;
```

Dependency List

The LISTDEP option produces a dependency list for each variable in the model program. For each variable, a list of variables that depend on it and a list of variables it depends on is given. The dependency list produced by the example program is shown in Figure 20.81.

```
                              The MODEL Procedure

                        Dependency Listing For Program

                  Block 1    Depends On All_Exogenous
                  k          Depends On Block 1 All_Exogenous
                  y          Depends On Block 1 All_Exogenous
```

Figure 20.82. The BLOCK Output for Klein's Model

One use for the block output is to put a model in recursive form. Simulations of the model can be done with the SEIDEL method, which is efficient if the model is recursive and if the equations are in recursive order. By examining the block output, you can determine how to reorder the model equations for the most efficient simulation.

Adjacency Graph

The GRAPH option displays the same information as the BLOCK option with the addition of an adjacency graph. An X in a column in an adjacency graph indicates that the variable associated with the row depends on the variable associated with the column. The output produced by the example is shown in Figure 20.83.

The first and last graphs are straightforward. The middle graph represents the dependencies of the nonexogenous variables after transitive closure has been performed (that is, A depends on B, and B depends on C, so A depends on C). The preceding transitive closure matrix indicates that K and Y do not directly or indirectly depend on each other.

```

Figure 20.83. The GRAPH Output for Klein’s Model

Examples

Example 20.1. OLS Single Nonlinear Equation

This example illustrates the use of the MODEL procedure for nonlinear ordinary least-squares (OLS) regression. The model is a logistic growth curve for the population of the United States. The data is the population in millions recorded at ten year intervals starting in 1790 and ending in 2000. For an explanation of the starting values given by the START= option, see "Troubleshooting Convergence Problems" earlier in this chapter. Portions of the output from the following code are shown in Output 20.1.1 and Output 20.1.2.

```
title 'Logistic Growth Curve Model of U.S. Population';
data uspop;
   input pop :6.3 @@;
   retain year 1780;
   year=year+10;
   label pop='U.S. Population in Millions';

                   Nonlinear OLS Summary of Residual Errors

                 DF      DF                                           Adj
   Equation   Model   Error        SSE        MSE   R-Square         R-Sq

   pop            3      18      345.6    19.2020     0.9972       0.9969

                      Nonlinear OLS Parameter Estimates

                               Approx                  Approx
Parameter       Estimate      Std Err    t Value     Pr > |t|    Label

a               387.9307      30.0404      12.91       <.0001    Maximum Population
b               3.990385       0.0695      57.44       <.0001    Location Parameter
c               0.022703      0.00107      21.22       <.0001    Initial Growth Rate
```

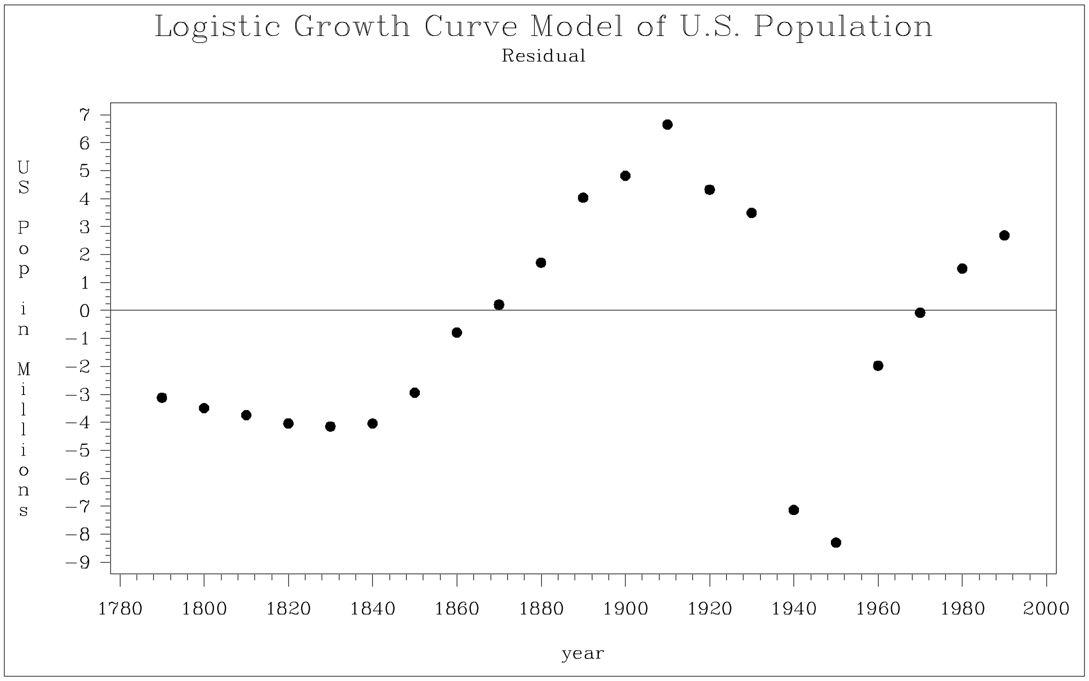
The adjusted R^2 value indicates the model fits the data well. There are only 21 observations and the model is nonlinear, so significance tests on the parameters are only approximate. The significance tests and associated approximate probabilities indicate that all the parameters are significantly different from 0.

The FIT statement included the options OUT=RESID and OUTRESID so that the residuals from the estimation are saved to the data set RESID. The residuals are plotted to check for heteroscedasticity using PROC GPLOT as follows.

```
   proc gplot data=resid;
    axis2 label=( a=-90 r=90 'US Pop in Millions' );
    plot pop*year / vref=0 vaxis=axis2
                    haxis=1780 to 2000 by 20;
    title2 "Residual";
    symbol1 v=dot;
   run;
```

The plot is shown in Output 20.1.3.

Output 20.1.3. Residual for Population Model (Actual - Predicted)



The residuals do not appear to be independent, and the model could be modified to explain the remaining nonrandom errors.

Example 20.2. A Consumer Demand Model

This example shows the estimation of a system of nonlinear consumer demand equations based on the translog functional form using seemingly unrelated regression (SUR). Expenditure shares and corresponding normalized prices are given for three goods.

Since the shares add up to one, the system is singular; therefore, one equation is omitted from the estimation process. The choice of which equation to omit is arbitrary. The nonlinear system is first estimated in unrestricted form.

```
title1 'Consumer Demand--Translog Functional Form';
title2 'Nonsymmetric Model';
proc model data=tlog1;
   endogenous share1 share2;
   parms a1 a2 b11 b12 b13 b21 b22 b23 b31 b32 b33;

```

The model is then estimated under the restriction of symmetry (b_{ij}=b_{ji}).

Hypothesis testing requires that the **S** matrix from the unrestricted model be imposed on the restricted model, as explained in "Tests on Parameters" in this chapter. The **S** matrix saved in the data set SMATRIX is requested by the SDATA= option.

A portion of the printed output produced in the following example is shown in Output 20.2.2.

```
title2 'Symmetric Model';
proc model data=tlog1;

                  b32 1.11 b33 .71 ) / sdata=smatrix sur;
   run;
```

A chi-square test is used to see if the hypothesis of symmetry is accepted or rejected. (*Oc*-*Ou*) has a chi-square distribution asymptotically, where *Oc* is the constrained OBJECTIVE*N and *Ou* is the unconstrained OBJECTIVE*N. The degrees of freedom is equal to the difference in the number of free parameters in the two models.

In this example, Ou is 76.9697 and Oc is 78.4097, resulting in a difference of 1.44 with 3 degrees of freedom. You can obtain the probability value by using the following statements:

```
   data _null_;
                    /* reduced-full, nrestrictions */
      p = 1-probchi( 1.44, 3 );
      put p=;
   run;
```

The output from this DATA step run is ‘P=0.6961858724’. With this probability you cannot reject the hypothesis of symmetry. This test is asymptotically valid.

Output 20.2.2. Estimation Results from the Restricted Model

Example 20.3. Vector AR(1) Estimation

This example shows the estimation of a two-variable vector AR(1) error process for the Grunfeld model (Grunfeld 1960) using the %AR macro. First, the full model is estimated. Second, the model is estimated with the restriction that the errors are univariate AR(1) instead of a vector process. The following produces Output 20.3.1 and Output 20.3.2.

```
data grunfeld;
   input year gei gef gec whi whf whc;
   label gei = 'Gross Investment GE'
         gec = 'Capital Stock Lagged GE'
         gef = 'Value of Outstanding Shares GE Lagged'
         whi = 'Gross Investment WH'
         whc = 'Capital Stock Lagged WH'
         whf = 'Value of Outstanding Shares Lagged WH';

title1 'Example of Vector AR(1) Error Process
            Using Grunfeld''s Model';
/* Note: GE stands for General Electric
            and WH for Westinghouse     */

proc model outmodel=grunmod;
   var gei whi gef gec whf whc;
   parms ge_int ge_f ge_c wh_int wh_f wh_c;
   label ge_int = 'GE Intercept'
         ge_f   = 'GE Lagged Share Value Coef'
         ge_c   = 'GE Lagged Capital Stock Coef'
         wh_int = 'WH Intercept'
         wh_f   = 'WH Lagged Share Value Coef'
         wh_c   = 'WH Lagged Capital Stock Coef';
   gei = ge_int + ge_f * gef + ge_c * gec;
   whi = wh_int + wh_f * whf + wh_c * whc;
run;
```

The preceding PROC MODEL step defines the structural model and stores it in the model file named GRUNMOD.

The following PROC MODEL step reads in the model, adds the vector autoregressive terms using %AR, and requests SUR estimation using the FIT statement.

```
title2 'With Unrestricted Vector AR(1) Error Process';
proc model data=grunfeld model=grunmod;
   %ar( ar, 1, gei whi )
   fit gei whi / sur;
run;
```

The final PROC MODEL step estimates the restricted model.

```
title2 'With restricted AR(1) Error Process';
proc model data=grunfeld model=grunmod;
   %ar( gei, 1 )
   %ar( whi, 1)
   fit gei whi / sur;
run;
```

Example 20.4. MA(1) Estimation

This example estimates parameters for an MA(1) error process for the Grunfeld model, using both the unconditional least-squares and the maximum-likelihood methods. The ARIMA procedure estimates for Westinghouse equation are shown for comparison. The output of the following code is summarized in Output 20.4.1:

```
title1 'Example of MA(1) Error Process Using Grunfeld''s Model';
title2 'MA(1) Error Process Using Unconditional Least Squares';
proc model data=grunfeld model=grunmod;
   %ma(gei,1, m=uls);
   %ma(whi,1, m=uls);
   fit whi gei start=( gei_m1 0.8 -0.8) / startiter=2;
run;
```

Output 20.4.1. PROC MODEL Results Using ULS Estimation

```

The model stored in Example 20.3 is read in using the MODEL= option and the moving average terms are added using the %MA macro.

The MA(1) model using maximum likelihood is estimated using the following:

```
   title2 'MA(1) Error Process Using Maximum Likelihood ';
   proc model data=grunfeld model=grunmod;
      %ma(gei,1, m=ml);
      %ma(whi,1, m=ml);
      fit whi gei;
   run;
```

For comparison, the model is estimated using PROC ARIMA as follows:

```
   title2 'PROC ARIMA Using Maximum Likelihood ';
   proc arima data=grunfeld;
      identify var=whi cross=(whf whc) noprint;
      estimate q=1 input=(whf whc) method=ml;
   run;
```

PROC ARIMA does not estimate systems so only one equation is evaluated.

The estimation results are shown in Output 20.4.3 and Output 20.4.4. The small differences in the parameter values between PROC MODEL and PROC ARIMA can be eliminated by tightening the convergence criteria for both procedures.

Example 20.5. Polynomial Distributed Lags Using %PDL

This example shows the use of the %PDL macro for polynomial distributed lag models. Simulated data is generated so that Y is a linear function of six lags of X, with the lag coefficients following a quadratic polynomial. The model is estimated using a fourth-degree polynomial, both with and without endpoint constraints. The example uses simulated data generated from the following model:

$$y_t = 10 + \sum_{z=0}^{6} f(z)x_{t-z} + \epsilon$$

$$f(z) = -5z^2 + 1.5z$$

The LIST option prints the model statements added by the %PDL macro.

```
/*--------------------------------------------------------------*/
/*  Generate Simulated Data for a Linear Model with a PDL on X  */
/*        y = 10 + x(6,2) + e                                   */
/*        pdl(x) = -5.*(lg)**2 + 1.5*(lg) + 0.                  */
/*--------------------------------------------------------------*/
data pdl;
   pdl2=-5.; pdl1=1.5; pdl0=0;
   array zz(i) z0-z6;
   do i=1 to 7;
      z=i-1;
      zz=pdl2*z**2 + pdl1*z + pdl0;
      end;
   do n=-11 to 30;
      x  =10*ranuni(1234567)-5;
      pdl=z0*x + z1*xl1 + z2*xl2 + z3*xl3 + z4*xl4 + z5*xl5 + z6*xl6;
      e  =10*rannor(123);
      y  =10+pdl+e;
      if n>=1 then output;
      xl6=xl5; xl5=xl4; xl4=xl3; xl3=xl2; xl2=xl1; xl1=x;
      end;
run;

```

The LIST output for the model without endpoint restrictions is shown in Output 20.5.1 and Output 20.5.2. The first seven statements in the generated program are the polynomial expressions for lag parameters XPDL_L0 through XPDL_L6. The estimated parameters are INT, XPDL_0, XPDL_1, XPDL_2, XPDL_3, and XPDL_4.

Portions of the output produced by the following PDL model with endpoints of the model restricted to 0 are presented in Output 20.5.3 and Output 20.5.4.

```
title3 'Estimation of PDL(6,4) Model-- Both Endpoint Restrictions';
proc model data=pdl ;
   parms int;                  /* declare the intercept parameter */
   %pdl( xpdl, 6, 4, r=both )  /* declare the lag distribution */
   y = int + %pdl( xpdl, x );  /* define the model equation */
   fit y /list;                /* estimate the parameters */
run;
```

Output 20.5.3. PROC MODEL Results Specifying Both Endpoint Restrictions

XPDL_2         13.88433         5.4361       2.55       0.0189    PDL(XPDL,6,4)
                                                                  parameter for (L)**2
XPDL_3          -9.3535         1.7602      -5.31       <.0001    PDL(XPDL,6,4)
                                                                  parameter for (L)**3
XPDL_4         1.032421         0.1471       7.02       <.0001    PDL(XPDL,6,4)
                                                                  parameter for (L)**4
```

Note that XPDL_0 and XPDL_1 are not shown in the estimate summary. They were used to satisfy the endpoint restrictions analytically by the generated %PDL macro code. Their values can be determined by back substitution.

To estimate the PDL model with one or more of the polynomial terms dropped, specify the largest degree of the polynomial desired with the %PDL macro and use the DROP= option on the FIT statement to remove the unwanted terms. The dropped parameters should be set to 0. The following PROC MODEL code demonstrates estimation with a PDL of degree 2 without the 0th order term.

```
title3 'Estimation of PDL(6,2) Model-- With XPDL_0 Dropped';
proc model data=pdl list;
   parms int;                  /* declare the intercept parameter */
   %pdl( xpdl, 6, 2 )          /* declare the lag distribution */
   y = int + %pdl( xpdl, x );  /* define the model equation */
   xpdl_0 =0;
   fit y drop=xpdl_0;          /* estimate the parameters */
run;
```

The results from this estimation are shown in Output 20.5.4.

Example 20.6. General-Form Equations

Data for this example are generated. General-form equations are estimated and forecast using PROC MODEL. The system is a basic supply-demand model. Portions of the output from the following code is shown in Output 20.6.1 through Output 20.6.4.

```
title1 "General Form Equations for Supply-Demand Model";

proc model;
   var price quantity income unitcost;
   parms d0-d2 s0-s2;
   eq.demand=d0+d1*price+d2*income-quantity;
   eq.supply=s0+s1*price+s2*unitcost-quantity;

/* estimate the model parameters */
   fit supply demand / data=history outest=est n2sls;
   instruments income unitcost year;
run;

/* produce forecasts for income and unitcost assumptions */
   solve price quantity / data=assume out=pq;
run;

/* produce goal-seeking solutions for
     income and quantity assumptions*/
   solve price unitcost / data=goal out=pc;
run;

title2 "Parameter Estimates for the System";
proc print data=est;
run;

title2 "Price Quantity Solution";
```

```
   proc print data=pq;
   run;

   title2 "Price Unitcost Solution";
   proc print data=pc;
   run;
```

Three data sets were used in this example. The first data set, HISTORY, was used to estimate the parameters of the model. The ASSUME data set was used to produce a forecast of PRICE and QUANTITY. Notice that the ASSUME data set does not have to contain the variables PRICE and QUANTITY.

```
   data history;
      input year income unitcost price quantity;
      datalines;
   1976    2221.87    3.31220     0.17903    266.714

Example 20.7. Spring and Damper Continuous System

This model simulates the mechanical behavior of a spring and damper system shown in Figure 20.84.

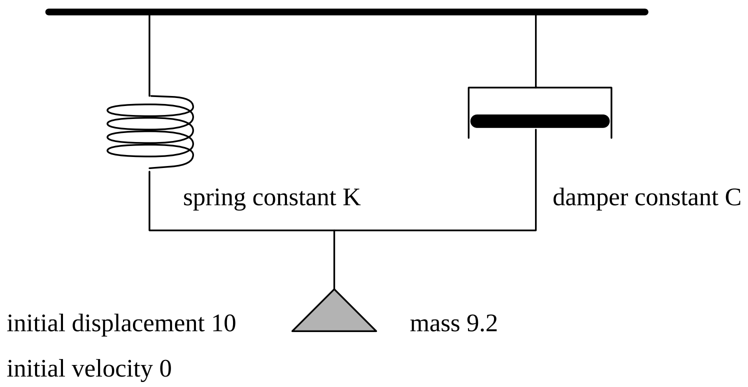

Figure 20.84. Spring and Damper System Model

A mass is hung from a spring with spring constant K. The motion is slowed by a damper with damper constant C. The damping force is proportional to the velocity, while the spring force is proportional to the displacement.

This is actually a continuous system; however, the behavior can be approximated by a discrete time model. We approximate the differential equation

$$\frac{\partial\, disp}{\partial\, time} = velocity$$

with the difference equation

$$\frac{\Delta\, disp}{\Delta\, time} = velocity$$

This is rewritten

$$\frac{disp - \mathrm{LAG(disp)}}{dt} = velocity$$

where *dt* is the time step used. In PROC MODEL, this is expressed with the program statement

```
disp = lag(disp) + vel * dt;
```

or

```
dert.disp = vel;
```

The first statement is simply a computing formula for Euler's approximation for the integral

$$disp = \int velocity\, dt$$

If the time step is small enough with respect to the changes in the system, the approximation is good. Although PROC MODEL does not have the variable step-size and error-monitoring features of simulators designed for continuous systems, the procedure is a good tool to use for less challenging continuous models.

The second form instructs the MODEL procedure to do the integration for you.

This model is unusual because there are no exogenous variables, and endogenous data are not needed. Although you still need a SAS data set to count the simulation periods, no actual data are brought in.

Since the variables DISP and VEL are lagged, initial values specified in the VAR statement determine the starting state of the system. The mass, time step, spring constant, and damper constant are declared and initialized by a CONTROL statement.

```
title1 'Simulation of Spring-Mass-Damper System';

/*- Generate some obs. to drive the simulation time periods ---*/
data one;
   do n=1 to 100;
      output;
   end;
run;
```

```
proc model data=one;
   var      force -200  disp  10  vel  0  accel -20  time 0;
   control  mass   9.2  c    1.5  dt  .1  k      20;
   force = -k * disp -c * vel;
   disp  = lag(disp) + vel * dt;
   vel   = lag(vel) + accel * dt;
   accel = force / mass;
   time  = lag(time) + dt;
```

The displacement scale is zeroed at the point where the force of gravity is offset, so the acceleration of the gravity constant is omitted from the force equation. The control variable C and K represent the damper and the spring constants respectively.

The model is simulated three times, and the simulation results are written to output data sets. The first run uses the original initial conditions specified in the VAR statement. In the second run, the initial displacement is doubled; the results show that the period of the motion is unaffected by the amplitude. In the third run, the DERT. syntax is used to do the integration. Notice that the path of the displacement is close to the old path, indicating that the original time step is short enough to yield an accurate solution. These simulations are performed by the following statements:

```
/*- Simulate the model for the base case -------------------*/
   control run '1';
   solve / out=a;
run;

/*- Simulate the model with twice the initial displacement -*/
   control run '2';
   var disp 20;
   solve / out=c;
run;

/*- Simulate the model with dert. syntax -------------*/
data two;
          do time = 0 to 10 by .2; output;end;
  run;
proc model data=two;
   var      force -200  disp  10  vel  0  accel -20  time 0;
   control  mass   9.2  c    1.5  dt  .1  k      20;
   control run '3' ;
   force = -k * disp -c * vel;
   dert.disp  = vel ;
   dert.vel   = accel;
   accel = force / mass;
   solve / out=b ;
        id time ;
run;
```

The output SAS data sets containing the solution results are merged and the displacement time paths for the three simulations are plotted. The three runs are identified on the plot as 1, 2, and 3. The following code produces Output 20.7.1 through Output 20.7.2.

```
/*- Plot the results ---------------------------------------*/
data p;
   set a b c;
run;

title2 'Overlay Plot of All Three Simulations';
proc gplot data=p;
   plot disp*time=run;
run;
```

Output 20.7.1. Printed Output Produced by PROC MODEL SOLVE Statements

Example 20.8. Nonlinear FIML Estimation

The data and model for this example were obtained from Bard (1974, p.133-138). The example is a two-equation econometric model used by Bodkin and Klein to fit U.S production data for the years 1909-1949. The model is the following:

$$g_1 = c_1 10^{c_2 z_4}(c_5 z_1^{-c_4} + (1 - c_5) z_2^{-c_4})^{-c_3/c_4} - z_3 = 0$$

$$g_2 = [c_5/(1 - c_5)](z_1/z_2)^{(-1-c_4)} - z_5 = 0$$

where z_1 is capital input, z_2 is labor input, z_3 is real output, z_4 is time in years with 1929 as year zero, and z_5 is the ratio of price of capital services to wage scale. The c_i's are the unknown parameters. z_1 and z_2 are considered

endogenous variables. A FIML estimation is performed.

Example 20.9. Circuit Estimation

Consider the nonlinear circuit shown in Figure 20.85.

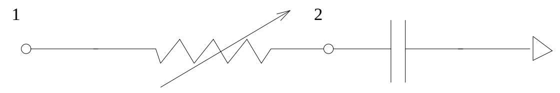

Figure 20.85. Nonlinear Resistor Capacitor Circuit

The theory of electric circuits is governed by Kirchhoff's laws: the sum of the currents flowing to a node is zero, and the net voltage drop around a closed loop is zero. In addition to Kirchhoff's laws, there are relationships between the current I through each element and the voltage drop V across the elements. For the circuit in Figure 20.85, the relationships are

$$C\frac{dV}{dt} = I$$

for the capacitor and

$$V = (R_1 + R_2(1 - \exp(-V)))I$$

for the nonlinear resistor. The following differential equation describes the current at node 2 as a function of time and voltage for this circuit:

label dvdt

$$C\frac{dV_2}{dt} - \frac{V_1 - V_2}{R_1 + R_2(1 - \exp(-V))} = 0$$

This equation can be written in the form

$$\frac{dV_2}{dt} = \frac{V_1 - V_2}{(R_1 + R_2(1 - \exp(-V)))C}$$

Consider the following data.

```

Example 20.10. Systems of Differential Equations

The following is a simplified reaction scheme for the competitive inhibitors with recombinant human renin (Morelock et al. 1995).

$$\begin{tikzcd}
E + D \arrow[r, shift left, "k1f"] & ED \arrow[l, shift left, "k1r"] \\
+ & \\
I \arrow[d, shift left, "k2f"] & \\
EI \arrow[u, shift left, "k2r"] &
\end{tikzcd}$$

Figure 20.86. Competitive Inhibition of Recombinant Human Renin

In Figure 20.86, E= enzyme, D= probe, and I= inhibitor.

The differential equations describing this reaction scheme are

$$\frac{dD}{dt} = k1r*ED - k1f*E*D$$

$$\frac{dED}{dt} = k1f*E*D - k1r*ED$$

$$\frac{dE}{dt} = k1r*ED - k1f*E*D + k2r*EI - k2f*E*I$$

$$\frac{dEI}{dt} = k2f*E*I - k2r*EI$$

$$\frac{dI}{dt} = k2r*EI - k2f*E*I$$

For this system, the initial values for the concentrations are derived from equilibrium considerations (as a function of parameters) or are provided as known values.

The experiment used to collect the data was carried out in two ways; pre-incubation (type='disassoc') and no pre-incubation (type='assoc'). The data also contain repeated measurements. The data contain values for fluorescence F, which is a function of concentration. Since there are no direct data for the concentrations, all the differential equations are simulated dynamically.

The SAS statements used to fit this model are

```
proc model data=fit;

   parameters qf  = 2.1e8
              qb  = 4.0e9
              k2f = 1.8e5
              k2r = 2.1e-3
              l   = 0;

              k1f = 6.85e6;
              k1r = 3.43e-4;

      /* Initial values for concentrations */
   control dt 5.0e-7
           et 5.0e-8
           it 8.05e-6;

      /* Association initial values --------------*/
   if type = 'assoc' and time=0 then
      do;
         ed = 0;
            /* solve quadratic equation ----------*/
         a = 1;
         b = -(&it+&et+(k2r/k2f));
         c = &it*&et;
         ei = (-b-(((b**2)-(4*a*c))**.5))/(2*a);
         d = &dt-ed;
         i = &it-ei;
         e = &et-ed-ei;
      end;

      /* Disassociation initial values ----------*/
   if type = 'disassoc' and time=0 then
      do;
         ei = 0;
         a = 1;
         b = -(&dt+&et+(&k1r/&k1f));
         c = &dt*&et;
         ed = (-b-(((b**2)-(4*a*c))**.5))/(2*a);
         d = &dt-ed;
         i = &it-ei;
         e = &et-ed-ei;
      end;

   if time ne 0 then
      do;
         dert.d = k1r* ed  - k1f *e *d;

         dert.ed = k1f* e *d - k1r*ed;

         dert.e = k1r* ed - k1f* e * d  + k2r * ei - k2f * e *i;

         dert.ei = k2f* e *i - k2r * ei;

         dert.i = k2r * ei - k2f* e *i;

      end;

      /* L - offset between curves  */
   if type = 'disassoc' then
           F = (qf*(d-ed)) + (qb*ed) -L;
   else
           F = (qf*(d-ed)) + (qb*ed);

   Fit F / method=marquardt;
run;
```

This estimation requires the repeated simulation of a system of 42 differential equations (5 base differential equations and 36 differential equations to compute the partials with respect to the parameters).

The results of the estimation are shown in Output 20.10.1.

Output 20.10.1. Kinetics Estimation

Example 20.11. Monte Carlo Simulation

This example illustrates how the form of the error in a ODE model affects the results from a static and dynamic estimation. The differential equation studied is

$$\frac{dy}{dt} = a - ay$$

The analytical solution to this differential equation is

$$y = 1 - \exp(-\mathrm{at})$$

The first data set contains errors that are strictly additive and independent. The data for this estimation are generated by the following DATA step:

```
data drive1;
   a = 0.5;
   do iter=1 to 100;
      do time = 0 to 50;
         y = 1 - exp(-a*time) + 0.1 *rannor(123);
         output;
      end;
   end;
```

The second data set contains errors that are cumulative in form.

```
data drive2;
   a = 0.5;
   yp = 1.0 + 0.01 *rannor(123);
   do iter=1 to 100;
```

```
         do time = 0 to 50;
            y = 1 - exp(-a)*(1 - yp);
            yp = y + 0.01 *rannor(123);
            output;
         end;
      end;
```

The following statements perform the 100 static estimations for each data set:

```
   proc model data=drive1 noprint;
      parm a 0.5;
      dert.y = a - a * y;
      fit y / outest=est;
      by iter;
   run;
```

Similar code is used to produce 100 dynamic estimations with a fixed and an unknown initial value. The first value in the data set is used to simulate an error in the initial value. The following PROC UNIVARIATE code processes the estimations:

```
   proc univariate data=est noprint;
      var a;
      output out=monte mean=mean p5=p5 p95=p95;
   run;

   proc print data=monte; run;
```

The results of these estimations are summarized in Table 20.5.

Table 20.5. Monte Carlo Summary, A=0.5

Estimation	Additive Error			Cumulative Error		
Type	mean	p95	p5	mean	p95	p5
static	0.77885	1.03524	0.54733	0.57863	1.16112	0.31334
dynamic fixed	0.48785	0.63273	0.37644	3.8546E24	8.88E10	-51.9249
dynamic unknown	0.48518	0.62452	0.36754	641704.51	1940.42	-25.6054

For this example model, it is evident that the static estimation is the least sensitive to misspecification.

Example 20.12. Cauchy Distribution Estimation

In this example a nonlinear model is estimated using the Cauchy distribution. Then a simulation is done for one observation in the data.

The following DATA step creates the data for the model.

```
       /* Generate a Cauchy distributed Y */
data c;
   format date monyy.;
   call streaminit(156789);
   do t=0 to 20 by 0.1;
      date=intnx('month','01jun90'd,(t*10)-1);
      x=rand('normal');
      e=rand('cauchy') + 10 ;
      y=exp(4*x)+e;
      output;
   end;
run;
```

The model to be estimated is

$$\begin{aligned} y &= e^{-a\,x} + \epsilon \\ \epsilon &\sim \text{Cauchy}(nc) \end{aligned}$$

That is, the residuals of the model are distributed as a Cauchy distribution with non-centrality parameter nc.

The log likelihood for the Cauchy distribution is

$$like = -\log(1 + (x - nc)^2 * \pi)$$

The following SAS statements specify the model and the log-likelihood function.

```
title2 'Cauchy Distribution';

proc model data=c ;
   dependent y;
   parm a -2 nc 4;
   y=exp(-a*x);

       /* Likelihood function for the residuals */
   obj = log(1+(-resid.y-nc)**2 * 3.1415926);

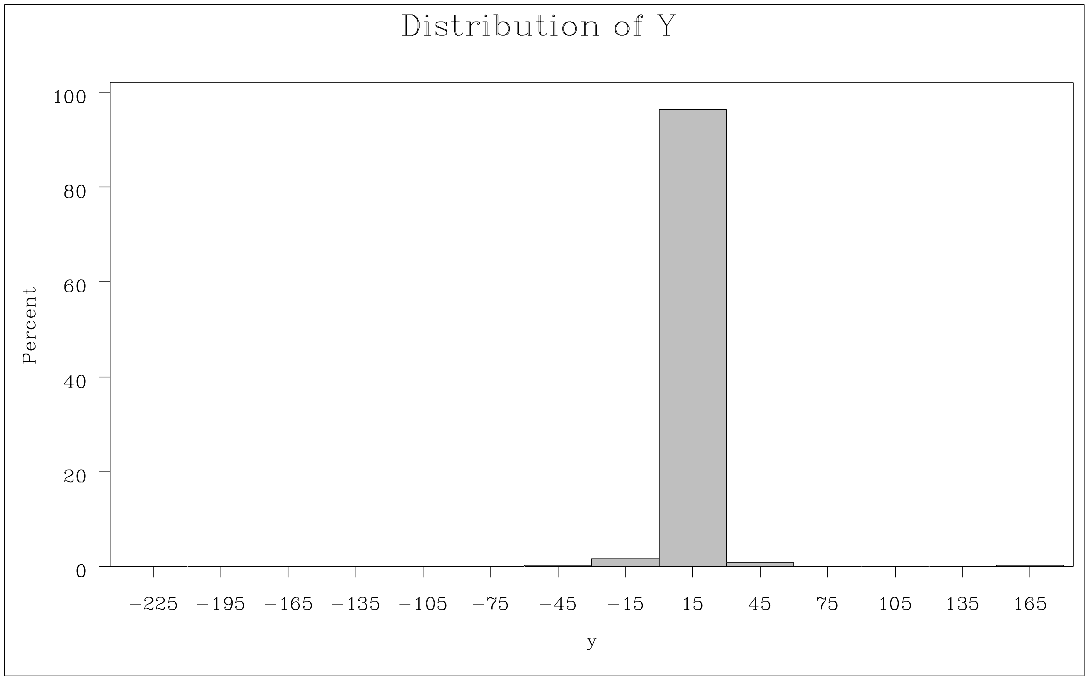
   errormodel y ~ general(obj) cdf=cauchy(nc);

   fit y / outsn=s1 method=marquardt;
   solve y / sdata=s1 data=c(obs=1) random=1000
             seed=256789 out=out1;
run;
```

The FIT statement uses the OUTSN= option to put out the Σ matrix for residuals from the normal distribution. The Σ matrix is 1×1 and has value 1.0 since it is a correlation matrix. The OUTS= matrix is the scalar 2989.0. Because the distribution is univariate (no covariances), the OUTS= would produce the same simulation results. The simulation is performed using the SOLVE statement.

The distribution of y is shown in the following output.

Output 20.12.1. Distribution of Y



Example 20.13. Switching Regression Example

Take the usual linear regression problem

$$y = X\beta + u$$

where *Y* denotes the *n* column vector of the dependent variable, *X* denotes the ($n \times k$) matrix of independent variables, β denotes the *k* column vector of coefficients to be estimated, *n* denotes the number of observations (*i*=1,2,...,*n*), and *k* denotes the number of independent variables.

You can take this basic equation and split it into two regimes, where the *i* th observation on *y* is generated by one regime or the other.

$$y_i = \sum_{j=1}^{k} \beta_{1j} X_{ji} + u_{1i} = x_i' \beta_1 + u_{1i}$$

$$y_i = \sum_{j=1}^{k} \beta_{2j} X_{ji} + u_{2i} = x_i' \beta_2 + u_{2i}$$

where x_{hi} and x_{hj} are the *i*th and *j*th observations, respec tively, on x_h. The errors, u_{1i} and u_{2i}, are assumed to be distributed normally and independently, with mean zero and constant variance. The variance for the first regime is σ_1^2, and the variance for the second regime is σ_2^2. If $\sigma_1^2 \neq \sigma_2^2$ and $\beta_1 \neq \beta_2$, the regression system given previously is thought to be switching between the two regimes.

The problem is to estimate β_1, β_2, σ_1, and σ_2 without knowing *a priori* which of the *n* values of the dependent variable, *y*, was generated by which regime. If it is known *a priori* which observations belong to which regime, a simple Chow test can be used to test $\sigma_1^2 = \sigma_2^2$ and $\beta_1 = \beta_2$.

Using Goldfeld and Quandt's D-method for switching regression, you can solve this problem. Assume that there exists observations on some exogenous variables z_{1i}, z_{2i}, ..., z_{pi}, where *z* determines whether the *i*th observation is generated from one equation or the other.

$$
\begin{aligned}
y_i &= x_i'\beta_1 + u_{1i} \quad \text{if} \sum_{j=1}^{p} \pi_j z_{ji} \le 0 \\
y_i &= x_i'\beta_2 + u_{2i} \quad \text{if} \sum_{j=1}^{p} \pi_j z_{ji} > 0
\end{aligned}
$$

where π_j are unknown coefficients to be estimated. Define $d(z_i)$ as a continuous approximation to a step function. Replacing the unit step function with a continuous approximation using the cumulative normal integral enables a more practical method that produces consistent estimates.

$$
d(z_i) = \frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{\sum \pi_j z_{ji}} exp\left[-\frac{1}{2} \frac{\xi^2}{\sigma^2} \right] d\xi
$$

D is the *n* dimensional diagonal matrix consisting of $d(z_i)$.

$$
D = \begin{bmatrix} d(z_1) & 0 & 0 & 0 \\ 0 & d(z_2) & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & d(z_n) \end{bmatrix}
$$

The parameters to estimate are now the *k* β_1's, the *k* β_2's, σ_1^2, σ_2^2, *p* π's, and the σ introduced in the $d(z_i)$ equation. The σ can be considered as given *a priori*, or it can be estimated, in which the estimated magnitude provides an estimate of the success in discriminating between the two regimes (Goldfeld and Quandt 1976).

$$
Y = (I - D)\, X\beta_1 + DX\beta_2 + W
$$

where $W = (I - D)U_1 + DU_2$, and *W* is a vector of unob servable and heteroscedastic error terms. The covariance matrix of *W* is denoted by Ω, where $\Omega = (I - D)^2\sigma_1^2 + D^2\sigma_2^2$. The maximum likelihood parameter estimates maximize the following log-likelihood function.

$$\begin{aligned} logL &= -\frac{n}{2}\log 2\pi - \frac{1}{2}\log \mid \Omega \mid - \\ &\frac{1}{2} * \left[[Y-(I-D)X\beta_1 - DX\beta_2]'\,\Omega^{-1}\,[Y-(I-D)X\beta_1 - DX\beta_2]\right] \end{aligned}$$

As an example, you now can use this switching regression likelihood to develop a model of housing starts as a function of changes in mortgage interest rates. The data for this example is from the U.S. Census Bureau and covers the period from January 1973 to March 1999. The hypothesis is that there will be different coefficients on your model based on whether the interest rates are going up or down.

So the model for z_i will be the following

$$z_i = p * (rate_i - rate_{i-1})$$

where $rate_i$ is the mortgage interest rate at time i and p is a scale parameter to be estimated.

The regression model will be the following

$$\begin{aligned} starts_i &= intercept_1 + ar1 * starts_{i-1} + djf1 * decjanfeb \qquad z_i < 0 \\ starts_i &= intercept_2 + ar2 * starts_{i-1} + djf2 * decjanfeb \qquad z_i >= 0 \end{aligned}$$

where $starts_i$ is the number of housing starts at month i and $decjanfeb$ is a dummy variable indicating that the current month is one of December, January, or February.

This model is written using the following SAS statements.

```
proc model data=switch;
   parms sig1=10 sig2=10 int1 b11 b13 int2 b21 b23 p;
   bounds 0.0001 < sig1 sig2;

   a = p*dif(rate);       /* Upper bound of integral */
   d = probnorm(a);       /* Normal CDF as an approx of switch */

                          /* Regime 1 */
   y1 = int1 + zlag(starts)*b11 + decjanfeb *b13 ;
                          /* Regime 2 */
   y2 = int2 + zlag(starts)*b21 + decjanfeb *b23 ;
                          /* Composite regression equation */
   starts  = (1 - d)*y1 +  d*y2;

                         /* Resulting log-likelihood function */
   logL = (1/2)*( (313*log(2*3.1415)) +
        log( (sig1**2)*((1-d)**2)+(sig2**2)*(d**2) )
       + (resid.starts*( 1/( (sig1**2)*((1-d)**2)+
        (sig2**2)*(d**2) ) )*resid.starts) ) ;
   errormodel starts ~ general(logL);

   fit starts / method=marquardt converge=1.0e-5;

     /* Test for significant differences in the parms */
   test int1 = int2 ,/ lm;
   test b11 = b21 ,/ lm;
   test b13 = b23 ,/ lm;
   test sig1 = sig2 ,/ lm;

run;
```

Four TEST statements were added to test the hypothesis that the parameters were the same in both regimes. The parameter estimates and ANOVA table from this run are shown in the following output.

Example 20.14. Simulating from a Mixture of Distributions

This example illustrates how to perform a multivariate simulation using models that have different error distributions. Three models are used. The first model has *t*-distributed errors. The second model is a GARCH(1,1) model with normally distributed errors. The third model has a non-central Cauchy distribution.

The following SAS statements generate the data for this example. The T and the CAUCHY data sets use a common seed so that those two series will be correlated.

```
%let df = 7.5;
%let sig1 = .5;
%let var2 = 2.5;

data t;
   format date monyy.;
   do date='1jun2001'd  to '1nov2002'd;
              /* t-distribution with df,sig1 */
      t = .05 * date + 5000  + &sig1*tinv(ranuni(1234),&df);
      output;
   end;
run;

data normal;
   format date monyy.;
   le = &var2;
   lv = &var2;
   do date='1jun2001'd  to '1nov2002'd;
              /* Normal with GARCH error structure */
      v = 0.0001 + 0.2 * le**2 + .75 * lv;
      e = sqrt( v) * rannor(12345) ;
      normal = 25 + e;
      le = e;
      lv = v;
      output;
   end;
run;

data cauchy;
   format date monyy.;
   PI = 3.1415926;
   do date='1jun2001'd  to '1nov2002'd;
      cauchy = -4 + tan((ranuni(1234) - 0.5) * PI);
      output;
   end;
run;
```

Since the multivariate joint likelihood is unknown, the models must be estimated separately. The residuals for each model are saved using the OUT= option. Also, each model is saved using the OUTMODEL= option. The ID statement is used to provide a variable in the residual data set to merge by. The XLAG function is used to model the GARCH(1,1) process. The XLAG function returns the lag of the first argument if it is nonmissing, otherwise it returns the second argument.

```
proc model data=t outmod=t;
   parms df 10 vt 4;
      t = a * date + c;
   errormodel t ~ t( vt, df );
   fit t / out=tresid;
   id date;
run;

proc model data=normal outmod=normal;
   normal = b0 ;
   h.normal = arch0 + arch1 * xlag(resid.normal **2 , mse.normal)
              + GARCH1 * xlag(h.normal, mse.normal);

   fit normal /fiml out=nresid;
   id date;
run;

proc model data= cauchy outmod=cauchy;
parms nc = 1;
     /* nc is noncentrality parm to Cauchy dist */
   cauchy = nc;
   obj = log(1+resid.cauchy**2 * 3.1415926);
   errormodel cauchy ~ general(obj) cdf=cauchy(nc);

   fit cauchy / out=cresid;
   id date;
run;
```

The simulation requires a covariance matrix created from normal residuals. The following Data Step code uses the inverse CDFs of the *t* and Cauchy distributions to convert the residuals to the normal distribution. The CORR procedure is used to create a correlation matrix using the converted residuals.

```
   /* Merge and normalize the 3 residual data sets */
data c; merge tresid nresid cresid; by date;
   t = probit(cdf("T", t/sqrt(0.2789), 16.58 ));
   cauchy = probit(cdf("CAUCHY", cauchy, -4.0623));
run;

proc corr data=c out=s;
   var t normal cauchy;
run;
```

Now the models can be simulated together using the MODEL procedure SOLVE statement. The data set created by the CORR procedure is used as the correlation matrix. Note that the errormodel statement is not saved with the model and must be restated for this simulation.

```
   /* Create one observation driver data set */
data sim; merge t normal cauchy; by date;
data sim; set sim(firstobs = 519 );

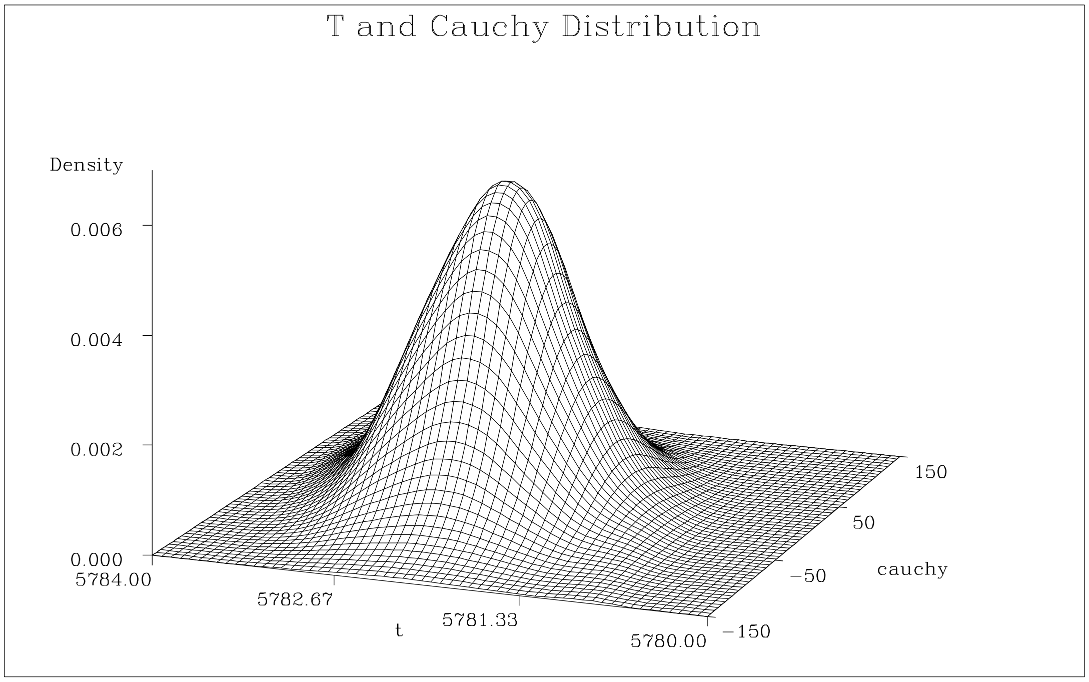
proc model data=sim model=( t normal cauchy);
   errormodel t ~ t( vt, df );
   errormodel cauchy ~ cauchy(nc);
   solve t cauchy normal / random=2000 seed=1962 out=monte
      sdata=s(where=(_type_="CORR"));
run;
```

An estimation of the joint density of the *t* and Cauchy distribution is created using the KDE procedure. Bounds were placed on the Cauchy dimension because of its fat tail behavior. The joint PDF is shown in the following output.

```
proc kde gridl=5780,-150 gridu=5784,150 data=monte out=density;
   var t cauchy;
run;

title "T and Cauchy Distribution";
proc g3d data=density;
   plot t*cauchy=density;
run;
```

Output 20.14.1. Density of T and CAUCHY Truncated in the CAUCHY dimension



Example 20.15. Simple Linear Regression

This example illustrates how to use SMM to estimate a simple linear regression model for the following process:

$$y = a + bx + \epsilon, \ \epsilon \sim iid\, N(0, s^2).$$

In the following SAS code, $ysim$ is simulated and the first moment and the second moment of $ysim$ is compared with those of the observed endogenous variable y.

```
data _tmpdata;
   do i=1 to 500;
     x = rannor( 1013 );
          Y = 2 + 1.5 * x + 1.5 * rannor( 9871 );
          output;
   end;
run;

proc model data=_tmpdata;
  parms a b s;
       instrument x;

       ysim = (a+b*x) + s * rannor( 8003 );

       y = ysim;
       eq.ysq = y*y - ysim*ysim;

       fit y ysq / gmm ndraw;
       bound s > 0;

run;
```

The output of the MODEL procedure is shown in Output 20.15.1:

Output 20.15.1. PROC MODEL Output

```

Example 20.16. AR(1) Process

This example illustrates how to use SMM to estimate an AR(1) regression model for the following process:

$$\begin{aligned} y_t &= a + bx_t + u_t, \\ u_t &= \alpha u_{t-1} + \epsilon_t, \\ \epsilon_t &\sim iid\, N(0, s^2). \end{aligned}$$

In the following SAS code, $ysim$ is simulated using this model and the endogenous variable y is set to be equal to $ysim$. The MOMENT statement creates two more moments for the estimation. One is the second moment and the other is the first order autocovariance. The NPREOBS=20 option instructs PROC MODEL to run the simulation 20 times before $ysim$ is compared to the first observation of y. Because the initial $zlag(u)$ is zero, the first $ysim$ is $a + b * x + s * rannor(8003)$. Without the NPREOBS option, this $ysim$ is matched with the first observation of y. With NPREOBS, this $ysim$, along with the next 19 $ysim$, is thrown away, and the moment match starts with the twenty-first $ysim$ with the first observation of y. This way, the initial values do not exert a large inference to the simulated endogenous variables.

```
%let nobs=500;

data _tmpdata;
   lu =0;
   do i=-10 to &nobs;
     x = rannor( 1011 );
          e = rannor( 9887 );
          u = .6 * lu + 1.5 * e;
          Y = 2 + 1.5 * x + u;
          lu = u;
          if i > 0 then output;
   end;
run;

proc model data=_tmpdata ;
  parms a b s 1 alpha .5;
       instrument x;

       u = alpha * zlag(u) + s * rannor( 8003 );

       ysim = a + b * x + u;

       y = ysim;
       eq.ysq = y*y - ysim*ysim;
       eq.ylagy = y * lag(y) - ysim * lag( ysim );

       fit y ysq ylagy / gmm npreobs=10 ndraw=10;
       bound s > 0, 1>alpha>0;

run;
```

Example 20.17. Stochastic Volatility Model

This example illustrates how to use SMM to estimate a stochastic volatility model as in Andersen and Sorensen (1996):

$$\begin{aligned} y_t &= \sigma_t z_t, \\ log(\sigma_t^2) &= a + b\,log(\sigma_{t-1}^2) + s u_t, \\ (z_t, u_t) &\sim iid\,N(0, I_2). \end{aligned}$$

This model is widely used in modeling the return process of stock prices and foreign exchange rates. This is called the stochastic volatility model because the volatility is stochastic as the random variable u_t appears in the volatility equation. The following SAS code uses three moments: absolute value, the second order moment, and absolute value of the first order autoregressive moment. Note the ADJSMMV option in the FIT statement to request the SMM covariance adjustment for the parameter estimates. Although these moments have closed form solution as shown by Andersen and Sorensen (1996), the simulation approach significantly simplifies the moment conditions.

```
%let nobs=1000;

data _tmpdata;
   a = -0.736; b=0.9; s=0.363;
   ll=sqrt( exp(a/(1-b)));;
   do i=-10 to &nobs;
     u = rannor( 101 );
          z = rannor( 98761 );
          lnssq = a+b*log(ll**2) +s*u;
          st = sqrt(exp(lnssq));
          ll = st;
          y = st * z;
          if i > 0 then output;
   end;
run;

proc model data=_tmpdata ;
  parms a b .5 s 1;
       instrument _exog_ / intonly;

       u = rannor( 8801 );
       z = rannor( 9701 );

       lsigmasq = xlag(sigmasq,exp(a));

       lnsigmasq = a + b * log(lsigmasq) + s * u;
       sigmasq = exp( lnsigmasq );

       ysim = sqrt(sigmasq) * z;

       eq.m1 = abs(y) - abs(ysim);

       eq.m2 = y**2 - ysim**2;

       eq.m5 = abs(y*lag(y))-abs(ysim*lag(ysim));

       fit m1 m2 m5 / gmm npreobs=10 ndraw=10;
       bound s > 0, 1>b>0;

run;
```

Example 20.18. Duration Data Model with Unobserved Heterogeneity

All of the previous three models actually have closed form moment conditions, so the simulation approach is not necessarily required for the estimation. This example illustrates how to use SMM to estimate a model for which there is no closed form solution for the moments and thus the traditional GMM method does not apply. The model is the duration data model with unobserved heterogeneity in Gourieroux and Monfort (1993):

$$\begin{aligned} y_i &= -exp(-bx_i - \sigma u_i)log(v_i), \\ u_i &\sim N(0,1) \quad v_i \sim U_{[0,1]}. \end{aligned}$$

The SAS code is:

```
%let nobs=1000;

data _tmpdata;
   b=0.9; s=0.5;
```

```
      do i=1 to &nobs;
        u = rannor( 1011 );
              v = ranuni( 9828 );
              x = 2 * ranuni( 7621 );
              y = -exp(-b * x + s * u) * log(v);
              output;
      end;
   run;

   proc model data=_tmpdata;
     parms b .5 s 1;
          instrument x;

          u = rannor( 9871 );
          v = ranuni( 7003 );

          y = -exp(-b * x + s * u) * log(v);

          moment y = (2 3 4);

          fit y / gmm ndraw=10;

          bound s > 0, b>0;

   run;
```

The output of the MODEL procedure is shown in Output 20.18.1.

Example 20.19. EMM Estimation of a Stochastic Volatility Model

The Efficient Method of Moments (EMM), introduced by Bansal et al. (1993 and 1995), and Gallant and Tauchen (2001), can be considered a variant of SMM. The idea is to match the efficiency of the Maximum Likelihood (ML) estimation with the flexibility of the SMM procedure. ML itself can be interpreted as a method of moments procedure, where the *score vector*, the vector of derivatives of the log-likelihood function with respect to the parameters, provides the exactly identifying moment conditions. EMM employs an auxiliary (or pseudo) model that closely matches the true model. The score vector of the auxilliary model provides the moment conditions in the SMM step.

This example uses the SMM feature of PROC MODEL to estimate the simple stochastic volatility (SV) model of Example 20.17 with the EMM method.

Suppose that your data are the time series $\{y_1, y_2, \ldots, y_n\}$, and the model that you want to estimate, or the structural model, is characterized by the vector of parameters $\boldsymbol{\theta}$. For the SV model, $\boldsymbol{\theta}$ is given by (a, b, s).

The first step of the EMM method is to fit the data with an auxiliary model (or score generator) that has transition density $f(y_t|Y_{t-1}, \boldsymbol{\eta})$, parametrized by the pseudo parameter $\boldsymbol{\eta}$, where $Y_{t-1} = \{y_{t-1}, \ldots, y_1\}$. The auxiliary model must approximate the true data generating process as closely as possible and be such that ML estimation is feasible.

The only identification requirement is that the dimension of the pseudo parameter $\boldsymbol{\eta}$ be greater than or equal to that of the structural parameter $\boldsymbol{\theta}$.

Andersen, Chung, and Sorensen (1999) showed that the GARCH(1,1) is an appropriate auxiliary model that leads to a good performance of the EMM estimator for the SV model.

The analytical expression for the GARCH(1,1) model with mean zero is

$$\begin{aligned} y_t &= \sigma_t z_t \\ \sigma_t^2 &= \omega + \alpha y_{t-1} + \beta \sigma_{t-1}^2 \end{aligned}$$

The pseudo parameter vector $\boldsymbol{\eta}$ is given by (ω, α, β).

One advantage of such a class of models is that the conditional density of y_t is Gaussian, that is,

$$f(y_t|Y_{t-1}, \boldsymbol{\eta}) \propto \frac{1}{\sigma_t} \exp\left(-\frac{y_t^2}{2\sigma_t^2}\right)$$

and therefore the score vector can easily be computed analytically.

The AUTOREG procedure provides the ML estimates, $\hat{\boldsymbol{\eta}}_n$. The output is stored in the garchout data set, while the estimates are stored in the garchest data set.

```
/*
/ estimate GARCH(1,1) model
/ ----------------------------------------------*/
proc autoreg data=_tmpdata(keep=y) outest=garchest noprint covout;
   model y =  / noint garch=(q=1,p=1) ;
   output out=garchout cev=gsigmasq r=resid;
run;
```

If the pseudo model is close enough to the structural model, in a suitable sense, Gallant and Long (1997) showed that a consistent estimator of the asymptotic covariance matrix of the sample pseudo-score vector can be obtained from the formula

$$\hat{V}_n = \frac{1}{n} \sum_{t=1}^{n} s_f(Y_t, \hat{\boldsymbol{\eta}}_n) s_f(Y_t, \hat{\boldsymbol{\eta}}_n)'$$

where $s_f(Y_t, \hat{\boldsymbol{\eta}}_n) = (\partial/\partial \boldsymbol{\eta}_n) \log f(y_t|Y_{t-1}, \hat{\boldsymbol{\eta}}_n)$ denotes the score function of the auxiliary model computed at the ML estimates.

The ML estimates of the GARCH(1,1) model are used in the following SAS statements to compute the variance-covariance matrix $\hat{V}_n$.

```
/*
/ compute the V matrix
/ ----------------------------------------------*/

data vvalues;
   set garchout(keep=y gsigmasq resid);

   /* compute scores of GARCH model */
   score_1 = (-1 + y**2/gsigmasq)/ gsigmasq;
   score_2 = (-1 + y**2/gsigmasq)*lag(gsigmasq) / gsigmasq;
   score_3 = (-1 + y**2/gsigmasq)*lag(y**2) / gsigmasq;

   array score{*} score_1-score_3;
   array v_t{*} v_t_1-v_t_6;
   array v{*} v_1-v_6;

   /* compute external product of score vector */
   do i=1 to 3;
      do j=i to 3;
         v_t{j*(j-1)/2 + i} = score{i}*score{j};
      end;
   end;

   /* average them over t */
   do s=1 to 6;
      v{s}+ v_t{s}/&nobs;
   end;
run;
```

The $\hat{V}$ matrix must be formatted to be used with the VDATA= option of the MODEL procedure. Please see the section "VDATA= Input data set" on page 1160 for more information regarding the VDATA= data set.

```
/*
/ Create a VDATA dataset acceptable to PROC MODEL
/ ------------------------------------------------ */

/* Transpose the last obs in the dataset */
proc transpose data=vvalues(firstobs=&nobs keep=v_1-v_6) out=tempv;
run;

/* Add eq and inst labels */
data vhat;
   set tempv(drop=_name_);
   value = col1;
   drop col1;
   input _type_ $ eq_row $ eq_col $ inst_row $ inst_col $;
   datalines;
      gmm m1 m1 1 1  /* intcpt is the only inst we use */
      gmm m1 m2 1 1
      gmm m2 m2 1 1
      gmm m1 m3 1 1
      gmm m2 m3 1 1
      gmm m3 m3 1 1
    ;
run;
```

The last step of the EMM procedure is to estimate $\boldsymbol{\theta}$ using SMM, where the moment conditions are given by the scores of the auxiliary model.

Given a fixed value of the parameter vector $\boldsymbol{\theta}$, and an arbitrarily large T, one can simulate a series $\{\hat{\mathrm{y}}_1(\boldsymbol{\theta}), \hat{\mathrm{y}}_2(\boldsymbol{\theta}), \ldots, \hat{\mathrm{y}}_T(\boldsymbol{\theta})\}$ from the structural model. The EMM estimator is the value $\hat{\boldsymbol{\theta}}_n$ that minimizes the quantity

$$m_T(\boldsymbol{\theta}, \hat{\boldsymbol{\eta}}_n)' \hat{V}_n^{-1} m_T(\boldsymbol{\theta}, \hat{\boldsymbol{\eta}}_n)$$

where

$$m_T(\boldsymbol{\theta}, \hat{\boldsymbol{\eta}}_n) = \frac{1}{T} \sum_{k=1}^{T} s_f(\widehat{\mathrm{Y}}_k(\boldsymbol{\theta}), \hat{\boldsymbol{\eta}}_n)$$

is the sample moment condition evaluated at the fixed estimated pseudo parameter $\hat{\boldsymbol{\eta}}_n$. Note that the target function depends on the parameter $\boldsymbol{\theta}$ only through the simulated series $\hat{y}_k$.

The following statements generate a data set that contains $T = 20,000$ replicates of the estimated pseudo parameter $\hat{\boldsymbol{\eta}}_n$ and that is then inputed to the MODEL procedure. The EMM estimates are found using the SMM option of the FIT statement. The $\hat{V}_n$ matrix computed above serves as weighting matrix using the VDATA= option, and the scores of the GARCH(1,1) auxiliary model evaluated at the ML estimates are the moment conditions in the GMM step.

Since the number of structural parameters to estimate (3) is equal to the number of moment equations (3) times the number of instrument (1), the model is exactly identified and the objective function will have value zero at the minimum.

For simplicity, the starting values are set to the true values of the parameters.

```
/*
/ USE SMM TO FIND EMM ESTIMATES
/ ---------------------------------------------------*/

/* Generate dataset of length T */
data emm;
   set garchest(obs=1 keep = _ah_0 _ah_1 _gh_1 _mse_);
   do i=1 to 20000;
      output;
   end;
   drop i;
run;

/* Find the EMM estimates */
proc model data=emm maxiter=1000;
   parms a -0.736 b 0.9 s 0.363;
   instrument _exog_ / intonly;

      /* Describe the structural model */
      u = rannor( 8801 );
      z = rannor( 9701 );
```

```
         lsigmasq = xlag(sigmasq,exp(a));

         lnsigmasq = a + b * log(lsigmasq) + s * u;
         sigmasq = exp( lnsigmasq );

         ysim = sqrt(sigmasq) * z;

         /* Volatility of the GARCH model */
         gsigmasq = _ah_0 + _gh_1*xlag(gsigmasq, _mse_)
                    + _ah_1*xlag(ysim**2, _mse_);

         /* Use scores of the GARCH model as moment conditions */
         eq.m1 = (-1 + ysim**2/gsigmasq)/ gsigmasq;

         eq.m2 = (-1 + ysim**2/gsigmasq)*xlag(gsigmasq, _mse_) / gsigmasq;

         eq.m3 = (-1 + ysim**2/gsigmasq)*xlag(ysim**2, _mse_) / gsigmasq;

       /* Fit scores using SMM and estimated Vhat */
       fit m1 m2 m3 / gmm npreobs=10 ndraw=1 /* smm options */
                      vdata=vhat /* use estimated Vhat */
                      kernel=(bart,0,) /* turn smoothing off */;
                     bounds s > 0, 1>b>0;

   run;
```

The output of the MODEL procedure is shown in Output 20.19.1.

Example 20.20. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. This is a continuation of the "Nonlinear Regression Analysis" in the section "Getting Started" on page 1003. These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the MODEL procedure, see the "ODS Graphics" section on page 1166.

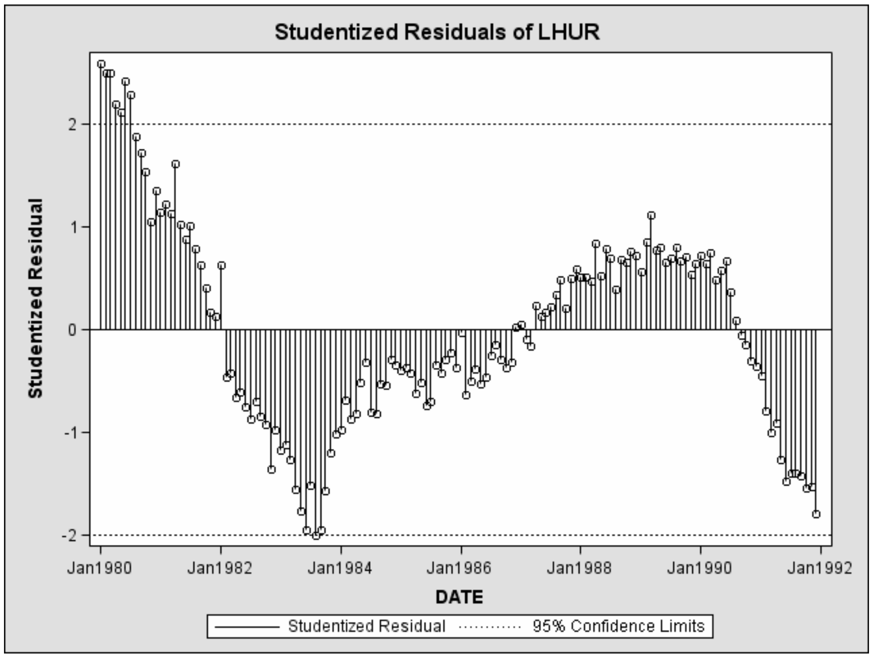
The following statements show how to generate ODS graphics plots with the MODEL procedure. The plots are displayed in Output 20.20.1 through Output 20.20.8. Note that the variable date in the ID statement is used to define the horizontal tick mark values when appropriate.

```
   ods html;
   ods graphics on;

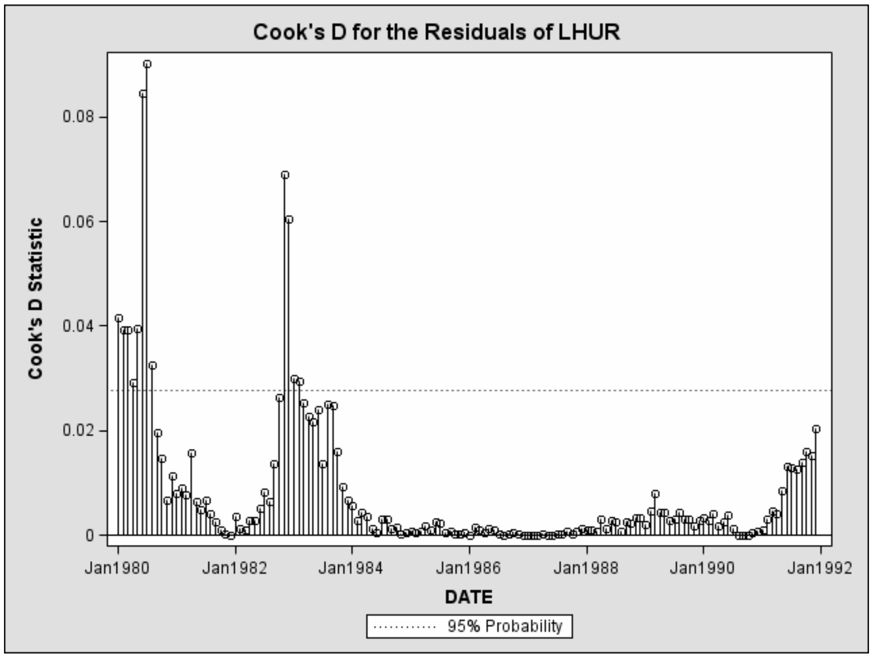
   proc model data=sashelp.citimon;
      lhur = 1/(a * ip + b) + c;
      fit lhur;
      id date;
   run;
   quit;

   ods graphics off;
   ods html close;
```

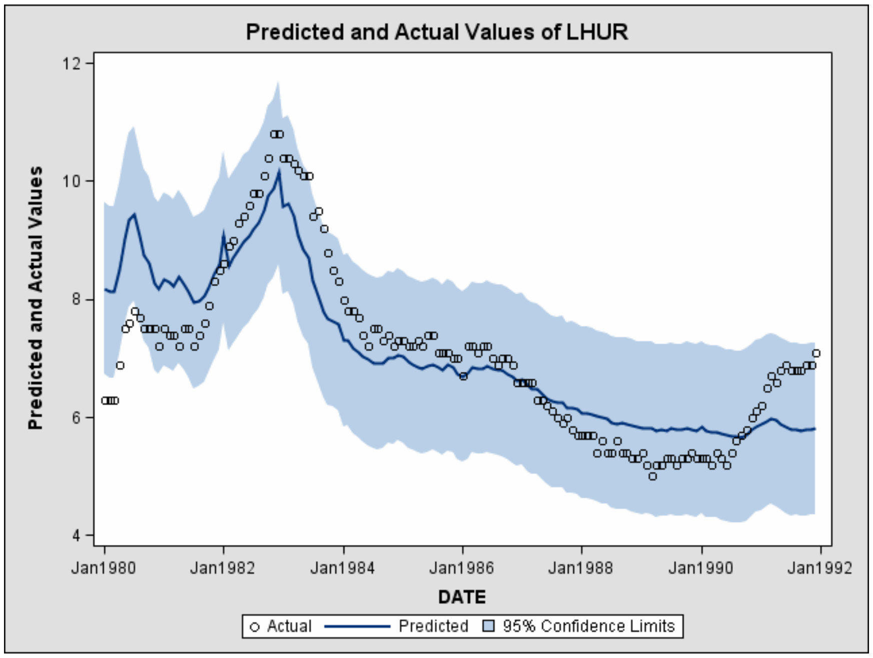
Output 20.20.1. Studentized Residuals Plot (Experimental)



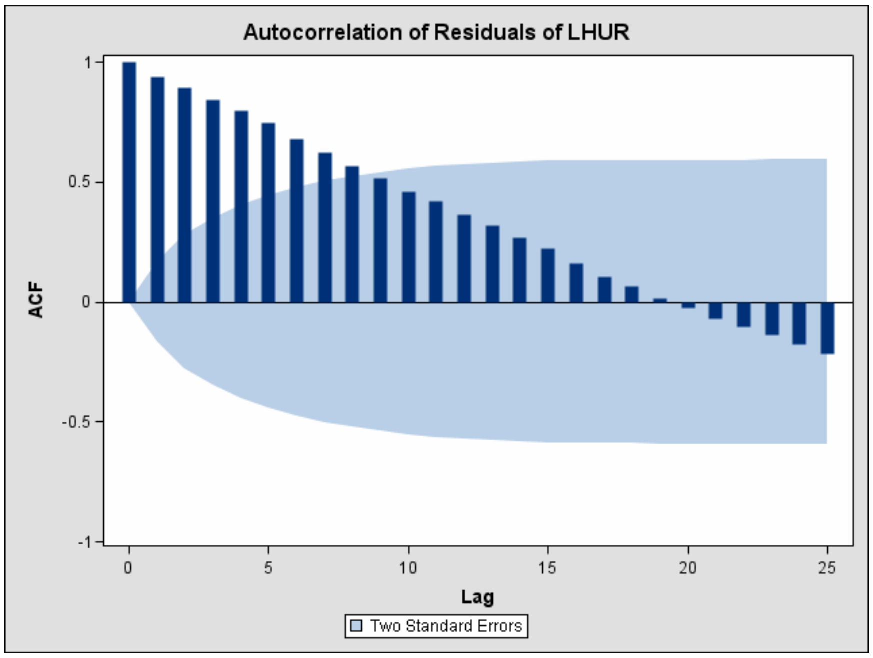
Output 20.20.2. Cook's D Plot (Experimental)



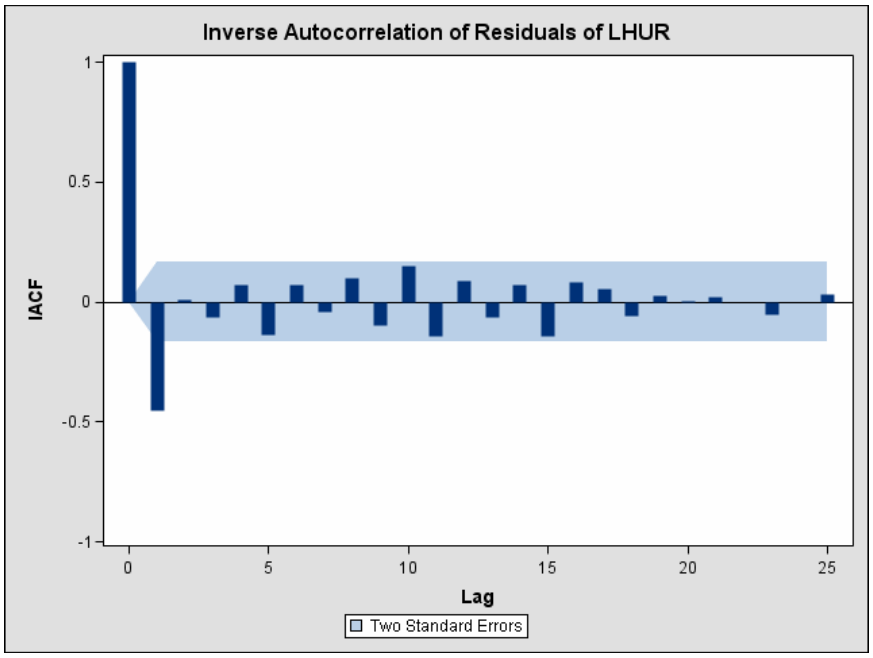
Output 20.20.3. Predicted vs Actual Plot (Experimental)



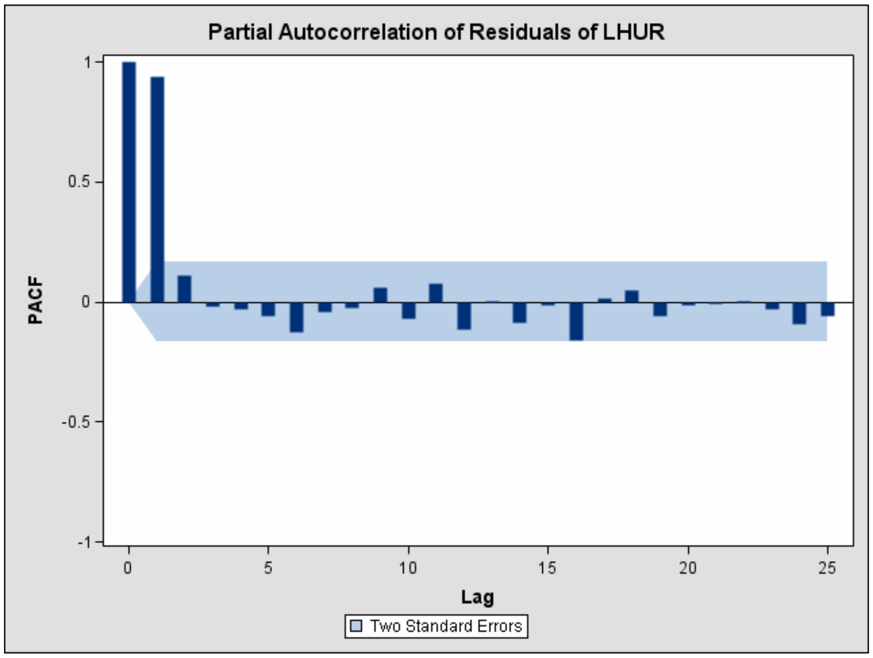
Output 20.20.4. Autocorrelation of Residuals Plot (Experimental)



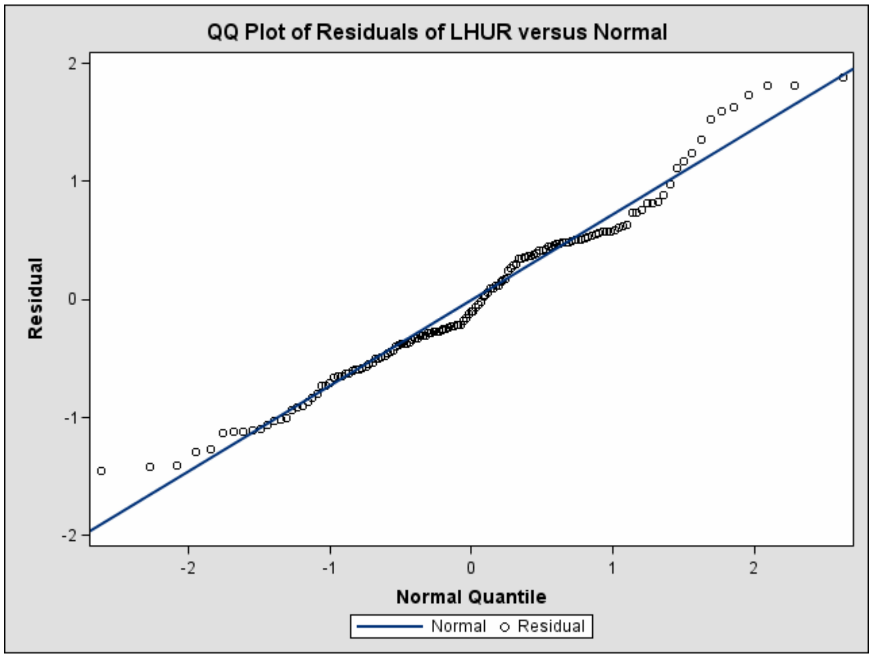
Output 20.20.5. Partial Autocorrelation of Residuals Plot (Experimental)



Output 20.20.6. Inverse Autocorrelation of Residuals Plot (Experimental)



Output 20.20.7. QQ Plot of Residuals (Experimental)



Output 20.20.8. Histogram of Residuals (Experimental)

Chapter 21
The PDLREG Procedure

Overview

The PDLREG procedure estimates regression models for time series data in which the effects of some of the regressor variables are distributed across time. The distributed lag model assumes that the effect of an input variable X on an output Y is distributed over time. If you change the value of X at time *t*, Y will experience some immediate effect at time *t*, and it will also experience a delayed effect at times $t+1$, $t+2$, and so on up to time $t+p$ for some limit *p*.

The regression model supported by PROC PDLREG can include any number of regressors with distribution lags and any number of covariates. (Simple regressors without lag distributions are called covariates.) For example, the two-regressor model with a distributed lag effect for one regressor is written

$$y_t = \alpha + \sum_{i=0}^{p} \beta_i x_{t-i} + \gamma z_t + u_t$$

Here, x_t is the regressor with a distributed lag effect, z_t is a simple covariate, and u_t is an error term.

The distribution of the lagged effects is modeled by Almon lag polynomials. The coefficients b_i of the lagged values of the regressor are assumed to lie on a polynomial curve. That is,

$$b_i = \alpha_0^* + \sum_{j=1}^{d} \alpha_j^* i^j$$

where $d (\leq p)$ is the degree of the polynomial. For the numerically efficient estimation, the PDLREG procedure uses *orthogonal polynomials*. The preceding equation can be transformed into orthogonal polynomials.

$$b_i = \alpha_0 + \sum_{j=1}^{d} \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree *j* in the lag length *i*, and α_j is a coefficient estimated from the data.

The PDLREG procedure supports endpoint restrictions for the polynomial. That is, you can constrain the estimated polynomial lag distribution curve so that $b_{-1} = 0$ or

$b_{p+1} = 0$, or both. You can also impose linear restrictions on the parameter estimates for the covariates.

You can specify a minimum degree and a maximum degree for the lag distribution polynomial, and the procedure fits polynomials for all degrees in the specified range. (However, if distributed lags are specified for more that one regressor, you can specify a range of degrees for only one of them.)

The PDLREG procedure can also test for autocorrelated residuals and perform autocorrelated error correction using the autoregressive error model. You can specify any order autoregressive error model and can specify several different estimation methods for the autoregressive model, including exact maximum likelihood.

The PDLREG procedure computes generalized Durbin-Watson statistics to test for autocorrelated residuals. For models with lagged dependent variables, the procedure can produce Durbin *h* and Durbin *t* statistics. You can request significance level *p*-values for the Durbin-Watson, Durbin *h*, and Durbin *t* statistics. See Chapter 12, “The AUTOREG Procedure,” for details about these statistics.

The PDLREG procedure assumes that the input observations form a time series. Thus, the PDLREG procedure should be used only for ordered and equally spaced time series data.

Getting Started

Use the MODEL statement to specify the regression model. The PDLREG procedure’s MODEL statement is written like MODEL statements in other SAS regression procedures, except that a regressor can be followed by a lag distribution specification enclosed in parentheses.

For example, the following MODEL statement regresses Y on X and Z and specifies a distributed lag for X:

```
model y = x(4,2) z;
```

The notation X(4,2) specifies that the model includes X and 4 lags of X, with the coefficients of X and its lags constrained to follow a second-degree (quadratic) polynomial. Thus, the regression model specified by this MODEL statement is

$$y_t = a + b_0 x_t + b_1 x_{t-1} + b_2 x_{t-2} + b_3 x_{t-3} + b_4 x_{t-4} + c z_t + u_t$$

$$b_i = \alpha_0 + \alpha_1 f_1(i) + \alpha_2 f_2(i)$$

where $f_1(i)$ is a polynomial of degree 1 in *i* and $f_2(i)$ is a polynomial of degree 2 in *i*.

Lag distribution specifications are enclosed in parentheses and follow the name of the regressor variable. The general form of the lag distribution specification is

regressor-name **(** *length, degree, minimum-degree, end-constraint* **)**

where:

length	is the length of the lag distribution; that is, the number of lags of the regressor to use
degree	is the degree of the distribution polynomial
minimum-degree	is an optional minimum degree for the distribution polynomial
end-constraint	is an optional endpoint restriction specification, which can have the values FIRST, LAST, or BOTH

If the *minimum-degree* option is specified, the PDLREG procedure estimates models for all degrees between *minimum-degree* and *degree*.

Introductory Example

The following statements generate simulated data for variables Y and X. Y depends on the first three lags of X, with coefficients .25, .5, and .25. Thus, the effect of changes of X on Y takes effect 25% after one period, 75% after two periods, and 100% after three periods.

```
data test;
   xl1 = 0; xl2 = 0; xl3 = 0;
   do t = -3 to 100;
      x = ranuni(1234);
      y = 10 + .25 * xl1 + .5 * xl2 + .25 * xl3 + .1 * rannor(1234);
      if t > 0 then output;
      xl3 = xl2; xl2 = xl1; xl1 = x;
      end;
run;
```

The following statements use the PDLREG procedure to regress Y on a distributed lag of X. The length of the lag distribution is 4, and the degree of the distribution polynomial is specified as 3.

```
proc pdlreg data=test;
   model y = x( 4, 3 );
run;
```

The PDLREG procedure first prints a table of statistics for the residuals of the model, as shown in Figure 21.1. See Chapter 12 for an explanation of these statistics.

```

Figure 21.1. Residual Statistics

The PDLREG procedure next prints a table of parameter estimates, standard errors, and *t*-tests, as shown in Figure 21.2.

```
                              The PDLREG Procedure

                                          Standard                 Approx
      Variable        DF      Estimate       Error    t Value    Pr > |t|

      Intercept        1       10.0030      0.0431     231.87      <.0001
      x**0             1        0.4406      0.0378      11.66      <.0001
      x**1             1        0.0113      0.0336       0.34      0.7377
      x**2             1       -0.4108      0.0322     -12.75      <.0001
      x**3             1        0.0331      0.0392       0.84      0.4007
```

Figure 21.2. Parameter Estimates

The preceding table shows the model intercept and the estimated parameters of the lag distribution polynomial. The parameter labeled X**0 is the constant term, α_0, of the distribution polynomial. X**1 is the linear coefficient, α_1, X**2 is the quadratic coefficient, α_2, and X**3 is the cubic coefficient, α_3.

The parameter estimates for the distribution polynomial are not of interest in themselves. Since the PDLREG procedure does not print the orthogonal polynomial basis that it constructs to represent the distribution polynomial, these coefficient values cannot be interpreted.

However, because these estimates are for an orthogonal basis, you can use these results to test the degree of the polynomial. For example, this table shows that the X**3 estimate is not significant; the *p*-value for its *t* ratio is .4007, while the X**2 estimate is highly significant ($p < .0001$). This indicates that a second-degree polynomial may be more appropriate for this data set.

The PDLREG procedure next prints the lag distribution coefficients and a graphical display of these coefficients, as shown in Figure 21.3.

```

Figure 21.3. Coefficients and Graph of Estimated Lag Distribution

The lag distribution coefficients are the coefficients of the lagged values of X in the regression model. These coefficients lie on the polynomial curve defined by the parameters shown in Figure 21.2. Note that the estimated values for X(1), X(2), and X(3) are highly significant, while X(0) and X(4) are not significantly different from 0. These estimates are reasonably close to the true values used to generate the simulated data.

The graphical display of the lag distribution coefficients plots the estimated lag distribution polynomial reported in Figure 21.2. The roughly quadratic shape of this plot is another indication that a third-degree distribution curve is not needed for this data set.

Syntax

The following statements can be used with the PDLREG procedure:

PROC PDLREG *option* **;**
  BY *variables* **;**
  MODEL *dependents = effects / options* **;**
  OUTPUT OUT= *SAS-data-set keyword = variables* **;**
  RESTRICT *restrictions* **;**

Functional Summary

The statements and options used with the PDLREG procedure are summarized in the following table:

Description	Statement	Option
Data Set Options		
specify the input data set	PDLREG	DATA=
write predicted values to an output data set	OUTPUT	OUT=
BY-Group Processing		
specify BY-group processing	BY	
Printing Control Options		
request all print options	MODEL	ALL
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
print DW statistics up to order *j*	MODEL	DW=*j*
print the marginal probability of DW statistics	MODEL	DWPROB
print inverse of the crossproducts matrix	MODEL	I
print details at each iteration step	MODEL	ITPRINT
print Durbin *t* statistic	MODEL	LAGDEP
print Durbin *h* statistic	MODEL	LAGDEP=
suppress printed output	MODEL	NOPRINT
print partial autocorrelations	MODEL	PARTIAL
print standardized parameter estimates	MODEL	STB
print crossproducts matrix	MODEL	XPX
Model Estimation Options		
specify order of autoregressive process	MODEL	NLAG=
suppress intercept parameter	MODEL	NOINT
specify convergence criterion	MODEL	CONVERGE=
specify maximum number of iterations	MODEL	MAXITER=
specify estimation method	MODEL	METHOD=
Output Control Options		
specify confidence limit size	OUTPUT	ALPHACLI=
specify confidence limit size for structural predicted values	OUTPUT	ALPHACLM=
output transformed intercept variable	OUTPUT	CONSTANT=
output lower confidence limit for predicted values	OUTPUT	LCL=
output lower confidence limit for structural predicted values	OUTPUT	LCLM=
output predicted values	OUTPUT	P=
output predicted values of the structural part	OUTPUT	PM=
output residuals from the predicted values	OUTPUT	R=
output residuals from the structural predicted values	OUTPUT	RM=

Description	**Statement**	**Option**
output transformed variables	OUTPUT	TRANSFORM=
output upper confidence limit for the predicted values	OUTPUT	UCL=
output upper confidence limit for the structural predicted values	OUTPUT	UCLM=

PROC PDLREG Statement

PROC PDLREG *option ;*

The PROC PDLREG statement has the following option:

DATA= *SAS-data-set*
specifies the name of the SAS data set containing the input data. If you do not specify the DATA= option, the most recently created SAS data set is used.

In addition, you can place any of the following MODEL statement options in the PROC PDLREG statement, which is equivalent to specifying the option for every MODEL statement: ALL, CONVERGE=, CORRB, COVB, DW=, DWPROB, ITPRINT, MAXITER=, METHOD=, NOINT, NOPRINT, and PARTIAL.

BY Statement

BY *variables ;*

A BY statement can be used with PROC PDLREG to obtain separate analyses on observations in groups defined by the BY variables.

MODEL Statement

MODEL *dependent = effects / options ;*

The MODEL statement specifies the regression model. The keyword MODEL is followed by the dependent variable name, an equal sign, and a list of independent effects. Only one MODEL statement is allowed.

Every variable in the model must be a numeric variable in the input data set. Specify an independent effect with a variable name optionally followed by a polynomial lag distribution specification.

Specifying Independent Effects

The general form of an effect is

variable (length, degree, minimum-degree, constraint)

The term in parentheses following the variable name specifies a polynomial distributed lag (PDL) for the variable. The PDL specification is as follows:

length	specifies the number of lags of the variable to include in the lag distribution.
degree	specifies the maximum degree of the distribution polynomial. If not specified, the degree defaults to the lag length.
minimum-degree	specifies the minimum degree of the polynomial. By default *minimum-degree* is the same as *degree*.
constraint	specifies endpoint restrictions on the polynomial. The value of *constraint* can be FIRST, LAST, or BOTH. If a value is not specified, there are no endpoint restrictions.

If you do not specify the *degree* or *minimum-degree* parameter, but you do specify endpoint restrictions, you must use commas to show which parameter, *degree* or *minimum-degree*, is left out.

MODEL Statement Options

The following options can appear in the MODEL statement after a slash (/):

ALL
prints all the matrices computed during the analysis of the model.

CORRB
prints the matrix of estimated correlations between the parameter estimates.

COVB
prints the matrix of estimated covariances between the parameter estimates.

DW= *j*
prints the generalized Durbin-Watson statistics up to the order of *j*. The default is DW=1. When you specify the LAGDEP or LAGDEP=*name* option, the Durbin-Watson statistic is not printed unless you specify the DW= option.

DWPROB
prints the marginal probability of the Durbin-Watson statistic.

CONVERGE= *value*
sets the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this amount, then convergence is assumed. The default is CONVERGE=.001.

I
prints $(\mathbf{X'X})^{-1}$, the inverse of the crossproducts matrix for the model; or, if restrictions are specified, prints $(\mathbf{X'X})^{-1}$ adjusted for the restrictions.

ITPRINT
prints information on each iteration.

LAGDEP
LAGDV
prints the *t* statistic for testing residual autocorrelation when regressors contain lagged dependent variables.

LAGDEP= *name*
LAGDV= *name*
prints the Durbin *h* statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. When the *h* statistic cannot be computed, the asymptotically equivalent *t* statistic is given.

MAXITER= *number*
sets the maximum number of iterations allowed. The default is MAXITER=50.

METHOD= *value*
specifies the type of estimates for the autoregressive component. The values of the METHOD= option are as follows:

METHOD=ML	specifies the maximum likelihood method
METHOD=ULS	specifies unconditional least squares
METHOD=YW	specifies the Yule-Walker method
METHOD=ITYW	specifies iterative Yule-Walker estimates

The default is METHOD=ML if you specified the LAGDEP or LAGDEP= option; otherwise, METHOD=YW is the default.

NLAG= *m*
NLAG= *(number-list)*
specifies the order of the autoregressive process or the subset of autoregressive lags to be fit. If you do not specify the NLAG= option, PROC PDLREG does not fit an autoregressive model.

NOINT
suppresses the intercept parameter from the model.

NOPRINT
suppresses the printed output.

PARTIAL
prints partial autocorrelations if the NLAG= option is specified.

STB
prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a *standardized parameter estimate* is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the regressed variable.

XPX
prints the crossproducts matrix, **X’X**, used for the model. **X** refers to the transformed matrix of regressors for the regression.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set keyword=option ... ;*

The OUTPUT statement creates an output SAS data set with variables as specified by the following keyword options. The associated computations for these options are described in the section "Predicted Values" in Chapter 12.

ALPHACLI= *number*
sets the confidence limit size for the estimates of future values of the current realization of the response time series to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has 1-*number* confidence. The default value for *number* is .05, corresponding to a 95% confidence interval.

ALPHACLM= *number*
sets the confidence limit size for the estimates of the structural or regression part of the model to *number*, where *number* is less than one and greater than zero. The resulting confidence interval has 1-*number* confidence. The default value for *number* is .05, corresponding to a 95% confidence interval.

OUT= *SAS-data-set*
names the output data.

The following specifications are of the form *KEYWORD=names*, where *KEYWORD=* specifies the statistic to include in the output data set and *names* gives names to the variables that contain the statistics.

CONSTANT= *variable*
writes the transformed intercept to the output data set.

LCL= *name*
requests that the lower confidence limit for the predicted value (specified in the PREDICTED= option) be added to the output data set under the name given.

LCLM= *name*
requests that the lower confidence limit for the structural predicted value (specified in the PREDICTEDM= option) be added to the output data set under the name given.

PREDICTED= *name*
P=*name*
stores the predicted values in the output data set under the name given.

PREDICTEDM= *name*
PM= *name*
stores the structural predicted values in the output data set under the name given. These values are formed from only the structural part of the model.

RESIDUAL= *name*
R= *name*
stores the residuals from the predicted values based on both the structural and time series parts of the model in the output data set under the name given.

RESIDUALM= *name*
RM= *name*
requests that the residuals from the structural prediction be given.

TRANSFORM= *variables*
requests that the specified variables from the input data set be transformed by the autoregressive model and put in the output data set. If you need to reproduce the data suitable for reestimation, you must also transform an intercept variable. To do this, transform a variable that only takes the value 1 or use the CONSTANT= option.

UCL= *name*
stores the upper confidence limit for the predicted value (specified in the PREDICTED= option) in the output data set under the name given.

UCLM= *name*
stores the upper confidence limit for the structural predicted value (specified in the PREDICTEDM= option) in the output data set under the name given.

For example, the SAS statements

```
proc pdlreg data=a;
   model y=x1 x2;
   output out=b p=yhat r=resid;
```

create an output data set named B. In addition to the input data set variables, the data set B contains the variable YHAT, whose values are predicted values of the dependent variable Y, and RESID, whose values are the residual values of Y.

RESTRICT Statement

RESTRICT *equation , ... , equation ;*

The RESTRICT statement places restrictions on the parameter estimates for covariates in the preceding MODEL statement. A parameter produced by a distributed lag cannot be restricted with the RESTRICT statement.

Each restriction is written as a linear equation. If you specify more than one restriction in a RESTRICT statement, the restrictions are separated by commas.

You can refer to parameters by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. You can use labels to distinguish results for different restrictions in the printed output. Labels are specified as follows:

label : **RESTRICT** . . . **;**

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1.

```
proc pdlreg data=a;
   model y = x1 x2;
   restrict x1 + x2 = 1;
run;
```

Parameter names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Raynor 1971). The estimates of these Lagrangian parameters are printed in the parameter estimates table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter, λ, measures the sensitivity of the SSE to the restriction. If the restriction is changed by a small amount ϵ, the SSE is changed by $2\lambda\epsilon$.

The *t* ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted ones.

You can specify any number of restrictions on a RESTRICT statement, and you can use any number of RESTRICT statements. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

Details

Missing Values

The PDLREG procedure skips any observations at the beginning of the data set that have missing values. The procedure uses all observations with nonmissing values for all the independent and dependent variables such that the lag distribution has sufficient nonmissing lagged independent variables.

Polynomial Distributed Lag Estimation

The simple finite distributed lag model is expressed in the form

$$y_t = \alpha + \sum_{i=0}^{p} \beta_i x_{t-i} + \epsilon_t$$

When the lag length (*p*) is long, severe multicollinearity can occur. Use the Almon or *polynomial distributed lag* model to avoid this problem, since the relatively low degree *d* ($\leq p$) polynomials can capture the true lag distribution. The lag coefficient can be written in the Almon polynomial lag

$$\beta_i = \alpha_0^* + \sum_{j=1}^{d} \alpha_j^* i^j$$

Emerson (1968) proposed an efficient method of constructing orthogonal polynomials from the preceding polynomial equation as

$$\beta_i = \alpha_0 + \sum_{j=1}^{d} \alpha_j f_j(i)$$

where $f_j(i)$ is a polynomial of degree *j* in the lag length *i*. The polynomials $f_j(i)$ are chosen so that they are orthogonal:

$$\sum_{i=1}^{n} w_i f_j(i) f_k(i) = \begin{cases} 1 & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases}$$

where w_i is the weighting factor, and $n = p + 1$. PROC PDLREG uses the equal weights ($w_i = 1$) for all *i*. To construct the orthogonal polynomials, the following recursive relation is used:

$$f_j(i) = (A_j i + B_j) f_{j-1}(i) - C_j f_{j-2}(i) \qquad j = 1, \ldots, d$$

The constants A_j, B_j, and C_j are determined as follows:

$$\begin{aligned}
A_j &= \left\{ \sum_{i=1}^{n} w_i i^2 f_{j-1}^2(i) \quad - \left(\sum_{i=1}^{n} w_i i f_{j-1}^2(i) \right)^2 \right. \\
&\qquad \left. - \left(\sum_{i=1}^{n} w_i i f_{j-1}(i) f_{j-2}(i) \right)^2 \right\}^{-1/2} \\
B_j &= -A_j \sum_{i=1}^{n} w_i i f_{j-1}^2(i) \\
C_j &= A_j \sum_{i=1}^{n} w_i i f_{j-1}(i) f_{j-2}(i)
\end{aligned}$$

where $f_{-1}(i) = 0$ and $f_0(i) = 1/\sqrt{\sum_{i=1}^{n} w_i}$.

PROC PDLREG estimates the orthogonal polynomial coefficients, $\alpha_0, \ldots, \alpha_d$, to compute the coefficient estimate of each independent variable (X) with distributed lags. For example, if an independent variable is specified as X(9,3), a third-degree polynomial is used to specify the distributed lag coefficients. The third-degree polynomial is fit as a constant term, a linear term, a quadratic term, and a cubic term. The four terms are constructed to be orthogonal. In the output produced by the PDLREG procedure for this case, parameter estimates with names X**0, X**1, X**2, and X**3 correspond to $\hat{\alpha}_0, \hat{\alpha}_1, \hat{\alpha}_2$, and $\hat{\alpha}_3$, respectively. A test using the *t* statistic and the approximate *p*-value ("Approx Pr $>$ $|t|$") associated with X**3 can determine whether a second-degree polynomial rather than a third-degree polynomial is appropriate. The estimates of the ten lag coefficients associated with the specification X(9,3) are labeled X(0), X(1), X(2), X(3), X(4), X(5), X(6), X(7), X(8), and X(9).

Autoregressive Error Model Estimation

The PDLREG procedure uses the same autoregressive error model estimation methods as the AUTOREG procedure. These two procedures share the same computational resources for computing estimates. See Chapter 12 for details about estimation methods for autoregressive error models.

OUT= Data Set

The OUT= data set produced by the PDLREG procedure's OUTPUT statement is similar in form to the OUT= data set produced by the AUTOREG procedure. See Chapter 12 for details on the OUT= data set.

Printed Output

The PDLREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least squares (OLS) estimates
3. the estimates of autocorrelations and of the autocovariance, and if line size permits, a graph of the autocorrelation at each lag. The autocorrelation for lag 0 is 1. These items are printed if you specify the NLAG= option.
4. the partial autocorrelations if the PARTIAL and NLAG= options are specified. The first partial autocorrelation is the autocorrelation for lag 1.
5. the preliminary mean square error, which results from solving the Yule-Walker equations if you specify the NLAG= option
6. the estimates of the autoregressive parameters, their standard errors, and the ratios of estimates to standard errors (*t*) if you specify the NLAG= option
7. the statistics of fit for the final model if you specify the NLAG= option. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the root mean square error (Root MSE), the Schwarz information criterion (SBC), the Akaike's information criterion

(AIC), the regression R^2 (Regress R-Square), the total R^2 (Total R-Square), and the Durbin-Watson statistic (Durbin-Watson). See Chapter 12 for details of the regression R^2 and the total R^2.

8. the parameter estimates for the structural model (B), a standard error estimate, the ratio of estimate to standard error (t), and an approximation to the significance probability for the parameter being 0 ("Approx Pr $> |t|$")
9. a plot of the lag distribution (estimate of lag distribution)
10. the covariance matrix of the parameter estimates if the COVB option is specified

ODS Table Names

PROC PDLREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 21.1. ODS Tables Produced in PROC PDLREG

ODS Table Name	Description	Option

Examples

Example 21.1. Industrial Conference Board Data

In the following example, a second-degree Almon polynomial lag model is fit to a model with a five-period lag, and dummy variables are used for quarter effects. The PDL model is estimated using capital appropriations data series for the period 1952 to 1967. The estimation model is written

$$\begin{aligned} CE_t = {} & a_0 + b_1 Q1_t + b_2 Q2_t + b_3 Q3_t \\ & + c_0 CA_t + c_1 CA_{t-1} + \ldots + c_5 CA_{t-5} \end{aligned}$$

where CE represents capital expenditures and CA represents capital appropriations.

The following statements use the REG procedure to fit the same polynomial distributed lag model. A DATA step computes lagged values of the regressor X, and

RESTRICT statements are used to impose the polynomial lag distribution. Refer to Judge, Griffiths, Hill, Lutkepohl, and Lee (1985, pp 357–359) for the restricted least squares estimation of the Almon distributed lag model.

```
   data b;
      set a;
      ca_1 = lag( ca );
      ca_2 = lag2( ca );
      ca_3 = lag3( ca );
      ca_4 = lag4( ca );
      ca_5 = lag5( ca );
   run;

   proc reg data=b;
      model  ce = q1 q2 q3 ca ca_1 ca_2 ca_3 ca_4 ca_5;
      restrict   - ca + 5*ca_1 - 10*ca_2 + 10*ca_3 - 5*ca_4 +   ca_5;
      restrict     ca - 3*ca_1 +  2*ca_2 +  2*ca_3 - 3*ca_4 +   ca_5;
      restrict  -5*ca + 7*ca_1 +  4*ca_2 -  4*ca_3 - 7*ca_4 + 5*ca_5;
   run;
```

The REG procedure output is shown in Output 21.1.2.

Example 21.2. Money Demand Model

This example estimates the demand for money using the following dynamic specification:

$$m_t = a_0 + b_0 m_{t-1} + \sum_{i=0}^{5} c_i y_{t-i} + \sum_{i=0}^{2} d_i r_{t-i} + \sum_{i=0}^{3} f_i p_{t-i} + u_t$$

where

m_t =log of real money stock (M1)

y_t =log of real GNP

r_t =interest rate (commercial paper rate)

p_t =inflation rate

c_i, d_i, and f_i $(i > 0)$are coefficients for the lagged variables

The following DATA step reads the data and transforms the real money and real GNP variables using the natural logarithm. Refer to Balke and Gordon (1986) for a description of the data.

```
data a;
   input m1 gnp gdf r @@;
   m    = log( 100 * m1 / gdf );
   lagm = lag( m );
   y    = log( gnp );
   p    = log( gdf / lag( gdf ) );
   date = intnx( 'qtr', '1jan1968'd, _n_-1 );
   format date yyqc6.;
   label m    = 'Real Money Stock (M1)'
         lagm = 'Lagged Real Money Stock'
         y    = 'Real GNP'
         r    = 'Commercial Paper Rate'
         p    = 'Inflation Rate';
cards;
   ... data lines are omitted ...
;

proc print data=a(obs=5);
   var date m lagm y r p;
run;
```

Output 21.2.1 shows a partial list of the data set.

Output 21.2.1. Partial List of the Data Set A

```

Chapter 22
The QLIM Procedure

Overview

The QLIM (Qualitative and LImited dependent variable Model) procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, tobit, selection, and multivariate models. The multivariate model can contain discrete choice and limited endogenous variables as well as continuous endogenous variables.

The QLIM procedure supports the following models:

- linear regression model with heteroscedasticity
- probit with heteroscedasticity
- logit with heteroscedasticity
- tobit (censored and truncated) with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- bivariate probit
- bivariate tobit
- sample selection and switching regression models
- multivariate limited dependent variables

Getting Started

The QLIM procedure is similar in use to the other regression or simultaneous equations model procedures in the SAS System. For example, the following statements are used to estimate a binary choice model using the probit probability function:

```
proc qlim data=a;
   model y = x1;
   endogenous y ~ discrete;
run;
```

The response variable, y, is numeric and has discrete values. PROC QLIM enables the user to specify the type of endogenous variables in the ENDOGENOUS statement. The binary probit model can be also specified as follows:

```
model y = x1 / discrete;
```

When multiple endogenous variables are specified in the QLIM procedure, these equations are estimated as a system. Multiple endogenous variables can be specified with one MODEL statement in the QLIM procedure when these models have the same exogenous variables:

```
model y1 y2 = x1 x2 / discrete;
```

The preceding specification is equivalent to

```
proc qlim data=a;
   model y1 = x1 x2;
   model y2 = x1 x2;
   endogenous y1 y2 ~ discrete;
run;
```

The standard tobit model is estimated by specifying the endogenous variable to be truncated or censored. The limits of the dependent variable can be specified with the CENSORED or TRUNCATED option in the ENDOGENOUS or MODEL statement when the data are limited by specific values or variables. For example, the two-limit censored model requires two variables that contain the lower (bottom) and upper (top) bound.

```
proc qlim data=a;
   model y = x1 x2 x3;
   endogenous y ~ censored(lb=bottom ub=top);
run;
```

The bounds can be numbers if they are fixed for all observations in the data set. For example, the standard tobit model can be specified as

```
proc qlim data=a;
   model y = x1 x2 x3;
   endogenous y ~ censored(lb=0);
run;
```

Introductory Example: Binary Probit and Logit Models

The following example illustrates the use of PROC QLIM. The data are originally published by Mroz (1987) and downloaded from Wooldridge (2002). This data set is based on a sample of 753 married white women. The dependent variable is a discrete variable of labor force participation (inlf). Explanatory variables are the number of children ages 5 or younger (kidslt6), the number of children ages 6 to 18 (kidsge6), the woman's age (age), the woman's years of schooling (educ), wife's labor experience (exper), square of experience (expersq), and the family income excluding the wife's wage (nwifeinc). The program (with data values omitted) is illustrated below.

```
title1 "Binary Data";
data mroz;
 input inlf nwifeinc educ exper expersq age kidslt6 kidsge6 lwage;
datalines;
1 10.91006    12 14  196   32  1   0   1.210154

  ...

;
run;

proc qlim data=mroz;
   model inlf = nwifeinc educ exper expersq age kidslt6 kidsge6  / discrete;
run;
```

Results of this analysis are shown in the following four figures. In the first table, shown in Figure 22.1, PROC QLIM provides frequency information on each choice. In this example, 428 women participate in the labor force (inlf=1).

```
                              Binary Data

                          The QLIM Procedure

                    Discrete Response Profile of inlf

              Index          Value           Frequency    Percent

                1              0                   325      43.16
                2              1                   428      56.84
```

Figure 22.1. Choice Frequency Summary

The second table is the estimation summary table shown in Figure 22.2. Included are the number of dependent variables, names of dependent variables, the number of observations, the log-likelihood function value, the maximum absolute gradient, the number of iterations, AIC, and Schwarz criterion.

```
                          Model Fit Summary

                   Number of Endogenous Variables             1
                   Endogenous Variable                     inlf
                   Number of Observations                   753
                   Log Likelihood                    -401.30219
                   Maximum Absolute Gradient          0.0004984
                   Number of Iterations                      15
                   AIC                                818.60439
                   Schwarz Criterion                  855.59691
```

Figure 22.2. Fit Summary Table of Binary Probit

Goodness-of-fit measures are displayed in Figure 22.3. All measures except McKelvey-Zavoina's definition are based on the log-likelihood function value. The likelihood ratio test statistic has chi-square distribution conditional on the null hypothesis that all slope coefficients are zero. In this example, the likelihood ratio statistic is used to test the hypothesis that kidslt6=kidge6=age=educ=exper=expersq=nwifeinc= 0.

```
                              Goodness-of-Fit Measures

  Measure                        Value    Formula

  Likelihood Ratio (R)          227.14    2 * (LogL - LogL0)
  Upper Bound of R (U)          1029.7    - 2 * LogL0
  Aldrich-Nelson                0.2317    R / (R+N)
  Cragg-Uhler 1                 0.2604    1 - exp(-R/N)
  Cragg-Uhler 2                 0.3494    (1-exp(-R/N)) / (1-exp(-U/N))
  Estrella                      0.2888    1 - (1-R/U)^(U/N)
  Adjusted Estrella             0.2693    1 - ((LogL-K)/LogL0)^(-2/N*LogL0)
  McFadden's LRI                0.2206    R / U
  Veall-Zimmermann              0.4012    (R * (U+N)) / (U * (R+N))
  McKelvey-Zavoina              0.4025

  N = # of observations, K = # of regressors
```

Figure 22.3. Goodness of Fit

Finally, the parameter estimates and standard errors are shown in Figure 22.4.

```

Figure 22.4. Parameter Estimates of Binary Probit

When the error term has a logistic distribution, the binary logit model is estimated. To specify a logistic distribution, add D=LOGIT option as follows,

```
   proc qlim data=mroz;
     model inlf = nwifeinc educ exper expersq age kidslt6 kidsge6  / discrete(d=logit);
   run;
```

The estimated parameters are shown in Figure 22.5.

```
                              The QLIM Procedure

```

Figure 22.5. Parameter Estimates of Binary Logit

The heteroscedastic logit model can be estimated using the HETERO statement. If the variance of the logit model is a function of the family income level excluding wife's income (nwifeinc), the variance can be specified as

$$Var(\epsilon_i) = \sigma^2 \exp(\gamma \, \text{nwifeinc}_i)$$

where σ^2 is normalized to 1 because the dependent variable is discrete. The following SAS statements estimate the heteroscedastic logit model:

```
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq age kidslt6 kidsge6 / discrete(d=logit);
  hetero inlf ~ nwifeinc / noconst;
run;
```

The parameter estimate (γ) of the heteroscedasticity variable is listed as _H.nwifeinc; see Figure 22.6.

```

Figure 22.6. Parameter Estimates of Binary Logit with Heteroscedasticity

Syntax

The QLIM procedure is controlled by the following statements:

PROC QLIM *options* **;**
  BOUNDS *bound1 [, bound2 . . .]* **;**
  BY *variables* **;**
  CLASS *variables* **;**
  ENDOGENOUS *variables* ∼ *options* **;**
  HETERO *dependent variables* ∼ *exogenous variables / options* **;**
  INIT *initvalue1 [, initvalue2 . . .]* **;**
  MODEL *dependent variables = regressors / options* **;**
  NLOPTIONS *options* **;**
  OUTPUT *options* **;**
  RESTRICT *restriction1 [, restriction2 . . .]* **;**
  WEIGHT *variable* **;**

At least one MODEL statement is required. If more than one MODEL statement is used, the QLIM procedure estimates a system of models. Main effects and higher-order terms can be specified in the MODEL statement, similar to the GLM procedure, and the PROBIT procedure in SAS/STAT. If a CLASS statement is used, it must precede the MODEL statement.

Functional Summary

The statements and options used with the QLIM procedure are summarized in the following table:

Description	Statement	Option
Data Set Options		
specify the input data set	QLIM	DATA=
write parameter estimates to an output data set	QLIM	OUTEST=
write predictions to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify classification variables	CLASS	
specify a weight variable	WEIGHT	
Printing Control Options		
request all printing options	QLIM	PRINTALL
print correlation matrix of the estimates	QLIM	CORRB
print covariance matrix of the estimates	QLIM	COVB
print a summary iteration listing	QLIM	ITPRINT

Description	Statement	Option
suppress the normal printed output	QLIM	NOPRINT
Options to Control the Optimization Process		
specify the optimization method	QLIM	METHOD=
specify the optimization options	NLOPTIONS	see Chapter 10
set initial values for parameters	INIT	
set linear restrictions on parameters	BOUNDS	
	RESTRICT	
Model Estimation Options		
specify options specific to Box-Cox transformation	MODEL	BOXCOX()
suppress the intercept parameter	MODEL	NOINT
specify a seed for pseudo-random number generation	QLIM	SEED=
specify number of draws for Monte Carlo integration	QLIM	NDRAW=
specify method to calculate parameter covariance	QLIM	COVEST=
Endogenous Variable Options		
specify discrete variable	ENDOGENOUS	DISCRETE()
specify censored variable	ENDOGENOUS	CENSORED()
specify truncated variable	ENDOGENOUS	TRUNCATED()
specify variable selection condition	ENDOGENOUS	SELECT()
Heteroscedasticity Model Options		
specify the function for heteroscedasticity models	HETERO	LINK=
square the function for heteroscedasticity models	HETERO	SQUARE
specify no constant for heteroscedasticity models	HETERO	NOCONST
Output Control Options		
output predicted values	OUTPUT	PREDICTED
output structured part	OUTPUT	XBETA
output residuals	OUTPUT	RESIDUAL
output error standard deviation	OUTPUT	ERRSTD
output marginal effects	OUTPUT	MARGINAL
output probability for the current response	OUTPUT	PROB
output probability for all responses	OUTPUT	PROBALL
output expected value	OUTPUT	EXPECTED
output conditional expected value	OUTPUT	CONDITIONAL
output inverse Mills ratio	OUTPUT	MILLS
include covariances in the OUTEST= data set	QLIM	COVOUT
include correlations in the OUTEST= data set	QLIM	CORROUT

PROC QLIM Statement

PROC QLIM *options* **;**

The following options can be used in the PROC QLIM statement:

Data Set Options

DATA= SAS-data-set
specifies the input SAS data set. If the DATA= option is not specified, PROC QLIM uses the most recently created SAS data set.

Output Data Set Options

OUTEST= SAS-data-set
writes the parameter estimates to an output data set.

COVOUT
writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

CORROUT
writes the correlation matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

Printing Options

NOPRINT
suppresses the normal printed output but does not suppress error listings. If NOPRINT option is set, then any other print option is turned off.

PRINTALL
turns on all the printing-control options. The options set by PRINTALL are COVB, CORRB.

CORRB
prints the correlation matrix of the parameter estimates.

COVB
prints the covariance matrix of the parameter estimates.

ITPRINT
prints the initial parameter estimates, convergence criteria, all constraints of the optimization. At each iteration, objective function value, step size, maximum gradient and slope of search direction are printed as well.

Model Estimation Options

COVEST= covariance-option
specify method to calculate the covariance matrix of parameter estimates. The supported covariance types are

OP	specifies the covariance from the outer product matrix

HESSIAN	specifies the covariance from the inverse Hessian matrix
QML	specifies the covariance from the outer product and Hessian matrices (the quasi-maximum likelihood estimates)

The default is COVEST=HESSIAN.

NDRAW= value
specify number of draws for Monte Carlo integration.

SEED= value
specify a seed for pseudo-random number generation in Monte Carlo integration.

Options to Control the Optimization Process

PROC QLIM uses the NonLinear Optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available from the NLOPTIONS statement. For details, see Chapter 10, "Nonlinear Optimization Methods."

METHOD=*value*

specifies the optimization method. If this option is specified, it overwrites the TECH= option in NLOPTIONS statement. Valid values are

CONGRA	performs a conjugate-gradient optimization
DBLDOG	performs a version of double dogleg optimization
NMSIMP	performs a Nelder-Mead simplex optimization
NEWRAP	performs a Newton-Raphson optimization combining a line-search algorithm with ridging
NRRIDG	performs a Newton-Raphson optimization with ridging
QUANEW	performs a quasi-Newton optimization
TRUREG	performs a trust region optimization

The default method is QUANEW.

BOUNDS Statement

BOUNDS *bound1 [, bound2 ...]* **;**

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the QLIM procedure. Any number of BOUNDS statements can be specified.

Each *bound* is composed of variables and constants and inequality operators:

item operator item [operator item [operator item . . .]]

Each *item* is a constant, the name of a parameter, or a list of parameter names. See the "Parameter Names" section for more details on how parameters are named in the QLIM procedure. Each *operator* is '<', '>', '<=', or '>='.

Both the BOUNDS statement and the RESTRICT statement can be used to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See the "RESTRICT Statement" section on page 1334 for more information.

The following BOUNDS statement constrains the estimates of the parameters associated with the variable ttime and the variables x1 through x10 to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < ttime x1-x10 < 1;
```

BY Statement

BY *variables* **;**

A BY statement can be used with PROC QLIM to obtain separate analyses on observations in groups defined by the BY variables.

CLASS Statement

CLASS *variables* **;**

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary*.

If the CLASS statement is used, it must appear before any of the MODEL statements.

ENDOGENOUS Statement

ENDOGENOUS *variables* ~ *options* **;**

The ENDOGENOUS statement specifies the type of endogenous variables.

Discrete Variable Options

DISCRETE <(*discrete-options***) >**
specifies that the endogenous variables in this statement are discrete. Valid *discrete-options* are as follows:

ORDER=DATA | FORMATTED | FREQ | INTERNAL
specifies the sorting order for the levels of the discrete variables specified in the ENDOGENOUS statement. This ordering determines which parameters in the model correspond to each level in the data. The following table shows how PROC QLIM interprets values of the ORDER= option.

Value of ORDER=	**Levels Sorted By**
DATA	order of appearance in the input data set
FORMATTED	formatted value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For the values FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter on the SORT procedure in the *SAS Procedures Guide*.

DISTRIBUTION=*distribution-type*
DIST=*distribution-type*
D=*distribution-type*
specifies the cumulative distribution function used to model the response probabilities. Valid values for *distribution-type* are

NORMAL	the normal distribution for the probit model
LOGISTIC	the logistic distribution for the logit model

By default, DISTRIBUTION=NORMAL.

Censored Variable Options

CENSORED < (*censored-options***) >**
specifies that the endogenous variables in this statement are censored. Valid *censored-options* are as follows:

LB=*value or variable*
LOWERBOUND=*value or variable*
specifies the lower bound of the censored variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*
UPPERBOUND=*value or variable*
specifies the upper bound of the censored variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Truncated Variable Options

TRUNCATED < (*truncated-options***) >**
specifies that the endogenous variables in this statement are truncated. Valid *truncated-options* are as follows:

LB=*value or variable*
LOWERBOUND=*value or variable*
specifies the lower bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no lower bound is set. By default, no lower bound is set.

UB=*value or variable*
UPPERBOUND=*value or variable*

specifies the upper bound of the truncated variables. If *value* is missing or the value in *variable* is missing, no upper bound is set. By default, no upper bound is set.

Selection Options

SELECT (*select-option***)**

specifies selection criteria for sample selection model. *Select-option* specifies the condition for the endogenous variable to be selected. It is written as a variable name, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a number:

variable operator number

The *variable* is the endogenous variable that the selection is based on. The *operator* can be =, <, >, <= , or >=. Multiple *select-options* can be combined with the logic operators: AND, OR. This example illustrates the use of SELECT option.

```
endogenous y1 ~ select(z=0);
endogenous y2 ~ select(z=1 and z=2);
```

HETERO Statement

HETERO *dependent variables* ∼ *exogenous variables / options*;

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance. The heteroscedastic regression model supported by PROC QLIM is

$$y_i = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

$$\epsilon_i \sim \mathrm{N}(0, \sigma_\mathrm{i}^2)$$

See the section "Heteroscedasticity" on page 1340 for more details on the specification of functional forms.

LINK=*value*

The functional form can be specified using the LINK= option. The following option values are allowed:

EXP specifies exponential link function

$$\sigma_i^2 \quad = \quad \sigma^2(1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma}))$$

LINEAR specifies linear link function

$$\sigma_i^2 = \sigma^2(1 + \mathbf{z}_i'\gamma)$$

When the LINK= option is not specified, the exponential link function is specified by default.

NOCONST
specifies that there is no constant in linear or exponential heteroscedasticity model.

$$\begin{aligned}\sigma_i^2 &= \sigma^2(\mathbf{z}_i'\gamma) \\ \sigma_i^2 &= \sigma^2\exp(\mathbf{z}_i'\gamma)\end{aligned}$$

SQUARE
estimates the model using the square of linear heteroscedasticity function. For example, you can specify the following heteroscedasticity function:

$$\sigma_i^2 = \sigma^2(1 + (\mathbf{z}_i'\gamma)^2)$$

```
model y = x1 x2 / discrete;
hetero y ~ z1 / link=linear square;
```

The option SQUARE does not apply to exponential heteroscedasticity function because the square of an exponential function of $\mathbf{z}_i'\gamma$ is the same the exponetial of $2\mathbf{z}_i'\gamma$. Hence the only difference is that all γ estimates are divided by two.

INIT Statement

INIT *initvalue1 [, initvalue2 . . .]* **;**

The INIT statement is used to set initial values for parameters in the optimization. Any number of INIT statements can be specified.

Each *initvalue* is written as a parameter or parameter list, followed by an optional equality operator (=), followed by a number:

parameter <=> number

MODEL Statement

MODEL *dependent = regressors / options ;*

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model.

The following options can be used in the MODEL statement after a slash (/).

LIMIT1=*value*
specifies the restriction of the threshold value of the first category when the ordinal probit or logit model is estimated. LIMIT1=ZERO is the default option. When LIMIT1=VARYING is specified, the threshold value is estimated.

NOINT
suppresses the intercept parameter.

Endogenous Variable Options

The endogenous variable options are the same as the options specified in the ENDOGENOUS statement. If an endogenous variable has endogenous option specified in both MODEL statement and ENDOGENOUS statement, the option in ENDOGENOUS statement is used.

BOXCOX Estimation Options

BOXCOX (*option-list***)**
specifies options that are used for Box-Cox regression or regressor transformation. For example, the Box-Cox regression is specified as

```
model y = x1 x2 / boxcox(y=lambda,x1 x2)
```

PROC QLIM estimates the following Box-Cox regression model:

$$y_i^{(\lambda)} = \beta_0 + \beta_1 x_{1i}^{(\lambda_2)} + \beta_2 x_{2i}^{(\lambda_2)} + \epsilon_i$$

The *option-list* takes the form of *variable-list* < = varname > separated by ’,’. The *variable-list* specifies the list of variables to have the same Box-Cox transformation. *varname* specifies the name of this Box-Cox coefficient. If *varname* is not specified, the coefficient is called _Lambda*i* where *i* increments sequentially.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

PROC QLIM uses the NonLinear Optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 10, “Nonlinear Optimization Methods.”

OUTPUT Statement

OUTPUT *<OUT=SAS-data-set> <output-options>***;**

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the estimates of $\mathbf{x}'\beta$, predicted value, residual, marginal effects, probability, standard deviation of the error, expected value, conditional expected value, inverse Mills ratio. When the response values are missing for the observation, all output estimates except residual are still computed as long as none of the explanatory variables is missing. This enables you to compute these statistics for prediction. You can only specify one OUTPUT statement.

Details on the specifications in the OUTPUT statement are as follows:

CONDITIONAL
output estimates of conditional expected values of continuous endogenous variables.

ERRSTD
output estimates of σ_j, the standard deviation of the error term.

EXPECTED
output estimates of expected values of continuous endogenous variables.

MARGINAL
output marginal effects.

MILLS
output estimates of inverse Mills ratios of continuous endogenous variables.

OUT=*SAS-data-set*
names the output data set.

PREDICTED
output estimates of predicted endogenous variables.

PROB
output estimates of probability of discrete endogenous variables taking the current observed responses.

PROBALL
output estimates of probability of discrete endogenous variables for all possible responses.

RESIDUAL
output estimates of residuals of continuous endogenous variables.

XBETA
output estimates of $\mathbf{x}'\beta$.

RESTRICT Statement

RESTRICT *restriction1 [, restriction2 ...]* **;**

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. Any number of RESTRICT statements can be specified.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <= , or >=. The operator and second expression are optional.

Restriction expressions can be composed of parameter names, times ($*$), plus ($+$) and minus ($-$) operators, and constants. Parameters named in restriction expressions must be among the parameters estimated by the model. The restriction expressions must be a linear function of the parameters.

The following is an example of the use of the RESTRICT statement:

```
proc qlim data=one;
model y = x1-x10 / discrete;
restrict x1*2 <= x2 + x3;
run;
```

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used in the estimation.

Details

Ordinal Discrete Choice Modeling

Binary Probit and Logit Model

The binary choice model is

$$y_i^* = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

where the sign of the dependent variable is only observed as follows:

$$\begin{aligned} y_i &= 1 \quad \text{if} \quad \mathrm{y_i^*} > 0 \\ &= 0 \quad \text{otherwise} \end{aligned}$$

The disturbance, ϵ_i, of the probit model has standard normal distribution with the distribution function (CDF)

$$\Phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp(-t^2/2)dt$$

The disturbance of the logit model has standard logistic distribution with the CDF

$$\Lambda(x) = \frac{\exp(x)}{1+\exp(x)} = \frac{1}{1+\exp(-x)}$$

The binary discrete choice model has the following probability that the event $\{y_i = 1\}$ occurs:

$$P(y_i = 1) = F(\mathbf{x}_i'\boldsymbol{\beta}) = \begin{cases} \Phi(\mathbf{x}_i'\boldsymbol{\beta}) & \text{(probit)} \\ \Lambda(\mathbf{x}_i'\boldsymbol{\beta}) & \text{(logit)} \end{cases}$$

The log-likelihood function is

$$\ell = \sum_{i=1}^{N} \left\{ y_i \log[F(\mathbf{x}_i'\boldsymbol{\beta})] + (1-y_i)\log[1 - F(\mathbf{x}_i'\boldsymbol{\beta})] \right\}$$

where the CDF $F(x)$ is defined as $\Phi(x)$ for the probit model while $F(x) = \Lambda(x)$ for logit. The first order derivative of the logit model are

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} (y_i - \Lambda(\mathbf{x}_i'\boldsymbol{\beta}))\mathbf{x}_i$$

The probit model has more complicated derivatives

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} \left[\frac{(2y_i - 1)\phi((2y_i-1)\mathbf{x}_i'\boldsymbol{\beta})}{\Phi((2y_i-1)\mathbf{x}_i'\boldsymbol{\beta})} \right] \mathbf{x}_i = \sum_{i=1}^{N} r_i \mathbf{x}_i$$

where

$$r_i = \frac{(2y_i - 1)\phi((2y_i-1)\mathbf{x}_i'\boldsymbol{\beta})}{\Phi((2y_i-1)\mathbf{x}_i'\boldsymbol{\beta})}$$

Note that logit maximum likelihood estimates are greater than probit maximum likelihood estimates by approximately $\frac{\pi}{\sqrt{3}}$, since the probit parameter estimates ($\boldsymbol{\beta}$) are standardized and the error term with logistic distribution has a variance of $\frac{\pi^2}{3}$.

Ordinal Probit/Logit

When the dependent variable is observed in sequence with M categories, binary discrete choice modeling is not appropriate for data analysis. McKelvey and Zavoina (1975) proposed the ordinal (or ordered) probit model.

Consider the following regression equation:

$$y_i^* = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

where error disturbances, ϵ_i, have the distribution function F. The unobserved continuous random variable, y_i^*, is identified as M categories. Suppose there are $M+1$ real numbers, $\mu_0, \cdots, \mu_M$, where $\mu_0 = -\infty$, $\mu_1 = 0$, $\mu_M = \infty$, and $\mu_0 \leq \mu_1 \leq \cdots \leq \mu_M$. Define that

$$R_{i,j} = \mu_j - \mathbf{x}_i'\boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the jth category can be written as

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The log-likelihood function is

$$\ell = \sum_{i=1}^{N} \sum_{j=1}^{M} d_{ij} \log \left[F(R_{i,j}) - F(R_{i,j-1}) \right]$$

where

$$d_{ij} = \begin{cases} 1 & \text{if } \mu_{j-1} < y_i \leq \mu_j \\ 0 & \text{otherwise} \end{cases}$$

The first derivatives are written as

$$\frac{\partial \ell}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} \sum_{j=1}^{M} d_{ij} \left[\frac{f(R_{i,j-1}) - f(R_{i,j})}{F(R_{i,j}) - F(R_{i,j-1})} \mathbf{x}_i \right]$$

$$\frac{\partial \ell}{\partial \mu_k} = \sum_{i=1}^{N} \sum_{j=1}^{M} d_{ij} \left[\frac{\delta_{j,k} f(R_{i,j}) - \delta_{j-1,k} f(R_{i,j-1})}{F(R_{i,j}) - F(R_{i,j-1})} \right]$$

where $f(x) = \frac{dF(x)}{dx}$ and $\delta_{j,k} = 1$ if $j = k$. When the ordinal probit is estimated, it is assumed that $F(R_{i,j}) = \Phi(R_{i,j})$. The ordinal logit model is estimated if $F(R_{i,j}) = \Lambda(R_{i,j})$. The first threshold parameter, μ_1, is estimated when the LIMIT1=VARYING option is specified. By default (LIMIT1=ZERO), so that $M-2$ threshold parameters $(\mu_2, \ldots, \mu_{M-1})$ are estimated.

The ordered probit models are analyzed by Aitchison and Silvey (1957), and Cox (1970) discussed ordered response data using the logit model. They defined the probability that y_i^* belongs to jth category as

$$P[\mu_{j-1} < y_i \leq \mu_j] = F(\mu_j + \mathbf{x}_i'\boldsymbol{\theta}) - F(\mu_{j-1} + \mathbf{x}_i'\boldsymbol{\theta})$$

where $\mu_0 = -\infty$ and $\mu_M = \infty$. Therefore, the ordered response model analyzed by Aitchison and Silvey can be estimated if the LIMIT1=VARYING option is specified. Note that $\boldsymbol{\theta} = -\boldsymbol{\beta}$.

Goodness-of-Fit Measures

McFadden (1974) suggested a likelihood ratio index that is analogous to the R^2 in the linear regression model.

$$R_M^2 = 1 - \frac{\ln L}{\ln L_0}$$

where L is the value of the maximum likelihood function and L_0 is a likelihood function when regression coefficients except an intercept term are zero. It can be shown that L_0 can be written as

$$L_0 = \sum_{j=1}^{M} N_j \ln(\frac{N_j}{N}),$$

where N_j is the number of responses in category j.

Estrella (1998) proposes the following requirements for a goodness-of-fit measure to be desirable in discrete choice modeling:

- The measure must take values in $[0, 1]$, where 0 represents no fit and 1 corresponds to perfect fit.
- The measure should be directly related to the valid test statistic for significance of all slope coefficients.
- The derivative of the measure with respect to the test statistic should comply with corresponding derivatives in a linear regression.

Estrella's measure is written

$$R_{E1}^2 = 1 - \left(\frac{\ln L}{\ln L_0}\right)^{-\frac{2}{N}\ln L_0}$$

An alternative measure suggested by Estrella is

$$R_{E2}^2 = 1 - [(\ln L - K)/\ln L_0]^{-\frac{2}{N}\ln L_0}$$

where $\ln L_0$ is computed with null slope parameter values, N is the number observations used, and K represents the number of estimated parameters.

Other goodness-of-fit measures are summarized as follows:

$$R^2_{CU1} = 1 - \left(\frac{L_0}{L}\right)^{\frac{2}{N}} \quad \text{(Cragg-Uhler 1)}$$

$$R^2_{CU2} = \frac{1 - (L_0/L)^{\frac{2}{N}}}{1 - L_0^{\frac{2}{N}}} \quad \text{(Cragg-Uhler 2)}$$

$$R^2_A = \frac{2(\ln L - \ln L_0)}{2(\ln L - \ln L_0) + N} \quad \text{(Aldrich-Nelson)}$$

$$R^2_{VZ} = R^2_A \frac{2\ln L_0 - N}{2\ln L_0} \quad \text{(Veall-Zimmermann)}$$

$$R^2_{MZ} = \frac{\sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}}_i)^2}{N + \sum_{i=1}^N (\hat{y}_i - \bar{\hat{y}}_i)^2} \quad \text{(McKelvey-Zavoina)}$$

where $\hat{y}_i = \mathbf{x}_i'\hat{\boldsymbol{\beta}}$ and $\bar{\hat{y}}_i = \sum_{i=1}^N \hat{y}_i/N$.

Limited Dependent Variable Models

Censored Regression Models

When the dependent variable is censored, values in a certain range are all transformed to a single value. For example, the standard tobit model can be defined as

$$y_i^* = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \le 0 \end{cases}$$

where $\epsilon_i \sim iidN(0, \sigma^2)$. The log-likelihood function of the standard censored regression model is

$$\ell = \sum_{i\in\{y_i=0\}} \ln[1 - \Phi(\mathbf{x}_i'\boldsymbol{\beta}/\sigma)] + \sum_{i\in\{y_i>0\}} \ln\left[\frac{\phi((y_i - \mathbf{x}_i'\boldsymbol{\beta})/\sigma)}{\sigma}\right]$$

where $\Phi(\cdot)$ is the cumulative density function of the standard normal distribution and $\phi(\cdot)$ is the probability density function of the standard normal distribution.

The tobit model can be generalized to handle observation-by-observation censoring. The censored model on both of the lower and upper limits can be defined as follows

$$y_i = \begin{cases} R_i & \text{if } y_i^* \geq R_i \\ y_i^* & \text{if } L_i < y_i^* < R_i \\ L_i & \text{if } y_i^* \leq L_i \end{cases}$$

The log-likelihood function can be written as

$$\begin{aligned} \ell &= \sum_{i \in \{L_i < y_i < R_i\}} \ln \phi(\frac{y_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})/\sigma + \sum_{i \in \{y_i = R_i\}} \ln \Phi(-\frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma}) + \\ & \sum_{i \in \{y_i = L_i\}} \ln \Phi(\frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma}) \end{aligned}$$

Log-likelihood functions of the lower- or upper-limit censored model are easily derived from the two-limit censored model. The log-likelihood function of the lower-limit censored model is

$$\ell = \sum_{i \in \{y_i > L_i\}} \ln \phi(\frac{y_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})/\sigma + \sum_{i \in \{y_i = L_i\}} \ln \Phi(\frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})$$

The log-likelihood function of the upper-limit censored model is

$$\ell = \sum_{i \in \{y_i < R_i\}} \ln \phi(\frac{y_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})/\sigma + \sum_{i \in \{y_i = R_i\}} \ln \left[1 - \Phi(\frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})\right]$$

Truncated Regression Models

In truncated model, the observed sample is a subset of the population where the dependent variable falls in a certain range. For example, when neither a dependent variable nor exogenous variables are observed for $y_i^* \leq 0$, the truncated regression model can be specified. The log-likelihood function of the truncated regression model is

$$\ell = \sum_{i \in \{y_i > 0\}} \left\{ -\ln \Phi(\mathbf{x}_i'\boldsymbol{\beta}/\sigma) + \ln \left[\frac{\phi((y_i - \mathbf{x}_i'\boldsymbol{\beta})/\sigma)}{\sigma}\right] \right\}$$

The two-limit truncation model is defined as

$$y_i = y_i^* \quad \text{if } L_i < y_i^* < R_i$$

The log-likelihood function of the two-limit truncated regression model is

$$\ell = \sum_{i=1}^{N} \left\{ \ln \phi(\frac{y_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})/\sigma - \ln \left[\Phi(\frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma}) - \Phi(\frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma})\right] \right\}$$

The log-likelihood functions of the lower- and upper-limit truncation model are

$$\begin{aligned}\ell &= \sum_{i=1}^{N}\left\{\ln\left[\phi\left(\frac{y_i-\mathbf{x}_i'\boldsymbol{\beta}}{\sigma}\right)/\sigma\right]-\ln\left[1-\Phi\left(\frac{L_i-\mathbf{x}_i'\boldsymbol{\beta}}{\sigma}\right)\right]\right\} \quad \text{(lower)}\\ \ell &= \sum_{i=1}^{N}\left\{\ln\left[\phi\left(\frac{y_i-\mathbf{x}_i'\boldsymbol{\beta}}{\sigma}\right)/\sigma\right]-\ln\left[\Phi\left(\frac{R_i-\mathbf{x}_i'\boldsymbol{\beta}}{\sigma}\right)\right]\right\} \quad \text{(upper)}\end{aligned}$$

Heteroscedasticity and Box-Cox Transformation

Heteroscedasticity

If the variance of regression disturbance (ϵ_i) is heteroscedastic, the variance can be specified as a function of variables

$$E(\epsilon_i^2) = \sigma_i^2 = f(\mathbf{z}_i'\boldsymbol{\gamma})$$

The following table shows various functional forms of heteroscedasticity and the corresponding options to request each model.

No.	Model	Options
1	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2(1+\exp(\mathbf{z}_i'\gamma))$	link=EXP (default)
2	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2\exp(\mathbf{z}_i'\gamma)$	link=EXP noconst
3	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2(1+\sum_{l=1}^{L}\gamma_l z_{li})$	link=LINEAR
4	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2(1+(\sum_{l=1}^{L}\gamma_l z_{li})^2)$	link=LINEAR square
5	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2(\sum_{l=1}^{L}\gamma_l z_{li})$	link=LINEAR noconst
6	$f(\mathbf{z}_i'\boldsymbol{\gamma}) = \sigma^2((\sum_{l=1}^{L}\gamma_l z_{li})^2)$	link=LINEAR square noconst

For discrete choice models, σ^2 is normalized ($\sigma^2 = 1$) since this parameter is not identified. Note that in models 3 and 5, it may be possible that variances of some observations are negative. Although the QLIM procedure assigns a large penalty to move the optimization away from such regions, sometimes the optimization may stuck in such regions. Signs of such outcome include extremely small likelihood values or missing standard errors in the estimates. In models 2 and 6, variances are guaranteed to be greater or equal to zero but it may be possible that variances of some observations are very close to zero. In these scenarios, standard errors may be missing. Models 1 and 4 do not have such problems. Variances in these models are always positive and never close to zero.

The heteroscedastic regression model is estimated using the following log-likelihood function:

$$\ell = -\frac{N}{2}\ln(2\pi) - \sum_{i=1}^{N}\frac{1}{2}\ln(\sigma_i^2) - \frac{1}{2}\sum_{i=1}^{N}\left(\frac{e_i}{\sigma_i}\right)^2$$

where $e_i = y_i - \mathbf{x}_i'\boldsymbol{\beta}$.

Box-Cox Modeling

The Box-Cox transformation on x is defined as

$$x^{(\lambda)} = \begin{cases} \frac{x^{\lambda}-1}{\lambda} & \text{if } \lambda \neq 0 \\ \ln(x) & \text{if } \lambda = 0 \end{cases}$$

The Box-Cox regression model with heteroscedasticity is written

$$\begin{aligned} y_i^{(\lambda_0)} &= \beta_0 + \sum_{k=1}^{K} \beta_k x_{ki}^{(\lambda_k)} + \epsilon_i \\ &= \mu_i + \epsilon_i \end{aligned}$$

where $\epsilon_i \sim N(0, \sigma_i^2)$ and transformed variables must be positive. In practice, too many transformation parameters cause numerical problems in model fitting. It is common to have the same Box-Cox transformation performed on all the variables, that is, $\lambda_0 = \lambda_1 = \cdots = \lambda_K$. It is required for the magnitude of transformed variables to be in the tolerable range if the corresponding transformation parameters are $|\lambda| > 1$.

The log-likelihood function of the Box-Cox regression model is written

$$\ell = -\frac{N}{2}\ln(2\pi) - \sum_{i=1}^{N} \ln(\sigma_i) - \frac{1}{2\sigma_i^2}\sum_{i=1}^{N} e_i^2 + (\lambda_0 - 1)\sum_{i=1}^{N} \ln(y_i)$$

where $e_i = y_i^{(\lambda_0)} - \mu_i$.

When the dependent variable is discrete, censored, or truncated, the Box-Cox transformation can only be applied to explanatory variables.

Bivariate Limited Dependent Variable Modeling

The generic form of a bivariate limited dependent variable model is

$$\begin{aligned} y_{1i}^* &= \mathbf{x}_{1i}'\boldsymbol{\beta}_1 + \epsilon_{1i} \\ y_{2i}^* &= \mathbf{x}_{2i}'\boldsymbol{\beta}_2 + \epsilon_{2i} \end{aligned}$$

where the disturbances, ϵ_{1i} and ϵ_{2i}, have normal distribution with zero mean, standard deviations σ_1 and σ_2, and correlation of ρ. y_1^* and y_2^* are latent variables. The dependent variables y_1 and y_2 are observed if the latent variables y_1^* and y_2^* fall in certain ranges.

$$\begin{aligned} y_1 = y_{1i} \quad & \text{if} \quad y_{1i}^* \in D_1(y_{1i}) \\ y_2 = y_{2i} \quad & \text{if} \quad y_{2i}^* \in D_2(y_{2i}) \end{aligned}$$

D is a transformation from (y_{1i}^*, y_{2i}^*) to (y_{1i}, y_{2i}). For example, if $y1$ and $y2$ are censored variables with lower bound 0, then

$$
\begin{array}{llll}
y_1 = y_{1i} & \text{if } \; y_{1i}^* > 0, & y_1 = 0 & \text{if } \; y_{1i}^* \leq 0 \\
y_2 = y_{2i} & \text{if } \; y_{2i}^* > 0, & y_2 = 0 & \text{if } \; y_{2i}^* \leq 0
\end{array}
$$

There are three cases for the log likelihood of (y_{1i}, y_{2i}). The first case is that $y_{1i} = y_{1i}^*$ and $y_{2i} = y_{2i}^*$. That is, this observation is mapped to one point in the space of latent variables. The log likelihood is computed from a bivariate normal density,

$$
\ell_i = \ln \phi_2\left(\frac{y_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}, \frac{y_2 - \mathbf{x_2}'\boldsymbol{\beta}_2}{\sigma_2}, \rho\right) - \ln \sigma_1 - \ln \sigma_2
$$

where $\phi_2(u, v, \rho)$ is the density function for standardized bivariate normal distribution with correlation ρ,

$$
\phi_2(u, v, \rho) = \frac{e^{-(1/2)(u^2 + v^2 - 2\rho uv)/(1-\rho^2)}}{2\pi(1-\rho^2)^{1/2}}
$$

The second case is that one observed dependent variable is mapped to a point of its latent variable and the other dependent variable is mapped to a segment in the space of its latent variable. For example, in the bivariate censored model specified, if observed $y1 > 0$ and $y2 = 0$, then $y1^* = y1$ and $y2^* \in (-\infty, 0]$. In general, the log likelihood for one observation can be written as follows (the subscript i is dropped for simplicity): If one set is a single point and the other set is a range, without loss of generality, let $D_1(y_1) = \{y_1\}$ and $D_2(y_2) = [L_2, R_2]$,

$$
\begin{aligned}
\ell_i &= \ln \phi\left(\frac{y_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}\right) - \ln \sigma_1 \\
&+ \ln\left[\Phi\left(\frac{R_2 - \mathbf{x_2}'\boldsymbol{\beta}_2 - \rho\frac{y_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2}\right) - \Phi\left(\frac{L_2 - \mathbf{x_2}'\boldsymbol{\beta}_2 - \rho\frac{y_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}}{\sigma_2}\right)\right]
\end{aligned}
$$

where ϕ and Φ are the density function and the cumulative probability function for standardized univariate normal distribution.

The third case is that both dependent variables are mapped to segments in the space of latent variables. For example, in the bivariate censored model specified, if observed $y1 = 0$ and $y2 = 0$, then $y1^* \in (-\infty, 0]$ and $y2^* \in (-\infty, 0]$. In general, if $D_1(y_1) = [L_1, R_1]$ and $D_2(y_2) = [L_2, R_2]$, the log likelihood is

$$
\ell_i = \ln \int_{\frac{L_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}}^{\frac{R_1 - \mathbf{x_1}'\boldsymbol{\beta}_1}{\sigma_1}} \int_{\frac{L_2 - \mathbf{x_2}'\boldsymbol{\beta}_2}{\sigma_2}}^{\frac{R_2 - \mathbf{x_2}'\boldsymbol{\beta}_2}{\sigma_2}} \phi_2(u, v, \rho)\, du\, dv
$$

Selection Models

In sample selection models, one or several dependent variables are observed when another variable takes certain values. For example, the standard Heckman selection model can be defined as

$$z_i^* = \mathbf{w}_i'\boldsymbol{\gamma} + u_i$$

$$z_i = \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \le 0 \end{cases}$$

$$y_i = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i \text{ if } z_i = 1$$

where u_i and ϵ_i are jointly normal with zero mean, standard deviations of 1 and σ, and correlation of ρ. z is the variable that the selection is based on and y is observed when z has a value of 1. Least squares regression using the observed data of y produces inconsistent estimates of $\boldsymbol{\beta}$. Maximum likelihood method is used to estimate selection models. The log-likelihood function of the Heckman selection model is written as

$$\begin{aligned} \ell &= \sum_{i\in\{z_i=0\}} \ln[1-\Phi(\mathbf{w}_i'\boldsymbol{\gamma})] \\ &+ \sum_{i\in\{z_i=1\}} \{\ln\phi(\frac{y_i-\mathbf{x_i}'\boldsymbol{\beta}}{\sigma}) - \ln\sigma + \ln\Phi(\mathbf{w}_i'\boldsymbol{\gamma} + \rho\frac{y_i-\mathbf{x_i}'\boldsymbol{\beta}}{\sigma})\} \end{aligned}$$

Only one variable is allowed for the selection to be based on, but the selection may lead to several variables. For example, in the following switch regression model,

$$z_i^* = \mathbf{w}_i'\boldsymbol{\gamma} + u_i$$

$$z_i = \begin{cases} 1 & \text{if } z_i^* > 0 \\ 0 & \text{if } z_i^* \le 0 \end{cases}$$

$$\begin{aligned} y_{1i} &= \mathbf{x}_{1i}'\boldsymbol{\beta}_1 + \epsilon_{1i} \text{ if } z_i = 0 \\ y_{2i} &= \mathbf{x}_{2i}'\boldsymbol{\beta}_2 + \epsilon_{2i} \text{ if } z_i = 1 \end{aligned}$$

z is the variable that the selection is based on. If $z = 0$, then y_1 is observed. If $z = 1$, then y_2 is observed. Because it is never the case that $y1$ and $y2$ are observed at the same time, the correlation between y_1 and y_2 cannot be estimated. Only the correlation between z and y_1 and the correlation between z and y_2 can be estimated. This estimation uses the maximum likelihood method.

Multivariate Limited Dependent Models

The multivariate model is similar to bivariate models. The generic form of the multivariate limited dependent variable model is

$$\begin{aligned} y^*_{1i} &= \mathbf{x}'_{1i}\boldsymbol{\beta}_1 + \epsilon_{1i} \\ y^*_{2i} &= \mathbf{x}'_{2i}\boldsymbol{\beta}_2 + \epsilon_{2i} \\ &\ldots \\ y^*_{mi} &= \mathbf{x}'_{mi}\boldsymbol{\beta}_m + \epsilon_{mi} \end{aligned}$$

where m is the number of models to be estimated. The vector ϵ has multivariate normal distribution with mean 0 and variance-covariance matrix Σ. Similar to bivariate models, the likelihood may involve computing multivariate normal integrations. This is done using Monte Carlo integration. (See Genz 1992; Hajivassiliou and McFadden D. 1998).

When the number of equations N increases in a system, the number of parameters increases at the rate of N^2 because of the correlation matrix. When the number of parameters is large, sometimes the optimization converges but some of the standard deviations are missing. This usually means that the model is overparameterized. The default method for computing the covariance is to use the inverse Hessian matrix. Hessian is computed by finite differences, and in overparameterized cases, the inverse cannot be computed. It is recommended to reduce the number of parameters in such cases. Sometimes using the outer product covariance matrix (COVEST=OP option) may also help.

Output

XBeta, Predicted, Residual

Xbeta is the structural part on the right-hand side of the model. Predicted value is the predicted dependent variable value. For censored variables, if the predicted value is outside the boundaries, it is reported as the closest boundary. For discrete variables, it is the level whose boundaries Xbeta falls in between. Residual is only defined for continuous variables and is defined as

$$Residual = Observed - Predicted$$

Error Standard Deviation

Error standard deviation is σ_i in the model. It only varies when the HETERO statement is used.

Marginal Effects

Marginal effect is the contribution of one control variable to the response variable. For the binary choice model and ordinal response model with M categories, specify

$M+1$ real numbers, $\mu_0, \cdots, \mu_M$, where $\mu_0 = -\infty$, $\mu_1 = 0$ (or estimated when LIMIT1=VARYING), $\mu_M = \infty$, and $\mu_0 \leq \mu_1 \leq \cdots \leq \mu_M$. Define that

$$R_{i,j} = \mu_j - \mathbf{x}_i'\boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the jth category can be written

$$P[\mu_{j-1} < y_i^* \leq \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The marginal effect of changes in the regressors on the probability of $y_i = j$ is then

$$\frac{\partial Prob[y_i = j]}{\partial \mathbf{x}} = [f(\mu_{j-1} - \mathbf{x}_i'\boldsymbol{\beta}) - f(\mu_j - \mathbf{x}_i'\boldsymbol{\beta})]\boldsymbol{\beta}$$

where $f(x) = \frac{dF(x)}{dx}$. In particular,

$$f(x) = \frac{dF(x)}{dx} = \begin{cases} \frac{1}{\sqrt{2\pi}} e^{-x^2/2} & \text{(probit)} \\ \frac{e^{-x}}{[1+e^{(-x)}]^2} & \text{(logit)} \end{cases}$$

The marginal effects in the Box-Cox regression model are

$$\frac{\partial E[y_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \frac{x^{\lambda_k - 1}}{y^{\lambda_0 - 1}}$$

The marginal effects in the truncated regression model are

$$\frac{\partial E[y_i | L_i < y_i^* < R_i]}{\partial \mathbf{x}} = \boldsymbol{\beta}\left[1 - \frac{(\phi(a_i) - \phi(b_i))^2}{(\Phi(b_i) - \Phi(a_i))^2} + \frac{a_i\phi(a_i) - b_i\phi(b_i)}{\Phi(b_i) - \Phi(a_i)}\right]$$

where $a_i = \frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$.

The marginal effects in the censored regression model are

$$\frac{\partial E[y|\mathbf{x}_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \times Prob[L_i < y_i^* < R_i]$$

Inverse Mills Ratio, Expected and Conditionally Expected Values

These values only apply to continuous variables. Let L_i and R_i be the lower boundary and upper boundary for the y_i. Define $a_i = \frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$. Then the Inverse Mills Ratio is defined as

$$\lambda = \frac{(\phi(a_i) - \phi(b_i))}{(\Phi(b_i) - \Phi(a_i))}$$

The expected value is the unconditional expectation of the dependent variable. For a censored variable, it is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i)(\Phi(a_i) - \Phi(b_i) + (1 - \Phi(b_i))R_i$$

For a noncensored variable, this is

$$E[y_i] = \mathbf{x}_i'\boldsymbol{\beta}$$

The conditional expected value is the expectation given that the variable is inside the boundaries.

$$E[y_i|L_i < y_i < R_i] = \mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i$$

Probability

Probability is only for discrete responses. It is the marginal probability that the discrete response is taking the value of the observation. If the PROBALL option is specified, then the probability for all of the possible responses of the discrete variables are computed.

Naming

Naming of Parameters

When there is only one equation in the estimation, parameters are named in the same way as other SAS procedures such as REG, PROBIT, etc. The constant in the regression equation is called Intercept. The coefficients on independent variables are named by the independent variables. The standard deviation of the errors is called _Sigma. If there are Box-Cox transformations, the coefficients are named _Lambda$i$, where i increments from 1, or as specified by the user. The limits for the discrete dependent variable are named _Limit$i$. If the LIMIT=varying option is specified, then _Limit$i$ starts from 1. If the LIMIT=varying option is not specified, then _Limit1 is set to 0 and the limit parameters start from $i = 2$. If the HETERO statement is included, the coefficients of the independent variables in the hetero equation are called _H.x where x is the name of the independent variable.

When there are multiple equations in the estimation, the parameters in the main equation are named in the format of $y.x$ where y is the name of the dependent variable and x is the name of the independent variable. The standard deviation of the errors is call _Sigma.y. Box-Cox parameters are called _Lambda$i.y$ and limit variables are called _Limit$i.y$. Parameters in the HETERO statement are named as _H.$y.x$. In the OUTEST= data set, all variables are changed from '.' to '_'.

Naming of Output Variables

The following table shows the option in the Output statement, with the corresponding variable names and their explanation.

Option	Name	Explanation
PREDICTED	P_y	Predicted value of y
RESIDUAL	RESID_y	Residual of y, (y-PredictedY)
XBETA	XBETA_y	Structure part ($\mathbf{x}'\boldsymbol{\beta}$) of y equation
ERRSTD	ERRSTD_y	Standard deviation of error term
PROB	PROB_y	Probability that y is taking the observed value in this observation. (Discrete y only)
PROBALL	PROBi_y	Probability that y is taking the i^{th} value. (Discrete y only)
MILLS	MILLS_y	Inverse Mills ratio for y
EXPECTED	EXPCT_y	Unconditional expected value of y
CONDITIONAL	CEXPCT_y	Conditional expected value of y, condition on the truncation.
MARGINAL	MEFF_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with single equation
	MEFF_y_x	Marginal effect of x on y ($\frac{\partial y}{\partial x}$) with multiple equations
	MEFF_Pi_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with single equation and discrete y
	MEFF_Pi_y_x	Marginal effect of x on y ($\frac{\partial Prob(y=i)}{\partial x}$) with multiple equations and discrete y

If you prefer to name the output variables differently, you can use the RENAME option in the data set. For example, the following statement renames the residual of y to *Resid*.

```
proc qlim data=one;
model y = x1-x10 / censored;
output out=outds(rename=(resid_y=resid)) residual;
run;
```

ODS Table Names

PROC QLIM assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 22.1. ODS Tables Produced in PROC QLIM

ODS Table Name	Description	Option
	ODS Tables Created by the Model Statement	
FitSummary	Summary of Nonlinear Estimation	default
ResponseProfile	Response Profile	default
GoodnessOfFit	Pseudo-R^2 Measures	default

Table 22.1. (continued)

ODS Table Name	Description	Option
ParameterEstimates	Parameter Estimates	default
CovB	Covariance of Parameter Estimates	COVB
CorrB	Correlation of Parameter Estimates	CORRB

Examples

Example 22.1. Ordered Data Modeling

Cameron and Trivedi (1986) studied an Australian Health Survey data. Variable definitions are given in Cameron and Trivedi (1998, p. 68). The dependent variable, dvisits, has nine ordered values. The following SAS statements estimate the ordinal probit model:

```
data docvisit;
   input sex age agesq income levyplus freepoor freerepa
         illness actdays hscore chcond1 chcond2 dvisits;
   y = (dvisits > 0);
   if ( dvisits > 8 ) then dvisits = 8;

  ...

 0 0.72 0.5184 0.25  0  0  1  0  0  0  0  0  0
;

title1 "Ordered Discrete Responses";
proc qlim data=docvisit;
  model dvisits = sex age agesq income levyplus
   freepoor freerepa illness actdays hscore
   chcond1 chcond2 / discrete;
run;
```

The output of the QLIM procedure for Ordered Data Modeling is shown in Output 22.1.1.

```

By default, ordinal probit/logit models are estimated assuming that the first threshold or limit parameter (μ_1) is 0. However, this parameter can also be estimated when the

LIMIT1=VARYING option is specified. The probability that y_i^* belongs to the jth category is defined as

$$P[\mu_{j-1} < y_i^* < \mu_j] = F(\mu_j - \mathbf{x}_i'\boldsymbol{\beta}) - F(\mu_{j-1} - \mathbf{x}_i'\boldsymbol{\beta})$$

where $F(\cdot)$ is the logistic or standard normal CDF, $\mu_0 = -\infty$ and $\mu_9 = \infty$. Output 22.1.2 lists ordinal or cumulative logit estimates. Note that the intercept term is suppressed for model identification when μ_1 is estimated.

Example 22.2. Tobit Analysis

The following table shows a subset of the Mroz (1987) data set. In this data, Hours is the number of hours the wife worked outside the household in a given year, Yrs_Ed is the years of education, and Yrs_Exp is the years of work experience. A Tobit model will be fit to the hours worked with years of education and experience as covariates.

```

Example 22.3. Bivariate Probit Analysis

This example shows how to estimate a bivariate probit model. Note the INIT statement in the code that set the initial values for some parameters in the optimization.

```
data a;
  keep y1 y2 x1 x2;
  do i = 1 to 500;
    x1 = rannor( 19283 );
    x2 = rannor( 98721 );
```

```
         u1 = rannor( 76527 );
         u2 = rannor( 65721 );
         y1l = 1 + 2 * x1 + 3 * x2 + u1;
         y2l = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
         if ( y1l > 0 ) then y1 = 1;
         else  y1 = 0;
         if ( y2l > 0 ) then y2 = 1;
         else  y2 = 0;
         output;
        end;
      run;

   proc qlim data=a method=qn;
     init y1.x1 2.8, y1.x2 2.1,
        _rho .1;
     model y1 = x1 x2;
     model y2 = x1 x2;
     endogenous y1 y2 ~ discrete;
   run;
```

Example 22.4. Sample Selection Model

The following example illustrates the use of PROC QLIM for sample selection models. The data set is the same one from Mroz (1987). The goal is to estimate a wage offer function for married women, accounting for potential selection bias. Of the 753 women, the wage is observed for 428 working women. The labor force participation equation estimated in the introductory example is used for selection. The wage equation use log wage (lwage) as dependent variable. The explanatory variables in the wage equation are the woman's years of schooling (educ), wife's labor experience (exper), square of experience (expersq). The program is illustrated below.

```
proc qlim data=mroz;
  model inlf = nwifeinc educ exper expersq age kidslt6 kidsge6 /discrete;
  model lwage = educ exper expersq / select(inlf=1);
run;
```

The output of the QLIM procedure is shown in Output 22.4.1.

     inlf.kidsge6            0.035873       0.043475       0.83      0.4093
     _Rho                    0.026605       0.147078       0.18      0.8565
```

Note the correlation estimate is insignificant. This indicates that selection bias is not a big problem in the estimation of wage equation.

Chapter 23
The SIMLIN Procedure

Chapter Contents

Chapter 23 The SIMLIN Procedure

Overview

The SIMLIN procedure reads the coefficients for a set of linear structural equations, which are usually produced by the SYSLIN procedure. PROC SIMLIN then computes the reduced form and, if input data are given, uses the reduced form equations to generate predicted values. PROC SIMLIN is especially useful when dealing with sets of structural difference equations. The SIMLIN procedure can perform simulation or forecasting of the endogenous variables.

The SIMLIN procedure can be applied only to models that are:

- linear with respect to the parameters
- linear with respect to the variables
- square (as many equations as endogenous variables)
- nonsingular (the coefficients of the endogenous variables form an invertible matrix)

Getting Started

The SIMLIN procedure processes the coefficients in a data set created by the SYSLIN procedure using the OUTEST= option or by another regression procedure such as PROC REG. To use PROC SIMLIN you must first produce the coefficient data set and then specify this data set on the EST= option of the PROC SIMLIN statement. You must also tell PROC SIMLIN which variables are endogenous and which variables are exogenous. List the endogenous variables in an ENDOGENOUS statement, and list the exogenous variables in an EXOGENOUS statement.

The following example illustrates the creation of an OUTEST= data set with PROC SYSLIN and the computation and printing of the reduced form coefficients for the model with PROC SIMLIN.

```
proc syslin data=in outest=e;
   model y1 = y2 x1;
   model y2 = y1 x2;
run;

proc simlin est=e;
   endogenous y1 y2;
   exogenous x1 x2;
run;
```

If the model contains lagged endogenous variables you must also use a LAGGED statement to tell PROC SIMLIN which variables contain lagged values, which endogenous variables they are lags of, and the number of periods of lagging. For dynamic models, the TOTAL and INTERIM= options can be used on the PROC SIMLIN statement to compute and print total and impact multipliers. (See "Dynamic Multipliers" later in this section for an explanation of multipliers.)

In the following example the variables Y1LAG1, Y2LAG1, and Y2LAG2 contain lagged values of the endogenous variables Y1 and Y2. Y1LAG1 and Y2LAG1 contain values of Y1 and Y2 for the previous observation, while Y2LAG2 contains 2 period lags of Y2. The LAGGED statement specifies the lagged relationships, and the TOTAL and INTERIM= options request multiplier analysis. The INTERIM=2 option prints matrices showing the impact that changes to the exogenous variables have on the endogenous variables after 1 and 2 periods.

```
data in; set in;
  y1lag1 = lag(y1);
  y2lag1 = lag(y2);
  y2lag2 = lag2(y2);
run;

proc syslin data=in outest=e;
   model y1 = y2 y1lag1 y2lag2 x1;
   model y2 = y1 y2lag1 x2;
run;

proc simlin est=e total interim=2;
   endogenous y1 y2;
   exogenous x1 x2;
   lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
run;
```

After the reduced form of the model is computed, the model can be simulated by specifying an input data set on the PROC SIMLIN statement and using an OUTPUT statement to write the simulation results to an output data set. The following example modifies the PROC SIMLIN step from the preceding example to simulate the model and stores the results in an output data set.

```
proc simlin est=e total interim=2 data=in;
   endogenous y1 y2;
   exogenous x1 x2;
   lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
   output out=sim predicted=y1hat y2hat
                  residual=y1resid y2resid;
run;
```

Prediction and Simulation

If an input data set is specified with the DATA= option in the PROC SIMLIN statement, the procedure reads the data and uses the reduced form equations to compute predicted and residual values for each of the endogenous variables. (If no data set is specified with the DATA= option, no simulation of the system is performed, and only the reduced form and multipliers are computed.)

The character of the prediction is based on the START= value. Until PROC SIMLIN encounters the START= observation, actual endogenous values are found and fed into the lagged endogenous terms. Once the START= observation is reached, dynamic simulation begins, where predicted values are fed into lagged endogenous terms until the end of the data set is reached.

The predicted and residual values generated here are different from those produced by the SYSLIN procedure since PROC SYSLIN uses the structural form with actual endogenous values. The predicted values computed by the SIMLIN procedure solve the simultaneous equation system. These reduced-form predicted values are functions only of the exogenous and lagged endogenous variables and do not depend on actual values of current period endogenous variables.

Syntax

The following statements can be used with PROC SIMLIN:

> **PROC SIMLIN** *options*;
> **BY** *variables*;
> **ENDOGENOUS** *variables*;
> **EXOGENOUS** *variables*;
> **ID** *variables*;
> **LAGGED** *lag-var endogenous-var number ellipsis* **;**
> **OUTPUT** *OUT=SAS-data-set options*;

Functional Summary

The statements and options controlling the SIMLIN procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set containing structural coefficients	PROC SIMLIN	EST=
specify type of estimates read from EST= data set	PROC SIMLIN	TYPE=
write reduced form coefficients and multipliers to an output data set	PROC SIMLIN	OUTEST=
specify the input data set for simulation	PROC SIMLIN	DATA=
write predicted and residual values to an output data set	OUTPUT	
Printing Control Options		
print the structural coefficients	PROC SIMLIN	ESTPRINT
suppress printing of reduced form coefficients	PROC SIMLIN	NORED
suppress all printed output	PROC SIMLIN	NOPRINT
Dynamic Multipliers		
compute interim multipliers	PROC SIMLIN	INTERIM=
compute total multipliers	PROC SIMLIN	TOTAL
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify the exogenous variables	EXOGENOUS	
specify identifying variables	ID	
specify lagged endogenous variables	LAGGED	

Description	Statement	Option
Controlling the Simulation		
specify the starting observation for dynamic simulation	PROC SIMLIN	START=

PROC SIMLIN Statement

PROC SIMLIN *options;*

The following options can be used in the PROC SIMLIN statement:

DATA= *SAS-data-set*
specifies the SAS data set containing input data for the simulation. If the DATA= option is used, the data set specified must supply values for all exogenous variables throughout the simulation. If the DATA= option is not specified, no simulation of the system is performed, and only the reduced form and multipliers are computed.

EST= *SAS-data-set*
specifies the input data set containing the structural coefficients of the system. If EST= is omitted the most recently created SAS data set is used. The EST= data set is normally a "TYPE=EST" data set produced by the OUTEST= option of PROC SYSLIN. However, you can also build the EST= data set with a SAS DATA step. See "The EST= Data Set" later in this chapter for details.

ESTPRINT
prints the structural coefficients read from the EST= data set.

INTERIM= *n*
rssbjixinterim multipliersSIMLIN procedure requests that interim multipliers be computed for interims 1 through *n*. If not specified, no interim multipliers are computed. This feature is available only if there are no lags greater than 1.

NOPRINT
suppresses all printed output.

NORED
suppresses the printing of the reduced form coefficients.

OUTEST= *SAS-data-set*
specifies an output SAS data set to contain the reduced form coefficients and multipliers, in addition to the structural coefficients read from the EST= data set. The OUTEST= data set has the same form as the EST= data set. If the OUTEST= option is not specified, the reduced form coefficients and multipliers are not written to a data set.

START= *n*

specifies the observation number in the DATA= data set where the dynamic simulation is to be started. By default, the dynamic simulation starts with the first observation in the DATA= data set for which all variables (including lags) are not missing.

TOTAL

requests that the total multipliers be computed. This feature is available only if there are no lags greater than 1.

TYPE= *value*

specifies the type of estimates to be read from the EST= data set. The TYPE= value must match the value of the _TYPE_ variable for the observations that you want to select from the EST= data set (TYPE=2SLS, for example).

BY Statement

BY *variables;*

A BY statement can be used with PROC SIMLIN to obtain separate analyses for groups of observations defined by the BY variables.

The BY statement can be applied to one or both of the EST= and the DATA= input data set. When a BY statement is used and both an EST= and a DATA= input data set are specified, PROC SIMLIN checks to see if one or both of the data sets contain the BY variables.

Thus, there are three ways of using the BY statement with PROC SIMLIN:

1. If the BY variables are found in the EST= data set only, PROC SIMLIN simulates over the entire DATA= data set once for each set of coefficients read from the BY groups in the EST= data set.
2. If the BY variables are found in the DATA= data set only, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set, using the single set of coefficients in the EST= data set.
3. If the BY variables are found in both the EST= and the DATA= data sets, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set using the coefficients from the corresponding BY group in the EST= data set.

ENDOGENOUS Statement

ENDOGENOUS *variables;*

List the names of the endogenous (jointly dependent) variables in the ENDOGENOUS statement. The ENDOGENOUS statement can be abbreviated as ENDOG or ENDO.

EXOGENOUS Statement

EXOGENOUS *variables;*

List the names of the exogenous (independent) variables in the EXOGENOUS statement. The EXOGENOUS statement can be abbreviated as EXOG or EXO.

ID Statement

ID *variables;*

The ID statement can be used to restrict the variables copied from the DATA= data set to the OUT= data set. Use the ID statement to list the variables you want copied to the OUT= data set besides the exogenous, endogenous, lagged endogenous, and BY variables. If the ID statement is omitted, all the variables in the DATA= data set are copied to the OUT= data set.

LAGGED Statement

LAGGED *lag-var endogenous-var number ellipsis ;*

For each lagged endogenous variable, specify the name of the lagged variable, the name of the endogenous variable that was lagged, and the degree of the lag. Only one LAGGED statement is allowed.

The following is an example of the use of the LAGGED statement:

```
proc simlin est=e;
   endog y1 y2;
   lagged y1lag1 y1 1  y2lag1 y2 1  y2lag3 y2 3;
```

This statement specifies that the variable Y1LAG1 contains the values of the endogenous variable Y1 lagged one period; the variable Y2LAG1 refers to the values of Y2 lagged one period; and the variable Y2LAG3 refers to the values of Y2 lagged three periods.

OUTPUT Statement

OUTPUT *OUT= SAS-data-set options;*

The OUTPUT statement specifies that predicted and residual values be put in an output data set. A DATA= input data set must be supplied if the OUTPUT statement is used, and only one OUTPUT statement is allowed. The following options can be used in the OUTPUT statement:

OUT= *SAS-data-set*
names the output SAS data set to contain the predicted values and residuals. If OUT= is not specified, the output data set is named using the DATA*n* convention.

PREDICTED= *names*
P= *names*
names the variables in the output data set that contain the predicted values of the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. If you specify names on the PREDICTED= option for only some of the endogenous variables, predicted values for the remaining variables are not output. The names must not match any variable name in the input data set.

RESIDUAL= *names*
R= *names*
names the variables in the output data set that contain the residual values from the simulation. The residuals are the differences between the actual values of the endogenous variables from the DATA= data set and the predicted values from the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. The names must not match any variable name in the input data set.

The following is an example of the use of the OUTPUT statement. This example outputs predicted values for Y1 and Y2 and outputs residuals for Y1.

```
proc simlin est=e;
   endog y1 y2;
   output out=b predicted=y1hat y2hat residual=y1resid;
```

Details

The following sections explain the structural and reduced forms, dynamic multipliers, input data sets, and the model simulation process in more detail.

Defining the Structural Form

An EST= input data set supplies the coefficients of the equation system. The data set containing the coefficients is normally a "TYPE=EST" data set created by the OUTEST= option of PROC SYSLIN or another regression procedure. The data set contains the special variables _TYPE_, _DEPVAR_, and INTERCEPT. You can also supply the structural coefficients of the system to PROC SIMLIN in a data set produced by a SAS DATA step as long as the data set is of the form TYPE=EST. Refer to SAS/STAT software documentation for a discussion of the special TYPE=EST type of SAS data set.

Suppose that there is a $g \times 1$ vector of endogenous variables $\mathbf{y}_t$, an $l \times 1$ vector of lagged endogenous variables $\mathbf{y}_t^L$, and a $k \times 1$ vector of exogenous variables $\mathbf{x}_t$, including the intercept. Then, there are g structural equations in the simultaneous system that can be written

$$\mathbf{G}\mathbf{y}_t = \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where $\mathbf{G}$ is the matrix of coefficients of current period endogenous variables, $\mathbf{C}$ is the matrix of coefficients of lagged endogenous variables, and $\mathbf{B}$ is the matrix of coefficients of exogenous variables. $\mathbf{G}$ is assumed to be nonsingular.

Computing the Reduced Form

First, the SIMLIN procedure computes reduced form coefficients by premultiplying by $\mathbf{G}^{-1}$:

$$\mathbf{y}_t = \mathbf{G}^{-1}\mathbf{C}\mathbf{y}_t^L + \mathbf{G}^{-1}\mathbf{B}\mathbf{x}_t$$

This can be written as

$$\mathbf{y}_t = \Pi_1\mathbf{y}_t^L + \Pi_2\mathbf{x}_t$$

where Π_1= $\mathbf{G}^{-1}\mathbf{C}$ and Π_2= $\mathbf{G}^{-1}\mathbf{B}$ are the reduced form coefficient matrices.

The reduced form matrices Π_1= $\mathbf{G}^{-1}\mathbf{C}$ and Π_2= $\mathbf{G}^{-1}\mathbf{B}$ are printed unless the NORED option is specified in the PROC SIMLIN statement. The structural coefficient matrices $\mathbf{G}$, $\mathbf{C}$, and $\mathbf{B}$ are printed when the ESTPRINT option is specified.

Dynamic Multipliers

For models that have only first-order lags, the equation of the reduced form of the system can be rewritten

$$\mathbf{y}_t = \mathbf{D}\mathbf{y}_{t-1} + \Pi_2 \mathbf{x}_t$$

D is a matrix formed from the columns of Π_1 plus some columns of zeros, arranged in the order in which the variables meet the lags. The elements of Π_2 are called *impact multipliers* because they show the immediate effect of changes in each exogenous variable on the values of the endogenous variables. This equation can be rewritten as

$$\mathbf{y}_t = \mathbf{D}^2\mathbf{y}_{t-2} + \mathbf{D}\Pi_2\mathbf{x}_{t-1} + \Pi_2 \mathbf{x}_t$$

The matrix formed by the product $\mathbf{D}\Pi_2$ shows the effect of the exogenous variables one lag back; the elements in this matrix are called *interim multipliers* and are computed and printed when the INTERIM= option is specified in the PROC SIMLIN statement. The *i*th period interim multipliers are formed by $\mathbf{D}^i\Pi_2$.

The series can be expanded as

$$\mathbf{y}_t = \mathbf{D}^{\infty}\mathbf{y}_{t-\infty} + \sum_{i=0}^{\infty} \mathbf{D}^i \Pi_2 \mathbf{x}_{t-i}$$

A permanent and constant setting of a value for *x* has the following cumulative effect:

$$\left(\sum_{i=0}^{\infty} \mathbf{D}^i \right) \Pi_2 \mathbf{x} = (\mathbf{I} - \mathbf{D})^{-1} \Pi_2 \mathbf{x}$$

The elements of $(\mathbf{I}\text{-}\mathbf{D})^{-1}\Pi_2$ are called the *total multipliers*. Assuming that the sum converges and that (**I-D**) is invertible, PROC SIMLIN computes the total multipliers when the TOTAL option is specified in the PROC SIMLIN statement.

Multipliers for Higher Order Lags

The dynamic multiplier options require the system to have no lags of order greater than one. This limitation can be circumvented, since any system with lags greater than one can be rewritten as a system where no lag is greater than one by forming new endogenous variables that are single-period lags.

For example, suppose you have the third-order single equation

$$y_t = a y_{t-3} + b\mathbf{x}_t$$

This can be converted to a first-order three-equation system by introducing two additional endogenous variables, $y_{1,t}$ and $y_{2,t}$, and computing corresponding first-order lagged variables for each endogenous variable: y_{t-1}, $y_{1,t-1}$, and $y_{2,t-1}$. The higher order lag relations are then produced by adding identities to link the endogenous and identical lagged endogenous variables:

$$y_{1,t} = y_{t-1}$$

$$y_{2,t} = y_{1,t-1}$$

$$y_t = ay_{2,t-1} + b\mathbf{X}_t$$

This conversion using the SYSLIN and SIMLIN procedures requires three steps:

1. Add the extra endogenous and lagged endogenous variables to the input data set using a DATA step. Note that two copies of each lagged endogenous variable are needed for each lag reduced, one to serve as an endogenous variable and one to serve as a lagged endogenous variable in the reduced system.
2. Add IDENTITY statements to the PROC SYSLIN step to equate each added endogenous variable to its lagged endogenous variable copy.
3. In the PROC SIMLIN step, declare the added endogenous variables in the ENDOGENOUS statement and define the lag relations in the LAGGED statement.

See Example 23.2 for an illustration of how to convert an equation system with higher-order lags into a larger system with only first-order lags.

EST= Data Set

Normally, PROC SIMLIN uses an EST= data set produced by PROC SYSLIN with the OUTEST= option. This data set is in the form expected by PROC SIMLIN. If there is more than one set of estimates produced by PROC SYSLIN, you must use the TYPE= option in the PROC SIMLIN statement to select the set to be simulated. Then PROC SIMLIN reads from the EST= data set only those observations with a _TYPE_ value corresponding to the TYPE= option (for example, TYPE=2SLS) or with a _TYPE_ value of IDENTITY.

The SIMLIN procedure can only solve square, nonsingular systems. If you have fewer equations than endogenous variables, you must specify IDENTITY statements in the PROC SYSLIN step to bring the system up to full rank. If there are *g* endogenous variables and *m*<*g* stochastic equations with unknown parameters, then you use *m* MODEL statements to specify the equations with parameters to be estimated and you must use *g*-*m* IDENTITY statements to complete the system.

You can build your own EST= data set with a DATA step rather than use PROC SYSLIN. The EST= data set must contain the endogenous variables, the lagged endogenous variables (if any), and the exogenous variables in the system (if any). If any of the equations have intercept terms, the variable INTERCEPT must supply these coefficients. The EST= data set should also contain the special character variable comp _DEPVAR_ to label the equations.

The EST= data set must contain one observation for each equation in the system. The values of the lagged endogenous variables must contain the **C** coefficients. The values of the exogenous variables and the INTERCEPT variable must contain the **B** coefficients. The values of the endogenous variables, however, must contain the negatives of the **G** coefficients. This is because the SYSLIN procedure writes the coefficients to the OUTEST= data set in the form

$$0 = \mathbf{H}\mathbf{y}_t + \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where **H=-G**.

See "Multipliers for Higher Order Lags" and Example 23.2 later in this chapter for more information on building the EST= data set.

DATA= Data Set

The DATA= data set must contain all of the exogenous variables. Values for all of the exogenous variables are required for each observation for which predicted endogenous values are desired. To forecast past the end of the historical data, the DATA= data set should contain nonmissing values for all of the exogenous variables and missing values for the endogenous variables for the forecast periods, in addition to the historical data. (See Example 23.1 for an illustration.)

In order for PROC SIMLIN to output residuals and compute statistics of fit, the DATA= data set must also contain the endogenous variables with nonmissing actual values for each observation for which residuals and statistics are to be computed.

If the system contains lags, initial values must be supplied for the lagged variables. This can be done by including either the lagged variables or the endogenous variables, or both, in the DATA= data set. If the lagged variables are not in the DATA= data set or if they have missing values in the early observations, PROC SIMLIN prints a warning and uses the endogenous variable values from the early observations to initialize the lags.

OUTEST= Data Set

The OUTEST= data set contains all the variables read from the EST= data set. The variables in the OUTEST= data set are as follows.

- the BY statement variables, if any
- _TYPE_, a character variable that identifies the type of observation
- _DEPVAR_, a character variable containing the name of the dependent variable for the observation
- the endogenous variables

- the lagged endogenous variables
- the exogenous variables
- INTERCEPT, a numeric variable containing the intercept values
- _MODEL_, a character variable containing the name of the equation
- _SIGMA_, a numeric variable containing the estimated error variance of the equation (output only if present in the EST= data set)

The observations read from the EST= data set that supply the structural coefficients are copied to the OUTEST= data set, except that the signs of endogenous coefficients are reversed. For these observations, the _TYPE_ variable values are the same as in the EST= data set.

In addition, the OUTEST= data set contains observations with the following _TYPE_ values:

REDUCED	the reduced form coefficients. The endogenous variables for this group of observations contain the inverse of the endogenous coefficient matrix **G**. The lagged endogenous variables contain the matrix $\Pi_1=\mathbf{G}^{-1}\mathbf{C}$. The exogenous variables contain the matrix $\Pi_2=\mathbf{G}^{-1}\mathbf{B}$.
IMULT*i*	the interim multipliers, if the INTERIM= option is specified. There are *gn* observations for the interim multipliers, where *g* is the number of endogenous variables and *n* is the value of the INTERIM=*n* option. For these observations the _TYPE_ variable has the value IMULT*i*, where the interim number *i* ranges from 1 to *n*. The exogenous variables in groups of *g* observations that have a _TYPE_ value of IMULT*i* contain the matrix $\mathbf{D}^i\Pi_2$ of multipliers at interim *i*. The endogenous and lagged endogenous variables for this group of observations are set to missing.
TOTAL	the total multipliers, if the TOTAL option is specified. The exogenous variables in this group of observations contain the matrix $(\mathbf{I}\text{-}\mathbf{D})^{-1}\Pi_2$. The endogenous and lagged endogenous variables for this group of observations are set to missing.

OUT= Data Set

The OUT= data set normally contains all of the variables in the input DATA= data set, plus the variables named in the PREDICTED= and RESIDUAL= options in the OUTPUT statement.

You can use an ID statement to restrict the variables that are copied from the input data set. If an ID statement is used, the OUT= data set contains only the BY variables (if any), the ID variables, the endogenous and lagged endogenous variables (if any), the exogenous variables, plus the PREDICTED= and RESIDUAL= variables.

The OUT= data set contains an observation for each observation in the DATA= data set. When the actual value of an endogenous variable is missing in the DATA= data set, or when the DATA= data set does not contain the endogenous variable, the corresponding residual is missing.

Printed Output

Structural Form

The following items are printed as they are read from the EST= input data set. Structural zeros are printed as dots in the listing of these matrices.

1. Structural Coefficients for Endogenous Variables. This is the **G** matrix, with g rows and g columns.
2. Structural Coefficients for Lagged Endogenous Variables. These coefficients make up the **C** matrix, with g rows and l columns.
3. Structural Coefficients for Exogenous Variables. These coefficients make up the **B** matrix, with g rows and k columns.

Reduced Form

1. The reduced form coefficients are obtained by inverting **G** so that the endogenous variables can be directly expressed as functions of only lagged endogenous and exogenous variables.
2. Inverse Coefficient Matrix for Endogenous Variables. This is the inverse of the **G** matrix.
3. Reduced Form for Lagged Endogenous Variables. This is $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$, with g rows and l columns. Each value is a dynamic multiplier that shows how past values of lagged endogenous variables affect values of each of the endogenous variables.
4. Reduced Form for Exogenous Variables. This is $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$, with g rows and k columns. Its values are called *impact multipliers* because they show the immediate effect of each exogenous variable on the value of the endogenous variables.

Multipliers

Interim and total multipliers show the effect of a change in an exogenous variable over time.

1. Interim Multipliers. These are the interim multiplier matrices. They are formed by multiplying Π_2 by powers of **D**. The dth interim multiplier is $\mathbf{D}^d\Pi_2$. The interim multiplier of order d shows the effects of a change in the exogenous variables after d periods. Interim multipliers are only available if the maximum lag of the endogenous variables is 1.
2. Total Multipliers. This is the matrix of total multipliers, $T=(\mathbf{I}\text{-}\mathbf{D})^{-1}\Pi_2$. This matrix shows the cumulative effect of changes in the exogenous variables. Total multipliers are only available if the maximum lag is one.

Statistics of Fit

If the DATA= option is used and the DATA= data set contains endogenous variables, PROC SIMLIN prints a statistics-of-fit report for the simulation. The statistics printed include the following. (Summations are over the observations for which both y_t and $\hat{y}_t$ are nonmissing.)

1. the number of nonmissing errors. (Number of observations for which both y_t and $\hat{y}_t$ are nonmissing.)
2. the mean error: $\frac{1}{n}\sum(y_t - \hat{y}_t)$
3. the mean percent error: $\frac{100}{n}\sum\frac{(y_t-\hat{y}_t)}{y_t}$
4. the mean absolute error: $\frac{1}{n}\sum|y_t - \hat{y}_t|$
5. the mean absolute percent error $\frac{100}{n}\sum\frac{|y_t-\hat{y}_t|}{y_t}$
6. the root mean square error: $\sqrt{\frac{1}{n}\sum(y_t - \hat{y}_t)^2}$
7. the root mean square percent error: $\sqrt{\frac{100}{n}\sum(\frac{(y_t-\hat{y}_t)}{y_t})^2}$

ODS Table Names

PROC SIMLIN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 23.1. ODS Tables Produced in PROC SIMLIN

ODS Table Name	**Description**	**Option**
Endogenous	Structural Coefficients for Endogenous Variables	default
LaggedEndogenous	Structural Coefficients for Lagged Endogenous Variables	default
Exogenous Structural	Coefficients for Exogenous Variables	default
InverseCoeff	Inverse Coefficient Matrix for Endogenous Variables	default
RedFormLagEndo	Reduced Form for Lagged Endogenous Variables	default
RedFormExog	Reduced Form for Exogenous Variables	default
InterimMult	Interim Multipliers	INTERIM= option
TotalMult	Total Multipliers	TOTAL= option
FitStatistics	Fit statistics	default

Examples

Example 23.1. Simulating Klein’s Model I

In this example, the SIMLIN procedure simulates a model of the U.S. economy called Klein’s Model I. The SAS data set KLEIN, shown in Output 23.1.1, is used as input to the SYSLIN and SIMLIN procedures.

```
data klein;
   input year c p w i x wp g t k wsum;
   date=mdy(1,1,year);
   format date year.;
   y   =c+i+g-t;
   yr  =year-1931;
   klag=lag(k);
   plag=lag(p);
   xlag=lag(x);
   if year>=1921;
   label c   ='consumption'
         p   ='profits'
         w   ='private wage bill'
         i   ='investment'
         k   ='capital stock'
         y   ='national income'
         x   ='private production'
         wsum='total wage bill'
         wp  ='govt wage bill'
         g   ='govt demand'
         t   ='taxes'
         klag='capital stock lagged'
         plag='profits lagged'
         xlag='private product lagged'
         yr  ='year-1931';
   datalines;
  ... data lines omitted ...
proc print data=klein;
run;
```

Output 23.1.1. PROC PRINT Listing of Input Data Set KLEIN

```

First, the model is specified and estimated using the SYSLIN procedure, and the parameter estimates are written to an OUTEST= data set. The printed output produced by the SYSLIN procedure is not shown here; see Example 26.1 in Chapter 26 for the printed output of the PROC SYSLIN step.

```
title1 'Simulation of Klein''s Model I using SIMLIN';
proc syslin 3sls data=klein outest=a;

   instruments klag plag xlag wp g t yr;
   endogenous c p w i x wsum k y;

   consume: model    c = p plag wsum;
   invest:  model    i = p plag klag;
   labor:   model    w = x xlag yr;

   product: identity x = c + i + g;
   income:  identity y = c + i + g - t;
   profit:  identity p = x - w - t;
   stock:   identity k = klag + i;
   wage:    identity wsum = w + wp;
run;

proc print data=a;
run;
```

The OUTEST= data set A created by the SYSLIN procedure contains parameter estimates to be used by the SIMLIN procedure. The OUTEST= data set is shown in Output 23.1.2.

Output 23.1.2. The OUTEST= Data Set Created by PROC SYSLIN

 14     .          .         -1.00000     .          .    -1.00000    -1     .     1.00000      .           .     .
 15     .          .           .          .          .      .          .     1      .           .          -1     .
 16    1.00000     .           .          .          .      .          1     .      .         -1.00000      .     .
```

Using the OUTEST= data set A produced by the SYSLIN procedure, the SIMLIN procedure can now compute the reduced form and simulate the model. The following statements perform the simulation.

```
proc simlin est=a data=klein type=3sls
            estprint total interim=2 outest=b;
   endogenous c p w i x wsum k y;
   exogenous  wp g t yr;
   lagged  klag k 1   plag p 1   xlag x 1;
   id year;
   output out=c p=chat phat what ihat xhat wsumhat khat yhat
                r=cres pres wres ires xres wsumres kres yres;
run;
```

The reduced form coefficients and multipliers are added to the information read from EST= data set A and written to the OUTEST= data set B. The predicted and residual values from the simulation are written to the OUT= data set C specified in the OUTPUT statement.

The SIMLIN procedure first prints the structural coefficient matrices read from the EST= data set, as shown in Output 23.1.3.

Output 23.1.3. SIMLIN Procedure Output – Structural Coefficients

```

The OUTEST= output data set contains all the observations read from the EST= data set, and in addition contains observations for the reduced form and multiplier matrices. The following statements produce a partial listing of the OUTEST= data set, as shown in Output 23.1.8.

```
proc print data=b;
   where _type_ = 'REDUCED' | _type_ = 'IMULT1';
run;
```

Output 23.1.8. Partial Listing of OUTEST= Data Set

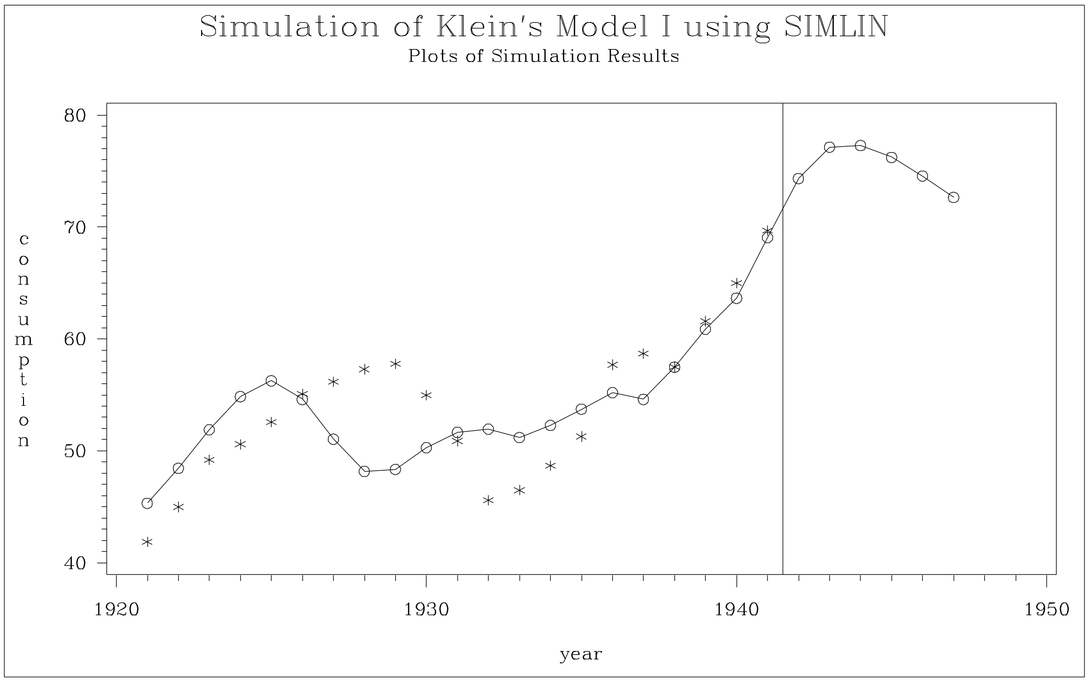
The actual and predicted values for the variable C are plotted in Output 23.1.9.

```
title2 h=1 'Plots of Simulation Results';
symbol1 i=none v=star;
symbol2 i=join v=circle;
proc gplot data=c;
   plot c*year=1 chat*year=2 / overlay href=1941.5;
run;
```

Output 23.1.9. Plot of Actual and Predicted Consumption



Example 23.2. Multipliers for a Third-Order System

This example shows how to fit and simulate a single equation dynamic model with third-order lags. It then shows how to convert the third-order equation into a three equation system with only first-order lags, so that the SIMLIN procedure can compute multipliers. (See the section "Multipliers for Higher Order Lags" earlier in this chapter for more information.)

The input data set TEST is created from simulated data. A partial listing of the data set TEST produced by PROC PRINT is shown in Output 23.2.1.

```
title1 'Simulate Equation with Third-Order Lags';
title2 'Listing of Simulated Input Data';
proc print data=test(obs=10);
run;
```

Output 23.2.1. Partial Listing of Input Data Set

Chapter 24
The SPECTRA Procedure

Chapter Contents

Chapter 24
The SPECTRA Procedure

Overview

The SPECTRA procedure performs spectral and cross-spectral analysis of time series. You can use spectral analysis techniques to look for periodicities or cyclical patterns in data.

The SPECTRA procedure produces estimates of the spectral and cross-spectral densities of a multivariate time series. Estimates of the spectral and cross-spectral densities of a multivariate time series are produced using a finite Fourier transform to obtain periodograms and cross-periodograms. The periodogram ordinates are smoothed by a moving average to produce estimated spectral and cross-spectral densities. PROC SPECTRA can also test whether or not the data are white noise.

PROC SPECTRA uses the finite Fourier transform to decompose data series into a sum of sine and cosine waves of different amplitudes and wavelengths. The Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^{m} [a_k cos(\omega_k t) + b_k sin(\omega_k t)]$$

where

t	is the time subscript, $t = 1, 2, \ldots , n$
x_t	are the data
n	is the number of observations in the time series
m	is the number of of frequencies in the Fourier decomposition: $m = \frac{n}{2}$ if n is even; $m = \frac{n-1}{2}$ if n is odd
a_0	is the mean term: $a_0 = 2\overline{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{n}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wave length to form *periodograms*. The amplitude periodogram J_k is defined as follows:

$$J_k = \frac{n}{2}(a_k^2 + b_k^2)$$

Several definitions of the term periodogram are used in the spectral analysis literature. The following discussion refers to the J_k sequence as the periodogram.

The periodogram can be interpreted as the contribution of the *k*th harmonic ω_k to the total sum of squares, in an analysis of variance sense, for the decomposition of the process into two-degree-of-freedom components for each of the *m* frequencies. When *n* is even, $sin(\omega_{\frac{n}{2}})$ is zero, and thus the last periodogram value is a one-degree-of-freedom component.

The periodogram is a volatile and inconsistent estimator of the spectrum. The spectral density estimate is produced by smoothing the periodogram. Smoothing reduces the variance of the estimator but introduces a bias. The weight function used for the smoothing process, W(), often called the kernel or spectral window, is specified with the WEIGHTS statement. It is related to another weight function, *w*(), the lag window, that is used in other methods to taper the correlogram rather than to smooth the periodogram. Many specific weighting functions have been suggested in the literature (Fuller 1976, Jenkins and Watts 1968, Priestly 1981). Table 24.1 later in this chapter gives the formulas relevant when the WEIGHTS statement is used.

Letting *i* represent the imaginary unit $\sqrt{-1}$, the cross-periodogram is defined as follows:

$$J_k^{xy} = \frac{n}{2}(a_k^x a_k^y + b_k^x b_k^y) + i\frac{n}{2}(a_k^x b_k^y - b_k^x a_k^y)$$

The cross-spectral density estimate is produced by smoothing the cross-periodogram in the same way as the periodograms are smoothed using the spectral window specified by the WEIGHTS statement.

The SPECTRA procedure creates an output SAS data set whose variables contain values of the periodograms, cross-periodograms, estimates of spectral densities, and estimates of cross-spectral densities. The form of the output data set is described in the section "OUT= Data Set" later in this chapter.

Getting Started

To use the SPECTRA procedure, specify the input and output data sets and options for the analysis you want on the PROC SPECTRA statement, and list the variables to analyze in the VAR statement.

For example, to take the Fourier transform of a variable X in a data set A, use the following statements:

```
proc spectra data=a out=b coef;
   var x;
run;
```

This PROC SPECTRA step writes the Fourier coefficients a_k and b_k to the variables COS_01 and SIN_01 in the output data set B.

When a WEIGHTS statement is specified, the periodogram is smoothed by a weighted moving average to produce an estimate for the spectral density of the series. The following statements write a spectral density estimate for X to the variable S_01 in the output data set B.

```
proc spectra data=a out=b s;
   var x;
   weights 1 2 3 4 3 2 1;
run;
```

When the VAR statement specifies more than one variable, you can perform cross-spectral analysis by specifying the CROSS option. The CROSS option by itself produces the cross-periodograms. For example, the following statements write the real and imaginary parts of the cross-periodogram of X and Y to the variable RP_01_02 and IP_01_02 in the output data set B.

```
proc spectra data=a out=b cross;
   var x y;
run;
```

To produce cross-spectral density estimates, combine the CROSS option and the S option. The cross-periodogram is smoothed using the weights specified by the WEIGHTS statement in the same way as the spectral density. The squared coherency and phase estimates of the cross-spectrum are computed when the K and PH options are used.

The following example computes cross-spectral density estimates for the variables X and Y.

```
proc spectra data=a out=b cross s;
   var x y;
   weights 1 2 3 4 3 2 1;
run;
```

The real part and imaginary part of the cross-spectral density estimates are written to the variable CS_01_02 and QS_01_02, respectively.

Syntax

The following statements are used with the SPECTRA procedure.

> **PROC SPECTRA** *options*;
>   **BY** *variables*;
>   **VAR** *variables*;
>   **WEIGHTS** *constants*;

Functional Summary

The statements and options controlling the SPECTRA procedure are summarized in the following table.

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify the variables to be analyzed	VAR	
specify weights for spectral density estimates	WEIGHTS	
Data Set Options		
specify the input data set	PROC SPECTRA	DATA=
specify the output data set	PROC SPECTRA	OUT=
Output Control Options		
output the amplitudes of the cross-spectrum	PROC SPECTRA	A
output the Fourier coefficients	PROC SPECTRA	COEF
output the periodogram	PROC SPECTRA	P
output the spectral density estimates	PROC SPECTRA	S
output cross-spectral analysis results	PROC SPECTRA	CROSS
output squared coherency of the cross-spectrum	PROC SPECTRA	K
output the phase of the cross-spectrum	PROC SPECTRA	PH
Smoothing Options		
specify the Bartlett kernel	WEIGHTS	BART
specify the Parzen kernel	WEIGHTS	PARZEN
specify the Quadratic Spectral kernel	WEIGHTS	QS
specify the Tukey-Hanning kernel	WEIGHTS	TUKEY
specify the Truncated kernel	WEIGHTS	TRUNCAT

Description	**Statement**	**Option**
Other Options		
subtract the series mean	PROC SPECTRA	ADJMEAN
specify an alternate quadrature spectrum estimate	PROC SPECTRA	ALTW
request tests for white noise	PROC SPECTRA	WHITETEST

PROC SPECTRA Statement

PROC SPECTRA *options;*

The following options can be used in the PROC SPECTRA statement.

A

outputs the amplitude variables (A_*nn*_*mm*) of the cross-spectrum.

ADJMEAN
CENTER

subtracts the series mean before performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than 2*n* times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

ALTW

specifies that the quadrature spectrum estimate is computed at the boundaries in the same way as the spectral density estimate and the cospectrum estimate are computed.

COEF

outputs the Fourier cosine and sine coefficients of each series, in addition to the periodogram.

CROSS

is used with the P and S options to output cross-periodograms and cross-spectral densities.

DATA= *SAS-data-set*

names the SAS data set containing the input data. If the DATA= option is omitted, the most recently created SAS data set is used.

K

outputs the squared coherency variables (K_*nn*_*mm*) of the cross-spectrum. The K_*nn*_*mm* variables are identically 1 unless weights are given in the WEIGHTS statement and the S option is specified.

OUT= *SAS-data-set*
names the output data set created by PROC SPECTRA to store the results. If the OUT= option is omitted, the output data set is named using the DATA*n* convention.

P
outputs the periodogram variables. The variables are named P_*nn*, where *nn* is an index of the original variable with which the periodogram variable is associated. When both the P and CROSS options are specified, the cross-periodogram variables RP_*nn*_*mm* and IP_*nn*_*mm* are also output.

PH
outputs the phase variables (PH_*nn*_*mm*) of the cross-spectrum.

S
outputs the spectral density estimates. The variables are named S_*nn*, where *nn* is an index of the original variable with which the estimate variable is associated. When both the S and CROSS options are specified, the cross-spectral variables CS_*nn*_*mm* and QS_*nn*_*mm* are also output.

WHITETEST
prints a test of the hypothesis that the series are white noise. See "White Noise Test" later in this chapter for details.

Note that the CROSS, A, K, and PH options are only meaningful if more than one variable is listed in the VAR statement.

BY Statement

BY *variables;*

A BY statement can be used with PROC SPECTRA to obtain separate analyses for groups of observations defined by the BY variables.

VAR Statement

VAR *variables;*

The VAR statement specifies one or more numeric variables containing the time series to analyze. The order of the variables in the VAR statement list determines the index, *nn*, used to name the output variables. The VAR statement is required.

WEIGHTS Statement

WEIGHTS *constant-specification* | *kernel-specification;*

The WEIGHTS statement specifies the relative weights used in the moving average applied to the periodogram ordinates to form the spectral density estimates. A WEIGHTS statement must be used to produce smoothed spectral density estimates. If the WEIGHTS statement is not used, only the periodogram is produced.

Using Constant Specifications

Any number of weighting constants can be specified. The constants should be positive and symmetric about the middle weight. The middle constant, (or the constant to the right of the middle if an even number of weight constants are specified), is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS statement scaled so that they sum to $\frac{1}{4\pi}$.

The moving average reflects at each end of the periodogram. The first periodogram ordinate is not used; the second periodogram ordinate is used in its place.

For example, a simple triangular weighting can be specified using the following WEIGHTS statement:

```
weights 1 2 3 2 1;
```

Using Kernel Specifications

You can specify five different kernels in the WEIGHTS statement. The syntax for the statement is

WEIGHTS [PARZEN][BART][TUKEY][TRUNCAT][QS] [c e];

where $c >= 0$ and $e >= 0$ are used to compute the bandwidth parameter as

$$\mathrm{l(q) = cq^e}$$

and q is the number of periodogram ordinates +1:

$$q = \mathrm{floor(n/2) + 1}$$

To specify the bandwidth explicitly, set $c =$ to the desired bandwidth and $e = 0$.

For example, a Parzen kernel can be specified using the following WEIGHTS statement:

```
weights parzen 0.5 0;
```

For details, see the “Kernels” section on page 1400, later in this chapter.

Details

Input Data

Observations in the data set analyzed by the SPECTRA procedure should form ordered, equally spaced time series. No more than 99 variables can be included in the analysis.

Data are often de-trended before analysis by the SPECTRA procedure. This can be done by using the residuals output by a SAS regression procedure. Optionally, the data can be centered using the ADJMEAN option in the PROC SPECTRA statement, since the zero periodogram ordinate corresponding to the mean is of little interest from the point of view of spectral analysis.

Missing Values

Missing values are essentially excluded from the analysis by the SPECTRA procedure. If the SPECTRA procedure encounters missing values for any variable listed in the VAR statement, the procedure determines the longest contiguous span of data that has no missing values for the variables listed in the VAR statement and uses it for the analysis.

Computational Method

If the number of observations *n* factors into prime integers that are less than or equal to 23, and the product of the square-free factors of *n* is less than 210, then PROC SPECTRA uses the Fast Fourier Transform developed by Cooley and Tukey and implemented by Singleton (1969). If *n* cannot be factored in this way, then PROC SPECTRA uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1976). To reduce memory requirements, when *n* is small the Fourier coefficients are computed directly using the defining formulas.

Kernels

Kernels are used to smooth the periodogram by using a weighted moving average of nearby points. A smoothed periodogram is defined by the following equation.

$$\hat{J}_i(\mathrm{l(q)}) = \sum_{\tau=-\mathrm{l(q)}}^{\mathrm{l(q)}} \mathrm{w}\left(\frac{\tau}{\mathrm{l(q)}}\right) \tilde{\mathrm{J}}_{\mathrm{i}+\tau}$$

where $\mathrm{w(x)}$ is the kernel or weight function. At the endpoints, the moving average is computed cyclically; that is,

$$\tilde{J}_{i+\tau} = \begin{cases} J_{i+\tau} & 0 <= \mathrm{i}+\tau <= \mathrm{q} \\ J_{-(i+\tau)} & \mathrm{i}+\tau < 0 \\ J_{q-(i+\tau)} & \mathrm{i}+\tau > \mathrm{q} \end{cases}$$

The SPECTRA procedure supports the following kernels. They are listed with their default bandwidth functions.

Bartlett: KERNEL BART

$$\begin{aligned} \mathrm{w(x)} &= \begin{cases} 1-|x| & |x| \le 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l(q)} &= \frac{1}{2} q^{1/3} \end{aligned}$$

Parzen: KERNEL PARZEN

$$\begin{aligned} \mathrm{w(x)} &= \begin{cases} 1-6|x|^2+6|x|^3 & 0 \le |x| \le \frac{1}{2} \\ 2(1-|x|)^3 & \frac{1}{2} \le |x| \le 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l(q)} &= q^{1/5} \end{aligned}$$

Quadratic Spectral: KERNEL QS

$$\begin{aligned} \mathrm{w(x)} &= \frac{25}{12\pi^2 x^2} \left(\frac{sin(6\pi x/5)}{6\pi x/5} - cos(6\pi x/5) \right) \\ \mathrm{l(q)} &= \frac{1}{2} q^{1/5} \end{aligned}$$

Tukey-Hanning: KERNEL TUKEY

$$\begin{aligned} \mathrm{w(x)} &= \begin{cases} (1+cos(\pi x))/2 & |x| \le 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l(q)} &= \frac{2}{3} q^{1/5} \end{aligned}$$

Truncated: KERNEL TRUNCAT

$$\begin{aligned} \mathrm{w(x)} &= \begin{cases} 1 & |x| \le 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l(q)} &= \frac{1}{4} q^{1/5} \end{aligned}$$

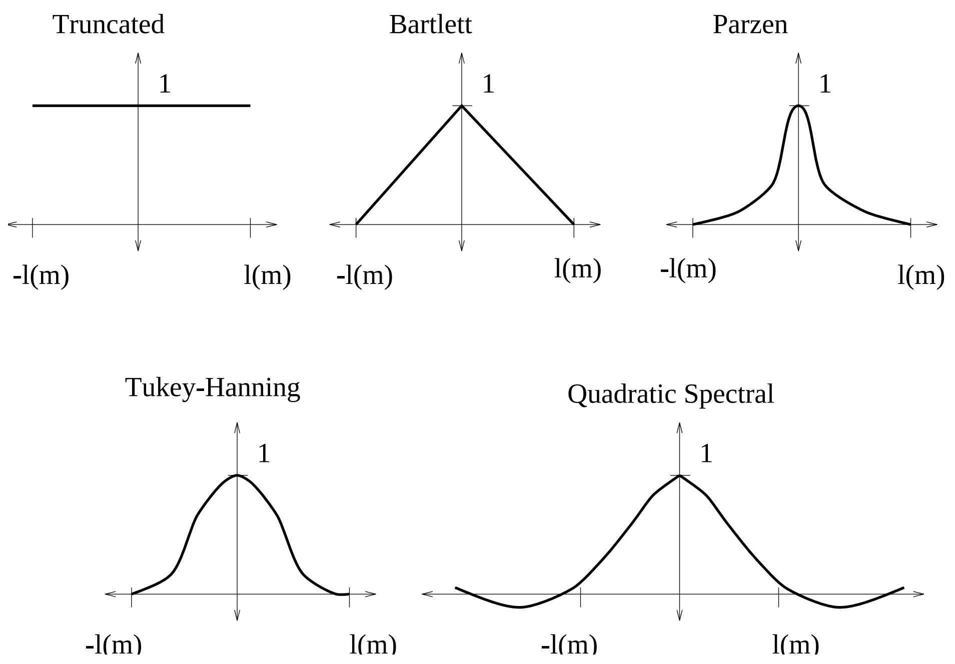

Figure 24.1. Kernels for Smoothing

Refer to Andrews (1991) for details on the properties of these kernels.

White Noise Test

PROC SPECTRA prints two test statistics for white noise when the WHITETEST option is specified: Fisher's Kappa (Davis 1941, Fuller 1976) and Bartlett's Kolmogorov-Smirnov statistic (Bartlett 1966, Fuller 1976, Durbin 1967).

If the time series is a sequence of independent random variables with mean 0 and variance σ^2, then the periodogram, J_k, will have the same expected value for all k. For a time series with nonzero autocorrelation, each ordinate of the periodogram, J_k, will have different expected values. The Fisher's Kappa statistic tests whether the largest J_k can be considered different from the mean of the J_k. Critical values for the Fisher's Kappa test can be found in Fuller 1976 and *SAS/ETS Software: Applications Guide 1*.

The Kolmogorov-Smirnov statistic reported by PROC SPECTRA has the same asymptotic distribution as Bartlett's test (Durbin 1967). The Kolmogorov-Smirnov statistic compares the normalized cumulative periodogram with the cumulative distribution function of a uniform(0,1) random variable. The normalized cumulative periodogram, F_j, of the series is

$$F_j = \frac{\sum_{k=1}^{j} J_k}{\sum_{k=1}^{m} J_k}, j = 1, 2 \ldots, m-1$$

where $m = \frac{n}{2}$ if n is even or $m = \frac{n-1}{2}$ if n is odd. The test statistic is the maximum absolute difference of the normalized cumulative periodogram and the uniform cumulative distribution function. For $m-1$ greater than 100, if Bartlett's Kolmogorov-Smirnov statistic exceeds the critical value

$$\frac{a}{\sqrt{m-1}}$$

where $a = 1.36$ or $a = 1.63$ corresponding to 5% or 1% significance levels respectively, then reject the null hypothesis that the series represents white noise. Critical values for $m-1 < 100$ can be found in a table of significance points of the Kolmogorov-Smirnov statistics with sample size $m-1$ (Miller 1956, Owen 1962).

Transforming Frequencies

The variable FREQ in the data set created by the SPECTRA procedure ranges from 0 to π. Sometimes it is preferable to express frequencies in cycles per observation period, which is equal to $\frac{2}{\pi}$FREQ.

To express frequencies in cycles per unit time (for example, in cycles per year), multiply FREQ by $\frac{d}{2\pi}$, where *d* is the number of observations per unit of time. For example, for monthly data, if the desired time unit is years then *d* is 12. The period of the cycle is $\frac{2\pi}{d \times \mathrm{FREQ}}$, which ranges from $\frac{2}{d}$ to infinity.

OUT= Data Set

The OUT= data set contains $\frac{n}{2}+1$ observations, if *n* is even, or $\frac{n+1}{2}$ observations, if *n* is odd, where *n* is the number of observations in the time series.

The variables in the new data set are named according to the following conventions. Each variable to be analyzed is associated with an index. The first variable listed in the VAR statement is indexed as 01, the second variable as 02, and so on. Output variables are named by combining indexes with prefixes. The prefix always identifies the nature of the new variable, and the indices identify the original variables from which the statistics were obtained.

Variables containing spectral analysis results have names consisting of a prefix, an underscore, and the index of the variable analyzed. For example, the variable S_01 contains spectral density estimates for the first variable in the VAR statement. Variables containing cross-spectral analysis results have names consisting of a prefix, an underscore, the index of the first variable, another underscore, and the index of the second variable. For example, the variable A_01_02 contains the amplitude of the cross-spectral density estimate for the first and second variables in the VAR statement.

Table 24.1 shows the formulas and naming conventions used for the variables in the OUT= data set. Let X be variable number *nn* in the VAR statement list and let Y be variable number *mm* in the VAR statement list. Table 24.1 shows the output variables containing the results of the spectral and cross-spectral analysis of X and Y.

In Table 24.1 the following notation is used. Let W_j be the vector of $2p+1$ smoothing weights given by the WEIGHTS statement, normalized to sum to $\frac{1}{4\pi}$. The subscript of W_j runs from W_{-p} to W_p, so that W_0 is the middle weight in the WEIGHTS statement list. Let $\omega_k = \frac{2\pi k}{n}$, where $k = 0, 1, \ldots, \mathrm{floor}(\frac{n}{2})$.

Table 24.1. Variables Created by PROC SPECTRA

Variable	**Description**
FREQ	frequency in radians from 0 to π (Note: Cycles per observation is $\frac{\mathrm{FREQ}}{2\pi}$.)
PERIOD	period or wavelength: $\frac{2\pi}{\mathrm{FREQ}}$ (Note: PERIOD is missing for FREQ=0.)
COS_X COS_WAVE	cosine transform of X: $a_k^x = \frac{2}{n}\sum_{t=1}^{n} X_t \cos(\omega_k(t-1))$
SIN_X SIN_WAVE	sine transform of X: $b_k^x = \frac{2}{n}\sum_{t=1}^{n} X_t \sin(\omega_k(t-1))$
P_*nn*	periodogram of X: $J_k^x = \frac{n}{2}[(a_k^x)^2 + (b_k^x)^2]$
S_*nn*	spectral density estimate of X: $F_k^x = \sum_{j=-p}^{p} W_j J_{k+j}^x$ (except across endpoints)
RP_*nn*_*mm*	real part of cross-periodogram X and Y: $\mathrm{real}(\mathrm{J_k^{xy}}) = \frac{\mathrm{n}}{2}(\mathrm{a_k^x a_k^y + b_k^x b_k^y})$
IP_*nn*_*mm*	imaginary part of cross-periodogram of X and Y: $\mathrm{imag}(\mathrm{J_k^{xy}}) = \frac{\mathrm{n}}{2}(\mathrm{a_k^x b_k^y - b_k^x a_k^y})$
CS_*nn*_*mm*	cospectrum estimate (real part of cross-spectrum) of X and Y: $C_k^{xy} = \sum_{j=-p}^{p} W_j \mathrm{real}(\mathrm{J_{k+j}^{xy}})$ (except across endpoints)
QS_*nn*_*mm*	quadrature spectrum estimate (imaginary part of cross-spectrum) of X and Y: $Q_k^{xy} = \sum_{j=-p}^{p} W_j \mathrm{imag}(\mathrm{J_{k+j}^{xy}})$ (except across endpoints)
A_*nn*_*mm*	amplitude (modulus) of cross-spectrum of X and Y: $A_k^{xy} = \sqrt{(C_k^{xy})^2 + (Q_k^{xy})^2}$
K_*nn*_*mm*	coherency squared of X and Y: $K_k^{xy} = (A_k^{xy})^2/(F_k^x F_k^y)$
PH_*nn*_*mm*	phase spectrum in radians of X and Y: $\Phi_k^{xy} = \arctan(Q_k^{xy}/C_k^{xy})$

Printed Output

By default PROC SPECTRA produced no printed output.

When the WHITETEST option is specified, the SPECTRA procedure prints the following statistics for each variable in the VAR statement:

1. the name of the variable
2. M-1, the number of two-degree-of-freedom periodogram ordinates used in the tests
3. MAX(P(*)), the maximum periodogram ordinate
4. SUM(P(*)), the sum of the periodogram ordinates
5. Fisher's Kappa statistic
6. Bartlett's Kolmogorov-Smirnov test statistic

See "White Noise Test" earlier in this chapter for details.

ODS Table Names

PROC SPECTRA assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 24.2. ODS Tables Produced in PROC SPECTRA

ODS Table Name	**Description**	**Option**
WhiteNoiseTest	White Noise Test	WHITETEST
Kappa	Fishers Kappa	WHITETEST
Bartlett	Bartletts Kolmogorov-Smirnov Statistic	WHITETEST

Examples

Example 24.1. Spectral Analysis of Sunspot Activity

This example analyzes Wolfer's sunspot data (Anderson 1971). The following statements read and plot the data.

```
title "Wolfer's Sunspot Data";
data sunspot;
   input year wolfer @@;
   datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96

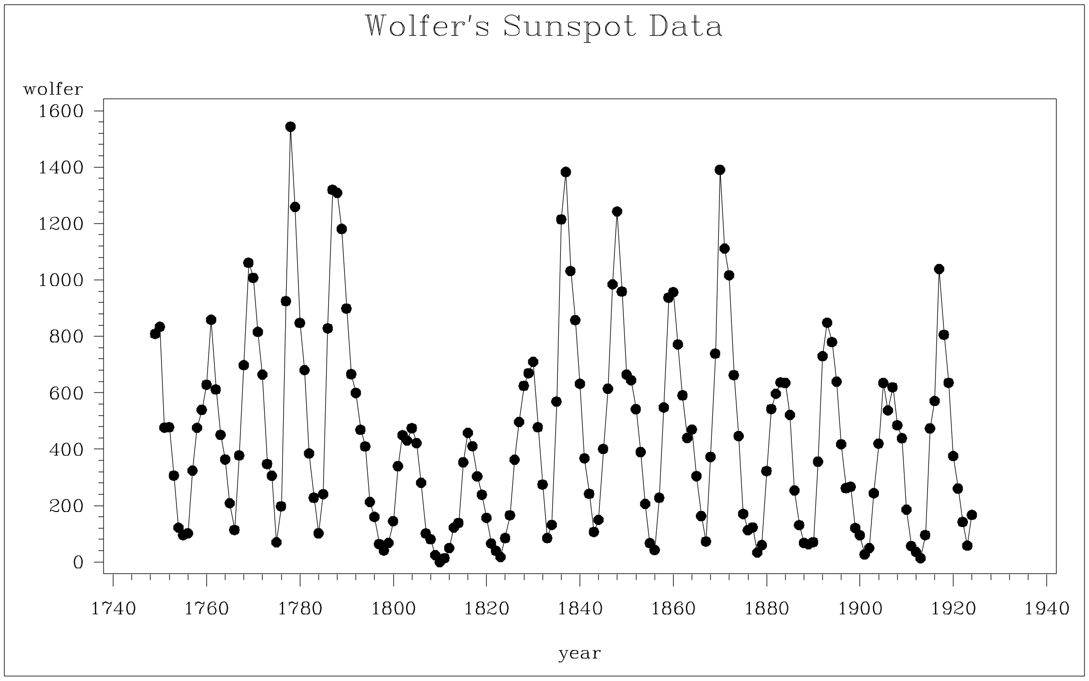
1924  167
;

symbol1 i=splines v=dot;
proc gplot data=sunspot;
   plot wolfer*year;
run;
```

The plot of the sunspot series is shown in Output 24.1.1.

Output 24.1.1. Plot of Original Data



The spectral analysis of the sunspot series is performed by the following statements:

```
proc spectra data=sunspot out=b p s adjmean whitetest;
   var wolfer;
   weights 1 2 3 4 3 2 1;
run;

proc print data=b(obs=12);
run;
```

The PROC SPECTRA statement specifies the P and S options to write the periodogram and spectral density estimates to the OUT= data set B. The WEIGHTS statement specifies a triangular spectral window for smoothing the periodogram to produce the spectral density estimate. The ADJMEAN option zeros the frequency 0 value and avoids the need to exclude that observation from the plots. The WHITETEST option prints tests for white noise.

The Fisher's Kappa test statistic of 16.070 is larger than the 5% critical value of 7.2, so the null hypothesis that the sunspot series is white noise is rejected.

The Bartlett's Kolmogorov-Smirnov statistic of 0.6501 is greater than

$$a\sqrt{1/(m-1)} = 1.36\sqrt{1/87} = 0.1458$$

so reject the null hypothesis that the spectrum represents white noise.

The printed output produced by PROC SPECTRA is shown in Output 24.1.2. The output data set B created by PROC SPECTRA is shown in part in Output 24.1.3.

Output 24.1.2. White Noise Test Results

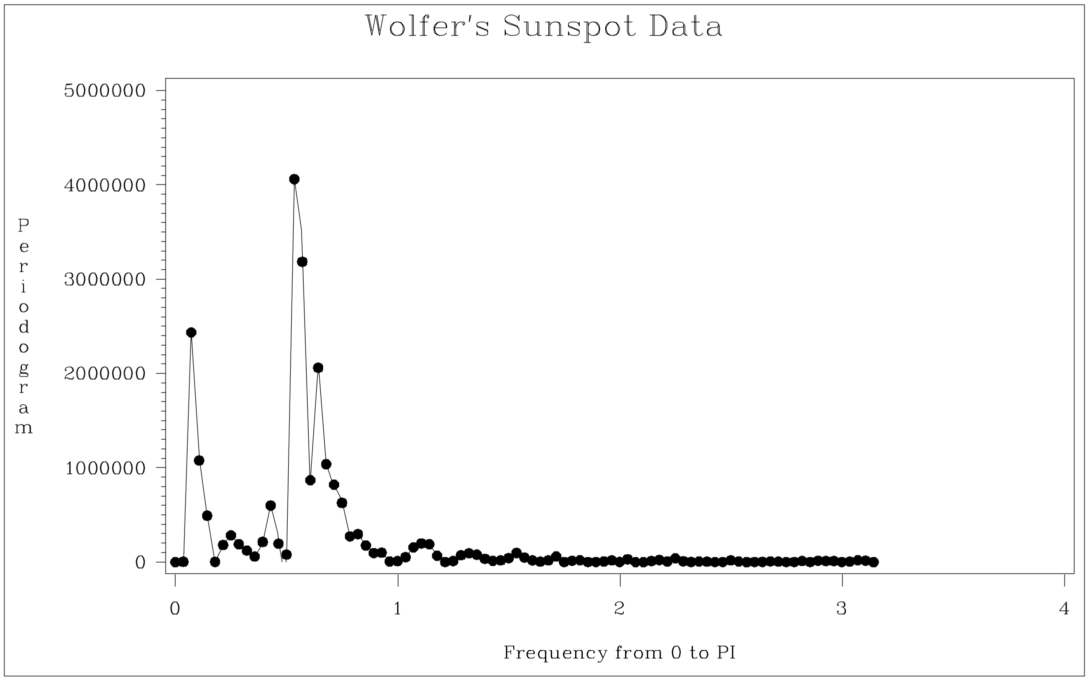
                6    0.17850      35.200         2581.12    36678.14
                7    0.21420      29.333       181163.15    20604.52
                8    0.24990      25.143       283057.60    15132.81
                9    0.28560      22.000       188672.97    13265.89
               10    0.32130      19.556       122673.94    14953.32
               11    0.35700      17.600        58532.93    16402.84
               12    0.39270      16.000       213405.16    18562.13
```

The following statements plot the periodogram and spectral density estimate:

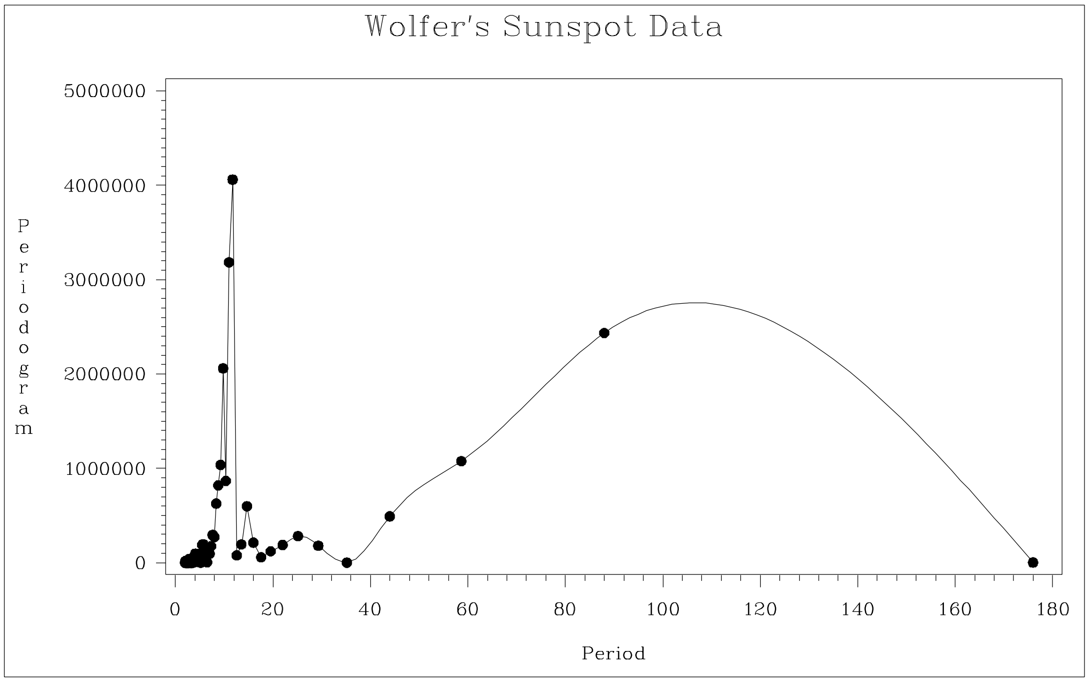
```
proc gplot data=b;
   plot p_01 * freq;
   plot p_01 * period;
   plot s_01 * freq;
   plot s_01 * period;
run;
```

The periodogram is plotted against frequency in Output 24.1.4 and plotted against period in Output 24.1.5. The spectral density estimate is plotted against frequency in Output 24.1.6 and plotted against period in Output 24.1.7.

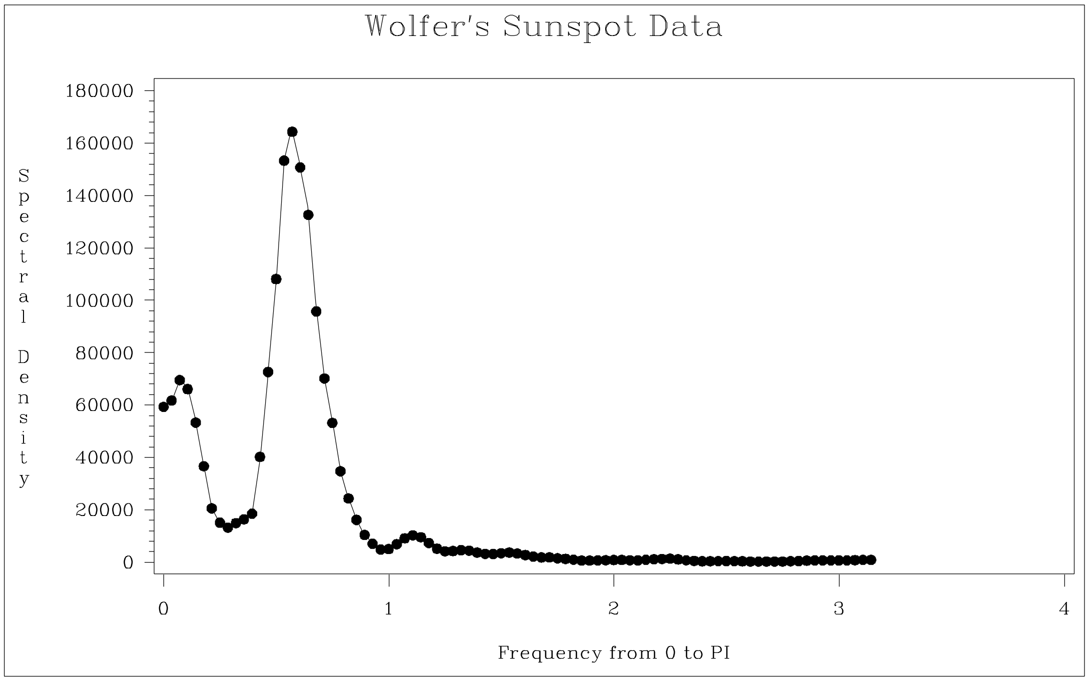
Output 24.1.4. Plot of Periodogram by Frequency



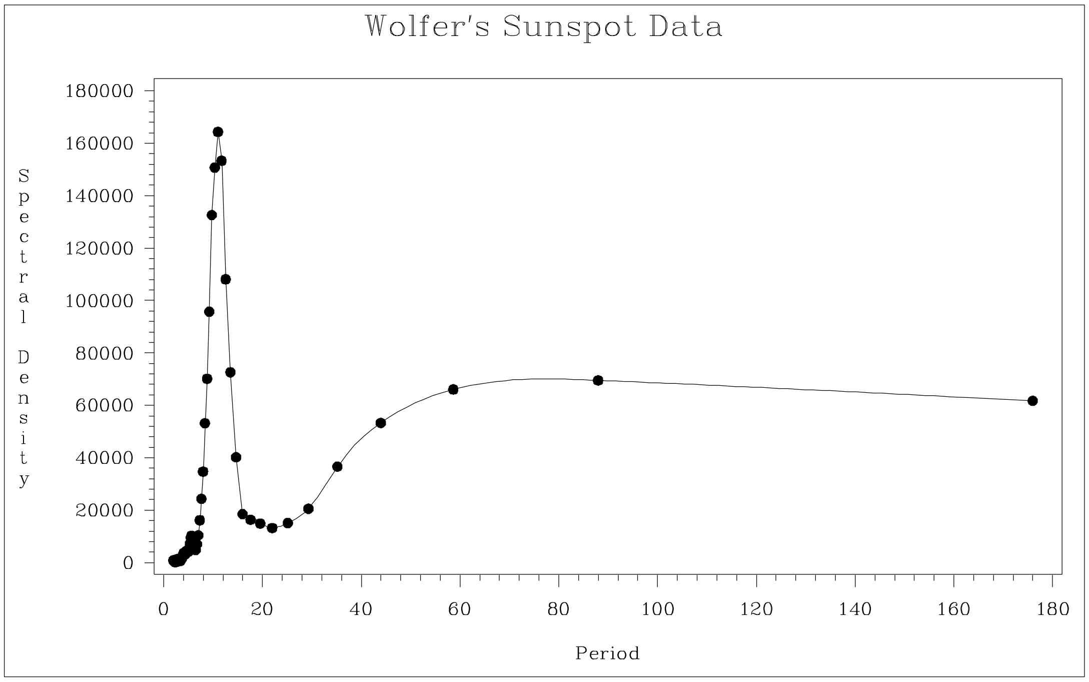
Output 24.1.5. Plot of Periodogram by Period



Output 24.1.6. Plot of Spectral Density Estimate by Frequency



Output 24.1.7. Plot of Spectral Density Estimate by Period



Since PERIOD is the reciprocal of frequency, the plot axis for PERIOD is stretched for low frequencies and compressed at high frequencies. One way to correct for this is to use a WHERE statement to restrict the plots and exclude the low frequency components. The following statements plot the spectral density for periods less than 50.

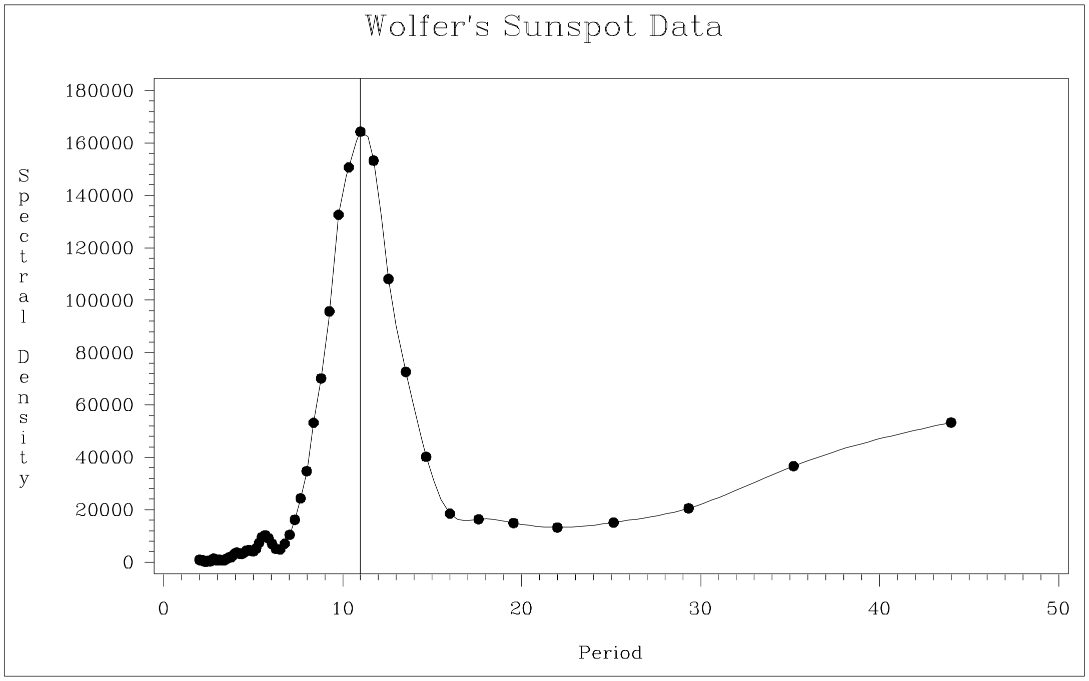
```
proc gplot data=b;
   where period < 50;
```

```
      plot s_01 * period / href=11;
   run;
```

The spectral analysis of the sunspot series confirms a strong 11-year cycle of sunspot activity. The plot makes this clear by drawing a reference line at the 11 year period, which highlights the position of the main peak in the spectral density.

Output 24.1.8 shows the plot. Contrast Output 24.1.8 with Output 24.1.7.

Output 24.1.8. Plot of Spectral Density Estimate by Period to 50 Years



Example 24.2. Cross-Spectral Analysis

This example shows cross-spectral analysis for two variables X and Y using simulated data. X is generated by an AR(1) process; Y is generated as white noise plus an input from X lagged 2 periods. All output options are specified on the PROC SPECTRA statement. PROC CONTENTS shows the contents of the OUT= data set.

```
   data a;
      xl = 0; xll = 0;
      do i = - 10 to 100;
         x = .4 * xl  + rannor(123);
         y = .5 * xll + rannor(123);
         if i > 0 then output;
         xll = xl; xl = x;
         end;
   run;

   proc spectra data=a out=b cross coef a k p ph s;
      var x y;
      weights 1 1.5 2 4 8 9 8 4 2 1.5 1;
   run;

   proc contents data=b position;
   run;
```

The PROC CONTENTS report for the output data set B is shown in Output 24.2.1.

Output 24.2.1. Contents of PROC SPECTRA OUT= Data Set

```

Chapter 25
The STATESPACE Procedure

Overview

The STATESPACE procedure analyzes and forecasts multivariate time series using the state space model. The STATESPACE procedure is appropriate for jointly forecasting several related time series that have dynamic interactions. By taking into account the autocorrelations among the whole set of variables, the STATESPACE procedure may give better forecasts than methods that model each series separately.

By default, the STATESPACE procedure automatically selects a state space model appropriate for the time series, making the procedure a good tool for automatic forecasting of multivariate time series. Alternatively, you can specify the state space model by giving the form of the state vector and the state transition and innovation matrices.

The methods used by the STATESPACE procedure assume that the time series are jointly stationary. Nonstationary series must be made stationary by some preliminary transformation, usually by differencing. The STATESPACE procedure allows you to specify differencing of the input data. When differencing is specified, the STATESPACE procedure automatically integrates forecasts of the differenced series to produce forecasts of the original series.

The State Space Model

The *state space model* represents a multivariate time series through auxiliary variables, some of which may not be directly observable. These auxiliary variables are called the *state vector*. The state vector summarizes all the information from the present and past values of the time series relevant to the prediction of future values of the series. The observed time series are expressed as linear combinations of the state variables. The state space model is also called a Markovian representation, or a canonical representation, of a multivariate time series process. The state space approach to modeling a multivariate stationary time series is summarized in Akaike (1976).

The state space form encompasses a very rich class of models. Any Gaussian multivariate stationary time series can be written in a state space form, provided that the dimension of the predictor space is finite. In particular, any autoregressive moving average (ARMA) process has a state space representation and, conversely, any state space process can be expressed in an ARMA form (Akaike 1974). More details on the relation of the state space and ARMA forms are given in "Relation of ARMA and State Space Forms" later in this chapter.

Let $\mathbf{x}_t$ be the $r \times 1$ vector of observed variables, after differencing (if differencing is specified) and subtracting the sample mean. Let $\mathbf{z}_t$ be the state vector of dimension s, $s \geq r$, where the first r components of $\mathbf{z}_t$ consist of $\mathbf{x}_t$. Let the notation $\mathbf{x}_{t+k|t}$

represent the conditional expectation (or prediction) of $\mathbf{x}_{t+k}$ based on the information available at time *t*. Then the last $s - r$ elements of $\mathbf{z}_t$ consist of elements of $\mathbf{x}_{t+k|t}$, where *k*>0 is specified or determined automatically by the procedure.

There are various forms of the state space model in use. The form of the state space model used by the STATESPACE procedure is based on Akaike (1976). The model is defined by the following *state transition equation*:

$$\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$$

In the state transition equation, the $s \times s$ coefficient matrix **F** is called the *transition matrix*; it determines the dynamic properties of the model.

The $s \times r$ coefficient matrix **G** is called the *input matrix*; it determines the variance structure of the transition equation. For model identification, the first *r* rows and columns of **G** are set to an $r \times r$ identity matrix.

The input vector $\mathbf{e}_t$ is a sequence of independent normally distributed random vectors of dimension *r* with mean **0** and covariance matrix $\Sigma_{\mathbf{ee}}$. The random error $\mathbf{e}_t$ is sometimes called the innovation vector or shock vector.

In addition to the state transition equation, state space models usually include a *measurement equation* or *observation equation* that gives the observed values $\mathbf{x}_t$ as a function of the state vector $\mathbf{z}_t$. However, since PROC STATESPACE always includes the observed values $\mathbf{x}_t$ in the state vector $\mathbf{z}_t$, the measurement equation in this case merely represents the extraction of the first *r* components of the state vector.

The measurement equation used by the STATESPACE procedure is

$$\mathbf{x}_t = [\mathbf{I}_r \mathbf{0}]\mathbf{z}_t$$

where $\mathbf{I}_r$ is an $r \times r$ identity matrix. In practice, PROC STATESPACE performs the extraction of $\mathbf{x}_t$ from $\mathbf{z}_t$ without reference to an explicit measurement equation.

In summary:

$\mathbf{x}_t$	is an observation vector of dimension *r*.
$\mathbf{z}_t$	is a state vector of dimension *s*, whose first *r* elements are $\mathbf{x}_t$ and whose last $s - r$ elements are conditional prediction of future $\mathbf{x}_t$.
F	is an $s \times s$ transition matrix.
G	is an $s \times r$ input matrix, with the identity matrix $\mathbf{I}_r$ forming the first *r* rows and columns.
$\mathbf{e}_t$	is a sequence of independent normally distributed random vectors of dimension *r* with mean **0** and covariance matrix $\Sigma_{\mathbf{ee}}$.

How PROC STATESPACE Works

The design of the STATESPACE procedure closely follows the modeling strategy proposed by Akaike (1976). This strategy employs canonical correlation analysis for the automatic identification of the state space model.

Following Akaike (1976), the procedure first fits a sequence of unrestricted vector autoregressive (VAR) models and computes Akaike's information criterion (AIC) for each model. The vector autoregressive models are estimated using the sample autocovariance matrices and the Yule-Walker equations. The order of the VAR model producing the smallest Akaike information criterion is chosen as the order (number of lags into the past) to use in the canonical correlation analysis.

The elements of the state vector are then determined via a sequence of canonical correlation analyses of the sample autocovariance matrices through the selected order. This analysis computes the sample canonical correlations of the past with an increasing number of steps into the future. Variables that yield significant correlations are added to the state vector; those that yield insignificant correlations are excluded from further consideration. The importance of the correlation is judged on the basis of another information criterion proposed by Akaike. See the section "Canonical Correlation Analysis" for details. If you specify the state vector explicitly, these model identification steps are omitted.

Once the state vector is determined, the state space model is fit to the data. The free parameters in the $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma_{ee}}$ matrices are estimated by approximate maximum likelihood. By default, the $\mathbf{F}$ and $\mathbf{G}$ matrices are unrestricted, except for identifiability requirements. Optionally, conditional least-squares estimates can be computed. You can impose restrictions on elements of the $\mathbf{F}$ and $\mathbf{G}$ matrices.

After the parameters are estimated, forecasts are produced from the fitted state space model using the Kalman filtering technique. If differencing was specified, the forecasts are integrated to produce forecasts of the original input variables.

Getting Started

The following introductory example uses simulated data for two variables X and Y. The following statements generate the X and Y series.

```
data in;
   x=10;  y=40;
   x1=0; y1=0;
   a1=0; b1=0;
   iseed=123;
   do t=-100 to 200;
      a=rannor(iseed);
      b=rannor(iseed);
      dx = 0.5*x1 + 0.3*y1 + a - 0.2*a1 - 0.1*b1;
      dy = 0.3*x1 + 0.5*y1 + b;
      x = x + dx + .25;
      y = y + dy + .25;
      if t >= 0 then output;
      x1 = dx; y1 = dy;
      a1 = a; b1 = b;
   end;
   keep t x y;
run;
```

The simulated series X and Y are shown in Figure 25.1.

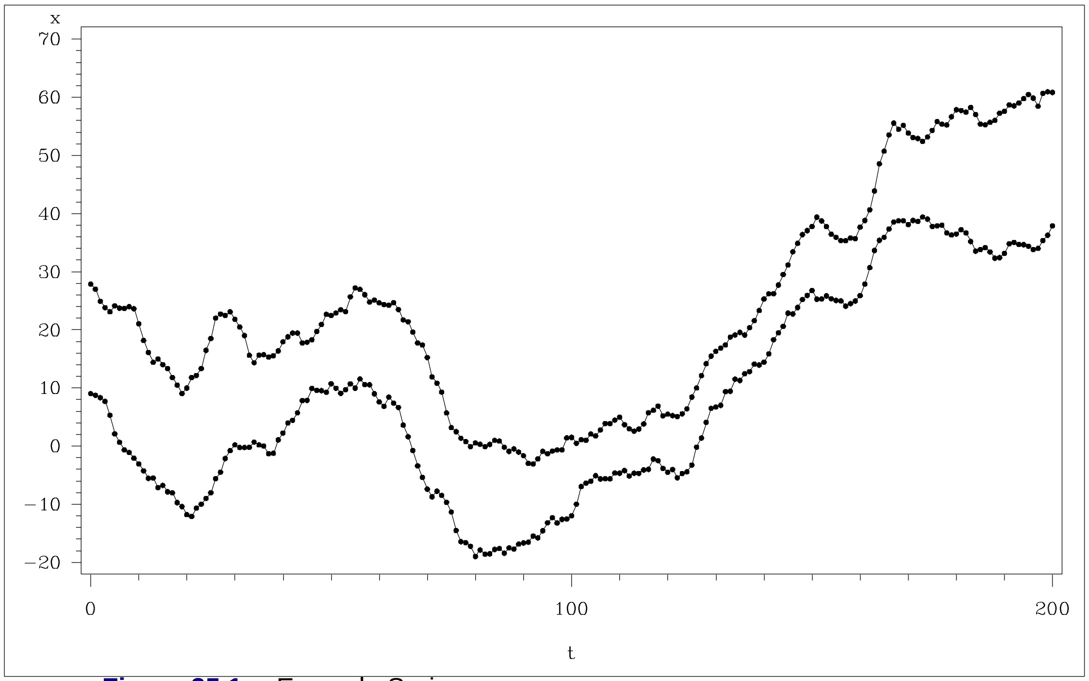

Figure 25.1. Example Series

Automatic State Space Model Selection

The STATESPACE procedure is designed to automatically select the best state space model for forecasting the series. You can specify your own model if you wish, and you can use the output from PROC STATESPACE to help you identify a state space model. However, the easiest way to use PROC STATESPACE is to let it choose the model.

Stationarity and Differencing

Although PROC STATESPACE selects the state space model automatically, it does assume that the input series are stationary. If the series are nonstationary, then the process may fail. Therefore the first step is to examine your data and test to see if differencing is required. (See the section "Stationarity and Differencing" later in this chapter for further discussion of this issue.)

The series shown in Figure 25.1 are nonstationary. In order to forecast X and Y with a state space model, you must difference them (or use some other de-trending method). If you fail to difference when needed and try to use PROC STATESPACE with nonstationary data, an inappropriate state space model may be selected, and the model estimation may fail to converge.

The following statements identify and fit a state space model for the first differences of X and Y, and forecast X and Y 10 periods ahead:

```
proc statespace data=in out=out lead=10;
   var x(1) y(1);
   id t;
run;
```

The DATA= option specifies the input data set and the OUT= option specifies the output data set for the forecasts. The LEAD= option specifies forecasting 10 observations past the end of the input data. The VAR statement specifies the variables to forecast and specifies differencing. The notation X(1) Y(1) specifies that the state space model analyzes the first differences of X and Y.

Descriptive Statistics and Preliminary Autoregressions

The first page of the printed output produced by the preceding statements is shown in Figure 25.2.

```

```

Figure 25.2. Descriptive Statistics and VAR Order Selection

Descriptive statistics are printed first, giving the number of nonmissing observations after differencing, and the sample means and standard deviations of the differenced series. The sample means are subtracted before the series are modeled (unless the NOCENTER option is specified), and the sample means are added back when the forecasts are produced.

Let X_t and Y_t be the observed values of X and Y, and let x_t and y_t be the values of X and Y after differencing and subtracting the mean difference. The series $\mathbf{x}_t$ modeled by the STATEPSPACE procedure is

$$\mathbf{x}_t = \begin{bmatrix} x_t \\ y_t \end{bmatrix} = \begin{bmatrix} (1-B)X_t - 0.144316 \\ (1-B)Y_t - 0.164871 \end{bmatrix}$$

where B represents the backshift operator.

After the descriptive statistics, PROC STATESPACE prints the Akaike information criterion (AIC) values for the autoregressive models fit to the series. The smallest AIC value, in this case 5.517 at lag 2, determines the number of autocovariance matrices analyzed in the canonical correlation phase.

A schematic representation of the autocorrelations is printed next. This indicates which elements of the autocorrelation matrices at different lags are significantly greater or less than 0.

The second page of the STATESPACE printed output is shown in Figure 25.3.

```

         y              0.292177    0.469297    -0.00537    -0.00048
```

Figure 25.3. Partial Autocorrelations and VAR Model

Figure 25.3 shows a schematic representation of the partial autocorrelations, similar to the autocorrelations shown in Figure 25.2. The selection of a second order autoregressive model by the AIC statistic looks reasonable in this case because the partial autocorrelations for lags greater than 2 are not significant.

Next, the Yule-Walker estimates for the selected autoregressive model are printed. This output shows the coefficient matrices of the vector autoregressive model at each lag.

Selected State Space Model Form and Preliminary Estimates

After the autoregressive order selection process has determined the number of lags to consider, the canonical correlation analysis phase selects the state vector. By default, output for this process is not printed. You can use the CANCORR option to print details of the canonical correlation analysis. See the section "Canonical Correlation Analysis" later in this chapter for an explanation of this process.

Once the state vector is selected the state space model is estimated by approximate maximum likelihood. Information from the canonical correlation analysis and from the preliminary autoregression is used to form preliminary estimates of the state space model parameters. These preliminary estimates are used as starting values for the iterative estimation process.

The form of the state vector and the preliminary estimates are printed next, as shown in Figure 25.4.

```

Figure 25.4. Preliminary Estimates of State Space Model

Figure 25.4 first prints the state vector as X[T;T] Y[T;T] X[T+1;T]. This notation indicates that the state vector is

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \end{bmatrix}$$

The notation $x_{t+1|t}$ indicates the conditional expectation or prediction of x_{t+1} based on the information available at time *t*, and $x_{t|t}$ and $y_{t|t}$ are x_t and y_t respectively.

The remainder of Figure 25.4 shows the preliminary estimates of the transition matrix $\mathbf{F}$, the input matrix $\mathbf{G}$, and the covariance matrix $\mathbf{\Sigma_{ee}}$.

Estimated State Space Model

The next page of the STATESPACE output prints the final estimates of the fitted model, as shown in Figure 25.5. This output has the same form as in Figure 25.4, but shows the maximum likelihood estimates instead of the preliminary estimates.

```

Figure 25.6. Final Parameter Estimates

Convergence Failures

The maximum likelihood estimates are computed by an iterative nonlinear maximization algorithm, which may not converge. If the estimates fail to converge, warning messages are printed in the output.

If you encounter convergence problems, you should recheck the stationarity of the data and ensure that the specified differencing orders are correct. Attempting to fit state space models to nonstationary data is a common cause of convergence failure. You can also use the MAXIT= option to increase the number of iterations allowed, or experiment with the convergence tolerance options DETTOL= and PARMTOL=.

Forecast Data Set

The following statements print the output data set. The WHERE statement excludes the first 190 observations from the output, so that only the forecasts and the last 10 actual observations are printed.

```
proc print data=out;
   id t;
   where t > 190;
run;
```

The PROC PRINT output is shown in Figure 25.7.

```

Figure 25.7. OUT= Data Set Produced by PROC STATESPACE

The OUT= data set produced by PROC STATESPACE contains the VAR and ID statement variables. In addition, for each VAR statement variable, the OUT= data set contains the variables FOR*i*, RES*i*, and STD*i*. These variables contain the predicted values, residuals, and forecast standard errors for the *i*th variable in the VAR statement list. In this case, X is listed first in the VAR statement, so FOR1 contains the forecasts of X, while FOR2 contains the forecasts of Y.

The following statements plot the forecasts and actuals for the series.

```
proc gplot data=out;
   plot for1*t=1 for2*t=1 x*t=2 y*t=2 /
        overlay href=200.5;
   symbol1 v=circle i=join;
   symbol2 v=star i=none;
   where t > 150;
run;
```

The forecast plot is shown in Figure 25.8. The last 50 observations are also plotted to provide context, and a reference line is drawn between the historical and forecast periods. The actual values are plotted with asterisks.

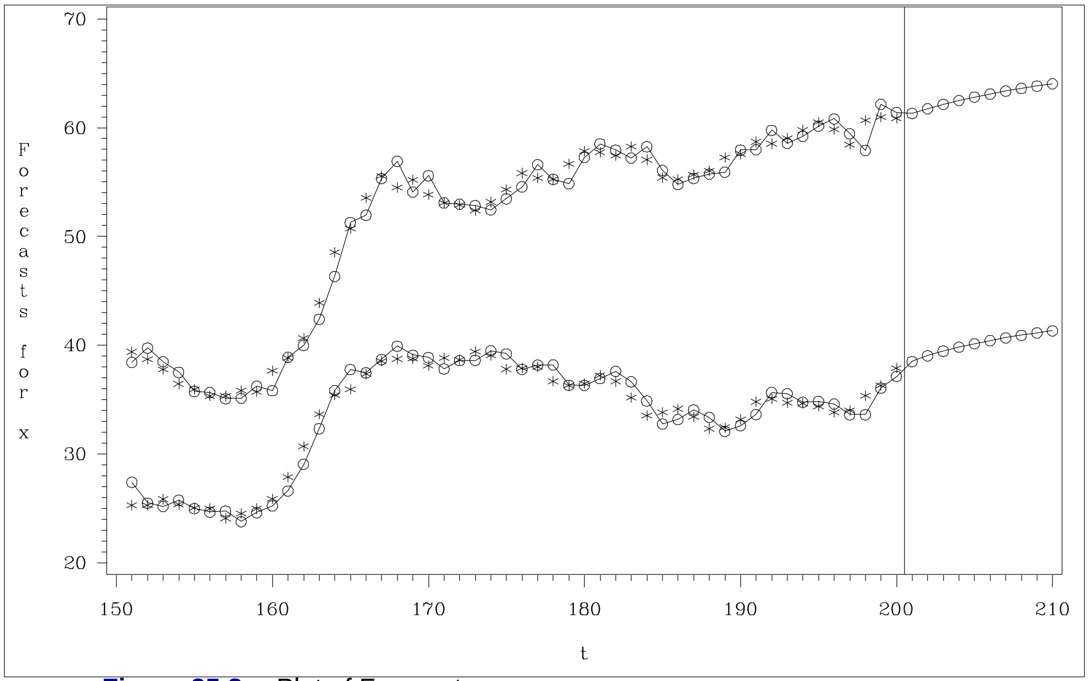

Figure 25.8. Plot of Forecasts

Controlling Printed Output

By default, the STATESPACE procedure produces a large amount of printed output. The NOPRINT option suppresses all printed output. You can suppress the printed output for the autoregressive model selection process with the PRINTOUT=NONE option. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. You can produce more detailed output with the PRINTOUT=LONG option and by specifying the printing control options CANCORR, COVB, and PRINT.

Specifying the State Space Model

Instead of allowing the STATESPACE procedure to select the model automatically, you can use FORM and RESTRICT statements to specify a state space model.

Specifying the State Vector

Use the FORM statement to control the form of the state vector. You can use this feature to force PROC STATESPACE to estimate and forecast a model different from the model it would select automatically. You can also use this feature to reestimate the automatically selected model (possibly with restrictions) without repeating the canonical correlation analysis.

The FORM statement specifies the number of lags of each variable to include in the state vector. For example, the statement FORM X 3; forces the state vector to include $x_{t|t}$, $x_{t+1|t}$, and $x_{t+2|t}$. The following statement specifies the state vector $(x_{t|t}, y_{t|t}, x_{t+1|t})$, which is the same state vector selected in the preceding example:

```
   form x 2 y 1;
```

You can specify the form for only some of the variables and allow PROC STATESPACE to select the form for the other variables. If only some of the variables are specified in the FORM statement, canonical correlation analysis is used to determine the number of lags included in the state vector for the remaining variables not specified by the FORM statement. If the FORM statement includes specifications for all the variables listed in the VAR statement, the state vector is completely defined and the canonical correlation analysis is not performed.

Restricting the F and G matrices

After you know the form of the state vector, you can use the RESTRICT statement to fix some parameters in the **F** and **G** matrices to specified values. One use of this feature is to remove insignificant parameters by restricting them to 0.

In the introductory example shown in the preceding section, the F[2,3] parameter is not significant. (The parameters estimation output shown in Figure 25.6 gives the *t* statistic for F[2,3] as -0.06. F[3,3] and F[3,1] also have low significance with $t < 2$.)

The following statements reestimate this model with F[2,3] restricted to 0. The FORM statement is used to specify the state vector and thus bypass the canonical correlation analysis.

```
   proc statespace data=in out=out lead=10;
      var x(1) y(1);
      id t;
      form x 2 y 1;
      restrict f(2,3)=0;
   run;
```

The final estimates produced by these statements are shown in Figure 25.9.

Figure 25.9. Results using RESTRICT Statement

Syntax

The STATESPACE procedure uses the following statements:

PROC STATESPACE *options*;
  BY *variable . . .* ;
  FORM *variable value . . .* ;
  ID *variable*;
  INITIAL **F**(*row,column*)=*value . . .* **G**(*row,column*)=*value ...* ;
  RESTRICT **F**(*row,column*)=*value . . .* **G**(*row,column*)=*value ...* ;
  VAR *variable (difference, difference, . . .) ...* ;

Functional Summary

The statements and options used by PROC STATESPACE are summarized in the following table.

Description	Statement	Option
Input Data Set Options		
specify the input data set	PROC STATESPACE	DATA=
prevent subtraction of sample mean	PROC STATESPACE	NOCENTER
specify the ID variable	ID	
specify the observed series and differencing	VAR	
Options for Autoregressive Estimates		
specify the maximum order	PROC STATESPACE	ARMAX=
specify maximum lag for autocovariances	PROC STATESPACE	LAGMAX=
output only minimum AIC model	PROC STATESPACE	MINIC
specify the amount of detail printed	PROC STATESPACE	PRINTOUT=
write preliminary AR models to a data set	PROC STATESPACE	OUTAR=
Options for Canonical Correlation Analysis		
print the sequence of canonical correlations	PROC STATESPACE	CANCORR
specify upper limit of dimension of state vector	PROC STATESPACE	DIMMAX=
specify the minimum number of lags	PROC STATESPACE	PASTMIN=
specify the multiplier of the degrees of freedom	PROC STATESPACE	SIGCORR=
Options for State Space Model Estimation		
specify starting values	INITIAL	
print covariance matrix of parameter estimates	PROC STATESPACE	COVB
specify the convergence criterion	PROC STATESPACE	DETTOL=
specify the convergence criterion	PROC STATESPACE	PARMTOL=

Description	Statement	Option
print the details of the iterations	PROC STATESPACE	ITPRINT
specify an upper limit of the number of lags	PROC STATESPACE	KLAG=
specify maximum number of iterations allowed	PROC STATESPACE	MAXIT=
suppress the final estimation	PROC STATESPACE	NOEST
write the state space model parameter estimates to an output data set	PROC STATESPACE	OUTMODEL=
use conditional least squares for final estimates	PROC STATESPACE	RESIDEST
specify criterion for testing for singularity	PROC STATESPACE	SINGULAR=
Options for Forecasting		
start forecasting before end of the input data	PROC STATESPACE	BACK=
specify the time interval between observations	PROC STATESPACE	INTERVAL=
specify multiple periods in the time series	PROC STATESPACE	INTPER=
specify how many periods to forecast	PROC STATESPACE	LEAD=
specify the output data set for forecasts	PROC STATESPACE	OUT=
print forecasts	PROC STATESPACE	PRINT
Options to Specify the State Space Model		
specify the state vector	FORM	
specify the parameter values	RESTRICT	
BY Groups		
specify BY-group processing	BY	
Printing		
suppresses all printed output	NOPRINT	

PROC STATESPACE Statement

PROC STATESPACE *options***;**

The following options can be specified in the PROC STATESPACE statement.

Printing Options

NOPRINT

suppresses all printed output.

Input Data Options

DATA= *SAS-data-set*

specifies the name of the SAS data set to be used by the procedure. If the DATA= option is omitted, the most recently created SAS data set is used.

LAGMAX= *k*

specifies the number of lags for which the sample autocovariance matrix is computed. The LAGMAX= option controls the number of lags printed in the schematic representation of the autocorrelations.

The sample autocovariance matrix of lag *i*, denoted as $\mathbf{C}_i$, is computed as

$$\mathbf{C}_i = \frac{1}{N-1}\sum_{t=1+i}^{N} \mathbf{x}_t\mathbf{x}'_{t-i}$$

where $\mathbf{x}_t$ is the differenced and centered data and N is the number of observations. (If the NOCENTER option is specified, 1 is not subtracted from N.) LAGMAX= *k* specifies that $\mathbf{C}_0$ through $\mathbf{C}_k$ are computed. The default is LAGMAX=10.

NOCENTER

prevents subtraction of the sample mean from the input series (after any specified differencing) before the analysis.

Options for Preliminary Autoregressive Models

ARMAX= *n*

specifies the maximum order of the preliminary autoregressive models. The ARMAX= option controls the autoregressive orders for which information criteria are printed, and controls the number of lags printed in the schematic representation of partial autocorrelations. The default is ARMAX=10. See "Preliminary Autoregressive Models" later in this chapter for details.

MINIC

writes to the OUTAR= data set only the preliminary Yule-Walker estimates for the VAR model producing the minimum AIC. See "OUTAR= Data Set" later in this chapter for details.

OUTAR= *SAS-data-set*

writes the Yule-Walker estimates of the preliminary autoregressive models to a SAS data set. See "OUTAR= Data Set" later in this chapter for details.

PRINTOUT= SHORT | LONG | NONE

determines the amount of detail printed. PRINTOUT=LONG prints the lagged covariance matrices, the partial autoregressive matrices, and estimates of the residual covariance matrices from the sequence of autoregressive models. PRINTOUT=NONE suppresses the output for the preliminary autoregressive models. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. PRINTOUT=SHORT is the default.

Canonical Correlation Analysis Options

CANCORR
prints the canonical correlations and information criterion for each candidate state vector considered. See "Canonical Correlation Analysis" later in this chapter for details.

DIMMAX= *n*
specifies the upper limit to the dimension of the state vector. The DIMMAX= option can be used to limit the size of the model selected. The default is DIMMAX=10.

PASTMIN= *n*
specifies the minimum number of lags to include in the canonical correlation analysis. The default is PASTMIN=0. See "Canonical Correlation Analysis" later in this chapter for details.

SIGCORR= *value*
specifies the multiplier of the degrees of freedom for the penalty term in the information criterion used to select the state space form. The default is SIGCORR=2. The larger the value of the SIGCORR= option, the smaller the state vector tends to be. Hence, a large value causes a simpler model to be fit. See "Canonical Correlations Analysis" later in this chapter for details.

State Space Model Estimation Options

COVB
prints the inverse of the observed information matrix for the parameter estimates. This matrix is an estimate of the covariance matrix for the parameter estimates.

DETTOL= *value*
specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is DETTOL=1E-5.

ITPRINT
prints the iterations during the estimation process.

KLAG= *n*
sets an upper limit for the number of lags of the sample autocovariance matrix used in computing the approximate likelihood function. If the data have a strong moving average character, a larger KLAG= value may be necessary to obtain good estimates. The default is KLAG=15. See "Parameter Estimation" later in this chapter for details.

MAXIT= *n*
sets an upper limit to the number of iterations in the maximum likelihood or conditional least-squares estimation. The default is MAXIT=50.

NOEST

suppresses the final maximum likelihood estimation of the selected model.

OUTMODEL= *SAS-data-set*

writes the parameter estimates and their standard errors to a SAS data set. See "OUTMODEL= Data Set" later in this chapter for details.

PARMTOL= *value*

specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is PARMTOL=.001.

RESIDEST

computes the final estimates using conditional least squares on the raw data. This type of estimation may be more stable than the default maximum likelihood method but is usually more computationally expensive. See "Parameter Estimation" later in this chapter for details of the conditional least squares method.

SINGULAR= *value*

specifies the criterion for testing for singularity of a matrix. A matrix is declared singular if a scaled pivot is less than the SINGULAR= value when sweeping the matrix. The default is SINGULAR=1E-7.

Forecasting Options

BACK= *n*

starts forecasting *n* periods before the end of the input data. The BACK= option value must not be greater than the number of observations. The default is BACK=0.

INTERVAL= *interval*

specifies the time interval between observations. The INTERVAL= value is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. See Chapter 3, "Date Intervals, Formats, and Functions," for details on the INTERVAL= values allowed.

INTPER= *n*

specifies that each input observation corresponds to *n* time periods. For example, the options INTERVAL=MONTH and INTPER=2 specify bimonthly data and are equivalent to specifying INTERVAL=MONTH2. If the INTERVAL= option is not specified, the INTPER= option controls the increment used to generate ID values for the forecast observations. The default is INTPER=1.

LEAD= *n*

specifies how many forecast observations are produced. The forecasts start at the point set by the BACK= option. The default is LEAD=0, which produces no forecasts.

OUT= *SAS-data-set*
writes the residuals, actual values, forecasts, and forecast standard errors to a SAS data set. See "OUT= Data Set" later in this chapter for details.

PRINT
prints the forecasts.

BY Statement

BY *variable ...* **;**

A BY statement can be used with the STATESPACE procedure to obtain separate analyses on observations in groups defined by the BY variables.

FORM Statement

FORM *variable value ...* **;**

The FORM statement specifies the number of times a variable is included in the state vector. Values can be specified for any variable listed in the VAR statement. If a value is specified for each variable in the VAR statement, the state vector for the state space model is entirely specified, and automatic selection of the state space model is not performed.

The FORM statement forces the state vector, $\mathbf{z}_t$, to contain a specific variable a given number of times. For example, if Y is one of the variables in $\mathbf{x}_t$, then the statement

```
form y 3;
```

forces the state vector to contain $Y_t, Y_{t+1|t}$, and $Y_{t+2|t}$, possibly along with other variables.

The following statements illustrate the use of the FORM statement:

```
proc statespace data=in;
   var x y;
   form x 3 y 2;
run;
```

These statements fit a state space model with the following state vector:

$$\mathbf{z_t} = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \\ y_{t+1|t} \\ x_{t+2|t} \end{bmatrix}$$

ID Statement

ID *variable***;**

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= and INTPER= options.

INITIAL Statement

INITIAL F *(row,column)***=** *value* **...** **G***(row, column)***=** *value* **... ;**

The INITIAL statement gives initial values to the specified elements of the **F** and **G** matrices. These initial values are used as starting values for the iterative estimation.

Parts of the **F** and **G** matrices represent fixed structural identities. If an element specified is a fixed structural element instead of a free parameter, the corresponding initialization is ignored.

The following is an example of an INITIAL statement:

```
initial f(3,2)=0 g(4,1)=0 g(5,1)=0;
```

RESTRICT Statement

RESTRICT F*(row,column)***=** *value* **...** **G***(row,column)***=** *value* **... ;**

The RESTRICT statement restricts the specified elements of the **F** and **G** matrices to the specified values.

To use the restrict statement you need to know the form of the model. Either specify the form of the model with the FORM statement, or do a preliminary run, perhaps with the NOEST option, to find the form of the model that PROC STATESPACE selects for the data.

The following is an example of a RESTRICT statement:

```
restrict f(3,2)=0 g(4,1)=0 g(5,1)=0 ;
```

Parts of the **F** and **G** matrices represent fixed structural identities. If a restriction is specified for an element that is a fixed structural element instead of a free parameter, the restriction is ignored.

VAR Statement

VAR *variable (difference, difference, ...) ...* **;**

The VAR statement specifies the variables in the input data set to model and forecast. The VAR statement also specifies differencing of the input variables. The VAR statement is required.

Differencing is specified by following the variable name with a list of difference periods separated by commas. See the section "Stationarity and Differencing" for more information on differencing of input variables.

The order in which variables are listed in the VAR statement controls the order in which variables are included in the state vector. Usually, potential inputs should be listed before potential outputs.

For example, assuming the input data are monthly, the following VAR statement specifies modeling and forecasting of the one period and seasonal second difference of X and Y:

```
var x(1,12) y(1,12);
```

In this example, the vector time series analyzed is

$$\mathbf{x}_t = \begin{bmatrix} (1-B)(1-B^{12})X_t - \overline{x} \\ (1-B)(1-B^{12})Y_t - \overline{y} \end{bmatrix}$$

where B represents the back shift operator, and $\overline{x}$ and $\overline{y}$ represent the means of the differenced series. If the NOCENTER option is specified the mean differences are not subtracted.

Details

Missing Values

The STATESPACE procedure does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the VAR statement variables. Observations at the beginning of the data set with missing values for any VAR statement variable are not used or included in the output data set.

Stationarity and Differencing

The state space model used by the STATESPACE procedure assumes that the time series are stationary. Hence, the data should be checked for stationarity. One way to check for stationarity is to plot the series. A graph of series over time can show a time trend or variability changes.

You can also check stationarity by using the sample autocorrelation functions displayed by the ARIMA procedure. The autocorrelation functions of nonstationary series tend to decay slowly. See Chapter 11, "The ARIMA Procedure," for more information.

Another alternative is to use the STATIONARITY= option on the IDENTIFY statement in PROC ARIMA to apply Dickey-Fuller tests for unit roots in the time series. See Chapter 11, "The ARIMA Procedure," for more information on Dickey-Fuller unit root tests.

The most popular way to transform a nonstationary series to stationarity is by differencing. Differencing of the time series is specified in the VAR statement. For example, to take a simple first difference of the series X, use this statement:

```
   var x(1);
```

In this example, the change in X from one period to the next is analyzed. When the series has a seasonal pattern, differencing at a period equal to the length of the seasonal cycle may be desirable. For example, suppose the variable X is measured quarterly and shows a seasonal cycle over the year. You can use the following statement to analyze the series of changes from the same quarter in the previous year:

```
   var x(4);
```

To difference twice, add another differencing period to the list. For example, the following statement analyzes the series of second differences $(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$:

```
   var x(1,1);
```

The following statement analyzes the seasonal second difference series.

```
var x(1,4);
```

The series modeled is the 1-period difference of the 4-period difference: $(X_t - X_{t-4}) - (X_{t-1} - X_{t-5}) = X_t - X_{t-1} - X_{t-4} + X_{t-5}$.

Another way to obtain stationary series is to use a regression on time to de-trend the data. If the time series has a deterministic linear trend, regressing the series on time produces residuals that should be stationary. The following statements write residuals of X and Y to the variable RX and RY in the output data set DETREND.

```
data a;
   set a;
   t=_n_;
run;

proc reg data=a;
   model x y = t;
   output out=detrend r=rx ry;
run;
```

You then use PROC STATESPACE to forecast the de-trended series RX and RY. A disadvantage of this method is that you need to add the trend back to the forecast series in an additional step. A more serious disadvantage of the de-trending method is that it assumes a deterministic trend. In practice, most time series appear to have a stochastic rather than a deterministic trend. Differencing is a more flexible and often more appropriate method.

There are several other methods to handle nonstationary time series. For more information and examples, refer to Brockwell and Davis (1991).

Preliminary Autoregressive Models

After computing the sample autocovariance matrices, PROC STATESPACE fits a sequence of vector autoregressive models. These preliminary autoregressive models are used to estimate the autoregressive order of the process and limit the order of the autocovariances considered in the state vector selection process.

Yule-Walker Equations for Forward and Backward Models

Unlike a univariate autoregressive model, a multivariate autoregressive model has different forms, depending on whether the present observation is being predicted from the past observations or from the future observations.

Let $\mathbf{x}_t$ be the *r*-component stationary time series given by the VAR statement after differencing and subtracting the vector of sample means. (If the NOCENTER option is specified, the mean is not subtracted.) Let *n* be the number of observations of $\mathbf{x}_t$ from the input data set.

Let $\mathbf{e}_t$ be a vector white noise sequence with mean vector **0** and variance matrix $\mathbf{\Sigma}_p$, and let $\mathbf{n}_t$ be a vector white noise sequence with mean vector **0** and variance matrix $\mathbf{\Omega}_p$. Let *p* be the order of the vector autoregressive model for $\mathbf{x}_t$.

The forward autoregressive form based on the past observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^{p} \mathbf{\Phi}_i^p \mathbf{x}_{t-i} + \mathbf{e}_t$$

The backward autoregressive form based on the future observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^{p} \mathbf{\Psi}_i^p \mathbf{x}_{t+i} + \mathbf{n}_t$$

Letting E denote the expected value operator, the autocovariance sequence for the $\mathbf{x}_t$ series, $\mathbf{\Gamma}_i$, is

$$\mathbf{\Gamma}_i = E\mathbf{x}_t\mathbf{x}'_{t-i}$$

The Yule-Walker equations for the autoregressive model that matches the first *p* elements of the autocovariance sequence are

$$\begin{bmatrix} \mathbf{\Gamma}_0 & \mathbf{\Gamma}_1 & \cdots & \mathbf{\Gamma}_{p-1} \\ \mathbf{\Gamma}'_1 & \mathbf{\Gamma}_0 & \cdots & \mathbf{\Gamma}_{p-2} \\ \vdots & \vdots & & \vdots \\ \mathbf{\Gamma}'_{p-1} & \mathbf{\Gamma}'_{p-2} & \cdots & \mathbf{\Gamma}_0 \end{bmatrix} \begin{bmatrix} \mathbf{\Phi}_1^p \\ \mathbf{\Phi}_2^p \\ \vdots \\ \mathbf{\Phi}_p^p \end{bmatrix} = \begin{bmatrix} \mathbf{\Gamma}_1 \\ \mathbf{\Gamma}_2 \\ \vdots \\ \mathbf{\Gamma}_p \end{bmatrix}$$

and

$$\begin{bmatrix} \mathbf{\Gamma}_0 & \mathbf{\Gamma}'_1 & \cdots & \mathbf{\Gamma}'_{p-1} \\ \mathbf{\Gamma}_1 & \mathbf{\Gamma}_0 & \cdots & \mathbf{\Gamma}'_{p-2} \\ \vdots & \vdots & & \vdots \\ \mathbf{\Gamma}_{p-1} & \mathbf{\Gamma}_{p-2} & \cdots & \mathbf{\Gamma}_0 \end{bmatrix} \begin{bmatrix} \mathbf{\Psi}_1^p \\ \mathbf{\Psi}_2^p \\ \vdots \\ \mathbf{\Psi}_p^p \end{bmatrix} = \begin{bmatrix} \mathbf{\Gamma}'_1 \\ \mathbf{\Gamma}'_2 \\ \vdots \\ \mathbf{\Gamma}'_p \end{bmatrix}$$

Here $\mathbf{\Phi}_i^p$ are the coefficient matrices for the past observation form of the vector autoregressive model, and $\mathbf{\Psi}_i^p$ are the coefficient matrices for the future observation form. More information on the Yule-Walker equations in the multivariate setting can be found in Whittle (1963) and Ansley and Newbold (1979).

The innovation variance matrices for the two forms can be written as follows:

$$\mathbf{\Sigma}_p = \mathbf{\Gamma}_0 - \sum_{i=1}^{p} \mathbf{\Phi}_i^p \mathbf{\Gamma}'_i$$

$$\mathbf{\Omega}_p = \mathbf{\Gamma}_0 - \sum_{i=1}^{p} \mathbf{\Psi}_i^p \mathbf{\Gamma}_i$$

The autoregressive models are fit to the data using the preceding Yule-Walker equations with $\mathbf{\Gamma}_i$ replaced by the sample covariance sequence $\mathbf{C_i}$. The covariance matrices are calculated as

$$\mathbf{C}_i = \frac{1}{N-1} \sum_{t=i+1}^{N} \mathbf{x}_t \mathbf{x}'_{t-i}$$

Let $\widehat{\mathbf{\Phi}}_p$, $\widehat{\mathbf{\Psi}}_p$, $\widehat{\mathbf{\Sigma}}_p$, and $\widehat{\mathbf{\Omega}}_p$ represent the Yule-Walker estimates of $\mathbf{\Phi}_p$, $\mathbf{\Psi}_p$, $\mathbf{\Sigma}_p$, and $\mathbf{\Omega}_p$ respectively. These matrices are written to an output data set when the OUTAR= option is specified.

When the PRINTOUT=LONG option is specified, the sequence of matrices $\widehat{\mathbf{\Sigma}}_p$ and the corresponding correlation matrices are printed. The sequence of matrices $\widehat{\mathbf{\Sigma}}_p$ is used to compute Akaike information criteria for selection of the autoregressive order of the process.

Akaike Information Criterion

The Akaike information criterion, or AIC, is defined as -2(*maximum of log likelihood*)+2(*number of parameters*). Since the vector autoregressive models are estimates from the Yule-Walker equations, not by maximum likelihood, the exact likelihood values are not available for computing the AIC. However, for the vector autoregressive model the maximum of the log likelihood can be approximated as

$$\ln(L) \approx -\frac{n}{2}\ln(|\widehat{\mathbf{\Sigma}}_p|)$$

Thus, the AIC for the order *p* model is computed as

$$AIC_p = n\ln(|\widehat{\mathbf{\Sigma}}_p|) + 2pr^2$$

You can use the printed AIC array to compute a likelihood ratio test of the autoregressive order. The log-likelihood ratio test statistic for testing the order *p* model against the order $p-1$ model is

$$-n\ln(|\widehat{\mathbf{\Sigma}}_p|) + n\ln(|\widehat{\mathbf{\Sigma}}_{p-1}|)$$

This quantity is asymptotically distributed as a χ^2 with r^2 degrees of freedom if the series is autoregressive of order $p-1$. It can be computed from the AIC array as

$$AIC_{p-1} - AIC_p + 2r^2$$

You can evaluate the significance of these test statistics with the PROBCHI function in a SAS DATA step, or with a χ^2 table.

Determining the Autoregressive Order

Although the autoregressive models can be used for prediction, their primary value is to aid in the selection of a suitable portion of the sample covariance matrix for use in computing canonical correlations. If the multivariate time series $\mathbf{x}_t$ is of autoregressive order *p*, then the vector of past values to lag *p* is considered to contain essentially all the information relevant for prediction of future values of the time series.

By default, PROC STATESPACE selects the order, *p*, producing the autoregressive model with the smallest AIC_p. If the value *p* for the minimum AIC_p is less than the value of the PASTMIN= option, then *p* is set to the PASTMIN= value. Alternatively, you can use the ARMAX= and PASTMIN= options to force PROC STATESPACE to use an order you select.

Significance Limits for Partial Autocorrelations

The STATESPACE procedure prints a schematic representation of the partial autocorrelation matrices indicating which partial autocorrelations are significantly greater or significantly less than 0. Figure 25.10 shows an example of this table.

```

```

Figure 25.10. Significant Partial Autocorrelations

The partial autocorrelations are from the sample partial autoregressive matrices $\hat{\mathbf{\Phi}}^p_p$. The standard errors used for the significance limits of the partial autocorrelations are computed from the sequence of matrices $\mathbf{\Sigma}_p$ and $\mathbf{\Omega}_p$.

Under the assumption that the observed series arises from an autoregressive process of order $p - 1$, the *p*th sample partial autoregressive matrix $\hat{\mathbf{\Phi}}^p_p$ has an asymptotic variance matrix $\frac{1}{n}\mathbf{\Omega}_p^{-1}\otimes\mathbf{\Sigma}_p$.

The significance limits for $\hat{\mathbf{\Phi}}^p_p$ used in the schematic plot of the sample partial autoregressive sequence are derived by replacing $\mathbf{\Omega}_p$ and $\mathbf{\Sigma}_p$ with their sample estimators to produce the variance estimate, as follows:

$$\widehat{Var}\left(\hat{\mathbf{\Phi}}^p_p\right) = \left(\frac{1}{n - rp}\right)\hat{\mathbf{\Omega}}_p^{-1}\otimes\hat{\mathbf{\Sigma}}_p$$

Canonical Correlation Analysis

Given the order *p*, let $\mathbf{p}_t$ be the vector of current and past values relevant to prediction of $\mathbf{x}_{t+1}$:

$$\mathbf{p}_t = (\mathbf{x}'_t, \mathbf{x}'_{t-1}, \cdots, \mathbf{x}'_{t-p})'$$

Let $\mathbf{f}_t$ be the vector of current and future values:

$$\mathbf{f}_t = (\mathbf{x}'_t, \mathbf{x}'_{t+1}, \cdots, \mathbf{x}'_{t+p})'$$

In the canonical correlation analysis, consider submatrices of the sample covariance matrix of $\mathbf{p}_t$ and $\mathbf{f}_t$. This covariance matrix, $\mathbf{V}$, has a block Hankel form:

$$\mathbf{V} = \begin{bmatrix} \mathbf{C}_0 & \mathbf{C}'_1 & \mathbf{C}'_2 & \cdots & \mathbf{C}'_p \\ \mathbf{C}'_1 & \mathbf{C}'_2 & \mathbf{C}'_3 & \cdots & \mathbf{C}'_{p+1} \\ \vdots & \vdots & \vdots & & \vdots \\ \mathbf{C}'_p & \mathbf{C}'_{p+1} & \mathbf{C}'_{p+2} & \cdots & \mathbf{C}'_{2p} \end{bmatrix}$$

State Vector Selection Process

The canonical correlation analysis forms a sequence of potential state vectors, $\mathbf{z}_t^j$. Examine a sequence, $\mathbf{f}_t^j$, of subvectors of $\mathbf{f}_t$, and form the submatrix, $\mathbf{V}^j$, consisting of the rows and columns of $\mathbf{V}$ corresponding to the components of $\mathbf{f}_t^j$, and compute its canonical correlations.

The smallest canonical correlation of $\mathbf{V}^j$ is then used in the selection of the components of the state vector. The selection process is described in the following. For more details about this process, refer to Akaike (1976).

In the following discussion, the notation $\mathbf{x}_{t+k|t}$ denotes the wide sense conditional expectation (best linear predictor) of $\mathbf{x}_{t+k}$, given all $\mathbf{x}_s$ with *s* less than or equal to *t*. In the notation $x_{i,t+1}$, the first subscript denotes the *i*th component of $\mathbf{x}_{t+1}$.

The initial state vector $\mathbf{z}_t^1$ is set to $\mathbf{x}_t$. The sequence $\mathbf{f}_t^j$ is initialized by setting

$$\mathbf{f}_t^1 = (\mathbf{z}_t^{1'}, x_{1,t+1|t})' = (\mathbf{x}'_t, x_{1,t+1|t})'$$

That is, start by considering whether to add $x_{1,t+1|t}$ to the initial state vector $\mathbf{z}_t^1$.

The procedure forms the submatrix $\mathbf{V}^1$ corresponding to $\mathbf{f}_t^1$ and computes its canonical correlations. Denote the smallest canonical correlation of $\mathbf{V}^1$ as ρ_{min}. If ρ_{min} is significantly greater than 0, $x_{1,t+1|t}$ is added to the state vector.

If the smallest canonical correlation of $\mathbf{V}^1$ is not significantly greater than 0, then a linear combination of $\mathbf{f}_t^1$ is uncorrelated with the past, $\mathbf{p}_t$. Assuming that the determinant of $\mathbf{C}_0$ is not 0, (that is, no input series is a constant), you can take the coefficient of $x_{1,t+1|t}$ in this linear combination to be 1. Denote the coefficients of $\mathbf{z}_t^1$ in this linear combination as ℓ. This gives the relationship:

$$x_{1,t+1|t} = \ell' \mathbf{x}_t$$

Therefore, the current state vector already contains all the past information useful for predicting $x_{1,t+1}$ and any greater leads of $x_{1,t}$. The variable $x_{1,t+1|t}$ is not added to the state vector, nor are any terms $x_{1,t+k|t}$ considered as possible components of the state vector. The variable x_1 is no longer active for state vector selection.

The process described for $x_{1,t+1|t}$ is repeated for the remaining elements of $\mathbf{f}_t$. The next candidate for inclusion in the state vector is the next component of $\mathbf{f}_t$ corresponding to an active variable. Components of $\mathbf{f}_t$ corresponding to inactive variables that produced a zero ρ_{min} in a previous step are skipped.

Denote the next candidate as $x_{l,t+k|t}$. The vector $\mathbf{f}_t^j$ is formed from the current state vector and $x_{l,t+k|t}$ as follows:

$$\mathbf{f}_t^j = (\mathbf{z}_t^{j'}, x_{l,t+k|t})'$$

The matrix $\mathbf{V}^j$ is formed from $\mathbf{f}_t^j$ and its canonical correlations are computed. The smallest canonical correlation of $\mathbf{V}^j$ is judged to be either greater than or equal to 0. If it is judged to be greater than 0, $x_{l,t+k|t}$ is added to the state vector. If it is judged to be 0, then a linear combination of $\mathbf{f}_t^j$ is uncorrelated with the $\mathbf{p}_t$, and the variable x_l is now inactive.

The state vector selection process continues until no active variables remain.

Testing Significance of Canonical Correlations

For each step in the canonical correlation sequence, the significance of the smallest canonical correlation, ρ_{min}, is judged by an information criterion from Akaike (1976). This information criterion is

$$-n\ln(1-\rho_{min}^2) - \lambda(r(p+1)-q+1)$$

where *q* is the dimension of $\mathbf{f}_t^j$ at the current step, *r* is the order of the state vector, *p* is the order of the vector autoregressive process, and λ is the value of the SIGCORR= option. The default is SIGCORR=2. If this information criterion is less than or equal to 0, ρ_{min} is taken to be 0; otherwise, it is taken to be significantly greater than 0. (Do not confuse this information criterion with the AIC.)

Variables in $\mathbf{x}_{t+p|t}$ are not added in the model, even with positive information criterion, because of the singularity of $\mathbf{V}$. You can force the consideration of more candidate state variables by increasing the size of the $\mathbf{V}$ matrix by specifying a PASTMIN= option value larger than *p*.

Printing the Canonical Correlations

To print the details of the canonical correlation analysis process, specify the CANCORR option in the PROC STATESPACE statement. The CANCORR option prints the candidate state vectors, the canonical correlations, and the information criteria for testing the significance of the smallest canonical correlation.

Bartlett's χ^2 and its degrees of freedom are also printed when the CANCORR option is specified. The formula used for Bartlett's χ^2 is

$$\chi^2 = -(n - .5(r(p+1) - q + 1))\ln(1 - \rho^2_{min})$$

with $r(p+1) - q + 1$ degrees of freedom.

Figure 25.11 shows the output of the CANCORR option for the introductory example shown in the "Getting Started" section of this chapter.

Figure 25.11. Canonical Correlations Analysis

New variables are added to the state vector if the information criteria are positive. In this example, $\mathbf{y}_{t+1|t}$ and $\mathbf{x}_{t+2|t}$ are not added to the state space vector because the information criteria for these models are negative.

If the information criterion is nearly 0, then you may want to investigate models that arise if the opposite decision is made regarding ρ_{min}. This investigation can be accomplished by using a FORM statement to specify part or all of the state vector.

Preliminary Estimates of $\mathbf{F}$

When a candidate variable $x_{l,t+k|t}$ yields a zero ρ_{min} and is not added to the state vector, a linear combination of $\mathbf{f}^j_t$ is uncorrelated with the $\mathbf{p}_t$. Because of the method used to construct the $\mathbf{f}^j_t$ sequence, the coefficient of $x_{l,t+k|t}$ in $\mathbf{l}$ can be taken as 1. Denote the coefficients of $\mathbf{z}^j_t$ in this linear combination as $\mathbf{l}$.

This gives the relationship:

$$x_{l,t+k|t} = \mathbf{l}'\mathbf{z}_t^j$$

The vector $\mathbf{l}$ is used as a preliminary estimate of the first *r* columns of the row of the transition matrix $\mathbf{F}$ corresponding to $x_{l,t+k-1|t}$.

Parameter Estimation

The model is $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$, where $\mathbf{e}_t$ is a sequence of independent multivariate normal innovations with mean vector **0** and variance $\Sigma_{\mathbf{ee}}$. The observed sequence, $\mathbf{x}_t$, composes the first *r* components of $\mathbf{z}_t$ and, thus, $\mathbf{x}_t = \mathbf{H}\mathbf{z}_t$, where $\mathbf{H}$ is the $r \times s$ matrix $[\mathbf{I}_r\ \mathbf{0}]$.

Let $\mathbf{E}$ be the $r \times n$ matrix of innovations:

$$\mathbf{E} = [\,\mathbf{e}_1 \quad \cdots \quad \mathbf{e}_n\,]$$

If the number of observations, *n*, is reasonably large, the log likelihood, L, can be approximated up to an additive constant as follows:

$$L = -\frac{n}{2}\ln(|\boldsymbol{\Sigma}_{\mathbf{ee}}|) - \frac{1}{2}trace(\boldsymbol{\Sigma}_{\mathbf{ee}}^{-1}\mathbf{E}\mathbf{E}')$$

The elements of $\boldsymbol{\Sigma}_{\mathbf{ee}}$ are taken as free parameters and are estimated as follows:

$$\mathbf{S}_0 = \frac{1}{n}\mathbf{E}\mathbf{E}'$$

Replacing $\boldsymbol{\Sigma}_{\mathbf{ee}}$ by $\mathbf{S}_0$ in the likelihood equation, the log likelihood, up to an additive constant, is

$$\mathbf{L} = -\frac{n}{2}\ln(|\mathbf{S}_0|)$$

Letting B be the backshift operator, the formal relation between $\mathbf{x}_t$ and $\mathbf{e}_t$ is

$$\mathbf{x}_t = \mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G}\mathbf{e}_t$$

$$\mathbf{e}_t = (\mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G})^{-1}\mathbf{x}_t = \sum_{i=0}^{\infty} \boldsymbol{\Xi}_i \mathbf{x}_{t-i}$$

Letting $\mathbf{C}_i$ be the *i*th lagged sample covariance of $\mathbf{x}_t$, and neglecting end effects, the matrix $\mathbf{S}_0$ is

$$\mathbf{S}_0 = \sum_{i,j=0}^{\infty} \mathbf{\Xi}_i \mathbf{C}_{-i+j} \mathbf{\Xi}_j^{'}$$

For the computation of $\mathbf{S}_0$, the infinite sum is truncated at the value of the KLAG= option. The value of the KLAG= option should be large enough that the sequence $\mathbf{\Xi}_i$ is approximately 0 beyond that point.

Let θ be the vector of free parameters in the $\mathbf{F}$ and $\mathbf{G}$ matrices. The derivative of the log likelihood with respect to the parameter θ is

$$\frac{\partial L}{\partial \theta} = -\frac{n}{2} \,\mathrm{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta} \right)$$

The second derivative is

$$\frac{\partial^2 \mathbf{L}}{\partial \theta \partial \theta'} = \frac{n}{2} \left(\mathrm{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta'} \mathbf{S}_0^{-1} \frac{\partial \mathbf{S}_0}{\partial \theta} \right) - \mathrm{trace} \left(\mathbf{S}_0^{-1} \frac{\partial^2 \mathbf{S}_0}{\partial \theta \partial \theta'} \right) \right)$$

Near the maximum, the first term is unimportant and the second term can be approximated to give the following second derivative approximation:

$$\frac{\partial^2 L}{\partial \theta \partial \theta'} \cong -n \,\mathrm{trace} \left(\mathbf{S}_0^{-1} \frac{\partial \mathbf{E}}{\partial \theta} \frac{\partial \mathbf{E}'}{\partial \theta'} \right)$$

The first derivative matrix and this second derivative matrix approximation are computed from the sample covariance matrix $\mathbf{C}_0$ and the truncated sequence $\mathbf{\Xi}_i$. The approximate likelihood function is maximized by a modified Newton-Raphson algorithm employing these derivative matrices.

The matrix $\mathbf{S}_0$ is used as the estimate of the innovation covariance matrix, $\mathbf{\Sigma_{ee}}$. The negative of the inverse of the second derivative matrix at the maximum is used as an approximate covariance matrix for the parameter estimates. The standard errors of the parameter estimates printed in the parameter estimates tables are taken from the diagonal of this covariance matrix. The parameter covariance matrix is printed when the COVB option is specified.

If the data are nearly nonstationary, a better estimate of $\mathbf{\Sigma_{ee}}$ and the other parameters can sometimes be obtained by specifying the RESIDEST option. The RESIDEST option estimates the parameters using conditional least squares instead of maximum likelihood.

The residuals are computed using the state space equation and the sample mean values of the variables in the model as start-up values. The estimate of $\mathbf{S}_0$ is then computed using the residuals from the *i*th observation on, where *i* is the maximum number of times any variable occurs in the state vector. A multivariate Gauss-Marquardt algorithm is used to minimize $|\mathbf{S}_0|$. Refer to Harvey (1981a) for a further description of this method.

Forecasting

Given estimates of $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma_{ee}}$, forecasts of $\mathbf{x}_t$ are computed from the conditional expectation of $\mathbf{z}_t$.

In forecasting, the parameters $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma_{ee}}$ are replaced with the estimates or by values specified in the RESTRICT statement. One-step-ahead forecasting is performed for the observation $\mathbf{x}_t$, where $t \leq n - b$. Here n is the number of observations and *b* is the value of the BACK= option. For the observation $\mathbf{x}_t$, where $t > n - b$, *m*-step-ahead forecasting is performed for $m = t - n + b$. The forecasts are generated recursively with the initial condition $\mathbf{z}_0 = 0$.

The *m*-step-ahead forecast of $\mathbf{z}_{t+m}$ is $\mathbf{z}_{t+m|t}$, where $\mathbf{z}_{t+m|t}$ denotes the conditional expectation of $\mathbf{z}_{t+m}$ given the information available at time *t*. The *m*-step-ahead forecast of $\mathbf{x}_{t+m}$ is $\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$, where the matrix $\mathbf{H} = [\mathbf{I}_r \mathbf{0}]$.

Let $\Psi_i = \mathbf{F}^i\mathbf{G}$. Note that the last $s - r$ elements of $\mathbf{z}_t$ consist of the elements of $\mathbf{x}_{u|t}$ for $u > t$.

The state vector $\mathbf{z}_{t+m}$ can be represented as

$$\mathbf{z}_{t+m} = \mathbf{F}^m\mathbf{z}_t + \sum_{i=0}^{m-1} \mathbf{\Psi}_i\mathbf{e}_{t+m-i}$$

Since $\mathbf{e}_{t+i|t} = \mathbf{0}$ for $i > 0$, the *m*-step-ahead forecast $\mathbf{z}_{t+m|t}$ is

$$\mathbf{z}_{t+m|t} = \mathbf{F}^m\mathbf{z}_t = \mathbf{F}\mathbf{z}_{t+m-1|t}$$

Therefore, the *m*-step-ahead forecast of $\mathbf{x}_{t+m}$ is

$$\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$$

The *m*-step-ahead forecast error is

$$\mathbf{z}_{t+m} - \mathbf{z}_{t+m|t} = \sum_{i=0}^{m-1} \mathbf{\Psi}_i\mathbf{e}_{t+m-i}$$

The variance of the *m*-step-ahead forecast error is

$$\mathbf{V}_{z,m} = \sum_{i=0}^{m-1} \boldsymbol{\Psi}_i \boldsymbol{\Sigma}_{\mathbf{ee}} \Psi_i'$$

Letting $\mathbf{V}_{z,0} = \mathbf{0}$, the variance of the *m*-step-ahead forecast error of $\mathbf{z}_{t+m}$, $\mathbf{V}_{z,m}$, can be computed recursively as follows:

$$\mathbf{V}_{z,m} = \mathbf{V}_{z,m-1} + \boldsymbol{\Psi}_{m-1} \boldsymbol{\Sigma}_{\mathbf{ee}} \boldsymbol{\Psi}_{m-1}^{'}$$

The variance of the *m*-step-ahead forecast error of $\mathbf{x}_{t+m}$ is the $r \times r$ left upper submatrix of $\mathbf{V}_{z,m}$; that is,

$$\mathbf{V}_{x,m} = \mathbf{H}\mathbf{V}_{z,m}\mathbf{H}'$$

Unless the NOCENTER option is specified, the sample mean vector is added to the forecast. When differencing is specified, the forecasts $\mathbf{x}_{t+m|t}$ plus the sample mean vector are integrated back to produce forecasts for the original series.

Let $\mathbf{y}_t$ be the original series specified by the VAR statement, with some 0 values appended corresponding to the unobserved past observations. Let B be the backshift operator, and let $\boldsymbol{\Delta}(B)$ be the $s \times s$ matrix polynomial in the backshift operator corresponding to the differencing specified by the VAR statement. The off-diagonal elements of $\boldsymbol{\Delta}_i$ are 0. Note that $\boldsymbol{\Delta}_0 = \mathbf{I}_s$, where $\mathbf{I}_s$ is the $s \times s$ identity matrix. Then $\mathbf{z}_t = \boldsymbol{\Delta}(B)\mathbf{y}_t$.

This gives the relationship

$$\mathbf{y}_t = \boldsymbol{\Delta}^{-1}(B)\mathbf{z}_t = \sum_{i=0}^{\infty} \boldsymbol{\Lambda}_i \mathbf{z}_{t-i}$$

where $\boldsymbol{\Delta}^{-1}(B) = \sum_{i=0}^{\infty} \boldsymbol{\Lambda}_i B^i$ and $\boldsymbol{\Lambda}_0 = \mathbf{I}_s$.

The *m*-step-ahead forecast of $\mathbf{y}_{t+m}$ is

$$\mathbf{y}_{t+m|t} = \sum_{i=0}^{m-1} \boldsymbol{\Lambda}_i \mathbf{z}_{t+m-i|t} + \sum_{i=m}^{\infty} \boldsymbol{\Lambda}_i \mathbf{z}_{t+m-i}$$

The *m*-step-ahead forecast error of $\mathbf{y}_{t+m}$ is

$$\sum_{i=0}^{m-1} \boldsymbol{\Lambda}_i \left(\mathbf{z}_{t+m-i} - \mathbf{z}_{t+m-i|t}\right) = \sum_{i=0}^{m-1} \left(\sum_{u=0}^{i} \boldsymbol{\Lambda}_u \boldsymbol{\Psi}_{i-u}\right) \mathbf{e}_{t+m-i}$$

Letting $\mathbf{V}_{y,0} = \mathbf{0}$, the variance of the *m*-step-ahead forecast error of $\mathbf{y}_{t+m}$, $\mathbf{V}_{y,m}$, is

$$\begin{aligned}\mathbf{V}_{y,m} &= \sum_{i=0}^{m-1}\left(\sum_{u=0}^{i}\mathbf{\Lambda}_u\mathbf{\Psi}_{i-u}\right)\mathbf{\Sigma}_{\mathbf{ee}}\left(\sum_{u=0}^{i}\mathbf{\Lambda}_u\mathbf{\Psi}_{i-u}\right)' \\ &= \mathbf{V}_{y,m-1} + \left(\sum_{u=0}^{m-1}\mathbf{\Lambda}_u\mathbf{\Psi}_{m-1-u}\right)\mathbf{\Sigma}_{\mathbf{ee}}\left(\sum_{u=0}^{m-1}\mathbf{\Lambda}_u\mathbf{\Psi}_{m-1-u}\right)'\end{aligned}$$

Relation of ARMA and State Space Forms

Every state space model has an ARMA representation, and conversely every ARMA model has a state space representation. This section discusses this equivalence. The following material is adapted from Akaike (1974), where there is a more complete discussion. Pham-Dinh-Tuan (1978) also contains a discussion of this material.

Suppose you are given the following ARMA model:

$$\mathbf{\Phi}(B)\mathbf{x}_t = \mathbf{\Theta}(B)\mathbf{e}_t$$

or, in more detail

$$\mathbf{x}_t - \mathbf{\Phi}_1\mathbf{x}_{t-1} - \cdots - \mathbf{\Phi}_p\mathbf{x}_{t-p} = \mathbf{e}_t + \mathbf{\Theta}_1\mathbf{e}_{t-1} + \cdots + \mathbf{\Theta}_q\mathbf{e}_{t-q} \qquad (1)$$

where $\mathbf{e}_t$ is a sequence of independent multivariate normal random vectors with mean $\mathbf{0}$ and variance matrix $\mathbf{\Sigma}_{\mathbf{ee}}$; B is the backshift operator ($B\mathbf{x}_t = \mathbf{x}_{t-1}$); $\mathbf{\Phi}(B)$ and $\mathbf{\Theta}(B)$ are matrix polynomials in B; and $\mathbf{x}_t$ is the observed process.

If the roots of the determinantial equation $|\mathbf{\Phi}(B)| = 0$ are outside the unit circle in the complex plane, the model can also be written as

$$\mathbf{x}_t = \mathbf{\Phi}^{-1}(B)\mathbf{\Theta}(B)\mathbf{e}_t = \sum_{i=0}^{\infty}\mathbf{\Psi}_i\mathbf{e}_{t-i}$$

The $\mathbf{\Psi}_i$ matrices are known as the impulse response matrices and can be computed as $\mathbf{\Phi}^{-1}(B)\mathbf{\Theta}(B)$.

You can assume $p > q$ since, if this is not initially true, you can add more terms $\mathbf{\Phi}_i$ that are identically 0 without changing the model.

To write this set of equations in a state space form, proceed as follows. Let $\mathbf{x}_{t+i|t}$ be the conditional expectation of $\mathbf{x}_{t+i}$ given $\mathbf{x}_w$ for $w \leq t$. The following relations hold:

$$\mathbf{x}_{t+i|t} = \sum_{j=i}^{\infty}\mathbf{\Psi}_j\mathbf{e}_{t+i-j}$$

$$\mathbf{x}_{t+i|t+1} = \mathbf{x}_{t+i|t} + \mathbf{\Psi}_{i-1}\mathbf{e}_{t+1}$$

However, from equation (1) you can derive the following relationship:

$$\mathbf{x}_{t+p|t} = \mathbf{\Phi}_1\mathbf{x}_{t+p-1|t} + \cdots + \mathbf{\Phi}_p\mathbf{x}_t \qquad (2)$$

Hence, when $i = p$, you can substitute for $\mathbf{x}_{t+p|t}$ in the right-hand side of equation (2) and close the system of equations.

This substitution results in the following model in the state space form $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$:

$$\begin{bmatrix} \mathbf{x}_{t+1} \\ \mathbf{x}_{t+2|t+1} \\ \vdots \\ \mathbf{x}_{t+p|t+1} \end{bmatrix} = \begin{bmatrix} 0 & \mathbf{I} & 0 & \cdots & 0 \\ 0 & 0 & \mathbf{I} & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ \mathbf{\Phi}_p & \mathbf{\Phi}_{p-1} & & \cdots & \mathbf{\Phi}_1 \end{bmatrix} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+p-1|t} \end{bmatrix} + \begin{bmatrix} \mathbf{I} \\ \mathbf{\Psi}_1 \\ \vdots \\ \mathbf{\Psi}_{p-1} \end{bmatrix} \mathbf{e}_{t+1}$$

Note that the state vector $\mathbf{z}_t$ is composed of conditional expectations of $\mathbf{x}_t$ and the first *r* components of $\mathbf{z}_t$ are equal to $\mathbf{x}_t$.

The state space form can be cast into an ARMA form by solving the system of difference equations for the first *r* components.

When converting from an ARMA form to a state space form, you can generate a state vector larger than needed; that is, the state space model may not be a minimal representation. When going from a state space form to an ARMA form, you can have nontrivial common factors in the autoregressive and moving average operators that yield an ARMA model larger than necessary.

If the state space form used is not a minimal representation, some but not all components of $\mathbf{x}_{t+i|t}$ may be linearly dependent. This situation corresponds to $[\mathbf{\Phi}_p\mathbf{\Theta}_{p-1}]$ being of less than full rank when $\mathbf{\Phi}(B)$ and $\mathbf{\Theta}(B)$ have no common nontrivial left factors. In this case, $\mathbf{z}_t$ consists of a subset of the possible components of $[\mathbf{x}_{t+i|t}] \quad i = 1, 2, \cdots, p-1$. However, once a component of $\mathbf{x}_{t+i|t}$ (for example, the *j*th one) is linearly dependent on the previous conditional expectations, then all subsequent *j*th components of $\mathbf{x}_{t+k|t}$ for $k > i$ must also be linearly dependent. Note that in this case, equivalent but seemingly different structures can arise if the order of the components within $\mathbf{x}_t$ is changed.

OUT= Data Set

The forecasts are contained in the output data set specified by the OUT= option on the PROC STATESPACE statement. The OUT= data set contains the following variables:

- the BY variables
- the ID variable

- the VAR statement variables. These variables contain the actual values from the input data set.
- FOR*i*, numeric variables containing the forecasts. The variable FOR*i* contains the forecasts for the *i*th variable in the VAR statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option.
- RES*i*, numeric variables containing the residual for the forecast of the *i*th variable in the VAR statement list. For forecast observations, the actual values are missing and the RES*i* variables contain missing values.
- STD*i*, numeric variables containing the standard deviation for the forecast of the *i*th variable in the VAR statement list. The values of the STD*i* variables can be used to construct univariate confidence limits for the corresponding forecasts. However, such confidence limits do not take into account the covariance of the forecasts.

OUTAR= Data Set

The OUTAR= data set contains the estimates of the preliminary autoregressive models. The OUTAR= data set contains the following variables:

- ORDER, a numeric variable containing the order p of the autoregressive model that the observation represents
- AIC, a numeric variable containing the value of the information criterion AIC_p
- SIGF*l*, numeric variables containing the estimate of the innovation covariance matrices for the forward autoregressive models. The variable SIGF*l* contains the *l*th column of $\hat{\mathbf{\Sigma}}_p$ in the observations with ORDER=*p*.
- SIGB*l*, numeric variables containing the estimate of the innovation covariance matrices for the backward autoregressive models. The variable SIGB*l* contains the *l*th column of $\hat{\mathbf{\Omega}}_p$ in the observations with ORDER=*p*.
- FOR*k_l*, numeric variables containing the estimates of the autoregressive parameter matrices for the forward models. The variable FOR*k_l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\hat{\mathbf{\Phi}}^p_k$ in the observations with ORDER=*p*.
- BAC*k_l*, numeric variables containing the estimates of the autoregressive parameter matrices for the backward models. The variable BAC*k_l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\hat{\mathbf{\Psi}}^p_k$ in the observations with ORDER=*p*.

The estimates for the order p autoregressive model can be selected as those observations with ORDER=*p*. Within these observations, the *k*,*l*th element of $\mathbf{\Phi}^p_i$ is given by the value of the FOR*i_l* variable in the *k*th observation. The *k*,*l*th element of $\mathbf{\Psi}^p_i$ is given by the value of BAC*i_l* variable in the *k*th observation. The *k*,*l*th element of $\mathbf{\Sigma}_p$ is given by SIGF*l* in the *k*th observation. The *k*,*l*th element of $\mathbf{\Omega}_p$ is given by SIGB*l* in the *k*th observation.

Table 25.1 shows an example of the OUTAR= data set, with ARMAX=3 and $\mathbf{x}_t$ of dimension 2. In Table 25.1, (i, j) indicate the *i*,*j*th element of the matrix.

The estimated autoregressive parameters can be used in the IML procedure to obtain autoregressive estimates of the spectral density function or forecasts based on the autoregressive models.

OUTMODEL= Data Set

The OUTMODEL= data set contains the estimates of the $\mathbf{F}$ and $\mathbf{G}$ matrices and their standard errors, the names of the components of the state vector, and the estimates of the innovation covariance matrix. The variables contained in the OUTMODEL= data set are as follows:

- the BY variables
- STATEVEC, a character variable containing the name of the component of the state vector corresponding to the observation. The STATEVEC variable has the value STD for standard deviations observations, which contain the standard errors for the estimates given in the preceding observation.
- F_*j*, numeric variables containing the columns of the $\mathbf{F}$ matrix. The variable F_*j* contains the *j*th column of $\mathbf{F}$. The number of F_*j* variables is equal to the value of the DIMMAX= option. If the model is of smaller dimension, the extraneous variables are set to missing.
- G_*j*, numeric variables containing the columns of the $\mathbf{G}$ matrix. The variable G_*j* contains the *j*th column of $\mathbf{G}$. The number of G_*j* variables is equal to *r*, the dimension of $\mathbf{x}_t$ given by the number of variables in the VAR statement.
- SIG_*j*, numeric variables containing the columns of the innovation covariance matrix. The variable SIG_*j* contains the *j*th column of $\mathbf{\Sigma}_{ee}$. There are *r* variables SIG_*j*.

Table 25.2 shows an example of the OUTMODEL= data set, with $\mathbf{x}_t = (x_t, y_t)'$, $\mathbf{z}_t = (x_t, y_t, x_{t+1|t})'$, and DIMMAX=4. In Table 25.2, $\mathbf{F}_{i,j}$ and $\mathbf{G}_{i,j}$ are the *i*,*j*th elements of $\mathbf{F}$ and $\mathbf{G}$ respectively. Note that all elements for F_4 are missing because $\mathbf{F}$ is a 3×3 matrix.

Table 25.2. Value in the OUTMODEL= Data Set

Printed Output

The printed output produced by the STATESPACE procedure is described in the following:

1. descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (Std), and the differencing operations used.
2. the Akaike information criteria for the sequence of preliminary autoregressive models
3. if the PRINTOUT=LONG option is specified, the sample autocovariance matrices of the input series at various lags.
4. if the PRINTOUT=LONG option is specified, the sample autocorrelation matrices of the input series.
5. a schematic representation of the autocorrelation matrices, showing the significant autocorrelations.
6. if the PRINTOUT=LONG option is specified, the partial autoregressive matrices. (These are $\mathbf{\Phi}_p^p$ as described in "Preliminary Autoregressive Models" earlier in this chapter.)
7. a schematic representation of the partial autocorrelation matrices, showing the significant partial autocorrelations.
8. the Yule-Walker estimates of the autoregressive parameters for the autoregressive model with the minimum AIC.
9. if the PRINTOUT=LONG option is specified, the autocovariance matrices of the residuals of the minimum AIC model. This is the sequence of estimated innovation variance matrices for the solutions of the Yule-Walker equations.
10. if the PRINTOUT=LONG option is specified, the autocorrelation matrices of the residuals of the minimum AIC model.
11. If the CANCORR option is specified, the canonical correlations analysis for each potential state vector considered in the state vector selection process. This includes the potential state vector, the canonical correlations, the information criterion for the smallest canonical correlation, Bartlett's χ^2 statistic ("Chi Square") for the smallest canonical correlation, and the degrees of freedom of Bartlett's χ^2.
12. the components of the chosen state vector.
13. the preliminary estimate of the transition matrix, $\mathbf{F}$, the input matrix, $\mathbf{G}$, and the variance matrix for the innovations, $\mathbf{\Sigma_{ee}}$.

14. if the ITPRINT option is specified, the iteration history of the likelihood maximization. For each iteration, this shows the iteration number, the number of step halvings, the determinant of the innovation variance matrix, the damping factor Lambda, and the values of the parameters.
15. the state vector, printed again to aid interpretation of the following listing of $\mathbf{F}$ and $\mathbf{G}$.
16. the final estimate of the transition matrix, $\mathbf{F}$.
17. the final estimate of the input matrix, $\mathbf{G}$.
18. the final estimate of the variance matrix for the innovations, $\mathbf{\Sigma_{ee}}$.
19. a table listing the estimates of the free parameters in $\mathbf{F}$ and $\mathbf{G}$ and their standard errors and *t* statistics.
20. if the COVB option is specified, the covariance matrix of the parameter estimates.
21. if the COVB option is specified, the correlation matrix of the parameter estimates.
22. if the PRINT option is specified, the forecasts and their standard errors.

ODS Table Names

PROC STATESPACE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 25.3. ODS Tables Produced in PROC STATESPACE

ODS Table Name	Description	Option
NObs	Number of observations	default
Summary	Simple summary statistics table	default
InfoCriterion	Information criterion table	default
CovLags	Covariance Matrices of Input Series	PRINTOUT=LONG
CorrLags	Correlation Matrices of Input Series	PRINTOUT=LONG
PartialAR	Partial Autoregressive Matrices	PRINTOUT=LONG
YWEstimates	Yule-Walker Estimates for Minimum AIC	default
CovResiduals	Covariance of Residuals	PRINTOUT=LONG
CorrResiduals	Residual Correlations from AR Models	PRINTOUT=LONG
StateVector	State vector table	default
CorrGraph	Schematic Representation of Correlations	default
TransitionMatrix	Transition Matrix	default
InputMatrix	Input Matrix	default
VarInnov	Variance Matrix for the Innovation	default
CovB	Covariance of Parameter Estimates	COVB
CorrB	Correlation of Parameter Estimates	COVB
CanCorr	Canonical Correlation Analysis	CANCORR

Examples

Example 25.1. Series J from Box and Jenkins

This example analyzes the gas furnace data (series J) from Box and Jenkins. (The data are not shown. Refer to Box and Jenkins (1976) for the data.)

First, a model is selected and fit automatically using the following statements.

```
title1 'Gas Furnace Data';
title2 'Box & Jenkins Series J';
title3 'Automatically Selected Model';

proc statespace data=seriesj cancorr;
   var x y;
run;
```

The results for the automatically selected model are shown in Output 25.1.1.

Output 25.1.1. Results for Automatically Selected Model

```

The two series are believed to have a transfer function relation with the gas rate (variable X) as the input and the CO_2 concentration (variable Y) as the output. Since the parameter estimates shown in Output 25.1.1 support this kind of model, the model is reestimated with the feedback parameters restricted to 0. The following statements fit the transfer function (no feedback) model.

```
title3 'Transfer Function Model';
proc statespace data=seriesj printout=none;
   var x y;
   restrict f(3,2)=0 f(3,4)=0
            g(3,2)=0 g(4,1)=0 g(5,1)=0;
run;
```

The last two pages of the output are shown in Output 25.1.2.

The SYSLIN Procedure

Chapter Contents

Chapter 26
The SYSLIN Procedure

Overview

The SYSLIN procedure estimates parameters in an interdependent system of linear regression equations.

Ordinary least squares (OLS) estimates are biased and inconsistent when current period endogenous variables appear as regressors in other equations in the system. The errors of a set of related regression equations are often correlated, and the efficiency of the estimates can be improved by taking these correlations into account. The SYSLIN procedure provides several techniques which produce consistent and asymptotically efficient estimates for systems of regression equations.

The SYSLIN procedure provides the following estimation methods:

- ordinary least squares (OLS)
- two-stage least squares (2SLS)
- limited information maximum likelihood (LIML)
- K-class
- seemingly unrelated regressions (SUR)
- iterated seemingly unrelated regressions (ITSUR)
- three-stage least squares (3SLS)
- iterated three-stage least squares (IT3SLS)
- full information maximum likelihood (FIML)
- minimum expected loss (MELO)

Other features of the SYSLIN procedure enable you to:

- impose linear restrictions on the parameter estimates.
- test linear hypotheses about the parameters.
- write predicted and residual values to an output SAS data set.
- write parameter estimates to an output SAS data set.
- write the crossproducts matrix (SSCP) to an output SAS data set.
- use raw data, correlations, covariances, or cross products as input.

Experimental graphics are now available with the SYSLIN procedure. For more information, see the "ODS Graphics" section on page 1514.

Getting Started

This section introduces the use of the SYSLIN procedure. The problem of dependent regressors is introduced using a supply-demand example. This section explains the terminology used for variables in a system of regression equations and introduces the SYSLIN procedure statements for declaring the roles the variables play. The syntax used for the different estimation methods and the output produced is shown.

An Example Model

In simultaneous systems of equations, endogenous variables are determined jointly rather than sequentially. Consider the following demand and supply functions for some product:

$$Q_D = a_1 + b_1 P + c_1 Y + d_1 S + \epsilon_1 \qquad \text{(demand)}$$

$$Q_S = a_2 + b_2 P + c_2 U + \epsilon_2 \qquad \text{(supply)}$$

$$Q = Q_D = Q_S \qquad \text{(market equilibrium)}$$

The variables in this system are as follows:

Q$_D$	quantity demanded
Q$_S$	quantity supplied
Q	the observed quantity sold, which equates quantity supplied and quantity demanded in equilibrium
P	price per unit
Y	income
S	price of substitutes
U	unit cost
ϵ_1	the random error term for the demand equation
ϵ_2	the random error term for the supply equation

In this system, quantity demanded depends on price, income, and the price of substitutes. Consumers normally purchase more of a product when prices are lower and when income and the price of substitute goods are higher. Quantity supplied depends on price and the unit cost of production. Producers will supply more when price is high and when unit cost is low. The actual price and quantity sold are determined jointly by the values that equate demand and supply.

Since price and quantity are jointly endogenous variables, both structural equations are necessary to adequately describe the observed values. A critical assumption of OLS is that the regressors are uncorrelated with the residual. When current endogenous variables appear as regressors in other equations (endogenous variables depend on each other), this assumption is violated and the OLS parameter estimates are biased and inconsistent. The bias caused by the violated assumptions is called *Simultaneous equation bias*. Neither the demand nor supply equation can be estimated consistently by OLS.

Variables in a System of Equations

Before explaining how to use the SYSLIN procedure, it is useful to define some terms. The variables in a system of equations can be classified as follows:

- *Endogenous variables*, which are also called *jointly dependent* or *response variables*, are the variables determined by the system. Endogenous variables can also appear on the right-hand side of equations.
- *Exogenous variables* are independent variables that do not depend on any of the endogenous variables in the system.
- *Predetermined variables* include both the exogenous variables and *lagged endogenous variables*, which are past values of endogenous variables determined at previous time periods. PROC SYSLIN does not compute lagged values; any lagged endogenous variables must be computed in a preceding DATA step.
- *Instrumental variables* are predetermined variables used in obtaining predicted values for the current period endogenous variables by a first-stage regression. The use of instrumental variables characterizes estimation methods such as two-stage least squares and three-stage least squares. Instrumental variables estimation methods substitute these first-stage predicted values for endogenous variables when they appear as regressors in model equations.

Using PROC SYSLIN

First specify the input data set and estimation method on the PROC SYSLIN statement. If any model uses dependent regressors, and you are using an instrumental variables regression method, declare the dependent regressors with an ENDOGENOUS statement and declare the instruments with an INSTRUMENTS statement. Next, use MODEL statements to specify the structural equations of the system.

The use of different estimation methods is shown by the following examples. These examples use the simulated dataset WORK.IN given below.

```
data in;
  label q = \quotes{Quantity}
        p = \quotes{Price}
        s = \quotes{Price of Substitutes}
        y = \quotes{Income}
        u = \quotes{Unit Cost};
  drop i e1 e2;
  p = 0; q = 0;
  do i = 1 to 60;
     y = 1 + .05*i  + .15*rannor(123);
     u = 2          + .05*rannor(123) + .05*rannor(123);
```

```
          s = 4 - .001*(i-10)*(i-110) + .5*rannor(123);
          e1 = .15 * rannor(123);
          e2 = .15 * rannor(123);
          demandx = 1 + .3 * y + .35 * s + e1;
          supplyx = -1 - 1 * u + e2 - .4*e1;
          q = 1.4/2.15 * demandx + .75/2.15 * supplyx;
          p = ( - q + supplyx ) / -1.4;
          output;
       end;
    run;
```

OLS Estimation

PROC SYSLIN performs OLS regression if you do not specify a method of estimation in the PROC SYSLIN statement. OLS does not use instruments, so the ENDOGENOUS and INSTRUMENTS statements can be omitted.

The following statements estimate the supply and demand model shown previously:

```
proc syslin data=in;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The PROC SYSLIN output for the demand equation is shown in Figure 26.1, and the output for the supply equation is shown in Figure 26.2.

Figure 26.2. OLS Results for Supply Equation

For each MODEL statement, the output first shows the model label and dependent variable name and label. This is followed by an Analysis of Variance table for the model, which shows the model, error, and total mean squares, and an *F* test for the no-regression hypothesis. Next, the procedure prints the root mean square error, dependent variable mean and coefficient of variation, and the R^2 and adjusted R^2 statistics.

Finally, the table of parameter estimates shows the estimated regression coefficients, standard errors, and *t*-tests. You would expect the price coefficient in a demand equation to be negative. However, note that the OLS estimate of the price coefficient P in the demand equation (.1233) has a positive sign. This could be caused by simultaneous equation bias.

Two-Stage Least Squares Estimation

In the supply and demand model, P is an endogenous variable, and consequently the OLS estimates are biased. The following example estimates this model using two-stage least squares.

```
proc syslin data=in 2sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The 2SLS option on the PROC SYSLIN statement specifies the two-stage least-squares method. The ENDOGENOUS statement specifies that P is an endogenous regressor for which first-stage predicted values are substituted. You only need to declare an endogenous variable in the ENDOGENOUS statement if it is used as a regressor; thus although Q is endogenous in this model, it is not necessary to list it in the ENDOGENOUS statement.

Usually, all predetermined variables that appear in the system are used as instruments. The INSTRUMENTS statement specifies that the exogenous variables Y, U, and S are used as instruments for the first-stage regression to predict P.

The 2SLS results are shown in Figure 26.3 and Figure 26.4. The first-stage regressions are not shown. To see the first-stage regression results, use the FIRST option on the MODEL statement.

```

Figure 26.4. 2SLS Results for Supply Equation

The 2SLS output is similar in form to the OLS output. However, the 2SLS results are based on predicted values for the endogenous regressors from the first stage instrumental regressions. This makes the analysis of variance table and the R^2 statistics difficult to interpret. See the sections "ANOVA Table for Instrumental Variables Methods" and "The R^2 Statistics" later in this chapter for details.

Note that, unlike the OLS results, the 2SLS estimate for the P coefficient in the demand equation (-1.115) is negative.

LIML, K-Class, and MELO Estimation

To obtain limited information maximum likelihood, general K-class, or minimum expected loss estimates, use the ENDOGENOUS, INSTRUMENTS, and MODEL statements as in the 2SLS case but specify the LIML, K=, or MELO option instead of 2SLS in the PROC SYSLIN statement. The following statements show this for K-class estimation.

```
proc syslin data=in k=.5;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

For more information on these estimation methods see the “Estimation Methods” in the “Details” section and consult econometrics textbooks.

SUR, 3SLS, and FIML Estimation

In a multivariate regression model, the errors in different equations may be correlated. In this case the efficiency of the estimation may be improved by taking these cross-equation correlations into account.

Seemingly Unrelated Regression

Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems. Like OLS, the SUR method assumes that all the regressors are independent variables, but SUR uses the correlations among the errors in different equations to improve the regression estimates. The SUR method requires an initial OLS regression to compute residuals. The OLS residuals are used to estimate the cross-equation covariance matrix.

The SUR option on the PROC SYSLIN statement specifies seemingly unrelated regression, as shown in the following statements:

```
proc syslin data=in sur;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

INSTRUMENTS and ENDOGENOUS statements are not needed for SUR, since the SUR method assumes there are no endogenous regressors. For SUR to be effective, the models must use different regressors. SUR produces the same results as OLS unless the model contains at least one regressor not used in the other equations.

Three-Stage Least Squares

The three-stage least-squares method generalizes the two-stage least-squares method to take account of the correlations between equations in the same way that SUR generalizes OLS. Three-stage least squares requires three steps: first-stage regressions to get predicted values for the endogenous regressors; a two-stage least-squares step to get residuals to estimate the cross-equation correlation matrix; and the final 3SLS estimation step.

The 3SLS option on the PROC SYSLIN statement specifies the three-stage least-squares method, as shown in the following statements.

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The 3SLS output begins with a two-stage least-squares regression to estimate the cross-model correlation matrix. This output is the same as the 2SLS results shown in Figure 26.3 and Figure 26.4, and is not repeated here. The next part of the 3SLS output prints the cross-model correlation matrix computed from the 2SLS residuals. This output is shown in Figure 26.5 and includes the cross-model covariances, correlations, the inverse of the correlation matrix, and the inverse covariance matrix.

Figure 26.6. Three-Stage Least Squares Results

This output first prints the system weighted mean square error and system weighted R^2 statistics. The system weighted MSE and system weighted R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances. See the section "The R^2 Statistics" for details.

Next, the table of 3SLS parameter estimates for each model is printed. This output has the same form as for the other estimation methods.

Note that the 3SLS and 2SLS results may be the same in some cases. This results from the same principle that causes OLS and SUR results to be identical unless an equation includes a regressor not used in the other equations of the system. However, the application of this principle is more complex when instrumental variables are used. When all the exogenous variables are used as instruments, linear combinations of all the exogenous variables appear in the third-stage regressions through substitution of first-stage predicted values.

In this example, 3SLS produces different (and, it is hoped, more efficient) estimates for the demand equation. However, the 3SLS and 2SLS results for the supply equation are the same. This is because the supply equation has one endogenous regressor and one exogenous regressor not used in other equations. In contrast, the demand equation has fewer endogenous regressors than exogenous regressors not used in other equations in the system.

Full Information Maximum Likelihood

The FIML option on the PROC SYSLIN statement specifies the full information maximum likelihood method, as shown in the following statements.

```
proc syslin data=in fiml;
   endogenous  p q;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The FIML results are shown in Figure 26.7.

Computing Reduced-Form Estimates

A system of structural equations with endogenous regressors can be represented as functions only of the predetermined variables. For this to be possible, there must be as many equations as endogenous variables. If there are more endogenous variables than regression models, you can use IDENTITY statements to complete the system. See "Reduced-Form Estimates" in the "Computational Details" section later in this chapter for details.

The REDUCED option on the PROC SYSLIN statement prints reduced form estimates. The following statements show this using the 3SLS estimates of the structural parameters.

```
proc syslin data=in 3sls reduced;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The first four pages of this output were as shown previously and are not repeated here. (See Figure 26.3, Figure 26.4, Figure 26.5, and Figure 26.6.) The final page of the output from this example contains the reduced-form coefficients from the 3SLS structural estimates, as shown in Figure 26.8.

Restricting Parameter Estimates

You can impose restrictions on the parameter estimates with RESTRICT and SRESTRICT statements. The RESTRICT statement imposes linear restrictions on parameters in the equation specified by the preceding MODEL statement. The SRESTRICT statement imposes linear restrictions that relate parameters in different models.

To impose restrictions involving parameters in different equations, use the SRESTRICT statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

Tests for the significance of the restrictions are printed when RESTRICT or SRESTRICT statements are used. You can label RESTRICT and SRESTRICT statements to identify the restrictions in the output.

The RESTRICT statement in the following example restricts the price coefficient in the demand equation to equal .015. The SRESTRICT statement restricts the estimate of the income coefficient in the demand equation to be .01 times the estimate of the unit cost coefficient in the supply equation.

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   peq015: restrict p = .015;
   supply: model q = p u;
   yeq01u: srestrict demand.y = .01 * supply.u;
run;
```

The restricted estimation results are shown in Figure 26.9.

```

Figure 26.9. Restricted Estimates

The standard error for P in the demand equation is 0, since the value of the P coefficient was specified by the RESTRICT statement and not estimated from the data. The Parameter Estimates table for the demand equation contains an additional row for the restriction specified by the RESTRICT statement. The “parameter estimate” for the restriction is the value of the Lagrange multiplier used to impose the restriction.

The restriction is highly “significant” ($t = 6.777$), which means that the data are not consistent with the restriction, and the model does not fit as well with the restriction imposed. See the section “RESTRICT Statement” for more information.

After the Parameter Estimates table for the supply equation, the results for the cross model restrictions are printed. This shows that the restriction specified by the SRESTRICT statement is not consistent with the data ($t = 8.98$). See the section “SRESTRICT Statement” for more information.

Testing Parameters

You can test linear hypotheses about the model parameters with TEST and STEST statements. The TEST statement tests hypotheses about parameters in the equation specified by the preceding MODEL statement. The STEST statement tests hypotheses that relate parameters in different models.

For example, the following statements test the hypothesis that the price coefficient in the demand equation is equal to .015.

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   test_1: test p = .015;
   supply: model q = p u;
run;
```

The TEST statement results are shown in Figure 26.10. This reports an *F*-test for the hypothesis specified by the TEST statement. In this case the *F* statistic is 6.79 (3.879/.571) with 1 and 113 degrees of freedom. The *p*-value for this *F* statistic is .0104, which indicates that the hypothesis tested is almost but not quite rejected at the .01 level. See the section “TEST Statement” for more information.

                           1         113       6.79    0.0104
```

Figure 26.10. TEST Statement Results

To test hypotheses involving parameters in different equations, use the STEST statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

For example, the following statements test the hypothesis that the income coefficient in the demand equation is .01 times the unit cost coefficient in the supply equation:

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
   stest1: stest demand.y = .01 * supply.u;
run;
```

The STEST statement results are shown in Figure 26.11. The form and interpretation of the STEST statement results is like the TEST statement results. In this case, the *F*-test produces a *p*-value less than .0001, and strongly rejects the hypothesis tested. See the section “STEST Statement” for more information.

```

Figure 26.11. STEST Statement Results

You can combine TEST and STEST statements with RESTRICT and SRESTRICT statements to perform hypothesis tests for restricted models. Of course, the validity of the TEST and STEST statement results will depend on the correctness of any restrictions you impose on the estimates.

Saving Residuals and Predicted Values

You can store predicted values and residuals from the estimated models in a SAS data set. Specify the OUT= option on the PROC SYSLIN statement and use the OUTPUT statement to specify names for new variables to contain the predicted and residual values.

For example, the following statements store the predicted quantity from the supply and demand equations in a data set PRED:

```
proc syslin data=in out=pred 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   output predicted=q_demand;
   supply: model q = p u;
   output predicted=q_supply;
run;
```

Plotting Residuals

You can plot the residuals against the regressors by specifying the PLOT option on the MODEL statement. For example, the following statements plot the 2SLS residuals for the demand model against price, income, price of substitutes, and the intercept.

```
proc syslin data=in 2sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s / plot;
run;
```

The plot for price is shown in Figure 26.12. The other plots are not shown.

         |                   1           1                                     |
         |                                  1                                  |
    -0.4 +                                                                     +
         |                                                                     |
         |                                                                     |
         |                                                                     |
    -0.6 +                                                                     +
         |                                                                     |
         |                                                                     |
         --+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+--

Syntax

The SYSLIN procedure uses the following statements:

PROC SYSLIN *options* **;**
BY *variables* **;**
ENDOGENOUS *variables* **;**
IDENTITY *identities* **;**
INSTRUMENTS *variables* **;**
MODEL *response = regressors / options* **;**
OUTPUT PREDICTED= *variable* **RESIDUAL=** *variable* **;**
RESTRICT *restrictions* **;**
SRESTRICT *restrictions* **;**
STEST *equations* **;**
TEST *equations* **;**
VAR *variables* **;**
WEIGHT *variable* **;**

Functional Summary

The SYSLIN procedure statements and options are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	PROC SYSLIN	DATA=
specify the output data set	PROC SYSLIN	OUT=
write parameter estimates to an output data set	PROC SYSLIN	OUTEST=
write covariances to the OUTEST= data set	PROC SYSLIN	OUTCOV
		OUTCOV3
write the SSCP matrix to an output data set	PROC SYSLIN	OUTSSCP=
Estimation Method Options		
specify full information maximum likelihood estimation	PROC SYSLIN	FIML
specify iterative SUR estimation	PROC SYSLIN	ITSUR
specify iterative 3SLS estimation	PROC SYSLIN	IT3SLS
specify K-class estimation	PROC SYSLIN	K=
specify limited information maximum likelihood estimation	PROC SYSLIN	LIML
specify minimum expected loss estimation	PROC SYSLIN	MELO
specify ordinary least squares estimation	PROC SYSLIN	OLS
specify seemingly unrelated estimation	PROC SYSLIN	SUR

Description	Statement	Option
specify two-stage least-squares estimation	PROC SYSLIN	2SLS
specify three-stage least-squares estimation	PROC SYSLIN	3SLS
specify Fuller's modification to LIML	PROC SYSLIN	ALPHA=
specify convergence criterion	PROC SYSLIN	CONVERGE=
specify maximum number of iterations	PROC SYSLIN	MAXIT=
use diagonal of **S** instead of **S**	PROC SYSLIN	SDIAG
exclude RESTRICT statements in final stage	PROC SYSLIN	NOINCLUDE
specify criterion for testing for singularity	PROC SYSLIN	SINGULAR=
specify denominator for variance estimates	PROC SYSLIN	VARDEF=
Printing Control Options		
print first-stage regression statistics	PROC SYSLIN	FIRST
print estimates and SSE at each iteration	PROC SYSLIN	ITPRINT
print the restricted reduced-form estimates	PROC SYSLIN	REDUCED
print descriptive statistics	PROC SYSLIN	SIMPLE
print uncorrected SSCP matrix	PROC SYSLIN	USSCP
print correlations of the parameter estimates	MODEL	CORRB
print covariances of the parameter estimates	MODEL	COVB
print Durbin-Watson statistics	MODEL	DW
print Basmann's test	MODEL	OVERID
plot residual values against regressors	MODEL	PLOT
print standardized parameter estimates	MODEL	STB
print unrestricted parameter estimates	MODEL	UNREST
print the model crossproducts matrix	MODEL	XPX
print the inverse of the crossproducts matrix	MODEL	I
suppress printed output	MODEL	NOPRINT
suppress all printed output	PROC SYSLIN	NOPRINT
Model Specification		
specify structural equations	MODEL	
suppress the intercept parameter	MODEL	NOINT
specify linear relationship among variables	IDENTITY	
perform weighted regression	WEIGHT	
Tests and Restrictions on Parameters		
place restrictions on parameter estimates	RESTRICT	
place restrictions on parameter estimates	SRESTRICT	
test linear hypothesis	STEST	
test linear hypothesis	TEST	
Other Statements		

Description	**Statement**	**Option**
specify BY-group processing	BY	
specify the endogenous variables	ENDOGENOUS	
specify instrumental variables	INSTRUMENTS	
write predicted and residual values to a data set	OUTPUT	
name variable for predicted values	OUTPUT	PREDICTED=
name variable for residual values	OUTPUT	RESIDUAL=
include additional variables in $X'X$ matrix	VAR	

PROC SYSLIN Statement

PROC SYSLIN *options;*

The following options can be used with the PROC SYSLIN statement.

Data Set Options

DATA= *SAS-data-set*
specifies the input data set. If the DATA= option is omitted, the most recently created SAS data set is used. In addition to ordinary SAS data sets, PROC SYSLIN can analyze data sets of TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, and TYPE=SSCP. See “Special TYPE= Input Data Set” in the “Input Data Set” section later in this chapter for more information.

OUT= *SAS-data-set*
specifies an output SAS data set for residuals and predicted values. The OUT= option is used in conjunction with the OUTPUT statement. See the section “OUT= Data Set” later in this chapter for more details.

OUTEST= *SAS-data-set*
writes the parameter estimates to an output data set. See the section “OUTEST= Data Set” later in this chapter for details.

OUTCOV
COVOUT
writes the covariance matrix of the parameter estimates to the OUTEST= data set in addition to the parameter estimates.

OUTCOV3
COV3OUT
writes covariance matrices for each model in a system to the OUTEST= data set when the 3SLS, SUR, or FIML option is used.

OUTSSCP= *SAS-data-set*
writes the sum-of-squares-and-crossproducts matrix to an output data set. See the section “OUTSSCP= Data Set” later in this chapter for details.

Estimation Method Options

2SLS
specifies the two-stage least-squares estimation method.

3SLS
specifies the three-stage least-squares estimation method.

FIML
specifies the full information maximum likelihood estimation method.

ITSUR
specifies the iterative seemingly unrelated estimation method.

IT3SLS
specifies the iterative three-stage least-squares estimation method.

K= *value*
specifies the K-class estimation method.

LIML
specifies the limited information maximum likelihood estimation method.

MELO
specifies the minimum expected loss estimation method.

OLS
specifies the ordinary least squares estimation method. This is the default.

SUR
specifies the seemingly unrelated estimation method.

Printing and Control Options

ALL
specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options for every MODEL statement.

ALPHA= *value*
specifies Fuller’s modification to the LIML estimation method. See “Fuller’s Modification to LIML *K* Value” later in this chapter for details.

CONVERGE= *value*
specifies the convergence criterion for the iterative estimation methods IT3SLS, ITSUR, and FIML. The default is CONVERGE=.0001.

FIRST
prints first-stage regression statistics for the endogenous variables regressed on the instruments. This output includes sums of squares, estimates, variances, and standard deviations.

ITPRINT

prints parameter estimates, system-weighted residual sum of squares, and R^2 at each iteration for the IT3SLS and ITSUR estimation methods. For the FIML method, the ITPRINT option prints parameter estimates, negative of log likelihood function, and norm of gradient vector at each iteration.

MAXITER= *n*

specifies the maximum number of iterations allowed for the IT3SLS, ITSUR, and FIML estimation methods. The MAXITER= option can be abbreviated as MAXIT=. The default is MAXITER=30.

NOINCLUDE

excludes the RESTRICT statements from the final stage for the 3SLS, IT3SLS, SUR, ITSUR estimation methods.

NOPRINT

suppresses all printed output. Specifying NOPRINT in the PROC SYSLIN statement is equivalent to specifying NOPRINT in every MODEL statement.

REDUCED

prints the reduced-form estimates. If the REDUCED option is specified, you should specify any IDENTITY statements needed to make the system square. See “Reduced-Form Estimates” in the section “Computational Details” later in this chapter for more information.

SDIAG

uses the diagonal of **S** instead of **S** to do the estimation, where **S** is the covariance matrix of equation errors. See “Uncorrelated Errors Across Equations” in the section “Computational Details” later in this chapter for more information.

SIMPLE

prints descriptive statistics for the dependent variables. The statistics printed include the sum, mean, uncorrected sum of squares, variance, and standard deviation.

SINGULAR= *value*

specifies a criterion for testing singularity of the crossproducts matrix. This is a tuning parameter used to make PROC SYSLIN more or less sensitive to singularities. The value must be between 0 and 1. The default is SINGULAR=1E-8.

USSCP

prints the uncorrected sum-of-squares-and-crossproducts matrix.

USSCP2

prints the uncorrected sum-of-squares-and-crossproducts matrix for all variables used in the analysis, including predicted values of variables generated by the procedure.

VARDEF= DF | N | WEIGHT | WGT

specifies the denominator to use in calculating cross-equation error covariances and parameter standard errors and covariances. The default is VARDEF=DF, which corrects for model degrees of freedom. VARDEF=N specifies no degrees-of-freedom correction. VARDEF=WEIGHT specifies the sum of the observation weights. VARDEF=WGT specifies the sum of the observation weights minus the model degrees of freedom. See "Computation of Standard Errors" in the section "Computational Details" later in this chapter for more information.

BY Statement

BY *variables ;*

A BY statement can be used with PROC SYSLIN to obtain separate analyses on observations in groups defined by the BY variables.

ENDOGENOUS Statement

ENDOGENOUS *variables ;*

The ENDOGENOUS statement declares the jointly dependent variables that are projected in the first-stage regression through the instrument variables. The ENDOGENOUS statement is not needed for the SUR, ITSUR, or OLS estimation methods. The default ENDOGENOUS list consists of all the dependent variables in the MODEL and IDENTITY statements that do not appear in the INSTRUMENTS statement.

IDENTITY Statement

IDENTITY *equation ;*

The IDENTITY statement specifies linear relationships among variables to write to the OUTEST= data set. It provides extra information in the OUTEST= data set but does not create or compute variables. The OUTEST= data set can be processed by the SIMLIN procedure in a later step.

The IDENTITY statement is also used to compute reduced-form coefficients when the REDUCED option in the PROC SYSLIN statement is specified. See "Reduced-Form Estimates" in the section "Computational Details" later in this chapter for more information.

The *equation* given by the IDENTITY statement has the same form as equations in the MODEL statement. A label can be specified for an IDENTITY statement as follows:

label: **IDENTITY** . . . **;**

INSTRUMENTS Statement

INSTRUMENTS *variables ;*

The INSTRUMENTS statement declares the variables used in obtaining first-stage predicted values. All the instruments specified are used in each first-stage regression. The INSTRUMENTS statement is required for the 2SLS, 3SLS, IT3SLS, LIML, MELO, and K-class estimation methods. The INSTRUMENTS statement is not needed for the SUR, ITSUR, OLS, or FIML estimation methods.

MODEL Statement

MODEL *response = regressors / options ;*

The MODEL statement regresses the response variable on the left side of the equal sign against the regressors listed on the right side.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. Model labels are also used in SRESTRICT and STEST statements to refer to parameters in different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label: **MODEL** . . . **;**

The following options can be used in the MODEL statement after a slash (/).

ALL
specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options.

ALPHA= *value*
specifies the α parameter for Fuller's modification to the LIML estimation method. See "Fuller's Modification to LIML" in the section "Computational Details" later in this chapter for more information.

CORRB
prints the matrix of estimated correlations between the parameter estimates.

COVB
prints the matrix of estimated covariances between the parameter estimates.

DW
prints Durbin-Watson statistics and autocorrelation coefficients for the residuals. If there are missing values, d' is calculated according to Savin and White (1978). Use the DW option only if the data set to be analyzed is an ordinary SAS data set with time series observations sorted in time order. The Durbin-Watson test is not valid for models with lagged dependent regressors.

I
prints the inverse of the crossproducts matrix for the model, $(\mathbf{X}'\mathbf{X})^{-1}$. If restrictions are specified, the crossproducts matrix printed is adjusted for the restrictions. See the section "Computational Details" for more information.

K= *value*
specifies K-class estimation.

NOINT
suppresses the intercept parameter from the model.

NOPRINT
suppresses the normal printed output.

OVERID
prints Basmann's (1960) test for over identifying restrictions. See "Over Identification Restrictions" in the section "Computational Details" later in this chapter for more information.

PLOT
plots residual values against regressors. A plot of the residuals for each regressor is printed.

STB
prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a standardized parameter estimate is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the response variable.

UNREST
prints parameter estimates computed before restrictions are applied. The UNREST option is valid only if a RESTRICT statement is specified.

XPX
prints the model crossproducts matrix, $X'X$. See the section "Computational Details" for more information.

OUTPUT Statement

OUTPUT PREDICTED=*variable* **RESIDUAL=***variable* **;**

The OUTPUT statement writes predicted values and residuals from the preceding model to the data set specified by the OUT= option on the PROC SYSLIN statement. An OUTPUT statement must come after the MODEL statement to which it applies. The OUT= option must be specified in the PROC SYSLIN statement.

The following options can be specified in the OUTPUT statement:

PREDICTED= *variable*
names a new variable to contain the predicted values for the response variable. The PREDICTED= option can be abbreviated as PREDICT=, PRED=, or P=.

RESIDUAL= *variable*
names a new variable to contain the residual values for the response variable. The RESIDUAL= option can be abbreviated as RESID= or R=.

For example, the following statements create an output data set named B. In addition to the variables in the input data set, the data set B contains the variable YHAT, with values that are predicted values of the response variable Y, and YRESID, with values that are the residual values of Y.

```
proc syslin data=a out=b;
   model y = x1 x2;
   output p=yhat r=yresid;
run;
```

For example, the following statements create an output data set named PRED. In addition to the variables in the input data set, the data set PRED contains the variables Q_DEMAND and Q_SUPPLY, with values that are predicted values of the response variable Q for the demand and supply equations respectively, and R_DEMAND and R_SUPPLY, with values that are the residual values of the demand and supply equations.

```
proc syslin data=in out=pred;
   demand: model q = p y s;
   output p=q_demand r=r_demand;
   supply: model q = p u;
   output p=q_supply r=r_supply;
run;
```

See the section “OUT= Data Set” later in this chapter for more details.

RESTRICT Statement

RESTRICT *equation , ... , equation ;*

The RESTRICT statement places restrictions on the parameter estimates for the preceding MODEL statement. Any number of restrict statements can follow a MODEL statement. Each restriction is written as a linear equation. If more than one restriction is specified in a single RESTRICT statement, the restrictions are separated by commas.

Parameters are referred to by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. The keyword INTERCEPT is used to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label **: RESTRICT** . . . **;**

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1.

```
proc syslin data=a;
   model y = x1 x2;
   restrict x1 + x2 = 1;
run;
```

Variable names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Raynor 1971). The estimates of these Lagrangian parameters are printed in the parameter estimates table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter, λ, measures the sensitivity of the SSE to the restriction. If the restriction is changed by a small amount ϵ, the SSE is changed by $2\lambda\epsilon$.

The *t*-ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted.

Any number of restrictions can be specified on a RESTRICT statement, and any number of RESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

Note: The RESTRICT statement is not supported for the FIML estimation method.

SRESTRICT Statement

SRESTRICT *equation , ... , equation ;*

The SRESTRICT statement imposes linear restrictions involving parameters in two or more MODEL statements. The SRESTRICT statement is like the RESTRICT statement but is used to impose restrictions across equations, whereas the RESTRICT statement only applies to parameters in the immediately preceding MODEL statement.

Each restriction is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

SRESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label **: SRESTRICT** . . . **;**

The following is an example of the use of the SRESTRICT statement, in which the coefficient for the regressor X2 is constrained to be the same in both models.

```
proc syslin data=a 3sls;
   endogenous y1 y2;
   instruments x1 x2;
   model y1 = y2 x1 x2;
   model y2 = y1 x2;
   srestrict y1.x2 = y2.x2;
run;
```

When no equal sign is used, the linear combination is set equal to 0. Thus the restriction in the preceding example can also be specified as

```
   srestrict y1.x2 - y2.x2;
```

Any number of restrictions can be specified on an SRESTRICT statement, and any number of SRESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

When a system restriction is requested for a single equation estimation method (such as OLS or 2SLS), PROC SYSLIN produces the restricted estimates by actually using a corresponding system method. For example, when SRESTRICT is specified along with OLS, PROC SYSLIN produces the restricted OLS estimates via a two-step process equivalent to using SUR estimation with the SDIAG option. First of all, the unrestricted OLS results are produced. Then the GLS (SUR) estimation with the system restriction is performed using the diagonal of the covariance matrix of the residuals. When SRESTRICT is specified along with 2SLS, PROC SYSLIN produces the restricted 2SLS estimates via a multistep process equivalent to using 3SLS estimation with the SDIAG option. First of all, the unrestricted 2SLS results are produced. Then the GLS (3SLS) estimation with the system restriction is performed using the diagonal of the covariance matrix of the residuals.

The results of the SRESTRICT statements are printed after the parameter estimates for all the models in the system. The format of the SRESTRICT statement output is the same as the parameter estimates table. In this output the "Parameter Estimate" is the Lagrangian parameter, λ, used to impose the restriction.

The Lagrangian parameter, λ, measures the sensitivity of the system sum of square errors to the restriction. The system SSE is the system MSE shown in the printed output multiplied by the degrees of freedom. If the restriction is changed by a small amount ϵ, the system SSE is changed by $2\lambda\epsilon$.

The *t*-ratio tests the significance of the restriction. If λ is zero, the restricted estimates are the same as the unrestricted estimates.

The model degrees of freedom are not adjusted for the cross-model restrictions imposed by SRESTRICT statements.

Note: The SRESTRICT statement is not supported for the LIML and the FIML estimation methods.

STEST Statement

STEST *equation , ... , equation / options ;*

The STEST statement performs an *F*-test for the joint hypotheses specified in the statement.

The hypothesis is represented in matrix notation as

$$\mathbf{L}\beta = \mathbf{c}$$

and the *F*-test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where *b* is the estimate of β, *m* is the number of restrictions, and $\hat{\sigma}^2$ is the system weighted mean square error. See the section "Computational Details" for information on the matrix $\mathbf{X}'\mathbf{X}$.

Each hypothesis to be tested is written as a linear equation. Parameters are referred to as *label.variable*, where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

STEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of STEST statements can be specified. Labels are specified as follows:

label: **STEST** . . . **;**

The following is an example of the STEST statement:

```
proc syslin data=a 3sls;
   endogenous y1 y2;
   instruments x1 x2;
   model y1 = y2 x1 x2;
   model y2 = y1 x2;
   stest y1.x2 = y2.x2;
run;
```

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the *F*-test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the STEST statement are conditional on the restrictions specified. The validity of the tests may be compromised if incorrect restrictions are imposed on the estimates.

The following are examples of STEST statements:

```
stest a.x1 + b.x2 = l;
stest 2 * b.x2 = c.x3 + c.x4 ,
      a.intercept + b.x2 = 0;
stest a.x1 = c.x2 = b.x3 = 1;
stest 2 * a.x1 - b.x2 = 0;
```

The PRINT option can be specified in the STEST statement after a slash (/):

PRINT
prints intermediate calculations for the hypothesis tests.

Note: The STEST statement is not supported for the FIML estimation method.

TEST Statement

TEST *equation , ... , equation / options ;*

The TEST statement performs *F*-tests of linear hypotheses about the parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Variable names must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT is used to refer to the model intercept.

TEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of TEST statements can be specified. Labels are specified as follows:

label: **TEST** . . . **;**

The following is an example of the use of TEST statement, which tests the hypothesis that the coefficients of X1 and X2 are the same:

```
proc syslin data=a;
   model y = x1 x2;
   test x1 = x2;
run;
```

The following statements perform *F*-tests for the hypothesis that the coefficients of X1 and X2 are equal, and that the sum of the X1 and X2 coefficients is twice the intercept, and for the joint hypothesis.

```
proc syslin data=a;
   model y = x1 x2;
   x1eqx2:  test x1 = x2;
   sumeq2i: test x1 + x2 = 2 * intercept;
   joint:   test x1 = x2, x1 + x2 = 2 * intercept;
run;
```

The following are additional examples of TEST statements:

```
test x1 + x2 = 1;
test x1 = x2 = x3 = 1;
test 2 * x1 = x2 + x3, intercept + x4 = 0;
test 2 * x1 - x2;
```

The TEST statement performs an *F*-test for the joint hypotheses specified. The hypothesis is represented in matrix notation as follows:

$$\mathbf{L}\beta = \mathbf{c}$$

The *F* test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where *b* is the estimate of β, *m* is the number of restrictions, and $\hat{\sigma}^2$ is the model mean square error. See the section "Computational Details" for information on the matrix $\mathbf{X}'\mathbf{X}$.

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the *F*-test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the TEST statement are conditional on the restrictions specified. The validity of the tests may be compromised if incorrect restrictions are imposed on the estimates.

The PRINT option can be specified in the TEST statement after a slash (/):

PRINT
prints intermediate calculations for the hypothesis tests.

Note: The TEST statement is not supported for the FIML estimation method.

VAR Statement

VAR *variables ;*

The VAR statement is used to include variables in the crossproducts matrix that are not specified in any MODEL statement. This statement is rarely used with PROC SYSLIN and is used only with the OUTSSCP= option in the PROC SYSLIN statement.

WEIGHT Statement

WEIGHT *variable ;*

The WEIGHT statement is used to perform weighted regression. The WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least-squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE).

Details

Input Data Set

PROC SYSLIN does not compute new values for regressors. For example, if you need a lagged variable, you must create it with a DATA step. No values are computed by IDENTITY statements; all values must be in the input data set.

Special TYPE= Input Data Set

The input data set for most applications of the SYSLIN procedure contains standard rectangular data. However, PROC SYSLIN can also process input data in the form of a crossproducts, covariance, or correlation matrix. Data sets containing such matrices are identified by values of the TYPE= data set option.

These special kinds of input data sets can be used to save computer time. It takes nk^2 operations, where n is the number of observations and k is the number of variables, to calculate cross products; the regressions are of the order k^3. When n is in the thousands and k is much smaller, you can save most of the computer time in later runs of PROC SYSLIN by reusing the SSCP matrix rather than recomputing it.

The SYSLIN procedure can process TYPE= CORR, COV, UCORR, UCOV, or SSCP data sets. TYPE=CORR and TYPE=COV data sets, usually created by the CORR procedure, contain means and standard deviations, and correlations or covariances. TYPE=SSCP data sets, usually created in previous runs of PROC SYSLIN, contain sums of squares and cross products. Refer to *SAS/STAT User's Guide* for more information on special SAS data sets.

When special SAS data sets are read, you must specify the TYPE= data set option. PROC CORR and PROC SYSLIN automatically set the type for output data sets; however, if you create the data set by some other means, you must specify its type with the TYPE= data set option.

When the special data sets are used, the DW (Durbin-Watson test) and PLOT options in the MODEL statement cannot be performed, and the OUTPUT statements are not valid.

Estimation Methods

A brief description of the methods used by the SYSLIN procedure follows. For more information on these methods, see the references at the end of this chapter.

There are two fundamental methods of estimation for simultaneous equations: least squares and maximum likelihood. There are two approaches within each of these categories: single equation methods, also referred to as limited information methods, and system methods, or full information methods. System methods take into account cross-equation correlations of the disturbances in estimating parameters, while single equation methods do not.

OLS, 2SLS, MELO, K-class, SUR, ITSUR, 3SLS, and IT3SLS use the least-squares method; LIML and FIML use the maximum likelihood method.

OLS, 2SLS, MELO, K-class and LIML are single equation methods. The system methods are SUR, ITSUR, 3SLS, IT3SLS, and FIML.

Single Equation Estimation Methods

Single equation methods do not take into account correlations of errors across equations. As a result, these estimators are not asymptotically efficient compared to full information methods, however, there are instances in which they may be preferred. (See "Choosing a Method for Simultaneous Equations" later in this chapter for more information.)

Let $\mathbf{y}_i$ be the dependent endogenous variable in equation i, and X_i and Y_i be the matrices of exogenous and endogenous variables appearing as regressors in the same equation.

The 2SLS method owes its name to the fact that, in a first stage, the instrumental variables are used as regressors to obtain a projected value $\hat{Y}_i$ that is uncorrelated with the residual in equation i. In a second stage, $\hat{Y}_i$ replaces Y_i on the right hand side to obtain consistent least squares estimators.

Normally, the predetermined variables of the system are used as the instruments. It is possible to use variables other than predetermined variables from your system as instruments, however, the estimation may not be as efficient. For consistent estimates, the instruments must be uncorrelated with the residual and correlated with the endogenous variables.

The LIML method results in consistent estimates that are equal to the 2SLS estimates when an equation is exactly identified. LIML can be viewed as a least-variance ratio estimation or as a maximum likelihood estimation. LIML involves minimizing the ratio $\lambda = (rvar\_eq)/(rvar\_sys)$, where $rvar\_eq$ is the residual variance associated with regressing the weighted endogenous variables on all predetermined variables appearing in that equation, and $rvar\_sys$ is the residual variance associated with regressing weighted endogenous variables on all predetermined variables in the system.

The MELO method computes the minimum expected loss estimator. MELO estimators “minimize the posterior expectation of generalized quadratic loss functions for structural coefficients of linear structural models” (Judge et al. 1985, p. 635).

K-class estimators are a class of estimators that depends on a user-specified parameter k. A *K*-value less than 1 is recommended but not required. k may be deterministic or stochastic, but its probability limit must equal 1 for consistent parameter estimates. When all the predetermined variables are listed as instruments, they include all the other single equation estimators supported by PROC SYSLIN. The instance when some of the predetermined variables are not listed among the instruments is not supported by PROC SYSLIN for the general K-class estimation. It is, however, supported for the other methods.

For $k = 1$, the K-class estimator is the 2SLS estimator, while for $k = 0$, the K-class estimator is the OLS estimator. The K-class interpretation of LIML is that $k = \lambda$. Note that *k* is stochastic in the LIML method, unlike for OLS and 2SLS.

MELO is a Bayesian K-class estimator. It yields estimates that can be expressed as a matrix-weighted average of the OLS and 2SLS estimates. MELO estimators have finite second moments and hence finite risk. Other frequently used K-class estimators may not have finite moments under some commonly encountered circumstances and hence there can be infinite risk relative to quadratic and other loss functions.

One way of comparing K-class estimators is to note that when *k*=1, the correlation between regressor and the residual is completely corrected for. In all other cases, it is only partially corrected for.

See “Computational Details” later in this section for more details on K-class estimators.

SUR and 3SLS Estimation Methods

SUR may improve the efficiency of parameter estimates when there is contemporaneous correlation of errors across equations. In practice, the contemporaneous correlation matrix is estimated using OLS residuals. Under two sets of circumstances, SUR parameter estimates are the same as those produced by OLS: when there is no contemporaneous correlation of errors across equations (the estimate of contemporaneous correlation matrix is diagonal,) and when the independent variables are the same across equations.

Theoretically, SUR parameter estimates will always be at least as efficient as OLS in large samples, provided that your equations are correctly specified. However, in small samples the need to estimate the covariance matrix from the OLS residuals increases the sampling variability of the SUR estimates, and this effect can cause SUR to be less efficient than OLS. If the sample size is small and the across-equation correlations are small, then OLS should be preferred to SUR. The consequences of specification error are also more serious with SUR than with OLS.

The 3SLS method combines the ideas of the 2SLS and SUR methods. Like 2SLS, the 3SLS method uses $\hat{Y}$ instead of Y for endogenous regressors, which results in consistent estimates. Like SUR, the 3SLS method takes the cross-equation error correlations into account to improve large sample efficiency. For 3SLS, the 2SLS residuals are used to estimate the cross-equation error covariance matrix.

The SUR and 3SLS methods can be iterated by recomputing the estimate of the cross-equation covariance matrix from the SUR or 3SLS residuals and then computing new SUR or 3SLS estimates based on this updated covariance matrix estimate. Continuing this iteration until convergence produces ITSUR or IT3SLS estimates.

FIML Estimation Method

The FIML estimator is a system generalization of the LIML estimator. The FIML method involves minimizing the determinant of the covariance matrix associated with residuals of the reduced form of the equation system. From a maximum likelihood standpoint, the LIML method involves assuming that the errors are normally distributed and then maximizing the likelihood function subject to restrictions on a particular equation. FIML is similar, except that the likelihood function is maximized subject to restrictions on all of the parameters in the model, not just those in the equation being estimated.

Note: the RESTRICT, SRESTRICT, TEST, and STEST statements are not supported when the FIML method is used.

Choosing a Method for Simultaneous Equations

A number of factors should be taken into account in choosing an estimation method. Although system methods are asymptotically most efficient in the absence of specification error, system methods are more sensitive to specification error than single equation methods.

In practice, models are never perfectly specified. It is a matter of judgment whether the misspecification is serious enough to warrant avoidance of system methods.

Another factor to consider is sample size. With small samples, 2SLS may be preferred to 3SLS. In general, it is difficult to say much about the small sample properties of K-class estimators because this depends on the regressors used.

LIML and FIML are invariant to the normalization rule imposed but are computationally more expensive than 2SLS or 3SLS.

If the reason for contemporaneous correlation among errors across equations is a common omitted variable, it is not necessarily best to apply SUR. SUR parameter estimates are more sensitive to specification error than OLS. OLS may produce better parameter estimates under these circumstances. SUR estimates are also affected by the sampling variation of the error covariance matrix. There is some evidence from Monte Carlo studies that SUR is less efficient than OLS in small samples.

ANOVA Table for Instrumental Variables Methods

In the instrumental variables methods (2SLS, LIML, K-class, MELO), first-stage predicted values are substituted for the endogenous regressors. As a result, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares for the dependent variable (TSS). The "Analysis of Variance" table printed for the second-stage results serves to display these sums of squares and the mean squares used for the *F*-test, but this table is not a variance decomposition in the usual analysis of variance sense.

The *F*-test shown in the instrumental variables case is a valid test of the no-regression hypothesis that the true coefficients of all regressors are 0. However, because of the first-stage projection of the regression mean square, this is a Wald-type test statistic, which is asymptotically *F* but not exactly F-distributed in finite samples. Thus, for small samples the *F*-test is only approximate when instrumental variables are used.

The R^2 Statistics

As explained in the section "ANOVA Table for Instrumental Variables Methods" on page 1505 when instrumental variables are used, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares. In this case, there are several ways that the R^2 statistic can be defined.

The definition of R^2 used by the SYSLIN procedure is

$$\mathrm{R}^2 = \frac{\mathrm{RSS}}{\mathrm{RSS} + \mathrm{ESS}}$$

This definition is consistent with the *F*-test of the null hypothesis that the true coefficients of all regressors are zero. However, this R^2 may not be a good measure of the goodness of fit of the model.

System Weighted R^2 and System Weighted Mean Square Error

The system weighted R^2, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows.

$$\mathrm{R}^2 = \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y}/\mathbf{Y}'\mathbf{W}\mathbf{Y}$$

In this equation the matrix **X'X** is $\mathbf{R}'\mathbf{W}\mathbf{R}$, and **W** is the projection matrix of the instruments:

$$\mathbf{W} = \mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$$

The matrix **Z** is the instrument set, **R** is the the regressor set, and **S** is the estimated cross-model covariance matrix.

The system weighted MSE, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows:

$$MSE = \frac{1}{tdf}(\mathbf{Y'WY} - \mathbf{Y'WR}(\mathbf{X'X})^{-1}\mathbf{R'WY})$$

In this equation *tdf* is the sum of the error degrees of freedom for the equations in the system.

Computational Details

This section discusses various computational details.

Computation of Least Squares-Based Estimators

Let the system be composed of G equations, and the ith equation be expressed in this form:

$$\mathbf{y}_i = Y_i \boldsymbol{\beta}_i + X_i \gamma_i + \mathbf{u}$$

where

$\mathbf{y}_i$	is the vector of observations on the dependent variable
Y_i	is the matrix of observations on the endogenous variables included in the equation
$\boldsymbol{\beta}_i$	is the vector of parameters associated with Y_i
X_i	is the matrix of observations on the predetermined variables included in the equation
γ_i	is the vector of parameters associated with X_i
$\mathbf{u}$	is a vector of errors

Let $\hat{V}_i = Y_i - \hat{Y}_i$, where $\hat{Y}_i$ is the projection of Y_i onto the space spanned by the instruments matrix Z.

Let

$$\boldsymbol{\delta}_i = \left[\begin{array}{c} \boldsymbol{\beta}_i \\ \gamma_i \end{array} \right]$$

be the vector of parameters associated with both the endogenous and exogenous variables.

The K class of estimators (Theil 1971) is defined by

$$\hat{\boldsymbol{\delta}}_{i,k} = \left[\begin{array}{cc} Y_i'Y_i - k\hat{V}_i'\hat{V}_i & Y_i'X_i \\ X_i'Y_i & X_i'X_i \end{array} \right]^{-1} \left[\begin{array}{c} (Y_i - kV_i)'y_i \\ X_i'y_i \end{array} \right]$$

where k is a user-defined value.

Let

$$R = [Y_i \quad X_i]$$

and

$$\hat{R} = [\hat{Y}_i \quad X_i]$$

The 2SLS estimator is defined as

$$\hat{\boldsymbol{\delta}}_{i,2SLS} = [\hat{R}_i' \, \hat{R}_i]^{-1} \hat{R}_i' y_i$$

Let $\mathbf{y}$ and $\boldsymbol{\delta}$ be the vectors obtained by stacking the vectors of dependent variables and parameters for all G equations, and let R and $\hat{R}$ be the block diagonal matrices formed by R_i and $\hat{R}_i$, respectively.

The SUR and ITSUR estimators are defined as

$$\hat{\boldsymbol{\delta}}_{(IT)SUR} = \left[R' \left(\hat{\Sigma}^{-1} \otimes I\right) R\right]^{-1} R' \left(\hat{\Sigma}^{-1} \otimes I\right) \mathbf{y}$$

while the 3SLS and IT3SLS estimators are defined as

$$\hat{\boldsymbol{\delta}}_{(IT)3SLS} = \left[\hat{R}' \left(\hat{\Sigma}^{-1} \otimes I\right) \hat{R}\right]^{-1} \hat{R}' \left(\hat{\Sigma}^{-1} \otimes I\right) \mathbf{y}$$

where I is the identity matrix, and $\hat{\Sigma}$ is an estimator of the cross-equation correlation matrix. For 3SLS, $\hat{\Sigma}$ is obtained from the 2SLS estimation, while for SUR it is derived from the OLS estimation. For IT3SLS and ITSUR, it is obtained iteratively from the previous estimation step, until convergence.

Computation of Standard Errors

The VARDEF= option in the PROC SYSLIN statement controls the denominator used in calculating the cross-equation covariance estimates and the parameter standard errors and covariances. The values of the VARDEF= option and the resulting denominator are as follows:

N	uses the number of nonmissing observations.
DF	uses the number of nonmissing observations less the degrees of freedom in the model.
WEIGHT	uses the sum of the observation weights given by the WEIGHTS statement.
WDF	uses the sum of the observation weights given by the WEIGHTS statement less the degrees of freedom in the model.

The VARDEF= option does not affect the model mean square error, root mean square error, or R^2 statistics. These statistics are always based on the error degrees of freedom, regardless of the VARDEF= option. The VARDEF= option also does not affect the dependent variable coefficient of variation (C.V.).

Reduced-Form Estimates

The REDUCED option on the PROC SYSLIN statement computes estimates of the reduced-form coefficients. The REDUCED option requires that the equation system be square. If there are fewer models than endogenous variables, IDENTITY statements can be used to complete the equation system.

The reduced-form coefficients are computed as follows. Represent the equation system, with all endogenous variables moved to the left-hand side of the equations and identities, as

$$\mathbf{BY} = \mathbf{\Gamma X}$$

Here **B** is the estimated coefficient matrix for the endogenous variables **Y**, and **Γ** is the estimated coefficient matrix for the exogenous (or predetermined) variables **X**.

The system can be solved for **Y** as follows, provided **B** is square and nonsingular:

$$\mathbf{Y} = \mathbf{B}^{-1}\mathbf{\Gamma X}$$

The reduced-form coefficients are the matrix $\mathbf{B}^{-1}\mathbf{\Gamma}$.

Uncorrelated Errors Across Equations

The SDIAG option in the PROC SYSLIN statement computes estimates assuming uncorrelated errors across equations. As a result, when the SDIAG option is used, the 3SLS estimates are identical to 2SLS estimates, and the SUR estimates are the same as the OLS estimates.

Over Identification Restrictions

The OVERID option in the MODEL statement can be used to test for over identifying restrictions on parameters of each equation. The null hypothesis is that the predetermined variables not appearing in any equation have zero coefficients. The alternative hypothesis is that at least one of the assumed zero coefficients is nonzero. The test is approximate and rejects the null hypothesis too frequently for small sample sizes.

The formula for the test is given as follows. Let $y_i = \beta_i \mathbf{Y}_i + \gamma_i \mathbf{Z}_i + e_i$ be the *i*th equation. $\mathbf{Y}_i$ are the endogenous variables that appear as regressors in the *i*th equation, and $\mathbf{Z}_i$ are the instrumental variables that appear as regressors in the *i*th equation. Let N_i be the number of variables in $\mathbf{Y}_i$ and $\mathbf{Z}_i$.

Let $v_i = y_i - \mathbf{Y}_i\hat{\beta}_i$. Let **Z** represent all instrumental variables, *T* be the total number of observations, and *K* be the total number of instrumental variables. Define $\hat{l}$ as follows:

$$\hat{l} = \frac{v'_i(\mathbf{I} - \mathbf{Z}_i(\mathbf{Z}'_i\mathbf{Z}_i)^{-1}\mathbf{Z}'_i)v_i}{v'_i(\mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}')v_i}$$

Then the test statistic

$$\frac{T-K}{K-N_i}(\hat{l}-1)$$

is distributed approximately as an F with $K-N_i$ and $T-K$ degrees of freedom. Refer to Basmann (1960) for more information.

Fuller's Modification to LIML

The ALPHA= option in the PROC SYSLIN and MODEL statements parameterizes Fuller's modification to LIML. This modification is $k = \gamma - (\alpha/(n-g))$, where α is the value of the ALPHA= option, γ is the LIML *k* value, *n* is the number of observations, and *g* is the number of predetermined variables. Fuller's modification is not used unless the ALPHA= option is specified. Refer to Fuller (1977) for more information.

Missing Values

Observations having a missing value for any variable in the analysis are excluded from the computations.

OUT= Data Set

The output SAS data set produced by the OUT= option in the PROC SYSLIN statement contains all the variables in the input data set and the variables containing predicted values and residuals specified by OUTPUT statements.

The residuals are computed as actual values minus predicted values. Predicted values never use lags of other predicted values, as would be desirable for dynamic simulation. For these applications, PROC SIMLIN is available to predict or simulate values from the estimated equations.

OUTEST= Data Set

The OUTEST= option produces a TYPE=EST output SAS data set containing estimates from the regressions. The variables in the OUTEST= data set are as follows:

BY variables	the BY statement variables are included in the OUTEST= data set
TYPE	identifies the estimation type for the observations. The _TYPE_ value INST indicates first-stage regression estimates. Other values indicate the estimation method used: 2SLS indicates two-stage least squares results, 3SLS indicates three-stage least squares results, LIML indicates limited information maximum likelihood results, and so forth. Observations added by IDENTITY statements have the _TYPE_ value IDENTITY.
MODEL	the model label. The model label is the label specified on the MODEL statement or the dependent variable name if no label is specified. For first-stage regression estimates, _MODEL_ has the value FIRST.

DEPVAR	the name of the dependent variable for the model
NAME	the names of the regressors for the rows of the covariance matrix, if the COVOUT option is specified. _NAME_ has a blank value for the parameter estimates observations. The _NAME_ variable is not included in the OUTEST= data set unless the COVOUT option is used to output the covariance of parameter estimates matrix.
SIGMA	contains the root mean square error for the model, which is an estimate of the standard deviation of the error term. The _SIGMA_ variable contains the same values reported as Root MSE in the printed output.
INTERCEPT	the intercept parameter estimates
regressors	the regressor variables from all the MODEL statements are included in the OUTEST= data set. Variables used in IDENTIFY statements are also included in the OUTEST= data set.

The parameter estimates are stored under the names of the regressor variables. The intercept parameters are stored in the variable INTERCEP. The dependent variable of the model is given a coefficient of -1. Variables not in a model have missing values for the OUTEST= observations for that model.

Some estimation methods require computation of preliminary estimates. All estimates computed are output to the OUTEST= data set. For each BY group and each estimation, the OUTEST= data set contains one observation for each MODEL or IDENTITY statement. Results for different estimations are identified by the _TYPE_ variable.

For example, consider the following statements:

```
proc syslin data=a outest=est 3sls;
   by b;
   endogenous y1 y2;
   instruments x1-x4;
   model y1 = y2 x1 x2;
   model y2 = y1 x3 x4;
   identity x1 = x3 + x4;
run;
```

The 3SLS method requires both a preliminary 2SLS stage and preliminary first stage regressions for the endogenous variable. The OUTEST= data set thus contains 3 different kinds of estimates. The observations for the first-stage regression estimates have the _TYPE_ value INST. The observations for the 2SLS estimates have the _TYPE_ value 2SLS. The observations for the final 3SLS estimates have the _TYPE_ value 3SLS.

Since there are 2 endogenous variables in this example, there are 2 first-stage regressions and 2 _TYPE_=INST observations in the OUTEST= data set. Since there are 2 model statements, there are 2 OUTEST= observations with _TYPE_=2SLS and 2 observations with _TYPE_=3SLS. In addition, the OUTEST= data set contains an observation with the _TYPE_ value IDENTITY containing the coefficients specified by the IDENTITY statement. All these observations are repeated for each BY-group in the input data set defined by the values of the BY variable B.

When the COVOUT option is specified, the estimated covariance matrix for the parameter estimates is included in the OUTEST= data set. Each observation for parameter estimates is followed by observations containing the rows of the parameter covariance matrix for that model. The row of the covariance matrix is identified by the variable _NAME_. For observations that contain parameter estimates, _NAME_ is blank. For covariance observations, _NAME_ contains the regressor name for the row of the covariance matrix, and the regressor variables contain the covariances.

See Example 26.1 for an example of the OUTEST= data set.

OUTSSCP= Data Set

The OUTSSCP= option produces a TYPE=SSCP output SAS data set containing sums of squares and cross products. The data set contains all variables used in the MODEL, IDENTITY, and VAR statements. Observations are identified by the variable _NAME_.

The OUTSSCP= data set can be useful when a large number of observations are to be explored in many different SYSLIN runs. The sum-of-squares-and-crossproducts matrix can be saved with the OUTSSCP= option and used as the DATA= data set on subsequent SYSLIN runs. This is much less expensive computationally because PROC SYSLIN never reads the original data again. In the step that creates the OUTSSCP= data set, include in the VAR statement all the variables you expect to use.

Printed Output

The printed output produced by the SYSLIN procedure is as follows:

1. If the SIMPLE option is used, a table of descriptive statistics is printed showing the sum, mean, sum of squares, variance, and standard deviation for all the variables used in the models.
2. First-stage regression results are printed if the FIRST option is specified and an instrumental variables method is used. This shows the regression of each endogenous variable on the variables in the INSTRUMENTS list.
3. The results of the second-stage regression are printed for each model. (See “Printed Output for Each Model,” which follows.)
4. If a systems method like 3SLS, SUR, or FIML is used, the cross-equation error covariance matrix is printed. This matrix is shown four ways: the covariance matrix itself, the correlation matrix form, the inverse of the correlation matrix, and the inverse of the covariance matrix.
5. If a systems method like 3SLS, SUR, or FIML is used, the system weighted mean square error and system weighted R^2 statistics are printed. The system weighted MSE and R^2 measure the fit of the joint model obtained by stacking

all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances.

6. If a systems method like 3SLS, SUR, or FIML is used, the final results are printed for each model.
7. If the REDUCED option is used, the reduced-form coefficients are printed. This consists of the structural coefficient matrix for the endogenous variables, the structural coefficient matrix for the exogenous variables, the inverse of the endogenous coefficient matrix, and the reduced-form coefficient matrix. The reduced-form coefficient matrix is the product of the inverse of the endogenous coefficient matrix and the exogenous structural coefficient matrix.

Printed Output for Each Model

The results printed for each model include the “Analysis of Variance” table, the “Parameter Estimates” table, and optional items requested by TEST statements or by options on the MODEL statement.

The printed output produced for each model is described in the following.

The Analysis of Variance table includes the following:

- the model degrees of freedom, sum of squares, and mean square
- the error degrees of freedom, sum of squares, and mean square. The error mean square is computed by dividing the error sum of squares by the error degrees of freedom and is not effected by the VARDEF= option.
- the corrected total degrees of freedom and total sum of squares. Note that for instrumental variables methods the model and error sums of squares do not add to the total sum of squares.
- the *F*-ratio, labeled “F Value,” and its significance, labeled “PROB>F,” for the test of the hypothesis that all the nonintercept parameters are 0
- the root mean square error. This is the square root of the error mean square.
- the dependent variable mean
- the coefficient of variation (C.V.) of the dependent variable
- the R^2 statistic. This R^2 is computed consistently with the calculation of the *F* statistic. It is valid for hypothesis tests but may not be a good measure of fit for models estimated by instrumental variables methods.
- the R^2 statistic adjusted for model degrees of freedom, labeled “Adj R-SQ”

The Parameter Estimates table includes the following.

- estimates of parameters for regressors in the model and the Lagrangian parameter for each restriction specified
- a degrees of freedom column labeled DF. Estimated model parameters have 1 degree of freedom. Restrictions have a DF of -1. Regressors or restrictions dropped from the model due to collinearity have a DF of 0.

- the standard errors of the parameter estimates
- the t statistics, which are the parameter estimates divided by the standard errors
- the significance of the *t*-tests for the hypothesis that the true parameter is 0, labeled "Pr > |t|." As previously noted, the significance tests are strictly valid in finite samples only for OLS estimates but are asymptotically valid for the other methods.
- the standardized regression coefficients, if the STB option is specified. This is the parameter estimate multiplied by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable.
- the labels of the regressor variables or restriction labels

In addition to the Analysis of Variance table and the Parameter Estimates table, the results printed for each model may include the following:

1. If TEST statements are specified, the test results are printed.
2. If the DW option is specified, the Durbin-Watson statistic and first-order autocorrelation coefficient are printed.
3. If the OVERID option is specified, the results of Basmann's test for overidentifying restrictions are printed.
4. If the PLOT option is used, plots of residual against each regressor are printed.
5. If the COVB or CORRB options are specified, the results for each model also include the covariance or correlation matrix of the parameter estimates. For systems methods like 3SLS and FIML, the COVB and CORB output is printed for the whole system after the output for the last model, instead of separately for each model.

The third stage output for 3SLS, SUR, IT3SLS, ITSUR, and FIML does not include the Analysis of Variance table. When a systems method is used, the second stage output does not include the optional output, except for the COVB and CORB matrices.

ODS Table Names

PROC SYSLIN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 26.1. ODS Tables Produced in PROC SYSLIN

ODS Table Name	Description	Option
ANOVA	Summary of the SSE, MSE for the equations	default
AugXPXMat	Model Crossproducts	XPX
AutoCorrStat	Autocorrelation Statistics	default
ConvCrit	Convergence criteria for estimation	default
ConvergenceStatus	Convergence status	default
CorrB	Correlations of parameters	CORRB
CorrResiduals	Correlations of residuals	CORRS
CovB	Covariance of parameters	COVB
CovResiduals	Covariance of residuals	
EndoMat	Endogenous Variables	
Equations	Listing of equations to estimate	default
ExogMat	Exogenous Variables	
FitStatistics	Statistics of Fit	default
InvCorrResiduals	Inverse Correlations of residuals	CORRS
InvCovResiduals	InvCovariance of residuals	COVS
InvEndoMat	Inverse Endogenous Variables	
InvXPX	$X'X$ inverse for System	I
IterHistory	Iteration printing	ITALL/ITPRINT
MissingValues	Missing values generated by the program	default
ModelVars	Name and label for the Model	default
ParameterEstimates	Parameter Estimates	default
RedMat	Reduced Form	REDUCED
SimpleStatistics	Descriptive statistics	SIMPLE
SSCP	Model Crossproducts	
TestResults	Test for Overidentifying Restrictions	
Weight	Weighted Model Statistics	
YPY	Y'Y matrices	USSCP2

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the SYSLIN procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

ODS Graph Names

PROC SYSLIN assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 26.2.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 26.2. ODS Graphics Produced by PROC SYSLIN

ODS Graph Name	Plot Description
ActualByPredicted	Predicted vs actual plot
QQPlot	QQ plot of residuals
ResidualHistogram	Histogram of the residuals
ResidualPlot	Residual plot

Examples

Example 26.1. Klein's Model I Estimated with LIML and 3SLS

This example uses PROC SYSLIN to estimate the classic Klein Model I. For a discussion of this model, see Theil (1971). The following statements read the data.

```
*---------------------------Klein's Model I---------------------------*
| By L.R. Klein, Economic Fluctuations in the United States, 1921-1941 |
| (1950), NY: John Wiley.   A macro-economic model of the U.S. with    |
| three behavioral equations, and several identities. See Theil, p.456.|
*----------------------------------------------------------------------*;

```

The following statements estimate the Klein model using the limited information maximum likelihood method. In addition, the parameter estimates are written to a SAS data set with the OUTEST= option.

```
proc syslin data=klein outest=b liml;
   endogenous c p w i x wsum k y;
   instruments klag plag xlag wp g t yr;
   consume: model c = p plag  wsum;
   invest:  model i = p plag  klag;
   labor:   model w = x xlag  yr;
run;

proc print data=b; run;
```

The PROC SYSLIN estimates are shown in Output 26.1.1 through Output 26.1.3.

The following statements estimate the model using the 3SLS method. The reduced-form estimates are produced by the REDUCED option; IDENTITY statements are used to make the model complete.

```
proc syslin data=klein 3sls reduced;
   endogenous c p w i x wsum k y;
   instruments klag plag xlag wp g t yr;
   consume: model    c = p plag wsum;
   invest:  model    i = p plag klag;
   labor:   model    w = x xlag yr;
   product: identity x = c + i + g;
   income:  identity y = c + i + g - t;
   profit:  identity p = y - w;
   stock:   identity k = klag + i;
   wage:    identity wsum = w + wp;
run;
```

The preliminary 2SLS results and estimated cross-model covariance matrix are not shown. The 3SLS estimates are shown in Output 26.1.5 through Output 26.1.7. The reduced-form estimates are shown in Output 26.1.8 through Output 26.1.11.

Example 26.2. Grunfeld’s Model Estimated with SUR

The following example was used by Zellner in his classic 1962 paper on seemingly unrelated regressions. Different stock prices often move in the same direction at a given point in time. The SUR technique may provide more efficient estimates than OLS in this situation.

The following statements read the data. (The prefix GE stands for General Electric and WH stands for Westinghouse.)

```

The following statements compute the SUR estimates for the Grunfeld model.

```
proc syslin data=grunfeld sur;
   ge:      model ge_i = ge_f ge_c;
```

```
      westing: model wh_i = wh_f wh_c;
   run;
```

The PROC SYSLIN output is shown in Output 26.2.1.

Example 26.3. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. This is a continuation of Example 26.1 on page 1515. These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the SYSLIN procedure, see the "ODS Graphics" section on page 1514.

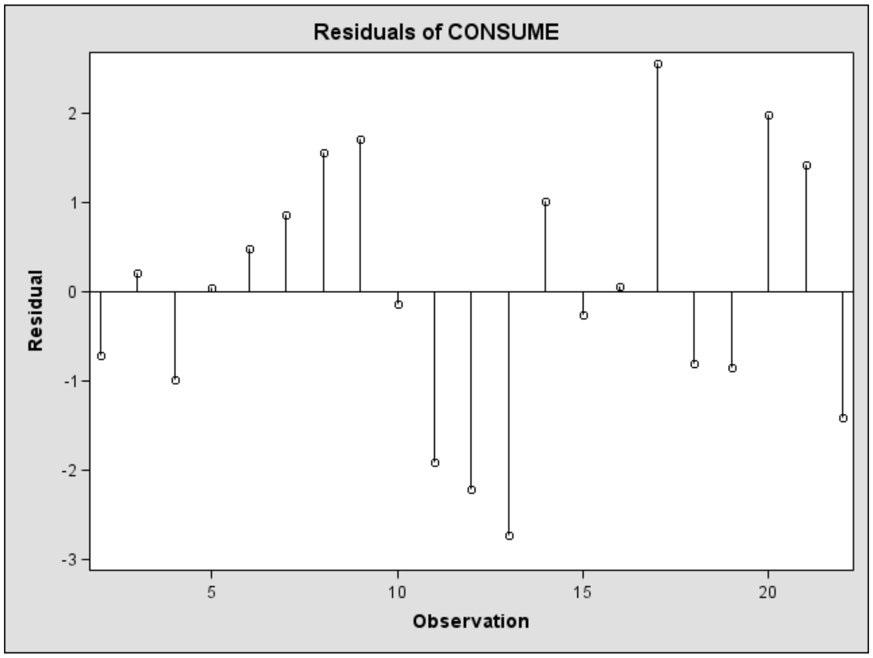
The following statements show how to generate ODS graphics plots with the SYSLIN procedure. The plots of residuals for each one of the equations in the model are displayed in Output 26.3.1 through Output 26.3.3.

```
ods html;
ods graphics on;

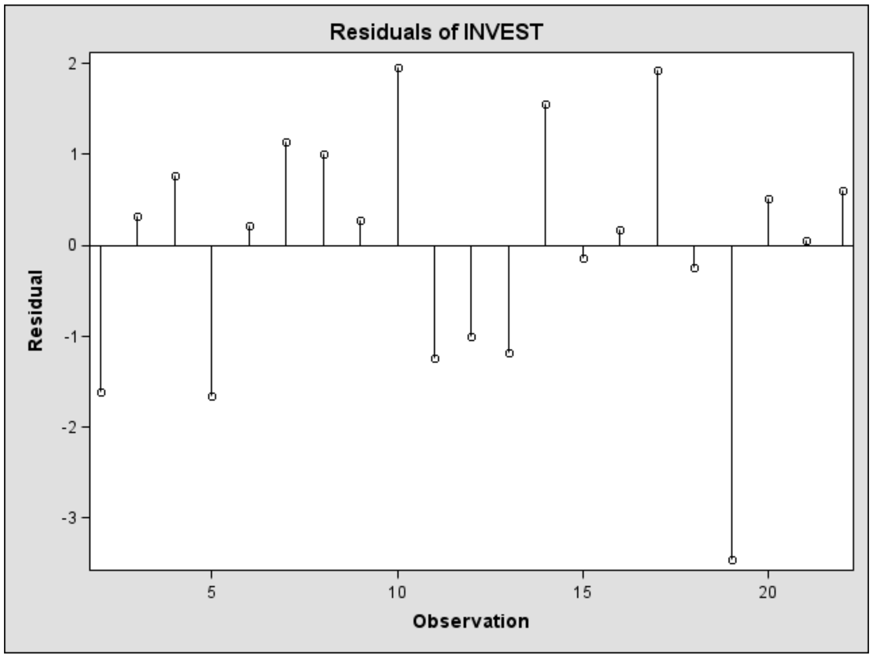
proc syslin data=klein outest=b liml;
   endogenous c p w i x wsum k y;
   instruments klag plag xlag wp g t yr;
   consume: model c = p plag  wsum;
   invest:  model i = p plag  klag;
   labor:   model w = x xlag  yr;
run;

ods graphics off;
ods html close;
```

Output 26.3.1. Residuals Plot for Consumption (Experimental)



Output 26.3.2. Residuals Plot for Investments (Experimental)



Output 26.3.3. Residuals Plot for Labor (Experimental)

The TSCSREG Procedure

Chapter Contents

Chapter 27
The TSCSREG Procedure

Overview

The TSCSREG (**T**ime **S**eries **C**ross **S**ection **Reg**ression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

Such models can be viewed as two-way designs with covariates

$$y_{it} = \sum_{k=1}^{K} X_{itk}\beta_k + u_{it} \quad i = 1, \ldots, N; \quad t = 1, \ldots, T$$

where *N* is the number of cross sections, *T* is the length of the time series for each cross section, and *K* is the number of exogenous or independent variables.

The performance of any estimation procedure for the model regression parameters depends on the statistical characteristics of the error components in the model. The TSCSREG procedure estimates the regression parameters in the preceding model under several common error structures. The error structures and the corresponding methods the TSCSREG procedure uses to analyze them are as follows:

- one and two-way fixed and random effects models. If the specification is dependent only on the cross section to which the observation belongs, such a model is referred to as a model with one-way effects. A specification that depends on both the cross section and the time series to which the observation belongs is called a model with two-way effects.
- Therefore, the specifications for the one-way model are

  $$u_{it} = \nu_i + \epsilon_{it}$$

  and the specifications for the two-way model are

  $$u_{it} = \nu_i + e_t + \epsilon_{it}$$

  where ϵ_{it} is a classical error term with zero mean and a homoscedastic covariance matrix.
- Apart from the possible one-way or two-way nature of the effect, the other dimension of difference between the possible specifications is that of the nature of the cross-sectional or time-series effect. The models are referred to as fixed effects models if the effects are nonrandom and as random effects models otherwise.

- first-order autoregressive model with contemporaneous correlation

$$u_{it} = \rho_i u_{i,t-1} + \epsilon_{it}$$

- The Parks method is used to estimate this model. This model assumes a first-order autoregressive error structure with contemporaneous correlation between cross sections. The covariance matrix is estimated by a two-stage procedure leading to the estimation of model regression parameters by GLS.
- mixed variance-component moving average error process

$$u_{it} = a_i + b_t + e_{it}$$

$$e_{it} = \alpha_0 \epsilon_t + \alpha_1 \epsilon_{t-1} + \ldots + \alpha_m \epsilon_{t-m}$$

- The Da Silva method is used to estimate this model. The Da Silva method estimates the regression parameters using a two-step GLS-type estimator.

The TSCSREG procedure analyzes panel data sets that consist of multiple time series observations on each of several individuals or cross-sectional units. The input data set must be in time series cross-sectional form. See Chapter 2, "Working with Time Series Data," for a discussion of how time series related by a cross-sectional dimension are stored in SAS data sets. The TSCSREG procedure requires that the time series for each cross section have the same number of observations and cover the same time range.

Getting Started

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A containing data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```
proc sort data=a;
   by state date;
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```
proc tscsreg data=a;
   id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options on the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed effects and random effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models using unbalanced data. The missing time series observations are recognized by the absence of time series id variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series id value and cross-sectional id value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Also, when PROC TSCSREG is processing balanced data, you now need to specify only the CS= parameter if you do not specify an ID statement. The TS= parameter is not required, since it can be inferred from the number of observations if the data is balanced.

Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement. The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

```
proc tscsreg data=a;
   id state date;
   model y = x1 x2;
run;
```

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. See the "Details" section later in this chapter for more information about these methods and the error structures they assume.

By default, the Fuller-Battese method is used. Thus, the preceding example is the same as specifying the FULLER option, as shown in the following statements:

```
proc tscsreg data=a;
   id state date;
```

```
      model y = x1 x2 / fuller;
   run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model using different options. See Example 27.1 in the section "Examples."

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an *F* statistic that tests the null hypothesis that the fixed effects parameters are all zero. The second is a Hausman *m*-statistic that provides information about the appropriateness of the random effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed effects model is more appropriate.

The procedure also provides the Buse R-squared measure, which is the most appropriate goodness-of-fit measure for models estimated using GLS. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-squared measure is equivalent to the usual R-squared measure.

Estimation Techniques

If the effects are fixed, the models are essentially regression models with dummy variables corresponding to the specified effects. For fixed effects models, ordinary least squares (OLS) estimation is best linear unbiased.

The other alternative is to assume that the effects are random. In the one-way case, $E(\nu_i) = 0$, $E(\nu_i^2) = \sigma_\nu^2$, and

$E(\nu_i \nu_j) = 0$ for $i \neq j$, and ν_i is uncorrelated with ϵ_{it} for all i and t. In the two-way case, in addition to all of the preceding, $E(e_t) = 0$, $E(e_t^2) = \sigma_e^2$, and

$E(e_t e_s) = 0$ for $t \neq s$, and the e_t are uncorrelated with the ν_i and the ϵ_{it} for all $i$and t. Thus, the model is a variance components model, with the variance components σ_ν^2 and σ_e^2, as well as σ_ϵ^2, to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.

Introductory Example

The following example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and COST is the log of cost in millions of dollars. Refer to Greene (1990) for details.

```
data greene;

     6 1955   9.37552   4.29114  6 1960   9.65188   4.59356
     6 1965  10.21163   4.93361  6 1970  10.34039   5.25520
;

proc sort data=greene;
   by firm year;
run;
```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the Fuller-Battese method adds the individual and time-specific random effects to the error disturbances, and the parameters are efficiently estimated using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^{K} X_{itk}\beta_k + v_i + e_t + \epsilon_{it} \quad i = 1, \ldots, N; \quad t = 1, \ldots, T$$

The following statements fit this model. Since the Fuller-Battese is the default method, no options are required.

```
proc tscsreg data=greene;
   model cost = output;
   id firm year;
run;
```

The TSCSREG procedure output is shown in Figure 27.1. A model description is printed first, which reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and *t*-tests.

Figure 27.1. The Variance Components Estimates

Syntax

The following statements are used with the TSCSREG procedure.

PROC TSCSREG *options*;
  BY *variables*;
  ID *cross-section-id-variable time-series-id-variable*;
  MODEL *dependent = regressor-variables / options*;
  label: **TEST** *equation [,equation...]*;

Functional Summary

The statements and options used with the TSCSREG procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	TSCSREG	DATA=
write parameter estimates to an output data set	TSCSREG	OUTEST=
include correlations in the OUTEST= data set	TSCSREG	CORROUT
include covariances in the OUTEST= data set	TSCSREG	COVOUT
specify number of time series observations	TSCSREG	TS=
specify number of cross sections	TSCSREG	CS=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the cross section and time ID variables	ID	
Printing Control Options		
print correlations of the estimates	MODEL	CORRB
print covariances of the estimates	MODEL	COVB
suppress printed output	MODEL	NOPRINT
perform tests of linear hypotheses	TEST	
Model Estimation Options		
specify the one-way fixed effects model	MODEL	FIXONE
specify the two-way fixed effects model	MODEL	FIXTWO
specify the one-way random effects model	MODEL	RANONE
specify the one-way random effects model	MODEL	RANTWO
specify Fuller-Battese method	MODEL	FULLER
specify PARKS	MODEL	PARKS
specify Da Silva method	MODEL	DASILVA
specify order of the moving average error process for Da Silva method	MODEL	M=
print Φ matrix for Parks method	MODEL	PHI
print autocorrelation coefficients for Parks method	MODEL	RHO
suppress the intercept term	MODEL	NOINT
control check for singularity	MODEL	SINGULAR=

PROC TSCSREG Statement

PROC TSCSREG *options;*

The following options can be specified on the PROC TSCSREG statement.

DATA= *SAS-data-set*
names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit DATA=, the most recently created SAS data set is used.

TS= *number*
specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

CS= *number*
specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

OUTEST= *SAS-data-set*
names an output data set to contain the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created. See the section "OUTEST= Data Set" later in this chapter for details on the structure of the OUTEST= data set.

OUTCOV
COVOUT
writes the covariance matrix of the parameter estimates to the OUTEST= data set. See the section "OUTEST= Data Set" later in this chapter for details.

OUTCORR
CORROUT
writes the correlation matrix of the parameter estimates to the OUTEST= data set. See the section "OUTEST= Data Set" later in this chapter for details.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement. See the section "MODEL Statement" for a complete description of each of these options.

BY Statement

BY *variables ;*

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example,

```
proc sort data=a;
   by byvar1 byvar2 csid tsid;
run;

proc tscsreg data=a;
   by byvar1 byvar2;
   id csid tsid;
   ...
run;
```

When both a BY statement and an ID statement are used, the data set may have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS=*N* and TS=*T* options must be specified and each BY group must contain $N \times T$ observations.

ID Statement

ID *cross-section-id-variable time-series-id-variable;*

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set.

```
proc sort data=a;
   by csid tsid;
run;

proc tscsreg data=a;
   id csid tsid;
   ... etc. ...
run;
```

If the ID statement is not used, the TS= and CS= options must be specified on the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length *T* is set to the minimum number of observations for any cross section, and only the first *T* observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

MODEL Statement

MODEL *response = regressors / options;*

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FULLER, PARKS, and DASILVA options. More than one of these three options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label **: MODEL** . . . **;**

The following options can be specified on the MODEL statement after a slash (/).

CORRB
CORR
prints the matrix of estimated correlations between the parameter estimates.

COVB
VAR
prints the matrix of estimated covariances between the parameter estimates.

FIXONE
specifies that a one-way fixed effects model be estimated.

FIXTWO
specifies that a two-way fixed effects model be estimated.

RANONE
specifies that a one-way random effects model be estimated.

RANTWO
specifies that a two-way random effects model be estimated.

FULLER
specifies that the model be estimated using the Fuller-Battese method, which assumes a variance components model for the error structure. See "Fuller-Battese Method" later in this chapter for details. FULLER is the default.

PARKS
specifies that the model be estimated using the Parks method, which assumes a first-order autoregressive model for the error structure. See "Parks Method" later in this chapter for details.

DASILVA

specifies that the model be estimated using the Da Silva method, which assumes a mixed variance-component moving average model for the error structure. See "Da Silva Method" later in this chapter for details.

M= *number*

specifies the order of the moving average process in the Da Silva method. The M= value must be less than $T - 1$. The default is M=1.

PHI

prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used. See "Parks Method" later in this chapter for details.

RHO

prints the estimated autocorrelation coefficients for the Parks method.

NOINT
NOMEAN

suppresses the intercept parameter from the model.

NOPRINT

suppresses the normal printed output.

SINGULAR= *number*

specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TEST Statement

label: **TEST** *equation [,equation...]***;**

The TEST statement performs *F*-tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following illustrates the use of the TEST statement:

```
proc tscsreg;
   model y = x1 x2 x3;
   test x1 = 0, x2/2 + 2*x3= 0;
   test_int: test intercept=0, x3 = 0;
```

Details

Notation

The discussion here is in the context of the usual panel structure,

$$y_{it} = \sum_{k=1}^{K} x_{itk}\beta_k + u_{it} \quad i = 1, \ldots N; \quad t = 1, \ldots T_i$$

with the specification of u_{it} dependent on the particular model. The total number of observations $M = \sum_{i=1}^{N} T_i$. For the balanced data case, $T_i = T$ for all i. The $M \times M$ covariance matrix of u_{it} is denoted by $\mathbf{V}$. Let $\mathbf{X}$ and $\mathbf{y}$ be the independent and dependent variables arranged by cross section and by time within each cross section. Let $\mathbf{X}_s$ be the X matrix without the intercept. Generally, all other notation is specific to each section.

The One-Way Fixed Effects Model

The specification for the one-way fixed effects model is

$$u_{it} = \nu_i + \epsilon_{it}$$

where the ν_is are nonrandom. Since including both the intercept and all the ν_is induces a redundancy (unless the intercept is suppressed with the NOINT option), the ν_i estimates are reported under the restriction that $\nu_N = 0$.

Let $\mathbf{Q}_0 = diag(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$.

The estimators for the intercept and the fixed effects are given by the usual OLS expressions.

If $\tilde{\mathbf{X}}_s = \mathbf{Q}_0\mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0\mathbf{y}$, the estimator of the slope coefficients is given by

$$\tilde{\beta}_s = (\tilde{\mathbf{X}}_s'\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}}$$

The estimator of the error variance is

$$\hat{\sigma}_\epsilon = \tilde{\mathbf{u}}'\mathbf{Q}_0\tilde{\mathbf{u}}/(M - N - (K-1))$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{J}_M\mathbf{j}'_M/M)(\mathbf{y} - \mathbf{X}_s\tilde{\beta}_s)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y} - \mathbf{X}_s\tilde{\beta}_s)$if there is not.

The Two-Way Fixed Effects Model

The specification for the two-way fixed effects model is

$$u_{it} = \nu_i + e_t + \epsilon_{it}$$

where the ν_is and e_ts are nonrandom. If you do not specify the NOINT option, which suppresses the intercept, the estimates for the fixed effects are reported under the restriction that $\nu_N = 0$ and $e_T = 0$. If you specify the NOINT option to suppress the intercept, only the restriction $e_T = 0$ is imposed.

Let $\mathbf{X}_*$ and $\mathbf{y}_*$ be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the TSCSREG procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in year t and let $\sum_t M_t = M$. Let $\mathbf{D}_t$ be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows corresponding to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}_1^{'}, \mathbf{D}_2^{'}, \ldots..\mathbf{D}_T^{'})^{'}$and $\mathbf{Z}_2 = diag(\mathbf{D}_1\mathbf{j}_N, \mathbf{D}_2\mathbf{j}_N, \ldots\ldots\mathbf{D}_T\mathbf{j}_N)$. The matrix $\mathbf{Z}$ gives the dummy variable structure for the two-way model.

Let

$$\Delta_N = \mathbf{Z}_1^{'}\mathbf{Z}_1, \quad \Delta_T = \mathbf{Z}_2^{'}\mathbf{Z}_2, \quad \mathbf{A} = \mathbf{Z}_2^{'}\mathbf{Z}_1$$

$$\bar{\mathbf{Z}} = \mathbf{Z}_2 - \mathbf{Z}_1\Delta_N^{-1}\mathbf{A}^{'}$$

$$\mathbf{Q} = \Delta_T - \mathbf{A}\Delta_N^{-1}\mathbf{A}^{'}$$

$$\mathbf{P} = (\mathbf{I}_M - \mathbf{Z}_1\Delta_N^{-1}\mathbf{Z}_1^{'}) - \bar{\mathbf{Z}}\mathbf{Q}^{-}\bar{\mathbf{Z}}^{'}$$

The estimators for the intercept and the fixed effects are given by the usual OLS expressions.

The estimate of the regression slope coefficients is given by

$$\tilde{\beta}_s = (\mathbf{X}_{*s}^{'}\mathbf{P}\mathbf{X}_{*s})^{-1}\mathbf{X}_{*s}^{'}\mathbf{P}\mathbf{y}_*$$

where $\mathbf{X}_{*s}$ is the $\mathbf{X}_*$ matrix without the vector of 1s.

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}^{'}\mathbf{P}\tilde{\mathbf{u}}/(M - T - N + 1 - (K - 1))$$

where the residuals are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M\mathbf{j}_M^{'}/M)(\mathbf{y}_* - \mathbf{X}_{*s}\tilde{\beta}_s)$if there is an intercept in the model and by $\tilde{\mathbf{u}} = \mathbf{y}_* - \mathbf{X}_{*s}\tilde{\beta}_s$if there is no intercept.

The One-Way Random Effects Model

The specification for the one-way random effects model is

$$u_{it} = \nu_i + \epsilon_{it}$$

Let $\mathbf{Z}_0 = diag(\mathbf{j}_{T_i})$, $\mathbf{P}_0 = diag(\bar{\mathbf{J}}_{T_i})$, and $\mathbf{Q}_0 = diag(\mathbf{E}_{T_i})$, with $\bar{\mathbf{J}}_{T_i} = \mathbf{J}_{T_i}/T_i$ and $\mathbf{E}_{T_i} = \mathbf{I}_{T_i} - \bar{\mathbf{J}}_{T_i}$. Define $\tilde{\mathbf{X}}_s = \mathbf{Q}_0\mathbf{X}_s$ and $\tilde{\mathbf{y}} = \mathbf{Q}_0\mathbf{y}$.

The fixed effects estimator of σ_ϵ^2 is still unbiased under the random effects assumptions, so you need to calculate only the estimate of σ_ν.

In the balanced data case, the estimation method for the variance components is the fitting constants method as applied to the one way model; refer to Baltagi and Chang (1994). Fuller and Battese (1974) apply this method to the two-way model.

Let

$$R(\nu) = \mathbf{y}^{'}\mathbf{Z}_0(\mathbf{Z}_0^{'}\mathbf{Z}_0)^{-1}\mathbf{Z}_0^{'}\mathbf{y}$$

$$R(\beta|\nu) = ((\tilde{\mathbf{X}}_s^{'}\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s^{'}\tilde{\mathbf{y}})^{'}(\tilde{\mathbf{X}}_s^{'}\tilde{\mathbf{y}})$$

$$R(\beta) = (\mathbf{X}^{'}\mathbf{y})^{'}(\mathbf{X}^{'}\mathbf{X})^{-1}\mathbf{X}^{'}\mathbf{y}$$

$$R(\nu|\beta) = R(\beta|\nu) + R(\nu) - R(\beta)$$

The estimator of the error variance is given by

$$\hat{\sigma}_\epsilon^2 = (\mathbf{y}^{'}\mathbf{y} - R(\beta|\nu) - R(\nu))/(M - N - (K-1))$$

and the estimator of the cross-sectional variance component is given by

$$\hat{\sigma}_\nu^2 = (R(\nu|\beta) - (N-1)\hat{\sigma}_\epsilon^2)/(M - \mathrm{tr}(\mathbf{Z}_0^{'}\mathbf{X}(\mathbf{X}^{'}\mathbf{X})^{-1}\mathbf{X}^{'}\mathbf{Z}_0))$$

The estimation of the one-way unbalanced data model is performed using a specialization (Baltagi and Chang 1994) of the approach used by Wansbeek and Kapteyn (1989) for unbalanced two-way models.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method. This involves focusing on quadratic forms of the centered residuals, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_1 = \tilde{\mathbf{u}}^{'}\mathbf{Q}_0\tilde{\mathbf{u}}$$

$$q_2 = \tilde{\mathbf{u}}^{'}\mathbf{P}_0\tilde{\mathbf{u}}$$

where the residuals $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M\mathbf{j}'_M/M)(\mathbf{y} - \mathbf{X}_s\tilde{\mathbf{X}}'_s\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}_s'\tilde{\mathbf{y}})$ if there is an intercept and by $tilde\mathbf{u} = (\mathbf{y} - \mathbf{X}_s(\tilde{\mathbf{X}}'_s\tilde{\mathbf{X}}_s)^{-1}\tilde{\mathbf{X}}'_s\tilde{\mathbf{y}})$ if there is not.

Consider the expected values

$$E(q_1) = (M - N - (K-1))\sigma_\epsilon^2$$

$$E(q_2) = (N - 1 + \mathrm{tr}[(\mathbf{X}_\mathrm{s}^{'}\mathbf{Q}_0\mathbf{X}_\mathrm{s})^{-1}\mathbf{X}_\mathrm{s}^{'}\mathbf{P}_0\mathbf{X}_\mathrm{s}] - \mathrm{tr}[(\mathbf{X}_\mathrm{s}^{'}\mathbf{Q}_0\mathbf{X}_\mathrm{s})^{-1}\mathbf{X}_\mathrm{s}^{'}\bar{\mathbf{J}}_\mathrm{M}\mathbf{X}_\mathrm{s}])\sigma_\epsilon^2$$

$$+[M - (\sum_i T_i^2/M)]\sigma_\nu^2$$

$\hat{\sigma}_\epsilon^2$ and $\hat{\sigma}_\nu^2$ are obtained by equating the quadratic forms to their expected values.

The estimated generalized least squares procedure substitutes the QUE estimates into the covariance matrix of u_{it}, which is given by

$$\mathbf{V} = \sigma_\nu^2 I_M + \sigma_\epsilon^2\mathbf{Z}_0\mathbf{Z}_0^{'}$$

The Two-Way Random Effects Model

The specification for the two way model is

$$u_{it} = \nu_i + e_t + \epsilon_{it}$$

For balanced data, the two-way random effects model is estimated using the method of Fuller and Battese (1974), so in this case, the RANTWO option is equivalent to the FULLER option already existing in PROC TSCSREG.

The following method (Wansbeek and Kapteyn 1989) is used to handle unbalanced data.

Let $\mathbf{X}_*$ and $\mathbf{y}_*$ be the independent and dependent variables arranged by time and by cross section within each time period. (Note that the input data set used by the TSCSREG procedure must be sorted by cross section and then by time within each cross section.) Let M_t be the number of cross sections observed in time t and $\sum_t M_t = M$. Let $\mathbf{D}_t$ be the $M_t \times N$ matrix obtained from the $N \times N$ identity matrix from which rows corresponding to cross sections not observed at time t have been omitted. Consider

$$\mathbf{Z} = (\mathbf{Z}_1, \mathbf{Z}_2)$$

where $\mathbf{Z}_1 = (\mathbf{D}_1^{'}, \mathbf{D}_2^{'}, \ldots..\mathbf{D}_T^{'})^{'}$and $\mathbf{Z}_2 = diag(\mathbf{D}_1\mathbf{j}_N, \mathbf{D}_2\mathbf{j}_N, \ldots\ldots\mathbf{D}_T\mathbf{j}_N)$.

The matrix $\mathbf{Z}$ gives the dummy variable structure for the two-way model.

Let

$$\Delta_N = \mathbf{Z}_1^{'}\mathbf{Z}_1, \quad \Delta_T = \mathbf{Z}_2^{'}\mathbf{Z}_2, \quad \mathbf{A} = \mathbf{Z}_2^{'}\mathbf{Z}_1$$

$$\bar{\mathbf{Z}} = \mathbf{Z}_2 - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{A}'$$

$$\mathbf{Q} = \Delta_T - \mathbf{A} \Delta_N^{-1} \mathbf{A}'$$

$$\mathbf{P} = (\mathbf{I}_M - \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1') - \bar{\mathbf{Z}} \mathbf{Q} - \bar{\mathbf{Z}}'$$

The estimator of the error variance is

$$\hat{\sigma}_\epsilon^2 = \tilde{\mathbf{u}}' \mathbf{P} \tilde{\mathbf{u}} / M - T - N + 1 - (K - 1))$$

where the $\tilde{\mathbf{u}}$ are given by $\tilde{\mathbf{u}} = (\mathbf{I}_M - \mathbf{j}_M \mathbf{j'}_M / M)(\mathbf{y}_* - \mathbf{X}_{*s} (\mathbf{X'}_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}_{*s}' \mathbf{P} \mathbf{y}_*)$ if there is an intercept and by $\tilde{\mathbf{u}} = (\mathbf{y}_* - \mathbf{X}_{*s} (\mathbf{X'}_{*s} \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X'}_{*s} \mathbf{P} \mathbf{y}_*$if there is not.

The estimation of the variance components is performed by using a quadratic unbiased estimation (QUE) method that involves focusing on quadratic forms of the residuals $\tilde{\mathbf{u}}$, equating their expected values to the realized quadratic forms, and solving for the variance components.

Let

$$q_N = \tilde{\mathbf{u}}' \mathbf{Z_2} \Delta_T^{-1} \mathbf{Z}_2' \tilde{\mathbf{u}}$$

$$q_T = \tilde{\mathbf{u}}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \tilde{\mathbf{u}}$$

Consider the expected values

$$E(q_N) = (T + k_N - (1 + k_0))\sigma^2 + (T - \frac{\lambda_1}{M})\sigma_\nu^2 + (M - \frac{\lambda_2}{M})\sigma_e^2$$

$$E(q_T) = (N + k_T - (1 + k_0))\sigma^2 + (M - \frac{\lambda_1}{M})\sigma_\nu^2 + (N - \frac{\lambda_2}{M})\sigma_e^2$$

where

$$k_0 = \mathbf{j}_M' \mathbf{X}_{*s} (\mathbf{X}_{*s}' \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}_{*s}' \mathbf{j}_M / M$$

$$k_N = tr((\mathbf{X}_{*s}' \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}_{*s}' \mathbf{Z}_2 \Delta_T^{-1} \mathbf{Z}_2' \mathbf{X}_{*s})$$

$$k_T = tr((\mathbf{X}_{*s}' \mathbf{P} \mathbf{X}_{*s})^{-1} \mathbf{X}_{*s}' \mathbf{Z}_1 \Delta_N^{-1} \mathbf{Z}_1' \mathbf{X}_{*s})$$

$$\lambda_1 = \mathbf{j}_M' \mathbf{Z}_1 \mathbf{Z}_1' \mathbf{j}_M$$

$$\lambda_2 = \mathbf{j}_M' \mathbf{Z}_2 \mathbf{Z}_2' \mathbf{j}_M$$

The quadratic unbiased estimators for σ_{ν}^{2} and σ_{e}^{2} are obtained by equating the expected values to the quadratic forms and solving for the two unknowns.

The estimated generalized least squares procedure substitute the QUE estimates into the covariance matrix of the composite error term u_{it}, which is given by

$$\mathbf{V} = \sigma_{\epsilon}^{2}\mathbf{I}_{M} + \sigma_{\nu}^{2}\mathbf{Z}_{1}\mathbf{Z}_{1}^{'} + \sigma_{e}^{2}\mathbf{Z}_{2}\mathbf{Z}_{2}^{'}$$

Parks Method (Autoregressive Model)

Parks (1967) considered the first-order autoregressive model in which the random errors $u_{it}, \quad i = 1, 2, \ldots, N, \quad t = 1, 2, \ldots, T$, have the structure

$$\begin{array}{rcll} E(u_{it}^{2}) & = & \sigma_{ii} & \text{(heteroscedasticity)} \\ E(u_{it}u_{jt}) & = & \sigma_{ij} & \text{(contemporaneously correlated)} \\ u_{it} & = & \rho_{i}u_{i,t-1} + \epsilon_{it} & \text{(autoregression)} \end{array}$$

where

$$\begin{array}{rcll} E(\epsilon_{it}) & = & 0 & \\ E(u_{i,t-1}\epsilon_{jt}) & = & 0 & \\ E(\epsilon_{it}\epsilon_{jt}) & = & \phi_{ij} & \\ E(\epsilon_{it}\epsilon_{js}) & = & 0 & (s{\neq}t) \\ E(u_{i0}) & = & 0 & \\ E(u_{i0}u_{j0}) & = & \sigma_{ij} = \phi_{ij}/(1-\rho_{i}\rho_{j}) & \end{array}$$

The model assumed is first-order autoregressive with contemporaneous correlation between cross sections. In this model, the covariance matrix for the vector of random errors **u** can be expressed as

$$E(\mathbf{u}\mathbf{u}^{'}) = \mathbf{V} = \begin{bmatrix} \sigma_{11}P_{11} & \sigma_{12}P_{12} & \ldots & \sigma_{1N}P_{1N} \\ \sigma_{21}P_{21} & \sigma_{22}P_{22} & \ldots & \sigma_{2N}P_{2N} \\ \vdots & \vdots & \vdots & \vdots \\ \sigma_{N1}P_{N1} & \sigma_{N2}P_{N2} & \ldots & \sigma_{NN}P_{NN} \end{bmatrix}$$

where

$$P_{ij} = \begin{bmatrix} 1 & \rho_j & \rho_j^2 & \dots & \rho_j^{T-1} \\ \rho_i & 1 & \rho_j & \dots & \rho_j^{T-2} \\ \rho_i^2 & \rho_i & 1 & \dots & \rho_j^{T-3} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \rho_i^{T-1} & \rho_i^{T-2} & \rho_i^{T-3} & \dots & 1 \end{bmatrix}$$

The matrix **V** is estimated by a two-stage procedure, and β is then estimated by generalized least squares. The first step in estimating **V** involves the use of ordinary least squares to estimate β and obtain the fitted residuals, as follows:

$$\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}\hat{\beta}_{OLS}$$

A consistent estimator of the first-order autoregressive parameter is then obtained in the usual manner, as follows:

$$\hat{\rho}_i = \left(\sum_{t=2}^{T} \hat{u}_{it}\hat{u}_{i,t-1} \right) \Bigg/ \left(\sum_{t=2}^{T} \hat{u}_{i,t-1}^2 \right) \quad i = 1, 2, \dots, N$$

Finally, the autoregressive characteristic of the data can be removed (asymptotically) by the usual transformation of taking weighted differences. That is, for $i = 1, 2, \dots, N$,

$$y_{i1}\sqrt{1-\hat{\rho}_i^2} = \sum_{k=1}^{p} X_{i1k}\beta_k\sqrt{1-\hat{\rho}_i^2} + u_{i1}\sqrt{1-\hat{\rho}_i^2}$$

$$y_{it} - \hat{\rho}_i y_{i,t-1} = \sum_{k=1}^{p} (X_{itk} - \hat{\rho}_i \mathbf{X}_{i,t-1,k})\beta_k + u_{it} - \hat{\rho}_i u_{i,t-1} \quad t = 2, \dots, T$$

which is written

$$y_{it}^* = \sum_{k=1}^{p} X_{itk}^*\beta_k + u_{it}^* \quad i = 1, 2, \dots, N; \quad t = 1, 2, \dots, T$$

Notice that the transformed model has not lost any observations (Seely and Zyskind 1971).

The second step in estimating the covariance matrix **V** is to apply ordinary least squares to the preceding transformed model, obtaining

$$\hat{\mathbf{u}}^* = \mathbf{y}^* - \mathbf{X}^* \beta^*_{OLS}$$

from which the consistent estimator of σ_{ij} is calculated:

$$s_{ij} = \frac{\hat{\phi}_{ij}}{(1 - \hat{\rho}_i \hat{\rho}_j)}$$

where

$$\hat{\phi}_{ij} = \frac{1}{(T-p)} \sum_{t=1}^{T} \hat{u}^*_{it} \hat{u}^*_{jt}$$

EGLS then proceeds in the usual manner,

$$\hat{\beta}_P = (\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{y}$$

where $\hat{\mathbf{V}}$ is the derived consistent estimator of **V**. For computational purposes, it should be pointed out that $\hat{\beta}_P$ is obtained directly from the transformed model,

$$\hat{\beta}_P = (\mathbf{X}^{*'}(\hat{\Phi}^{-1} \otimes I_T)\mathbf{X}^*)^{-1}\mathbf{X}^{*'}(\hat{\Phi}^{-1} \otimes I_T)\mathbf{y}^*$$

where $\hat{\Phi} = [\hat{\phi}_{ij}]_{i,j=1,\ldots,N}$.

The preceding procedure is equivalent to Zellner's two-stage methodology applied to the transformed model (Zellner 1962).

Parks demonstrates that his estimator is consistent and asymptotically, normally distributed with

$$\mathrm{Var}(\hat{\beta}_{\mathrm{P}}) = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$$

Standard Corrections

For the PARKS option, the first-order autocorrelation coefficient must be estimated for each cross section. Let ρ be the $N * 1$ vector of true parameters and $R = (r_1, \ldots, r_N)'$ be the corresponding vector of estimates. Then, to ensure that only range-preserving estimates are used in PROC TSCSREG, the following modification for R is made:

$$r_i = \begin{cases} r_i & \text{if } |r_i| < 1 \\ max(.95, rmax) & \text{if } r_i \geq 1 \\ min(-.95, rmin) & \text{if } r_i \leq -1 \end{cases}$$

where

$$rmax = \begin{cases} 0 & \text{if } r_i < 0 \text{ or } r_i \geq 1 \text{ for all i} \\ \max_j [r_j : 0 \leq r_j < 1] & \text{otherwise} \end{cases}$$

and

$$rmin = \begin{cases} 0 & \text{if } r_i > 0 \text{ or } r_i \leq -1 \text{ for all i} \\ \max_j [r_j : -1 < r_j \leq 0] & \text{otherwise} \end{cases}$$

Whenever this correction is made, a warning message is printed.

Da Silva Method (Variance-Component Moving Average Model)

Suppose you have a sample of observations at *T* time points on each of *N* cross-sectional units. The Da Silva method assumes that the observed value of the dependent variable at the *t*th time point on the *i*th cross-sectional unit can be expressed as

$$y_{it} = \mathbf{x}_{it}^{'}\beta + a_i + b_t + e_{it} \quad i = 1, \ldots, N; \quad t = 1, \ldots, T$$

where

$\mathbf{x}_{it}^{'} = (x_{it1}, \ldots, x_{itp})$is a vector of explanatory variables for the *t*th time point and *i*th cross-sectional unit

$\beta = (\beta_1, \ldots, \beta_p)'$ is the vector of parameters

a_i is a time-invariant, cross-sectional unit effect

b_t is a cross-sectionally invariant time effect

e_{it} is a residual effect unaccounted for by the explanatory variables and the specific time and cross-sectional unit effects

Since the observations are arranged first by cross sections, then by time periods within cross sections, these equations can be written in matrix notation as

$$\mathbf{y} = \mathbf{X}\beta + \mathbf{u}$$

where

$$\mathbf{u} = (\mathbf{a} \otimes \mathbf{1}_T) + (\mathbf{1}_N \otimes \mathbf{b}) + \mathbf{e}$$

$$\mathbf{y} = (y_{11}, \ldots, y_{1T}, y_{21}, \ldots, y_{NT})'$$

$$\mathbf{X} = (\mathbf{x}_{11}, \ldots, \mathbf{x}_{1T}, \mathbf{x}_{21}, \ldots, \mathbf{x}_{NT})'$$

$$\mathbf{a} = (a_1 \ldots a_N)'$$

$$\mathbf{b} = (b_1 \ldots b_T)'$$

$$\mathbf{e} = (e_{11}, \ldots, e_{1T}, e_{21}, \ldots, e_{NT})'$$

Here $\mathbf{1}_N$ is an $N \times 1$ vector with all elements equal to 1, and $\otimes$ denotes the Kronecker product.

It is assumed that

1. $\mathbf{x}_{it}$ is a sequence of nonstochastic, known $p \times 1$ vectors in $\Re^p$ whose elements are uniformly bounded in $\Re^p$. The matrix **X** has a full column rank *p*.
2. β is a $p \times 1$ constant vector of unknown parameters.
3. **a** is a vector of uncorrelated random variables such that $E(a_i) = 0$ and $var(a_i) = \sigma_a^2$, $\sigma_a^2 > 0, i = 1, \ldots, N$.
4. **b** is a vector of uncorrelated random variables such that $E(b_t) = 0$ and $var(b_t) = \sigma_b^2, \sigma_b^2 > 0, t = 1, \ldots, T$.
5. $\mathbf{e}_i = (e_{i1}, \ldots, e_{iT})'$ is a sample of a realization of a finite moving average time series of order $m < T - 1$ for each *i*; hence,

$$e_{it} = \alpha_0 \epsilon_t + \alpha_1 \epsilon_{t-1} + \ldots + \alpha_m \epsilon_{t-m}, \quad t = 1, \ldots, T; \quad i = 1, \ldots, N$$

   where $\alpha_0, \alpha_1, \ldots, \alpha_m$ are unknown constants such that $\alpha_0 \neq 0$ and $\alpha_m \neq 0$, and $\{\epsilon_j\}_{j=-\infty}^{j=\infty}$ is a white noise process, that is, a sequence of uncorrelated random variables with $E(\epsilon_t) = 0, E(\epsilon_t^2) = \sigma_\epsilon^2$, and $\sigma_\epsilon^2 > 0$.
6. The sets of random variables $\{a_i\}_{i=1}^N$, $\{b_t\}_{t=1}^T$, and $\{e_{it}\}_{t=1}^T$ for $i = 1, \ldots, N$ are mutually uncorrelated.
7. The random terms have normal distributions: $a_i \sim N(0, \sigma_a^2), b_t \sim N(0, \sigma_b^2)$,and $\epsilon_{t-k} \sim N(0, \sigma_\epsilon^2)$, for $i = 1, \ldots, N; t = 1, \ldots T; k = 1, \ldots, m$.

If assumptions 1-6 are satisfied, then

$$E(\mathbf{y}) = \mathbf{X}\beta$$

and

$$var(\mathbf{y}) = \sigma_a^2 (I_N \otimes J_T) + \sigma_b^2 (J_N \otimes I_T) + (I_N \otimes \Gamma_T)$$

where Γ_T is a $T \times T$ matrix with elements γ_{ts} as follows:

$$cov(e_{it}e_{is}) = \begin{cases} \gamma(|t-s|) & \text{if } |t-s| \leq \text{m} \\ 0 & \text{if } |t-s| > \text{m} \end{cases}$$

where $\gamma(k) = \sigma_\epsilon^2 \sum_{j=0}^{m-k} \alpha_j \alpha_{j+k}$ for $k = |t-s|$. For the definition of I_N, I_T, J_N, and J_T, see the "Fuller-Battese Method" section earlier in this chapter.

The covariance matrix, denoted by **V**, can be written in the form

$$\mathbf{V} = \sigma_a^2(I_N \otimes J_T) + \sigma_b^2(J_N \otimes I_T) + \sum_{k=0}^{m} \gamma(k)(I_N \otimes \Gamma_T^{(k)})$$

where $\Gamma_T^{(0)} = I_T$, and, for *k*=1,. . ., *m*, $\Gamma_T^{(k)}$ is a band matrix whose *k*th off-diagonal elements are 1's and all other elements are 0's.

Thus, the covariance matrix of the vector of observations **y** has the form

$$var(\mathbf{y}) = \sum_{k=1}^{m+3} \nu_k V_k$$

where

$$\begin{array}{lcll} \nu_1 & = & \sigma_a^2 & \\ \nu_2 & = & \sigma_b^2 & \\ \nu_k & = & \gamma(k-3) & k = 3, \ldots, m+3 \\ V_1 & = & I_N \otimes J_T & \\ V_2 & = & J_N \otimes I_T & \\ V_k & = & I_N \otimes \Gamma_T^{(k-3)} & k = 3, \ldots, m+3 \end{array}$$

The estimator of β is a two-step GLS-type estimator, that is, GLS with the unknown covariance matrix replaced by a suitable estimator of **V**. It is obtained by substituting Seely estimates for the scalar multiples $\nu_k, k = 1, 2, \ldots, m+3$.

Seely (1969) presents a general theory of unbiased estimation when the choice of estimators is restricted to finite dimensional vector spaces, with a special emphasis on quadratic estimation of functions of the form $\sum_{i=1}^{n} \delta_i \nu_i$.

The parameters ν_i (*i*=1,. . ., n) are associated with a linear model E(**y**)=**X**β with covariance matrix $\sum_{i=1}^{n} \nu_i V_i$ where V_i (*i*=1, . . ., n) are real symmetric matrices. The method is also discussed by Seely (1970a,1970b) and Seely and Zyskind (1971). Seely and Soong (1971) consider the MINQUE principle, using an approach along the lines of Seely (1969).

Linear Hypothesis Testing

For a linear hypothesis of the form $\mathbf{R}\ \beta$=$\mathbf{r}$ where $\mathbf{R}$ is $J{\times}L$ and $\mathbf{r}$ is $J{\times}1$, the *F*-statistic with $J, M-L$ degrees of freedom is computed as

$$(\mathbf{R}\beta-\mathbf{r})^{'}[\mathbf{R}(\mathbf{X}^{'}\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{R}']^{-1}\mathbf{R}(\mathbf{R}\beta-\mathbf{r})$$

R-squared

The conventional R-squared measure is inappropriate for all models that the TSCSREG procedure estimates using GLS since a number outside the 0-to-1 range may be produced. Hence, a generalization of the R-squared measure is reported. The following goodness-of-fit measure (Buse 1973) is reported:

$$R^2 = 1 - \frac{\hat{\mathbf{u}}^{'}\hat{\mathbf{V}}^{-1}\hat{\mathbf{u}}}{\mathbf{y}^{'}\mathbf{D}^{'}\hat{\mathbf{V}}^{-1}\mathbf{D}\mathbf{y}}$$

where $\hat{\mathbf{u}}$ are the residuals of the transformed model, $\hat{\mathbf{u}} = \mathbf{y} - \mathbf{X}(\mathbf{X}^{'}\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}^{'}\hat{\mathbf{V}}^{-1}\mathbf{y}$,

and $\mathbf{D} = \mathbf{I}_M - \mathbf{j}_M\mathbf{j}_M^{'}(\frac{\hat{\mathbf{V}}^{-1}}{\mathbf{j}_M^{'}\hat{\mathbf{V}}^{-1}\mathbf{j}_M})$.

This is a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables.

If there is no intercept in the model, the corresponding measure (Theil 1961) is

$$R^2 = 1 - \frac{\hat{\mathbf{u}}^{'}\hat{\mathbf{V}}^{-1}\hat{\mathbf{u}}}{\mathbf{y}^{'}\hat{\mathbf{V}}^{-1}\mathbf{y}}$$

Clearly, in the case of OLS estimation, both the R-squared formulas given here reduce to the usual R-squared formula.

Specification Tests

The TSCSREG procedure outputs the results of one specification test for fixed effects and one specification test for random effects.

For fixed effects, let β_f be the n dimensional vector of fixed effects parameters. The specification test reported is the conventional *F*-statistic for the hypothesis $\beta_f = \mathbf{0}$. The *F*-statistic with $n, M-K$ degrees of freedom is computed as

$$\hat{\beta}_f\hat{\mathbf{S}}_f^{-1}\hat{\beta}_f/n$$

where $\hat{\mathbf{S}}_f$ is the estimated covariance matrix of the fixed effects parameters.

Hausman's (1978) specification test or *m*-statistic can be used to test hypotheses in terms of bias or inconsistency of an estimator. This test was also proposed by Wu

(1973) and further extended in Hausman and Taylor (1982). Hausman's *m*-statistic is as follows.

Consider two estimators, $\hat{\beta}_a$ and $\hat{\beta}_b$, which under the null hypothesis are both consistent, but only $\hat{\beta}_a$ is asymptotically efficient. Under the alternative hypothesis, only $\hat{\beta}_b$ is consistent. The *m*-statistic is

$$m = (\hat{\beta}_b - \hat{\beta}_a)'(\hat{\mathbf{S}}_b - \hat{\mathbf{S}}_a)^{-}(\hat{\beta}_b - \hat{\beta}_a)$$

where $\hat{\mathbf{S}}_b$ and $\hat{\mathbf{S}}_a$ are consistent estimates of the asymptotic covariance matrices of $\hat{\beta}_b$ and $\hat{\beta}_a$. Then m is distributed χ^2 with k degrees of freedom, where k is the dimension of $\hat{\beta}_a$ and $\hat{\beta}_b$.

In the random effects specification, the null hypothesis of no correlation between effects and regressors implies that the OLS estimates of the slope parameters are consistent and inefficient but the GLS estimates of the slope parameters are consistent and efficient. This facilitates a Hausman specification test. The reported χ^2 statistic has degrees of freedom equal to the number of slope parameters.

OUTEST= Data Set

PROC TSCSREG writes the parameter estimates to an output data set when the OUTEST= option is specified. The OUTEST= data set contains the following variables:

MODEL	a character variable containing the label for the MODEL statement if a label is specified
METHOD	a character variable identifying the estimation method. Current methods are FULLER, PARKS, and DASILVA.
TYPE	a character variable that identifies the type of observation. Values of the _TYPE_ variable are CORRB, COVB, CSPARMS, and PARMS; the CORRB observation contains correlations of the parameter estimates; the COVB observation contains covariances of the parameter estimates; the CSPARMS observation contains cross-sectional parameter estimates; and the PARMS observation contains parameter estimates.
NAME	a character variable containing the name of a regressor variable for COVB and CORRB observations and left blank for other observations. The _NAME_ variable is used in conjunction with the _TYPE_ values COVB and CORRB to identify rows of the correlation or covariance matrix.
DEPVAR	a character variable containing the name of the response variable
MSE	the mean square error of the transformed model
CSID	the value of the cross section ID for CSPARMS observations. _CSID_ is used with the _TYPE_ value CSPARMS to identify the cross section for the first order autoregressive parameter estimate

	contained in the observation. _CSID_ is missing for observations with other _TYPE_ values. (Currently only the _A_1 variable contains values for CSPARMS observations.)
VARCS	the variance component estimate due to cross sections. _VARCS_ is included in the OUTEST= data set when either the FULLER or DASILVA option is specified.
VARTS	the variance component estimate due to time series. _VARTS_ is included in the OUTEST= data set when either the FULLER or DASILVA option is specified.
VARERR	the variance component estimate due to error. _VARERR_ is included in the OUTEST= data set when the FULLER option is specified.
_A_1	the first order autoregressive parameter estimate. _A_1 is included in the OUTEST= data set when the PARKS option is specified. The values of _A_1 are cross-sectional parameters, meaning that they are estimated for each cross section separately. _A_1 has a value only for _TYPE_=CSPARMS observations. The cross section to which the estimate belongs is indicated by the _CSID_ variable.
INTERCEP	the intercept parameter estimate. (INTERCEP will be missing for models for which the NOINT option is specified.)
regressors	the regressor variables specified in the MODEL statement. The regressor variables in the OUTEST= data set contain the corresponding parameter estimates for the model identified by _MODEL_ for _TYPE_=PARMS observations, and the corresponding covariance or correlation matrix elements for _TYPE_=COVB and _TYPE_=CORRB observations. The response variable contains the value -1 for the _TYPE_=PARMS observation for its model.

Printed Output

For each MODEL statement, the printed output from PROC TSCSREG includes the following:

1. a model description, which gives the estimation method used, the model statement label if specified, the number of cross sections and the number of observations in each cross section, and the order of moving average error process for the DASILVA option
2. the estimates of the underlying error structure parameters
3. the regression parameter estimates and analysis. For each regressor, this includes the name of the regressor, the degrees of freedom, the parameter estimate, the standard error of the estimate, a *t* statistic for testing whether the estimate is significantly different from 0, and the significance probability of the *t* statistic. Whenever possible, the notation of the original reference is followed.

Optionally, PROC TSCSREG prints the following:

4. the covariance and correlation of the resulting regression parameter estimates for each model and assumed error structure
5. the $\hat{\Phi}$ matrix that is the estimated contemporaneous covariance matrix for the PARKS option

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, "Using the Output Delivery System."

Table 27.1. ODS Tables Produced in PROC TSCSREG

ODS Table Name	**Description**	**Option**
	ODS Tables Created by the MODEL Statement	
ModelDescription	Model Description

Example

Example 27.1. Analyzing Demand for Liquid Assets

In this example, the demand equations for liquid assets are estimated. The demand function for the demand deposits is estimated under three error structures while demand equations for time deposits and savings and loan (S & L) association shares are calculated using the Parks method. The data for seven states (CA, DC, FL, IL, NY, TX, and WA) are selected out of 49 states. Refer to Feige (1964) for data description. All variables were transformed via natural logarithm. The first five observations of the data set A are shown in Output 27.1.1.

```
data a;
   input state $ year d t s y rd rt rs;
   label d = 'Per Capita Demand Deposits'
         t = 'Per Capita Time Deposits'
         s = 'Per Capita S & L Association Shares'
         y = 'Permanent Per Capita Personal Income'
         rd = 'Service Charge on Demand Deposits'
         rt = 'Interest on Time Deposits'
         rs = 'Interest on S & L Association Shares';
datalines;
   ... data lines are omitted ...
;

proc print data=a(obs=5);
run;
```

Output 27.1.1. A Sample of Liquid Assets Data

```
Obs  state  year     d        t        s        y        rd       rt       rs

  1   CA    1949  6.2785   6.1924   4.4998   7.2056   -1.0700  0.1080  1.0664
  2   CA    1950  6.4019   6.2106   4.6821   7.2889   -1.0106  0.1501  1.0767
  3   CA    1951  6.5058   6.2729   4.8598   7.3827   -1.0024  0.4008  1.1291
  4   CA    1952  6.4785   6.2729   5.0039   7.4000   -0.9970  0.4492  1.1227
  5   CA    1953  6.4118   6.2538   5.1761   7.4200   -0.8916  0.4662  1.2110
```

The SORT procedure is used to sort the data into the required time series cross-sectional format. Then PROC TSCSREG analyzes the data.

```
proc sort data=a;
   by state year;
run;

title 'Demand for Liquid Assets';
proc tscsreg data=a;
   model d = y rd rt rs / fuller parks dasilva m=7;
   model t = y rd rt rs / parks;
   model s = y rd rt rs / parks;
   id state year;
run;
```

The income elasticities for liquid assets are greater than 1 except for the demand deposit income elasticity (0.692757) estimated by the Da Silva method. In Output 27.1.2, Output 27.1.3 and Output 27.1.4, the coefficient estimates (-0.29094, -0.43591, and -0.27736) of demand deposits (RD) imply that demand deposits increase significantly as the service charge is reduced. The price elasticities (0.227152 and 0.408066) for time deposits (RT) and S & L association shares (RS) have the expected sign and thus an increase in the interest rate on time deposits or S & L shares will increase the demand for the corresponding liquid asset. Demand deposits and S & L shares appear to be substitutes (Output 27.1.2, Output 27.1.3, Output 27.1.4, and Output 27.1.6). Time deposits are also substitutes for S & L shares in the time deposit demand equation (Output 27.1.5), while these liquid assets are independent of each other in Output 27.1.6 (insignificant coefficient estimate of RT, -0.02705). Demand deposits and time deposits appear to be weak complements in Output 27.1.3 and Output 27.1.4, while the cross elasticities between demand deposits and time deposits are not significant in Output 27.1.2 and Output 27.1.5.

Acknowledgments

The TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979.

Dr. Drummond, now deceased, was with the Center for Survey Statistics, Research Triangle Park, NC. Dr. Drummond programmed the Parks and Fuller-Battese methods. Professor Gallant, who is currently with the University of North Carolina at Chapell Hill, programmed the Da Silva method and generously contributed his time to the support of PROC TSCSREG after Dr. Drummond’s death.

The version of PROC TSCSREG documented here was produced by converting the older SUGI Supplemental Library version of the procedure to Version 6 of SAS software. This conversion work was performed by SAS Institute, which now supports the procedure. Although several features were added during the conversion (such as the OUTEST= option, ID statement, and BY statement), credit for the statistical aspects and general design of the TSCSREG procedure belongs to Dr. Drummond and Professor Gallant.

The TIMESERIES Procedure

Chapter Contents

Chapter 28 The TIMESERIES Procedure

Overview

The TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. Once the transactional data are accumulated, time domain and frequency domain analysis can be performed on the accumulated time series.

For seasonal analysis of the transaction data, various statistics can be computed for each season. For trend analysis of the transaction data, various statistics can be computed for each time period. The analysis is similar to applying the MEANS procedure of Base SAS software to each season or time period of concern.

Once the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple and/or seasonal differencing. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

Time series analyses performed by the TIMESERIES procedure include:

- Descriptive (Global) Statistics
- Seasonal Decomposition/Adjustment Analysis
- Correlation Analysis
- Cross-correlation Analysis

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

Experimental graphics are now available with the TIMESERIES procedure. For more information, see the "ODS Graphics" section on page 1603.

The TIMESERIES procedure can process large amounts of time-stamped transactional data. Therefore, the analysis results are useful for large-scale time series analysis or (temporal) data mining. All of the results can be stored in output data sets in either a time series format (default) or in coordinate format (transposed). The time series format is useful for preparing the data for subsequent analysis using other SAS/ETS procedures. For example, the working time series can be further analyzed, modeled, and forecast using other SAS/ETS procedures. The coordinate format is useful when using this procedure with SAS/STAT procedures or Enterprise Miner. For example, clustering time-stamped transactional data can be achieved by using the results of this procedure with the clustering procedures of SAS/STAT and the nodes of Enterprise Miner.

The EXPAND procedure can be used for the frequency conversion and transformations of time series output from this procedure.

Getting Started

This section outlines the use of the TIMESERIES procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMESERIES procedure can form time series as follows:

```
PROC TIMESERIES DATA=<input-data-set> OUT=<output-data-set>;
   ID <time-ID-variable> INTERVAL=<frequency>
                         ACCUMULATE=<statistic>;
   VAR <time-series-variables>;
RUN;
```

The TIMESERIES procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats using the Output Delivery System (ODS). The following examples are more fully illustrated in the "Examples" section on page 1606.

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wishes to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains four variables related to these transactions: CUSTOMER, DATE, WITHDRAWAL, and DEPOSITS. The following examples illustrate possible ways to analyze these transactions using the TIMESERIES procedure.

The following statements illustrate how to use the TIMESERIES procedure to accumulate time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and DEPOSITS).

```
proc timeseries data=transactions out=timeseries;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The OUT=TIMESERIES option specifies that the resulting time series data for each customer is to be stored in the data set WORK.TIMESERIES. The INTERVAL=DAY option specifies that the transactions are to accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions are to be accumulated. Once the transactional data are accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the time series data.

For example, the ARIMA procedure can be used to model and forecast each customer's transactions using an ARIMA(0,1,1)(0,1,1)$_s$ model (where the number of seasons is s=7 days in a week) using the following statements:

```
proc arima data=timeseries;
   identify var=withdrawals(1,7) noprint;
   estimate q=(1,7) outest=estimates noprint;
   forecast id=date interval=day out=forecasts;
quit;
```

The OUTEST=ESTIMATES data set will contain the parameter estimates of the model specified. The OUT=FORECASTS data set will contain forecasts based on the model specified. See the ARIMA procedure for more detail.

A single set of transactions can be very large and must be summarized in order to analyze them effectively. Analysts often want to examine transactional data for trends and seasonal variation. To analyze transactional data for trends and seasonality, statistics must be computed for each time period and season of concern. For each observation, the time period and season must be determined and the data must be analyzed based on this determination.

The following statements illustrate how to use the TIMESERIES procedure to perform trend and seasonal analysis of time-stamped transactional data.

```
proc timeseries data=transactions out=out
     outseason=season outtrend=trend;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

Since the INTERVAL=DAY option is specified, the length of the seasonal cycle is seven (7) where the first season is Sunday and the last season is Saturday. The output data set specified by the OUTSEASON=SEASON option contains the seasonal statistics for each day of the week by each customer. The output data set specified by the OUTTREND=TREND option contains the trend statistics for each day of the calendar by each customer.

Often it is desired to seasonally decompose into seasonal, trend, cycle, and irregular components or seasonally adjust a time series. These techniques describe how the changing seasons influence the time series.

The following statements illustrate how to use the TIMESERIES procedure to perform seasonal adjustment/decomposition analysis of time-stamped transactional data.

```
proc timeseries data=transactions out=out outdecomp=decompose;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The output data set specified by the OUTDECOMP=DECOMPOSE data set contains the decomposed/adjusted time series for each customer.

A single time series can be very large. Often, a time series must be summarized with respect to time lags in order to be efficiently analyzed. Analysts often want to analyze time series data using time domain techniques. These techniques help describe how a current observation is related to the past observations with respect to the time (season) lag.

The following statements illustrate how to use the TIMESERIES procedure to perform time domain analysis of time-stamped transactional data.

```
proc timeseries data=transactions out=out outcorr=timedomain;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The output data set specified by the OUTCORR=TIMEDOMAIN data set contains the time domain statistics by each customer.

Syntax

The following statements are used with the TIMESERIES procedure.

PROC TIMESERIES *options*;
  BY *variables*;
  CORR *statistics-list / options*;
  CROSSCORR *statistics-list / options*;
  DECOMP *component-list / options*;
  SEASON *statistics-list / options*;
  TREND *statistics-list / options*;
  VAR *variable-list / options*;
  CROSSVAR *variable-list / options*;
  ID *variable* **INTERVAL=** *interval options*;

Functional Summary

The statements and options controlling the TIMESERIES procedure are summarized in the following table.

Description	Statement	Option
Statements		
specify BY-group processing	BY	
specify variables to analyze	VAR	
specify cross-variables to analyze	CROSSVAR	
specify the time ID variable	ID	
specify correlation options	CORR	
specify cross-correlation optons	CROSSCORR

Description	Statement	Option
limits error and warning messages	PROC TIMESERIES	MAXERROR=

PROC TIMESERIES Statement

PROC TIMESERIES *options***;**

The following options can be used in the PROC TIMESERIES statement.

DATA= *SAS-data-set*
names the SAS data set containing the input data for the procedure to create time series. If the DATA= option is not specified, the most recently created SAS data set is used.

MAXERROR= *number*
limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages.

OUT= *SAS-data-set*
names the output data set to contain the the time series variables specified in the subsequent VAR statements. If an ID variable is specified, it will also be included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= and/ or ACCUMULATE= option. The OUT= data set is particularly useful when you wish to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTCORR= *SAS-data-set*
names the output data set to contain the univariate time domain statistics.

OUTCROSSCORR= *SAS-data-set*
names the output data set to contain the cross-correlation statistics.

OUTDECOMP= *SAS-data-set*
names the output data set to contain the decomposed and/or seasonally adjusted time series.

OUTSEASON= *SAS-data-set*
names the output data set to contain the seasonal statistics. The statistics are computed for each season as specified by the INTERVAL= option or the SEASONALITY= option. The OUTSEASON= data set is particularly useful when analyzing transactional data for seasonal variations.

OUTSUM= *SAS-data-set*
names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= or

SETMISSING= options are specified. The OUTSUM= data set is particularly useful when analyzing large numbers of series and a summary of the results are needed.

OUTTREND= *SAS-data-set*
names the output data set to contain the trend statistics. The statistics are computed for each time period as specified by the INTERVAL= option. The OUTTREND= data set is particularly useful when analyzing transactional data for trends.

PRINT= *option* **| (***options***)**
specifies the printed output desired. By default, the TIMESERIES procedure produces no printed output. The following printing options are available:

DECOMP	prints the seasonal decomposition/adjustment table. (OUTDECOMP= data set)
SEASONS	prints the seasonal statistics table. (OUTSEASON= data set)
DESCSTATS	prints the descriptive statistics for the accumulated time series. (OUTSUM= data set)
SUMMARY	prints the descriptive statistics table for all time series. (OUTSUM= data set)
TRENDS	prints the trend statistics table. (OUTTREND= data set)

For example, PRINT=SEASONS prints the seasonal statistics. The PRINT= option produces printed output for these results utilizing the Output Delivery System (ODS). The PRINT= option produces results similar to the data sets listed next to the above options in parenthesis.

PRINTDETAILS
specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY= *number*
specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is twelve.

SORTNAMES
specifies that the variables specified in the VAR statements are processed in sorted order by the variable names.

BY Statement

BY *variables;*

A BY statement can be used with PROC TIMESERIES to obtain separate analyses for groups of observations defined by the BY variables.

CORR Statement

CORR *statistics / options*;

A CORR statement can be used with the TIMESERIES procedure to specify options related to time domain analysis of the accumulated time series. Only one CORR statement is allowed.

The following time domain statistics are available:

LAG	Time lag
N	Number of Variance Products
ACOV	Autocovariances
ACF	Autocorrelations
ACFSTD	Autocorrelation Standard Errors
ACF2STD	Indicates ACF Beyond Two Standard Errors
ACFNORM	Normalized Autocorrelations
ACFPROB	Autocorrelation Probabilities
ACFLPROB	Autocorrelation Log Probabilities
PACF	Partial Autocorrelations
PACFSTD	Partial Autocorrelation Standard Errors
PACF2STD	Indicates PACF Beyond Two Standard Errors
PACFNORM	Partial Normalized Autocorrelations
PACFPROB	Partial Autocorrelation Probabilities
PACFLPROB	Partial Autocorrelation Log Probabilities
IACF	Inverse Autocorrelations
IACFSTD	Inverse Autocorrelation Standard Errors
IACF2STD	Indicates IACF Beyond Two Standard Errors
IACFNORM	Normalized Inverse Autocorrelations
IACFPROB	Inverse Autocorrelation Probabilities
IACFLPROB	Inverse Autocorrelation Log Probabilities
WN	White Noise Test Statistics
WNPROB	White Noise Test Probabilities
WNLPROB	White Noise Test Log Probabilities

If none of the correlation statistics are specified, the default is as follows:

```
corr lag n acov acf acfstd pacf pacfstd iacf iacfstd wn wnprob;
```

The following options can be specified in the CORR statement following the slash (/):

NLAG= *number*
LAGS= *(numlist)*
specifies the number of lags or list of lags to be stored in OUTCORR= data set or printed. The default is 24 or three times the length of the seasonal cycle whichever is smaller.

NPARMS= *number*
specifies the number of parameters used in the model that created the residual time series. The number of parameters determines the degrees of freedom associated with the Ljung-Box statistics. The default is NPARMS=0.

TRANSPOSE=NO | YES
TRANSPOSE=YES specifies that the OUTCORR= data set is recorded with the lags as the column names instead of the correlation statistics as the column names. The TRANSPOSE=NO option is particularly useful for graphing the correlation results using SAS/GRAPH procedures. The TRANSPOSE=YES option is particularly useful for analyzing the correlation results using other SAS/STAT procedures or Enterprise Miner. The default is TRANSPOSE=NO.

CROSSCORR Statement

CROSSCORR *statistics / options*;

A CROSSCORR statement can be used with the TIMESERIES procedure to specify options related to cross-correlation analysis of the accumulated time series. Only one CROSSCORR statement is allowed.

The following time domain statistics are available:

LAG	Time lag
N	Number of Variance Products
CCOV	Cross-Covariances
CCF	Cross-correlations
CCFSTD	Cross-correlation Standard Errors
CCF2STD	Indicates CCF Beyond Two Standard Errors
CCFNORM	Normalized Cross-correlations
CCFPROB	Cross-correlations Probabilities
CCFLPROB	Cross-correlations Log Probabilities

If none of the correlation statistics are specified, the default is as follows:

```
crosscorr lag n ccov ccf ccfstd;
```

The following options can be specified in the CROSSCORR statement following the slash (/):

NLAG= *number*
LAGS= *(numlist)*

specifies the number of lags or list of lags to be stored in OUTCROSSCORR= data set or printed. The default is 24 or three times the length of the seasonal cycle whichever is smaller.

TRANSPOSE=NO | YES

TRANSPOSE=YES specifies that the OUTCROSSCORR= data set is recorded with the lags as the column names instead of the cross-correlation statistics as the column names. The TRANSPOSE=NO option is particularly useful for graphing the cross-correlation results using SAS/GRAPH procedures. The TRANSPOSE=YES option is particularly useful for analyzing the cross-correlation results using other SAS/STAT procedures or Enterprise Miner. The default is TRANSPOSE=NO.

DECOMP Statement

DECOMP *components / options*;

A DECOMP statement can be used with the TIMESERIES procedure to specify options related to classical seasonal decomposition of the time series data. Only one DECOMP statement is allowed. The options specified affects all variables specified in the VAR statements. Decomposition can be performed only when the length of the seasonal cycle implied by the INTERVAL= option or specified by the SEASONALITY= option is greater than one.

The following seasonal decomposition components are available:

ORIG|ORIGINAL	Original Series
TCC|TRENDCYCLE	Trend-Cycle Component
SIC|SEASONIRREGULAR	Seasonal-Irregular Component
SC|SEASONAL	Seasonal Component
SCSTD	Seasonal Component Standard Errors
TCS|TRENDCYCLESEASON	Trend-Cycle-Seasonal Component
IC|IRREGULAR	Irregular Component
SA|ADJUSTED	Seasonal Adjusted
PCSA	Percent Change Seasonal Adjusted
TC	Trend Component
CC|CYCLE	Cycle Component

If none of the components are specified, the default is as follows:

```
decomp orig tcc sc ic sa;
```

The following options can be specified in the DECOMP statement following the slash (/):

MODE=ADD|ADDITIVE
MODE=MULT|MULTIPLICATIVE
MODE=LOGADD|LOGADDITIVE
MODE=PSEUDOADD|PSEUDOADDITIVE
MODE=MULTORADD

specifies the type of decomposition is to be used to decompose the time series. Multiplicative and log additive decomposition requires a positive-valued time series. If the accumulated time series contains nonpositive values and the MODE=MULT or MODE=LOGADD option is specified, an error results. Pseudo-additive decomposition requires a nonnegative-valued time series. If the accumulated time series contains negative values and the MODE=PSEUDOADD option is specified, an error results. The MODE=MULTORADD option specifies that multiplicative decomposition is used when the accumulated time series contains only positive values, that pseudo-additive decomposition is used when the accumulated time series contains only nonnegative values, and that additive decomposition is used otherwise. The default is MODE=MULTORADD.

LAMBDA= *number*

specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. The default is LAMBDA=1600. If filtering is not specified this option is ignored.

NPERIODS= *number*

specifies the number of time periods to be stored in the OUTDECOMP= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE=NO option is specified, the NPERIODS= option is ignored. If the NPERIODS= option is positive the first or beginning time periods are recorded. If the NPERIODS= option is negative the last or ending time periods are recorded. The NPERIODS= option specifies the number of OUTDECOMP= data set variables to contain the seasonal decomposition and is therefore limited to the maximum allowable number of SAS variables. If the number of time periods exceeds this limit a warning is printed in the log and the number periods stored is reduced to the limit.

If NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If either of the START= or END= options are not specified, the default magnitude is the seasonality specified by the TIMESERIES statement SEASONALITY= option or implied by the INTERVAL= option. If only the START= option is specified, the default sign is positive. If only the END= option is specified, the default sign is negative.

```
/* NPERIODS=10 because there are ten months between
   the specified start and end dates */
   id date interval=month accumulate=total
      start='01JAN2000'D end='01OCT2000'D;
   decomp / transpose=yes;

/* NPERIODS=10 because there are ten months between
   the specified start and end dates */
```

```
      id date interval=month accumulate=total
         start='01JAN2000'D end='01OCT2000'D;
      decomp / transpose=yes nperiods=100;

   /* NPERIODS=12 because there are twelve months in a year
      and only the start date is specified */
      id date interval=month accumulate=total
         start='01JAN2000'D;
      decomp / transpose=yes;

   /* NPERIODS=-12 because there are twelve months in a year
      and only the end date is specified */
      id date interval=month accumulate=total
         end='01OCT2000'D;
      decomp / transpose=yes;
```

TRANSPOSE=NO | YES

TRANSPOSE=YES specifies that the OUTDECOMP= data set is recorded with the time periods as the column names instead of the statistics as the column names. The first and last time period stored in the OUTDECOMP= data set corresponds to the period of the ID statement START= option and END= option, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option or END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is particularly useful for analyzing the decomposition results using other SAS/ETS procedures or graphing the decomposition results using SAS/GRAPH procedures such as the GPLOT procedure. The TRANSPOSE=YES option is particularly useful for analyzing the decomposition results using other SAS/STAT procedures or Enterprise Miner. The default is TRANSPOSE=NO.

ID Statement

ID *variable* **INTERVAL=** *interval options*;

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables specified in subsequent VAR statements. If the ID statement is specified, the INTERVAL= option must also be specified. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following options can be used with the ID statement.

ACCUMULATE= *option*

specifies how the data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is particularly useful when there are zero or more than one input observations coinciding with a particular time period (e.g., time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following options determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE | AVG	Observations are accumulated based on the average of their values.
MINIMUM | MIN	Observations are accumulated based on the minimum of their values.
MEDIAN | MED	Observations are accumulated based on the median of their values.
MAXIMUM | MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of non-missing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV |STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The DETAILS section describes accumulation in greater detail.

ALIGN= *option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option accepts the following values: BEGINNING|BEG|B, MIDDLE|MID|M, and ENDING|END|E. BEGINNING is the default.

END= *option*

specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. This START= and END= option can be used to ensure that data associated within each BY group contains the same number of observations.

FORMAT= *format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

INTERVAL= *interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations.

NOTSORTED

specifies that the time ID values are not in sorted order. The TIMESERIES procedure will sort the data with respect to the time ID prior to analysis.

SETMISSING= *option* **|** *number*

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series. If a number is specified, missing values are set to number. If a missing value indicates an unknown value, this option should not be used. If a missing value indicates no value, a SETMISSING=0 should be used. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE | AVG	Missing values are set to the accumulated average value.
MINIMUM | MIN	Missing values are set to the accumulated minimum value.
MEDIAN | MED	Missing values are set to the accumulated median value.

MAXIMUM | MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first non-missing value.
LAST	Missing values are set to the accumulated last non-missing value.
PREVIOUS | PREV	Missing values are set to the previous period's accumulated non-missing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated non-missing value. Missing values at the end of the accumulated series remain missing.

START= *option*

specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prepended with missing values. If the first time ID variable value is less than the START= value, the series is truncated. This START= and END= option can be used to ensure that data associated with each by group contains the same number of observations.

SEASON Statement

SEASON *statistics / options*;

A SEASON statement can be used with the TIMESERIES procedure to specify options related to seasonal analysis of the time-stamped transactional data. Only one SEASON statement is allowed. The options specified affects all variables specified in the VAR statements. Seasonal analysis can be performed only when the length of the seasonal cycle implied by the INTERVAL= option or specified by the SEASONALITY= option is greater than one.

The following seasonal statistics are available:

NOBS	Number of Observations
N	Number of Non-Missing Observations
NMISS	Number of Missing Observations
MINIMUM	Minimum Value
MAXIMUM	Maximum Value
RANGE	Range Value
SUM	Summation Value
MEAN	Mean Value
STDDEV	Standard Deviation
CSS	Corrected Sum of Squares
USS	Uncorrected Sum of Squares

MEDIAN	Median Value

If none of the season statistics is specified, the default is as follows:

```
season n min max mean std;
```

The following options can be specified in the SEASON statement following the slash (/):

TRANSPOSE=NO | YES

TRANSPOSE=YES specifies that the OUTSEASON= data set is recorded with the seasonal indices as the column names instead of the statistics as the column names. The TRANSPOSE=NO option is particularly useful for graphing the seasonal analysis results using SAS/GRAPH procedures. The TRANSPOSE=YES option is particularly useful for analyzing the seasonal analysis results using other SAS/STAT procedures or Enterprise Miner. The default is TRANSPOSE=NO.

TREND Statement

TREND *statistics / options* **;**

A TREND statement can be used with the TIMESERIES procedure to specify options related to trend analysis of the time-stamped transactional data. Only one TREND statement is allowed. The options specified affects all variables specified in the VAR statements.

The following trend statistics are available:

NOBS	Number of Observations
N	Number of Non-Missing Observations
NMISS	Number of Missing Observations
MINIMUM	Minimum Value
MAXIMUM	Maximum Value
RANGE	Range Value
SUM	Summation Value
MEAN	Mean Value
STDDEV	Standard Deviation
CSS	Corrected Sum of Squares
USS	Uncorrected Sum of Squares
MEDIAN	Median Value

If none of the trend statistics is specified, the default is as follows:

```
trend n min max mean std;
```

The following options can be specified in the TREND statement following the slash (/):

NPERIODS= *number*

Specifies the number of time periods to be stored in the OUTTREND= data set when the TRANSPOSE option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTTREND= data set variables to contain the trend statistics and is therefore limited to the maximum allowable number of SAS variables.

If NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If either of the START= or END= options are not specified, the default is the seasonality specified by the ID statement SEASONALITY= option or implied by the INTERVAL= option. If the seasonality is zero, the default is NPERIODS=5.

TRANSPOSE=NO | YES

TRANSPOSE=YES specifies that the OUTTREND= data set is recorded with the time periods as the column names instead of the statistics as the column names. The first and last time period stored in the OUTTREND= data set corresponds to the period of the ID statement START= option and END= option, respectively. If only the ID statement END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the ID statement START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option or END= option is specified with the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. The TRANSPOSE=NO option is particularly useful for analyzing the trend analysis results using other SAS/ETS procedures or graphing the trend analysis results using SAS/GRAPH procedures such as the GPLOT procedure. The TRANSPOSE=YES option is particularly useful for analyzing the trend analysis results using other SAS/STAT procedures or Enterprise Miner. The default is TRANSPOSE=YES.

VAR and CROSSVAR Statements

VAR *variable-list / options*;

CROSSVAR *variable-list / options*;

The VAR and CROSSVAR statement lists the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR or CROSSVAR statement. Any number of VAR and CROSSVAR statements can be used. The following options can be used with the VAR and CROSSVAR statement.

ACCUMULATE= *option*

specifies how the data set observations are accumulated within each time period for the variables listed in the VAR statement. If the ACCUMULATE= option is not specified in the VAR statement, accumulation is determined by the ACCUMULATE=

option of the ID statement. See the ID statement ACCUMULATE= option for more details.

DIF= *numlist*
specifies the differencing to be applied to the accumulated time series.

SDIF= *numlist*
specifies the seasonal differencing to be applied to the accumulated time series.

SETMISS= *option* **|** *number*
SETMISSING= *option* **|** *number*
option specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series for variables listed in the VAR statement. If the SETMISSING= option is not specified in the VAR statement, missing values are set based on the SETMISSING= option of the ID statement. See the ID statement SETMISSING= option for more details.

TRANSFORM= *option*
specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation
SQRT	Square-root transformation
LOGISTIC	Logistic transformation
BOXCOX(*n*)	Box-Cox transformation with parameter number where number is between -5 and 5

When the TRANSFORM= option is specified the time series must be strictly positive.

Details

The TIMESERIES procedure can be used to perform trend and seasonal analysis on transactional data. For trend analysis, various sample statistics are computed for each time period defined by the time ID variable and INTERVAL= option. For seasonal analysis, various sample statistics are computed for each season defined by the INTERVAL= or the SEASONALITY= option. For example, if the transactional data ranges from June 1990 to January 2000 and the data are to be accumulated on a monthly basis, then the trend statistics are computed for every month: June 1990, July 1990, ..., January 2000. The seasonal statistics are computed for each season: January, February, ..., December.

The TIMESERIES procedure can be used to form time series data from transactional data. The accumulated time series can then be analyzed using time series techniques.

1. Accumulation	ACCUMULATE= option
2. Missing Value Interpretation	SETMISSING= option
3. Time Series Transformation	TRANSFORM= option
4. Time Series Differencing	DIF= and SDIF= option
5. Descriptive Statistics	OUTSUM= option, PRINT=DESCSTATS
6. Seasonal Decomposition	DECOMP statement, OUTDECOMP= option
7. Correlation Analysis	CORR statement, OUTCORR= option
8. Cross-correlation Analysis	CROSSCORR statement, OUTCROSSCORR= option

Accumulation

If the ACCUMULATE= option is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH is specified, all of the above observations fall within three time periods of March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified:

```
O1MAR1999    40
O1APR1999     .
O1MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified:

```
O1MAR1999    20
O1APR1999     .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified:

```
O1MAR1999    10
O1APR1999     .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified:

```
O1MAR1999    20
01APR1999     .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified:

```
O1MAR1999    30
O1APR1999     .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified:

```
O1MAR1999    10
O1APR1999     .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified:

```
O1MAR1999    30
O1APR1999     .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified:

```
01MAR1999    14.14
01APR1999    .
01MAY1999    17.32
```

As can be seen from the above examples, even though the data set observations contained no missing values, the accumulated time series may have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value, i.e. zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log — is the logarithmic transformation.

$$w_t = \ln(\mathrm{y_t})$$

Logistic — is the logistic transformation.

$$w_t = \ln(\mathrm{cy_t}/(1 - \mathrm{cy_t}))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\mathrm{ceil}(\log_{10}(\max(\mathrm{y_t})))}$$

and $\mathrm{ceil(x)}$ is the smallest integer greater than or equal to *x*.

Square Root — is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox — is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^{\lambda}-1}{\lambda}, & \lambda \neq 0 \\ \ln(\mathrm{y_t}), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed using the EXPAND procedure of SAS/ETS.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced using the VAR statement DIF= and SDIF= option. For example, suppose y_t is a monthly time series, the following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally assuming y_t is strictly positive, the VAR statement TRANSFORM= option, DIF= and SDIF= options can be combined.

Descriptive Statistics

Descriptive statistics can be computed from the working series by specifying the OUTSUM= option or the PRINT=DESCSTATS.

Seasonal Decomposition

Seasonal decomposition/analysis can be performed on the working series by specifying the OUTDECOMP= option, the PRINT=DECOMP option, or one of the PLOT= option associated with decomposition. The DECOMP statement enables you to specify options related to decomposition. The TIMESERIES procedure uses classical decomposition. More complex seasonal decomposition/adjustment analysis can be performed using the X11 or the X12 procedure of SAS/ETS.

The DECOMP statement MODE= option determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (MODE=MULT), additive (MODE=ADD), pseudo-additive (MODE=PSEUDOADD), and log-additive (MODE=LOGADD) decomposition. The default is MODE=MULTORADD which specifies MODE=MULT for series that are strictly positive, MODE=PSEUDOADD for series that are nonnegative, and MODE=ADD for series that are not.

When MODE=LOGADD is specified, the components are exponentiated to the original metric.

The DECOMP statement LAMBDA= option specifies the Hodrick-Prescott filter parameter. The default is LAMBDA=1600. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and cycle component in an additive fashion. A smaller parameter assigns less significance to the cycle, that is, LAMBDA=0 implies no cycle component.

The notation and keywords associated with seasonal decomposition/adjustment analysis are defined as follows:

Table 28.1. Seasonal Adjustment Formulas

Component	**Keyword**	**MULT**	**ADD**	**LOGADD**	**PSEUDOADD**
Original	ORIGINAL	$O_t = TC_tS_tI_t$	$O_t = TC_t + S_t + I_t$	$log(O_t) = TC_t + S_t + I_t$	$O_t = TC_t(S_t + I_t - 1)$
Trend-Cycle Component	TCC	Centered Moving Average of O_t	Centered Moving Average of O_t	Centered Moving Average of $log(O_t)$	Centered Moving Average of O_t
Seasonal-Irregular Component	SIC	$SI_t = S_tI_t = O_t/TC_t$	$SI_t = S_t + I_t = O_t - TC_t$	$SI_t = S_t + I_t = log(O_t) - TC_t$	$SI_t = S_t + I_t - 1 = O_t/TC_t$

Correlation Analysis

Correlation analysis can be performed on the working series by specifying the OUTCORR= option or one of the PLOT= options associated with correlation. The CORR statement enables you to specify options related to correlation analysis.

Autocovariance Statistics

LAGS	$h \in \{0, \ldots, H\}$
N	N_h is the number of observed products at lag h ignoring missing values
ACOV	$\hat{\gamma}(h) = \frac{1}{T}\sum_{t=h+1}^{T}(y_t - \overline{y})(y_{t-h} - \overline{y})$
ACOV	$\hat{\gamma}(h) = \frac{1}{N_h}\sum_{t=h+1}^{T}(y_t - \overline{y})(y_{t-h} - \overline{y})$ embedded missing values

Autocorrelation Statistics

ACF	$\hat{\rho}(h) = \hat{\gamma}(h)/\hat{\gamma}(0)$
ACFSTD	$Std(\hat{\rho}(h)) = \sqrt{\frac{1}{T}\left(1 + 2\sum_{j=1}^{h-1}\hat{\rho}(j)^2\right)}$
ACFNORM	$Norm(\hat{\rho}(h)) = \hat{\rho}(h)/Std(\hat{\rho}(h))$
ACFPROB	$Prob(\hat{\rho}(h)) = 2\,(1 - \Phi\,(\lvert Norm(\hat{\rho}(h))\rvert))$
ACFLPROB	$LogProb(\hat{\rho}(h)) = -\log_{10}(Prob(\hat{\rho}(h))$
ACF2STD	$Flag(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2Std(\hat{\rho}(h)) \\ 0 & -2Std(\hat{\rho}(h)) < \hat{\rho}(h) < 2Std(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2Std(\hat{\rho}(h)) \end{cases}$

Partial Autocorrelation Statistics

PACF	$\hat{\varphi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^{h}$
PACFSTD	$Std(\hat{\varphi}(h)) = 1/\sqrt{N_0}$
PCFNORM	$Norm(\hat{\varphi}(h)) = \hat{\varphi}(h)/Std(\hat{\varphi}(h))$
PACFPROB	$Prob(\hat{\varphi}(h)) = 2\,(1 - \Phi\,(\lvert Norm(\hat{\varphi}(h))\rvert))$
PACFLPROB	$LogProb(\hat{\varphi}(h)) = -\log_{10}(Prob(\hat{\varphi}(h))$
PACF2STD	$Flag(\hat{\varphi}(h)) = \begin{cases} 1 & \hat{\varphi}(h) > 2Std(\hat{\varphi}(h)) \\ 0 & -2Std(\hat{\varphi}(h)) < \hat{\varphi}(h) < 2Std(\hat{\varphi}(h)) \\ -1 & \hat{\varphi}(h) < -2Std(\hat{\varphi}(h)) \end{cases}$

Inverse Autocorrelation Statistics

IACF	$\hat{\theta}(h)$
IACFSTD	$Std(\hat{\theta}(h)) = 1/\sqrt{N_0}$
IACFNORM	$Norm(\hat{\theta}(h)) = \hat{\theta}(h)/Std(\hat{\theta}(h))$
IACFPROB	$Prob(\hat{\theta}(h)) = 2\left(1 - \Phi\left(\lvert Norm(\hat{\theta}(h))\rvert\right)\right)$

IACFLPROB	$LogProb(\hat{\theta}(h)) = -\log_{10}(Prob(\hat{\theta}(h))$
IACF2STD	$Flag(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2Std(\hat{\theta}(h)) \\ 0 & -2Std(\hat{\theta}(h)) < \hat{\theta}(h) < 2Std(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2Std(\hat{\theta}(h)) \end{cases}$

White Noise Statistics

WN	$Q(h) = T(T+2)\sum_{j=1}^{h} \rho(j)^2/(T-j)$
WN	$Q(h) = \sum_{j=1}^{h} N_j \rho(j)^2$ embedded missing values
WNPROB	$Prob(Q(h)) = \chi_{\max(1,h-p)}(Q(h))$
WNLPROB	$LogProb(Q(h)) = -\log_{10}(Prob(Q(h))$

Cross-correlation Analysis

Cross-correlation analysis can be performed on the working series by specifying the OUTCROSSCORR= option or one of the CROSSPLOT= options associated with cross-correlation. The CROSSCORR statement enables you to specify options related to cross-correlation analysis.

Cross-correlation Statistics

LAGS	$h \in \{0, \ldots, H\}$
N	N_h is the number of observed products at lag h ignoring missing values
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{T}\sum_{t=h+1}^{T}(x_t - \overline{x})(y_{t-h} - \overline{y})$
CCOV	$\hat{\gamma}_{x,y}(h) = \frac{1}{N_h}\sum_{t=h+1}^{T}(x_t - \overline{x})(y_{t-h} - \overline{y})$ embedded missing values
CCF	$\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h)/\sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$
CCFSTD	$Std(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$
CCFNORM	$Norm(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h)/Std(\hat{\rho}_{x,y}(h))$
CCFPROB	$Prob(\hat{\rho}_{x,y}(h)) = 2\left(1 - \Phi\left(\lvert Norm(\hat{\rho}_{x,y}(h))\rvert\right)\right)$
CCFLPROB	$LogProb(\hat{\rho}_{x,y}(h)) = -\log_{10}(Prob(\hat{\rho}_{x,y}(h))$
CCF2STD	$Flag(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2Std(\hat{\rho}_{x,y}(h)) \\ 0 & -2Std(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2Std(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2Std(\hat{\rho}_{x,y}(h)) \end{cases}$

Data Set Output

The TIMESERIES procedure can create the OUT=, and OUTSUM= data sets. In general, these data sets will contain the variables listed in the BY statement. In general, if an analysis step related to an output data step fails, the values of this step are not recorded or are set to missing in the related output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, and VAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option and missing values are interpreted based on the SETMISSING= option.

OUTCORR= Data Set

The OUTCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCORR= data set records the correlations for each variable specified in a VAR statement.

When the CORR statement TRANSPOSE=NO option is specified, the variable *names* are related to correlation statistics specified in the CORR statement options; the variable *values* are related to the NLAG= or LAGS= options.

NAME	Variable name
LAG	Time lag
N	Number of Variance Products
ACOV	Autocovariances
ACF	Autocorrelations
ACFSTD	Autocorrelation Standard Errors
ACF2STD	Indicates ACF Beyond Two Standard Errors
ACFNORM	Normalized Autocorrelations
ACFPROB	Autocorrelation Probabilities
ACFLPROB	Autocorrelation Log Probabilities
PACF	Partial Autocorrelations
PACFSTD	Partial Autocorrelation Standard Errors
PACF2STD	Indicates PACF Beyond Two Standard Errors
PACFNORM	Partial Normalized Autocorrelations
PACFPROB	Partial Autocorrelation Probabilities
PACFLPROB	Partial Autocorrelation Log Probabilities
IACF	Inverse Autocorrelations
IACFSTD	Inverse Autocorrelation Standard Errors
IACF2STD	Indicates IACF Beyond Two Standard Errors
IACFNORM	Normalized Inverse Autocorrelations
IACFPROB	Inverse Autocorrelation Probabilities
IACFLPROB	Inverse Autocorrelation Log Probabilities
WN	White Noise Test Statistics

WNPROB	White Noise Test Probabilities
WNLPROB	White Noise Test Log Probabilities

The above correlation statistics are computed for each specified time lag.

When the CORR statement TRANSPOSE=YES option is specified, the variable *values* are related to correlation statistics specified in the CORR statement; the variable *names* are related to the NLAG= or LAGS= options.

NAME	Variable name
STAT	Correlation statistic name
LABEL	Correlation statistic label
LAG*h*	Correlation statistics for lag *h*

OUTCROSSCORR= Data Set

The OUTCROSSCORR= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTCROSSCORR= data set records the cross-correlations for each variable specified in a VAR statement.

When the CROSSCORR statement TRANSPOSE=NO option is specified, the variable *names* are related to cross-correlation statistics specified in the CROSSCORR statement options; the variable *values* are related to the NLAG= or LAGS= options.

NAME	Variable name
CROSS	Cross Variable name
LAG	Time lag
N	Number of Variance Products
CCOV	Cross-Covariances
CCF	Cross-correlations
CCFSTD	Cross-correlation Standard Errors
CCF2STD	Indicates CCF Beyond Two Standard Errors
CCFNORM	Normalized Cross-correlations
CCFPROB	Cross-correlation Probabilities
CCFLPROB	Cross-correlation Log Probabilities

The above cross-correlation statistics are computed for each specified time lag.

When the CROSSCORR statement TRANSPOSE=YES option is specified, the variable *values* are related to cross-correlation statistics specified in the CROSSCORR statement; the variable *names* are related to the NLAG= or LAGS= options.

NAME	Variable name
CROSS	Cross Variable name
STAT	Cross-correlation statistic name
LABEL	Cross-correlation statistic label
LAG*h*	Cross-correlation statistics for lag *h*

OUTDECOMP= Data Set

The OUTDECOMP= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTDECOMP= data set records the seasonal decomposition/adjustments for each variable specified in a VAR statement.

When the DECOMP statement TRANSPOSE=NO option is specified, the variable *names* are related to decomposition/adjustments specified in the DECOMP statement; the variable *values* are related to the INTERVAL= and SEASONALITY= options.

NAME	Variable name
MODE	Mode of decomposition
TIMEID	Time ID values
SEASON	Seasonal index
ORIGINAL	Original series values
TCC	Trend-Cycle Component
SIC	Seasonal-Irregular Component
SC	Seasonal Component
SCSTD	Seasonal Component Standard Errors
TCS	Trend-Cycle-Seasonal Component
IC	Irregular Component
SA	Seasonal Adjusted Component
PCSA	Percent Change Seasonal Adjusted Component
TC	Trend Component
CC	CYCLE Component

The above decomposition components are computed for each time period.

When the DECOMP statement TRANSPOSE=YES option is specified, the variable *values* are related to decomposition/adjustments specified in the DECOMP statement; the variable *names* are related to the INTERVAL=, SEASONALITY=, and NPERIODS= options.

NAME	Variable name
MODE	Mode of decomposition name

COMP	Decomposition component name
LABEL	Decomposition component label
PERIOD*t*	Decomposition component value for time period *t*

OUTSEASON= Data Set

The OUTSEASON= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSEASON= data set records the seasonal statistics for each variable specified in a VAR statement.

When the SEASON statement TRANSPOSE=NO option is specified, the variable *names* are related to seasonal statistics specified in the SEASON statement; the variable *values* are related to the INTERVAL= or SEASONALITY= options.

NAME	Variable name
TIMEID	Time ID values
SEASON	Seasonal index
NOBS	Number of Observations
N	Number of Non-Missing Observations
NMISS	Number of Missing Observations
MINIMUM	Minimum Value
MAXIMUM	Maximum Value
RANGE	Maximum Value
SUM	Summation Value
MEAN	Mean Value
STDDEV	Standard Deviation
CSS	Corrected Sum of Squares
USS	Uncorrected Sum of Squares
MEDIAN	Median Value

The above statistics are computed for each season.

When the SEASON statement TRANSPOSE=YES option is specified, the variable *values* are related to seasonal statistics specified in the SEASON statement; the variable *names* are related to the INTERVAL= or SEASONALITY= options.

NAME	Variable name
STAT	Season statistic name
LABEL	Season statistic name
SEASON*s*	Season statistic value for season *s*

OUTSUM= Data Set

The OUTSUM= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSUM= data set records the descriptive statistics for each variable specified in a VAR statement.

Variables related to descripive statistics are based on the ACCUMULATE= and SETMISSING= options:

NAME	Variable name
STATUS	Status flag that indicates whether the requested analyses were successful
NOBS	Number of Observations
N	Number of Non-Missing Observations
NMISS	Number of Missing Observations
MINIMUM	Minimum Value
MAXIMUM	Maximum Value
AVG	Average Value
STDDEV	Standard Deviation

The OUTSUM= data set contains the descriptive statistics of the (accumulated) time series.

OUTTREND= Data Set

The OUTTREND= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTTREND= data set records the trend statistics for each variable specified in a VAR statement.

When the TREND statement TRANSPOSE=NO option is specified, the variable *names* are related to trend statistics specified in the TREND statement; the variable *values* are related to the INTERVAL= or SEASONALITY= options.

NAME	Variable name
TIMEID	Time ID values
SEASON	Seasonal index
NOBS	Number of Observations
N	Number of Non-Missing Observations
NMISS	Number of Missing Observations
MINIMUM	Minimum Value
MAXIMUM	Maximum Value
RANGE	Maximum Value
SUM	Summation Value

MEAN	Mean Value
STDDEV	Standard Deviation
CSS	Corrected Sum of Squares
USS	Uncorrected Sum of Squares
MEDIAN	Median Value

The above statistics are computed for each time period.

When the TREND statement TRANSPOSE=YES option is specified, the variable *values* related to trend statistics specified in the TREND statement; the variable *name* are related to the INTERVAL=, SEASONALITY=, and NPERIODS= options.

NAME	Variable name
STAT	Trend statistic name
LABEL	Trend statistic name
PERIOD*t*	Trend statistic value for time period *t*

Printed Output

The TIMESERIES procedure optionally produces printed output for these results utilizing the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options associated with the PROC TIMESERIES statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error and/or warning messages are recorded in the log. The printed output is similar to the output data set and these similarities are described below.

PRINT=DECOMP

prints the seasonal decomposition similar to the OUTDECOMP= data set.

PRINT=DESCSTATS

prints a table of descriptive statistics for each variable.

PRINT=SEASONS

prints the seasonal statistics similar to the OUTSEASON= data set.

PRINT=SUMMARY

prints the summary statistics similar to the OUTSUM= data set.

PRINT=TRENDS

prints the trend statistics similar to the OUTTREND= data set.

PRINTDETAILS

The PRINTDETAILS option prints each table with greater detail.

Specifically, if PRINT=SEASONS and the PRINTDETAILS options are specified, all seasonal statistics are printed.

ODS Table Names

The table below relates the PRINT= options to ODS tables:

Table 28.2. ODS Tables Produced in PROC TIMESERIES

ODS Table Name	Description	Option
ODS Tables Created by the PRINT=DECOMP option		
SeasonalDecomposition	Seasonal Decomposition	
ODS Tables Created by the PRINT=DESCSTATS option		
DescStats	Descriptive Statistics	
ODS Tables Created by the PRINT=SEASONS option		
GlobalStatistics	Global Statistics	
SeasonStatistics	Season Statistics	
ODS Tables Created by the PRINT=SUMMARY option		
StatisticsSummary	Statistics Summary	
ODS Tables Created by the PRINT=TRENDS option		
GlobalStatistics	Global Statistics	
TrendStatistics	Trend Statistics	

The tables are related to a single series within a BY group.

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the TIMESERIES procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. In addition, you can specify the PLOT= or CROSSPLOT= option in the TIMESERIES statement according to the following syntax. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

PLOT= *option* **| (***options***)**

specifies the univariate graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES	plots time series graphics. (OUT= data set)
RESIDUAL	plots residual time series graphics. (OUT= data set)
CORR	plots correlation panel graphics. (OUTCORR= data set)

ACF	plots autocorrelation function graphics. (OUTCORR= data set)
PACF	plots partial autocorrelation function graphics. (OUTCORR= data set)
IACF	plots inverse autocorrelation function graphics. (OUTCORR= data set)
WN	plots white noise graphics. (OUTCORR= data set)
DECOMP	plots seasonal adjustment panel graphics. (OUTDECOMP= data set)
TCS	plots the trend-cycle-seasonal component graphics. (OUTDECOMP= data set)
TCC	plots the trend-cycle component graphics. (OUTDECOMP= data set)
SIC	plots the seasonal-irregular component graphics. (OUTDECOMP= data set)
SC	plots the seasonal component graphics. (OUTDECOMP= data set)
SA	plots the seasonal adjusted graphics. (OUTDECOMP= data set)
PCSA	plots the percent change seasonal adjusted graphics. (OUTDECOMP= data set)
IC	plots the irregular component graphics. (OUTDECOMP= data set)
TC	plots the trend component graphics. (OUTDECOMP= data set)
CC	plots the cycle component graphics. (OUTDECOMP= data set)
ALL	Same as PLOT=(SERIES ACF PACF IACF WN).

For example, PLOT=SERIES plots the time series. The PLOT= option produces graphical output for these results utilizing the Output Delivery System (ODS). The PLOT= option produces results similar to the data sets listed next to the above options in parenthesis.

CROSSPLOT= *option* **|** **(***options***)**

specifies the cross-variable graphical output desired. By default, the TIMESERIES procedure produces no graphical output. The following plotting options are available:

SERIES	plots time series graphics. (OUT= data set)
CCF	plots autocorrelation function graphics. (OUTCORR= data set)
ALL	Same as PLOT=(SERIES CCF).

For example, CROSSPLOT=SERIES plots the two time series. The CROSSPLOT= option produces graphical output for these results utilizing the Output Delivery System (ODS). The CROSSPLOT= option produces results similar to the data sets listed next to the above options in parenthesis.

ODS Graph Names

PROC TIMESERIES assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 28.3.

To request these graphs, you must specify the ODS GRAPHICS statement. In addition, you can specify the PLOT= or CROSSPLOT= option in the TIMESERIES statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 28.3. ODS Graphics Produced by PROC TIMESERIES

ODS Graph Name	Plot Description	Statement	PLOT= Option
ACFPlot	Autocorrelation Function	TIMESERIES	PLOT=ACF
ACFNORMPlot	Standardized Autocorrelation Function	TIMESERIES	PLOT=ACF
CCFNORMPlot	Standardized Cross-correlation Function	TIMESERIES	CROSSPLOT=CCF
CCFPlot	Cross-correlation Function	TIMESERIES	CROSSPLOT=CCF
CorrelationPlots	Correlation Graphics Panel	TIMESERIES	PLOT=CORR
CrossSeriesPlot	Cross Series Plot	TIMESERIES	CROSSPLOT=SERIES
CycleComponentPlot	Cycle Component	TIMESERIES	PLOT=CC
DecompositionPlots	Decomposition Graphiics Panel	TIMESERIES	PLOT=DECOMP
IACFPlot	Inverse Autocorrelation Function	TIMESERIES	PLOT=IACF
IACFNORMPlot	Standardized Inver-se Autocorrelation Function	TIMESERIES	PLOT=IACF
IrregularComponentPlot	Irregular Component	TIMESERIES	PLOT=IC
PACFPlot	Partial Autocorrelation Function	TIMESERIES	PLOT=PACF
PACFNORMPlot	Standardized Partial Autocorrelation Function	TIMESERIES	PLOT=PACF
PercentChangeAdjustedplot	Percent-Change Seasonally Adjusted	TIMESERIES	PLOT=SA

Examples

Example 28.1. Accumulating Transactional Data into Time Series Data

This example illustrates the accumulation of time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency using the TIMESERIES procedure. Once the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP.

The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START=’01JAN1998’D) and last day of 2000 (END=’31JAN2000’D).are considered and if needed extended to include this range.

```
proc timeseries data=work.retail out=mseries;
   by store;
   id timestamp interval=month accumulate=median setmiss=0
      start=’01jan1998’d
      end  =’31dec2000’d;
   var _ALL_;
run;
```

The monthly time series data are stored in the data WORK.MSERIES. Each BY group associated with the BY variable STORE will contain an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation will contain the variable STORE, TIMESTAMP, and each of the analysis variables in the input data set.

Once each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM.

```
proc expand data=mseries out=smoothed from=month;
   by store;
   id date;
   convert storeitem=smooth / transform=(ewma 0,1);
run;
```

The decomposed series are stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contained SAS datetime values instead of SAS date values, the INTERVAL= , START=, and END= option must be changed accordingly and the following statements could be used.

```
proc timeseries data=work.retail out=tseries;
   by store;
   id timestamp interval=dtmonth accumulate=median setmiss=0
      start='01jan1998:00:00:00'dt
      end  ='31dec2000:00:00:00'dt;
   var _ALL_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES and the time ID values use a SAS datetime representation.

Example 28.2. Trend and Seasonal Analysis

This example illustrates trend and seasonal analysis of time-stamped transactional data using the TIMESERIES procedure.

Suppose that the data set SASHELP.AIR contains two variable DATE and AIR. The variable DATE contains sorted SAS date values recorded at no particular frequency. The variable AIR contains the transaction values to be analyzed.

The following statements accumulate the transactional data on an average basis to form a quarterly time series and perform trend and seasonal analysis on the transactions.

```
proc timeseries data=sashelp.air out=series
                outtrend=trend outseason=season print=seasons;
   id date interval=qtr accumulate=avg;
   var air;
run;
```

The time series is stored in the data set WORK.SERIES, the trend statistics are stored in the data set WORK.TREND, and the seasonal statistics are stored in the data set WORK.SEASON. Additionally, the seasonal statistics are printed (PRINT=SEASONS) and the results of the seasonal analysis are shown in Output 28.2.1.

Output 28.2.1. Seasonal Statistics Table

```
                              The TIMESERIES Procedure

                         Season Statistics for Variable AIR

Season                                                                    Standard
 Index        N      Minimum      Maximum          Sum         Mean      Deviation

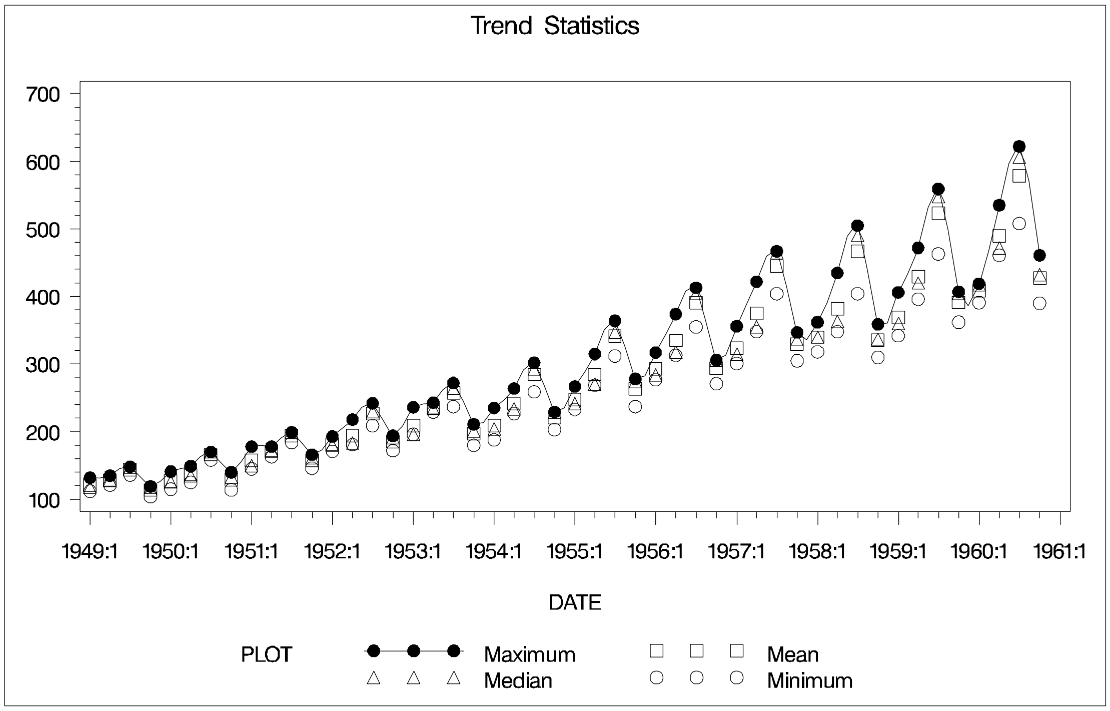
     1       36     112.0000     419.0000      8963.00     248.9722       95.65189
     2       36     121.0000     535.0000     10207.00     283.5278      117.61839
     3       36     136.0000     622.0000     12058.00     334.9444      143.97935
     4       36     104.0000     461.0000      9135.00     253.7500      101.34732
```

Using the trend statistics stored in the WORK.TREND data set, the following statements plot various trend statistics associated with each time period over time.

```
title1 "Trend Statistics";
legend1 value=("Maximum" "Mean" "Median" "Minimum");
symbol interpol=spline;
axis2 label=none;
proc gplot data=trend;
   plot max    *date
        mean   *date
        median *date
        min    *date
        / overlay vaxis=axis2 legend=legend1;
 run;
```

The results of this trend analysis are shown in Output 28.2.2.

Output 28.2.2. Trend Statistics Plot

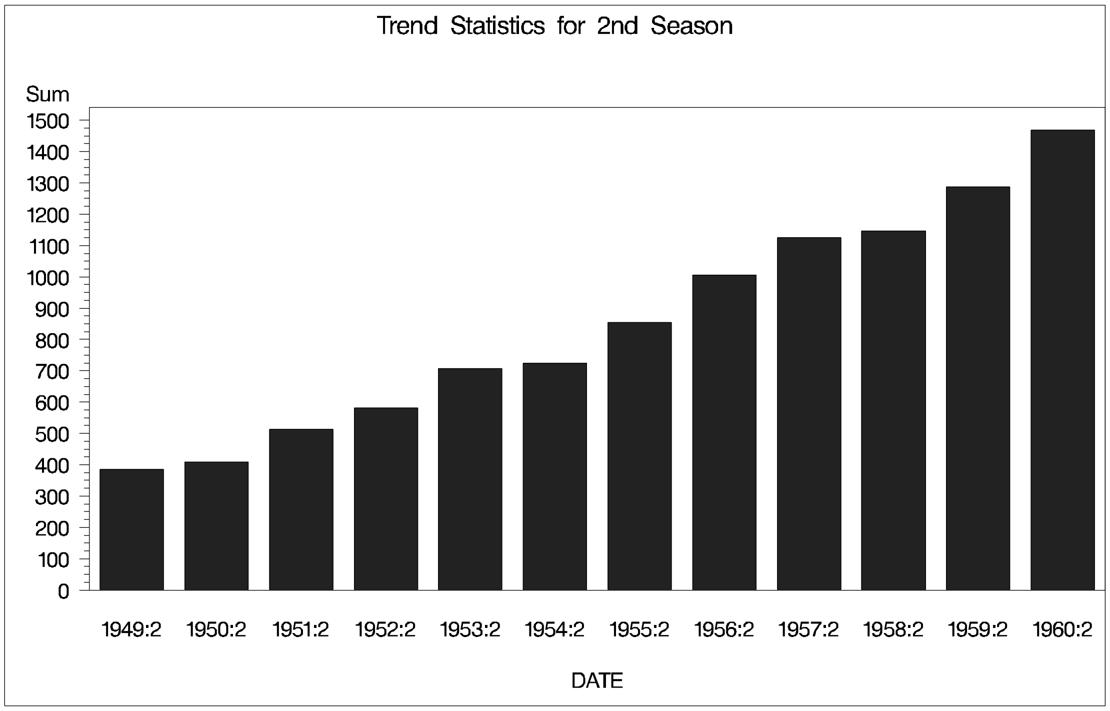


Using the trend statistics stored in the WORK.TREND data set, the following statements chart the sum of the transactions associated with each time period for the second season over time.

```
title1 "Trend Statistics for 2nd Season";
proc gchart data=trend;
   where _season_ = 2;
   vbar date / sumvar=sum discrete;
run;
quit;
```

The results of this trend analysis are shown in Output 28.2.3.

Output 28.2.3. Trend Statistics Plot



Using the trend statistics stored in the WORK.TREND data set, the following statements plot the mean of the transactions associated with each time period by each year over time.

```
data trend;
   set trend;

Example 28.3. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics.

The following statements utilize the SASHELP.WORKERS data set to study the time series of electrical workers, and its interaction with the series of masonry workers. The series plot, the correlation panel, the seasonal adjustment panel, and all cross-series plots are requested. Output 28.3.1 through Output 28.3.4 show a selection of the plots created.

The graphical displays are requested by specifying the experimental ODS GRAPHICS statement and the experimental PLOT= or CROSSPLOT= options in the PROC TIMESERIES statement. For general information about ODS graphics, see Chapter 9, “Statistical Graphics Using ODS.” For specific information about the graphics available in the TIMESERIES procedure, see the “ODS Graphics” section on page 1603.

Chapter 29
The UCM Procedure

Overview

The UCM procedure analyzes and forecasts equally spaced univariate time series data using the Unobserved Components Models (UCM). The UCMs are also called *Structural Models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in *explaining* and *predicting* its behavior. Harvey (1989) is a good reference for time series modeling using the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the Exponential Smoothing models, have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of the UCM and ARIMA modeling is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *Dynamic Models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS you can use PROC ARIMA for the ARIMA modeling and the Time Series Forecasting System for a point-and-click interface to the ARIMA and exponential smoothing modeling.

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of the time series analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety purposes. For example, it can be used for

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or “smoothed” estimates of the component series in the model

Experimental graphics are now available with the UCM procedure. For more information, see the "ODS Graphics" section on page 1664.

Getting Started

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for modeling the commonly observed features in time series. These models are discussed in detail later in this section. First the procedure is illustrated using a few examples.

A Seasonal Series with a Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a continual rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. These trend and seasonal features of the series are apparent in the following plot (Figure 29.1):

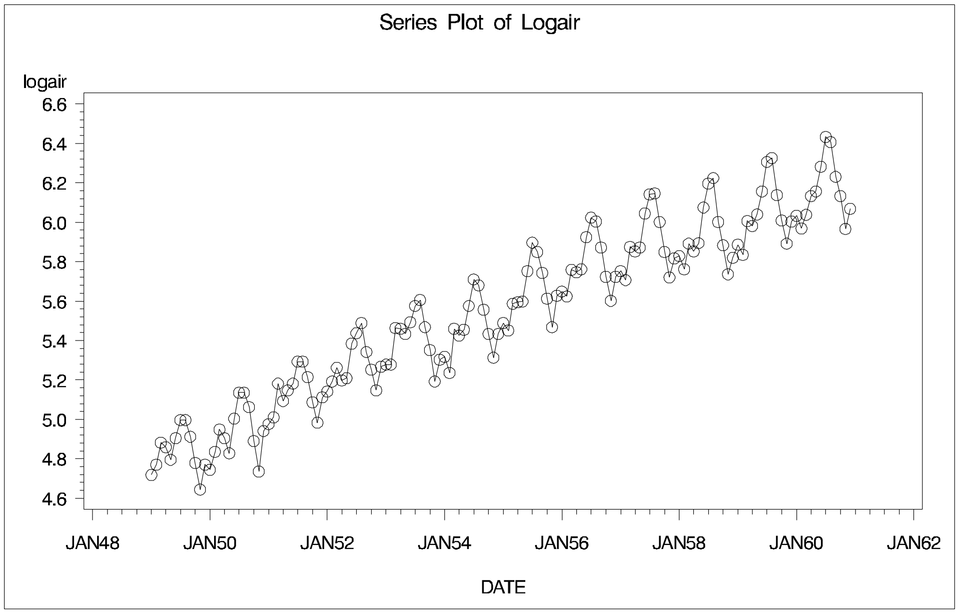

Figure 29.1. Series Plot of Log Transformed Airline Passenger Series

In this example this series will be modeled using an unobserved component model called the Basic Structural Model (BSM). The BSM models a time series as a sum of three stochastic components; a trend component μ_t, a seasonal component γ_t, and random error ϵ_t. Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t, also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (i.i.d.) zero mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad & \eta_t &\sim i.i.d.\ N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d.\ N(0, \sigma_\xi^2) \end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective equations. Some interesting special cases of this model arise by manipulating these disturbance variances. For example, if the variance of ξ_t is zero, the slope will be constant (equal to β_0) and, if in addition, the variance of η_t is also zero, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later. However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following SAS statements specify a BSM with these three components:

```
proc ucm data=series_g;
     id date interval=month;
     model logair;
     irregular;
     level;
     slope;
     season length=12 type=trig print=smooth;
     estimate;
     forecast lead=24 print=decomp;
 run;
```

The PROC statement signifies the start of the UCM procedure and the input data set containing the dependent series is specified there. The optional ID statement is used to specify a date, datetime, or time identification variable, *date* in this example, to label the observations. The INTERVAL=MONTH option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the MODEL statement, where the dependent series is specified (*logair* in this case). After this the components in the model are specified using separate statements that enable controlling their individual properties. The IRREGULAR statement is used to specify the irregular component ϵ_t, and the trend component μ_t is specified using the LEVEL and SLOPE statements. The seasonal component γ_t is specified using the SEASON statement. The specifics of the seasonal characteristics such as its season length, its stochastic evolution properties, etc, are specified using the options in the SEASON statement. The seasonal used in this example has season length 12, corresponding to the monthly seasonality, and is of the *trigonometric* type (different types of seasonals are explained later in this section). The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t, β_t and γ_t and the variance of the *irregular* component ϵ_t. These parameters are estimated by maximizing the likelihood of the data. The ESTIMATE statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts, for example, PRINT=SMOOTH option in the SEASON statement requests the displaying of smoothed forecasts of the seasonal component γ_t. The series forecasts and forecasts of the sum of components can be requested using the FORECAST statement. The option PRINT=DECOMP in the FORECAST statement requests the printing of the smoothed trend μ_t and the trend plus seasonal ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in Figure 29.2.

```
                                The UCM Procedure

                       Final Estimates of the Free Parameters

                                                       Approx                 Approx
Component    Parameter          Estimate    Std Error    t Value    Pr > |t|

Irregular    Error Variance     0.00023436    0.0001079       2.17      0.0298
Level        Error Variance     0.00029828    0.0001057       2.82      0.0048
Slope        Error Variance     9.8572E-13   6.7141E-10       0.00      0.9988
Season       Error Variance     0.00000356   1.32347E-6       2.69      0.0072
```

Figure 29.2. BSM for the Logair Series

The estimates suggest that except for the slope component the disturbance variances of all the components are significant, that is, all these components are stochastic. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It may then be useful to check if the slope component can be dropped from the model, that is if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in Figure 29.3.

```
                    Significance Analysis of Components
                         (Based on the Final State)

                Component         DF     Chi-Square     Pr > ChiSq

                Irregular          1           0.08         0.7747
                Level              1         117867         <.0001
                Slope              1          43.78         <.0001
                Season            11         507.75         <.0001
```

Figure 29.3. Component Significance Analysis for the Logair Series

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic then this analysis only pertains to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant towards the end of the estimation span, however, since it is a *stochastic* component it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
   slope variance=0 noest;
```

After a tentative model is fit its adequacy can be checked by examining different Goodness of Fit measures and other diagnostic tests and plots that are based on the model residuals. The table given in Figure 29.4 shows the goodness fit statistics that are computed using the one step ahead prediction errors (see "Statistics of Fit"). These measures indicate a good agreement between the model and the data. Additional diagnostics measures are also printed by default but are not shown here.

```
                              The UCM Procedure

                       Fit Statistics Based on Residuals

                 Mean Squared Error                     0.00147
                 Root Mean Squared Error                0.03830
                 Mean Absolute Percentage Error         0.54132

                 Amemiya's Adjusted R-Square            0.99017

                   Number of non-missing residuals used for
                      computing the fit statistics = 131
```

Figure 29.4. Fit Statistics for the Logair Series

Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the model. The plots of component forecasts can be useful in understanding their contributions to the series. In what follows, a few such plots are shown. The first plot (Figure 29.5) shows the smoothed trend of the series.

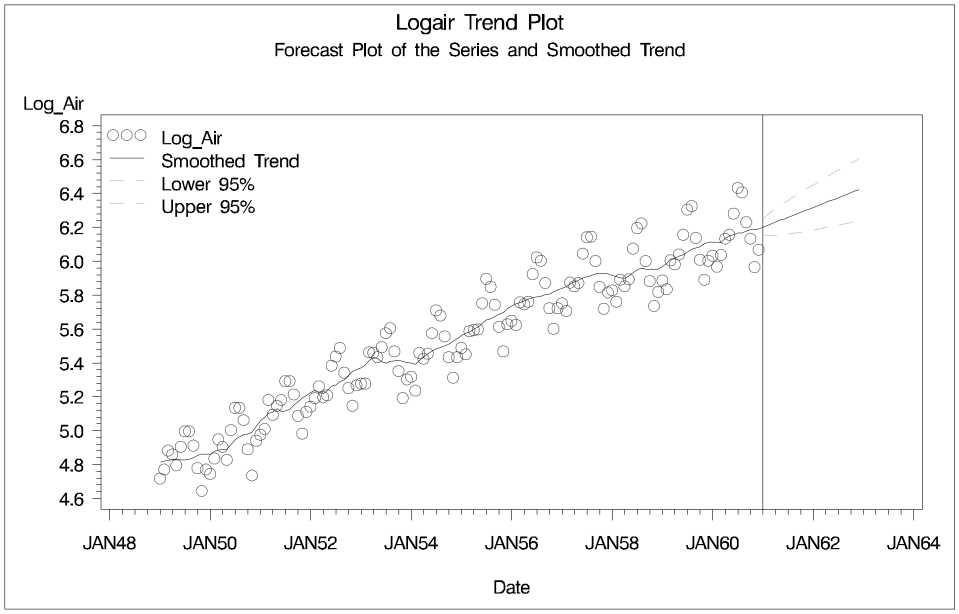

Figure 29.5. Smoothed Trend in the Logair Series

The second plot (Figure 29.6) shows the seasonal component by itself.

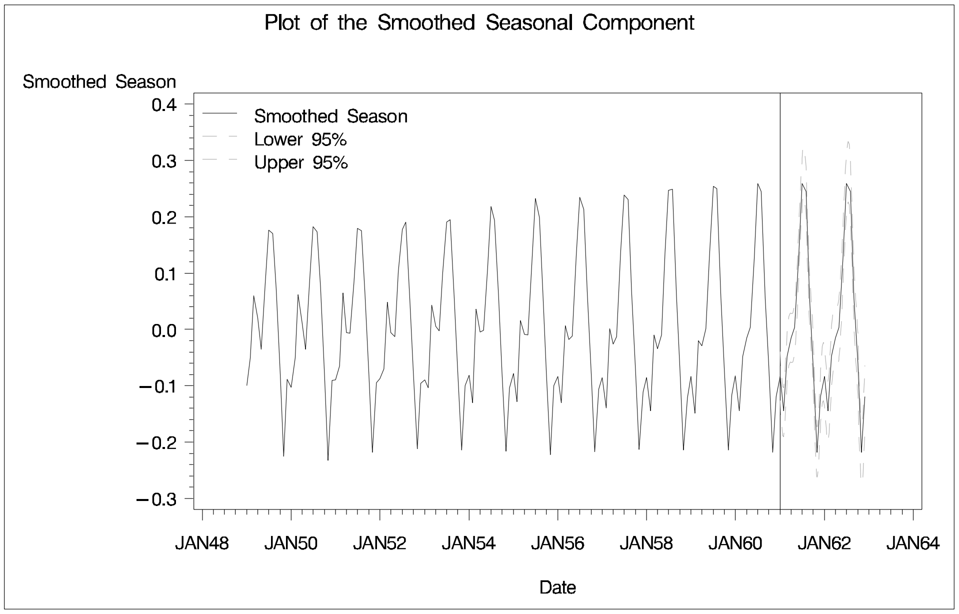

Figure 29.6. Smoothed Seasonal in the Logair Series

The plot of the sum of trend and seasonal is shown in Figure 29.7. You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future.

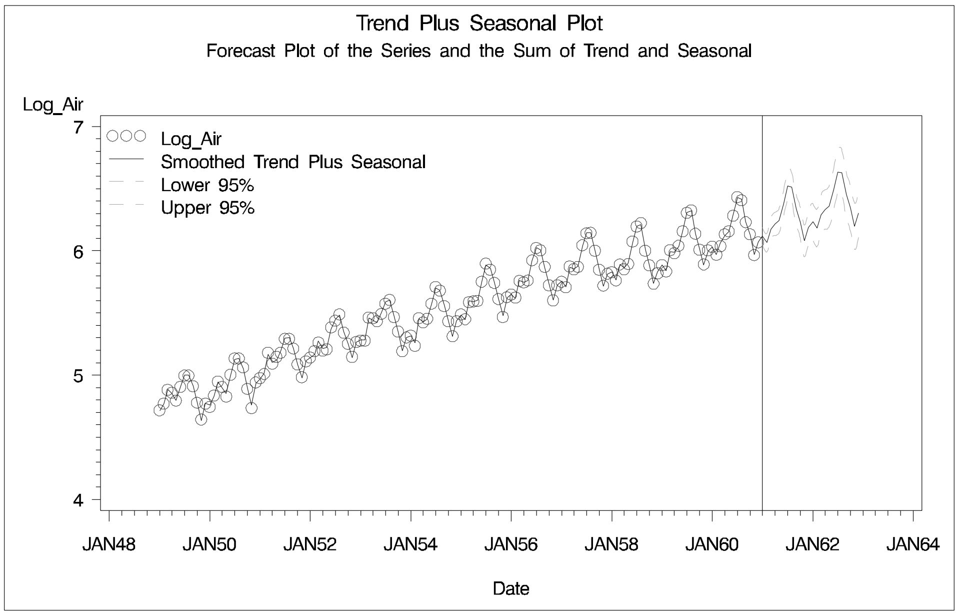

Figure 29.7. Smoothed Trend plus Seasonal in the Logair Series

A Series with Cyclical Component

In this example another well known series, Wolfer's sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with period of about eleven years. A time series plot of this series is given in Figure 29.8. From the plot it is difficult to discern any other specific pattern to these numbers.

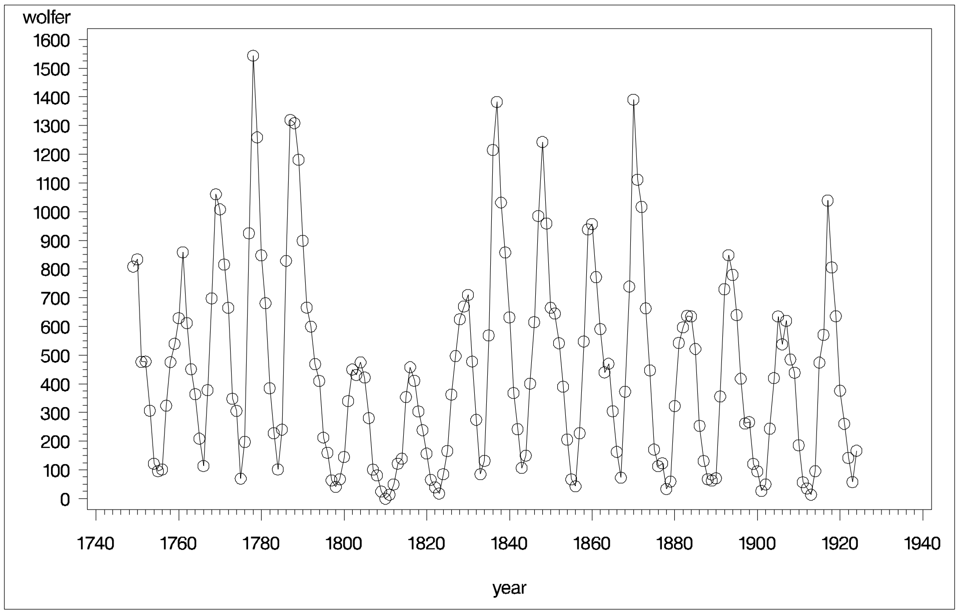

Figure 29.8. Wolfer Sunspot Numbers

The following syntax specifies a UCM that includes a cycle component and a level component.

```
proc ucm data=sunspot;
     id year interval=year;
     model wolfer;
     irregular;
     level;
     cycle print=smooth;
     estimate;
     forecast lead=12 print=decomp;
 run;
```

In this model the trend of the series is modeled as a time-varying level component without any persistent upward or downward drift, that is, no slope component is included. The cyclical behavior of the series is modeled using a cycle component that is a damped sinusoidal with fixed period and time varying amplitude. The parameters of the cycle are its period, the damping factor, and the variance of the disturbance terms in its stochastic equations. They are estimated from the data. In this case the estimate of the cycle period turns out to be approximately 10.58 years, consistent with the known results. As in the earlier example, it is informative to see the decomposition plots of the series. The first plot (Figure 29.9) shows the smoothed trend of the series.

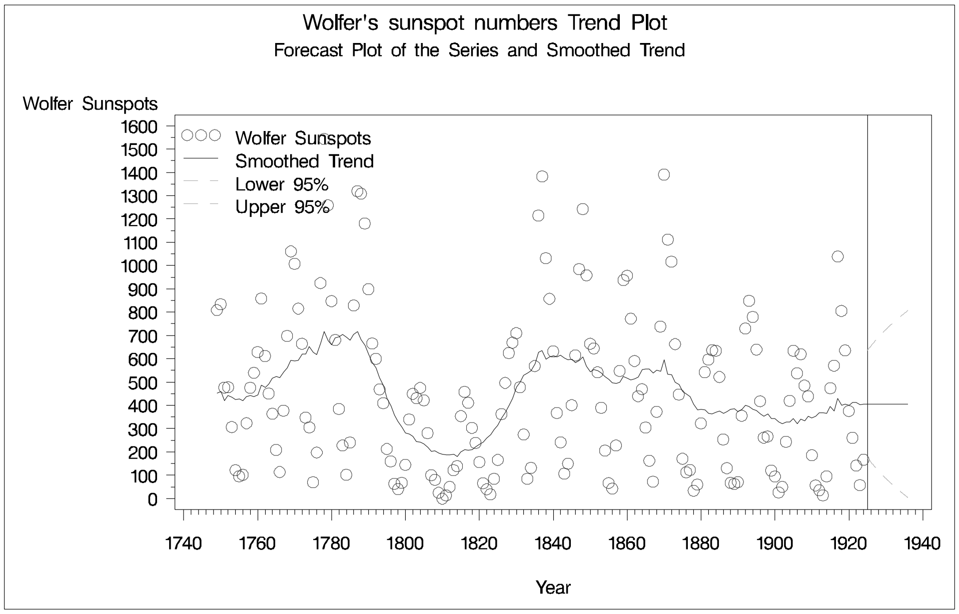

Figure 29.9. Smoothed Trend

The second plot shows the cycle component (Figure 29.10).

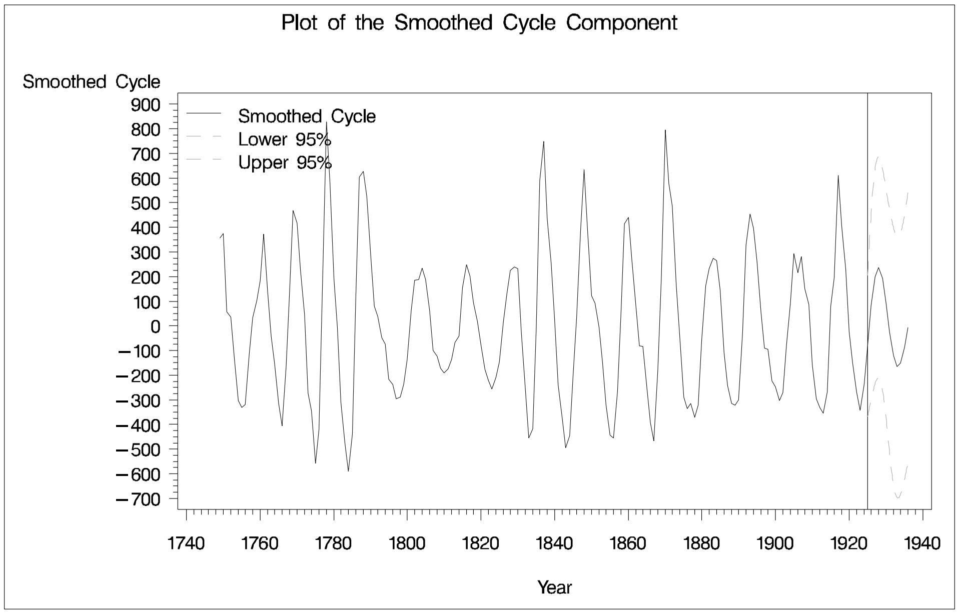

Figure 29.10. Smoothed Cycle

The plot of sum of trend and cycle is shown in Figure 29.11.

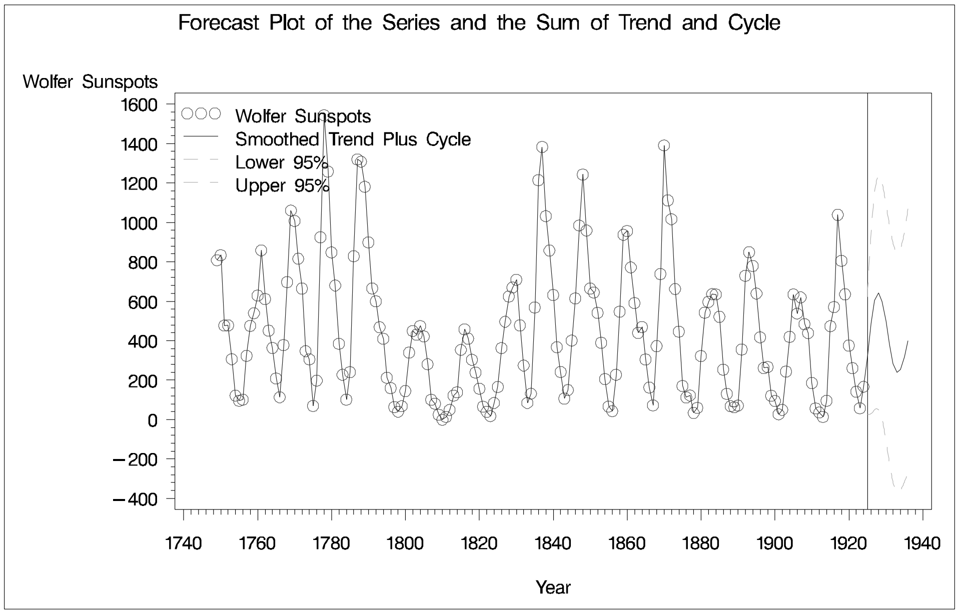

Figure 29.11. Plot of Smoothed Trend Plus Cycle

A Series with Level Shift

In this example the series consists of the yearly level readings of the river Nile recorded at Aswan (see Cobb 1978). The data consists of readings from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in Figure 29.12.

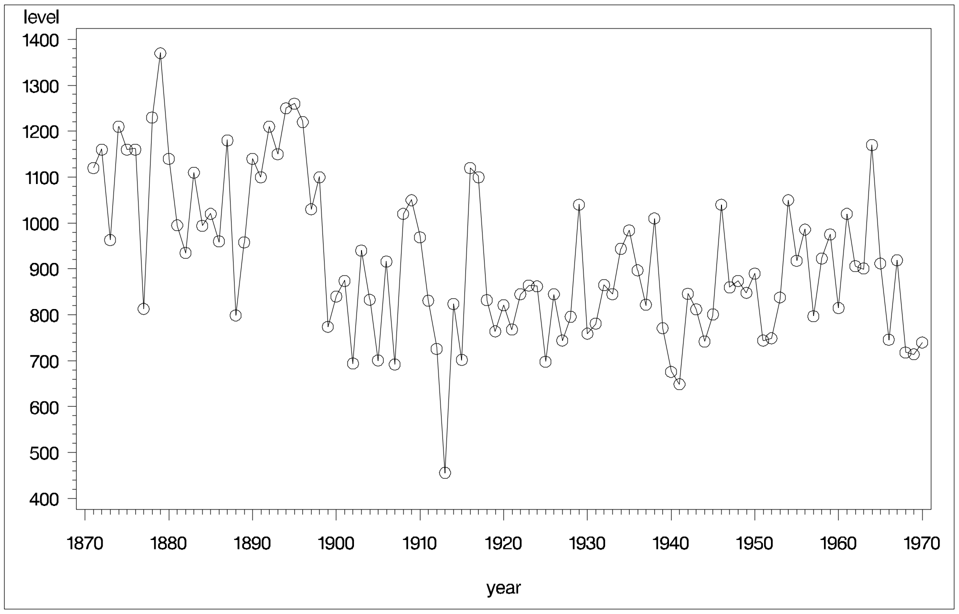

Figure 29.12. Nile River Level

The following syntax specifies a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (Shift1899).

```
proc ucm data=nile;
   id year interval=year;
   model nile_level = shift1899;
   irregular;
   level;
   estimate;
   forecast print=decomp;
run;
```

The decomposition plots of this model can be easily obtained. However, it is instructive to see the plot of the smoothed trend obtained without using this regressor in the model. This plot is given in Figure 29.13. The plot shows a noticeable drop in the smoothed river level around 1899.

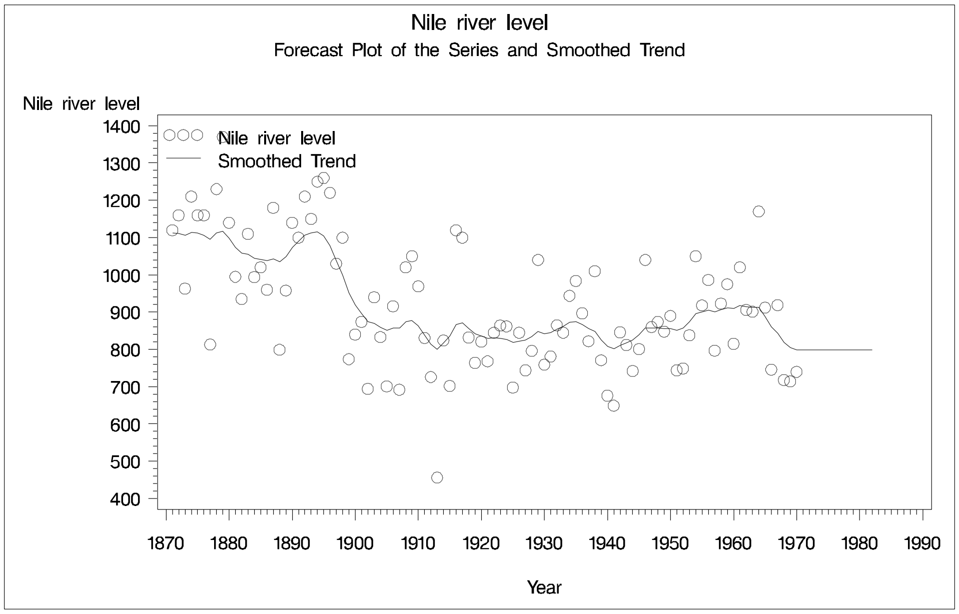

Figure 29.13. Smoothed Trend without the Shift of 1899

The second plot shows the smoothed trend including the correction due to the shift in the year 1899 (Figure 29.14). Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

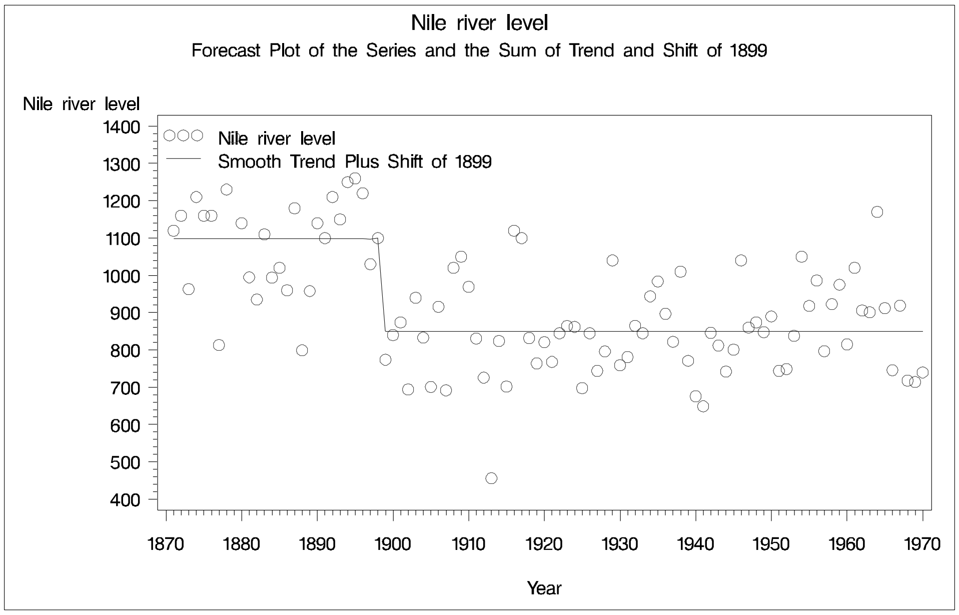

Figure 29.14. Smoothed Trend Plus Shift of 1899

An Introduction to Unobserved Component Models

A general UCM considered in this procedure can be described as

$$\begin{aligned} y_t &= \mu_t + \gamma_t + \psi_t + r_t + \sum_{i=1}^{p} \phi_i y_{t-i} + \sum_{j=1}^{m} \beta_j x_{jt} + \epsilon_t \\ \epsilon_t &\sim i.i.d.\ N(0, \sigma_\epsilon^2) \end{aligned}$$

The terms μ_t, γ_t, ψ_t, and r_t represent the trend, seasonal, cyclical and the autoregressive components, respectively. In fact the model can contain multiple seasonals and cycles, and the seasonals can be of different types. For simplicity of discussion the above model contains only one of each of these components. The regression term, $\sum_{j=1}^{m} \beta_j x_{jt}$, includes variables with values supplied in the input dataset. The $\sum_{i=1}^{p} \phi_i y_{t-i}$ is a regression term involving the lags of the dependent variable. It is written separately because its mathematical treatment is slightly different (see "Details"). The disturbance term ϵ_t, also called the $irregular$ component, is assumed to be a Gaussian white noise with variance σ_ϵ^2. By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t, γ_t, ψ_t, and r_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t. The first model, called the Random Walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d.\ N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$ then the model becomes $\mu_t = constant$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The model for μ_t is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim i.i.d.\ N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, \qquad \xi_t \sim i.i.d.\ N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to zero. If σ_ξ^2 is set equal to zero then you get a linear trend model with fixed slope. If σ_η^2 is set to zero then the resulting model usually has a smoother trend. If both the variances are set to zero then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

These trend patterns can be incorporated in your model using the LEVEL and SLOPE statements in PROC UCM.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ, $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $(\alpha^2 + \beta^2)^{1/2}$, and phase $\tan^{-1}(\beta/\alpha)$. However, if ψ_t is measured only at the integer values it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k. The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed period but time varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t:

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ, for additional modeling flexibility. This model can be described as follows:

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where $0 \le \rho \le 1$, and the disturbances ν_t and ν_t^* are independent $N(0, \sigma_\nu^2)$ variables. The resulting stochastic cycle has a fixed period but time varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ. If $\rho < 1$, ψ_t has a stationary distribution with mean zero and variance $\sigma_\nu^2/(1-\rho^2)$. If $\rho = 1$, ψ_t is non-stationary.

A cycle is incorporated in a UCM by using a CYCLE statement in PROC UCM. Multiple cycles can be included in the model using separate CYCLE statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonals is considered next.

Modeling a Seasonal

The seasonal fluctuations are a common source of variation in the time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \qquad \omega_t \sim i.i.d.\ N(0, \sigma_\omega^2)$$

The other type of model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given as follows:

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and equals $(s-1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos\lambda_j & \sin\lambda_j \\ -\sin\lambda_j & \cos\lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j, $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals the situation may not be so transparent; however, similar considerations still apply. Note that, if the disturbance variance $\sigma_\omega^2 = 0$ then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

The dummy and the trigonometric type seasonals defined above can be considered as *saturated* seasonals that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal may be more appropriate. This is particularly useful for seasonals with large season lengths. Parsimonious representations of the seasonals can be obtained in several different ways. Some of these ways involve the reuse of the already introduced cycle and seasonal components. One possibility is to consider special cases of the trigonometric seasonals obtained by deleting a few of the $[s/2]$ harmonics used in the sum. For example, a slightly smoother seasonal of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest frequency harmonic of period 2. That is, such a seasonal will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. Another possibility is to consider a seasonal of a large season length as a sum of two or more seasonals that are each of much smaller season lengths. One more possibility is to restrict the seasonal values within certain blocks to be the same. An example of such a situation is as follows: Consider an hourly series that may show periodic variation that is attributable to the day of the week, and to the hour of the day. The hour of the day effect can be modeled as a simple saturated seasonal of season length 24. The day of the week effect could be modeled as a seasonal of season length 168 that restricts the seasonal values within a given day to be equal. Such a seasonal could be called a block-seasonal of season length 7 and block length 24.

These different types of seasonal patterns can be included in a UCM using a combination of SEASON, BLOCKSEASON, and CYCLE statements in PROC UCM.

Modeling the Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π. Modeling this special case separately helps interpretation and parameter estimation. The auto-regression component r_t is modeled as follows:

$$r_t = \rho r_{t-1} + \nu_t, \quad \nu_t \ \sim \ i.i.d. \ \ N(0, \sigma_\nu^2)$$

where $-1 \leq \rho < 1$.

The Regression Terms

The regression terms $\sum_{j=1}^{m} \beta_j x_{jt}$ and $\sum_{i=1}^{p} \phi_i y_{t-i}$ supply additional flexibility to the model. Lags, differences, and other transformations can be applied to the variables.

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and the seasonal components. This model is called the Basic Structural Model (BSM) by Harvey. The syntax for a BSM with monthly seasonality of trigonometric type is

```
model y;
   irregular;
   level;
   slope;
   season length=12 type=trig;
```

Similarly the syntax

```
model y = x;
   irregular;
   level;
   slope variance=0 noest;
   season length=12 type=dummy;
```

specifies a BSM with dependent variable y, a regressor x and dummy type monthly seasonality. Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
   irregular;
   level;
   cycle;
   cycle;
```

Syntax

Syntax

The UCM procedure uses the following statements.

PROC UCM *options*;
  BY *variables*;
  ID *variable options*;
  MODEL *dependent variable < = regressors >* ;
  IRREGULAR *options*;
  LEVEL *options*;
  SLOPE *options*;
  SEASON *options*;
  BLOCKSEASON *options*;
  CYCLE *options*;
  AUTOREG *options*;
  DEPLAG *options*;
  ESTIMATE *options*;
  FORECAST *options*;
  NLOPTIONS *options*;

Functional Summary

The statements and options controlling the UCM procedure are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify the input data set	PROC UCM	DATA=
write parameter estimates to an output data set	ESTIMATE	OUTEST=
write forecasts and smoothed values of the response series and components to an output data set	FORECAST	OUTFOR=
BY Groups		
specify BY-group processing	BY	
ID Variable		
specify a date or time identification variable	ID	
specify the time interval between observations	ID	INTERVAL=
control the alignment of SAS Date values	ID	ALIGN=
Options for Specifying the Model		

Description	Statement	Option
specify the response series and, optionally, the predictor series	MODEL	
specify the initial value for the disturbance variance of the irregular component	IRREGULAR	VARIANCE=
fix the value of the disturbance variance of the irregular component to the specified initial value	IRREGULAR	NOEST
specify the initial value for the disturbance variance of the level component	LEVEL	VARIANCE=
fix the value of the disturbance variance of the level component to the specified initial value	LEVEL	NOEST
specify the initial value for the disturbance variance of the slope component	SLOPE	VARIANCE=
fix the value of the disturbance variance of the slope component to the specified initial value	SLOPE	NOEST
specify the season length of a seasonal component	SEASON	LENGTH=
specify the type of a seasonal component	SEASON	TYPE=
specify the initial value for the disturbance variance of a seasonal component	SEASON	VARIANCE=
fix the value of the disturbance variance of the seasonal component to the specified initial value	SEASON	NOEST
specify the block size of a block seasonal component	BLOCKSEASON	BLOCKSIZE=
specify the number of blocks of a block seasonal component	BLOCKSEASON	NBLOCKS=
specify the relative position of the first observation within the block of a block seasonal component	BLOCKSEASON	OFFSET=
specify the initial value for the disturbance variance of a block seasonal component	BLOCKSEASON	VARIANCE=
fix the value of the disturbance variance of the block seasonal component to the specified initial value	BLOCKSEASON	NOEST
specify the initial value for the period of a cycle component	CYCLE	PERIOD=
specify the initial value for the damping factor of a cycle component	CYCLE	RHO=
specify the initial value for the disturbance variance of the cycle component	CYCLE	VARIANCE=
fix the values of the parameters of the cycle component to the specified initial values	CYCLE	NOEST=
specify the initial value for the damping factor of the autoreg component	AUTOREG	RHO=
specify the initial value for the disturbance variance of the autoreg component	AUTOREG	VARIANCE=
fix the values of the parameters of the autoreg component to the specified initial values	AUTOREG	NOEST=

Description	**Statement**	**Option**
specify the lags of the response series to be included in the model	DEPLAG	LAGS=
specify the initial values for the lag coefficients for the response lags	DEPLAG	PHI=
fix the values of lag coefficients to the specified initial values	DEPLAG	NOEST
Options to Control the Nonlinear Optimization in Estimation Process		
specify an optimization algorithm	NLOPTIONS	TECH=
limit number of iterations during the optimization	NLOPTIONS	MAXITER=
limit number of function evaluations	NLOPTIONS	MAXFUNC=
specify function convergence criteria	NLOPTIONS	ABSFTOL=
specify gradient convergence criteria	NLOPTIONS	ABSGTOL=
specify parameter convergence criteria	NLOPTIONS	ABSXTOL=
Options to Control the Observation Span in Estimation and Forecasting		
specify how many starting response series measurements to exclude during the model estimation phase	ESTIMATE	SKIPFIRST=
specify how many ending response series measurements to exclude during the model estimation phase	ESTIMATE	BACK=
specify how many starting response series measurements to exclude during the forecasting phase	FORECAST	SKIPFIRST=
specify how many ending response series measurements to exclude during the forecasting phase	FORECAST	BACK=
specify how many periods to forecast beyond the forecast span	FORECAST	LEAD=
specify size of forecast confidence limits	FORECAST	ALPHA=
Options to Control the Printing		
suppress printing altogether	PROC UCM	NOPRINT
turn all the print options on	PROC UCM	PRINTALL
suppress the printing of parameter estimates, goodness of fit statistics, and other estimation output	ESTIMATE	PRINT=
suppress printing of forecast output	FORECAST	PRINT=
print filtered or smoothed estimate of the irregular component	IRREGULAR	PRINT=
print filtered or smoothed estimate of the level component	LEVEL	PRINT=
print filtered or smoothed estimate of the slope component	SLOPE	PRINT=
print filtered or smoothed estimate of the autoreg component	AUTOREG	PRINT=
print filtered or smoothed estimate of a cycle component	CYCLE	PRINT=

Description	**Statement**	**Option**
print filtered or smoothed estimate of a seasonal component	SEASON	PRINT=
print filtered or smoothed estimate of a block seasonal component	BLOCKSEASON	PRINT=
print parameter estimation related information	ESTIMATE	PRINT=
print forecasts, and smoothed estimates of model decomposition	FORECAST	PRINT=

PROC UCM Statement

PROC UCM *options;*

The following options can be used in the PROC UCM statement:

DATA= *SAS-data-set*
specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in PROC UCM statement, the most recently created SAS data set is used.

NOPRINT
turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PRINTALL
turns on all the printing options for the procedure. The subsequent noprint options in the procedure are ignored.

BY Statement

BY *variables;*

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables.

ID Statement

ID *variable* **INTERVAL=** *value* < **ALIGN=** *value* > **;**

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. Note that the ID *variable* is usually a SAS date, time, or date-time variable. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN= *value*
controls the alignment of SAS dates used to identify output observations. The

ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL= *value*

specifies the time interval between observations. This option is required in the ID statement. The INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data.

MODEL Statement

MODEL *dependent* < = *regressors* > **;**

The MODEL statement specifies the response variable and, optionally, the predictor variables for the UCM model. This is a required statement in the procedure.

IRREGULAR Statement

IRREGULAR < *options* > **;**

The IRREGULAR statement is used to include an *irregular* component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error, ϵ_t, in the model; it is modeled as a sequence of independent, zero mean, Gaussian random variables with variance σ_ϵ^2. The options in this statement enable you to specify the value of σ_ϵ^2 and to output the forecasts of ϵ_t. As a default, σ_ϵ^2 is estimated using the data and the component forecasts are not saved or displayed. A few examples of the IRREGULAR statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an *irregular* component with unknown variance.

```
irregular;
```

The following statement provides a starting value for σ_ϵ^2, to be used in the non-linear parameter estimation process. It also requests the printing of smoothed predictions of ϵ_t. The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

NOEST

This option fixes the value of σ_ϵ^2 to the value specified in the VARIANCE= option.

PRINT= FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)

This option requests printing of filtered or smoothed estimate of the irregular component.

VARIANCE= *value*

This option is used to supply an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

LEVEL Statement

LEVEL < *options* > **;**

The LEVEL statement is used to include a *level* component in the model. The level component, either by itself or, together with a *slope* component, form the *trend* component, μ_t, of the model. If the slope component is absent, the resulting trend is a Random Walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim i.i.d.\ N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a SLOPE statement that is explained later, a Locally Linear Trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad & \eta_t &\sim i.i.d.\ N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim i.i.d.\ N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the LEVEL statement are used to specify the value of σ_η^2 and to request forecasts of μ_t. The SLOPE statement is used for similar purposes in the case of slope β_t. The following examples illustrate the use of LEVEL statement. Assuming that a SLOPE statement is not added subsequently, a simple Random Walk trend is specified by the following statement:

```
level;
```

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t. The value of σ_ξ^2, the disturbance variance in the slope equation, will be estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

NOEST
This option fixes the value of σ_η^2 to the value specified in the VARIANCE= option.

PRINT=FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)
This option requests printing of filtered or smoothed estimate of the level component.

VARIANCE= *value*
This option is used to supply an initial value for σ_η^2, the disturbance variance in the μ_t equation, at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SLOPE Statement

SLOPE < *options* > **;**

The SLOPE statement is used to include a *slope* component in the model. The slope component cannot be used without the level component. The level and slope specifications jointly define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement will be ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t, are as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim i.i.d.\ N(0, \sigma^2_\eta) \\ \beta_t &= \beta_{t-1} + \xi_t, \qquad\qquad \xi_t \sim i.i.d.\ N(0, \sigma^2_\xi)\end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ^2_ξ, in the slope equation, and to request forecasts of β_t. The following examples illustrate this statement:

```
level;
slope;
```

These statements request including a locally linear trend in the model. The disturbance variances σ^2_η and σ^2_ξ will be estimated from the data. You can request a locally linear trend with fixed slope using the following statements:

```
level;
slope variance=0 noest;
```

NOEST

This option fixes the value of the disturbance variance, σ^2_ξ, to the value specified in the VARIANCE= option.

PRINT=FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)

This option requests printing of filtered or smoothed estimate of the slope component β_t.

VARIANCE= *value*

This option is used to supply an initial value for the disturbance variance, σ^2_ξ, in the β_t equation, at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SEASON Statement

SEASON LENGTH= *integer* < *options* > **;**

The SEASON or the SEASONAL statement is used to specify a *seasonal* component, γ_t, in the model. A seasonal can be one of the two types, DUMMY or TRIGONOMETRIC. A DUMMY type seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \qquad \omega_t \sim i.i.d.\ N(0, \sigma_\omega^2)$$

The equations for a TRIGONOMETRIC type seasonal are as follows:

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and equals $(s-1)/2$ if it is odd. The sinusoids $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma^*_{j,t} \end{bmatrix} = \begin{bmatrix} \cos\lambda_j & \sin\lambda_j \\ -\sin\lambda_j & \cos\lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma^*_{j,t-1} \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega^*_{j,t} \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega^*_{j,t}$ are assumed to be independent and, for fixed j, $\omega_{j,t}$ and $\omega^*_{j,t} \sim N(0, \sigma_\omega^2)$. If s is even then the equation for $\gamma^*_{s/2,t}$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

Note that, whether the seasonal type is DUMMY or TRIGONOMETRIC, there is only one parameter, the disturbance variance σ_ω^2, in the seasonal model.

There can be more than one seasonal components in the model, necessarily with different season lengths. Each seasonal component is specified using a separate SEASONAL statement. A model with multiple seasonal components can easily become quite complex and may need large amount of data and computing resources for its estimation and forecasting. Currently, at most three seasonals can be included in a model. The following code examples illustrate the use of SEASON statement:

```
season length=4;
```

This statement specifies a DUMMY type (default), seasonal component with season length four, corresponding to the quarterly seasonality. The disturbance variance σ_ω^2 will be estimated from the data. The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ_ω^2.

```
      season length=12 type=trig variance=4;
```

LENGTH= *integer*

This option is used to specify the season length, *s*. This is a required option in this statement. The season length can be any integer larger than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST

This option fixes the value of the the disturbance variance parameter to the value specified in the VARIANCE= option.

PRINT=FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)

This option requests printing of filtered or smoothed estimate of the seasonal component γ_t.

TYPE= DUMMY | TRIG

This option specifies the type of the seasonal component. The default type is DUMMY.

VARIANCE= *value*

This option is used to supply an initial value for the disturbance variance, σ_ω^2, in the γ_t equation, at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON NBLOCKS= *integer*
BLOCKSIZE= *integer* < *options* > **;**

The BLOCKSEASON or BLOCKSEASONAL statement is used to specify a seasonal γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size *m* and number of blocks *k* if its season length, *s*, can be factored as $s = m * k$ and its seasonal effects have a block form, that is, the first *m* seasonal effects are all equal to some number τ_1, the next *m* effects are all equal to some number τ_2, and so on. This type of seasonal structure can be appropriate in some cases, for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the *hour of the day* effect and the *day of the week* effect are *additive*. In this situation the hour of the week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour of the day effect is modeled using a simple seasonal of season length 24, while the day of the week effect is modeled as a block seasonal that has the days of the week as blocks. This day of the week block seasonal will have seven blocks, each of size 24. A block seasonal specification requires, at the minimum, the block size *m* and the number of blocks in the seasonal *k*. These are specified using the BLOCKSIZE= and NBLOCKS= options, respectively. In addition, you may need to specify the position of the first observation of the series using the OFFSET= option, if it is not at the beginning of one of the blocks. In the example just considered, this will correspond to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as OFFSET=7.

The other options of this statement are very similar to the options in the SEASONAL statement, for example, a block seasonal can also be of one of the two types, DUMMY or TRIGONOMETRIC. There can be more than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour of the week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

BLOCKSIZE= *integer*

This option is used to specify the block size, *m*. This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS= *integer*

This option is used to specify the number of blocks, *k*. This is a required option in this statement. The number of blocks can be any integer larger than or equal to two.

NOEST

This option fixes the value of the the disturbance variance parameter to the value specified in the VARIANCE= option.

OFFSET= *integer*

This option is used to specify the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between one and the block size. The default value is one. The *first measurement* refers to the start of the *estimation span* and the *forecast span*. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PRINT=FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)

This option requests the printing of filtered or smoothed estimate of the block seasonal component γ_t.

TYPE= DUMMY | TRIG

This option specifies the type of the seasonal component. The default type is DUMMY.

VARIANCE= *value*

This option is used to supply an initial value for the disturbance variance, σ_ω^2, in the

γ_t equation, at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

CYCLE Statement

CYCLE < *options* > **;**

The CYCLE statement is used to specify a *cycle* component, ψ_t, in the model. The stochastic equation governing a cycle component of period *p* and damping factor ρ is as follows:

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero mean, Gaussian disturbances with variance σ_ν^2 and $\lambda = 2 * \pi/p$ is the angular frequency of the cycle. Any *p* strictly larger than two is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and π, which correspond to the periods equal to infinity and two respectively, can be specified using the AUTOREG statement. The values of ρ smaller than one give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ, *p*, and σ_ν^2 are estimated from the data. However, if necessary, you can fix the values of some, or all, of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. Currently, you can specify up to 50 cycles in a model.

The following examples illustrate the use of the CYCLE statement:

```
cycle;
cycle;
```

These statements request including two cycles in the model. The parameters of each of these cycles will be estimated from the data.

```
cycle rho=1 noest=rho;
```

This statement requests inclusion of a nonstationary cycle in the model. The cycle period *p* and the disturbance variance σ_ν^2 will be estimated from the data. In the following statement a nonstationary cycle with fixed period of 12 is specified. Moreover, a starting value is supplied for σ_ν^2.

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

NOEST=PERIOD
NOEST=RHO
NOEST=VARIANCE
NOEST= (< RHO > < PERIOD > < VARIANCE >)

This option fixes the values of the component parameters to those specified in RHO=, PERIOD=, and VARIANCE= options. This option enables you to fix any combination of parameter values.

PERIOD= *value*
This option is used to supply an initial value for the cycle period during the parameter estimation process. Period value must be strictly larger than 2.

PRINT=FILTER
PRINT= SMOOTH
PRINT= (FILTER SMOOTH)
This option requests the printing of a filtered or smoothed estimate of the cycle component ψ_t.

RHO= *value*
This option is used to supply an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE= *value*
This option is used to supply an initial value for the disturbance variance parameter, σ_ν^2, to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

AUTOREG Statement

AUTOREG < *options* > **;**

The AUTOREG statement specifies an *autoregressive* component of the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or π. It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + \nu_t, \quad \nu_t \sim i.i.d. \;\; N(0, \sigma_\nu^2)$$

The damping factor ρ can take any value in the interval (-1, 1), including -1 but excluding 1. If $\rho = 1$ the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$ the autoregressive component corresponds to a seasonal component with season length 2, or a nonstationary cycle with period 2. If $|\rho| < 1$ then the autoregressive component is stationary. The following examples illustrate the AUTOREG statement:

```
autoreg;
```

This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_ν^2 are estimated from the data.

NOEST=RHO
NOEST= VARIANCE
NOEST= (RHO VARIANCE)

This option fixes the values of ρ and σ_ν^2 to those specified in RHO= and VARIANCE= options.

PRINT=FILTER
PRINT=SMOOTH
PRINT=(FILTER SMOOTH)
This option requests printing of filtered or smoothed estimate of the autoreg component.

RHO= *value*
This option is used to supply an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval (-1, 1), including -1 but excluding 1.

VARIANCE= *value*
This option is used to supply an initial value for the disturbance variance σ_ν^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

DEPLAG Statement

DEPLAG LAGS= *order* **<PHI=** *value ...* **> < NOEST > ;**

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of DEPLAG statement:

```
deplag lags=2;
```

If the dependent series is denoted by y_t, this statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data. The following statement requests including $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and -1.2.

```
deplag lags=(1)(4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an *irregular* component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement if an initial value is supplied for any one of the parameters, the initial values must be supplied for all other parameters also.

LAGS= *order*
LAGS= (*lag, ..., lag***) ... (***lag, ..., lag***)**

This is a required option in this statement. LAGS=(l_1, l_2, ..., l_k) defines a model with specified lags of the dependent variable included as predictors. LAGS= *order* is equivalent to LAGS=(1, 2, ..., *order*).

A concatenation of parenthesized lists specifies a factored model. For example, LAGS=(1)(12) specifies that the lag values, 1, 12 and 13, corresponding to the following polynomial in the backward shift operator, be included in the model

$$(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^{12})$$

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

PHI= *value* **...**
lists starting values for the coefficients of the lagged dependent variable.

NOEST
This option fixes the values of the parameters to those specified in PHI= options.

ESTIMATE Statement

ESTIMATE *< options >* **;**

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model using the SKIPFIRST= and BACK= options. This can be useful in model diagnostics. You can request a variety of goodness of fit statistics and other model diagnostic information. Note that this statement is not used to control the nonlinear optimization process itself. That is done using the NLOPTIONS statement where you can control the number of iterations, choose between the different optimization techniques, etc. The estimated parameters and other related information can be stored in a data set using the OUTEST= option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model fitting process. The actual observation span used to fit the model is decided as follows: First the observations are scanned and the observation numbers of the first and last non-missing values of the dependent variable are determined. Suppose that the observation numbers of the first and the last non-missing values are n_0 and n_1, respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers $n_0 + 11$ to $n_1 - 24$ form the estimation span. Of course, the model fitting may not take place if there are insufficient data in the resulting span. The model fitting will also not take place if there are regressors in the model that have missing values in the estimation span.

BACK= *integer*
SKIPLAST= *integer*
This option is used if some ending part of the data needs to be ignored during the parameter estimation. This can be useful when one wants to study the forecasting performance of the model on the observed data. SKIPLAST=10 results in skipping

the last 10 measurements of the response series during the parameter estimation. The default is SKIPLAST=0.

OUTEST= *SAS Dataset*
This option is used to specify an output data set for the estimated parameters.

PRINT=NONE
suppresses all the printed output related to the model fitting; for example, the parameter estimates, the goodness of fit statistics, etc.

SKIPFIRST= *integer*
This option is used if some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < *options* > **;**

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, are specified using the LEAD= and ALPHA= options. You can request one step ahead series and component forecasts using the PRINT= option. The series forecasts, and the model based decomposition of the series, can be saved in a data set using the OUTFOR= option. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 measurements and the last 24 response values be excluded during the forecast computations. The forecast horizon is 30 periods, that is multi step forecasting will begin at the end of the historical period and continue for 30 periods. The actual observation span used to compute the multi step forecasting is decided as follows: First the observations are scanned and the observation numbers of the first and last non-missing values of the response variable are determined. Suppose that the observation numbers of the first and last non-missing values are n_0 and n_1, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multi step forecasts are produced for the next 30 periods, that is, for the observation numbers $n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations may fail because of insufficient data in the forecast span. It can also fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon, that is between the observations $n_1 - 23$ to $n_1 + 6$, the forecast horizon is reduced accordingly.

ALPHA= *value*
specifies the significance level of the forecast confidence intervals, e.g., ALPHA=0.05 results in a 95% confidence interval.

BACK= *integer*
SKIPLAST= *integer*
This can be useful to specify the holdout sample for the evaluation of the forecasting performance of the model. SKIPLAST=10 results in treating the last 10 observed values of the response series as being unobserved. The default is SKIPLAST=0.

LEAD= *integer*
This option is used to specify the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and SKIPLAST= options, for example, LEAD=10 will result in the forecasting of 10 future values of the response series. The default is LEAD=12.

OUTFOR= *SAS Dataset*
This option is used to specify an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one step ahead and out of sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series and, the smoothed forecasts produced as a result of the model-based decomposition of the series.

PRINT=DECOMP
PRINT=FORECASTS
PRINT=NONE
PRINT=(FORECASTS DECOMP)
This option can be used to control the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option, that is, the one step ahead forecasts during the entire forecast span are not printed. You can request forecasts for the entire forecast span by specifying the PRINT=FORECASTS option. Using the PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model then they are ignored. You can use PRINT=NONE to suppress the printing of all of the forecast output.

SKIPFIRST= *integer*
This option is used if some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

PROC UCM uses the NonLinear Optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the default settings of the optimization process are adequate, however, in some cases it may be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows

```
nloptions tech=dbldog maxiter=200;
```

This will set the maximum number of iterations to 200 and change the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in the chapter on Nonlinear Optimization Methods (Chapter 10, "Nonlinear Optimization Methods."). In PROC UCM all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

Details

Throughout this section, $Diag\,[a, b, \ldots\,]$ will denote a diagonal matrix with diagonal entries $[a, b, \ldots\,]$, and the transpose of a matrix T will be denoted as $T^{'}$.

The UCMs as State Space Models

It is well known that the UCMs considered in PROC UCM can be thought of as special cases of more general models, the (linear) Gaussian State Space Models (GSSM). A GSSM suitable for our purposes can be described as follows:

$$\begin{aligned} y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \qquad \zeta_t \sim \mathrm{N}(0, Q_t) \\ \alpha_1 &\sim \mathrm{N}(0, P) \end{aligned}$$

The first equation, called the *Observation Equation*, relates the observed series y_t to a state vector α_t that is usually unobserved. The second equation describes the evolution of the state vector in time and is called the *State Equation*. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero mean, Gaussian vectors with covariance matrices Q_t. For most of the UCMs considered here, the system matrices Z_t and T_t, and the noise covariances Q_t, are time invariant, i.e., they do not depend on time. In a few cases, however, some or all of them may depend on time. The initial state vector

α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially *diffuse*. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite, i.e., you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the following form:

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞. In the case of UCMs considered here P_∞ is always a diagonal matrix consisting of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* is zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out of sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM need not be unique. In the representation used here, the unobserved components in the UCM are taken as elements of the state vector. This makes the elements of the state interpretable and, more importantly, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information on the computational aspects of the state space modeling, see Durbin and Koopman (2001). Next some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \ldots, n\}$ be the observed sample from a series satisfying a state space model. Next, for $1 \le t \le n$, let the one step ahead forecasts of the series and the states, and their variances, be defined as follows:

$$\begin{aligned}
\hat{\alpha}_t &= E(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \\
\Gamma_t &= Var(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \\
\hat{y}_t &= E(y_t | y_1, y_2, \ldots, y_{t-1}) \\
F_t &= Var(y_t | y_1, y_2, \ldots, y_{t-1})
\end{aligned}$$

using the usual notation to denote the conditional expectations and conditional variances. These are also called the filtered estimates of the series and the states. Similarly, for $t \ge 1$, let

$$\begin{aligned}
\tilde{\alpha}_t &= E(\alpha_t | y_1, y_2, \ldots, y_n) \\
\Delta_t &= Var(\alpha_t | y_1, y_2, \ldots, y_n) \\
\tilde{y}_t &= E(y_t | y_1, y_2, \ldots, y_n) \\
G_t &= Var(y_t | y_1, y_2, \ldots, y_n)
\end{aligned}$$

denote the full-sample estimates of the series and the state values at time t. If the time t is in the historical period, i.e., if $1 \le t \le n$, then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out of sample forecasts. Note that, if $1 \le t \le n$, $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates $\hat{\alpha}_t, \tilde{\alpha}_t, \ldots, G_t$ are computed using the filtering and smoothing algorithms given in Durbin and Koopman (2001). These algorithms are iterative. If the initial state is diffuse, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse, that is, during these iterations the one step ahead series and state forecast variances F_t and Γ_t have the following form

$$\begin{aligned}\Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}\\ F_t &= F_{*t} + \kappa F_{\infty t}\end{aligned}$$

The actual number of iterations, say d, affected by this improper prior depends on the nature of the matrix sequence T_t, the rank of P_∞, and the pattern of missing values in the dependent series. After d iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become zero and the one step ahead series and state forecasts have proper distributions. In certain missing value patterns it can happen that d exceeds the sample size; that is, the sample information is insufficient to create a proper prior for the filtering process. In these cases no parameter estimation or forecasting is done. The forecasting computations can also fail if the specified model contains components that are essentially multicollinear and the process of computing one step ahead or multi step ahead forecasts is unstable. This condition can also manifest itself as failure to initialize a proper prior for the filtering process.

The log-likelihood of the sample, which takes account of this diffuse initialization steps, is computed using the one step ahead series forecasts as follows

$$\log L_d(y_1, \ldots, y_n) = -\frac{n}{2}\log 2\pi - \frac{1}{2}\sum_{t=1}^{d} w_t - \frac{1}{2}\sum_{t=d+1}^{n}(\log F_t + \frac{\nu_t^2}{F_t})$$

where $\nu_t = y_t - Z_t\hat{\alpha}_t$ are the one step ahead residuals and

$$\begin{aligned}w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0\\ &= \log F_{*t} + \frac{\nu_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0\end{aligned}$$

If y_t is missing at some time t, then the corresponding summand in the log-likelihood expression is deleted, and the constant term is adjusted suitably.

The portion of the log-likelihood corresponding to the post-initialization period is called the non-diffuse log-likelihood. The non-diffuse log-likelihood is given by

$$\log L(y_1, \ldots, y_n) = -\frac{1}{2}\sum_{t=d+1}^{n}(\log F_t + \frac{\nu_t^2}{F_t})$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^{d} w_t$, does not depend on the model parameters, and in these cases the maximization of non-diffuse and diffuse likelihoods is equivalent. However, in some cases, for example, when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and non-diffuse likelihood can produce different results.

In the remainder of this section the state space formulation of UCMs is further explained using some particular UCMs as examples. The examples will show that the state space formulation of the UCMs depends upon the components in the model in a simple fashion; for example, the system matrix T will usually be a block diagonal matrix with blocks corresponding to the components in the model. The only exception to this pattern is the UCMs consisting of the lags of dependent variable. This case is considered at the end of the section.

Local Level Model

Recall that the dynamics of a local level model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t, η_t, and ξ_t are independent, mean zero Gaussian disturbance sequences with variances $\sigma^2_\epsilon, \sigma^2_\eta$ and σ^2_ξ respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\ \epsilon_t\ \mu_t\ \beta_t\ ]'$ and the state noise $\zeta_t = [\ \epsilon_t\ \eta_t\ \xi_t\ ]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T, Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [\ 1\ 1\ 0\ ], \quad T = \begin{bmatrix} 0\ 0\ 0 \\ 0\ 1\ 1 \\ 0\ 0\ 1 \end{bmatrix} \quad \text{and} \quad Q = Diag\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi\right]$$

The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma^2_\epsilon, 0, 0\right]$ and $P_\infty = Diag\,[0, 1, 1]$. The parameter vector θ consists of all the disturbance variances, that is, $\theta = (\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi)$.

Basic Structural Model

Basic Structural Model (BSM) is obtained by adding a seasonal component, γ_t, to the local level model. In order to economize on the space, the state space formulation of a BSM with relatively short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and the state noise vectors are $\alpha_t = [\ \epsilon_t\ \mu_t\ \beta_t\ \gamma_{1,t}\ \gamma_{2,t}\ \gamma_{3,t}\ ]'$ and $\zeta_t = [\ \epsilon_t\ \eta_t\ \xi_t\ \omega_t\ 0\ 0\ ]'$. The first three elements of the state vector are the irregular, level, and the slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t. $\gamma_{1,t}$ corresponds to lag zero, that is, the same as γ_t, $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices can be seen to be

$$Z = [\,1\;1\;0\;1\;0\;0\,],\quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \text{-1} & \text{-1} & \text{-1} \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = Diag\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, 0, 0\right]$. The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma^2_\epsilon, 0, 0, 0, 0, 0\right]$ and $P_\infty = Diag\,[0, 1, 1, 1, 1, 1]$.

In the case of trigonometric form of seasonality, $\alpha_t = \left[\;\epsilon_t\;\mu_t\;\beta_t\;\gamma_{1,t}\;\gamma^*_{1,t}\;\gamma_{2,t}\;\right]'$ and $\zeta_t = \left[\;\epsilon_t\;\eta_t\;\xi_t\;\omega_{1,t}\;\omega^*_{1,t}\;\omega_{2,t}\;\right]'$. The disturbance sequences, $\omega_{j,t}, 1 \leq j \leq 2$, and $\omega^*_{1,t}$ are independent, zero mean, Gaussian sequences with variance σ^2_ω.

$$Z = [\,1\;1\;0\;1\;0\;1\,],\quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos\lambda_1 & \sin\lambda_1 & 0 \\ 0 & 0 & 0 & -\sin\lambda_1 & \cos\lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos\lambda_2 \end{bmatrix}$$

and $Q = Diag\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, \sigma^2_\omega, \sigma^2_\omega\right]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma^2_\epsilon, 0, 0, 0, 0, 0\right]$ and $P_\infty = Diag\,[0, 1, 1, 1, 1, 1]$. The parameter vector, in both the cases, is $\theta = (\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega)$.

Seasonals with Blocked Seasonal Values

Block seasonals are special seasonals that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure, that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with DUMMY type seasonality is as follows: The state and the state noise vectors are $\alpha_t = \left[\;\epsilon_t\;\mu_t\;\beta_t\;\gamma_{1,t}\;\gamma_{2,t}\;\gamma_{3,t}\;\right]'$ and $\zeta_t = \left[\;\epsilon_t\;\eta_t\;\xi_t\;\omega_t\;0\;0\;\right]'$. The first three elements of the state vector are the irregular, level, and the slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t. $\gamma_{1,t}$ corresponds to lag zero, that is, the same as γ_t, $\gamma_{2,t}$ to lag

m and $\gamma_{3,t}$ to lag $2m$. All the system matrices are time invariant, except the matrix T. They can be seen to be $Z = [\ 1\ 1\ 0\ 1\ 0\ 0\ ]$, $Q = Diag\left[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0\right]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \text{-1} & \text{-1} & \text{-1} \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m, the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma_\epsilon^2, 0, 0, 0, 0, 0\right]$ and $P_\infty = Diag\,[0, 1, 1, 1, 1, 1]$.

Similarly in the case of trigonometric form of seasonality, $\alpha_t = \left[\ \epsilon_t\ \mu_t\ \beta_t\ \gamma_{1,t}\ \gamma_{1,t}^*\ \gamma_{2,t}\ \right]'$ and $\zeta_t = \left[\ \epsilon_t\ \eta_t\ \xi_t\ \omega_{1,t}\ \omega_{1,t}^*\ \omega_{2,t}\ \right]'$. The disturbance sequences, $\omega_{j,t}, 1 \le j \le 2$, and $\omega_{1,t}^*$ are independent, zero mean, Gaussian sequences with variance σ_ω^2. $Z = [\ 1\ 1\ 0\ 1\ 0\ 1\ ]$, $Q = Diag\left[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2\right]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos\lambda_1 & \sin\lambda_1 & 0 \\ 0 & 0 & 0 & -\sin\lambda_1 & \cos\lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos\lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m, the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma_\epsilon^2, 0, 0, 0, 0, 0\right]$ and $P_\infty = Diag\left[0, 1, 1, 1, 1, 1\right]$. The parameter vector, in both the cases, is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Auto-Regression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There one can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ, $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero mean Gaussian disturbances with variance σ_ν^2. In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = \left[\, \epsilon_t \; \psi_t \; \psi_t^* \,\right]'$, state noise vector $\zeta_t = \left[\, \epsilon_t \; \nu_t \; \nu_t^* \,\right]'$. The system matrices are

$$Z = [\,1\;1\;0\,] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho\cos\lambda & \rho\sin\lambda \\ 0 & -\rho\sin\lambda & \rho\cos\lambda \end{bmatrix} \quad Q = Diag\left[\sigma_\epsilon^2, \sigma_\nu^2, \sigma_\nu^2\right]$$

The distribution of the initial state vector α_1 is proper with $P_* = Diag\left[\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2\right]$ where $\sigma_\psi^2 = \sigma_\nu^2(1-\rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_\nu^2)$.

An auto-regression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π. In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an auto-regressive component and an irregular component, the state space model simplifies to the following form:

The state vector $\alpha_t = \left[\, \epsilon_t \; r_t \,\right]'$, state noise vector $\zeta_t = \left[\, \epsilon_t \; \nu_t \,\right]'$. The system matrices are

$$Z = [\,1\;1\,], \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = Diag\left[\sigma_\epsilon^2, \sigma_\nu^2\right]$$

The distribution of the initial state vector α_1 is proper with $P_* = Diag\left[\sigma_\epsilon^2, \sigma_r^2\right]$ where $\sigma_r^2 = \sigma_\nu^2(1-\rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_\nu^2)$.

Incorporating the Predictors

As with earlier examples, how to obtain a state space form of a UCM consisting of predictors is illustrated using a simple special case. Consider a random walk model with predictors x_1 and x_2. The dynamics of this model are

$$\begin{aligned} y_t &= \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \end{aligned}$$

This dynamics can be captured in the state space form by taking $\alpha_t = [\ \epsilon_t\ \mu_t\ \beta_1\ \beta_2\ ]^{'}$, $\zeta_t = [\ \epsilon_t\ \eta_t\ 0\ 0\ ]^{'}$, and

$$Z_t = [\ 1\ 1\ x_{1t}\ x_{2t}\ ] \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad Q = Diag\left[\sigma^2_\epsilon, \sigma^2_\eta, 0, 0\right]$$

Note that the regression coefficients are elements of the state vector, and that the system matrix Z_t is not time invariant. The distribution of the initial state vector α_1 is diffuse with $P_* = Diag\left[\sigma^2_\epsilon, 0, 0, 0\right]$ and $P_\infty = Diag\,[0, 1, 1, 1]$. The parameters of this model are the disturbance variances, σ^2_ϵ and σ^2_η, and the regression coefficients, β_1 and β_2. The disturbance variances, being elements of the system matrix Q, are estimated by maximizing the likelihood, while the regression parameters get implicitly estimated during the state estimation (smoothing).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Suppose that the preceding random walk with predictors model also includes a few, say k, lags of the dependent variable. That is

$$\begin{aligned} y_t &= \sum_{i=1}^{k} \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \end{aligned}$$

The state space form of this augmented model can be described in terms of the state space form of the preceding random walk with predictors model. A superscript † has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha^\dagger_t = \left[\ \alpha^{'}_t\ y_t\ y_{t-1}\ \ldots\ y_{t-k+1}\ \right]^{'}$ and the new state noise vector $\zeta^\dagger_t = \left[\ \zeta^{'}_t\ u_t\ 0 \ldots\ 0\ \right]^{'}$ where u_t is the matrix product $Z_t\zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in the block form, are

$$Z^\dagger_t = [\ 0\ 0\ 0\ 0\ 1\ \ldots\ 0\ ], \quad T^\dagger_t = \begin{bmatrix} T_t & 0 & \ldots & 0 \\ Z_{t+1}T_t & \phi_1 & \ldots & \phi_k \\ 0 & I_{k-1,k-1} & & 0 \end{bmatrix}$$

where $I_{k-1,k-1}$ is the $k-1$ dimensional identity matrix and,

$$Q_t^\dagger = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, in the expressions above their time indices are kept because it illustrates the pattern for more general models. The initial state vector is diffuse with

$$P_*^\dagger = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix} \quad P_\infty^\dagger = \begin{bmatrix} P_\infty & 0 \\ 0 & I_{k,k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_ϵ^2 and σ_η^2, the lag coefficients $\phi_1, \phi_2, \ldots, \phi_k$, and the regression coefficients β_1 and β_2. As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling; however, no embedded missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can create problems for some models. For example, if in a monthly series all values are missing for a certain month, say May, then a BSM with monthly seasonality cannot be fit to these data. A non-seasonal model such as a local linear model can still be fit to these data.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the non-diffuse likelihood. The decision to use the full diffuse likelihood or the non-diffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the non-diffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either the full or the non-diffuse, is carried out using one of several non-linear optimization algorithms. The user can control many aspects of the optimization process using the NLOPTIONS statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

t-values

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully, therefore the probability values corresponding to a *t* distribution should be interpreted carefully as they may be misleading. This is particularly true if the parameters in question are close to the boundary of the parameter space. Harvey (1989, 2001) are good references for information on this topic.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower order terms. The computing time for the parameter estimation also depends on m and n, as well as on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Printed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set that includes the dataset name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, which includes the names of the variables in the model, their categorization as the dependent or predictor, the index of the beginning and the ending observations in the spans, the total number of observations and the number of missing observations, the smallest and the largest measurements, and the mean and the standard deviation
- information about the model parameters at the start of the model fitting stage that includes the fixed parameters in the model and the initial estimates of the free parameters in the model

- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting stage that includes the parameter estimates, their approximate standard errors, *t*-statistics, and the approximate P-value
- the likelihood-based goodness of fit statistics that include the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of the *innovations* normalized by their standard errors, and the Akike and the Bayesian information criteria AIC and BIC
- the fit statistics that are based on the raw residuals (observed - predicted), that include the mean squared error (MSE), root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R-Square, the adjusted R-Square, the Random Walk R-Square, and the Amemiya's R-Square
- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the cycles, seasonals, and block seasonals present in the model
- the multi step series forecasts

ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table:

Table 29.1. ODS Tables Produced in the UCM Procedure

ODS Table Name	Description	Option
ODS Tables Summarizing the Estimation and Forecast Spans		
EstimationSpan	Estimation span summary information	default
ForecastSpan	Forecast span summary information	default
ODS Tables Related to the Model Parameters		
ConvergenceStatus	Convergence status of the estimation process	default
FixedParameters	Fixed parameters in the model	default
InitialParameters	Initial estimates of the free parameters	default
ParameterEstimates	Final estimates of the free parameters	default
ODS Tables Related to the Model Information and Diagnostics		
BlockSeasonDescription	Information about the block seasonals in the model	default

Table 29.1. (ODS Tables Continued)

ODS Table Name	Description	Option
ComponentSignificance	Significance analysis of the components in the model	default
CycleDescription	Information about the cycles in the model	default
FitStatistics	Fit statistics based on the one step ahead predictions	default
FitSummary	Likelihood based fit statistics	default
SeasonDescription	Information about the seasonals in the model	default
ODS Tables Related to the Component Estimates		
FilteredAutoReg	Filtered Estimate of an Autoreg Component. AUTOREG statement	PRINT=FILTER
FilteredBlockSeason	Filtered Estimate of a Block Seasonal Component. BLOCKSEASON statement	PRINT=FILTER
FilteredCycle	Filtered Estimate of a Cycle Component. CYCLE statement	PRINT=FILTER
FilteredIrregular	Filtered Estimate of the Irregular Component. IRREGULAR statement	PRINT=FILTER
FilteredLevel	Filtered Estimate of the Level Component. LEVEL statement	PRINT=FILTER
FilteredSeason	Filtered Estimate of a Seasonal Component. SEASON statement	PRINT=FILTER
FilteredSlope	Filtered Estimate of the Slope Component. SLOPE statement	PRINT=FILTER
SmoothedAutoReg	Smoothed Estimate of an Autoreg Component. AUTOREG statement	PRINT=SMOOTH
SmoothedBlockSeason	Smoothed Estimate of a Block Seasonal Component. BLOCKSEASON statement	PRINT=SMOOTH
SmoothedCycle	Smoothed Estimate of the Cycle Component. CYCLE statement	PRINT=SMOOTH
SmoothedIrregular	Smoothed Estimate of the Irregular Component. IRREGULAR statement	PRINT=SMOOTH
SmoothedLevel	Smoothed Estimate of the Level Component. LEVEL statement	PRINT=SMOOTH
SmoothedSeason	Smoothed Estimate of a Seasonal Component. SEASON statement	PRINT=SMOOTH
SmoothedSlope	Smoothed Estimate of the Slope Component. SLOPE statement	PRINT=SMOOTH
ODS Tables Related to the FORECAST Statement		

Table 29.1. (ODS Tables Continued)

ODS Table Name	**Description**	**Option**
Forecasts	Dependent Series Forecasts	default
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonals, or block seasonals, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal and PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named as SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal.

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the UCM procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, “Statistical Graphics Using ODS.”

When the ODS GRAPHICS are in effect, the UCM procedure produces a variety of plots. The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested using the PLOT= option in the respective component statements. For example, the use of PLOT=SMOOTH option in a CYCLE statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained using the PLOT= option in the ESTIMATE statement.
- Plots of series forecasts and model decompositions can be obtained using the PLOT= option in the FORECAST statement.

The details of the PLOT= option in different statements are given below.

The PLOT= option in the IRREGULAR, LEVEL, SLOPE, CYCLE, and AUTOREG statements is identical. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the respective components as follows:

PLOT= FILTER
PLOT= SMOOTH
PLOT= (FILTER SMOOTH)

In the SEASON and BLOCKSEASON statements, the PLOT= option is as follows:

PLOT= FILTER
PLOT= SMOOTH
PLOT= F_ANNUAL
PLOT= S_ANNUAL
PLOT= (<FILTER> <SMOOTH> <F_ANNUAL> <S_ANNUAL>)

You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the seasonal or block seasonal component γ_t. The F_ANNUAL and S_ANNUAL options can be used to get the plots of "annual" variation in the filtered and smoothed estimates of γ_t. The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here the "month" and the "year" are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. The different possibilities are as follows:

PLOT= RESIDUAL
PLOT= ACF
PLOT= NORMAL
PLOT= WN
PLOT= (<RESIDUAL> <ACF> <NORMAL> <WN>)

The RESIDUAL option results in the residual plot, the ACF option gives the plot of the auto-correlations of the residuals, the NORMAL option gives the histogram of residuals, and the WN option gives the plot of White Noise test probabilities.

In the FORECAST statement, the PLOT= option can be used to obtain forecast and model decomposition plots. The details are as follows:

PLOT= FORECASTS
PLOT= TREND
PLOT= DECOMP
PLOT= DECOMPVAR
PLOT= FDECOMP
PLOT= FDECOMPVAR
PLOT= (<FORECASTS> <TREND> <DECOMP> <DECOMPVAR> <FDECOMP>

<FDECOMPVAR>)

The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of these components, and the FDECOMP and FDECOMPVAR provide the same plots for the filtered decomposition estimates and their variances.

For an example of how to set up the ODS GRAPHICS environment and use the different PLOT= options, see Example 29.4.

ODS Graph Names

PROC UCM assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 29.2.

Table 29.2. ODS Graphics Produced by PROC UCM

ODS Graph Name	Plot Description	PLOT= Option
	ODS Plots Related to the Residual Analysis	
ErrorACFPlot	Prediction Error Autocorrelation Plot. ESTIMATE statement.	PLOT=ACF
ErrorHistogram	Prediction Error Histogram. ESTIMATE statement.	PLOT=NORMAL
ErrorPlot	Plot of Prediction Errors. ESTIMATE statement.	PLOT=RESIDUAL
	ODS Plots Related to the Series Forecasts	
ForecastsOnlyPlot	Series Forecasts Beyond the Historical Period. FORECAST statement.	DEFAULT
ModelForecastsPlot	One-Step-Ahead as well as Multi-Step-Ahead Forecasts. FORECAST statement.	PLOT=FORECASTS
	ODS Plots Related to the Individual Components	
FilteredAutoregPlot	Plot of Filtered Autoreg Component. AUTOREG statement.	PLOT=FILTER
FilteredBlockSeasonPlot	Plot of Filtered Block Season Component. BLOCKSEASON statement.	PLOT=FILTER
FilteredCyclePlot	Plot of Filtered Cycle Component. CYCLE statement.	PLOT=FILTER
FilteredIrregularPlot	Plot of Filtered Irregular Component. IRREGULAR statement.	PLOT=FILTER

Table 29.2. (continued)

ODS Graph Name	Plot Description	Option
FilteredLevelPlot	Plot of Filtered Level Component. LEVEL statement.	PLOT=FILTER
FilteredSeasonPlot	Plot of Filtered Season Component. SEASON statement.	PLOT=FILTER
FilteredSlopePlot	Plot of Filtered Slope Component. SLOPE statement.	PLOT=FILTER
SmoothedAutoregPlot	Plot of Smoothed Autoreg Component. AUTOREG statement.	PLOT=SMOOTH
SmoothedBlockSeasonPlot	Plot of Smoothed Block Season Component. BLOCKSEASON statement.	PLOT=SMOOTH
SmoothedCyclePlot	Plot of Smoothed Cycle Component. CYCLE statement.	PLOT=SMOOTH
SmoothedIrregularPlot	Plot of Smoothed Irregular Component. IRREGULAR statement.	PLOT=SMOOTH
SmoothedLevelPlot	Plot of Smoothed Level Component. LEVEL statement.	PLOT=SMOOTH
SmoothedSeasonPlot	Plot of Smoothed Season Component. SEASON statement.	PLOT=SMOOTH

SmoothedTrendRegPlot	Plot of Smoothed Trend Plus Regression Effects. FORECAST statement.	PLOT= DECOMP

OUTFOR= Data Set

You can use OUTFOR= option in the FORECAST statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified then a numerical variable, _ID_, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- FORECAST, a numerical variable containing the one step ahead predicted values and the multi step forecasts
- RESIDUAL, a numerical variable containing the difference between the actual and forecast values
- STD, a numerical variable containing the standard error of prediction
- LCL and UCL, numerical variables containing the lower and upper forecast confidence limits
- S_SERIES and VS_SERIES, numerical variables containing the smoothed values of the dependent series and their variances
- S_IRREG and VS_IRREG, numerical variables containing the smoothed values of the IRREGULAR component and their variances. These variables are present only if the model has an IRREGULAR component.
- F_LEVEL, VF_LEVEL, S_LEVEL, and VS_LEVEL, numerical variables containing the filtered and smoothed values of the LEVEL component and the respective variances. These variables are present only if the model has a LEVEL component.
- F_SLOPE, VF_SLOPE, S_SLOPE, and VS_SLOPE, numerical variables containing the filtered and smoothed values of the SLOPE component and the respective variances. These variables are present only if the model has a SLOPE component.
- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the AUTOREG component and the respective variances. These variables are present only if the model has an AUTOREG component.
- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the CYCLE component and the respective variances. If there are multiple cycles in the model, these variables

are sequentially numbered as F_CYCLE1, F_CYCLE2, etc. These variables are present only if the model has at least one CYCLE component.

- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the SEASON component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as F_SEASON1, F_SEASON2, etc. These variables are present only if the model has at least one SEASON component.
- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the BLOCKSEASON component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as F_BLKSEAS1, F_BLKSEAS2, etc. These variables are present only if the model has at least one BLOCKSEASON component.
- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.
- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.
- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one season or block season component.

OUTEST= Data Set

You can use OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was FIXED by the user or it was ESTIMATED
- _STATUS_, a character variable indicating whether the parameter estimation process Converged, Failed, or there was an Error of some other kind.
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This will have a missing value if the parameter value is fixed.

- TVALUE, a numerical variable containing the *t*-statistic. This will have a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the *p*-value. This will have a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulae, *n* is the number of non-missing prediction errors and *k* is the number of fitted parameters in the model. Moreover, the sum of square errors, $SSE = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $SST = \sum (y_t - \overline{y})^2$, where $\overline{y}$ is the series mean and the sums are over all the non-missing prediction errors.

Mean Square Error
The mean squared prediction error, MSE, calculated from the one step ahead forecasts. $MSE = \frac{1}{n} SSE$.

Root Mean Square Error
The root mean square error (RMSE), $\sqrt{MSE}$.

Mean Absolute Percent Error
The mean absolute percent prediction error (MAPE), $\frac{100}{n} \sum_{t=1}^{n} |(y_t - \hat{y}_t)/y_t|$.
The summation ignores observations where $y_t = 0$.

R-Square
The R^2 statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares, *SSE*, may be larger than *SST* and the R^2 statistic will be negative.

Adjusted R-Square
The adjusted R^2 statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$.

Amemiya's Adjusted R-Square
Amemiya's adjusted R^2, $1 - (\frac{n+k}{n-k})(1 - R^2)$.

Random Walk R-Square
The random walk R^2 statistic (Harvey's R^2 statistic using the random walk model for comparison), $1 - (\frac{n-1}{n}) SSE/RWSSE$, where $RWSSE = \sum_{t=2}^{n} (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^{n} (y_t - y_{t-1})$.

Maximum Percent Error
The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately. They include the full log-likelihood, the diffuse part of the log-likelihood (see "Details"), the normalized residual sum of squares, and the Akaike and Bayesian information criteria. Let L denote the log-likelihood, k denote the sum of number of estimated parameters and the number of diffuse elements in the state vector, and n be the number of non-missing measurements in the estimation span. Moreover, let d denote the initialization period, and, ν_t and F_t denote the one step ahead prediction errors and their variances.

Normalized Residual Sum of Squares
Normalized Residual Sum of Squares, $\sum_{t=d+1}^{n} \frac{\nu_t^2}{F_t}$.

Akaike's Information Criterion
Akaike's information criterion (AIC), $-2L + 2k$.

Schwarz Bayesian Information Criterion
Schwarz Bayesian information criterion (SBC or BIC),
$-2L + k \log(n)$.

Examples

Example 29.1. An Example of a BSM

The series in this example, the monthly Airline Passenger series, has already been discussed in an example in the Getting Started section, see "A Seasonal Series with a Linear Trend". Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here we will examine additional output and use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following syntax fits a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the SLOPE component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements.

```
   data series_g;
        set sashelp.air;
        logair = log(air);
   run;

proc ucm data = series_g;
     id date interval = month;
     model logair;
     irregular;
```

```
         level;
         slope var = 0 noest;
         season length = 12 type=trig;
         estimate back=24;
         forecast back=12 lead=24 print=forecasts;
    run;
```

The following tables display the summary of data used in estimation and forecasting (Output 29.1.1 and Output 29.1.2). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the start and end dates of the span, number of non-missing values, etc.

Output 29.1.1. Observation Span Used in Parameter Estimation (partial output)

```
                          Estimation Span Summary

     Variable      Type         First       Last      Nobs           Mean

      logair     Dependent     JAN1949     DEC1958      120        5.43035
```

Output 29.1.2. Observation Span Used in Forecasting (partial output)

```
                           Forecast Span Summary

     Variable      Type         First       Last      Nobs           Mean

      logair     Dependent     JAN1949     DEC1959      132        5.48654
```

The following tables display the fixed parameters in the model, the preliminary estimates of the free parameters, and the final estimates of the free parameters (Output 29.1.3, Output 29.1.4, and Output 29.1.5).

Output 29.1.3. Fixed Parameters in the Model

Two types of goodness of fit statistics are reported after a model is fit to the series (see Output 29.1.6 and Output 29.1.7). The first type is the likelihood-based goodness of fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see "Details"), and the Akike and Bayesian Information criteria. The second type of statistics is based on the raw residuals, residual = observed - predicted. If the model is non-stationary, then one step ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

Output 29.1.6. Likelihood Based Fit Statistics for the Airline Data

```
                          Likelihood Based Fit Statistics

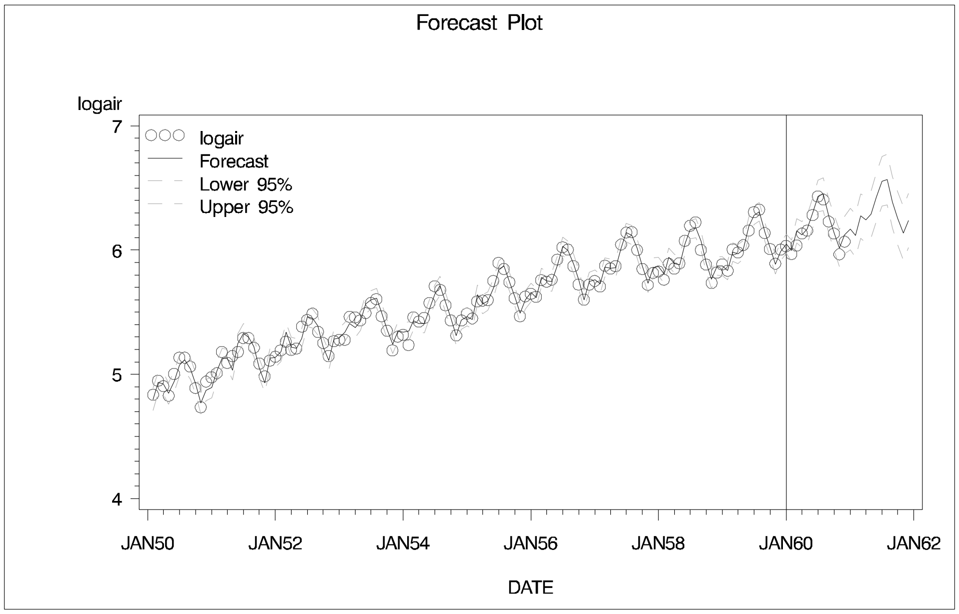
The figure Output 29.1.9 shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.

Output 29.1.9. Forecast Plot of the Airline Series Using a BSM



Example 29.2. Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (http://www.york.ac.uk/depts/maths/data/ts/welcome.htm (series number 26)). The following DATA step statements read the data in a SAS data set.

```
data star;
    input magnitude @@;
    datalines;

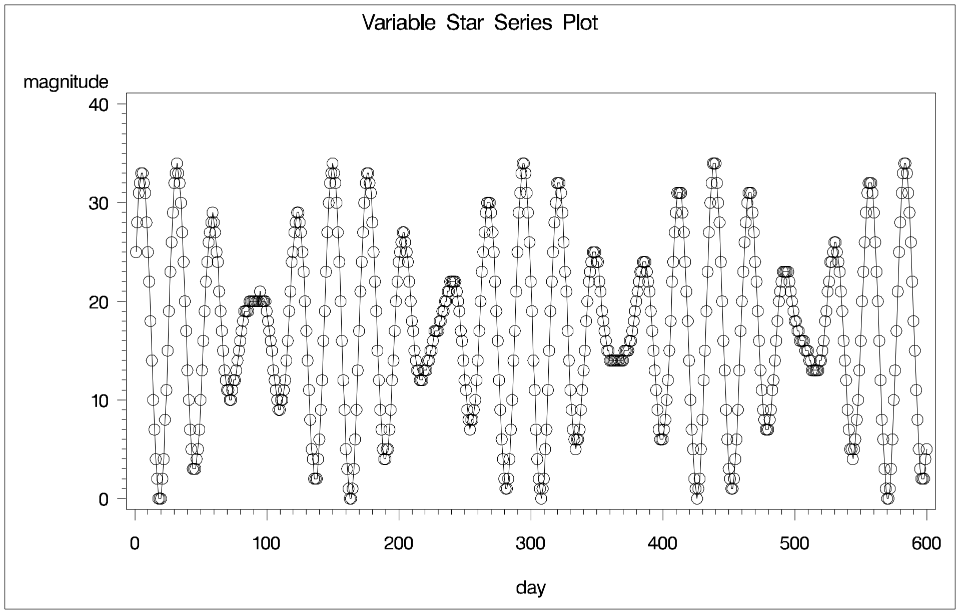
        25 28 31 32 33 33 32 31 28 25
        22 18 14 10  7  4  2  0  0  0
         2  4  8 11 15 19 23 26 29 32

        /* -- data lines removed - */

        31 33 34 34 33 31 29 26 22 18
        15 11  8  5  3  2  2  2  4  5
     ;
```

The plot of the series is shown in figure Output 29.2.1.

Output 29.2.1. Plot of Star Brightness on Successive Days



The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also shows the difficulty involved in estimating the periods from the data (see Bloomfield 2000, Chapter 3). The parameters are estimated by the least squares, and the sum of squares surface has multiple local optima and ridges. In this example we will use the UCM procedure to model this series. We begin with a model that consists of only one stochastic cycle and the level and irregular components. This is because it is quite possible that a single stochastic cycle with time varying amplitude and phase may be adequate to explain the observed series.

```
proc ucm data=star;
    model magnitude;
    irregular;
    level;
    cycle;
    forecast print=forecasts;
run;
```

The final parameter estimates and the goodness of fit statistics are shown below (see Output 29.2.2 and Output 29.2.3).

Output 29.2.2. Parameter Estimates in Single Cycle Model

```
                          Fit Statistics Based on Residuals

                  Mean Squared Error                     0.31481
                  Root Mean Squared Error                0.56108
                  Mean Absolute Percentage Error         4.55372
                  Maximum Percent Error                 60.57167
                  R-Square                               0.99609
                  Adjusted R-Square                      0.99607
                  Random Walk R-Square                   0.94510
                  Amemiya’s Adjusted R-Square            0.99603

                    Number of non-missing residuals used for
                       computing the fit statistics = 599
```

A description of the cycle in the model is given below (Output 29.2.4).

Output 29.2.4. Summary of the Cycle in the Single Cycle Model

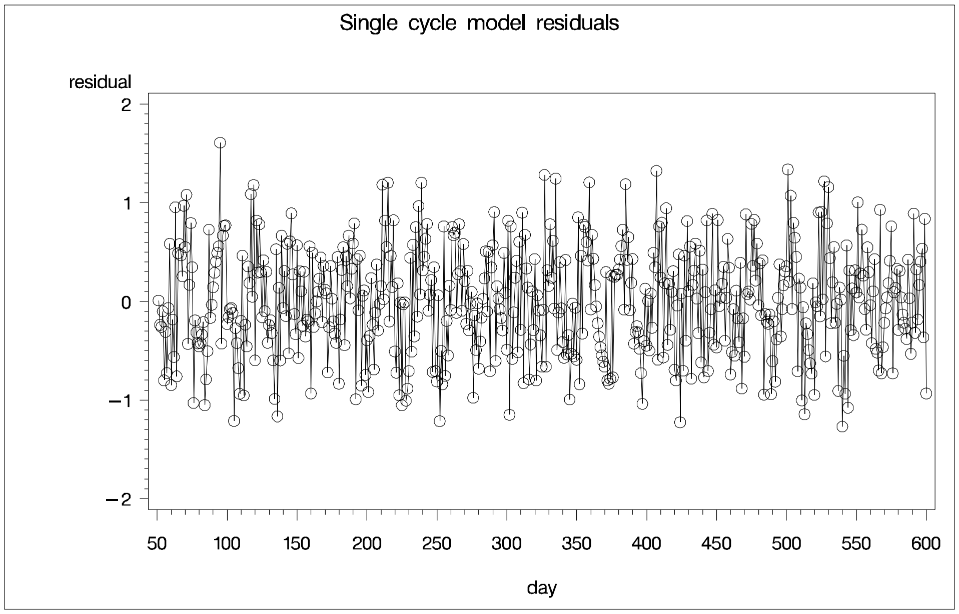
```
                        Cycle description (partial output)

Name         Type             period            Rho         CycleVar         ErrorVar

Cycle    Stationary         27.12640        0.99906        106.68773          0.20111
```

From the model fit it appears that the single stochastic cycle model with a period of approximately 27 days fits the data reasonably well. However, the residual plot in Output 29.2.5 indicates that the series may contain an additional cycle. The autocorrelation plot of residuals shows this more clearly (this plot is not shown).

Output 29.2.5. Residual Plot for the Single Cycle Model



The following statements fit a two-cycle model to the series.

```
proc ucm data=star;
    model magnitude;
    irregular;
    level var=0 noest;
    cycle rho=1 noest=rho;
    cycle rho=1 noest=rho;
    forecast print=forecasts;
run;
```

The model has two cycles, both with damping factors of one, and a constant level component. The final parameter estimates and the goodness of fit statistics are shown below (see Output 29.2.6 and Output 29.2.7).

Output 29.2.6. Parameter Estimates in Two Cycle Model

```
                                  The UCM Procedure

                    Number of non-missing residuals used for
                       computing the fit statistics = 595
```

A description of the cycles in the model is given in Output 29.2.8.

Output 29.2.8. Summary of the Cycles in the Two Cycle Model

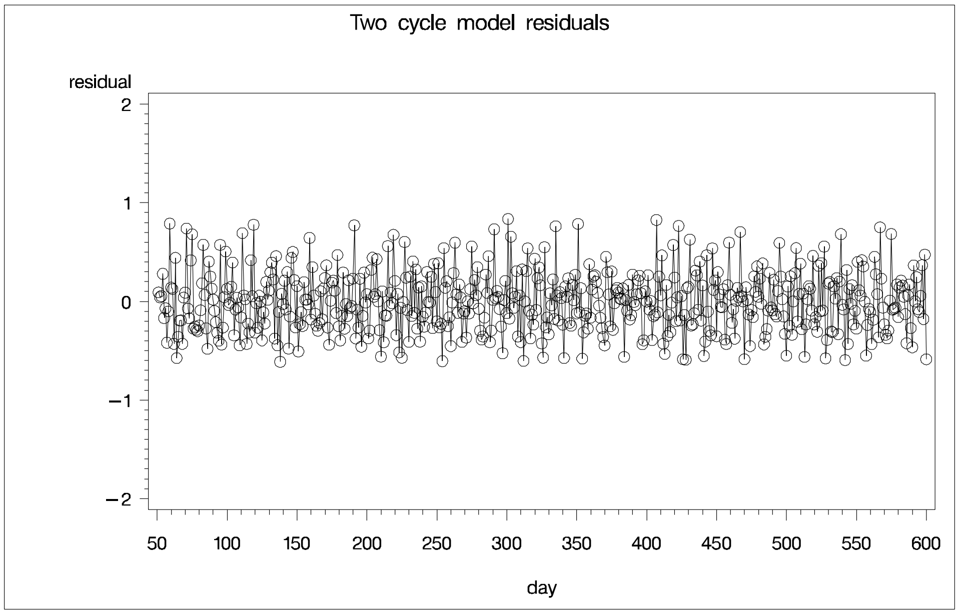
```
                 Cycle description (partial output)

       Name          Type               period          Rho       ErrorVar

      Cycle_1    Non-Stationary       24.00010      1.00000    2.89893E-12
      Cycle_2    Non-Stationary       29.00027      1.00000     2.7808E-12
```

Note that the estimated periods are the same as Bloomfield's model, and the disturbance variances are very close to zero, implying deterministic cycles. In fact, this model is identical to Bloomfield's model. The residual plot shown below also shows (Output 29.2.9) the improvement in the fit; for easy comparison the scale of the vertical axis is purposely set to be the same as the residual plot of the single-cycle model.

Output 29.2.9. Residual Plot for the Two Cycle Model



Example 29.3. Modeling Long Seasonal Patterns

In this example the use of the UCM procedure to model complex seasonal patterns is illustrated. Only a broad outline of the analysis is presented. The time series used in this example consists of number of calls received per shift at a call center. Each shift is of a three-hour duration, and the first shift of the day begins at midnight, resulting in eight shifts per day. The observations are available from December 15, 1999, up to April 30, 2000. Initial exploration of the series clearly shows that the time of the day and the day of the week have a significant influence on the number of calls received; however, the series does not show any significant trend. This suggests a simple random walk trend model along with a seasonal component with season length of 56. After fitting this model and examining the residual plots (not shown), the following modified model seems to fit the data quite well.

```
proc ucm data=callcenter;
    id datetime interval=dthour3;
    model calls;
    irregular;
    level;
    season length=56 type=trig;
    deplag lags=2;
    estimate back=112;
    forecast back=112 lead = 112;
run;
```

Along with the seasonal component of length 56 and the level and irregular components, this model also includes two lags of the dependent variable. The last two weeks of the data are withheld to examine the forecasting performance of the model on the observed data. The table in Output 29.3.1 shows the fit statistics for this model, and the plot in Output 29.3.2 shows the fit of the model on the withheld data.

Output 29.3.1. Model Fit for the Saturated Seasonal Model

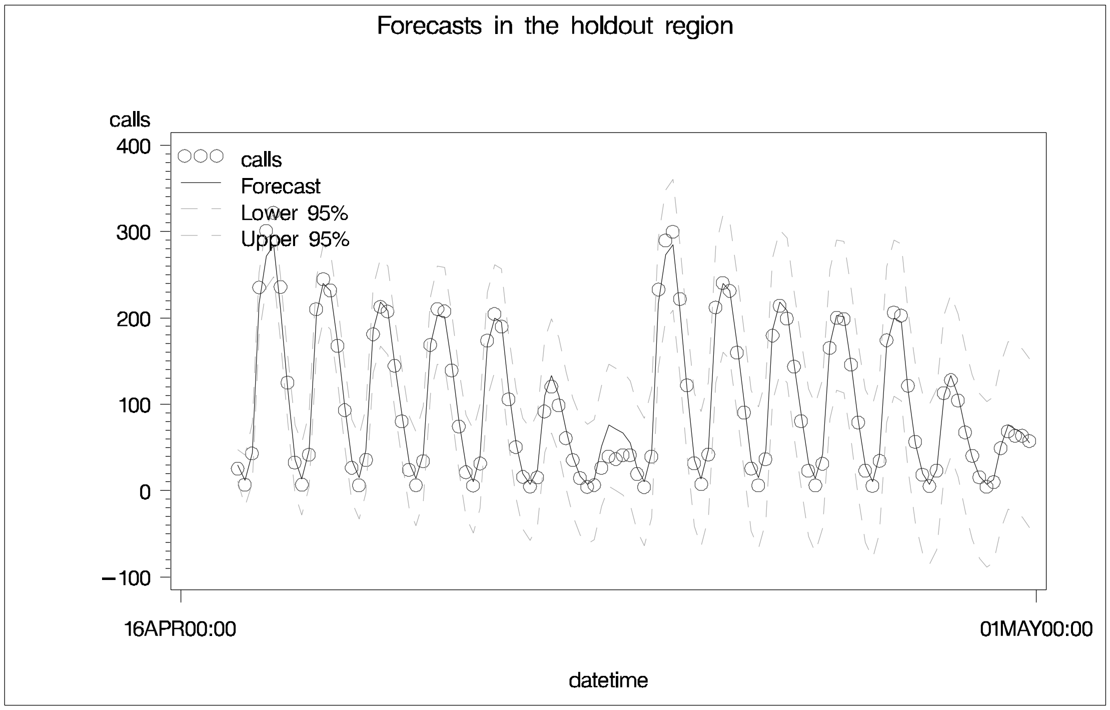
```
                         The UCM Procedure

                  Fit Statistics Based on Residuals

         Mean Squared Error                        93.91316
         Root Mean Squared Error                    9.69088
         Mean Absolute Percentage Error            19.75413
         Maximum Percent Error                   1102.00394
         R-Square                                   0.98664
         Adjusted R-Square                          0.98666
         Random Walk R-Square                       0.97575
         Amemiya’s Adjusted R-Square                0.98664

           Number of non-missing residuals used for
              computing the fit statistics = 934
```

Output 29.3.2. Forecasts for the Saturated Seasonal Model



This model fits the data well; however, it takes a considerable amount of time to estimate because the dimension of the state vector in the underlying state space model is large, about 60 (see “Details”). This problem becomes more acute for larger season lengths. More importantly, this model does not offer any insight into the structure of the particular seasonal pattern present at this call center; for example, it may be possible that a similar calling pattern may repeat during each day of the week except for different mean number of calls for different days of the week. Such a pattern is implied by a combination of two components, a simple seasonal of season length 8, for capturing the within day variation, and a block seasonal component of 7 blocks (a block for each day of the week) with block size of 8 that models the day to day variation during the week. The state vector of this model has dimension 17. Examination of the fit of this model reveals that the model fit is poorer than the above saturated seasonal model. The forecasts for Sundays and Mondays are particularly bad. This behavior can be improved somewhat by including dummy variables corresponding to some of the shifts on these days. The following statements specify one such model.

```
proc ucm data=callcenter;
    id datetime interval=dthour3;
    model calls = s_shift3 s_shift4 s_shift6
                  m_shift1 m_shift3 m_shift6;
    irregular;
    level;
    season length=8 type=trig;
    blockseason nblocks=7 blocksize=8 type=trig;
    deplag lags=2;
    estimate back=112;
    forecast back=112 lead = 112 print=forecasts;
run;
```

The model contains dummy regressors for three shifts on Sundays, shifts 3, 4, and 6, and three shifts on Mondays, shifts 1, 3, and 6. The table in Output 29.3.3 shows the fit statistics for this model, and the plot in Output 29.3.4 shows the fit of the model on the withheld data.

Output 29.3.3. Model Fit for the Block Seasonal Model

```
                                The UCM Procedure

                        Fit Statistics Based on Residuals

                 Mean Squared Error                   183.66579
                 Root Mean Squared Error               13.55234
                 Mean Absolute Percentage Error        38.34285

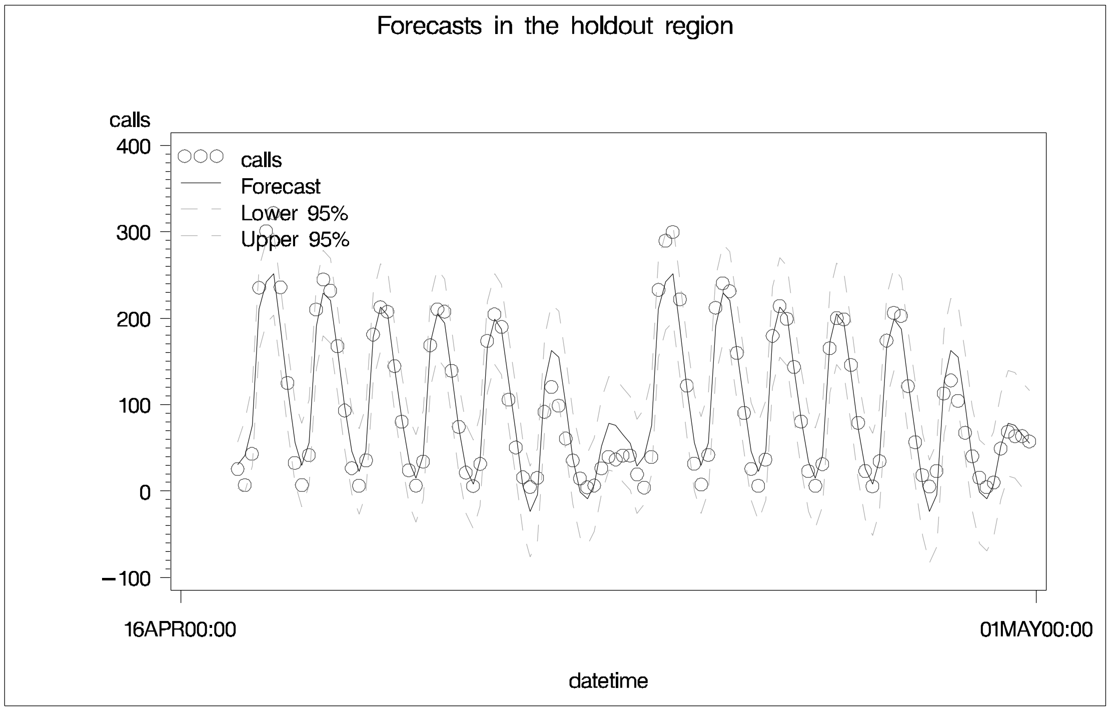
```

Output 29.3.4. Forecasts for the Block Seasonal Model



This model can be improved further using similar considerations. The use of block seasonals is only one of several ways to model seasonals with long season lengths. Alternatively, you can also use a smaller set of harmonics than the full set used in the saturated model. This is done by specifying a separate cycle statement for each of the harmonics included in the model.

Example 29.4. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. The graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the UCM procedure, see the "ODS Graphics" section on page 1664.

The following code shows how you can use the PLOT= option in different statements of the UCM procedure to get useful plots for the Airline Passenger example discussed earlier; see Example 29.1. The PLOT=SMOOTH option in the SEASON statement requests plotting of the smoothed estimate of that seasonal component. The use of PLOT=(RESIDUAL NORMAL ACF) in the ESTIMATE statement produces the time series plot of residuals, the histogram of residuals, and the autocorrelation plot of residuals, respectively. Finally, the use of PLOT=(FORECASTS DECOMP) option in the FORECAST statement produces the forecast, the trend, and the trend plus season plots.

The VARMAX Procedure

Chapter Contents

Chapter 30
The VARMAX Procedure

Overview

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts associated with Vector AutoRegressive Moving-Average processes with eXogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated to each other, they are also correlated to each other's past values. The VARMAX procedure can be used to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model both the dynamic relationship between the dependent variables and between the dependent and independent variables.

VARMAX models are defined in terms of the orders of the autoregressive or moving-average process (or both). When you use the VARMAX procedure, these orders can be specified by options or they can be automatically determined. Criteria for automatically determining these orders include

- Akaike Information Criterion (AIC)
- Corrected AIC (AICC)
- Hannan-Quinn (HQ) Criterion
- Final Prediction Error (FPE)
- Schwarz Bayesian Criterion (SBC), also known as Bayesian Information Criterion (BIC)

If you do not wish to use the automatic order selection, the VARMAX procedure provides AR order identification aids:

- partial cross-correlations
- Yule-Walker estimates
- partial autoregressive coefficients
- partial canonical correlations

For situations where the stationarity of the time series is in question, the VARMAX procedure provides tests to aid in determining the presence of unit roots and cointegration. These tests include

- Dickey-Fuller tests

- Johansen cointegration test for nonstationary vector processes of integrated order one
- Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
- Johansen cointegration test for nonstationary vector processes of integrated order two

For stationary vector times series (or nonstationary series made stationary by appropriate differencing), the VARMAX procedure provides for both Vector AutoRegressive (VAR) and Bayesian Vector AutoRegressive (BVAR) models. To cope with the problem of high dimensionality in the parameters of the VAR model, the VARMAX procedure provides both the Vector Error Correction Model (VECM) and Bayesian Vector Error Correction Model (BVECM). Bayesian models are used when prior information about the model parameters is available. The VARMAX procedure can allow independent (exogenous) variables with their distributed lags to influence dependent (endogenous) variables. The model parameter estimation methods are

- Least Squares (LS)
- Maximum Likelihood (ML)

The VARMAX procedure provides various hypothesis tests of long-run effects and adjustment coefficients using the likelihood ratio test based on Johansen cointegration analysis. The VARMAX procedure offers the likelihood ratio test of the weak exogeneity for each variable.

After fitting the model parameters, the VARMAX procedure provides for model checks and residual analysis using the following tests:

- Durbin-Watson (DW) statistics
- F test for autoregressive conditional heteroscedastic (ARCH) disturbance
- F test for AR disturbance
- Jarque-Bera normality test
- Portmanteau test

Forecasting is one of the main objectives of multivariate time series analysis. After successfully fitting the VAR, VARX, BVAR, VARMA, VECM, and BVECM model parameters, the VARMAX procedure computes predicted values based on the parameter estimates and the past values of the vector time series.

The VARMAX procedure supports several modeling features, including

- seasonal deterministic terms
- subset models
- multiple regression with distributed lags

- dead-start model that does not have present values of the exogenous variables
- GARCH-type multivariate conditional heteroscedasticity models

The VARMAX procedure provides a Granger-Causality test to determine the Granger-causal relationships between two distinct groups of variables. It also provides

- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle
- contemporaneous relationships among the components of the vector time series

Experimental graphics are now available with the VARMAX procedure. For more information, see the "ODS Graphics" section on page 1825.

Getting Started

This section outlines the use of the VARMAX procedure and gives five different examples of the kind of models supported.

Vector Autoregressive Process

Let $\mathbf{y}_t = (y_{1t}, \ldots, y_{kt})'$, $t = 1, 2, \ldots$, denote a k-dimensional time series vector of random variables of interest. The pth-order VAR process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \cdots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where the $\boldsymbol{\epsilon}_t$ is a vector white noise process with $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \ldots, \epsilon_{kt})'$ such that $\mathrm{E}(\boldsymbol{\epsilon}_t) = 0$, $\mathrm{E}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') = \Sigma$, and $\mathrm{E}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_s') = 0$ for $t \neq s$; $\boldsymbol{\delta} = (\delta_1, \ldots, \delta_k)'$ is a constant vector and Φ_i is a $k \times k$ matrix.

Analyzing and modeling the series jointly enables you to understand the dynamic relationships over time among the series and to improve the accuracy of forecasts for individual series by utilizing the additional information available from the related series and their forecasts.

Example of Vector Autoregressive Model

Consider the first-order stationary vector autoregressive model

$$\mathbf{y}_t = \begin{pmatrix} 1.2 & -0.5 \\ 0.6 & 0.3 \end{pmatrix} \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t, \quad \text{with } \Sigma = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.25 \end{pmatrix}$$

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
   sig = {1.0  0.5, 0.5 1.25};
   phi = {1.2 -0.5, 0.6 0.3};
   /* simulate the vector time series */
   call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
   cn = {'y1' 'y2'};
   create simul1 from y[colname=cn];
   append from y;
quit;
```

The following statements plot the simulated vector time series $\mathbf{y}_t$ shown in Figure 30.1:

```
data simul1;
   set simul1;
   date = intnx( 'year', '01jan1900'd, _n_-1 );
   format date year4.;

proc gplot data=simul1;
   symbol1 v = none i = join l = 1;
   symbol2 v = none i = join l = 2;
   plot y1 * date = 1
        y2 * date = 2 / overlay;
run;
```

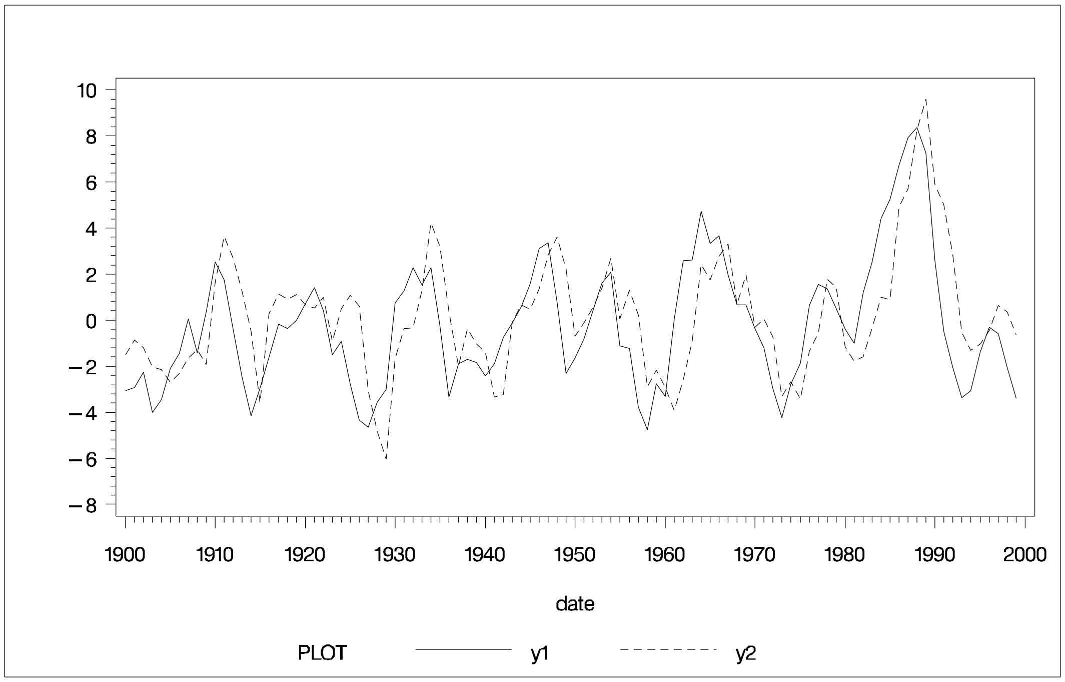

Figure 30.1. Plot of Generated Data Process

The following statements fit a VAR(1) model to the simulated data. You first specify the input data set in the PROC VARMAX statement. Then, you use the MODEL statement to read the time series y_1 and y_2. To estimate a VAR model with mean zero, you specify the order of the autoregressive model with the P= option and the NOINT option. The MODEL statement fits the model to the data and prints parameter estimates and various diagnostic tests. The LAGMAX=3 option is used to print the output for the residual diagnostic checks. For the forecasts, you specify the OUTPUT statement. If you wish to forecast five steps ahead, you use the option LEAD=5. The ID statement specifies the yearly interval between observations and provides the Time column in the forecast output.

The VARMAX procedure output is shown in Figure 30.2 through Figure 30.10.

```
proc varmax data=simul1;
   id date interval=year;
   model y1 y2 / p=1 noint lagmax=3;
   output lead=5;
run;
```

```
                              The VARMAX Procedure

                        Number of Observations        100
                        Number of Pairwise Missing      0

                           Model Parameter Estimates

                                            Standard
Equation Parameter      Estimate           Error t Value Pr > |t| Variable

y1       AR1_1_1         1.15977         0.05508   21.06   0.0001 y1(t-1)
         AR1_1_2        -0.51058         0.05898   -8.66   0.0001 y2(t-1)
y2       AR1_2_1         0.54634         0.05779    9.45   0.0001 y1(t-1)
         AR1_2_2         0.38499         0.06188    6.22   0.0001 y2(t-1)
```

Figure 30.3. Parameter Estimates

Figure 30.3 shows the AR coefficient matrix in terms of lag 1, the parameter estimates, and their significance, which can indicate how well the model fits the data.

The second table schematically represents the parameter estimates and allows for easy verification of their significance in matrix form.

In the last table, the first column gives the left-hand-side variable of the equation; the second column, the parameter name ARl_i_j, which indicates the (i,j)th element of the lag l autoregressive coefficient; the last column, the regressor corresponding to its parameter.

The fitted VAR(1) model with estimated standard errors in parentheses is given as

$$\mathbf{y}_t = \left(\begin{array}{rr} 1.160 & -0.511 \\ (0.055) & (0.059) \\ 0.546 & 0.385 \\ (0.058) & (0.062) \end{array} \right) \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

Clearly, all parameter estimates in the coefficient matrix Φ_1 are significant.

The model can also be written as two univariate regression equations.

$$\begin{aligned} y_{1t} &= 1.160\, y_{1,t-1} - 0.511\, y_{2,t-1} + \epsilon_{1t} \\ y_{2t} &= 0.546\, y_{1,t-1} + 0.385\, y_{2,t-1} + \epsilon_{2t} \end{aligned}$$

Figure 30.8. Univariate Diagnostic Checks

The VARMAX procedure provides diagnostic checks for the univariate form of the equations. The table in Figure 30.8 describes how well each univariate equation fits the data. From two univariate regression equations in Figure 30.3, the values of R^2 in the second column are 0.84 and 0.80 for each equation. The standard deviations in the third column are the square roots of the diagonal elements of the covariance matrix from Figure 30.4. The F statistics are in the fourth column for hypotheses to test $\phi_{11} = \phi_{12} = 0$ and $\phi_{21} = \phi_{22} = 0$, respectively, where ϕ_{ij} is the (i, j)th element of the matrix Φ_1. The last column shows the p-values of the F statistics. The results show that each univariate model is significant.

Figure 30.9. Univariate Diagnostic Checks Continued

The check for white noise residuals in terms of the univariate equation is shown in Figure 30.9. This output contains information that indicates whether the residuals are correlated and heteroscedastic. In the first table, the second column contains the Durbin-Watson test statistics; the third and fourth columns show the Jarque-Bera normality test statistics and their p-values; the last two columns show F statistics and their p-values for ARCH(1) disturbances. The second table includes F statistics and their p-values for AR(1) to AR(4) disturbances.

Bayesian Vector Autoregressive Process

The Bayesian Vector AutoRegressive (BVAR) model is used to avoid problems of collinearity and over-parameterization that often occur with the use of VAR models. BVAR models do this by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data. You specify the PRIOR= option with the hyper-parameters. The options LAMBDA=0.9 and THETA=0.1 are hyper-parameters controlling the prior covariance. Part of the VARMAX procedure output is shown in Figure 30.11.

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint
                 prior=(lambda=0.9 theta=0.1);
run;
```

```

Figure 30.11. Parameter Estimates for the BVAR(1) Model

The output in Figure 30.11 shows that parameter estimates are slightly different from those in Figure 30.3. By choosing the appropriate priors, you may be able to get more accurate forecasts using a BVAR model rather than using an unconstrained VAR model.

Vector Error Correction Model

A Vector Error Correction Model (VECM) can lead to a better understanding of the nature of any nonstationarity among the different component series and can also improve longer term forecasting over an unconstrained model.

The VECM(p) form with the cointegration rank $r(\leq k)$ is written as

$$\Delta\mathbf{y}_t = \boldsymbol{\delta} + \Pi\mathbf{y}_{t-1} + \sum_{i=1}^{p-1}\Phi_i^*\Delta\mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where Δ is the differencing operator, such that $\Delta\mathbf{y}_t = \mathbf{y}_t - \mathbf{y}_{t-1}$; $\Pi = \alpha\beta'$, where α and β are $k \times r$ matrices; Φ_i^* is a $k \times k$ matrix.

It has an equivalent VAR(p) representation as described in the preceding section.

$$\mathbf{y}_t = \boldsymbol{\delta} + (I_k + \Pi + \Phi_1^*)\mathbf{y}_{t-1} + \sum_{i=2}^{p-1}(\Phi_i^* - \Phi_{i-1}^*)\mathbf{y}_{t-i} - \Phi_{p-1}^*\mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

where I_k is a $k \times k$ identity matrix.

Example of Vector Error Correction Model

An example of the second-order nonstationary vector autoregressive model is

$$\mathbf{y}_t = \begin{pmatrix} -0.2 & 0.1 \\ 0.5 & 0.2 \end{pmatrix} \mathbf{y}_{t-1} + \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

with

$$\Sigma = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \text{ and } \mathbf{y}_0 = 0$$

This process can be given the following VECM(2) representation with the cointegration rank one:

$$\Delta\mathbf{y}_t = \begin{pmatrix} -0.4 \\ 0.1 \end{pmatrix} (1, -2)\mathbf{y}_{t-1} - \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \Delta\mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The following PROC IML statements generate simulated data for the VECM(2) form specified above and plot the data as shown in Figure 30.12:

```
proc iml;
   sig = 100*i(2);
   phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
   call varmasim(y,phi) sigma = sig n = 100 initial = 0
                        seed = 45876;
   cn = {'y1' 'y2'};
   create simul2 from y[colname=cn];
   append from y;
quit;

data simul2;
   set simul2;
   t+1;

proc gplot data=simul2;
   symbol1 v = none i = join l = 1;
   symbol2 v = none i = join l = 2;
   plot y1 * t = 1
        y2 * t = 2 / overlay;
run;
```

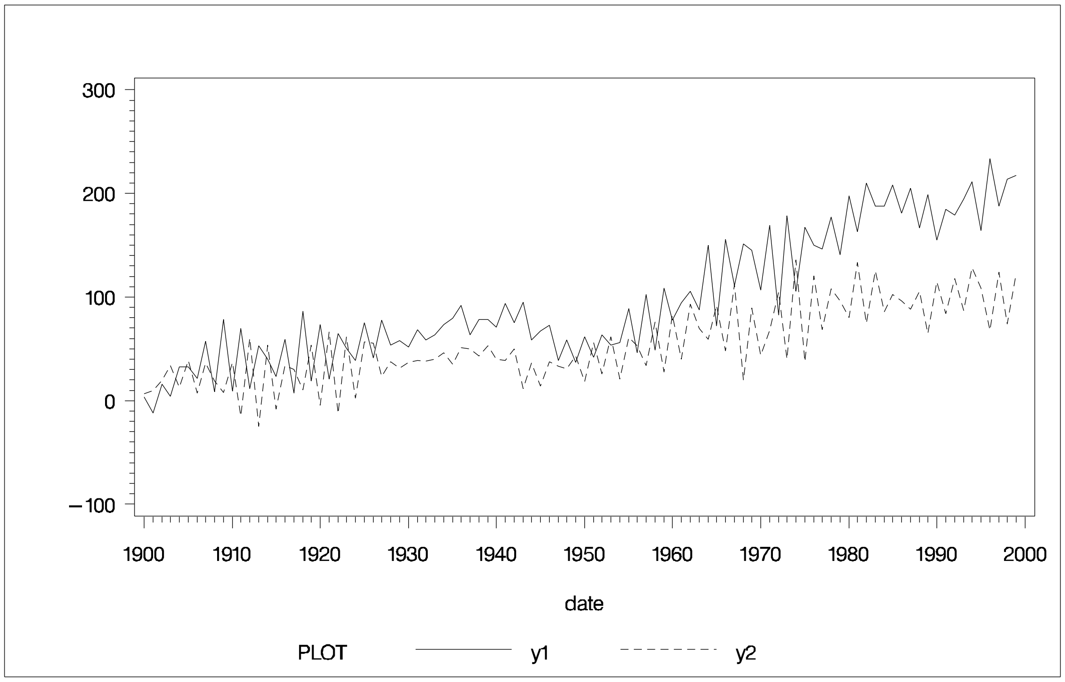

Figure 30.12. Plot of Generated Data Process

Cointegration Testing

The following statements use the Johansen cointegration rank test. The COINTTEST=(JOHANSEN) option does the Johansen trace test and is equivalent to the COINTTEST or COINTTEST=(JOHANSEN=(TYPE=TRACE)) option.

```
proc varmax data=simul2;
   model y1 y2 / p=2 noint dftest cointtest=(johansen);
run;
```

```
                              The VARMAX Procedure

```

Figure 30.13. Dickey-Fuller Tests and Cointegration Rank Test

Figure 30.13 shows the output for Dickey-Fuller tests for the nonstationarity of each series and Johansen cointegration rank test between series.

In Dickey-Fuller tests, the second column specifies three types of models, which are zero mean, single mean, or trend. The third column (Rho) and the fifth column (Tau) are the test statistics for unit root testing. Other colummns are their p-values. You can see that both series have unit roots.

In the cointegration rank test, the last two columns explain the drift in the model or process. Since the NOINT option is specified, the model is

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \Phi_1^* \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

The column DriftInECM means there is no separate drift in the error correction model, and the column DriftInProcess means the process has a constant drift before differencing.

H0 is the null hypothesis and H1 is the alternative hypothesis. The first row tests $r = 0$ against $r > 0$; the second row tests $r = 1$ against $r > 1$. The Trace test statistics in the fourth column are computed by $-T \sum_{i=r+1}^{k} \log(1 - \lambda_i)$ where T is the available number of observations and λ_i is the eigenvalue in the third column. By default, the critical values at 5% significance level are used for testing. You can compare the test statistics and critical values in each row; there is one cointegrated process.

The following statements fit a VECM(2) form to the simulated data. From the result in Figure 30.13, the time series are cointegrated with rank=1. You specify the ECM= option with the option RANK=1. For normalizing the value of the cointegrated vector, you specify the normalized variable with the NORMALIZE= option.

The PRINT=(IARR) option provides the VAR(2) representation. The VARMAX procedure output is shown in Figure 30.14 through Figure 30.16.

```
proc varmax data=simul2;
   model y1 y2 / p=2 noint print=(iarr) lagmax=3
                 ecm=(rank=1 normalize=y1);
run;
```

```

```

Figure 30.14. Parameter Estimates for the VECM(2) Form

The ECM= option produces the estimates of the long-run parameter, $\boldsymbol{\beta}$, and the adjustment coefficient, $\boldsymbol{\alpha}$. In Figure 30.14, "1" indicates the first column of the $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ matrices. Since the cointegration rank is 1 in the bivariate system, $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are two-dimensional vectors. The estimated cointegrating vector is $\hat{\boldsymbol{\beta}} = (1, -1.96)'$; the long-run relationship between y_{1t} and y_{2t} is $y_{1t} = 1.96y_{2t}$. The first element of $\hat{\boldsymbol{\beta}}$ is 1 since y_1 is specified as the normalized variable.

Figure 30.15. Parameter Estimates for the VECM(2) Form Continued

Figure 30.15 shows the parameter estimates in terms of one lagged coefficient, $\mathbf{y}_{t-1}$, and one differenced lagged coefficient, $\Delta\mathbf{y}_{t-1}$, and their significance. “Alpha * Beta$'$” indicates the coefficient of $\mathbf{y}_{t-1}$ and is obtained by multiplying the “Alpha” and “Beta” estimates in Figure 30.14. The parameter AR1_i_j corresponds to the elements in the “Alpha * Beta$'$” matrix. The t values and p-values corresponding to the parameters AR1_i_j are missing since the parameters AR1_i_j have non-Gaussian distributions. The parameter AR2_i_j corresponds to the elements in the differenced lagged AR coefficient matrix. The “D_” prefixed to a variable name in Figure 30.15 implies differencing.

The fitted model is given as

$$\Delta\mathbf{y}_t = \left(\begin{array}{rr} -0.467 & 0.913 \\ (0.048) & (0.094) \\ 0.107 & -0.209 \\ (0.051) & (0.100) \end{array}\right)\mathbf{y}_{t-1} + \left(\begin{array}{rr} -0.743 & -0.746 \\ (0.045) & (0.048) \\ 0.405 & -0.572 \\ (0.049) & (0.051) \end{array}\right)\Delta\mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

Figure 30.16. Change the VECM(2) Form to the VAR(2) Model

The PRINT=(IARR) option in the previous SAS statements prints the reparameterized coefficient estimates. For the LAGMAX=3 in the SAS statements, the coefficent matrix of lag 3 is zero.

The VECM(2) form in Figure 30.16 can be rewritten as the following second-order vector autoregressive model:

$$\mathbf{y}_t = \left(\begin{array}{rr} -0.210 & 0.167 \\ 0.512 & 0.220 \end{array} \right) \mathbf{y}_{t-1} + \left(\begin{array}{rr} 0.743 & 0.746 \\ -0.405 & 0.572 \end{array} \right) \mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

Bayesian Vector Error Correction Model

Bayesian inference on a cointegrated system begins by using the priors of $\boldsymbol{\beta}$ obtained from the VECM(p) form. Bayesian vector error correction models can improve forecast accuracy for cointegrated processes. The following statements fit a BVECM(2) form to the simulated data. You specify both the PRIOR= and ECM= options for the Bayesian vector error correction model. The VARMAX procedure output is shown in Figure 30.17.

```
proc varmax data=simul2;
   model y1 y2 / p=2 noint
                 prior=(lambda=0.5 theta=0.2)
                 ecm=(rank=1 normalize=y1);
run;
```

```

```

Figure 30.17. Parameter Estimates for the BVECM(2) Form

Figure 30.17 shows the model type fitted the data, the estimates of the adjustment coefficient $\boldsymbol{\alpha}$, the parameter estimates in terms of one lagged coefficient, and one differenced lagged coefficient.

Vector Autoregressive Process with Exogenous Variables

A VAR process can be affected by other observable variables that are determined outside the system of interest. Such variables are called exogenous (independent) variables. Exogenous variables can be stochastic or nonstochastic. The process can also be affected by the lags of exogenous variables. A model used to describe this process is called a VARX(p,s) model.

The VARX(p,s) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^{s} \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{x}_t = (x_{1t}, \ldots, x_{rt})'$ is an r-dimensional time series vector and Θ_i^* is a $k \times r$ matrix.

For example, a VARX(1,0) model is

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \Theta_0^* \mathbf{x}_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_t = (y_{1t}, y_{2t}, y_{3t})'$ and $\mathbf{x}_t = (x_{1t}, x_{2t})'$.

The following statements fit the VARX(1,0) model to the given data:

```
data grunfeld;
   input year y1 y2 y3 x1 x2 x3;
   label y1='Gross Investment GE'
         y2='Capital Stock Lagged GE'

```

Figure 30.19. Parameter Estimates for the VARX(1, 0) Model

Figure 30.19 shows the parameter estimates for the constant, the lag zero coefficients of exogenous variables, and the lag one AR coefficients. From the schematic representation of parameter estimates, the significance of the parameter estimates can be easily verified. The symbol “C” means the constant and “XL0” the lag zero coefficients of exogenous variables.

Figure 30.20. Parameter Estimates for the VARX(1, 0) Model Continued

Figure 30.20 shows the parameter estimates and their significance.

The fitted model is given as

$$\begin{pmatrix} y_{1t} \\ y_{2t} \\ y_{3t} \end{pmatrix} = \begin{pmatrix} -12.013 \\ (27.471) \\ 702.086 \\ (256.480) \\ -22.421 \\ (10.312) \end{pmatrix} + \begin{pmatrix} 1.693 & -0.009 \\ (0.544) & (0.054) \\ -6.099 & 2.580 \\ (5.078) & (0.501) \\ -0.023 & -0.013 \\ (0.204) & (0.020) \end{pmatrix} \begin{pmatrix} x_{1t} \\ x_{2t} \end{pmatrix}$$

$$+ \begin{pmatrix} 0.237 & 0.008 & 0.029 \\ (0.207) & (0.016) & (0.049) \\ -2.467 & 0.164 & -0.841 \\ (1.930) & (0.152) & (0.453) \\ 0.951 & 0.002 & 0.938 \\ (0.078) & (0.006) & (0.018) \end{pmatrix} \begin{pmatrix} y_{1,t-1} \\ y_{2,t-1} \\ y_{3,t-1} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \\ \epsilon_{3t} \end{pmatrix}$$

Parameter Estimation and Testing on Restrictions

In the previous example, the VARX(1,0) model is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \Theta_0^* \mathbf{x}_t + \Phi_1 \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

with

$$\Theta_0^* = \begin{pmatrix} \theta_{11}^* & \theta_{12}^* \\ \theta_{21}^* & \theta_{22}^* \\ \theta_{31}^* & \theta_{32}^* \end{pmatrix} \quad \Phi_1 = \begin{pmatrix} \phi_{11} & \phi_{12} & \phi_{13} \\ \phi_{21} & \phi_{22} & \phi_{23} \\ \phi_{31} & \phi_{32} & \phi_{33} \end{pmatrix}$$

In Figure 30.20, you can see the coefficients XL_0_1_2, AR_1_1_2, and AR_1_3_2 are insignificant. The following statements restrict the coefficients of $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model.

```
proc varmax data=grunfeld;
   model y1-y3 = x1 x2 / p=1;
   restrict XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

```

        AR1_3_2            55.42191          164.03075        0.34       0.7524
```

Figure 30.22. RESTRICT Statement Results

The output in Figure 30.22 shows the estimates of the Lagrangian parameters and their significance. You cannot reject the null hypotheses $\theta^*_{12} = 0$, $\phi_{12} = 0$, and $\phi_{32} = 0$ with the 0.05 significance level.

The TEST statement in the following example tests $\phi_{31} = 0$ and $\theta^*_{12} = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model:

```
proc varmax data=grunfeld;
   model y1-y3 = x1 x2/ p=1;
   test AR(1,3,1)=0;
   test XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

```
                              The VARMAX Procedure

                           Testing of the Parameters

                      Test         DF     Chi-Square     Pr > ChiSq

                         1          1         150.31         <.0001
                         2          3           0.34         0.9522
```

Figure 30.23. TEST Statement Results

The output in Figure 30.23 shows that the first column in the output is the index corresponding to each TEST statement; you can reject the hypothesis test $\phi_{31} = 0$ at the 0.05 significance level; you cannot reject the joint hypothesis test $\theta^*_{12} = \phi_{12} = \phi_{32} = 0$ at the 0.05 significance level.

Causality Testing

The following statements use the CAUSAL statement to compute the Granger-Causality test for the VAR(1) model. For the Granger-Causality tests, the autoregressive order should be defined by the option P= in the MODEL statement. The variables in groups are defined in the MODEL statement as well. Regardless whether the variables in groups are either dependent or independent in the MODEL statement, the CAUSAL statement fits the VAR(p) model using the variables in two groups considering them as dependent variables.

```
proc varmax data=grunfeld;
   model y1-y3 = x1 x2 / p=1 noprint;
   causal group1=(x1) group2=(y1-y3);
   causal group1=(y3) group2=(y1 y2);
run;
```

```
                         The VARMAX Procedure

                      Granger-Causality Wald Test

                Test        DF    Chi-Square    Pr > ChiSq

                   1         3          2.40        0.4946
                   2         2        262.88        <.0001

                 Test 1:  Group 1 Variables:  x1
                          Group 2 Variables:  y1 y2 y3

                   Test 2:  Group 1 Variables:  y3
                            Group 2 Variables:  y1 y2
```

Figure 30.24. CAUSAL Statement Results

The output in Figure 30.24 is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model using the variabls $y1$, $y2$, $y3$, and $x1$; the second CAUSAL statement fits the VAR(1) model using the variabls $y1$, $y3$, and $y2$.

The first column in the output is the index corresponding to each CAUSAL statement. The output shows that you cannot reject that $x1$ is influenced by itself and not by $(y1, y2, y3)$ at the 0.05 significance level for Test 1; you can reject that $y3$ is influenced by itself and not by $(y1, y2)$ for Test 2.

Functional Summary

The statements and options used with the VARMAX procedure are summarized in the following table:

Description	Statement	Option
Data Set Options		
specify the input data set	VARMAX	DATA=
write parameter estimates to an output data set	VARMAX	OUTEST=
include covariances in the OUTEST= data set	VARMAX	OUTCOV
write the diagnostic checking tests for a model and the cointegration test results to an output data set	VARMAX	OUTSTAT=
write actuals, predictions, residuals, and confidence limits to an output data set	OUTPUT	OUT=
BY Groups		
specify BY-group processing	BY	
ID Variable		
specify identifying variable	ID	
specify the time interval between observations	ID	INTERVAL=
control the alignment of SAS Date values	ID	ALIGN=
Options to Control the Optimization Process		
specify the optimization options	NLOPTIONS	see Chapter 10
Printing Control Options		
specify how many lags to print results	MODEL	LAGMAX=
suppress the printed output	MODEL	NOPRINT
request all printing options	MODEL	PRINTALL
request the printing format	MODEL	PRINTFORM=
PRINT= Option		
print the correlation matrix of parameter estimates	MODEL	CORRB
print the cross-correlation matrices of independent variables	MODEL	CORRX
print the cross-correlation of dependent variables	MODEL	CORRY
print the covariance matrices of prediction errors	MODEL	COVPE
print the cross-covariance matrices of the independent variables	MODEL	COVX
print the cross-covariance matrices of the dependent variables	MODEL	COVY
print the covariance matrix of parameter estimates	MODEL	COVB
print the decomposition of the prediction error covariance matrix	MODEL	DECOMPOSE

Description	Statement	Option
print the contemporaneous relationships among the components of the vector time series	MODEL	DYNAMIC
print the infinite order AR representation	MODEL	IARR
print the impulse response function	MODEL	IMPULSE=
print the impulse response function in the transfer function	MODEL	IMPULSX=
print the partial autoregressive coefficient matrices	MODEL	PARCOEF
print the partial canonical correlation matrices	MODEL	PCANCORR
print the partial correlation matrices	MODEL	PCORR
print the eigenvalues of the companion matrix	MODEL	ROOTS
print the Yule-Walker estimates	MODEL	YW
Model Estimation and Order Selection Options		
center the dependent variables	MODEL	CENTER
specify the degrees of differencing for the specified model variables	MODEL	DIF=
specify the degrees of differencing for all independent variables	MODEL	DIFX=
specify the degrees of differencing for all dependent variables	MODEL	DIFY=
specify the vector error correction model	MODEL	ECM=
specify the GARCH-type model	MODEL	GARCH=
specify the estimation method	MODEL	METHOD=
select the tentative order	MODEL	MINIC=
suppress the current values of independent variables	MODEL	NOCURRENTX
suppress the intercept parameters	MODEL	NOINT
specify the number of seasonal periods	MODEL	NSEASON=
specify the order of autoregressive polynomial	MODEL	P=
specify the Bayesian prior model	MODEL	PRIOR=
specify the order of moving-average polynomial	MODEL	Q=
center the seasonal dummies	MODEL	SCENTER
specify the degree of time trend polynomial	MODEL	TREND=
specify the denominator for error covariance matrix estimates	MODEL	VARDEF=
specify the lag order of independent variables	MODEL	XLAG=
Cointegration Related Options		
print the results from the weak exogeneity test of the long-run parameters	COINTEG	EXOGENEITY
specify the restriction on the cointegrated coefficient matrix	COINTEG	H=
specify the restriction on the adjustment coefficient matrix	COINTEG	J=

Description	Statement	Option
specify the variable name whose cointegrating vectors are normalized	COINTEG	NORMALIZE=
specify a cointegration rank	COINTEG	RANK=
print the Johansen cointegration rank test	MODEL	COINTTEST= (JOHANSEN=)
print the Stock-Watson common trends test	MODEL	COINTTEST=(SW=)
print the Dickey-Fuller unit root test	MODEL	DFTEST=
Tests and Restrictions on Parameters		
test the Granger-Causality	CAUSAL	GROUP1= GROUP2=
place and test restrictions on parameter estimates	RESTRICT	
test hypotheses	TEST	
Output Control Options		
specify the size of confidence limits for forecasting	OUTPUT	ALPHA=
start forecasting before end of the input data	OUTPUT	BACK=
specify how many periods to forecast	OUTPUT	LEAD=
suppress the printed forecasts	OUTPUT	NOPRINT

PROC VARMAX Statement

PROC VARMAX *options* **;**

The following options can be used in the PROC VARMAX statement:

DATA= *SAS-data-set*
specifies the input SAS data set. If the DATA= option is not specified, the PROC VARMAX statement uses the most recently created SAS data set.

OUTEST= *SAS-data-set*
writes the parameter estimates to the output data set.

COVOUT
OUTCOV
writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

OUTSTAT= *SAS-data-set*
writes residual diagnostic results to an output data set. If the COINTTEST=(JOHANSEN) option is specified, the results of this option are also written to the output data set.

The following statements are the examples of the options in the PROC VARMAX statement:

```
proc varmax data=one outest=est outcov outstat=stat;
   model y1-y3 / p=1;
run;
```

```
proc varmax data=one outest=est outstat=stat;
   model y1-y3 / p=1 cointtest=(johansen);
run;
```

Other Options

In addition, any of the following MODEL statement options can be specified in the PROC VARMAX statement, which is equivalent to specifying the option for every MODEL statement: CENTER, DFTEST=, DIF=, DIFX=, DIFY=, LAGMAX=, METHOD=, MINIC=, NOCURRENTX, NOINT, NOPRINT, NSEASON=, P=, PRINT=, PRINTALL, PRINTFORM=, Q=, SCENTER, TREND=, VARDEF=, and XLAG= options.

The following statement is an example of the options in the PROC VARMAX statement:

```
proc varmax data=one lagmax=3 method=ml;
   model y1-y3 / p=1;
run;
```

BY Statement

BY *variables***;**

A BY statement can be used with the PROC VARMAX statement to obtain separate analyses on observations in groups defined by the BY variables.

The following statement is an example of the BY statement:

```
proc varmax data=one;
   by region;
   model y1-y3 / p=1;
run;
```

CAUSAL Statement

CAUSAL GROUP1=*(variables)* **GROUP2=***(variables)***;**

A CAUSAL statement prints the Granger-Causality test by fitting the VAR(p) model using all variables defined in GROUP1 and GROUP2. Any number of CAUSAL statements can be specified. The CAUSAL statement proceeds with the MODEL statement and uses the variables and the autoregressive order, p, specified in the MODEL statement. Variables in the GROUP1= and GROUP2= options should be defined in the MODEL statement. If the option P=0 is specified in the MODEL statement, the CAUSAL statement is not applicable.

The null hypothesis of the Granger-Causality test is that GROUP1 is influenced only by itself, and not by GROUP2. If the test of hypothesis fails to reject the null, the variables in the GROUP1 may be considered as independent variables.

See the "VAR Modeling" section on page 1766 for details.

The following is an example of the CAUSAL statement. You specify the CAUSAL statement with the GROUP1= and GROUP2= options.

```
proc varmax data=one;
   model y1-y3 = x1 / p=1;
   causal group1=(x1) group2=(y1-y3);
   causal group1=(y2) group2=(y1 y3);
run;
```

The first CAUSAL statement fits the VAR(1) model using the variables $y1$, $y2$, $y3$, and $x1$ and tests the null hypothesis that $x1$ causes the other variables $y1$, $y2$, and $y3$, but the other variables do not cause $x1$. The second CAUSAL statement fits the VAR(1) model using the variables $y1$, $y3$, and $y2$ and tests the null hypothesis that $y2$ causes the other variables $y1$ and $y3$, but the other variables do not cause $y2$.

COINTEG Statement

COINTEG RANK= *number* < **H=** *(matrix)* > < **J=** *(matrix)* >
< **EXOGENEITY** > < **NORMALIZE=** *variable* > **;**

The COINTEG statement fits the vector error correction model to the data, tests the restrictions of the long-run parameters and the adjustment parameters, and tests for the weak exogeneity in the long-run parameters. The cointegrated system uses the maximum likelihood analysis proposed by Johansen and Juselius (1990) and Johansen (1995a, 1995b). Only one COINTEG statement is allowed.

You specify the ECM= option or the COINTEG statement for fitting the VECM(p) with the P= option in the MODEL statement.

The following statements are equivalent for fitting the VECM(2).

```
proc varmax data=one;
   model y1-y3 / p=2 ecm=(rank=1);
run;
```

```
proc varmax data=one;
   model y1-y3 / p=2;
   cointeg rank=1;
run;
```

For testing of the restrictions of either α or β or both, you specify either J= or H= or both. You specify the EXOGENEITY option for tests of the weak exogeneity in the long-run parameters.

The following statement is an example of the COINTEG statement.

```
proc varmax data=one;
   model y1-y3 / p=2;
   cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1)
           j=(1 0, 0 0, 0 1) exogeneity;
run;
```

The following options can be used in the COINTEG statement:

EXOGENEITY

formulates the likelihood ratio tests for testing weak exogeneity in the long-run parameters. The hypothesis is that one variable is weakly exogenous for the others.

H= (*matrix*)

specifies the restrictions H on the $k \times r$ or $(k+1) \times r$ cointegrated coefficient matrix $\boldsymbol{\beta}$ such that $\boldsymbol{\beta} = H\phi$, where H is known and ϕ is unknown. The $k \times m$ or $(k+1) \times m$ matrix H is specified using this option, where k is the number of dependent variables, and m is $r \leq m < k$ with the option RANK=r. For example, consider that the system contains four variables and the option RANK=1 with $\boldsymbol{\beta} = (\beta_1, \beta_2, \beta_3, \beta_4)'$. The restriction matrix for the test of $\beta_1 + \beta_2 = 0$ can be specified as

```
cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1);
```

Here the matrix H is 4×3 where $k = 4$ and $m = 3$, and each row of the matrix H is divided by commas (,).

When the series has no separate deterministic trend, the constant term should be restricted by $\boldsymbol{\alpha}'_{\perp}\boldsymbol{\delta} = 0$. In the example above, the $\boldsymbol{\beta}$ can be either $\boldsymbol{\beta} = (\beta_1, \beta_2, \beta_3, \beta_4, 1)'$ or $\boldsymbol{\beta} = (\beta_1, \beta_2, \beta_3, \beta_4, t)'$. Then, you can specify the restriction matrix for the previous test of $\beta_1 + \beta_2 = 0$ as follows:

```
cointeg rank=1
   h=(1 0 0 0, -1 0 0 0, 0 1 0 0, 0 0 1 0, 0 0 0 1);
```

When the cointegrated system contains three dependent variables and the option RANK=2, you can specify the restriction matrix for the test of $\beta_{1j} = -\beta_{2j}$ for $j = 1, 2$ as follows:

```
cointeg rank=2 h=(1 0, -1 0, 0 1);
```

J= (*matrix*)

specifies the restrictions J on the $k \times r$ adjustment matrix $\boldsymbol{\alpha}$ such that $\boldsymbol{\alpha} = J\psi$, where J is known and ψ is unknown. The $k \times m$ matrix J is specified using this option, where k is the number of dependent variables, and m is $r \leq m < k$ with the option RANK=r. For example, when the system contains four variables and the option RANK=1, you can specify the restriction matrix for the test of $\alpha_j = 0$ for $j = 2, 3, 4$ as follows:

```
cointeg rank=1 j=(1, 0, 0, 0);
```

When the system contains three variables and the option RANK=2, you can specify the restriction matrix for the test of $\alpha_{2j} = 0$ for $j = 1, 2$ as follows:

```
cointeg rank=2 j=(1 0, 0 0, 0 1);
```

NORMALIZE= *variable*
specifies a single dependent (endogenous) variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTTEST=(JOHANSEN=) or ECM= option in the MODEL statement, the variable name specified in the COINTEG statement is used. If the normalized variable is not specified, cointegrating vectors are not normalized.

RANK= *number*
specifies the cointegration rank of the cointegrated system. This option is required in the COINTEG statement. The rank of cointegration should be greater than zero and less than the number of dependent (endogenous) variables. If the value of the RANK= option in the COINTEG statement is different from that specified in the ECM= option, the rank specified in the COINTEG statement is used.

ID Statement

ID *variable* **INTERVAL=** *value* < **ALIGN=** *value* > **;**

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. Note that the ID *variable* is usually a SAS date valued variable. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN= *value*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL= *value*
specifies the time interval between observations. This option is required in the ID statement. The option INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data.

The following statement is an example of the ID statement:

```
proc varmax data=one;
   id date interval=qtr align=mid;
   model y1-y3 / p=1;
run;
```

MODEL Statement

MODEL *dependents < = regressors >*
<, dependents < = regressors > ... >
</ options > **;**

The MODEL statement specifies dependent (endogenous) variables and independent (exogenous) variables for the VARMAX model. The multivariate model can have the same or different independent variables corresponding to the dependent variables. As a special case, the VARMAX procedure allows you to analyze one dependent variable. The one MODEL statement is required.

For example, the following statements are equivalent ways of specifying the multivariate model for the vector $(y1, y2, y3)$:

```
model y1 y2 y3 </options>;
model y1-y3 </options>;
```

The following statements are equivalent ways of specifying the multivariate model for the vectors $(y1, y2, y3, y4)$ and $(x1, x2, x3, x4, x5)$:

```
model y1 y2 y3 y4 = x1 x2 x3 x4 x5 </options>;
model y1 y2 y3 y4 = x1-x5 </options>;
model y1 = x1-x5, y2 = x1-x5, y3 y4 = x1-x5 </options>;
model y1-y4 = x1-x5 </options>;
```

When the multivariate model has different independent variables corresponding to the dependent variables, equations are separated by commas (,) and the model can be specified as illustrated by the following MODEL statement:

```
model y1 = x1-x3, y2 = x3-x5, y3 y4 = x1-x5 </options>;
```

The following options can be used in the MODEL statement after a forward slash (/):

General Options

CENTER
centers dependent (endogenous) variables by subtracting their means. Note that centering is done after differencing when the DIF= or DIFY= option is specified. If there are exogenous (independent) variables, this option is not applicable.

```
model y1 y2 / p=1 center;
```

DIF(*variable***(***number-list***)<...** *variable***(***number-list***)>)**
DIF= (*variable***(***number-list***)<...** *variable***(***number-list***)>)**
specifies the degrees of differencing to be applied to the specified dependent or independent variables. The differencing can be the same for all variables, or it can vary

among variables. For example, the option DIF=(y_1(1,4) y_3(1) x_2(2)) specifies that the series y_1 is differenced at lag 1 and at lag 4, which is

$$(1 - B^4)(1 - B)y_{1t} = (y_{1t} - y_{1,t-1}) - (y_{1,t-4} - y_{1,t-5})$$

the series y_3 is differenced at lag 1, which is $(y_{3t} - y_{3,t-1})$; the series x_2 is differenced at lag 2, which is $(x_{2t} - x_{2,t-2})$.

```
   model y1 y2 = x1 x2 / p=1 dif=(y1(1) x2(2));
```

When you fit the model above, you use the data $dy1$, $y2$, $x1$, and $dx2$, where $dy1 = (1 - B)y_{1t}$ and $dx2 = (1 - B)x_{2t}$.

DIFX(*number-list***)**
DIFX= (*number-list***)**
specifies the degrees of differencing to be applied to all exogenous (independent) variables. For example, the option DIFX=(1) specifies that the series are differenced once at lag 1; the option DIFX=(1,4) specifies that the series are differenced at lag 1 and at lag 4. If exogenous variables are specified in the DIF= option, this option is ignored.

```
   model y1 y2 = x1 x2 / p=1 difx(1);
```

When you fit the model above, you use the data $y1$, $y2$, $dx1$, and $dx2$, where $dx1 = (1 - B)x_{1t}$ and $dx2 = (1 - B)x_{2t}$.

DIFY(*number-list***)**
DIFY= (*number-list***)**
specifies the degrees of differencing to be applied to all dependent (endogenous) variables. For details, see the DIFX= option. If dependent variables are specified in the DIF= option, this option is ignored.

```
   model y1 y2 / p=1 dify(1);
```

METHOD= *value*
requests the type of estimates to be computed. The possible values of the METHOD= option are

LS	specifies least-squares estimates.
ML	specifies maximum likelihood estimates.

When the options ECM=, GARCH=, PRIOR=, and Q= are specified, the default MLE method is used regardless of the method given by the option METHOD=. The option XLAG= is specified, the default LS method is used regardless of the method given by the option METHOD=. The pure VAR model uses the method given by the option METHOD=, but the default for the pure VAR model is the LS method.

```
   model y1 y2 / p=1 method=ml;
```

NOCURRENTX

suppresses the current values x_t of exogenous (independent) variables. In general, the VARX(p, s) model is

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^{s} \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

For this model with $p = 1$ and $s = 2$,

```
   model y1 y2 = x1 x2 / p=1 xlag=2;
```

If this option is specified, it suppresses the current values $\mathbf{x}_t$ and starts with $\mathbf{x}_{t-1}$.

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \sum_{i=1}^{s} \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

For this model with $p = 1$ and $s = 2$,

```
   model y1 y2 = x1 x2 / p=1 xlag=2 nocurrentx;
```

NOINT

suppresses the intercept parameter $\boldsymbol{\delta}$.

```
   model y1 y2 / p=1 noint;
```

NSEASON= *number*

specifies the number of seasonal periods. When the NSEASON=*number* option is specified, (*number*-1) seasonal dummies are added to the regressors. If the NOINT option is specified, the NSEASON= option is not applicable.

```
   model y1 y2 / p=1 nseason=4;
```

SCENTER

centers seasonal dummies specified by the NSEASON= option. The centered seasonal dummies are generated by $c - (1/s)$, where c is a seasonal dummy generated by the NSEASON=s option.

```
   model y1 y2 / p=1 nseason=4 scenter;
```

TREND= *value*

specifies the degree of deterministic time trend included in the model. Valid values are as follows:

LINEAR	includes a linear time trend as a regressor.
QUAD	includes linear and quadratic time trends as regressors.

The TREND=QUAD option is not applicable for a cointegration analysis.

```
model y1 y2 / p=1 trend=linear;
```

VARDEF= *value*

corrects for the degrees of freedom of the denominator. This option is used to calculate an error covariance matrix for the option METHOD=LS. If the option METHOD=ML is specified, the option VARDEF=N is used. Valid values are as follows:

DF	specifies that the number of nonmissing observation minus the number of regressors be used.
N	specifies that the number of nonmissing observation be used.

```
model y1 y2 / p=1 vardef=n;
```

Printing Control Options

LAGMAX= *number*

specifies the lag to compute and display the results obtained by the option PRINT=(CORRX CORRY COVX COVY IARR IMPULSE= IMPULSX= PARCOEF PCANCORR PCORR). This option is also used to print cross-covariances and cross-correlations of residuals. The default is LAGMAX=min(12, T-2), where T is the number of nonmissing observations.

```
model y1 y2 / p=1 lagmax=6;
```

NOPRINT

suppresses all printed output.

```
model y1 y2 / p=1 noprint;
```

PRINTALL

requests all printing control options. The options set by the option PRINTALL are DFTEST=, MINIC=, PRINTFORM=BOTH, and PRINT=(CORRB CORRX CORRY COVB COVPE COVX COVY DECOMPOSE DYNAMIC IARR IMPULSE=(ALL) IMPULSX=(ALL) PARCOEF PCANCORR PCORR ROOTS YW).

You can also specify this option as the option ALL.

```
   model y1 y2 / p=1 printall;
```

PRINTFORM= *value*

requests the printing format of outputs of the PRINT= option and cross-covariances and cross-correlations of residuals. Valid values are as follows:

BOTH	prints outputs in both MATRIX and UNIVARIATE forms.
MATRIX	prints outputs in matrix form. This is the default.
UNIVARIATE	prints outputs by variables.

```
   model y1 y2 / p=1 print=(impulse) printform=univariate;
```

Printing Options

PRINT=(*options***)**

The following options can be used in the PRINT=( ) option. The options are listed within parentheses.

CORRB

prints the estimated correlations of the parameter estimates. If the number in parentheses follow the options listed below, the options print the number of lags specified by *number* in parentheses. The default is the number of lags specified by the option LAGMAX=*number*.

CORRX
CORRX(*number***)**

prints the cross-correlation matrices of exogenous (independent) variables.

CORRY
CORRY(*number***)**

prints the cross-correlation matrices of dependent (endogenous) variables.

COVB

prints the estimated covariances of the parameter estimates.

COVPE
COVPE(*number***)**

prints the covariance matrices of *number*-ahead prediction errors for the VARMAX(p,q,s) model. If the DIF= or DIFY= option is specified, the covariance matrices of multistep-ahead prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the “Forecasting” section on page 1756 for details.

COVX
COVX(*number***)**

prints the cross-covariance matrices of exogenous (independent) variables.

COVY
COVY(*number*)

prints the cross-covariance matrices of dependent (endogenous) variables.

DECOMPOSE
DECOMPOSE(*number*)

prints the decomposition of the prediction error covariances using the number of lags specified by *number* in parentheses for the VARMA(p,q) model. It can be interpreted as the contribution of innovations in one variable to the mean squared error of the multistep-ahead forecast of another variable. The DECOMPOSE option also prints proportions of the forecast error variance.

If the DIF= or DIFY= option is specified, the covariance matrices of multistep-ahead prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. See the "Forecasting" section on page 1756 for details.

DYNAMIC

prints the contemporaneous relationships among the components of the vector time series.

IARR
IARR(*number*)

prints the infinite order AR representation of a VARMA process. If the ECM= option is specified, the reparameterized AR coefficient matrices are printed.

IMPULSE
IMPULSE(*number*)
IMPULSE= (SIMPLE ACCUM ORTH STDERR ALL)
IMPULSE(*number*)= (SIMPLE ACCUM ORTH STDERR ALL)

prints the impulse response function. It investigates the response of one variable to an impulse in another variable in a system that involves a number of other variables as well. It is an infinite order MA representation of a VARMA process. See the "Forecasting" section on page 1756 for details.

The following options can be used in the IMPULSE=( ) option. The options are listed within parentheses.

ACCUM	prints the accumulated impulse function.
ALL	equivalent to specifying all of SIMPLE, ACCUM, ORTH, and STDERR.
ORTH	prints the orthogonalized impulse function.
SIMPLE	prints the impulse response function. This is the default.
STDERR	prints the standard errors of the impulse response function, the accumulated impulse response function, or the orthogonalized impulse response function. If the exogenous variables are used to fit the model, this option is ignored.

IMPULSX
IMPULSX(*number*)
IMPULSX= (SIMPLE ACCUM ALL)

IMPULSX(*number*)= (SIMPLE ACCUM ALL)

prints the impulse response function related to exogenous (independent) variables. See the "Forecasting" section on page 1756 for details.

The following options can be used in the IMPULSX=( ) option. The options are listed within parentheses.

ACCUM	prints the accumulated impulse response matrices in the transfer function.
ALL	equivalent to specifying both SIMPLE and ACCUM.
SIMPLE	prints the impulse response matrices in the transfer function. This is the default.

PARCOEF
PARCOEF(*number*)

prints the partial autoregression coefficient matrices, Φ_{mm}. With a VAR process, this option is useful for the identification of the order since the Φ_{mm} have the characteristic property that they equal zero for $m > p$ under the hypothetical assumption of a VAR(p) model. See the "Tentative Order Selection" section on page 1761 for details.

PCANCORR
PCANCORR(*number*)

prints the partial canonical correlations of the process at lag m and the test for testing Φ_m=0 for $m > p$. The lag m partial canonical correlations are the canonical correlations between $\mathbf{y}_t$ and $\mathbf{y}_{t-m}$, after adjustment for the dependence of these variables on the intervening values $\mathbf{y}_{t-1}, \ldots, \mathbf{y}_{t-m+1}$. See the "Tentative Order Selection" section on page 1761 for details.

PCORR
PCORR(*number*)

prints the partial correlation matrices. With a VAR process, this option is useful for a tentative order selection by the same property as the partial autoregression coefficient matrices, as described in the PRINT=(PARCOEF) option. See the "Tentative Order Selection" section on page 1761 for details.

ROOTS

prints the eigenvalues of the $kp \times kp$ companion matrix associated with the AR characteristic function $\Phi(B)$, where k is the number of dependent (endogenous) variables, and $\Phi(B)$ is the finite order matrix polynomial in the backshift operator B, such that $B^i\mathbf{y}_t = \mathbf{y}_{t-i}$. These eigenvalues indicate the stationary condition of the process since the stationary condition on the roots of $|\Phi(B)| = 0$ in the VAR(p) model is equivalent to the condition in the corresponding VAR(1) representation that all eigenvalues of the companion matrix be less than one in absolute value. Similarly, you can use this option to check the invertibility of the MA process. In addition, when the GARCH= option is specified, this option prints the roots of the GARCH characteristic polynomials to check covariance stationarity for the GARCH process.

YW

prints Yule-Walker estimates of the preliminary autoregressive model for the dependent (endogenous) variables. The coefficient matrices are printed using the maximum order of the autoregressive process.

Some examples of the PRINT= option are as follows:

```
model y1 y2 / p=1 print=(covy(10) corry(10));
model y1 y2 / p=1 print=(parcoef pcancorr pcorr);
model y1 y2 / p=1 print=(impulse(8) decompose(6) covpe(6));
model y1 y2 / p=1 print=(dynamic roots yw);
```

Lag Specification Options

P= *number*
P= (*number-list***)**

specifies the order of the vector autoregressive process. Subset models of vector autoregressive orders can be specified as, for example, the option P=(1,3,4). the option P=3 is equivalent to the option P=(1,2,3). The default is P=0.

If the option P=0 and there are no exogenous (independent) variables, the AR polynomial order is automatically determined by minimizing an information criterion; if P=0 and the PRIOR= or ECM= option or both is specified the AR polynomial order is determined.

If the ECM= option is specified, subset models of vector autoregressive orders are not allowed and the AR maximum order is used.

```
model y1 y2 / p=3;
model y1 y2 / p=(1,3);
model y1 y2 / p=(1,3) prior;
```

Q= *number*
Q= (*number-list***)**

specifies the order of the moving-average error process. Subset models of moving-average orders can be specified as, for example, the option Q=(1,5). The default is Q=0. The Q= option is ignored when either the GARCH= or XLAG= option is specified.

```
model y1 y2 / p=1 q=1;
model y1 y2 / q=(2);
```

XLAG= *number*
XLAG= (*number-list***)**

specifies the lags of exogenous (independent) variables. Subset models of distributed lags can be specified as, for example, the option XLAG=(2). The default is XLAG=0. To exclude the present values of exogenous (independent) variables from the model, the NOCURRENTX option must be used.

```
model y1 y2 = x1-x3 / xlag=2 nocurrentx;
model y1 y2 = x1-x3 / p=1 xlag=(2);
```

Tentative Order Selection Options

MINIC
MINIC= (TYPE=*value* **P=***number* **Q=***number* **PERROR=***number***)**

prints the information criterion for the appropriate AR and MA tentative order selection and for the diagnostic checks of the fitted model.

If the MINIC= option is not specified, all types of information criteria are printed for diagnostic checks of the fitted model.

The following options can be used in the MINIC=( ) option. The options are listed within parentheses.

P= *number*
P= (p_{min}**:**p_{max}**)**

specifies the range of AR orders. The default is P=(0:5).

PERROR= *number*
PERROR= ($p_{\epsilon,min}$**:**$p_{\epsilon,max}$**)**

specifies the range of AR orders for obtaining the error series. The default is PERROR=($p_{max} : p_{max} + q_{max}$).

Q= *number*
Q= (q_{min}**:**q_{max}**)**

specifies the range of MA orders. The default is Q=(0:5).

TYPE= *value*

specifies the criterion for the model order selection. Valid criteria are as follows:

AIC	specifies the Akaike Information Criterion.
AICC	specifies the Corrected Akaike Information Criterion. This is the default criterion.
FPE	specifies the Final Prediction Error criterion.
HQC	specifies the Hanna-Quinn Criterion.
SBC	specifies the Schwarz Bayesian Criterion. You can also specify this value as TYPE=BIC.

```
model y1 y2 / minic;
model y1 y2 / minic=(type=aic p=5);
```

Cointegration Related Options

There are two options related integrated time series; one is the DFTEST option for a unit root test and the other is the COINTTEST option for a cointegration test.

DFTEST
DFTEST= (DLAG=*number***)**
DFTEST= (DLAG=(*number***) . . . (***number***))**

prints the Dickey-Fuller unit root tests. The option DLAG=(*number*) . . . (*number*) specifies the regular or seasonal unit root test. The *number* should be in {1, 2, 4, 12}. If the *number* is greater than one, a seasonal Dickey-Fuller test is performed. If the

TREND= option is specified, the seasonal unit root test is not available. The default is DLAG=1.

For example, the DFTEST=(DLAG=(1)(12)) option provides two tables, the Dickey-Fuller regular unit root test and the seasonal unit root test.

Some examples of the DFTEST= option are

```
model y1 y2 / p=2 dftest;
model y1 y2 / p=2 dftest=(dlag=4);
model y1 y2 / p=2 dftest=(dlag=(1)(12));
model y1 y2 / p=2 dftest cointtest;
```

COINTTEST
COINTTEST= (JOHANSEN<(=*options*)> SW<(=*options*)> SIGLEVEL=*number*)

The following options can be used in the COINTTEST=( ) option. The options are listed within parentheses.

JOHANSEN
JOHANSEN= (TYPE=*value* IORDER=*number* NORMALIZE=*variable*)

prints the cointegration rank test for multivariate time series based on Johansen method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 11. See the "Vector Error Correction Modeling" section on page 1786 for details.

The VAR(p) model can be written as the error correction model

$$\Delta \mathbf{y}_t = \Pi \mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

where Π, Φ_i^*, and A are coefficient parameters; D_t is a deterministic term such as a constant, a linear trend, or seasonal dummies.

The $I(1)$ model is defined by one reduced-rank condition. If the cointegration rank is $r < k$, then there exist $k \times r$ matrices $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ of rank r such that $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$.

The $I(1)$ model is rewritten as the $I(2)$ model

$$\Delta^2 \mathbf{y}_t = \Pi \mathbf{y}_{t-1} - \Psi \Delta \mathbf{y}_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 \mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

where $\Psi = I_k - \sum_{i=1}^{p-1} \Phi_i^*$ and $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_i^*$.

The $I(2)$ model is defined by two reduced-rank conditions. One is that $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$, where $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are $k \times r$ matrices of full-rank r. The other is that $\boldsymbol{\alpha}_\perp' \Psi \boldsymbol{\beta}_\perp = \boldsymbol{\xi}\boldsymbol{\eta}'$ where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are $(k-r) \times s$ matrices with $s \leq k - r$; $\boldsymbol{\alpha}_\perp$ and $\boldsymbol{\beta}_\perp$ are $k \times (k-r)$ matrices of full-rank $k - r$ such that $\boldsymbol{\alpha}'\boldsymbol{\alpha}_\perp = 0$ and $\boldsymbol{\beta}'\boldsymbol{\beta}_\perp = 0$.

The following options can be used in the JOHANSEN=( ) option. The options are listed within parentheses.

IORDER= *number* specifies the integrated order.

IORDER=1	prints the cointegration rank test for an integrated order 1 and prints the long-run parameter, β, and the adjustment coefficient, α. This is the default. If the option IORDER=1 is specified, the AR order should be greater than or equal to 1. When the option P=0, the value of P is temporarily set to 1 for the Johansen test.
IORDER=2	prints the cointegration rank test for integrated orders 1 and 2. If the option IORDER=2 is specified, the AR order should be greater than or equal to 2. If the option P=1, the option IORDER=1 is used; if the option P=0, the value of P is temporarily set to 2.

NORMALIZE= *variable* specifies the dependent (endogenous) variable name whose cointegration vectors are to be normalized. If the normalized variable is different from that specified in the ECM= option or the COINTEG statement, the latter is used.

TYPE= *value* specifies the type of cointegration rank test to be printed. Valid values are as follows:

MAX	prints the cointegration maximum eigenvalue test.
TRACE	prints the cointegration trace test. This is the default.

If the NOINT option is not specified, the procedure prints two different cointegration rank tests in the presence of the unrestricted and restricted deterministic terms (constant or linear trend) models. If the option IORDER=2 is specified, the procedure automatically determines that the option TYPE=TRACE.

```
model y1 y2 / p=2 cointtest=(johansen=(type=max normalize=y1));
model y1 y2 / p=2 cointtest=(johansen=(iorder=2 normalize=y1));
```

SIGLEVEL= *value*

sets the size of cointegration rank tests and common trends tests.
The SIGLEVEL= *value* option must be one of 0.1, 0.05, or 0.01. The default is SIGLEVEL=0.05.

```
model y1 y2 / p=2 cointtest=(johansen siglevel=0.1);
model y1 y2 / p=2 cointtest=(sw siglevel=0.1);
```

SW
SW= (TYPE=*value* **LAG=***number***)**

prints common trends tests for a multivariate time series based on the Stock-Watson method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 6. See the “Common Trends” section on page 1783 for details.

The following options can be used in the SW=( ) option. The options are listed within parentheses.

LAG= *number*	specifies the number of lags. The default is LAG=max(1,p) for the option TYPE=FILTDIF or TYPE=FILTRES, where p is the AR maximum order specified by the P= option; LAG=$O(T^{1/4})$ for the option TYPE=KERNEL, where T is the number of nonmissing observations. If the option LAG= exceeds the default, it is replaced by the default.
TYPE= *value*	specifies the type of common trends test to be printed. Valid values are as follows:

FILTDIF	prints the common trends test based on the filtering method applied to the differenced series. This is the default.
FILTRES	prints the common trends test based on the filtering method applied to the residual series.
KERNEL	prints the common trends test based on the kernel method.

```
model y1 y2 / p=2 cointtest=(sw);
model y1 y2 / p=2 cointtest=(sw=(type=kernel));
```

Bayesian VAR Estimation Options

PRIOR
PRIOR= (MEAN=(*vector***) LAMBDA=***value* **THETA=***value* **IVAR<=(***variables***)>**
NREP=*number* **SEED=***number***)**

specifies the prior value of parameters for the BVAR(p) model. The BVAR model allows the subset model. If the ECM= option is specified with the PRIOR option, the BVECM(p) form is fitted. For the standard errors of the predictors, the bootstrap procedure is used. See the “Bayesian VAR Modeling” section on page 1773 for details.

The following options can be used in the PRIOR=( ) option. The options are listed within parentheses.

IVAR
IVAR= (*variables***)**

specifies an integrated BVAR(p) model. If you use the IVAR option without *variables*, it sets the overall prior mean of the first lag of each variable equal to one in its own equation and sets all other coefficients to zero. If *variables* are specified, it sets the prior mean of the first lag of the specified variables equal to one in its own equation and sets all other coefficients to zero. When the series $\mathbf{y}_t = (y_1, y_2)'$ follows a bivariate BVAR(2) process, the IVAR or IVAR=(y_1 y_2) option is equivalent to specifying MEAN=(1 0 0 0 0 1 0 0).

If the PRIOR=(MEAN=) or ECM= option is specified, the IVAR= option is ignored.

LAMBDA= *value*

specifies the prior standard deviation of the AR coefficient parameter matrices. It should be a positive number. The default is LAMBDA=1. As the value of the option LAMBDA= is larger, a BVAR(p) model is close to a VAR(p) model.

MEAN= (*vector***)**

specifies the mean vector in the prior distribution for the AR coefficients. If the vector is not specified, the prior value is assumed to be a zero vector. See the "Bayesian VAR Modeling" section on page 1773 for details.

You can specify the mean vector by order of the equation. Let $(\delta, \Phi_1, ..., \Phi_p)$ be the parameter sets to be estimated and $\Phi = (\Phi_1, ..., \Phi_p)$ be the AR parameter sets. Then the mean vector is specified by row-wise from the Φ; that is, the option MEAN=($\text{vec}(\Phi')$).

For the PRIOR=(mean) option in the BVAR(2),

$$\Phi = \left(\begin{array}{cccc} \phi_{1,11} & \phi_{1,12} & \phi_{2,11} & \phi_{2,12} \\ \phi_{1,21} & \phi_{1,22} & \phi_{2,21} & \phi_{2,22} \end{array} \right) = \left(\begin{array}{cccc} 2 & 0.1 & 1 & 0 \\ 0.5 & 3 & 0 & -1 \end{array} \right)$$

$$\mathbf{model\ \ y1\ \ y2\ \ /\ \ p = 2\ \ prior} = (\mathbf{mean} = (\ \mathbf{2\ \ 0.1\ \ 1\ \ 0\ \ 0.5\ \ 3\ \ 0\ \ -1}));$$

The deterministic terms are considered to shrink toward zero; you must omit prior means of deterministic terms such as a constant, seasonal dummies, or trends.

For a Bayesian error correction model, you specify a mean vector for only lagged AR coefficients, Φ_i^*, in terms of regressors $\Delta\mathbf{y}_{t-i}$, for $i = 1, ..., (p-1)$ in the VECM(p) representation. The diffused prior variance of $\boldsymbol{\alpha}$ is used since $\boldsymbol{\beta}$ is replaced by $\hat{\boldsymbol{\beta}}$ estimated in a nonconstrained VECM(p) form.

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\mathbf{z}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{z}_t = \boldsymbol{\beta}'\mathbf{y}_t$.

For example, in the case of a bivariate ($k = 2$) BVECM(2) form, the option

$$\mathrm{MEAN} = (\phi^*_{1,11}\ \phi^*_{1,12}\ \phi^*_{1,21}\ \phi^*_{1,22})$$

where $\phi^*_{1,ij}$ is the (i,j)th element of the matrix Φ^*_1.

NREP= *number*
specifies the number of bootstrap replications. The default is NREP=100.

SEED= *number*
specifies seeds to generate uniform random numbers for resampling. By default, the system clock is used to generate the random seed.

THETA= *value*
specifies the prior standard deviation of the AR coefficient parameter matrices. The *value* is in the interval (0,1). The default is THETA=0.1. As the value of the THETA= option is close to 1, a BVAR(p) model is close to a VAR(p) model.

Some examples of the PRIOR= option are

```
model y1 y2 / p=2 prior;
model y1 y2 / p=2 prior=(theta=0.2 lambda=5);
```

Vector Error Correction Model Options

ECM=(RANK=*number* **NORMALIZE=***variable* **ECTREND)**
specifies a vector error correction model.

The following options can be used in the ECM=( ) option. The options are listed within parentheses.

NORMALIZE= *variable*
specifies a single dependent variable name whose cointegrating vectors are normalized. If the variable name is different from that specified in the COINTEG statement, the latter is used.

RANK= *number*
specifies the cointegration rank. This option is required in the ECM= option. The value of the RANK= option should be greater than zero and less than or equal to the number of dependent (endogenous) variables, k. If the rank is different from that specified in the COINTEG statement, the latter is used.

ECTREND
specifies the restriction on the drift in the VECM(p) form.

- There is no separate drift in the VECM(p) form, but a constant enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_0)(\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi^*_i \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

$$\mathbf{model\ \ y1\ \ y2\ \ /\ \ p = 2\ \ ecm = (rank = 1\ \ ectrend);}$$

- There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only through the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_1)(\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

$$\mathbf{model\ \ y1\ \ y2\ \ /\ \ p = 2\ \ ecm = (rank = 1\ \ ectrend)\ \ trend = linear};$$

If the NSEASON option is specified, then the NSEASON option is ignored; if the NOINT option is specified, then the ECTREND option is ignored.

Some examples of the ECM= option are

```
model y1 y2 / p=2 ecm=(rank=1 normalized=y1);
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
```

GARCH Model Estimation Options

GARCH=(Q=*number* **P=***number* **FORM=** *value* **MEAN)** Experimental

specifies a GARCH-type multivariate conditional heteroscedasticity model. The GARCH= option in the MODEL statement specifies the family of GARCH models to be estimated. See the "Multivariate GARCH Modeling" section on page 1804 for details.

The following options can be used in the GARCH= option.

FORM= *value*

specifies the representation for a GARCH model. Valid values are as follows:

BEKK	specifies a *BEKK* representation. This is the default.
BEW	specifies a vectorized representation.
DIAG	specifies a diagonal representation.

MEAN

specifies the GARCH-M model.

P=*number*
P=(*number-list***)**

specifies the order of the process or the subset of GARCH terms to be fitted. By default, P=0.

Q=*number*
Q=(*number-list***)**

specifies the order of the process or the subset of ARCH terms to be fitted. This option is required in the GARCH= option.

For the VAR(1)-ARCH(1) model,

```
model y1 y2 / p=1 garch=(q=1);
```

For the multivariate GARCH(1,1) model,

```
   model y1 y2 / garch=(q=1 p=1 form=diag);
```

For the multivariate ARCH(1)-M model,

```
   model y1 y2 / garch=(q=1 mean);
```

Other multivariate GARCH-type models are

```
   model y1 y2 = x1 / garch=(q=1 mean);
   model y1 y2 = x1 / p=1 xlag=1 garch=(q=1 form=bew);
```

NLOPTIONS Statement

NLOPTIONS *options* **;**

PROC VARMAX uses the NonLinear Optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 10, "Nonlinear Optimization Methods."

An example of the NLOPTIONS statement is

```
   proc varmax data=one;
      nloptions tech=qn;
      model y1 y2 / p=2;
   run;
```

OUTPUT Statement

OUTPUT < *options* >**;**

The OUTPUT statement generates and prints forecasts based on the model estimated in the previous MODEL statement and, optionally, creates an output SAS data set that contains these forecasts.

ALPHA= *value*

sets the forecast confidence limits. The option ALPHA=*value* must be between 0 and 1. When you specify the option ALPHA=α, the upper and lower confidence limits define the $1 - \alpha$ confidence interval. The default is ALPHA=0.05, which produces 95% confidence intervals.

BACK= *number*

specifies the number of observations before the end of the data at which the multistep-ahead forecasts are to begin. The BACK= option value must be less than or equal to the number of observations minus the number of lagged regressors in the model. The default is BACK=0, which means that the forecast starts at the end of the available data.

LEAD= *number*
specifies the number of multistep-ahead forecast values to compute. The default is LEAD=12.

NOPRINT
suppresses the printed forecast values of each dependent (endogenous) variable.

OUT= *SAS-data-set*
writes the forecast values to an output data set.

Some examples of the OUTPUT statements are

```
proc varmax data=one;
   model y1 y2 / p=2;
   output lead=6 back=2;
run;

proc varmax data=one;
   model y1 y2 / p=2;
   output out=for noprint;
run;
```

RESTRICT Statement

RESTRICT *restriction ... restriction* **;**

The RESTRICT statement restricts the specified parameters to the specified values. Only one RESTRICT statement is allowed.

The *restriction*'s form is *parameter = value* and each restriction is separated by commas. Parameters are referred by the following keywords:

- CONST(i) is the intercept parameter of the current value ith time series y_{it}
- AR(l,i,j) is the autoregressive parameter of the previous lag l value of the jth dependent (endogenous) variable, $y_{j,t-l}$, to the ith dependent variable at time t, y_{it}
- MA(l,i,j) is the moving-average parameter of the previous lag l value of the jth error process, $\boldsymbol{\epsilon}_{j,t-l}$, to the ith dependent variable at time t, y_{it}
- XL(l,i,j) is the exogenous parameter of the previous lag l value of the jth exogenous (independent) variable, $x_{j,t-l}$, to the ith dependent variable at time t, y_{it}
- SDUMMY(i,j) is the jth seasonal dummy of the ith time series at time t, y_{it}, where $j = 1, \ldots, (nseason - 1)$
- LTREND(i) is the linear trend parameter of the current value ith time series y_{it}
- QTREND(i) is the quadratic trend parameter of the current value ith time series y_{it}

The following keywords are for the fitted GARCH model. The indexes i and j refer to the position of the element in the coefficient matrix.

- GCHM(i,j) is the GARCH-M parameter of $\mathrm{vech}(H_t)$ for $i = 1, \ldots, k$ and $j = 1, \ldots, k(k+1)/2$
- GCHC(i,j) is the constant parameter of the covariance matrix, H_t, for $1 \le i \le j \le k$
- ACH(l,i,j) is the ARCH parameter of the previous lag l value of $\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t'$
- GCH(l,i,j) is the GARCH parameter of the previous lag l value of covariance matrix, H_t

The indexes i and j for ACH(l,i,j) and GCH(l,i,j) have different ranges according to the GARCH model representation. For example, $i, j = 1, \ldots, k$ for a *BEKK* representation, $i, j = 1, \ldots, k(k+1)/2$ for a *BEW* representation, and $i = j = 1, \ldots, k(k+1)/2$ for a *diagonal* representation.

To use the RESTRICT statement, you need to know the form of the model. If you do not specify any order of the model, the RESTRICT statement is not applicable.

Restricted parameter estimates are computed by introducing a Lagrangian parameter for each restriction (Pringle and Raynor 1971). The Lagrangian parameter measures the sensitivity of the sum of square errors to the restriction. The estimates of these Lagrangian parameters and their significance are printed in the restriction results table.

The following are examples of the RESTRICT statement. The first example shows a bivariate (k=2) VAR(2) model,

```
proc varmax data=one;
   model y1 y2 / p=2;
   restrict AR(1,1,2)=0, AR(2,1,2)=0.3;
run;
```

The following shows a bivariate (k=2) VARX(1,1) model with three exogenous variables,

```
proc varmax data=two;
   model y1 = x1 x2, y2 = x2 x3 / p=1 xlag=1;
   restrict XL(0,1,1)=-1.2, XL(1,2,3)=0;
run;
```

TEST Statement

TEST *restriction ... restriction* **;**

The TEST statement performs the Wald test for the joint hypothesis specified in the statement. The *restriction*'s form is *parameter* = *value* and each restriction is separated by commas. The *restriction*'s form is referred to by the same rule in the RESTRICT statement. Any number of TEST statements can be specified.

To use the TEST statement, you need to know the form of the model. If you do not specify any order of the model, the TEST statement is not applicable.

See the “Granger-Causality Test” section on page 1769 for the Wald test.

The following is an example of the TEST statement. In case of a bivariate (k=2) VAR(2) model,

```
proc varmax data=one;
   model y1 y2 / p=2;
   test AR(1,1,2)=0, AR(2,1,2)=0;
run;
```

Details

Missing Values

The VARMAX procedure currently does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the MODEL statement variables. Observations at the beginning of the data set with missing values for any MODEL statement variables are not used or included in the output data set. At the end of the data set, observations can have dependent (endogenous) variables with missing values and independent (exogenous)variables with nonmissing values.

VARMAX Modeling

The vector autoregressive moving-average model with exogenous variables is called the VARMAX(p,q,s) model. The form of the model can be written as

$$\mathbf{y}_t = \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^{s} \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^{q} \Theta_i \boldsymbol{\epsilon}_{t-i}$$

where the output variables of interest, $\mathbf{y}_t = (y_{1t}, \ldots, y_{kt})'$, can be influenced by other input variables, $\mathbf{x}_t = (x_{1t}, \ldots, x_{rt})'$, which are determined outside the system of interest. The variables $\mathbf{y}_t$ are referred to as dependent, response, or endogenous variables, and the variables $\mathbf{x}_t$ are referred to as independent, input, predictor, regressor, or exogenous variables. The unobserved noise variables, $\boldsymbol{\epsilon}_t = (\epsilon_{1t}, \ldots, \epsilon_{kt})'$, are a vector white noise process.

The VARMAX(p,q,s) model can be written

$$\Phi(B)\mathbf{y}_t \quad = \quad \Theta^*(B)\mathbf{x}_t + \Theta(B)\epsilon_t$$

where

$$\begin{aligned} \Phi(B) &= I_k - \Phi_1 B - \cdots - \Phi_p B^p \\ \Theta^*(B) &= \Theta_0^* + \Theta_1^* B + \cdots + \Theta_s^* B^s \\ \Theta(B) &= I_k - \Theta_1 B - \cdots - \Theta_q B^q \end{aligned}$$

are matrix polynomials in B in the backshift operator, such that $B^i \mathbf{y}_t = \mathbf{y}_{t-i}$, the Φ_i and Θ_i are $k \times k$ matrices, and the Θ_i^* are $k \times r$ matrices.

The following assumptions are made:

- $\mathrm{E}(\boldsymbol{\epsilon}_t) = 0$, $\mathrm{E}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_t') = \Sigma$, which is positive-definite, and $\mathrm{E}(\boldsymbol{\epsilon}_t \boldsymbol{\epsilon}_s') = 0$ for $t \neq s$.
- For stationarity and invertibility of the VARMAX process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.
- The exogenous (independent) variables $\mathbf{x}_t$ are not correlated with residuals $\boldsymbol{\epsilon}_t$, $\mathrm{E}(\mathbf{x}_t \boldsymbol{\epsilon}_t') = 0$. The exogenous variables can be stochastic or nonstochastic. When the exogenous variables are stochastic and their future values are unknown, then forecasts of these future values are needed in the forecasting of the future values of the endogenous variables. On occasion, future values of the exogenous variables can be assumed to be known because they are deterministic variables. Note that the VARMAX procedure assumes that the exogenous variables are nonstochastic if future values are available in the input data set. Otherwise, the exogenous variables are assumed to be stochastic and their future values are forecasted by assuming that they follow the VARMA(p,q) model.

State-Space Modeling

Another representation of the VARMAX(p,q,s) model is in the form of a state-variable or a state-space model, which consists of a state equation

$$\mathbf{z}_t = F\mathbf{z}_{t-1} + K\mathbf{x}_t + G\boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H\mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \vdots \\ \mathbf{y}_{t-p+1} \\ \mathbf{x}_t \\ \vdots \\ \mathbf{x}_{t-s+1} \\ \boldsymbol{\epsilon}_t \\ \vdots \\ \boldsymbol{\epsilon}_{t-q+1} \end{bmatrix}, \quad K = \begin{bmatrix} \Theta_0^* \\ 0_{k\times r} \\ \vdots \\ 0_{k\times r} \\ I_r \\ 0_{r\times r} \\ \vdots \\ 0_{r\times r} \\ 0_{k\times r} \\ \vdots \\ 0_{k\times r} \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ 0_{k\times k} \\ \vdots \\ 0_{k\times k} \\ 0_{r\times k} \\ \vdots \\ 0_{r\times k} \\ I_{k\times k} \\ 0_{k\times k} \\ \vdots \\ 0_{k\times k} \end{bmatrix}$$

$$F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{p-1} & \Phi_p & \Theta_1^* & \cdots & \Theta_{s-1}^* & \Theta_s^* & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & I_r & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & I_r & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

and

$$H = [I_k, 0_{k\times k}, \ldots, 0_{k\times k}, 0_{k\times r}, \ldots, 0_{k\times r}, 0_{k\times k}, \ldots, 0_{k\times k}]$$

On the other hand, it is assumed that $\mathbf{x}_t$ follows a VARMA(p,q) model

$$\mathbf{x}_t = \sum_{i=1}^{p} A_i \mathbf{x}_{t-i} + \mathbf{a}_t - \sum_{i=1}^{q} C_i \mathbf{a}_{t-i}$$

or $A(B)\mathbf{x}_t = C(B)\mathbf{a}_t$, where $A(B) = I_r - A_1 B - \cdots - A_p B^p$ and $C(B) = I_r - C_1 B - \cdots - C_q B^q$ are matrix polynomials in B, and the A_i and C_i are $r \times r$ matrices. Without loss of generality, the AR and MA orders can be taken to be the same as the VARMAX(p,q,s) model, and $\mathbf{a}_t$ and $\boldsymbol{\epsilon}_t$ are independent white noise processes.

Under suitable (such as stationarity) conditions, $\mathbf{x}_t$ is represented by an infinite order moving-average process

$$\mathbf{x}_t = A(B)^{-1}C(B)\mathbf{a}_t = \Psi^x(B)\mathbf{a}_t = \sum_{j=0}^{\infty} \Psi_j^x \mathbf{a}_{t-j}$$

where $\Psi^x(B) = A(B)^{-1}C(B) = \sum_{j=0}^{\infty} \Psi_j^x B^j$.

The optimal (Minimum Mean Squared Error, MMSE) i-step-ahead forecast of $\mathbf{x}_{t+i}$ is

$$\begin{aligned} \mathbf{x}_{t+i|t} &= \sum_{j=i}^{\infty} \Psi_j^x \mathbf{a}_{t+i-j} \\ \mathbf{x}_{t+i|t+1} &= \mathbf{x}_{t+i|t} + \Psi_{i-1}^x \mathbf{a}_{t+1} \end{aligned}$$

For $i > q$,

$$\mathbf{x}_{t+i|t} = \sum_{j=1}^{p} A_j \mathbf{x}_{t+i-j|t}$$

The VARMAX(p,q,s) model has an absolutely convergent representation as

$$\begin{aligned}
\mathbf{y}_t &= \Phi(B)^{-1}\Theta^*(B)\mathbf{x}_t + \Phi(B)^{-1}\Theta(B)\boldsymbol{\epsilon}_t \\
&= \Psi^*(B)\Psi^x(B)\mathbf{a}_t + \Phi(B)^{-1}\Theta(B)\boldsymbol{\epsilon}_t \\
&= V(B)\mathbf{a}_t + \Psi(B)\boldsymbol{\epsilon}_t
\end{aligned}$$

or

$$\mathbf{y}_t = \sum_{j=0}^{\infty} V_j \mathbf{a}_{t-j} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$, $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B)$, and $V(B) = \Psi^*(B)\Psi^x(B) = \sum_{j=0}^{\infty} V_j B^j$.

The optimal (MMSE) i-step-ahead forecast of $\mathbf{y}_{t+i}$ is

$$\begin{aligned}
\mathbf{y}_{t+i|t} &= \sum_{j=i}^{\infty} V_j \mathbf{a}_{t+i-j} + \sum_{j=i}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+i-j} \\
\mathbf{y}_{t+i|t+1} &= \mathbf{y}_{t+i|t} + V_{i-1}\mathbf{a}_{t+1} + \Psi_{i-1}\boldsymbol{\epsilon}_{t+1}
\end{aligned}$$

for $i = 1, \ldots, v$ with $v = \max(p, q+1)$. For $i > q$,

$$\begin{aligned}
\mathbf{y}_{t+i|t} &= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=0}^{s} \Theta_j^* \mathbf{x}_{t+i-j|t} \\
&= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \mathbf{x}_{t+i|t} + \sum_{j=1}^{s} \Theta_j^* \mathbf{x}_{t+i-j|t} \\
&= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+i-j|t} + \Theta_0^* \sum_{j=1}^{p} A_j \mathbf{x}_{t+i-j|t} + \sum_{j=1}^{s} \Theta_j^* \mathbf{x}_{t+i-j|t} \\
&= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+i-j|t} + \sum_{j=1}^{u} (\Theta_0^* A_j + \Theta_j^*) \mathbf{x}_{t+i-j|t}
\end{aligned}$$

where $u = \max(p, s)$.

Define $\Pi_j = \Theta_0^* A_j + \Theta_j^*$. For $i = v > q$ with $v = \max(p, q+1)$, you obtain

$$\begin{aligned}
\mathbf{y}_{t+v|t} &= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^{u} \Pi_j \mathbf{x}_{t+v-j|t} \ \text{ for } \ u \le v \\
\mathbf{y}_{t+v|t} &= \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+v-j|t} + \sum_{j=1}^{r} \Pi_j \mathbf{x}_{t+v-j|t} \ \text{ for } \ u > v
\end{aligned}$$

From the preceding relations, a state equation is

$$\mathbf{z}_{t+1} = F\mathbf{z}_t + K\mathbf{x}_t^* + G\mathbf{e}_{t+1}$$

and an observation equation is

$$\mathbf{y}_t = H\mathbf{z}_t$$

where

$$\mathbf{z}_t = \begin{bmatrix} \mathbf{y}_t \\ \mathbf{y}_{t+1|t} \\ \vdots \\ \mathbf{y}_{t+v-1|t} \\ \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+v-1|t} \end{bmatrix}, \quad \mathbf{x}_t^* = \begin{bmatrix} \mathbf{x}_{t+v-u} \\ \mathbf{x}_{t+v-u+1} \\ \vdots \\ \mathbf{x}_{t-1} \end{bmatrix}, \quad \mathbf{e}_{t+1} = \begin{bmatrix} \mathbf{a}_{t+1} \\ \boldsymbol{\epsilon}_{t+1} \end{bmatrix}$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 & \Pi_v & \Pi_{v-1} & \Pi_{v-2} & \cdots & \Pi_1 \\ 0 & 0 & 0 & \cdots & 0 & 0 & I_r & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 & I_r & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & A_v & A_{v-1} & A_{v-2} & \cdots & A_1 \end{bmatrix}$$

$$K = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ \Pi_u & \Pi_{u-1} & \cdots & \Pi_{v+1} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}, \quad G = \begin{bmatrix} V_0 & I_k \\ V_1 & \Psi_1 \\ \vdots & \vdots \\ V_{v-1} & \Psi_{v-1} \\ I_r & 0_{r\times k} \\ \Psi_1^x & 0_{r\times k} \\ \vdots & \vdots \\ \Psi_{v-1}^x & 0_{r\times k} \end{bmatrix}$$

and

$$H = [I_k, 0_{k\times k}, \ldots, 0_{k\times k}, 0_{k\times r}, \ldots, 0_{k\times r}]$$

Note that the matrix K and the input vector $\mathbf{x}_t^*$ are defined only when $u > v$.

Dynamic Simultaneous Equations Modeling

In the econometrics literature, the VARMAX(p,q,s) model could be written in the following slightly different form, which is referred to as a *dynamic simultaneous equations* model or a *dynamic structural equations* model.

Since $\mathrm{E}(\boldsymbol{\epsilon}_t\boldsymbol{\epsilon}_t') = \Sigma$ is assumed to be positive-definite, there exists a lower triangular matrix A_0 with ones on the diagonals such that $A_0\Sigma A_0' = \Sigma^d$, where Σ^d is a diagonal matrix with positive diagonal elements.

$$A_0\mathbf{y}_t = \sum_{i=1}^{p} A_i\mathbf{y}_{t-i} + \sum_{i=0}^{s} C_i^*\mathbf{x}_{t-i} + C_0\boldsymbol{\epsilon}_t - \sum_{i=1}^{q} C_i\boldsymbol{\epsilon}_{t-i}$$

where $A_i = A_0\Phi_i$, $C_i^* = A_0\Theta_i^*$, $C_0 = A_0$, and $C_i = A_0\Theta_i$.

As an alternative form,

$$A_0\mathbf{y}_t = \sum_{i=1}^{p} A_i\mathbf{y}_{t-i} + \sum_{i=0}^{s} C_i^*\mathbf{x}_{t-i} + \mathbf{a_t} - \sum_{\mathbf{i=1}}^{\mathbf{q}} \mathbf{C_i a_{t-i}}$$

where $A_i = A_0\Phi_i$, $C_i^* = A_0\Theta_i^*$, $C_i = A_0\Theta_i A_0^{-1}$, and $\mathbf{a_t} = \mathbf{C_0}\boldsymbol{\epsilon}_\mathbf{t}$ has a diagonal covariance matrix Σ^d. The PRINT=(DYNAMIC) option follows this form.

A dynamic simultaneous equations model involves a leading (lower triangular) coefficient matrix for $\mathbf{y}_t$ at lag 0 or a leading coefficient matrix for $\boldsymbol{\epsilon}_t$ at lag 0. Such a representation of the VARMAX(p,q,s) model can be more useful in certain circumstances than the standard representation. From the linear combination of the dependent variables obtained by $A_0\mathbf{y}_t$, you can easily see the relationship between the dependent variables in the current time.

The following statements provide the dynamic simultaneous equations of the VAR(1) model.

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint print=(dynamic);
run;
```

Figure 30.25. Dynamic Simultaneous Equations (DYNAMIC Option)

In Figure 30.4 on page 1699, the covariance of ϵ_t is

$$\Sigma_{\boldsymbol{\epsilon}} = \left(\begin{array}{rr} 1.28875 & 0.39751 \\ 0.39751 & 1.41839 \end{array} \right)$$

By the decomposition of $\Sigma_{\boldsymbol{\epsilon}}$, you get a diagonal matrix ($\Sigma_{\mathbf{a}}$) and a lower triangular matrix (A_0) such as $\Sigma_{\mathbf{a}} = A_0 \Sigma_{\boldsymbol{\epsilon}} A_0'$ where

$$\Sigma_{\mathbf{a}} = \left(\begin{array}{rr} 1.28875 & 0 \\ 0 & 1.29578 \end{array} \right) \text{ and } A_0 = \left(\begin{array}{rr} 1 & 0 \\ -0.30845 & 1 \end{array} \right)$$

The simultaneous equations model is written as

$$\left(\begin{array}{rr} 1 & 0 \\ -0.30845 & 1 \end{array} \right) \mathbf{y}_t = \left(\begin{array}{rr} 1.15977 & -0.51058 \\ 0.18861 & 0.54247 \end{array} \right) \mathbf{y}_{t-1} + \mathbf{a_t}$$

Two univariate equations can be written as

$$\begin{aligned} y_{1t} &= 1.15977 y_{1,t-1} - 0.51058 y_{2,t-1} + a_{1t} \\ y_{2t} &= 0.30845 y_{1t} + 0.18861 y_{1,t-1} + 0.54247 y_{2,t-1} + a_{2t} \end{aligned}$$

Impulse Response Function

The VARMAX(p,q,s) model has a convergent representation

$$\mathbf{y}_t = \Psi^*(B)\mathbf{x}_t + \Psi(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) = \sum_{j=0}^{\infty} \Psi_j^* B^j$ and $\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$.

The elements of the matrices Ψ_j from the operator $\Psi(B)$, called the impulse response, can be interpreted as the impact that a shock in one variable has on another variable. Let $\psi_{j,in}$ be the *element* of the Ψ_j. The notation i is the index for the impulse variable, and n is the index for the response variable (impulse $\rightarrow$ response). For instance, $\psi_{j,11}$ is an impulse response to $y_{1t} \rightarrow y_{1t}$, and $\psi_{j,12}$ is an impulse response to $y_{1t} \rightarrow y_{2t}$.

The accumulated impulse response function is the cumulative sum of the impulse response function, $\Psi_l^a = \sum_{j=0}^{l} \Psi_j$.

The MA representation with a standardized white noise innovation process offers a further possibility to interpret a VARMA(p,q) model. Since Σ is positive-definite, there is a lower triangular matrix P such that $\Sigma = PP'$. The alternate MA representation is written as

$$\mathbf{y}_t = \Psi^o(B)\mathbf{u}_t$$

where $\Psi^o(B) = \sum_{j=0}^{\infty} \Psi_j^o B^j$, $\Psi_j^o = \Psi_j P$, and $\mathbf{u}_t = P^{-1}\boldsymbol{\epsilon}_t$.

The elements of the matrices Ψ_j^o, called the *orthogonal impulse response*, can be interpreted as the effects of the components of the standardized shock process $\mathbf{u}_t$ on the process $\mathbf{y}_t$ at the lag j.

The coefficient matrix Ψ_j^* from the transfer function operator $\Psi^*(B)$ can be interpreted as the effects that changes in the exogenous variables $\mathbf{x}_t$ have on the output variable $\mathbf{y}_t$ at the lag j, and is called an impulse response matrix in the transfer function.

The accumulated impulse response in the transfer function is the cumulative sum of the impulse response in the transfer function, $\Psi_l^{*a} = \sum_{j=0}^{l} \Psi_j^*$.

The asymptotic distributions of the impulse functions can be seen in the "VAR Modeling" section on page 1766.

The following statements provide the impulse response and the accumulated impulse response in the transfer function for a VARX(1,0) model. Parts of the VARMAX procedure output are shown in Figure 30.26 and Figure 30.27

```
proc varmax data=grunfeld;
   model y1-y3 = x1 x2 / p=1 print=(impulsx=(all)) lagmax=15
                          printform=univariate;
run;
```

```

Figure 30.26. Impulse Response in Transfer Function (IMPULSX= Option)

In Figure 30.26, the variables $x1$ and $x2$ are impulses and the variables $y1$, $y2$, and $y3$ are responses. You can read the table matching the pairs of $impulse \rightarrow response$ such as $x1 \rightarrow y1$, $x1 \rightarrow y2$, $x1 \rightarrow y3$, $x2 \rightarrow y1$, $x2 \rightarrow y2$, and $x2 \rightarrow y3$. In the pair of $x1 \rightarrow y1$, you can see the long-run responses of $y1$ to an impulse in $x1$ (the values are 1.69281, 0.35399, 0.09090,... for lag 0, lag 1, lag 2,...).

```

Figure 30.28. Impulse Response Function (IMPULSE= Option)

Figure 30.28 is the part of the output in a univariate format associated with the PRINT=(IMPULSE=) option for the impulse response function. The keyword STD stands for the standard errors of the elements. The matrix in terms of the lag 0 does not print since it is the identity. In Figure 30.28, the horizontal variables $y1$ and $y2$ are impulses and the vertical variables $y1$ and $y2$ are responses. You can read the table matching the pairs of $impulse(horizontal) \rightarrow response(vertical)$ such as $y1 \rightarrow y1$, $y1 \rightarrow y2$, $y2 \rightarrow y1$, and $y2 \rightarrow y2$. For example, in the pair of $y1 \rightarrow y1$, you can see the long-run responses of $y1$ to an impulse in itself. The first two lags are significant (the value of lag 1 is 1.15977 with the standard error 0.05508 and the value of lag 2 is 1.06612 with the standard error 0.10450), but the last two lags are insignificant (the value of lag 14 is 0.08202 with the standard error 0.10579 and the value of lag 15 is 0.11080 with the standard error 0.09277).

Figure 30.30. Orthogonalized Impulse Response Function (IMPULSE= Option)

Figure 30.30 is the part of the output in a univariate format associated with the PRINT=(IMPULSE=) option for the orthogonalized impulse response function. The horizontal variables $y1\_innovation$ and $y2\_innovation$ are impulses and the vertical variables $y1$ and $y2$ are responses. You can read the table matching the pairs of $impulse(horizontal) \rightarrow response(vertical)$ such as $y1\_innovation \rightarrow y1$, $y1\_innovation \rightarrow y2$, $y2\_innovation \rightarrow y1$, and $y2\_innovation \rightarrow y2$.

In Figure 30.4 on page 1699, there is a positive correlation between ε_{1t} and ε_{2t}. A shock in $y1$ may be accompanied by a shock in $y2$ in the same period. For example, in the pair of $y1\_innovation \rightarrow y2$, you can see the long-run responses of $y2$ to an impulse in $y1\_innovation$. The first three lags are significant (the value of lag 0 is 0.35016 with the standard error 0.11676, the value of lag 1 is 0.75503 with the standard error 0.06949, and the value of lag 2 is 0.91231 with the standard error 0.10553), but the last two lags are insignificant (the value of lag 14 is 0.00910 with the standard error 0.09504 and the value of lag 15 is 0.05987 with the standard error 0.08779).

Forecasting

The optimal (MMSE) l-step-ahead forecast of $\mathbf{y}_{t+l}$ is

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^{s} \Theta_j^* \mathbf{x}_{t+l-j|t} - \sum_{j=l}^{q} \Theta_j \boldsymbol{\epsilon}_{t+l-j}, \quad l \leq q$$

$$\mathbf{y}_{t+l|t} = \sum_{j=1}^{p} \Phi_j \mathbf{y}_{t+l-j|t} + \sum_{j=0}^{s} \Theta_j^* \mathbf{x}_{t+l-j|t}, \quad l > q$$

with $\mathbf{y}_{t+l-j|t} = \mathbf{y}_{t+l-j}$ and $\mathbf{x}_{t+l-j|t} = \mathbf{x}_{t+l-j}$ for $l \leq j$. For the forecasts $\mathbf{x}_{t+l-j|t}$, see the State-Space Modeling section.

Covariance Matrices of Prediction Errors without Exogenous (Independent) Variables

Under the stationarity assumption, the optimal (MMSE) l-step-ahead forecast of $\mathbf{y}_{t+l}$ has an infinite moving-average form, $\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$. The prediction error of the optimal l-step-ahead forecast is $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$, with zero mean and covariance matrix

$$\Sigma(l) = \mathrm{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi_j' = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o'}$$

where $\Psi_j^o = \Psi_j P$ with a lower triangular matrix P such that $\Sigma = PP'$. Under the assumption of normality of the $\boldsymbol{\epsilon}_t$, the l-step-ahead prediction error $\mathbf{e}_{t+l|t}$ is also normally distributed as multivariate $N(0, \Sigma(l))$. Hence, it follows that the diagonal elements $\sigma_{ii}^2(l)$ of $\Sigma(l)$ can be used, together with the point forecasts $y_{i,t+l|t}$, to construct l-step-ahead prediction interval forecasts of the future values of the component series, $y_{i,t+l}$.

The following statements use the COVPE option to compute the covariance matrices of the prediction errors for a VAR(1) model. The parts of the VARMAX procedure output are shown in Figure 30.31 and Figure 30.32.

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint print=(covpe(15))
                 printform=both;
run;
```

```

Figure 30.32. Covariances of Prediction Errors Continued

Figure 30.32 is the output in a univariate format associated with the COVPE option for the prediction error covariances. This printing format more easily explains the forecast limit of each variable.

Covariance Matrices of Prediction Errors in the Presence of Exogenous (Independent) Variables

Exogenous variables can be both stochastic and nonstochastic (deterministic) variables. Considering the forecasts in the VARMAX(p,q,s) model, there are two cases.

When exogenous (independent) variables are stochastic (future values not specified)

As defined in the "State-space Modeling" section, $\mathbf{y}_{t+l|t}$ has the representation

$$\mathbf{y}_{t+l|t} = \sum_{j=l}^{\infty} V_j \mathbf{a}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and hence

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} V_j \mathbf{a}_{t+l-j} + \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Therefore, the covariance matrix of the l-step-ahead prediction error is given as

$$\Sigma(l) = \mathrm{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} V_j \Sigma_a V_j' + \sum_{j=0}^{l-1} \Psi_j \Sigma_\epsilon \Psi_j'$$

where Σ_a is the covariance of the white noise series $\mathbf{a}_t$, where $\mathbf{a}_t$ is the white noise series for the VARMA(p,q) model of exogenous (independent) variables, which is assumed not to be correlated with $\boldsymbol{\epsilon}_t$ or its lags.

When future exogenous (independent) variables are specified

The optimal forecast $\mathbf{y}_{t+l|t}$ of $\mathbf{y}_t$ conditioned on the past information and also on known future values $\mathbf{x}_{t+1}, \ldots, \mathbf{x}_{t+l}$ can be represented as

$$\mathbf{y}_{t+l|t} = \sum_{j=0}^{\infty} \Psi_j^* \mathbf{x}_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

and the forecast error is

$$\mathbf{e}_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \boldsymbol{\epsilon}_{t+l-j}$$

Thus, the covariance matrix of the l-step-ahead prediction error is given as

$$\Sigma(l) = \mathrm{Cov}(\mathbf{e}_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma_\epsilon \Psi_j'$$

Decomposition of Prediction Error Covariances

In the relation $\Sigma(l) = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j^{o\prime}$, the diagonal elements can be interpreted as providing a decomposition of the l-step-ahead prediction error covariance $\sigma_{ii}^2(l)$ for each component series y_{it} into contributions from the components of the standardized innovations $\boldsymbol{\epsilon}_t$.

If you denote the (i,n)th element of Ψ_j^o by $\psi_{j,in}$, the MSE of $y_{i,t+h|t}$ is

$$\mathrm{MSE}(y_{i,t+h|t}) = \mathrm{E}(y_{i,t+h} - y_{i,t+h|t})^2 = \sum_{j=0}^{l-1}\sum_{n=1}^{k} \psi_{j,in}^2$$

Note that $\sum_{j=0}^{l-1} \psi_{j,in}^2$ is interpreted as the contribution of innovations in variable n to the prediction error covariance of the l-step-ahead forecast of variable i.

The proportion, $\omega_{l,in}$, of the l-step-ahead forecast error covariance of variable i accounting for the innovations in variable n is

$$\omega_{l,in} = \sum_{j=0}^{l-1} \psi_{j,in}^2 / \mathrm{MSE}(y_{i,t+h|t})$$

The following statements use the DECOMPOSE option to compute the decomposition of prediction error covariances and their proportions for a VAR(1) model:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint print=(decompose(15))
                 printform=univariate;
run;
```

```

                              14        0.46611        0.53389
                              15        0.46473        0.53527
```

Figure 30.33. Decomposition of Prediction Error Covariances (DECOMPOSE Option)

The proportions of decomposition of prediction error covariances of two variables are given in Figure 30.33. The output explains that about 91% of the one-step-ahead prediction error covariances of the variable y_{2t} is accounted for by its own innovations and about 9% is accounted for by y_{1t} innovations. For the long-term forecasts, 53.5% and 46.5% of the error variance is accounted for by y_{2t} and y_{1t} innovations.

Forecasting of the Centered Series

If the CENTER option is specified, the sample mean vector is added to the forecast.

Forecasting of the Differenced Series

If dependent (endogenous) variables are differenced, the final forecasts and their prediction error covariances are produced by integrating those of the differenced series. However, if the PRIOR option is specified, the forecasts and their prediction error variances of the differenced series are produced.

Let $\mathbf{z}_t$ be the original series with some zero values appended corresponding to the unobserved past observations. Let $\Delta(B)$ be the $k \times k$ matrix polynomial in the backshift operator corresponding to the differencing specified by the MODEL statement. The off-diagonal elements of Δ_i are zero and the diagonal elements can be different. Then $\mathbf{y}_t = \Delta(B)\mathbf{z}_t$.

This gives the relationship

$$\mathbf{z}_t = \Delta^{-1}(B)\mathbf{y}_t = \sum_{j=0}^{\infty} \Lambda_j \mathbf{y}_{t-j}$$

where $\Delta^{-1}(B) = \sum_{j=0}^{\infty} \Lambda_j B^j$ and $\Lambda_0 = I_k$.

The l-step-ahead prediction of $\mathbf{z}_{t+l}$ is

$$\mathbf{z}_{t+l|t} = \sum_{j=0}^{l-1} \Lambda_j \mathbf{y}_{t+l-j|t} + \sum_{j=l}^{\infty} \Lambda_j \mathbf{y}_{t+l-j}$$

The l-step-ahead prediction error of $\mathbf{z}_{t+l}$ is

$$\sum_{j=0}^{l-1} \Lambda_j \left(\mathbf{y}_{t+l-j} - \mathbf{y}_{t+l-j|t}\right) = \sum_{j=0}^{l-1} \left(\sum_{u=0}^{j} \Lambda_u \Psi_{j-u} \right) \boldsymbol{\epsilon}_{t+l-j}$$

Letting $\Sigma_{\mathbf{z}}(0) = 0$, the covariance matrix of the l-step-ahead prediction error of $\mathbf{z}_{t+l}$, $\Sigma_{\mathbf{z}}(l)$, is

$$\Sigma_{\mathbf{z}}(l) \quad = \quad \sum_{j=0}^{l-1} \left(\sum_{u=0}^{j} \Lambda_u \Psi_{j-u} \right) \Sigma_{\epsilon} \left(\sum_{u=0}^{j} \Lambda_u \Psi_{j-u} \right)'$$

$$= \quad \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j}\right) \Sigma_{\epsilon} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j}\right)'$$

If there are stochastic exogenous (independent) variables, the covariance matrix of the l-step-ahead prediction error of $\mathbf{z}_{t+l}$, $\Sigma_{\mathbf{z}}(l)$, is

$$\begin{aligned}\Sigma_{\mathbf{z}}(l) \quad &= \quad \Sigma_{\mathbf{z}}(l-1) + \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j}\right) \Sigma_{\epsilon} \left(\sum_{j=0}^{l-1} \Lambda_j \Psi_{l-1-j}\right)' \\ &\quad + \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j}\right) \Sigma_{a} \left(\sum_{j=0}^{l-1} \Lambda_j V_{l-1-j}\right)'\end{aligned}$$

Tentative Order Selection

Sample Cross-Covariance and Cross-Correlation Matrices

Given a stationary multivariate time series $\mathbf{y}_t$, cross-covariance matrices are

$$\Gamma(l) = \mathrm{E}[(\mathbf{y}_t - \boldsymbol{\mu})(\mathbf{y}_{t+l} - \boldsymbol{\mu})']$$

where $\boldsymbol{\mu} = \mathrm{E}(\mathbf{y}_t)$, and cross-correlation matrices are

$$\rho(l) = D^{-1}\Gamma(l)D^{-1}$$

where D is a diagonal matrix with the standard deviations of the components of $\mathbf{y}_t$ on the diagonal.

The sample cross-covariance matrix at lag l, denoted as $C(l)$, is computed as

$$\hat{\Gamma}(l) = C(l) = \frac{1}{T}\sum_{t=1}^{T-l} \tilde{\mathbf{y}}_t \tilde{\mathbf{y}}'_{t+l}$$

where $\tilde{\mathbf{y}}_t$ is the centered data and T is the number of nonmissing observations. Thus, $\hat{\Gamma}(l)$ has (i,j)th element $\hat{\gamma}_{ij}(l) = c_{ij}(l)$. The sample cross-correlation matrix at lag l is computed as

$$\hat{\rho}_{ij}(l) = c_{ij}(l)/[c_{ii}(0)c_{jj}(0)]^{1/2}, \;\; i,j = 1,\ldots,k$$

The following statements use the CORRY option to compute the sample cross-correlation matrices and their summary indicator plots in terms of $+$, $-$, and $\cdot$:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3 print=(corry)
                 printform=univariate;
run;
```

```

Figure 30.34. Cross-Correlations (CORRY Option)

Figure 30.34 shows the sample cross-correlation matrices of y_{1t} and y_{2t}. As shown, the sample autocorrelation functions for each variable decay quickly, but are significant with respect to two standard errors.

Partial Autoregressive Matrices

For each $m = 1, 2, \ldots,$ you can define a sequence of matrices Φ_{mm}, which is called the partial autoregression matrices of lag m, as the solution for Φ_{mm} to the Yule-Walker equations of order m,

$$\Gamma(l) = \sum_{i=1}^{m} \Gamma(l-i)\Phi'_{im}, \quad l = 1, 2, \ldots, m$$

The sequence of the partial autoregression matrices Φ_{mm} of order m has the characteristic property that if the process follows the AR(p), then $\Phi_{pp} = \Phi_p$ and $\Phi_{mm} = 0$ for $m > p$. Hence, the matrices Φ_{mm} have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR model.

The following statements use the PARCOEF option to compute the partial autoregression matrices:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3 print=(parcoef);
run;
```

```

```

Figure 30.35. Partial Autoregression Matrices (PARCOEF Option)

Figure 30.35 shows that the model can be obtained by an AR order $m = 1$ since partial autoregression matrices are insignificant after lag 1 with respect to two standard errors. The matrix for lag 1 is the same as the Yule-Walker autoregressive matrix.

Partial Correlation Matrices

Define the forward autoregression

$$\mathbf{y}_t = \sum_{i=1}^{m-1} \Phi_{i,m-1}\mathbf{y}_{t-i} + \mathbf{u}_{m,t}$$

and the backward autoregression

$$\mathbf{y}_{t-m} = \sum_{i=1}^{m-1} \Phi^*_{i,m-1}\mathbf{y}_{t-m+i} + \mathbf{u}^*_{m,t-m}$$

The matrices $P(m)$ defined by Ansley and Newbold (1979) are given by

$$P(m) = \Sigma^{*1/2}_{m-1}\Phi'_{mm}\Sigma^{-1/2}_{m-1}$$

where

$$\Sigma_{m-1} = \mathrm{Cov}(\mathbf{u}_{m,t}) = \Gamma(0) - \sum_{i=1}^{m-1}\Gamma(-i)\Phi'_{i,m-1}$$

and

$$\Sigma^*_{m-1} = \mathrm{Cov}(\mathbf{u}^*_{m,t-m}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(m-i)\Phi^{*'}_{m-i,m-1}$$

$P(m)$ is called the partial cross-correlations matrices at lag m between the elements of $\mathbf{y}_t$ and $\mathbf{y}_{t-m}$, given $\mathbf{y}_{t-1}, \ldots, \mathbf{y}_{t-m+1}$. The matrices $P(m)$ have the cutoff property for a VAR(p) model, and so they can be useful in the identification of the order of a pure VAR structure.

The following statements use the PCORR option to compute the partial cross-correlations matrices:

```
   proc varmax data=simul1;
      model y1 y2 / p=1 noint lagmax=3 print=(pcorr)
                    printform=univariate;
   run;
```

```
                                The VARMAX Procedure

                          -2*std error,  . is between
```

Figure 30.36. Partial Correlations (PCORR Option)

The partial cross-correlation matrices in Figure 30.36 are insignificant after lag 1 with respect to two standard errors. This indicates that an AR order of $m = 1$ can be an appropriate choice.

Partial Canonical Correlation Matrices

The partial canonical correlations at lag m between the vectors $\mathbf{y}_t$ and $\mathbf{y}_{t-m}$, given $\mathbf{y}_{t-1}, \ldots, \mathbf{y}_{t-m+1}$, are $1 \geq \rho_1(m) \geq \rho_2(m) \cdots \geq \rho_k(m)$. The partial canonical correlations are the canonical correlations between the residual series $\mathbf{u}_{m,t}$ and $\mathbf{u}^*_{m,t-m}$, where $\mathbf{u}_{m,t}$ and $\mathbf{u}^*_{m,t-m}$ are defined in the previous section. Thus, the squared partial canonical correlations $\rho_i^2(m)$ are the eigenvalues of the matrix

$$\{\mathrm{Cov}(\mathbf{u}_{m,t})\}^{-1}\mathrm{E}(\mathbf{u}_{m,t}\mathbf{u}^{*'}_{m,t-m})\{\mathrm{Cov}(\mathbf{u}^*_{m,t-m})\}^{-1}\mathrm{E}(\mathbf{u}^*_{m,t-m}\mathbf{u}^{'}_{m,t}) = \Phi^{*'}_{mm}\Phi^{'}_{mm}$$

It follows that the test statistic to test for $\Phi_m = 0$ in the VAR model of order $m > p$ is approximately

$$(T-m)\ \mathrm{tr}\ \{\Phi^{*'}_{mm}\Phi^{'}_{mm}\} \approx (T-m)\sum_{i=1}^{k}\rho_i^2(m)$$

and has an asymptotic chi-square distribution with k^2 degrees of freedom for $m > p$.

The following statements use the PCANCORR option to compute the partial canonical correlations:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3 print=(pcancorr);
run;
```

```
                              The VARMAX Procedure

                        Partial Canonical Correlations

     1          0.91783          0.77335          4         142.61         <.0001
     2          0.09171          0.01816          4           0.86         0.9307
     3          0.10861          0.01078          4           1.16         0.8854
```

Figure 30.37. Partial Canonical Correlations (PCANCORR Option)

Figure 30.37 shows that the partial canonical correlations $\rho_i(m)$ between $\mathbf{y}_t$ and $\mathbf{y}_{t-m}$ are {0.918, 0.773}, {0.092, 0.018}, and {0.109, 0.011} for lags m =1 to 3. After lag m =1, the partial canonical correlations are insignificant with respect to the 0.05 significance level, indicating that an AR order of $m = 1$ can be an appropriate choice.

The Minimum Information Criterion (MINIC) Method

The **MIN**imum **I**nformation **C**riterion (MINIC) method can tentatively identify the orders of a VARMA(p,q) process. Note that Spliid (1983), Koreisha and Pukkila (1989), and Quinn (1980) proposed this method. The first step of this method is to obtain estimates of the innovations series, $\boldsymbol{\epsilon}_t$, from the VAR(p_ϵ), where p_ϵ is chosen sufficiently large. The choice of the autoregressive order, p_ϵ, is determined by use of a selection criterion. From the selected VAR(p_ϵ) model, you obtain estimates of residual series

$$\tilde{\boldsymbol{\epsilon}}_t = \mathbf{y}_t - \sum_{i=1}^{p_\epsilon} \hat{\Phi}_i^{p_\epsilon} \mathbf{y}_{t-i} - \hat{\boldsymbol{\delta}}^{p_\epsilon}, \;\; t = p_\epsilon + 1, \ldots, T$$

In the second step, you select the order (p, q) of the VARMA model for p in $(p_{min} : p_{max})$ and q in $(q_{min} : q_{max})$

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} - \sum_{i=1}^{q} \Theta_i \tilde{\boldsymbol{\epsilon}}_{t-i} + \boldsymbol{\epsilon}_t$$

which minimizes a selection criterion like SBC or HQ.

The following statements use the MINIC= option to compute a table containing the information criterion associated with various AR and MA orders:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint minic=(p=3 q=3);
run;
```

```
                           The VARMAX Procedure

                      Minimum Information Criterion

       Lag            MA 0           MA 1           MA 2           MA 3

       AR 0      3.2859653      3.0570091      2.7272377      2.3526368
       AR 1      0.4862246      0.6507991      0.7120257      0.7859524
       AR 2      0.5800236      0.7407785       0.802996       0.850487
       AR 3      0.6696452      0.8131261      0.8395558      0.9094856
```

Figure 30.38. MINIC= Option

Figure 30.38 shows the output associated with the MINIC= option. The criterion takes the smallest value at AR order 1.

VAR Modeling

The pth-order VAR process is written as

$$\mathbf{y}_t - \boldsymbol{\mu} = \sum_{i=1}^{p} \Phi_i (\mathbf{y}_{t-i} - \boldsymbol{\mu}) + \boldsymbol{\epsilon}_t \;\; \text{or} \;\; \Phi(B)(\mathbf{y}_t - \boldsymbol{\mu}) = \boldsymbol{\epsilon}_t$$

Equivalently, it can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t \;\; \text{or} \;\; \Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

with $\boldsymbol{\delta} = (I_k - \sum_{i=1}^{p} \Phi_i)\boldsymbol{\mu}$.

Stationarity

For stationarity of the VAR process, it must be expressible in the convergent causal infinite MA form as

$$\mathbf{y}_t = \boldsymbol{\mu} + \sum_{j=0}^{\infty} \Psi_j \boldsymbol{\epsilon}_{t-j}$$

where $\Psi(B) = \Phi(B)^{-1} = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\sum_{j=0}^{\infty} ||\Psi_j|| < \infty$, where $||A||$ denotes a norm for the matrix A such as $||A||^2 = \mathrm{tr}\{A'A\}$. The matrix Ψ_j can be recursively obtained from the relation $\Phi(B)\Psi(B) = I$, and is

$$\Psi_j = \Phi_1\Psi_{j-1} + \Phi_2\Psi_{j-2} + \cdots + \Phi_p\Psi_{j-p}$$

where $\Psi_0 = I_k$ and $\Psi_j = 0$ for $j < 0$.

The stationarity condition is satisfied if all roots of $|\Phi(z)| = 0$ are outside of the unit circle. The stationarity condition is equivalent to the condition in the corresponding VAR(1) representation, $\mathbf{Y}_t = \Phi\mathbf{Y}_{t-1} + \boldsymbol{\varepsilon}_t$, that all eigenvalues of the $kp \times kp$ companion matrix Φ be less than one in absolute value, where $\mathbf{Y}_t = (\mathbf{y}'_t, \ldots, \mathbf{y}'_{t-p+1})'$, $\boldsymbol{\varepsilon}_t = (\boldsymbol{\epsilon}'_t, 0', \ldots, 0')'$, and

$$\Phi = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

If the stationarity condition is not satisfied, a nonstationary model (a differenced model or an error correction model) may be more appropriate.

The following statements estimate a VAR(1) model and use the ROOTS option to compute the characteristic polynomial roots:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint print=(roots);
run;
```

```
                           The VARMAX Procedure

                   Roots of AR Characteristic Polynomial

Index          Real       Imaginary        Modulus         Radian         Degree

    1       0.77238         0.35899         0.8517         0.4351        24.9284
    2       0.77238        -0.35899         0.8517        -0.4351       -24.9284
```

Figure 30.39. Stationarity (ROOTS Option)

Figure 30.39 shows the output associated with the ROOTS option, which indicates that the series is stationary since the modulus of the eigenvalue is less than one.

Parameter Estimation

Consider the stationary VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_{-p+1}, \ldots, \mathbf{y}_0$ are assumed to be available (for convenience of notation). This can be represented by the general form of the multivariate linear model,

$$Y = XB + E \;\text{ or }\; \mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned}
Y &= (\mathbf{y}_1, \ldots, \mathbf{y}_T)' \\
B &= (\boldsymbol{\delta}, \Phi_1, \ldots, \Phi_p)' \\
X &= (X_0, \ldots, X_{T-1})' \\
X_t &= (1, \mathbf{y}'_t, \ldots, \mathbf{y}'_{t-p+1})' \\
E &= (\boldsymbol{\epsilon}_1, \ldots, \boldsymbol{\epsilon}_T)' \\
\mathbf{y} &= \text{vec}(Y') \\
\boldsymbol{\beta} &= \text{vec}(B') \\
\mathbf{e} &= \text{vec}(E')
\end{aligned}$$

with *vec* denoting the column stacking operator.

The conditional least-squares estimator of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = ((X'X)^{-1}X' \otimes I_k)\mathbf{y}$$

and the estimate of Σ is

$$\hat{\Sigma} = (T - (kp+1))^{-1} \sum_{t=1}^{T} \hat{\boldsymbol{\epsilon}}_t \hat{\boldsymbol{\epsilon}}_t{}'$$

where $\hat{\boldsymbol{\epsilon}}_t$ is the residual vectors. Consistency and asymptotic normality of the LS estimator are that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

where $X'X/T$ converges in probability to Γ_p and $\xrightarrow{d}$ denotes convergence in distribution.

The (conditional) maximum likelihood estimator in the VAR(p) model is equal to the (conditional) least-squares estimator on the assumption of normality of the error vectors.

Asymptotic Distributions of Impulse Response Functions

As before, *vec* denotes the column stacking operator and *vech* is the corresponding operator that stacks the elements on and below the diagonal. The commutation matrix K_k defines as $K_k\text{vec}(A) = \text{vec}(A')$; the duplication matrix D_k, $D_k\text{vech}(A) = \text{vec}(A)$; the elimination matrix L_k, $L_k\text{vec}(A) = \text{vech}(A)$, for any $k \times k$ matrix A.

The asymptotic distributions of the impulse response function is

$$\sqrt{T}\text{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G_j') \;\; j = 1, 2, \ldots$$

where $\Sigma_{\boldsymbol{\beta}} = \Gamma_p^{-1} \otimes \Sigma$ and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{J}(\boldsymbol{\Phi}')^{j-1-i} \otimes \Psi_i$$

where $\mathbf{J} = [I_k, 0, \ldots, 0]$ is a $k \times kp$ matrix and $\boldsymbol{\Phi}$ is a $kp \times kp$ companion matrix.

The asymptotic distributions of the accumulated impulse response function is

$$\sqrt{T}\text{vec}(\hat{\Psi}_l^a - \Psi_l^a) \xrightarrow{d} N(0, F_l \Sigma_{\boldsymbol{\beta}} F_l') \;\; l = 1, 2, \ldots$$

where $F_l = \sum_{j=1}^{l} G_j$.

The asymptotic distributions of the orthogonalized impulse response function is

$$\sqrt{T}\text{vec}(\hat{\Psi}_j^o - \Psi_j^o) \xrightarrow{d} N(0, C_j \Sigma_{\boldsymbol{\beta}} C_j' + \bar{C}_j \Sigma_{\boldsymbol{\sigma}} \bar{C}_j') \;\; j = 0, 1, 2, \ldots$$

where $C_0 = 0$, $C_j = (\Psi_0^{o'} \otimes I_k)G_j$, $\bar{C}_j = (I_k \otimes \Psi_j)H$ and

$$H = \frac{\partial \text{vec}(\Psi_0^o)}{\partial \boldsymbol{\sigma}'} = L_k'\{L_k(I_{k^2} + K_k)(\Psi_0^o \otimes I_k)L_k'\}^{-1}$$

and $\Sigma_{\boldsymbol{\sigma}} = 2D_k^+(\Sigma \otimes \Sigma)D_k^{+'}$ with $D_k^+ = (D_k' D_k)^{-1} D_k'$ and $\boldsymbol{\sigma} = \text{vech}(\Sigma)$.

Granger-Causality Test

Let $\mathbf{y}_t$ be arranged and partitioned in subgroups $\mathbf{y}_{1t}$ and $\mathbf{y}_{2t}$ with dimensions k_1 and k_2, respectively ($k = k_1 + k_2$); that is, $\mathbf{y}_t = (\mathbf{y}_{1t}', \mathbf{y}_{2t}')'$ with the corresponding white noise process $\boldsymbol{\epsilon}_t = (\boldsymbol{\epsilon}_{1t}', \boldsymbol{\epsilon}_{2t}')'$. Consider the VAR($p$) model with partitioned coefficients $\Phi_{ij}(B)$ for $i, j = 1, 2$ as follows:

$$\begin{bmatrix} \Phi_{11}(B) & \Phi_{12}(B) \\ \Phi_{21}(B) & \Phi_{22}(B) \end{bmatrix} \begin{bmatrix} \mathbf{y}_{1t} \\ \mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\delta}_1 \\ \boldsymbol{\delta}_2 \end{bmatrix} + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The variables $\mathbf{y}_{1t}$ are said to cause $\mathbf{y}_{2t}$, but $\mathbf{y}_{2t}$ do not cause $\mathbf{y}_{1t}$ if $\Phi_{12}(B) = 0$. The implication of this model structure is that future values of the process $\mathbf{y}_{1t}$ are influenced only by its own past and not by the past of $\mathbf{y}_{2t}$, where future values of $\mathbf{y}_{2t}$ are influenced by the past of both $\mathbf{y}_{1t}$ and $\mathbf{y}_{2t}$. If the future $\mathbf{y}_{1t}$ are not influenced by the past values of $\mathbf{y}_{2t}$, then it can be better to model $\mathbf{y}_{1t}$ separately from $\mathbf{y}_{2t}$.

Consider testing $H_0\colon C\boldsymbol{\beta} = c$, where C is a $s \times (k^2p + k)$ matrix of rank s and c is a s-dimensional vector where $s = k_1k_2p$. Assuming that

$$\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)$$

you get the Wald statistic

$$T(C\hat{\boldsymbol{\beta}} - c)'[C(\hat{\Gamma}_p^{-1} \otimes \hat{\Sigma})C']^{-1}(C\hat{\boldsymbol{\beta}} - c) \xrightarrow{d} \chi^2(s)$$

For the Granger-Causality Test, the matrix C consists of zeros or ones and c is the zero vector.

VARX Modeling

The Vector AutoRegressive model with eXogenous variables is called the VARX(p,s) model. The form of the VARX(p,s) model can be written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \sum_{i=0}^{s} \Theta_i^* \mathbf{x}_{t-i} + \boldsymbol{\epsilon}_t$$

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

$$Y = XB + E \ \text{ or } \ \mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

where

$$\begin{aligned}
Y &= (\mathbf{y}_1, \ldots, \mathbf{y}_T)' \\
B &= (\boldsymbol{\delta}, \Phi_1, \ldots, \Phi_p, \Theta_0^*, \ldots, \Theta_s^*)' \\
X &= (X_0, \ldots, X_{T-1})' \\
X_t &= (1, \mathbf{y}_t', \ldots, \mathbf{y}_{t-p+1}', \mathbf{x}_{t+1}', \ldots, \mathbf{x}_{t-s+1}')' \\
E &= (\boldsymbol{\epsilon}_1, \ldots, \boldsymbol{\epsilon}_T)' \\
\mathbf{y} &= \text{vec}(Y') \\
\boldsymbol{\beta} &= \text{vec}(B') \\
\mathbf{e} &= \text{vec}(E')
\end{aligned}$$

The conditional least-squares estimator of β can be obtained using the same method in a VAR(p) modeling. If the multivariate linear model has different independent variables corresponding to dependent variables, the SUR (Seemingly Unrelated Regression) method is used to improve the regression estimates.

The following example fits the ordinary regression model:

```
proc varmax data=one;
   model y1-y3 = x1-x5;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software.

```
proc reg data=one;
   model y1 = x1-x5;
   model y2 = x1-x5;
   model y3 = x1-x5;
run;
```

The following example fits the second-order lagged regression model:

```
proc varmax data=two;
   model y1 y2 = x / xlag=2;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software.

```
data three;
   set two;
   xlag1 = lag1(x);
   xlag2 = lag2(x);
run;

proc reg data=three;
   model y1 = x xlag1 xlag2;
   model y2 = x xlag1 xlag2;
run;
```

The following example fits the ordinary regression model with different regressors:

```
proc varmax data=one;
   model y1 = x1-x3, y2 = x2 x3;
run;
```

This is equivalent to the following SYSLIN procedure statements.

```
proc syslin data=one vardef=nf sur;
   endogenous y1 y2;
   model y1 = x1-x3;
   model y2 = x2 x3;
run;
```

From the output in Figure 30.20 on page 1714, you can see that the parameters, XL0_1_2, XL0_2_1, XL0_3_1, and XL0_3_2, are not significant. The following example fits the VARX(1,0) model with different regressors:

```
proc varmax data=grunfeld;
   model y1 = x1, y2 = x2, y3 / p=1;
run;
```

```

Figure 30.40. Parameter Estimates for the VARX(1, 0) Model

As you can see in Figure 30.40, the symbol '_' in the elements of matrix correspond to endogenous variables that do not take exogenous variables.

Model Diagnostic Checks

Multivariate Model Diagnostic Checks

- Information Criterion

  Various model selection criteria (normalized by T) can be used to choose the appropriate model. The following list includes the Akaike Information Criterion (AIC), the corrected Akaike Information Criterion (AICC), the Final Prediction Error criterion (FPE), the Hannan-Quinn Criterion (HQC), and the Schwarz Bayesian Criterion (SBC), also referred to as BIC.

$$\begin{aligned}
\text{AIC} &= \log(|\tilde{\Sigma}|) + 2r/T \\
\text{AICC} &= \log(|\tilde{\Sigma}|) + 2r/(T - r/k) \\
\text{FPE} &= (\frac{T + r/k}{T - r/k})^k |\tilde{\Sigma}| \\
\text{HQC} &= \log(|\tilde{\Sigma}|) + 2r\log(\log(T))/T \\
\text{SBC} &= \log(|\tilde{\Sigma}|) + r\log(T)/T
\end{aligned}$$

  where r denotes the number of parameters estimated and $\tilde{\Sigma}$ is the maximum likelihood estimate of Σ.

  An example of the output was displayed in Figure 30.4 on page 1699.

- Portmanteau Statistic Q_s

  Let $C_\epsilon(l)$ be the residual cross-covariance matrices and $\hat{\rho}_\epsilon(l)$ be the residual cross-correlation matrices as

$$C_\epsilon(l) = T^{-1}\sum_{t=1}^{T-l} \boldsymbol{\epsilon}_t \boldsymbol{\epsilon}'_{t+l}$$

and

$$\hat{\rho}_\epsilon(l) = \hat{V}_\epsilon^{-1/2} C_\epsilon(l) \hat{V}_\epsilon^{-1/2} \text{ and } \hat{\rho}_\epsilon(-l) = \hat{\rho}_\epsilon(l)'$$

where $\hat{V}_\epsilon = \mathrm{Diag}(\hat{\sigma}_{11}^2, \ldots, \hat{\sigma}_{kk}^2)$ and $\hat{\sigma}_{ii}^2$ are the diagonal elements of $\hat{\Sigma}$. The multivariate portmanteau test defined in Hosking (1980) is

$$Q_s = T^2 \sum_{l=1}^{s} (T-l)^{-1} \mathrm{tr}\{\hat{\rho}_\epsilon(l) \Sigma^{-1} \hat{\rho}_\epsilon(-l) \Sigma^{-1}\}$$

The statistic Q_s has approximately the chi-square distribution with $k^2(s-p-q)$ degrees of freedom. An example of the output was displayed in Figure 30.7 on page 1700.

Univariate Model Diagnostic Checks

There are various ways to perform diagnostic checks for a univariate model. For details, see the chapter on the ARIMA or AUTOREG procedure. An example of the output was displayed in Figure 30.8 and Figure 30.9 on page 1701.

- Durbin-Watson (DW) statistics: The test statistics are computed from the residuals of the autoregressive model with order 1.
- F tests for autoregressive conditional heteroscedastic (ARCH) disturbances: These test statistics are computed from the residuals of the ARCH(1) model.
- F tests for AR disturbance: These test statistics are computed from the residuals of the univariate AR(1), AR(2), AR(3), and AR(4) models.
- Jarque-Bera normality test: This test is helpful in determining whether the model residuals represent a white noise process.

Bayesian VAR Modeling

Consider the VAR(p) model

$$\mathbf{y}_t = \boldsymbol{\delta} + \Phi_1 \mathbf{y}_{t-1} + \cdots + \Phi_p \mathbf{y}_{t-p} + \boldsymbol{\epsilon}_t$$

or

$$\mathbf{y} = (X \otimes I_k)\boldsymbol{\beta} + \mathbf{e}$$

When the parameter vector $\boldsymbol{\beta}$ has a prior multivariate normal distribution with known mean $\boldsymbol{\beta}^*$ and covariance matrix V_β, the prior density is written as

$$f(\boldsymbol{\beta}) = (\frac{1}{2\pi})^{k^2p/2} |V_\beta|^{-1/2} \exp[-\frac{1}{2}(\boldsymbol{\beta} - \boldsymbol{\beta}^*) V_\beta^{-1} (\boldsymbol{\beta} - \boldsymbol{\beta}^*)]$$

The likelihood function for the Gaussian process becomes

$$\begin{aligned}\ell(\boldsymbol{\beta}|\mathbf{y}) &= (\frac{1}{2\pi})^{kT/2}|I_T \otimes \Sigma|^{-1/2} \times \\ &\quad \exp[-\frac{1}{2}(\mathbf{y}-(X\otimes I_k)\boldsymbol{\beta})'(I_T\otimes\Sigma^{-1})(\mathbf{y}-(X\otimes I_k)\boldsymbol{\beta})]\end{aligned}$$

Therefore, the posterior density is derived as

$$f(\boldsymbol{\beta}|\mathbf{y}) \propto \exp[-\frac{1}{2}(\boldsymbol{\beta}-\bar{\boldsymbol{\beta}})'\bar{\Sigma}_{\beta}^{-1}(\boldsymbol{\beta}-\bar{\boldsymbol{\beta}})]$$

where the posterior mean is

$$\bar{\boldsymbol{\beta}} = [V_{\beta}^{-1} + (X'X\otimes\Sigma^{-1})]^{-1}[V_{\beta}^{-1}\boldsymbol{\beta}^{*} + (X'\otimes\Sigma^{-1})\mathbf{y}]$$

and the posterior covariance matrix is

$$\bar{\Sigma}_{\beta} = [V_{\beta}^{-1} + (X'X\otimes\Sigma^{-1})]^{-1}$$

In practice, the prior mean $\boldsymbol{\beta}^{*}$ and the prior variance V_{β} need to be specified. If all the parameters are considered to shrink toward zero, the null prior mean should be specified. According to Litterman (1986), the prior variance can be given by

$$v_{ij}(l) = \begin{cases} (\lambda/l)^2 & \text{if } i=j \\ (\lambda\theta\sigma_{ii}/l\sigma_{jj})^2 & \text{if } i\neq j \end{cases}$$

where $v_{ij}(l)$ is the prior variance of the (i,j)th element of Φ_l, λ is the prior standard deviation of the diagonal elements of Φ_l, θ is a constant in the interval $(0,1)$, and σ_{ii}^2 is the ith diagonal element of Σ. The deterministic terms have diffused prior variance. In practice, you replace the σ_{ii}^2 by the diagonal element of the ML estimator of Σ in the nonconstrained model.

For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + \phi_{1,11}y_{1,t-1} + \phi_{1,12}y_{2,t-1} + \phi_{2,11}y_{1,t-2} + \phi_{2,12}y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + \phi_{1,21}y_{1,t-1} + \phi_{1,22}y_{2,t-1} + \phi_{2,21}y_{1,t-2} + \phi_{2,22}y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

with the prior covariance matrix

$$\begin{aligned} V_{\beta} = \text{Diag} \quad (& \infty, \lambda^2, (\lambda\theta\sigma_1/\sigma_2)^2, (\lambda/2)^2, (\lambda\theta\sigma_1/2\sigma_2)^2, \\ & \infty, (\lambda\theta\sigma_2/\sigma_1)^2, \lambda^2, (\lambda\theta\sigma_2/2\sigma_1)^2, (\lambda/2)^2 \ ) \end{aligned}$$

For the Bayesian Estimation of integrated systems, the prior mean is set to the first lag of each variable equal to one in its own equation and all other coefficients at zero. For example, for a bivariate BVAR(2) model,

$$\begin{aligned} y_{1t} &= 0 + 1\ y_{1,t-1} + 0\ y_{2,t-1} + 0\ y_{1,t-2} + 0\ y_{2,t-2} + \epsilon_{1t} \\ y_{2t} &= 0 + 0\ y_{1,t-1} + 1\ y_{2,t-1} + 0\ y_{1,t-2} + 0\ y_{2,t-2} + \epsilon_{2t} \end{aligned}$$

Forecasting of BVAR Modeling

The bootstrap procedure is used to estimate standard errors of the forecast (Litterman 1986). NREP=*B* simulations are performed. In each simulation the following steps are taken:

1. The procedure generates the available number of observations, T, and uniform random integers I_t, where $t = 1, \ldots T$.
2. A new observation, $\tilde{\mathbf{y}}_t$, is obtained as a sum of the forecast based on the estimates coefficients plus the vector of residuals from the I_t; that is,

$$\tilde{\mathbf{y}}_t = \sum_{j=1}^{p} \hat{\Phi}_j \mathbf{y}_{t-j} + \hat{\boldsymbol{\epsilon}}_{I_t}$$

3. A new BVAR model is estimated by using the most recent observations, and a prediction value is made of the most recent observations.

The MSE measure of the l-step-ahead forecast is

$$MSE(l) = \frac{1}{B} \sum_{i=1}^{B} (\tilde{\mathbf{y}}^i_{t+l|t} - \bar{\tilde{\mathbf{y}}}_t)^2$$

where $\bar{\tilde{\mathbf{y}}}_t = (1/B) \sum_{i=1}^{B} \bar{\tilde{\mathbf{y}}}^i_t$.

VARMA Modeling

A VARMA(p, q) process is written as

$$\mathbf{y}_t = \boldsymbol{\delta} + \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{i=1}^{q} \Theta_i \boldsymbol{\epsilon}_{t-i}$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\delta} + \Theta(B)\boldsymbol{\epsilon}_t$$

where $\Phi(B) = I_k - \sum_{i=1}^{p} \Phi_i B^i$ and $\Theta(B) = I_k - \sum_{i=1}^{q} \Theta_i B^i$.

Stationarity and Invertibility

For stationarity and invertibility of the VARMA process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.

Parameter Estimation

Under the assumption of normality of the $\boldsymbol{\epsilon}_t$ with mean vector zero and nonsingular covariance matrix Σ, consider the conditional (approximate) log-likelihood function of a VARMA(p,q) model with mean zero.

Define $Y = (\mathbf{y}_1, \ldots, \mathbf{y}_T)'$ and $E = (\boldsymbol{\epsilon}_1, \ldots, \boldsymbol{\epsilon}_T)'$ with $B^iY = (\mathbf{y}_{1-i}, \ldots, \mathbf{y}_{T-i})'$ and $B^iE = (\boldsymbol{\epsilon}_{1-i}, \ldots, \boldsymbol{\epsilon}_{T-i})'$; define $\mathbf{y} = \mathrm{vec}(Y')$ and $\mathbf{e} = \mathrm{vec}(E')$. Then

$$\mathbf{y} - \sum_{i=1}^{p}(I_T \otimes \Phi_i)B^i\mathbf{y} = \mathbf{e} - \sum_{i=1}^{q}(I_T \otimes \Theta_i)B^i\mathbf{e}$$

where $B^i\mathbf{y} = \mathrm{vec}[(B^iY)']$ and $B^i\mathbf{e} = \mathrm{vec}[(B^iE)']$.

Then, the conditional (approximate) log-likelihood function can be written as the following (see Reinsel 1997):

$$\begin{aligned} \ell &= -\frac{T}{2}\log|\Sigma| - \frac{1}{2}\sum_{t=1}^{T}\boldsymbol{\epsilon}_t'\Sigma^{-1}\boldsymbol{\epsilon}_t \\ &= -\frac{T}{2}\log|\Sigma| - \frac{1}{2}\mathbf{w}'\Theta'^{-1}(I_T \otimes \Sigma^{-1})\Theta^{-1}\mathbf{w} \end{aligned}$$

where $\mathbf{w} = \mathbf{y} - \sum_{i=1}^{p}(I_T \otimes \Phi_i)B^i\mathbf{y}$; Θ such that $\mathbf{e} - \sum_{i=1}^{q}(I_T \otimes \Theta_i)B^i\mathbf{e} = \Theta\mathbf{e}$.

For the exact log-likelihood function of a VARMA(p,q) model, the Kalman filtering method is used transforming the VARMA process into the state-space form (see Reinsel 1997).

The state-space form of the VARMA(p,q) model consists of a state equation

$$\mathbf{z}_t = F\mathbf{z}_{t-1} + G\boldsymbol{\epsilon}_t$$

and an observation equation

$$\mathbf{y}_t = H\mathbf{z}_t$$

where for $v = \max(p, q+1)$

$$\mathbf{z}_t = (\mathbf{y}_t', \mathbf{y}_{t+1|t}', \ldots, \mathbf{y}_{t+v-1|t}')'$$

$$F = \begin{bmatrix} 0 & I_k & 0 & \cdots & 0 \\ 0 & 0 & I_k & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Phi_v & \Phi_{v-1} & \Phi_{v-2} & \cdots & \Phi_1 \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ \Psi_1 \\ \vdots \\ \Psi_{v-1} \end{bmatrix}$$

and

$$H = [I_k, 0, \ldots, 0]$$

The Kalman filtering approach is used for evaluation of the likelihood function. The updating equation is

$$\hat{\mathbf{z}}_{t|t} = \hat{\mathbf{z}}_{t|t-1} + K_t \boldsymbol{\epsilon}_{t|t-1}$$

with

$$K_t = P_{t|t-1} H' [H P_{t|t-1} H']^{-1}$$

and the prediction equation is

$$\hat{\mathbf{z}}_{t|t-1} = F \hat{\mathbf{z}}_{t-1|t-1}, \;\; P_{t|t-1} = F P_{t-1|t-1} F' + G \Sigma G'$$

with $P_{t|t} = [I - K_t H] P_{t|t-1}$ for $t = 1, 2, \ldots, n$.

The log-likelihood function can be expressed as

$$\ell = -\frac{1}{2} \sum_{t=1}^{T} [\log |\Sigma_{t|t-1}| - (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})' \Sigma_{t|t-1}^{-1} (\mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1})]$$

where $\hat{\mathbf{y}}_{t|t-1}$ and $\Sigma_{t|t-1}$ determined recursively from the Kalman filter procedure. From Kalman filtering, to construct the likelihood function you obtain $\hat{\mathbf{y}}_{t|t-1} = H \hat{\mathbf{z}}_{t|t-1}$, $\hat{\boldsymbol{\epsilon}}_{t|t-1} = \mathbf{y}_t - \hat{\mathbf{y}}_{t|t-1}$, and $\Sigma_{t|t-1} = H P_{t|t-1} H'$.

Define the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi_1', \ldots, \phi_p', \theta_1', \ldots, \theta_q', \mathrm{vech}(\Sigma))'$$

where $\phi_i = \mathrm{vec}(\Phi_i)$ and $\theta_i = \mathrm{vec}(\Theta_i)$.

The log-likelihood equations are solved by iterative numerical procedures such as the quasi-Newton optimization. The starting values for the AR and MA parameters are obtained from the least squares estimates.

Asymptotic Distribution of the Parameter Estimates

Under the assumptions of stationarity and invertibility for the VARMA model, and the assumption that $\boldsymbol{\epsilon}_t$ is a white noise process, $\hat{\boldsymbol{\beta}}$ is a consistent estimator for $\boldsymbol{\beta}$ and $\sqrt{T}(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta})$ converges in distribution to the multivariate normal $N(0, V^{-1})$ as $T \to \infty$, where V is the asymptotic information matrix of $\boldsymbol{\beta}$.

Asymptotic Distributions of Impulse Response Functions

Defining the vector $\boldsymbol{\beta}$

$$\boldsymbol{\beta} = (\phi_1', \ldots, \phi_p', \theta_1', \ldots, \theta_q')'$$

the asymptotic distribution of the impulse response function for a VARMA(p, q) model is

$$\sqrt{T}\mathrm{vec}(\hat{\Psi}_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_{\boldsymbol{\beta}} G_j') \;\; j = 1, 2, \ldots$$

where $\Sigma_{\boldsymbol{\beta}}$ is the covariance matrix of the parameter estimates and

$$G_j = \frac{\partial \mathrm{vec}(\Psi_j)}{\partial \boldsymbol{\beta}'} = \sum_{i=0}^{j-1} \mathbf{H}'(\mathbf{A}')^{j-1-i} \otimes \mathbf{J}\mathbf{A}^i\mathbf{J}'$$

where $\mathbf{H} = [I_k, 0, \ldots, 0, I_k, 0, \ldots, 0]'$ is a $k(p+q) \times k$ matrix with the second I_k follows after p block matrices; $\mathbf{J} = [I_k, 0, \ldots, 0]$ is a $k \times k(p+q)$ matrix; $\mathbf{A}$ is a $k(p+q) \times k(p+q)$ matrix that

$$\mathbf{A} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

where

$$A_{11} = \begin{bmatrix} \Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix} \quad A_{12} = \begin{bmatrix} -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ 0 & \cdots & 0 & 0 \\ 0 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 \end{bmatrix}$$

A_{21} is a $kq \times kp$ zero matrix, and

$$A_{22} = \begin{bmatrix} 0 & 0 & \cdots & 0 & 0 \\ I_k & 0 & \cdots & 0 & 0 \\ 0 & I_k & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

An Example of a VARMA(1,1) Model

Consider a VARMA(1,1) model with mean zero

$$\mathbf{y}_t = \Phi_1 \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \Theta_1 \boldsymbol{\epsilon}_{t-1}$$

where $\boldsymbol{\epsilon}_t$ is the white noise process with a mean zero vector and the positive-definite covariance matrix Σ.

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
   sig = {1.0  0.5, 0.5 1.25};
   phi = {1.2 -0.5, 0.6 0.3};
   theta = {0.5 -0.2, 0.1 0.3};
   /* to simulate the vector time series */
   call varmasim(y,phi,theta) sigma=sig n=100 seed=34657;
   cn = {'y1' 'y2'};
   create simul3 from y[colname=cn];
   append from y;
quit;
```

The following statements fit a VARMA(1,1) model to the simulated data. You specify the order of the autoregressive model with the P= option and the order of moving-average model with the Q= option. You specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization method.

```
proc varmax data=simul3;
   nloptions tech=qn;
   model y1 y2 / p=1 q=1 noint;
run;
```

```
                     The VARMAX Procedure

Figure 30.45. Parameter Estimates for the VARMA(1, 1) Model

Figure 30.45 shows the AR coefficient matrix in terms of lag 1, the MA coefficient matrix in terms of lag 1, the parameter estimates, and their significance that indicates how well the model fits the data.

The fitted VARMA(1,1) model with estimated standard errors in parentheses are given as

$$\mathbf{y}_t = \begin{pmatrix} 1.018 & -0.387 \\ (0.045) & (0.057) \\ 0.392 & 0.553 \\ (0.043) & (0.053) \end{pmatrix} \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t - \begin{pmatrix} 0.323 & -0.022 \\ (0.120) & (0.126) \\ -0.165 & 0.586 \\ (0.115) & (0.144) \end{pmatrix} \boldsymbol{\epsilon}_{t-1}$$

Cointegration

This section briefly introduces the concepts of cointegration.

Definition 1. *(Engle and Granger 1987): If a series y_t with no deterministic components can be represented by a stationary and invertible ARMA process after differencing d times, the series is integrated of order d, that is, $y_t \sim I(d)$.*

Definition 2. *(Engle and Granger 1987): If all elements of the vector $\mathbf{y}_t$ are $I(d)$ and there exists a cointegrating vector $\boldsymbol{\beta} \neq 0$ such that $\boldsymbol{\beta}'\mathbf{y}_t \sim I(d-b)$ for any $b > 0$, the vector process is said to be cointegrated $CI(d, b)$.*

A simple example of a cointegrated process is the following bivariate system:

$$\begin{aligned} y_{1t} &= \gamma y_{2t} + \epsilon_{1t} \\ y_{2t} &= y_{2,t-1} + \epsilon_{2t} \end{aligned}$$

with ϵ_{1t} and ϵ_{2t} being uncorrelated white noise processes. In the second equation, y_{2t} is a random walk, $\Delta y_{2t} = \epsilon_{2t}$, $\Delta \equiv 1 - B$. Differencing the first equation results in

$$\Delta y_{1t} = \gamma \Delta y_{2t} + \Delta \epsilon_{1t} = \gamma \epsilon_{2t} + \epsilon_{1t} - \epsilon_{1,t-1}$$

Thus, both y_{1t} and y_{2t} are $I(1)$ processes, but the linear combination $y_{1t} - \gamma y_{2t}$ is stationary. Hence $\mathbf{y}_t = (y_{1t}, y_{2t})'$ is cointegrated with a cointegrating vector $\boldsymbol{\beta} = (1, -\gamma)'$.

In general, if the vector process $\mathbf{y}_t$ has k components, then there can be more than one cointegrating vector $\boldsymbol{\beta}'$. It is assumed that there are r linearly independent cointegrating vectors with $r < k$, which make the $k \times r$ matrix $\boldsymbol{\beta}$. The rank of matrix $\boldsymbol{\beta}$ is r, which is called the *cointegration rank* of $\mathbf{y}_t$.

Common Trends

This section briefly discusses the implication of cointegration for the moving-average representation. Let $\mathbf{y}_t$ be cointegrated $CI(1, 1)$, then $\Delta\mathbf{y}_t$ has the Wold representation.

$$\Delta\mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t, \ \sum_{j=0}^{\infty} j|\Psi_j| < \infty$$

where $\boldsymbol{\epsilon}_t$ is $iid(0, \Sigma)$ and $\Psi(B) = \sum_{j=0}^{\infty} \Psi_j B^j$ with $\Psi_0 = I_k$.

Assume that $\boldsymbol{\epsilon}_t = 0$ if $t \leq 0$ and $\mathbf{y}_0$ is a nonrandom initial value. Then the difference equation implies that

$$\mathbf{y}_t = \mathbf{y}_0 + \boldsymbol{\delta} t + \Psi(1) \sum_{i=0}^{t} \boldsymbol{\epsilon}_i + \Psi^*(B)\boldsymbol{\epsilon}_t$$

where $\Psi^*(B) = (1-B)^{-1}(\Psi(B) - \Psi(1))$ and $\Psi^*(B)$ is absolutely summable.

Assume that the rank of $\Psi(1)$ is $m = k - r$. When the process $\mathbf{y}_t$ is cointegrated, there is a cointegrating $k \times r$ matrix $\boldsymbol{\beta}$ such that $\boldsymbol{\beta}'\mathbf{y}_t$ is stationary.

Premultiplying $\mathbf{y}_t$ by $\boldsymbol{\beta}'$ results in

$$\boldsymbol{\beta}'\mathbf{y}_t = \boldsymbol{\beta}'\mathbf{y}_0 + \boldsymbol{\beta}'\Psi^*(B)\boldsymbol{\epsilon}_t$$

because $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$.

Stock and Watson (1988) showed that the cointegrated process $\mathbf{y}_t$ has a common trends representation derived from the moving-average representation. Since the rank of $\Psi(1)$ is $m = k - r$, there is a $k \times r$ matrix H_1 with rank r such that $\Psi(1)H_1 = 0$. Let H_2 be a $k \times m$ matrix with rank m such that $H_2' H_1 = 0$, then $A = C(1)H_2$ has rank m. The $H = (H_1, H_2)$ has rank k. By construction of H,

$$\Psi(1)H = [0, A] = AS_m$$

where $S_m = (0_{m \times r}, I_m)$. Since $\boldsymbol{\beta}'\Psi(1) = 0$ and $\boldsymbol{\beta}'\boldsymbol{\delta} = 0$, $\boldsymbol{\delta}$ lies in the column space of $\Psi(1)$ and can be written

$$\boldsymbol{\delta} = C(1)\tilde{\boldsymbol{\delta}}$$

where $\tilde{\boldsymbol{\delta}}$ is a k-dimensional vector. The common trends representation is written as

$$\begin{aligned}
\mathbf{y}_t &= \mathbf{y}_0 + \Psi(1)[\tilde{\boldsymbol{\delta}} t + \sum_{i=0}^{t} \boldsymbol{\epsilon}_i] + \Psi^*(B)\boldsymbol{\epsilon}_t \\
&= \mathbf{y}_0 + \Psi(1)H[H^{-1}\tilde{\boldsymbol{\delta}} t + H^{-1}\sum_{i=0}^{t} \boldsymbol{\epsilon}_i] + \mathbf{a}_t \\
&= \mathbf{y}_0 + A\boldsymbol{\tau}_t + \mathbf{a}_t
\end{aligned}$$

and

$$\boldsymbol{\tau}_t = \pi + \boldsymbol{\tau}_{t-1} + \mathbf{v}_t$$

where $\mathbf{a}_t = \Psi^*(B)\boldsymbol{\epsilon}_t$, $\pi = S_m H^{-1}\tilde{\boldsymbol{\delta}}$, $\boldsymbol{\tau}_t = S_m[H^{-1}\tilde{\boldsymbol{\delta}} t + H^{-1}\sum_{i=0}^{t} \boldsymbol{\epsilon}_i]$, and $\mathbf{v}_t = S_m H^{-1}\boldsymbol{\epsilon}_t$.

Stock and Watson showed that the common trends representation expresses $\mathbf{y}_t$ as a linear combination of m random walks ($\boldsymbol{\tau}_t$) with drift π plus $I(0)$ components ($\mathbf{a}_t$).

Test for the Common Trends

Stock and Watson (1988) proposed statistics for common trends testing. The null hypothesis is that k-dimensional time series $\mathbf{y}_t$ has $m \leq k$ common stochastic trends, and the alternative is that it has $s < m$ common trends. The test procedure of m vs s common stochastic trends is performed based on the first-order serial correlation matrix of $\mathbf{y}_t$. Let $\boldsymbol{\beta}_\perp$ be a $k \times m$ matrix orthogonal to the cointegrating matrix such that $\boldsymbol{\beta}_\perp^{'}\boldsymbol{\beta} = 0$, and $\boldsymbol{\beta}_\perp\boldsymbol{\beta}_\perp^{'} = I_m$. Let $\mathbf{z}_t = \boldsymbol{\beta}'\mathbf{y}_t$ and $\mathbf{w}_t = \boldsymbol{\beta}_\perp^{'}\mathbf{y}_t$. Then

$$\mathbf{w}_t = \boldsymbol{\beta}'_\perp\mathbf{y}_0 + \boldsymbol{\beta}'_\perp\boldsymbol{\delta}t + \boldsymbol{\beta}'_\perp\Psi(1)\sum_{i=0}^{t}\boldsymbol{\epsilon}_i + \boldsymbol{\beta}'_\perp\Psi^*(B)\boldsymbol{\epsilon}_t$$

Combining the expression of $\mathbf{z}_t$ and $\mathbf{w}_t$,

$$\begin{aligned}\begin{bmatrix}\mathbf{z}_t\\ \mathbf{w}_t\end{bmatrix} &= \begin{bmatrix}\boldsymbol{\beta}'\mathbf{y}_0\\ \boldsymbol{\beta}_\perp^{'}\mathbf{y}_0\end{bmatrix} + \begin{bmatrix}0\\ \boldsymbol{\beta}_\perp^{'}\boldsymbol{\delta}\end{bmatrix}t + \begin{bmatrix}0\\ \boldsymbol{\beta}_\perp^{'}\Psi(1)\end{bmatrix}\sum_{i=1}^{t}\boldsymbol{\epsilon}_i\\ &+ \begin{bmatrix}\boldsymbol{\beta}'\Psi^*(B)\\ \boldsymbol{\beta}'_\perp\Psi^*(B)\end{bmatrix}\boldsymbol{\epsilon}_t\end{aligned}$$

The Stock-Watson common trends test is performed based on the component $\mathbf{w}_t$ by testing whether $\boldsymbol{\beta}_\perp^{'}\Psi(1)$ has rank m against rank s.

The following statements test Stock-Watson common trends:

```
proc varmax data=simul2;
   model y1 y2 / p=2 cointtest=(sw);
run;
```

```
                              The VARMAX Procedure

```

Figure 30.46. Common Trends Test (COINTTEST=(SW) Option)

In Figure 30.46, the first column is the null hypothesis that $\mathbf{y}_t$ has $m \leq k$ common trends; the second column, the alternative hypothesis that $\mathbf{y}_t$ has $s < m$ common trends; the fourth column, the test statistics using AR(2) filtering the data. The test statistics for testing for 2 versus 1 common trends are more negative (-35.1) than the critical value (-23.0). The test rejects the null hypothesis, which means that the series has a single common trend.

Vector Error Correction Modeling

This section discusses the implication of cointegration for the autoregressive representation. Assume that the cointegrated series can be represented by a vector error correction model according to the Granger representation theorem (Engle and Granger 1987). Consider the vector autoregressive process with Gaussian errors defined by

$$\mathbf{y}_t = \sum_{i=1}^{p} \Phi_i \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

or

$$\Phi(B)\mathbf{y}_t = \boldsymbol{\epsilon}_t$$

where the initial values, $\mathbf{y}_{-p+1}, \ldots, \mathbf{y}_0$, are fixed and $\boldsymbol{\epsilon}_t \sim N(0, \Sigma)$. Since the AR operator $\Phi(B)$ can be re-expressed as $\Phi(B) = \Phi^*(B)(1-B) + \Phi(1)B$ where $\Phi^*(B) = I_k - \sum_{i=1}^{p-1} \Phi_i^* B^i$ with $\Phi_i^* = -\sum_{j=i+1}^{p} \Phi_j$, the vector error correction model is

$$\Phi^*(B)(1-B)\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t$$

or

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

where $\boldsymbol{\alpha}\boldsymbol{\beta}' = -\Phi(1) = -I_k + \Phi_1 + \Phi_2 + \cdots + \Phi_p$.

One motivation for the VECM(p) form is to consider the relation $\boldsymbol{\beta}'\mathbf{y}_t = \mathbf{c}$ as defining the underlying economic relations and assume that the agents react to the disequilibrium error $\boldsymbol{\beta}'\mathbf{y}_t - \mathbf{c}$ through the adjustment coefficient $\boldsymbol{\alpha}$ to restore equilibrium; that is, they satisfy the economic relations. The cointegrating vector, $\boldsymbol{\beta}$ is sometimes called the *long-run parameters*.

You can consider a vector error correction model with a deterministic term. The deterministic term D_t can contain a constant, a linear trend, seasonal dummy variables, or nonstochastic regressors.

$$\Delta\mathbf{y}_t = \Pi\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta\mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

where $\Pi = \boldsymbol{\alpha}\boldsymbol{\beta}'$.

The alternative vector error correction representation considers the error correction term at lag $t-p$ and is written as

$$\Delta\mathbf{y}_t = \sum_{i=1}^{p-1} \Phi_i^{\sharp} \Delta\mathbf{y}_{t-i} + \Pi^{\sharp}\mathbf{y}_{t-p} + AD_t + \boldsymbol{\epsilon}_t$$

If the matrix Π has a full-rank ($r = k$), all components of $\mathbf{y}_t$ are $I(0)$. On the other hand, $\mathbf{y}_t$ are stationary in difference if $rank(\Pi) = 0$. When the rank of the matrix Π is $r < k$, there are $k - r$ linear combinations that are nonstationary and r stationary cointegrating relations. Note that the linearly independent vector $\mathbf{z}_t = \boldsymbol{\beta}'\mathbf{y}_t$ is stationary and this transformation is not unique unless $r = 1$. There does not exist a unique cointegrating matrix $\boldsymbol{\beta}$ since the coefficient matrix Π can also be decomposed as

$$\Pi = \boldsymbol{\alpha} M M^{-1} \boldsymbol{\beta}' = \boldsymbol{\alpha}^* \boldsymbol{\beta}^{*'}$$

where M is an $r \times r$ nonsingular matrix.

Test for the Cointegration

The cointegration rank test determines the linearly independent columns of Π. Johansen (1988, 1995a) and Johansen and Juselius (1990) proposed the cointegration rank test using the reduced rank regression.

Different Specifications of Deterministic Trends

When you construct the VECM(p) form from the VAR(p) model, the deterministic terms in the VECM(p) form can differ from those in the VAR(p) model. When there are deterministic cointegrated relationships among variables, deterministic terms in the VAR(p) model will not be present in the VECM(p) form. On the other hand, if there are stochastic cointegrated relationships, deterministic terms appear in the VECM(p) form via the error correction term or as an independent term in the VECM(p) form.

- **Case 1:** There is no separate drift in the VECM(p) form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

- **Case 2:** There is no separate drift in the VECM(p) form, but a constant enters only via the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_0)(\mathbf{y}'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\epsilon}_t$$

- **Case 3:** There is a separate drift and no separate linear trend in the VECM(p) form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

- **Case 4:** There is a separate drift and no separate linear trend in the VECM(p) form, but a linear trend enters only via the error correction term.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}(\boldsymbol{\beta}', \beta_1)(\mathbf{y}'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\epsilon}_t$$

- **Case 5:** There is a separate linear trend in the VECM(p) form.

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + \boldsymbol{\delta}_0 + \boldsymbol{\delta}_1 t + \boldsymbol{\epsilon}_t$$

First, focus on cases 1, 3, and 5 to test the null hypothesis that there are at most r cointegrating vectors. Let

$$\begin{aligned} Z_{0t} &= \Delta \mathbf{y}_t \\ Z_{1t} &= \mathbf{y}_{t-1} \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \ldots, \Delta \mathbf{y}'_{t-p+1}, D_t]' \\ Z_0 &= [Z_{01}, \ldots, Z_{0T}]' \\ Z_1 &= [Z_{11}, \ldots, Z_{1T}]' \\ Z_2 &= [Z_{21}, \ldots, Z_{2T}]' \end{aligned}$$

where D_t can be empty for Case 1; 1 for Case 3; $(1, t)$ for Case 5.

In case 2, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, 1]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \ldots, \Delta \mathbf{y}'_{t-p+1}]' \end{aligned}$$

In case 4, Z_{1t} and Z_{2t} are defined as

$$\begin{aligned} Z_{1t} &= [\mathbf{y}'_{t-1}, t]' \\ Z_{2t} &= [\Delta \mathbf{y}'_{t-1}, \ldots, \Delta \mathbf{y}'_{t-p+1}, 1]' \end{aligned}$$

Let Ψ be the matrix of parameters consisting of $\Phi_1^*, \ldots, \Phi_{p-1}^*$ and A, where parameters A corresponds to regressors D_t. Then the VECM(p) form is rewritten in these variables as

$$Z_{0t} = \boldsymbol{\alpha}\boldsymbol{\beta}' Z_{1t} + \Psi Z_{2t} + \boldsymbol{\epsilon}_t$$

The log-likelihood function is given by

$$\begin{aligned}\ell &= -\frac{kT}{2}\log 2\pi - \frac{T}{2}\log|\Sigma| \\ &\quad -\frac{1}{2}\sum_{t=1}^{T}(Z_{0t}-\boldsymbol{\alpha\beta}'Z_{1t}-\Psi Z_{2t})'\Sigma^{-1}(Z_{0t}-\boldsymbol{\alpha\beta}'Z_{1t}-\Psi Z_{2t})\end{aligned}$$

The residuals, R_{0t} and R_{1t}, are obtained by regressing Z_{0t} and Z_{1t} on Z_{2t}, respectively. The regression equation in residuals is

$$R_{0t} = \boldsymbol{\alpha\beta}'R_{1t} + \hat{\boldsymbol{\epsilon}}_t$$

The crossproducts matrices are computed

$$S_{ij} = \frac{1}{T}\sum_{t=1}^{T} R_{it}R'_{jt}, \;\; i,j = 0,1$$

Then the maximum likelihood estimator for $\boldsymbol{\beta}$ is obtained from the eigenvectors corresponding to the r largest eigenvalues of the following equation:

$$|\lambda S_{11} - S_{10}S_{00}^{-1}S_{01}| = 0$$

The eigenvalues of the preceding equation are squared canonical correlations between R_{0t} and R_{1t}, and the eigenvectors corresponding to the r largest eigenvalues are the r linear combinations of $\mathbf{y}_{t-1}$, which have the largest squared partial correlations with the stationary process $\Delta\mathbf{y}_t$ after correcting for lags and deterministic terms. Such an analysis calls for a reduced rank regression of $\Delta\mathbf{y}_t$ on $\mathbf{y}_{t-1}$ corrected for $(\Delta\mathbf{y}_{t-1},\ldots,\Delta\mathbf{y}_{t-p+1},D_t)$, as discussed by Anderson (1951). Johansen (1988) suggested two test statistics to test the null hypothesis that there are at most r cointegrating vectors

$$\mathrm{H}_0 : \lambda_i = 0 \;\text{ for }\; i = r+1,\ldots,k$$

Trace Test

$$\lambda_{trace} = -T\sum_{i=r+1}^{k}\log(1-\lambda_i)$$

The asymptotic distribution of this statistic is given by

$$tr\left\{\int_0^1 (dW)\tilde{W}'\left(\int_0^1 \tilde{W}\tilde{W}'dr\right)^{-1}\int_0^1 \tilde{W}(dW)'\right\}$$

where $tr(A)$ is the trace of a matrix A, W is the $k-r$ dimensional Brownian motion, and $\tilde{W}$ is the Brownian motion itself, or the demeaned or detrended Brownian motion according to the different specifications of deterministic trends in the vector error correction model.

Maximum Eigenvalue Test

$$\lambda_{max} = -T \log(1 - \lambda_{r+1})$$

The asymptotic distribution of this statistic is given by

$$max\{\int_0^1 (dW)\tilde{W}'(\int_0^1 \tilde{W}\tilde{W}'dr)^{-1}\int_0^1 \tilde{W}(dW)'\}$$

where $max(A)$ is the maximum eigenvalue of a matrix A. Osterwald-Lenum (1992) provided the detailed tables of critical values of these statistics.

In case 2, consider that $Z_{1t} = (\mathbf{y}_t', 1)'$ and $Z_{2t} = (\Delta\mathbf{y}_{t-1}', \ldots, \Delta\mathbf{y}_{t-p+1}')'$. In case 4, $Z_{1t} = (\mathbf{y}_t', t)'$ and $Z_{2t} = (\Delta\mathbf{y}_{t-1}', \ldots, \Delta\mathbf{y}_{t-p+1}', 1)'$.

The following statements use the JOHANSEN option to compute the Johansen cointegration rank test of integrated order 1:

```
proc varmax data=simul2;
   model y1 y2 / p=2 cointtest=(johansen=(normalize=y1));
run;
```

```

```

Figure 30.48. Cointegration Rank Test Continued

Figure 30.48 shows which result, either case 2 (the hypothesis H_0) or case 3 (the hypothesis H_1), is appropriate. Since the cointegration rank is chosen to be 1 by the result in Figure 30.47, look at the last row corresponding to rank=1. Since the p-value is 0.054, the case 2 cannot be rejected at the significance level 5%, but it can be rejected at the significance level 10%. For modeling of two cases, see Figure 30.51 and Figure 30.52.

                    y2                 0.12538          0.03722
```

Figure 30.50. Cointegration Rank Test Continued

Figure 30.50 shows the estimates of long-run parameter and adjustment coefficients based on case 2. Considering that the cointegration rank is 1, the long-run relationship of the series is

$$y_{1t} = 2.044\, y_{2t} - 6.760$$

Estimation of Vector Error Correction Model

The preceding log-likelihood function is maximized for

$$\begin{aligned}
\hat{\boldsymbol{\beta}} &= S_{11}^{-1/2}[v_1, \ldots, v_r] \\
\hat{\boldsymbol{\alpha}} &= S_{01}\hat{\boldsymbol{\beta}}(\hat{\boldsymbol{\beta}}' S_{11}\hat{\boldsymbol{\beta}})^{-1} \\
\hat{\Pi} &= \hat{\boldsymbol{\alpha}}\hat{\boldsymbol{\beta}}' \\
\hat{\Psi} &= (Z_2' Z_2)^{-1} Z_2'(Z_0 - Z_1\hat{\Pi}') \\
\hat{\Sigma} &= (Z_0 - Z_2\hat{\Psi}' - Z_1\hat{\Pi}')'(Z_0 - Z_2\hat{\Psi}' - Z_1\hat{\Pi}')/T
\end{aligned}$$

The estimators of the orthogonal complements of $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are

$$\hat{\boldsymbol{\beta}}_{\perp} = S_{11}[v_{r+1}, \ldots, v_k]$$

and

$$\hat{\boldsymbol{\alpha}}_{\perp} = S_{00}^{-1} S_{01}[v_{r+1}, \ldots, v_k]$$

The ML estimators have the following asymptotic properties:

$$\sqrt{T}\mathrm{vec}([\hat{\Pi}, \hat{\Psi}] - [\Pi, \Psi]) \xrightarrow{d} N(0, \Sigma_{co})$$

where

$$\Sigma_{co} = \Sigma \otimes \left(\left[\begin{array}{cc} \boldsymbol{\beta} & 0 \\ 0 & I_k \end{array} \right] \Omega^{-1} \left[\begin{array}{cc} \boldsymbol{\beta}' & 0 \\ 0 & I_k \end{array} \right] \right)$$

and

$$\Omega = \mathrm{plim} \frac{1}{T} \left[\begin{array}{cc} \boldsymbol{\beta}' Z_1' Z_1 \boldsymbol{\beta} & \boldsymbol{\beta}' Z_1' Z_2 \\ Z_2' Z_1 \boldsymbol{\beta} & Z_2' Z_2 \end{array} \right]$$

The following statements are the examples of fitting the different types of the vector error correction models mentioned in the previous section.

For fitting case 1,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) noint;
```

For fitting case 2,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend);
```

For fitting case 3,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
```

For fitting case 4,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend)
              trend=linear;
```

For fitting case 5,

```
model y1 y2 / p=2 ecm=(rank=1 normalize=y1) trend=linear;
```

From Figure 30.48 on page 1791 using the COINTTEST=(JOHANSEN) option, you can fit the model using either case 2 or case 3. Here both models are fitted to show the difference in output display. Figure 30.51 is for case 2 and Figure 30.52 is for case 3.

For case 2,

```
proc varmax data=simul2;
   model y1 y2 / p=2 ecm=(rank=1 normalize=y1 ectrend);
run;
```

```

Figure 30.52. Parameter Estimation without the ECTREND Option

Figure 30.52 can be reported as follows:

$$\begin{aligned}\Delta \mathbf{y}_t &= \left[\begin{array}{rr} -0.46421 & 0.95103 \\ 0.17535 & -0.35293 \end{array}\right] \mathbf{y}_{t-1} + \left[\begin{array}{rr} -0.74052 & -0.76305 \\ 0.34820 & -0.51194 \end{array}\right] \Delta \mathbf{y}_{t-1} \\ &+ \left[\begin{array}{r} -2.60825 \\ 3.43005 \end{array}\right] + \boldsymbol{\epsilon}_t\end{aligned}$$

Test for the Linear Restriction of β

Consider the example with the variables m_t, log real money, y_t, log real income, i_t^d, deposit interest rate, and i_t^b, bond interest rate. It seems a natural hypothesis that in the long-run relation, money and income have equal coefficients with opposite signs. This can be formulated as the hypothesis that the cointegrated relation contains only m_t and y_t through $m_t - y_t$. For the analysis, you can express these restrictions in the parameterization of H such that $\boldsymbol{\beta} = H\psi$, where H is a known $k \times s$ matrix and ψ is the $s \times r (r \leq s < k)$ parameter matrix to be estimated. For this example, H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Restriction H_0: $\boldsymbol{\beta} = H\phi$

When the linear restriction $\boldsymbol{\beta} = H\phi$ is given, it implies that the same restrictions are imposed on all cointegrating vectors. You obtain the maximum likelihood estimator of $\boldsymbol{\beta}$ by reduced rank regression of $\Delta\mathbf{y}_t$ on $H\mathbf{y}_{t-1}$ corrected for $(\Delta\mathbf{y}_{t-1}, \ldots, \Delta\mathbf{y}_{t-p+1}, D_t)$, solving the following equation

$$|\rho H' S_{11} H - H' S_{10} S_{00}^{-1} S_{01} H| = 0$$

for the eigenvalues $1 > \rho_1 > \cdots > \rho_s > 0$ and eigenvectors $(v_1, \ldots, v_s)$, S_{ij} are given in the preceding section. Then choose $\hat{\phi} = (v_1, \ldots, v_r)$ corresponding to the r largest eigenvalues, and the $\hat{\boldsymbol{\beta}}$ is $H\hat{\phi}$.

The test statistic for H_0: $\boldsymbol{\beta} = H\phi$ is given by

$$T \sum_{i=1}^{r} \log\{(1-\rho_i)/(1-\lambda_i)\} \xrightarrow{d} \chi^2_{r(k-s)}$$

If the series has no deterministic trend, the constant term should be restricted by $\boldsymbol{\alpha}'_{\perp}\boldsymbol{\delta}_0 = 0$ like Case 2. Then H is given by

$$H = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The following statements test that $\beta_1 + 2\beta 2 = 0$:

```
proc varmax data=simul2;
   model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
   cointeg rank=1 h=(1,-2);
run;
```

```

```

Figure 30.53. Testing of Linear Restriction $\boldsymbol{\beta}$ (H= Option)

Figure 30.53 shows the results of testing $H_0\colon \beta_1 + 2\beta 2 = 0$. The input H matrix is $H = (1, -2)'$. The adjustment coefficient is reestimated under the restriction, and the test indicates that you cannot reject the null hypothesis.

Test for the Weak Exogeneity and Restrictions of α

Consider a vector error correction model:

$$\Delta \mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta \mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

Divide the process $\mathbf{y}_t$ into $(\mathbf{y}_{1t}', \mathbf{y}_{2t}')'$ with dimension k_1 and k_2 and the Σ into

$$\Sigma = \left[\begin{array}{cc} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{array} \right]$$

Similarly, the parameters can be decomposed as follows:

$$\boldsymbol{\alpha} = \left[\begin{array}{c} \boldsymbol{\alpha_1} \\ \boldsymbol{\alpha_2} \end{array} \right] \quad \Phi_i^* = \left[\begin{array}{c} \Phi_{1i}^* \\ \Phi_{2i}^* \end{array} \right] \quad A = \left[\begin{array}{c} A_1 \\ A_2 \end{array} \right]$$

Then the VECM(p) form can be rewritten using the decomposed parameters and processes:

$$\begin{bmatrix} \Delta\mathbf{y}_{1t} \\ \Delta\mathbf{y}_{2t} \end{bmatrix} = \begin{bmatrix} \boldsymbol{\alpha_1} \\ \boldsymbol{\alpha_2} \end{bmatrix} \boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \Delta\mathbf{y}_{t-i} + \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} D_t + \begin{bmatrix} \boldsymbol{\epsilon}_{1t} \\ \boldsymbol{\epsilon}_{2t} \end{bmatrix}$$

The conditional model for $\mathbf{y}_{1t}$ given $\mathbf{y}_{2t}$ is

$$\begin{aligned} \Delta\mathbf{y}_{1t} &= \omega\Delta\mathbf{y}_{2t} + (\alpha_1 - \omega\alpha_2)\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1}(\Phi_{1i}^* - \omega\Phi_{2i}^*)\Delta\mathbf{y}_{t-i} \\ &\quad +(A_1 - \omega A_2)D_t + \boldsymbol{\epsilon}_{1t} - \omega\boldsymbol{\epsilon}_{2t} \end{aligned}$$

and the marginal model of $\mathbf{y}_{2t}$,

$$\Delta\mathbf{y}_{2t} = \alpha_2\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_{2i}^*\Delta\mathbf{y}_{t-i} + A_2 D_t + \boldsymbol{\epsilon}_{2t}$$

where $\omega = \Sigma_{12}\Sigma_{22}^{-1}$.

The test of weak exogeneity of $\mathbf{y}_{2t}$ for the parameters $(\alpha_1, \boldsymbol{\beta})$ determines whether $\alpha_2 = 0$. Weak exogeneity means that there is no information about $\boldsymbol{\beta}$ in the marginal model or that the variables $\mathbf{y}_{2t}$ do not react to a disequilibrium.

Restriction H_0: $\boldsymbol{\alpha} = J\psi$

Consider the null hypothesis H_0: $\boldsymbol{\alpha} = J\psi$, where J is a $k \times m$ matrix with $r \leq m < k$.

From the previous residual regression equation

$$R_{0t} = \boldsymbol{\alpha}\boldsymbol{\beta}'R_{1t} + \hat{\boldsymbol{\epsilon}}_t = J\psi\boldsymbol{\beta}'R_{1t} + \hat{\boldsymbol{\epsilon}}_t$$

you can obtain

$$\begin{aligned} \bar{J}'R_{0t} &= \psi\boldsymbol{\beta}'R_{1t} + \bar{J}'\hat{\boldsymbol{\epsilon}}_t \\ J_\perp' R_{0t} &= J_\perp'\hat{\boldsymbol{\epsilon}}_t \end{aligned}$$

where $\bar{J} = J(J'J)^{-1}$ and $J_\perp$ is orthogonal to J such that $J_\perp' J = 0$.

Define

$$\Sigma_{JJ_\perp} = \bar{J}'\Sigma J_\perp \text{ and } \Sigma_{J_\perp J_\perp} = J_\perp'\Sigma J_\perp$$

and let $\omega = \Sigma_{JJ_\perp}\Sigma_{J_\perp J_\perp}^{-1}$. Then $\bar{J}'R_{0t}$ can be written

$$\bar{J}'R_{0t} = \psi\boldsymbol{\beta}'R_{1t} + \omega J_\perp' R_{0t} + \bar{J}'\hat{\boldsymbol{\epsilon}}_t - \omega J_\perp'\hat{\boldsymbol{\epsilon}}_t$$

Using the marginal distribution of $J_\perp' R_{0t}$ and the conditional distribution of $\bar{J}' R_{0t}$, the new residuals are computed as

$$\begin{aligned}\tilde{R}_{Jt} &= \bar{J}' R_{0t} - S_{JJ_\perp} S_{J_\perp J_\perp}^{-1} J_\perp' R_{0t} \\ \tilde{R}_{1t} &= R_{1t} - S_{1J_\perp} S_{J_\perp J_\perp}^{-1} J_\perp' R_{0t}\end{aligned}$$

where

$$S_{JJ_\perp} = \bar{J}' S_{00} J_\perp, \;\; S_{J_\perp J_\perp} = J_\perp' S_{00} J_\perp, \;\; \text{and} \;\; S_{J_\perp 1} = J_\perp' S_{01}$$

In terms of $\tilde{R}_{Jt}$ and $\tilde{R}_{1t}$, the MLE of $\boldsymbol{\beta}$ is computed by using the reduced rank regression. Let

$$S_{ij.J_\perp} = \frac{1}{T}\sum_{t=1}^{T} \tilde{R}_{it}\tilde{R}_{jt}', \;\; \text{for} \;\; i,j = 1, J$$

Under the null hypothesis $H_0 \colon \boldsymbol{\alpha} = J\psi$, the MLE $\tilde{\boldsymbol{\beta}}$ is computed by solving the equation

$$|\rho S_{11.J_\perp} - S_{1J.J_\perp} S_{JJ.J_\perp}^{-1} S_{J1.J_\perp}| = 0$$

Then $\tilde{\boldsymbol{\beta}} = (v_1, \ldots, v_r)$, where the eigenvectors correspond to the r largest eigenvalues. The likelihood ratio test for $H_0 \colon \boldsymbol{\alpha} = J\psi$ is

$$T\sum_{i=1}^{r} \log\{(1-\rho_i)/(1-\lambda_i)\} \xrightarrow{d} \chi^2_{r(k-m)}$$

The test of weak exogeneity of $\mathbf{y}_{2t}$ is the special case of the test $\boldsymbol{\alpha} = J\psi$, considering $J = (I_{k_1}, 0)'$. Consider the previous example with four variables (m_t, y_t, i_t^b, i_t^d). If $r = 1$, you formulate the weak exogeneity of (y_t, i_t^b, i_t^d) for m_t as $J = [1, 0, 0, 0]'$ and the weak exogeneity of i_t^d for (m_t, y_t, i_t^b) as $J = [I_3, 0]'$.

The following statements test the weak exogeneity of other variables:

```
proc varmax data=simul2;
   model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
   cointeg rank=1 exogeneity;
run;
```

```
                      The VARMAX Procedure

            Testing Weak Exogeneity of Each Variables

          Variable        DF    Chi-Square    Pr > ChiSq

          y1               1         53.46        <.0001
          y2               1          8.76        0.0031
```

Figure 30.54. Testing of Weak Exogeneity (EXOGENEITY Option)

Figure 30.54 shows that each variable is not the weak exogeneity of other variable.

Forecasting of the VECM

Consider the cointegrated moving-average representation of the differenced process of $\mathbf{y}_t$

$$\Delta\mathbf{y}_t = \boldsymbol{\delta} + \Psi(B)\boldsymbol{\epsilon}_t$$

Assume that $\mathbf{y}_0 = 0$. The linear process $\mathbf{y}_t$ can be written

$$\mathbf{y}_t = \boldsymbol{\delta}t + \sum_{i=1}^{t}\sum_{j=0}^{t-i}\Psi_j\boldsymbol{\epsilon}_i$$

Therefore, for any $l > 0$,

$$\mathbf{y}_{t+l} = \boldsymbol{\delta}(t+l) + \sum_{i=1}^{t}\sum_{j=0}^{t+l-i}\Psi_j\boldsymbol{\epsilon}_i + \sum_{i=1}^{l}\sum_{j=0}^{l-i}\Psi_j\boldsymbol{\epsilon}_{t+i}$$

The l-step-ahead forecast is derived from the preceding equation:

$$\mathbf{y}_{t+l|t} = \boldsymbol{\delta}(t+l) + \sum_{i=1}^{t}\sum_{j=0}^{t+l-i}\Psi_j\boldsymbol{\epsilon}_i$$

Note that

$$\lim_{l\to\infty}\boldsymbol{\beta}'\mathbf{y}_{t+l|t} = 0$$

since $\lim_{l\to\infty}\sum_{j=0}^{t+l-i}\Psi_j = \Psi(1)$ and $\boldsymbol{\beta}'\Psi(1) = 0$. The long-run forecast of the cointegrated system shows that the cointegrated relationship holds, though there might exist some deviations from the equilibrium status in the short-run. The covariance matrix of the predict error $\mathbf{e}_{t+l|t} = \mathbf{y}_{t+l} - \mathbf{y}_{t+l|t}$ is

$$\Sigma(l) = \sum_{i=1}^{l}[(\sum_{j=0}^{l-i}\Psi_j)\Sigma(\sum_{j=0}^{l-i}\Psi_j')]$$

When the linear process is represented as a VECM(p) model, you can obtain

$$\Delta\mathbf{y}_t = \Pi\mathbf{y}_{t-1} + \sum_{j=1}^{p-1}\Phi_j^*\Delta\mathbf{y}_{t-j} + \boldsymbol{\delta} + \boldsymbol{\epsilon}_t$$

The transition equation is defined as

$$\mathbf{z}_t = F\mathbf{z}_{t-1} + \mathbf{e}_t$$

where $\mathbf{z}_t = (\mathbf{y}'_{t-1}, \Delta\mathbf{y}'_t, \Delta\mathbf{y}'_{t-1}, \cdots, \Delta\mathbf{y}'_{t-p+2})'$ is a state vector and the transition matrix is

$$F = \begin{bmatrix} I_k & I_k & 0 & \cdots & 0 \\ \Pi & (\Pi + \Phi_1^*) & \Phi_2^* & \cdots & \Phi_{p-1}^* \\ 0 & I_k & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & I_k & 0 \end{bmatrix}$$

where 0 is a $k \times k$ zero matrix. The observation equation can be written

$$\mathbf{y}_t = \boldsymbol{\delta} t + H\mathbf{z}_t$$

where $H = [I_k, I_k, 0, \ldots, 0]$.

The l-step-ahead forecast is computed as

$$\mathbf{y}_{t+l|t} = \boldsymbol{\delta}(t+l) + HF^l\mathbf{z}_t$$

$\mathrm{I}(2)$ Model

The VAR(p) model can be written as the error correction form.

$$\Delta\mathbf{y}_t = \boldsymbol{\alpha}\boldsymbol{\beta}'\mathbf{y}_{t-1} + \sum_{i=1}^{p-1} \Phi_i^*\Delta\mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

Let $\Phi^* = I_k - \sum_{i=1}^{p-1}\Phi_i^*$. If $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ have full-rank r, and if

$$rank(\boldsymbol{\alpha}'_\perp \Phi^* \boldsymbol{\beta}_\perp) = k - r$$

then $\mathbf{y}_t$ is an $I(1)$ process. If the condition $rank(\boldsymbol{\alpha}'_\perp \Phi^* \boldsymbol{\beta}_\perp) = k - r$ fails and $\boldsymbol{\alpha}'_\perp \Phi^* \boldsymbol{\beta}_\perp$ has reduced-rank $\boldsymbol{\alpha}'_\perp \Phi^* \boldsymbol{\beta}_\perp = \boldsymbol{\xi}\boldsymbol{\eta}'$ where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are $(k-r)\times s$ matrices with $s \le k-r$, $\boldsymbol{\alpha}_\perp$ and $\boldsymbol{\beta}_\perp$ are defined as $k \times (k-r)$ matrices of full rank such that $\boldsymbol{\alpha}'\boldsymbol{\alpha}_\perp = 0$ and $\boldsymbol{\beta}'\boldsymbol{\beta}_\perp = 0$. If $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ have full-rank s, then the process $\mathbf{y}_t$ is $I(2)$, which has the implication of $I(2)$ model for the moving-average representation.

$$\mathbf{y}_t = B_0 + B_1 t + C_2 \sum_{j=1}^{t}\sum_{i=1}^{j} \boldsymbol{\epsilon}_i + C_1 \sum_{i=1}^{t} \boldsymbol{\epsilon}_i + C_0(B)\boldsymbol{\epsilon}_t$$

The matrices C_1, C_2, and $C_0(B)$ are determined by the cointegration properties of the process, and B_0 and B_1 are determined by the initial values. For details, see Johansen (1995a).

The implication of the $I(2)$ model for the autoregressive representation is given by

$$\Delta^2\mathbf{y}_t = \Pi\mathbf{y}_{t-1} - \Phi^*\Delta\mathbf{y}_{t-1} + \sum_{i=1}^{p-2} \Psi_i\Delta^2\mathbf{y}_{t-i} + AD_t + \boldsymbol{\epsilon}_t$$

where $\Psi_i = -\sum_{j=i+1}^{p-1}\Phi_i^*$ and $\Phi^* = I_k - \sum_{i=1}^{p-1}\Phi_i^*$.

Test for $\mathrm{I}(2)$

The $I(2)$ cointegrated model is given by the following parameter restrictions:

$$H_{r,s}\colon \Pi = \boldsymbol{\alpha}\boldsymbol{\beta}' \text{ and } \boldsymbol{\alpha}_\perp' \Phi^* \boldsymbol{\beta}_\perp = \boldsymbol{\xi}\boldsymbol{\eta}'$$

where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ are $(k-r)\times s$ matrices with $0 \le s \le k-r$. Let H_r^0 represent the $I(1)$ model where $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ have full-rank r, let $H_{r,s}^0$ represent the $I(2)$ model where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ have full-rank s, and let $H_{r,s}$ represent the $I(2)$ model where $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$ have rank $\le s$. The following table shows the relation between the $I(1)$ models and the $I(2)$ models.

Table 30.1. Relation between the $I(1)$ and $I(2)$ Models

					$I(2)$					$I(1)$	
$r\backslash k-r-s$	k		k-1		$\cdots$		1				
0	H_{00}	$\subset$	H_{01}	$\subset$	$\cdots$	$\subset$	$H_{0,k-1}$	$\subset$	H_{0k}	$=$	H_0^0
1			H_{10}	$\subset$	$\cdots$	$\subset$	$H_{1,k-2}$	$\subset$	$H_{1,k-1}$	$=$	H_1^0
$\vdots$							$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$k-1$							$H_{k-1,0}$	$\subset$	$H_{k-1,1}$	$=$	H_{k-1}^0

Johansen (1995a) proposed the two-step procedure to analyze the $I(2)$ model. In the first step, the values of $(r, \boldsymbol{\alpha}, \boldsymbol{\beta})$ are estimated using the reduced rank regression analysis, performing the regression analysis $\Delta^2\mathbf{y}_t$, $\Delta\mathbf{y}_{t-1}$, and $\mathbf{y}_{t-1}$ on $\Delta^2\mathbf{y}_{t-1},\ldots,\Delta^2\mathbf{y}_{t-p+2}, D_t$. This gives residuals R_{0t}, R_{1t}, and R_{2t} and residual product moment matrices

$$M_{ij} = \frac{1}{T}\sum_{t=1}^{T} R_{it}R_{jt}' \text{ for } i,j = 0,1,2$$

Perform the reduced rank regression analysis $\Delta^2\mathbf{y}_t$ on $\mathbf{y}_{t-1}$ corrected for $\Delta\mathbf{y}_{t-1}$, $\Delta^2\mathbf{y}_{t-1},\ldots,\Delta^2\mathbf{y}_{t-p+2}, D_t$ and solve the eigenvalue problem of the equation

$$|\lambda M_{22.1} - M_{20.1}M_{00.1}^{-1}M_{02.1}| = 0$$

where $M_{ij.1} = M_{ij} - M_{i1}M_{11}^{-1}M_{1j}$ for $i,j = 0,2$.

In the second step, if $(r, \boldsymbol{\alpha}, \boldsymbol{\beta})$ are known, the values of $(s, \boldsymbol{\xi}, \boldsymbol{\eta})$ are determined using the reduced rank regression analysis, regressing $\hat{\boldsymbol{\alpha}}_\perp'\Delta^2\mathbf{y}_t$ on $\hat{\boldsymbol{\beta}}_\perp'\Delta\mathbf{y}_{t-1}$ corrected for $\Delta^2\mathbf{y}_{t-1},\ldots,\Delta^2\mathbf{y}_{t-p+2}, D_t$ and $\hat{\boldsymbol{\beta}}'\Delta\mathbf{y}_{t-1}$.

The reduced rank regression analysis reduces to the solution of an eigenvalue problem for the equation

$$|\rho M_{\boldsymbol{\beta}_\perp\boldsymbol{\beta}_\perp.\boldsymbol{\beta}} - M_{\boldsymbol{\beta}_\perp\boldsymbol{\alpha}_\perp.\boldsymbol{\beta}}M_{\boldsymbol{\alpha}_\perp\boldsymbol{\alpha}_\perp.\boldsymbol{\beta}}^{-1}M_{\boldsymbol{\alpha}_\perp\boldsymbol{\beta}_\perp.\boldsymbol{\beta}}| = 0$$

where

$$M_{\boldsymbol{\beta}_\perp\boldsymbol{\beta}_\perp.\boldsymbol{\beta}} = \boldsymbol{\beta}_\perp'(M_{11} - M_{11}\boldsymbol{\beta}(\boldsymbol{\beta}'M_{11}\boldsymbol{\beta})^{-1}\boldsymbol{\beta}'M_{11})\boldsymbol{\beta}_\perp$$

$$\begin{aligned} M'_{\boldsymbol{\beta}_\perp \boldsymbol{\alpha}_\perp . \boldsymbol{\beta}} &= M_{\boldsymbol{\alpha}_\perp \boldsymbol{\beta}_\perp . \boldsymbol{\beta}} = \bar{\boldsymbol{\alpha}}'_\perp (M_{01} - M_{01}\boldsymbol{\beta}(\boldsymbol{\beta}' M_{11}\boldsymbol{\beta})^{-1}\boldsymbol{\beta}' M_{11})\boldsymbol{\beta}_\perp \\ M_{\boldsymbol{\alpha}_\perp \boldsymbol{\alpha}_\perp . \boldsymbol{\beta}} &= \bar{\boldsymbol{\alpha}}'_\perp (M_{00} - M_{01}\boldsymbol{\beta}(\boldsymbol{\beta}' M_{11}\boldsymbol{\beta})^{-1}\boldsymbol{\beta}' M_{10})\bar{\boldsymbol{\alpha}}_\perp \end{aligned}$$

where $\bar{\boldsymbol{\alpha}} = \boldsymbol{\alpha}(\boldsymbol{\alpha}'\boldsymbol{\alpha})^{-1}$.

The solution gives eigenvalues $1 > \rho_1 > \cdots > \rho_s > 0$ and eigenvectors $(v_1, \ldots, v_s)$. Then, the ML estimators are

$$\begin{aligned} \hat{\boldsymbol{\eta}} &= (v_1, \ldots, v_s) \\ \hat{\boldsymbol{\xi}} &= M_{\boldsymbol{\alpha}_\perp \boldsymbol{\beta}_\perp . \boldsymbol{\beta}} \hat{\eta} \end{aligned}$$

The likelihood ratio test for the reduced rank model $H_{r,s}$ with rank $\leq s$ in the model $H_{r,k-r} = H_r^0$ is given by

$$Q_{r,s} = -T \sum_{i=s+1}^{k-r} \log(1-\rho_i), \;\; s = 0, \ldots, k-r-1$$

The following statements are to test the rank test for the cointegrated order 2:

```
proc varmax data=simul2;
   model y1 y2 / p=2 cointtest=(johansen=(iorder=2));
run;
```

```
                              The VARMAX Procedure

                        Cointegration Rank Test for I(2)

                                                          Trace      5% CV of

Figure 30.55. Cointegrated I(2) Test (IORDER= Option)

The last two columns in Figure 30.55 explain the cointegration rank test with integrated order 1. The results indicate that there is the cointegrated relationship with the cointegration rank 1 with respect to the 0.05 significance level. Now, look at the row in case of $r = 1$. Compare the value to the critical value for the cointegrated order 2. There is no evidence that the series are integrated order 2 with the 0.05 significance level.

Multivariate GARCH Modeling (Experimental)

To study the volatility of time series, GARCH models are widely used since they provide a good approach to conditional variance modeling. In addition, stochastic volatility modeling is important in finance.

Multivariate GARCH

There are three representations of a multivariate GARCH model:

- *BEKK* representation,
- *BEW* representation,
- *diagonal* representation.

Engle and Kroner (1995) proposed a general multivariate GARCH model and called it a *BEKK* representation. Let $\mathcal{F}(t-1)$ be the sigma field generated by the past values of $\boldsymbol{\epsilon}_t$ and H_t be the conditional covariance matrix of the k-dimensional random vector $\boldsymbol{\epsilon}_t$. Let H_t be measurable with respect to $\mathcal{F}(t-1)$, then the multivariate GARCH model can be written as

$$\begin{aligned} \boldsymbol{\epsilon}_t|\mathcal{F}(t-1) &\sim N(0,H_t) \\ H_t &= C_0'C_0 + \sum_{i=1}^{q} A_i'\boldsymbol{\epsilon}_{t-i}\boldsymbol{\epsilon}_{t-i}'A_i + \sum_{i=1}^{p} G_i'H_{t-i}G_i \end{aligned}$$

where C_0, A_i and G_i are $k \times k$ parameter matrices with C_0 is an upper triangular matrix.

Consider a bivariate GARCH(1,1) model as follows:

$$\begin{aligned} H_t &= C_0'C_0 + \left[\begin{array}{cc} a_{11} & a_{12} \\ a_{21} & a_{22} \end{array}\right]' \left[\begin{array}{cc} \epsilon_{1,t-1}^2 & \epsilon_{1,t-1}\epsilon_{2,t-1} \\ \epsilon_{2,t-1}\epsilon_{1,t-1} & \epsilon_{2,t-1}^2 \end{array}\right] \left[\begin{array}{cc} a_{11} & a_{12} \\ a_{21} & a_{22} \end{array}\right] \\ &+ \left[\begin{array}{cc} g_{11} & g_{12} \\ g_{21} & g_{22} \end{array}\right]' H_{t-1} \left[\begin{array}{cc} g_{11} & g_{12} \\ g_{21} & g_{22} \end{array}\right] \end{aligned}$$

or, representing the univariate model,

$$\begin{aligned} h_{11,t} &= c_1 + a_{11}^2\epsilon_{1,t-1}^2 + 2a_{11}a_{21}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}^2\epsilon_{2,t-1}^2 \\ &\quad + g_{11}^2h_{11,t-1} + 2g_{11}g_{21}h_{12,t-1} + g_{21}^2h_{22,t-1} \\ h_{12,t} &= c_2 + a_{11}a_{12}\epsilon_{1,t-1}^2 + (a_{21}a_{12}+a_{11}a_{22})\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{21}a_{22}\epsilon_{2,t-1}^2 \\ &\quad + g_{11}g_{12}h_{11,t-1} + (g_{21}g_{12}+g_{11}g_{22})h_{12,t-1} + g_{21}g_{22}h_{22,t-1} \\ h_{22,t} &= c_3 + a_{12}^2\epsilon_{1,t-1}^2 + 2a_{12}a_{22}\epsilon_{1,t-1}\epsilon_{2,t-1} + a_{22}^2\epsilon_{2,t-1}^2 \\ &\quad + g_{12}^2h_{11,t-1} + 2g_{12}g_{22}h_{12,t-1} + g_{22}^2h_{22,t-1} \end{aligned}$$

For the *BEKK* representation, the SAS statement is

```
model y1 y2 / garch=(q=1 p=1 form=bekk);
```

An alternative multivariate GARCH model is suggested by Bollerslev, Engle, and Wooldridge (1988) and is called the *BEW* representation.

$$\text{vech}(H_t) = \mathbf{c}^* + \sum_{i=1}^{q} A_i^* \text{vech}(\boldsymbol{\epsilon}_{t-i}\boldsymbol{\epsilon}'_{t-i}) + \sum_{i=1}^{p} G_i^* \text{vech}(H_{t-i})$$

where $\mathbf{c}^*$ is a $k(k+1)/2$-dimensional vector; A_i^* and G_i^* are $k(k+1)/2 \times k(k+1)/2$ matrices.

For the *BEW* representation, the SAS statement is

```
model y1 y2 / garch=(q=1 p=1 form=bew);
```

For empirical implementation, it can be restricted as the diagonal representation and is called the *diagonal* representation. The *diagonal* representation has the A_i^* and G_i^* are $k(k+1)/2 \times k(k+1)/2$ diagonal matrices.

For the *diagonal* representation, the SAS statement is

```
model y1 y2 / garch=(q=1 p=1 form=diag);
```

Applying a multivariate GARCH model to a regression model with the second moments appearing, the model is called a multivariate GARCH-M model. In addition, it can be extended to VAR-GARCH models, GARCH-regression (VX-GARCH) models, and VARX-GARCH models.

$$\begin{aligned}
\Phi(B)\mathbf{y}_t &= \boldsymbol{\delta} + \Theta^*(B)\mathbf{x}_t + \Lambda\mathbf{h}_t + \boldsymbol{\epsilon}_t \\
\boldsymbol{\epsilon}_t|\mathcal{F}(t-1) &\sim N(0, H_t) \\
H_t &= C_0'C_0 + \sum_{i=1}^{q} A_i'\boldsymbol{\epsilon}_{t-i}\boldsymbol{\epsilon}'_{t-i}A_i + \sum_{i=1}^{p} G_i'H_{t-i}G_i
\end{aligned}$$

where $\mathbf{y}_t$ is a k-dimensional vector of endogenous variables and $\Phi(B) = I - \Phi_1 B - \cdots - \Phi_{p^0} B^{p^0}$ is a finite order matrix polynomial; $\mathbf{x}_t$ is an m-dimensional vector of exogenous variables and $\Theta^*(B) = \Theta_0^* + \Theta_1^* B + \cdots + \Theta_s^* B^s$ is a finite order matrix polynomial; $\mathbf{h}_t = \text{vech}(H_t)$ and Λ is a $k \times k(k+1)/2$ parameter matrix.

General GARCH models can be also applied to *BEW* and *diagonal* representations.

The following statements are examples of the GARCH= option:

```
model y1 y2 = x1 / p=1 garch=(q=1 p=1 mean form=bekk);
model y1 y2 = x1 / p=1 garch=(q=1 p=1 mean form=bew);
model y1 y2 = x1 / p=1 garch=(q=1 p=1 mean form=diag);
model y1 y2 = x1 / p=1 xlag=1 garch=(q=1);
```

The log-likelihood function of the multivariate GARCH model is written without a constant term

$$\ell = -\frac{1}{2}\sum_{t=1}^{T}[\log|H_t| - \boldsymbol{\epsilon}_t' H_t^{-1}\boldsymbol{\epsilon}_t]$$

The log-likelihood function is maximized by the iterative numerical procedure such as the quasi-Newton optimization. The starting values for the regression parameters are obtained from the least squares estimates; the covariance of $\boldsymbol{\epsilon}_t$ is used as the starting values for the GARCH constant parameters, and the starting value 10^{-6} is used for the other GARCH parameters. For the identification of the parameters of a *BEKK* representation GARCH model, the diagonal elements of the GARCH constant parameters and the first element of the ARCH and GARCH parameters are restricted to be positive.

Covariance Stationarity

Define the multivariate GARCH process as

$$\mathbf{h}_t = \sum_{i=1}^{\infty} G(B)^{i-1}[\mathbf{c} + A(B)\boldsymbol{\eta}_t]$$

where $\mathbf{h}_t = \text{vec}(H_t)$, $\mathbf{c} = \text{vec}(C_0'C_0)$, and $\boldsymbol{\eta}_t = \text{vec}(\boldsymbol{\epsilon}_t\boldsymbol{\epsilon}_t')$ This representation is equivalent to a GARCH(p,q) model by the following algebra:

$$\begin{aligned}
\mathbf{h}_t &= \mathbf{c} + A(B)\boldsymbol{\eta}_t + \sum_{i=2}^{\infty} G(B)^{i-1}[\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\
&= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B)\sum_{i=1}^{\infty} G(B)^{i-1}[\mathbf{c} + A(B)\boldsymbol{\eta}_t] \\
&= \mathbf{c} + A(B)\boldsymbol{\eta}_t + G(B)\mathbf{h}_t
\end{aligned}$$

Defining $A(B) = \sum_{i=1}^{q}(A_i \otimes A_i)'B^i$ and $G(B) = \sum_{i=1}^{p}(G_i \otimes G_i)'B^i$ gives a *BEKK* representation; defining $\mathbf{h}_t = \text{vech}(H_t)$, $\mathbf{c} = \mathbf{c}^*$, $\boldsymbol{\eta}_t = \text{vech}(\boldsymbol{\epsilon}_t\boldsymbol{\epsilon}_t')$, $A(B) = \sum_{i=1}^{q} A_i^* B^i$, and $G(B) = \sum_{i=1}^{p} G_i^* B^i$ gives other representations.

The necessary and sufficient conditions for covariance stationarity of the multivariate GARCH process is that all the eigenvalues of $A(1) + G(1)$ are less than one in modulus.

An Example of a VAR(1)-ARCH(1) Model

The following DATA steps simulate a bivariate vector time series to provide test data for the multivariate GARCH model:

```
data garch;
   retain seed 16587;
   esq1 = 0; esq2 = 0;
```

```
      ly1 = 0;  ly2 = 0;
      do i = 1 to 1000;
         ht = 6.25 + 0.5*esq1;
         call rannor(seed,ehat);
         e1 = sqrt(ht)*ehat;
         ht = 1.25 + 0.7*esq2;
         call rannor(seed,ehat);
         e2 = sqrt(ht)*ehat;
         y1 = 2 + 1.2*ly1 - 0.5*ly2 + e1;
         y2 = 4 + 0.6*ly1 + 0.3*ly2 + e2;
         if i>500 then output;
         esq1 = e1*e1; esq2 = e2*e2;
         ly1 = y1;  ly2 = y2;
      end;
      keep y1 y2;
   run;
```

First fit a VAR(1) model to the data.

```
   proc varmax data=garch;
      model y1 y2 / p=1;
   run;
```

```
                             The VARMAX Procedure

                                  Schematic

```

Figure 30.56. Parameter Estimates and Model Diagnostics for the VAR(1) Model

In Figure 30.56, you can see that the AR coefficients are significant. In the information criteria table, the AICC value is 3.7087. The normality and ARCH effect tests of residuals show that the fitted VAR(1) model is not good for the data.

The following statements fit a VAR(1)-ARCH(1) model to the data. For an AR-ARCH model, you specify the order of the autoregressive model with the P=1 option and the GARCH=(Q=1) option; you specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization technique.

```
proc varmax data=garch;
   model y1 y2 / p=1 garch=(q=1);
   nloptions tech=qn;
run;
```

```
                              The VARMAX Procedure

                         h2                 -0.20012         -0.72855
```

Figure 30.60. Parameter Estimates for the VAR(1)-ARCH(1) Model

Figure 30.60 shows that the conditional variance fits the *BEKK* representation ARCH(1) model.

$$\begin{aligned}
\boldsymbol{\epsilon}_t|\mathcal{F}(t-1) &\sim N(0,H_t) \\
H_t &= \begin{bmatrix} 8.3634 & -0.1534 \\ -0.1534 & 1.6011 \end{bmatrix} \\
&+ \begin{bmatrix} 0.3707 & 0.0532 \\ 0.0287 & 0.7121 \end{bmatrix}' \boldsymbol{\epsilon}_{t-1}\boldsymbol{\epsilon}'_{t-1} \begin{bmatrix} 0.3707 & 0.0532 \\ 0.0287 & 0.7121 \end{bmatrix}
\end{aligned}$$

Since $C_0 = \begin{bmatrix} 2.8920 & -0.0531 \\ 0 & 1.2643 \end{bmatrix}$ is an upper triangular matrix, the constant term of the ARCH model is obtained by $C_0'C_0 = \begin{bmatrix} 8.3634 & -0.1534 \\ -0.1534 & 1.6011 \end{bmatrix}$.

```

Figure 30.62. Roots for the VAR(1)-ARCH(1) Model

Figure 30.62 shows the roots of the AR and ARCH characteristic polynomials; the eigenvalues have a modulus less than one.

Add the OUTPUT statement in the previous example. The LEAD= and BACK= options are ignored when you fit the GARCH-type models. The created data set, FOR, includes the predicted values of the dependent variables within samples.

```
proc varmax data=garch;
   model y1 y2 / p=1 garch=(q=1);
   nloptions tech=qn;
   output out=for lead=5 back=3;
run;
```

OUT= Data Set

The OUT= data set contains the forecast values produced by the OUTPUT statement. The following output variables can be created:

- the BY variables
- the ID variable
- the MODEL statement dependent (endogenous) variables. These variables contain the actual values from the input data set.
- FOR*i*, numeric variables containing the forecasts. The FOR*i* variables contain the forecasts for the *i*th endogenous variable in the MODEL statement list. Forecasts are 1-step-ahead predictions until the end of the data or until the observation specified by the BACK= option.
- RES*i*, numeric variables containing the residual for the forecast of the *i*th endogenous variable in the MODEL statement list. For forecast observations, the actual values are missing and the RES*i* variables contain missing values.

- STD*i*, numeric variables containing the standard deviation for the forecast of the *i*th endogenous variable in the MODEL statement list. The values of the STD*i* variables can be used to construct univariate confidence limits for the corresponding forecasts.
- LCI*i*, numeric variables containing the lower confidence limits for the corresponding forecasts of the *i*th endogenous variable in the MODEL statement list.
- UCI*i*, numeric variables containing the upper confidence limits for the corresponding forecasts of the *i*th endogenous variable in the MODEL statement list.

Table 30.2. OUT= Data Set

Obs	ID variable	y1	FOR1	RES1	STD1	LCI1	UCI1
1	date	y_{11}	f_{11}	r_{11}	σ_{11}	l_{11}	u_{11}
2	date	y_{12}	f_{12}	r_{12}	σ_{11}	l_{12}	u_{12}
⋮

Figure 30.63. OUT= Data Set

The output in Figure 30.63 shows the part of the results of the OUT= data set.

OUTEST= Data Set

The OUTEST= data set contains estimation results of the fitted model. The following output variables can be created:

- the BY variables
- NAME, a character variable containing the name of endogenous (dependent) variables or the name of the parameters for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified
- TYPE, a character variable containing the value EST for parameter estimates, the value STD for standard error of parameter estimates, and the value COV for the covariance of the matrix of the parameter estimates if the OUTCOV option is specified
- CONST, a numeric variable containing the estimates of constant parameters and their standard errors
- SEASON_i, a numeric variable containing the estimates of seasonal dummy parameters and their standard errors, where $i = 1, \ldots, (nseason - 1)$
- LTREND, a numeric variable containing the estimates of linear trend parameters and their standard errors
- QTREND, a numeric variable containing the estimates of quadratic trend parameters and their standard errors
- XLl_i, numeric variables containing the estimates of exogenous parameters and their standard errors, where l is the lag lth coefficient matrix and $i = 1, \ldots, r$, where r is the number of exogenous variables

- ARl_i, numeric variables containing the estimates of autoregressive parameters and their standard errors, where l is the lag lth coefficient matrix and $i = 1, \ldots, k$, where k is the number of endogenous variables
- MAl_i, numeric variables containing the estimates of moving-average parameters and their standard errors, where l is the lag lth coefficient matrix and $i = 1, \ldots, k$, where k is the number of endogenous variables
- GCHM_i are numeric variables containing the estimates of the GARCH-M parameters of the covariance matrix and their standard errors, where $i = 1, \ldots, k(k+1)/2$, k is the number of endogenous variables.
- ACHl_i are numeric variables containing the estimates of the ARCH parameters of the covariance matrix and their standard errors, where l is the lag lth coefficient matrix and $i = 1, \ldots, k$ for a *BEKK* representation, or $i = 1, \ldots, k(k+1)/2$ for other representations. k is the number of endogenous variables.
- GCHl_i are numeric variables containing the estimates of the GARCH parameters of the covariance matrix and their standard errors, where l is the lag lth coefficient matrix and $i = 1, \ldots, k$ for a *BEKK* representation, or $i = 1, \ldots, k(k+1)/2$ for other representations. k is the number of endogenous variables.
- GCHC_i are numeric variables containing the estimates of the constant parameters of the covariance matrix and their standard errors, where $i = 1, \ldots, k$ for a *BEKK* representation, k is the number of endogenous variables. $i = 1$ for other representations.

Table 30.3. OUTEST= Data Set

Obs	NAME	TYPE	CONST	AR1_1	AR1_2	AR2_1	AR2_2

```

Figure 30.64. OUTEST= Data Set

The output in Figure 30.64 shows the part of results of the OUTEST= data set.

OUTSTAT= Data Set

The OUTSTAT= data set contains estimation results of the fitted model. The following output variables can be created. The sub-index i is $1, \ldots, k$, where k is the number of endogenous variables.

- the BY variables
- NAME, a character variable containing the name of endogenous (dependent) variables
- SIGMA_i, numeric variables containing the estimate covariance of the innovation covariance matrix
- AICC, a numeric variable containing the corrected Akaike's information criteria value
- RSquare, a numeric variable containing R^2
- FValue, a numeric variable containing the F statistics
- PValue, a numeric variable containing p-value for the F statistics

If the JOHANSEN= option is specified, the following items are added:

- Eigenvalue, a numeric variable containing eigenvalues for the cointegration rank test of integrated order 1
- RestrictedEigenvalue, a numeric variable containing eigenvalues for the cointegration rank test of integrated order 1 when the NOINT option is not specified
- Beta_i, numeric variables containing $\boldsymbol{\beta}$ long-run effect parameter estimates
- Alpha_i, numeric variables containing $\boldsymbol{\alpha}$ adjustment parameter estimates

If the JOHANSEN=(IORDER=2) option is specified, the following items are added:

- EValueI2_i, numeric variables containing eigenvalues for the cointegration rank test of integrated order 2
- EValueI1, a numeric variable containing eigenvalues for the cointegration rank test of integrated order 1

- Eta_i, numeric variables containing $\boldsymbol{\eta}$ parameter estimates in integrated order 2
- Xi_i, numeric variables containing $\boldsymbol{\xi}$ parameter estimates in integrated order 2

Table 30.4. OUTSTAT= Data Set

Figure 30.65. OUTSTAT= Data Set

The output in Figure 30.65 shows the part of results of the OUTSTAT= data set.

Printed Output

The default printed output produced by the VARMAX procedure is described in the following list:

- descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (STD), their minimums and maximums, the differencing operations used, and the labels of the variables
- a type of model to fit the data and an estimate method
- the estimates of the constant vector (or seasonal constant matrix), the trend vector, the coefficients matrices of the distributed lags, the AR coefficients matrices, and the MA coefficients matrices
- a table of parameter estimates showing the following for each parameter: the variable name for the left-hand side of equations, the parameter name, the parameter estimate, the approximate standard error, *t* value, the approximate probability ($Pr > |t|$), and the variable name for the right-hand side of equations in terms of each parameter
- the innovation covariance matrix
- the Information criteria

- the cross-covariance and cross-correlation matrices of the residuals
- the tables of test statistics for the hypothesis that the residuals of the model are white noise:
  - Durbin-Watson (DW) statistics
  - F test for autoregressive conditional heteroscedastic (ARCH) disturbances
  - F test for AR disturbance
  - Jarque-Bera normality test
  - Portmanteau test

ODS Table Names

The VARMAX procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table:

Table 30.5. ODS Tables Produced in the VARMAX Procedure

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
AccumImpulse	Accumulated Impulse Response Matrices	IMPULSE=(ACCUM) IMPULSE=(ALL)
AccumImpulsebyVar	Accumulated Impulse Response by Variable	IMPULSE=(ACCUM) IMPULSE=(ALL)
AccumImpulseX	Accumulated Transfer Function Matrices	IMPULSX=(ACCUM) IMPULSX=(ALL)
AccumImpulseXbyVar	Accumulated Transfer Function by Variable	IMPULSX=(ACCUM) IMPULSX=(ALL)
Alpha	α Coefficients	JOHANSEN=
AlphaInECM	α Coefficients When Rank=r	ECM=
AlphaOnDrift	α Coefficients under the Restriction of a Deterministic Term	JOHANSEN=

ODS Graphics (Experimental)

This section describes the use of ODS for creating statistical graphs with the VARMAX procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in the future release.

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

When the ODS GRAPHICS are in effect, the VARMAX procedure produces a variety of plots for each dependent variable.

The plots available are as follows:

- The procedure displays the following plots for each dependent variable in the MODEL statement:
  - Time series and predicted series
  - Residual series
  - Histogram of the residuals
  - ACF of the residuals
  - PACF of the residuals
  - White noise test of the residuals
- The procedure displays forecast plots for each dependent variable in the OUTPUT statement.

ODS Graph Names

PROC VARMAX assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 30.6.

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, "Statistical Graphics Using ODS."

Table 30.6. ODS Graphics Produced in the VARMAX Procedure

ODS Graph Name	Plot Description	Statement
ErrorACFPlot#	Autocorrelation Function of Residuals	Model
ErrorHistogram#	Histogram of Residuals	Model
ErrorPACFPlot#	Partial Autocorrelation Function of Residuals	Model
ErrorPlot#	Residuals	Model
ErrorWhiteNoisePlot#	White Noise Test of Residuals	Model
ForecastsOnlyPlot#	Forecasts	OUTPUT
ModelForecastsPlot#	Time Series and Forecasts	OUTPUT
ModelPlot#	Time Series and Predicted Series	Model

Note that the symbol “#” that follows the ODS graphics names is the number corresponding to the order in which the dependent variable appears in the MODEL statement.

Examples

Example 30.1. Analysis of U.S. Economic Variables

Consider the following four-dimensional system of U.S. economic variables. Quarterly data for the years 1954 to 1987 are used (Lütkepohl 1993, Table E.3.). The following statements plot the series and proceed with the VARMAX procedure.

```
symbol1 v=none height=1 c=black;
symbol2 v=none height=1 c=black;

   title 'Analysis of U.S. Economic Variables';
   data us_money;
      date=intnx( 'qtr', '01jan54'd, _n_-1 );
      format date yyq. ;
      input y1 y2 y3 y4 @@;
      y1=log(y1);
      y2=log(y2);
      label y1='log(real money stock M1)'
            y2='log(GNP in bil. of 1982 dollars)'
            y3='Discount rate on 91-day T-bills'
            y4='Yield on 20-year Treasury bonds';
      datalines;
      ... data lines omitted ...
      ;

   legend1 across=1 frame label=none;

   proc gplot data=us_money;
      symbol1 i = join l = 1;
      symbol2 i = join l = 2;
      axis2 label = (a=-90 r=90 " ");
      plot y1 * date = 1 y2 * date = 2 /
           overlay vaxis=axis2 legend=legend1;
   run;

   proc gplot data=us_money;
      symbol1 i = join l = 1;
      symbol2 i = join l = 2;
      axis2 label = (a=-90 r=90 " ");
      plot y3 * date = 1 y4 * date = 2 /
           overlay vaxis=axis2 legend=legend1;
   run;

   proc varmax data=us_money;
      id date interval=qtr;
      model y1-y4 / p=2 lagmax=6 dftest
                    print=(iarr(3))
```

```
                     cointtest=(johansen=(iorder=2))
                     ecm=(rank=1 normalize=y1);
      cointeg rank=1 normalize=y1 exogeneity;
   run;
```

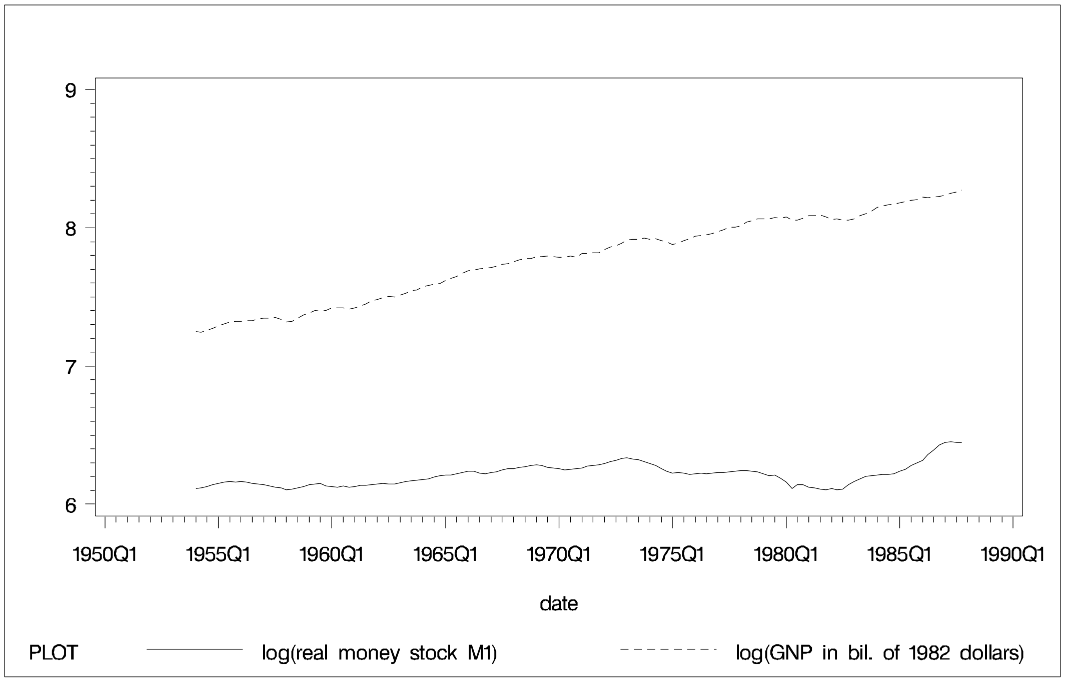
This example performs the Dickey-Fuller test for stationarity, the Johansen cointegrated test integrated order 2, and the exogeneity test. The VECM(2) fits the data. From the outputs shown below, you can see that the series has unit roots and is cointegrated in rank 1 with integrated order 1. The fitted VECM(2) is given as

$$\begin{aligned}\Delta \mathbf{y}_t &= \begin{pmatrix} 0.0408 \\ 0.0860 \\ 0.0052 \\ -0.0144 \end{pmatrix} + \begin{pmatrix} -0.0140 & 0.0065 & -0.2026 & 0.1306 \\ -0.0281 & 0.0131 & -0.4080 & 0.2630 \\ -0.0022 & 0.0010 & -0.0312 & 0.0201 \\ 0.0051 & -0.0024 & 0.0741 & -0.0477 \end{pmatrix} \mathbf{y}_{t-1} \\ &+ \begin{pmatrix} 0.3460 & 0.0913 & -0.3535 & -0.9690 \\ 0.0994 & 0.0379 & 0.2390 & 0.2866 \\ 0.1812 & 0.0786 & 0.0223 & 0.4051 \\ 0.0322 & 0.0496 & -0.0329 & 0.1857 \end{pmatrix} \Delta \mathbf{y}_{t-1} + \boldsymbol{\epsilon}_t\end{aligned}$$

The Δ prefixed to a variable name implies differencing.

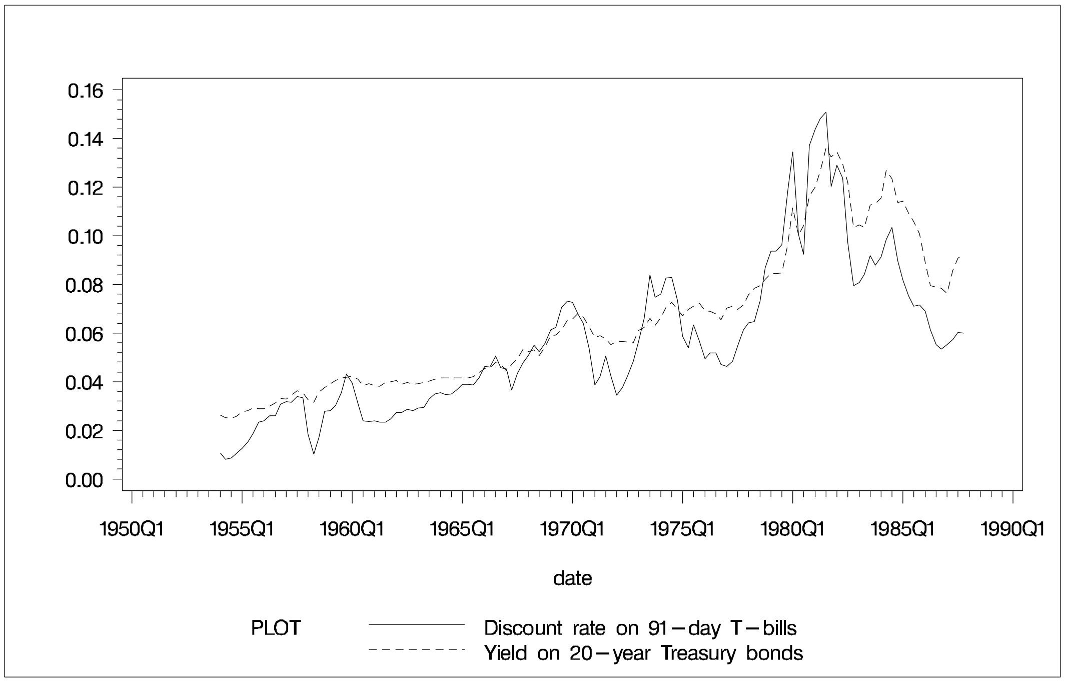
The following outputs show the details.

Output 30.1.1. Plot of Data



Output 30.1.1 shows the plot of the variables $y1$ and $y2$.

Output 30.1.2. Plot of Data Continued



Output 30.1.2 shows the plot of the variables $y3$ and $y4$.

Output 30.1.3. Descriptive Statistics

                 y1               1          6.55        0.0105
                 y2               1         12.54        0.0004
                 y3               1          0.09        0.7695
                 y4               1          1.81        0.1786
```

Output 30.1.12 shows whether each variable is the weak exogeneity of other variables. The variable $y1$ is not the weak exogeneity of other variables, $y2$, $y3$, and $y4$; the variable $y2$ is not the weak exogeneity of other variables, $y1$, $y3$, and $y4$.

Example 30.2. Analysis of German Economic Variables

This example considers a three-dimensional VAR(2) model. The model contains the logarithms of a quarterly, seasonally adjusted West German fixed investment, disposable income, and consumption expenditures. The data used are in Lütkepohl (1993, Table E.1).

```
title 'Analysis of German Economic Variables';
data west;
   date = intnx( 'qtr', '01jan60'd, _n_-1 );
   format date yyq. ;
   input y1 y2 y3 @@;
   y1 = log(y1);
   y2 = log(y2);
   y3 = log(y3);
   label y1 = 'logarithm of investment'
         y2 = 'logarithm of income'
         y3 = 'logarithm of consumption';

   datalines;
   ... data lines omitted ...
   ;

data use;
   set west;
   where  date < '01jan79'd;
   keep date y1 y2 y3;

proc varmax data=use;
   id date interval=qtr align=E;
   model y1-y3 / p=2 dify=(1)
                 print=(decompose(6) impulse=(stderr))
```

```
                     printform=both lagmax=3;
      causal group1=(y1) group2=(y2 y3);
      output lead=5;
   run;
```

First the data is fitted to the differenced VAR(2) model as follows.

$$\Delta\mathbf{y}_t = \begin{pmatrix} -0.01672 \\ 0.01577 \\ 0.01293 \end{pmatrix} + \begin{pmatrix} -0.31963 & 0.14599 & 0.96122 \\ 0.04393 & -0.15273 & 0.28850 \\ -0.00242 & 0.22481 & -0.26397 \end{pmatrix} \Delta\mathbf{y}_{t-1} + \begin{pmatrix} -0.16055 & 0.11460 & 0.93439 \\ 0.05003 & 0.01917 & -0.01020 \\ 0.03388 & 0.35491 & -0.02223 \end{pmatrix} \Delta\mathbf{y}_{t-2} + \boldsymbol{\epsilon}_t$$

The parameter estimates AR1_1_2, AR1_1_3, AR2_1_2, and AR2_1_3 are insignificant, and the VARX model is fitted in the next step.

The detailed output is shown in Output 30.2.1 through Output 30.2.8.

Output 30.2.1. Descriptive Statistics

```

The table in Output 30.2.8 gives forecasts and their prediction error covariances.

Output 30.2.9. Granger-Causality Tests

```
                                 The VARMAX Procedure

                              Granger-Causality Wald Test

                        Test        DF    Chi-Square    Pr > ChiSq

                           1         4          6.37        0.1734

                           Test 1:  Group 1 Variables:  y1
                                    Group 2 Variables:  y2 y3
```

Output 30.2.9 shows that you cannot reject Granger-noncausality from $(y2, y3)$ to $y1$ using the 0.05 significance level.

The following SAS statements show that the variable $y1$ is the exogenous variable, and fit the VARX(2,1) model to the data.

```
   proc varmax data=use;
      id date interval=qtr align=E;
      model y2 y3 = y1 / p=2 dify=(1) difx=(1) xlag=1
                         lagmax=3;
   run;
```

The fitted VARX(2,1) model is written as

$$\begin{pmatrix} \Delta y_{2t} \\ \Delta y_{3t} \end{pmatrix} = \begin{pmatrix} 0.01542 \\ 0.01319 \end{pmatrix} + \begin{pmatrix} 0.02520 \\ 0.05130 \end{pmatrix} \Delta y_{1t} + \begin{pmatrix} 0.03870 \\ 0.00363 \end{pmatrix} \Delta y_{1,t-1}$$
$$+ \begin{pmatrix} -0.12258 & 0.25811 \\ 0.24367 & -0.31809 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-1} \\ \Delta y_{3,t-1} \end{pmatrix}$$
$$+ \begin{pmatrix} 0.01651 & 0.03498 \\ 0.34921 & -0.01664 \end{pmatrix} \begin{pmatrix} \Delta y_{2,t-2} \\ \Delta y_{3,t-2} \end{pmatrix} + \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{pmatrix}$$

The detailed output is shown in Output 30.2.10 through Output 30.2.13.

Output 30.2.10. Parameter Estimates

Example 30.3. Numerous Examples

The following are examples of syntax for model fitting:

```
/* Data ’a’ Generated Process */
  proc iml;
     sig = {1.0  0.5, 0.5  1.25};
     phi = {1.2 -0.5, 0.6  0.3};
     call varmasim(y,phi) sigma = sig n = 100 seed = 46859;
     cn = {’y1’ ’y2’};
     create a from y[colname=cn];
     append from y;
  quit;

/* when the series has a linear trend */
  proc varmax data=a;
     model y1 y2 / p=1 trend=linear;
  run;

/* Fit subset of AR order 1 and 3 */
  proc varmax data=a;
     model y1 y2 / p=(1,3);
  run;
```

```
/* Check if the series is nonstationary */
  proc varmax data=a;
     model y1 y2 / p=1 dftest print=(roots);
  run;

/* Fit VAR(1) in differencing */
  proc varmax data=a;
     model y1 y2 / p=1 print=(roots) dify=(1);
  run;

/* Fit VAR(1) in seasonal differencing */
  proc varmax data=a;
     model y1 y2 / p=1 dify=(4) lagmax=5;
  run;

/* Fit VAR(1) in both regular and seasonal differencing */
  proc varmax data=a;
     model y1 y2 / p=1 dify=(1,4) lagmax=5;
  run;

/* Fit VAR(1) in different differencing */

```

Example 30.4. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers. The series and predict plots, the residual plot, and the forecast plot are created in Output 30.4.1 through Output 30.4.3. These are a selection of the plots created by the VARMAX procedure.

The graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter

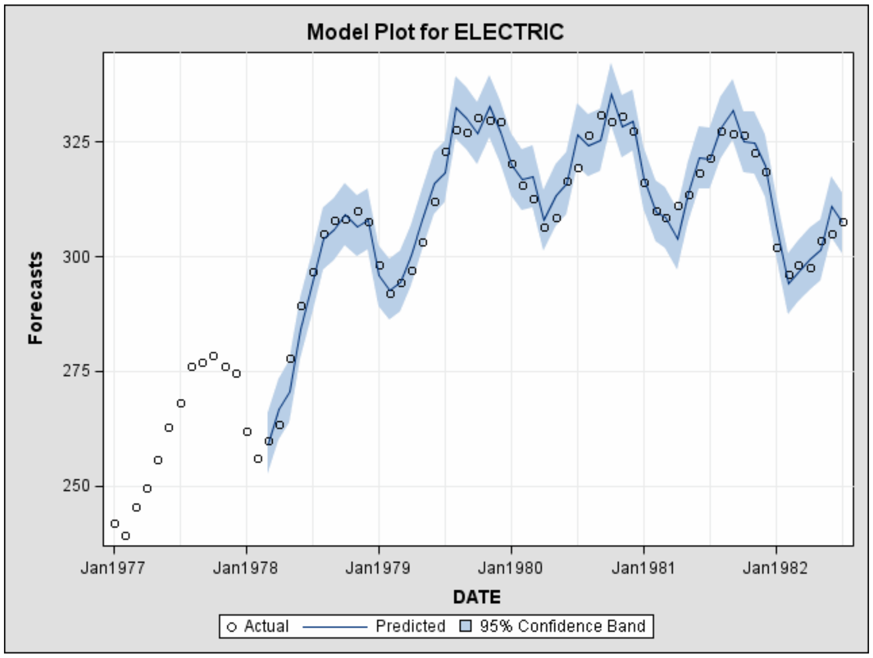
9, “Statistical Graphics Using ODS.” For specific information about the graphics available in the VARMAX procedure, see the “ODS Graphics” section on page 1825.

```
ods html;
ods graphics on;

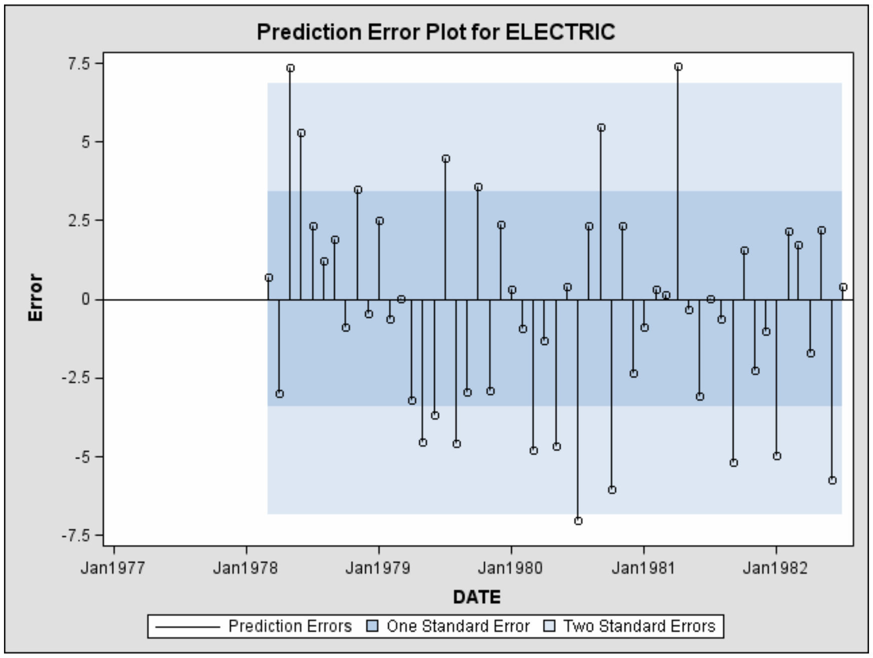
title "Illustration of ODS Graphics";
proc varmax data=sashelp.workers;
   id date interval=month;
   model electric masonry / dify=(1,12) noint p=1;
   output lead=12;
run;

ods graphics off;
ods html close;
```

Output 30.4.1. Series and Predicted Series Plots (Experimental)



Output 30.4.2. Residual Plot (Experimental)



Output 30.4.3. Series and Forecast Plots (Experimental)

Chapter 31
The X11 Procedure

Overview

The X11 procedure, an adaptation of the U.S. Bureau of the Census X-11 Seasonal Adjustment program, seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X11 procedure also provides the X-11-ARIMA method developed by Statistics Canada. This method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data becomes available.

The X11 procedure incorporates Sliding Spans Analysis. This type of analysis provides a diagnostic for determining the suitability of seasonal adjustment for an economic series.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t, t=1,...,n, and separated from trend cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, S_t, is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend cycle component, C_t, includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, D_t, is the variation that can be attributed to the composition of the calendar. The irregular component, I_t, is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). A seasonally adjusted time series, $C_t I_t$, consists of only the trend cycle and irregular components.

Getting Started

The most common use of the X11 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X11 to produce a seasonally adjusted series, C_tI_t from an original series $O_t = S_tC_tD_tI_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t, while S_t, D_t, and I_t vary around 1.0. In all printed tables and in the output data set, these latter components are expressed as percentages, and thus will vary around 100.0 (in the additive case, they vary around 0.0).

The naming convention used in PROC X11 for the tables follows the original U.S. Bureau of the Census X-11 Seasonal Adjustment program specification; refer the U.S. Bureau of the Census, 1967, and "Printed Output" later in this chapter. This convention is outlined in Figure 31.1.

The tables corresponding to parts A - C are intermediate calculations. The final estimates of the individual components are found in the D tables: table D10 contains the final seasonal factors, table D12 contains the final trend cycle, and table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you only need to look at table D11, the final seasonally adjusted series.

Basic Seasonal Adjustment

Suppose you have monthly retail sales data starting in September, 1978, in a SAS data set named SALES. At this point you do not suspect that any calendar effects are present and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the MONTHLY statement, which associates a SAS date value to each observation. To see the results of the seasonal adjustment, you must request table D11, the final seasonally adjusted series, in a TABLES statement.

```
data sales;
   input sales @@;
   date = intnx( 'month', '01sep1978'd, _n_-1 );
   format date monyy7.;
   datalines;
run;

proc x11 data=sales;
   monthly date=date;
   var sales;
   tables d11;
run;
```

```
                           The X11 Procedure

                    X-11 Seasonal Adjustment Program
                       U. S. Bureau of the Census
                 Economic Research and Analysis Division
                           November 1, 1968

           The X-11 program is divided into seven major parts.
            Part         Description
             A.  Prior adjustments, if any
             B.  Preliminary estimates of irregular component weights
                     and regression trading day factors
             C.  Final estimates of above
             D.  Final estimates of seasonal, trend-cycle and
                     irregular components
             E.  Analytical tables
             F.  Summary measures
             G.  Charts

                            Series - sales
                  Period covered - 9/1978 to 8/1990
              Type of run: multiplicative seasonal adjustment.
                        No printout.   No charts.
           Sigma limits for graduating extreme values are 1.5 and 2.5
           Irregular values outside of 2.5-sigma limits are excluded
                           from trading day regression

Figure 31.1. Basic Seasonal Adjustment

You can compare the original series, table B1, and the final seasonally adjusted series, table D11 by plotting them together. These tables are requested and named in the OUTPUT statement.

```
title 'Monthly Retail Sales Data (in $1000)';

proc x11 data=sales noprint;
   monthly date=date;
   var sales;
   output out=out b1=sales d11=adjusted;
run;

symbol1 i=join v='star';
symbol2 i=join v='circle';
legend1 label=none value=('original' 'adjusted');
```

```
proc gplot data=out;
   plot sales    * date = 1
        adjusted * date = 2 / overlay legend=legend1;
run;
```

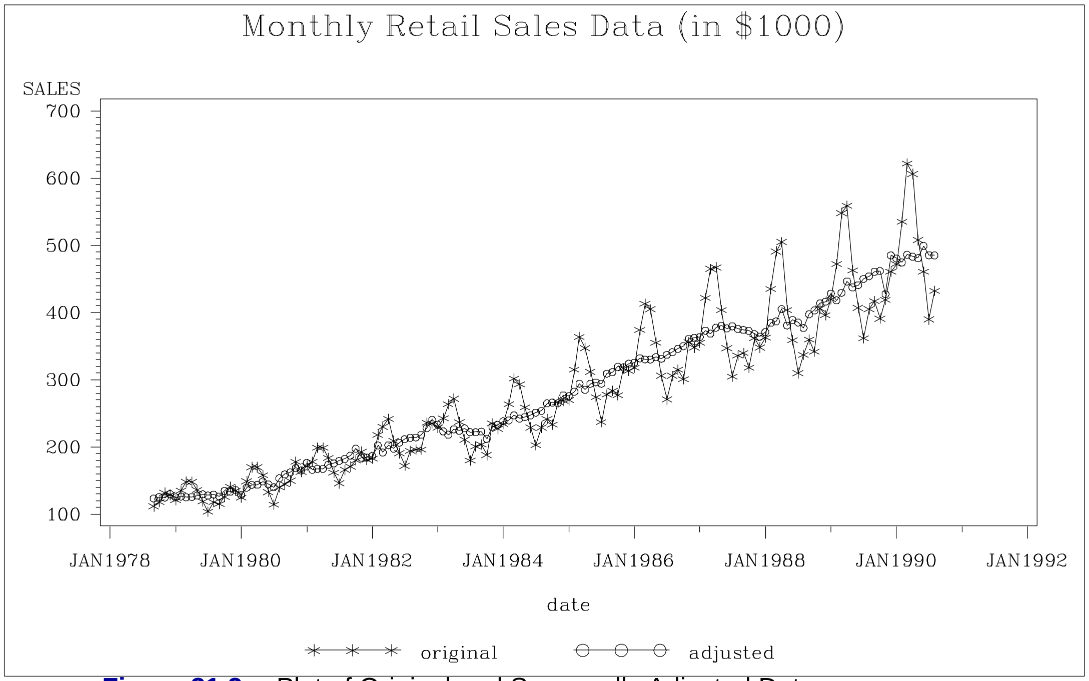

Figure 31.2. Plot of Original and Seasonally Adjusted Data

X-11-ARIMA

An inherent problem with the X-11 method is the revision of the seasonal factor estimates as new data becomes available. The X-11 method uses a set of centered moving averages to estimate the seasonal components. These moving averages apply symmetric weights to all observations except those at the beginning and end of the series, where asymmetric weights have to be applied. These asymmetric weights can cause poor estimates of the seasonal factors, which then can cause large revisions when new data becomes available.

While large revisions to seasonally adjusted values are not common, they can happen. When they do happen, it undermine the credibility of the X-11 seasonal adjustment method.

A method to address this problem was developed at Statistics Canada (Dagum, 1980, 1982b). This method, known as X-11-ARIMA, applies an ARIMA model to the original data (after adjustments, if any) to forecast the series one or more years. This extended series is then seasonally adjusted, allowing symmetric weights to be applied to the end of the original data. This method was tested against a large number of Canadian economic series and was found to greatly reduce the amount of revisions as new data were added.

The X-11-ARIMA method is available in PROC X11 through the use of the ARIMA statement. The ARIMA statement extends the original series either with a user-specified ARIMA model or by an automatic selection process in which the best model from a set of five predefined ARIMA models is used.

The following example illustrates the use of the ARIMA statement. The ARIMA statement does not contain a user-specified model, so the best model is chosen by the automatic selection process. Forecasts from this best model are then used to extend the original series by one year. The partial listing below shows parameter estimates and model diagnostics for the ARIMA model chosen by the automatic selection process.

```
proc x11 data=sales;
   monthly date=date;
   var sales;
   arima;
run;
```

```

                  Conditional Least Squares Estimation

                 Variance  Estimate =    0.0014313
                 Std Error Estimate =    0.0378326
                 AIC                =    -482.2412    *
                 SBC                =    -470.7404    *
                 Number of Residuals=          131

                   * Does not include log determinant

           Criteria Summary for Model 2: (0,1,2)(0,1,1)s, Log Transform

                 Box-Ljung Chi-square: 22.03 with 21 df Prob= 0.40
                              (Criteria prob > 0.05)
              Test for over-differencing: sum of MA parameters = 0.57
                                 (must be < 0.90)
               MAPE - Last Three Years:     2.84 (Must be < 15.00 %)
                              - Last Year:            3.04
                              - Next to Last Year:    1.96
                              - Third from Last Year: 3.51
```

Figure 31.3. X-11-ARIMA Model Selection

Table D11 (final seasonally adjusted series) is now constructed using symmetric weights on observations at the end of the actual data. This should result in better estimates of the seasonal factors and, thus, smaller revisions in D11 as more data become available.

Syntax

The X11 procedure uses the following statements:

PROC X11 *options*;
  ARIMA *options*;
  BY *variables*;
  ID *variables*;
  MACURVES *option*;
  MONTHLY *options*;
  OUTPUT *OUT=dataset options*;
  PDWEIGHTS *option*;
  QUARTERLY *options*;
  SSPAN *options* ;
  TABLES *tablenames*;
  VAR *variables*;

Either the MONTHLY or QUARTERLY statement must be specified, depending on the type of time series data you have. The PDWEIGHTS and MACURVES statements can be used only with the MONTHLY statement. The TABLES statement controls the printing of tables, while the OUTPUT statement controls the creation of the OUT= data set.

Functional Summary

The statements and options controlling the X11 procedures are summarized in the following table.

Description	Statement	Option
Data Set Options		
specify input data set	PROC X11	DATA=
write the trading-day regression results to an output data set	PROC X11	OUTTDR=
write the stable seasonality test results to an output data set	PROC X11	OUTSTB=
write table values to an output data set	OUTPUT	OUT=
add extrapolated values to the output data set	PROC X11	OUTEX
add year ahead estimates to the output data set	PROC X11	YRAHEADOUT
write the sliding spans analysis results to an output data set	PROC X11	OUTSPAN=

Description	Statement	Option
Printing Control Options		
suppress all printed output	PROC X11	NOPRINT
suppress all printed ARIMA output	ARIMA	NOPRINT
print all ARIMA output	ARIMA	PRINTALL
print selected tables and charts	TABLES	
print selected groups of tables	MONTHLY	PRINTOUT=
	QUARTERLY	PRINTOUT=
print selected groups of charts	MONTHLY	CHARTS=
	QUARTERLY	CHARTS=
print preliminary tables associated with ARIMA processing	ARIMA	PRINTFP
specify number of decimals for printed tables	MONTHLY	NDEC=
	QUARTERLY	NDEC=
suppress all printed SSPAN output	SSPAN	NOPRINT
print all SSPAN output	SSPAN	PRINTALL
Date Information Options		
specify a SAS Date variable	MONTHLY	DATE=
	QUARTERLY	DATE=
specify the beginning date	MONTHLY	START=
	QUARTERLY	START=
specify the ending date	MONTHLY	END=
	QUARTERLY	END=
specify beginning year for trading-day regression	MONTHLY	TDCOMPUTE=
Declaring the Role of Variables		
specify BY-group processing	BY	
specify the variables to be seasonally adjusted	VAR	
specify identifying variables	ID	
specify the prior monthly factor	MONTHLY	PMFACTOR=
Controlling the table computations		
use additive adjustment	MONTHLY	ADDITIVE
	QUARTERLY	ADDITIVE
specify seasonal factor moving average length	MACURVES	
specify the extreme value limit for trading-day regression	MONTHLY	EXCLUDE=
specify the lower bound for extreme irregulars	MONTHLY	FULLWEIGHT=
	QUARTERLY	FULLWEIGHT=
specify the upper bound for extreme irregulars	MONTHLY	ZEROWEIGHT=
	QUARTERLY	ZEROWEIGHT=

Description	Statement	Option
include the length-of-month in trading-day regression	MONTHLY	LENGTH
specify trading-day regression action	MONTHLY	TDREGR=
compute summary measure only	MONTHLY	SUMMARY
	QUARTERLY	SUMMARY
modify extreme irregulars prior to trend cycle estimation	MONTHLY	TRENDADJ
	QUARTERLY	TRENDADJ
specify moving average length in trend cycle estimation	MONTHLY	TRENDMA=
	QUARTERLY	TRENDMA=
specify weights for prior trading-day factors	PDWEIGHTS	

PROC X11 Statement

PROC X11 *options;*

The following options can appear in the PROC X11 statement:

DATA= *SAS-data-set*
specifies the input SAS data set used. If it is omitted, the most recently created SAS data set is used.

OUTEXTRAP
adds the extra observations used in ARIMA processing to the output data set.

When ARIMA forecasting/backcasting is requested, extra observations are appended on the ends of the series, and the calculations are carried out on this extended series. The appended observations are not normally written to the OUT= data set. However, if OUTEXTRAP is specified, these extra observations are written to the output data set. If a DATE= variable is specified in the MONTHLY/QUARTERLY statement, the date variable is extrapolated to identify forecasts/backcasts. The OUTEXTRAP option can be abbreviated as OUTEX.

NOPRINT
suppresses any printed output. The NOPRINT option overrides any PRINTOUT=, CHARTS=, or TABLES statement and any output associated with the ARIMA statement.

OUTSPAN= *SAS-data-set*
Specifies the output data set to store the sliding spans analysis results. Tables A1, C18, D10 and D11 for each span are written to this data set. See "OUTSPAN Data Set" later in this chapter for details.

OUTSTB= *SAS-data-set*
Specifies the output data set to store the stable seasonality test results (table D8). All the information in the analysis of variance table associated with the stable seasonality test is contained in the variables written to this data set. See "OUTSTB Data Set" later in this chapter for details.

OUTTDR= *SAS-data-set*

Specifies the output data set to store the trading-day regression results (tables B15 and C15). All the information in the analysis of variance table associated with the trading-day regression is contained in the variables written to this data set. This option is valid only when TDREGR=PRINT, TEST, or ADJUST is specified in the MONTHLY statement. See "OUTTDR Data Set" later in this chapter for details.

YRAHEADOUT

adds one-year-ahead forecast values to the output data set for tables C16, C18 and D10. The original purpose of this option was to avoid recomputation of the seasonal adjustment factors when new data became available. While computing costs were an important factor when the X-11 method was developed, this is no longer the case and this option is obsolete. See "The YRAHEADOUT Option" later in this chapter for details.

ARIMA Statement

ARIMA *options;*

The ARIMA statement applies the X-11-ARIMA method to the series specified in the VAR statement. This method uses an ARIMA model estimated from the original data to extend the series one or more years. The ARIMA statement options control the ARIMA model used and the estimation, forecasting, and printing of this model.

There are two ways of obtaining an ARIMA model to extend the series. A model can be given explicitly with the MODEL= and TRANSFORM= options. Alternatively, the best fitting model from a set of five predefined models is found automatically whenever the MODEL= option is absent. See "Automatic Model Selection" later in this chapter for details.

BACKCAST= *n*

Specifies the number of years to backcast the series. The default is BACKCAST= 0. See "Effect of Backcast and Forecast Length" later in this chapter for details.

CHICR= *value*

specifies the criteria for the significance level for the Box-Ljung chi-square test for lack of fit when testing the five predefined models. The default is CHICR= 0.05. The CHICR= option values must be between 0.01 and 0.90. The hypothesis being tested is that of model adequacy. Nonrejection of the hypothesis is evidence for an adequate model. Making the CHICR= value smaller makes it easier to accept the model. See "Criteria Details" later in this chapter for further details on the CHICR= option.

CONVERGE= *value*

specifies the convergence criterion for the estimation of an ARIMA model. The default value is 0.001. The CONVERGE= value must be positive.

FORECAST= *n*

Specifies the number of years to forecast the series. The default is FORECAST= 1. See "Effect of Backcast and Forecast Length" later in this chapter for details.

MAPECR= *value*

specifies the criteria for the Mean Absolute Percent Error (MAPE) when testing the five predefined models. A small MAPE value is evidence for an adequate model; a large MAPE value results in the model being rejected. The MAPECR= value is the boundary for acceptance/rejection. Thus a larger MAPECR= value would make it easier for a model to pass the criteria. The default is MAPECR= 15. The MAPECR= option values must be between 1 and 100. See "Criteria Details" later in this chapter for further details on the MAPECR= option.

MAXITER= *n*

specifies the maximum number of iterations in the estimation process. MAXITER must be between 1 and 60; the default value is 15.

METHOD= CLS
METHOD= ULS
METHOD= ML

specifies the estimation method. ML requests maximum likelihood, ULS requests unconditional least-squares, and CLS requests conditional least-squares. METHOD=CLS is the default. The maximum likelihood estimates are more expensive to compute than the conditional least-squares estimates. In some cases, however, they may be preferable. For further information on the estimation methods, see "Estimation Details" in Chapter 11, "The ARIMA Procedure."

MODEL= (P=*n1* **Q=***n2* **SP=***n3* **SQ=***n4* **DIF=***n5* **SDIF=***n6* **<NOINT> <CENTER>)**

specifies the ARIMA model. The AR and MA orders are given by P=*n1* and Q=*n2* respectively, while the seasonal AR and MA orders are given by SP=*n3* and SQ=*n4*. The lag corresponding to seasonality is determined by the MONTHLY or QUARTERLY statement. Similarly, differencing and seasonal differencing are given by DIF=*n5* and SDIF=*n6* respectively.

For example

```
   arima model=( p=2 q=1 sp=1 dif=1 sdif=1 );
```

specifies a (2,1,1)(1,1,0)*s* model, where *s*, the seasonality is either 12 (monthly) or 4 (quarterly). More examples of the MODEL= syntax is given in the "Automatic Model Selection" section.

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

CENTER

centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

For example, to fit an AR(1) model on the centered data without an intercept, use the following ARIMA statement.

```
   arima model=( p=1 center noint );
```

NOPRINT

suppresses the normal printout generated by the ARIMA statement. Note that the effect of NOPRINT on the ARIMA statement is different from NOPRINT on the PROC statement, since the former only affects ARIMA output.

OVDIFCR= *value*

specifies the criteria for the over-differencing test when testing the five predefined models. When the MA parameters in one of these models sum to a number close to 1.0, this is an indication of over-parameterization and the model is rejected. The OVDIFCR= value is the boundary for this rejection; values greater than this value fail the over-differencing test. A larger OVDIFCR= value would make it easier for a model to pass the criteria. The default is OVDIFCR= 0.90. The OVDIFCR= option values must be between 0.80 and 0.99. See "Criteria Details" later in this chapter for further details on the OVDIFCR= option.

PRINTALL

provides the same output as the default printing for all models fit and, in addition, prints an estimation summary and chi-square statistics for each model fit. See "Printed Output" later in this chapter for details.

PRINTFP

prints the results for the initial pass of X11 made to exclude trading-day effects. This option has an effect only when the TDREGR= option specifies ADJUST, TEST, or PRINT. In these cases, an initial pass of the standard X11 method is required to get rid of calendar effects before doing any ARIMA estimation. Usually this first pass is not of interest, and by default no tables are printed. However, specifying PRINTFP on the ARIMA statement causes any tables printed in the final pass to also be printed for this initial pass.

TRANSFORM= (LOG) | LOG
TRANSFORM= (*constant ** power* **)**

The ARIMA statement in PROC X11 allows certain transformations on the series before estimation. The specified transformation is applied only to a user-specified model. If TRANSFORM= is specified without a MODEL=, the transformation request is ignored and a warning is printed.

The LOG transformation requests that the natural log of the series be used for estimation. The resulting forecasted values are transformed back to the original scale.

A general power transformation of the form $X_t \rightarrow (X_t + a)^b$ is obtained by specifying

```
   transform= ( a ** b )
```

If the constant *a* is not specified, it is assumed to be zero. The specified ARIMA model is then estimated using the transformed series. The resulting forecasted values are transformed back to the original scale.

BY Statement

BY *variables;*

A BY statement can be used with PROC X11 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID *variables;*

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the MONTHLY or QUARTERLY statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from ARIMA forecasting, backcasting, or from YRAHEADOUT) are extrapolated, while all other ID variables are missing.

MACURVES Statement

MACURVES *month=option ...;*

The MACURVES statement specifies the length of the moving average curves for estimating the seasonal factors for any month. This statement can be used only with monthly time series data.

The *month=option* specifications consist of the month name (or the first three letters of the month name), an equal sign, and one of the following option values.

’3’	specifies a three-term moving average for the month
’3X3’	specifies a three-by-three moving average
’3X5’	specifies a three-by-five moving average
’3X9’	specifies a three-by-nine moving average
STABLE	specifies a stable seasonal factor (average of all values for the month)

For example, the statement

```
   macurves jan='3' feb='3x3' march='3x5' april='3x9';
```

uses a three-term moving average to estimate seasonal factors for January, a 3x3 (a three-term moving average of a three term moving average) for February, a 3x5 (a three-term moving average of a five-term moving average) for March, and a 3x9 (a three-term moving average of a nine-term moving average) for April.

The numeric values used for the weights of the various moving averages and a discussion of the derivation of these weights are given in U.S. Bureau of Census, 1967. A general discussion of moving average weights is given in Dagum, 1985.

If the specification for a month is omitted, the X11 procedure uses a three-by-three moving average for the first estimate of each iteration and a three-by-five average for the second estimate.

MONTHLY Statement

MONTHLY *options;*

The MONTHLY statement must be used when the input data to PROC X11 is a monthly time series. The MONTHLY statement specifies options that determine the computations performed by PROC X11 and what is included in its output. Either the DATE= or START= option must be used.

The following options can appear in the MONTHLY statement:

ADDITIVE

performs additive adjustments. If the ADDITIVE option is omitted, PROC X11 performs multiplicative adjustments.

CHARTS= STANDARD
CHARTS= FULL
CHARTS= NONE

specifies the charts produced by the procedure. The default is CHARTS=STANDARD, which specifies 12 monthly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE.

The TABLES statement can also be used to specify particular monthly charts to be printed. If no CHARTS= is given, and a TABLES statement is given, the TABLES statement overrides the default value of CHARTS=STANDARD; that is, no charts (or tables) are printed except those specified in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. You would specify the following statements.

```
monthly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have 12 years of monthly data (144 observations, no missing values) beginning in January, 1970 and ending in December, 1981, and you only wanted to seasonally adjust six years beginning in January of 1974. Specifying

```
monthly date=date start=jan1974 end=dec1979;
```

would seasonally adjust only this subset of the data. If, instead, you wanted to adjust the last eight years of data, only the START= is needed:

```
monthly date=date start=jan1974;
```

END= *mmmyyyy*

specifies that only the part of the input series ending with the month and year given be adjusted (for example, END=DEC1970). See the DATE=*variable* option for using the START= and END= options to subset a series for processing.

EXCLUDE= *value*

excludes from the trading-day regression any irregular values that are more than *value* standard deviations from the mean. The EXCLUDE=value must be between .1 and 9.9, with the default value being 2.5.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= *value* (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The FULLWEIGHT=value must be between .1 and 9.9 but must be less than the ZEROWEIGHT=value. The default is FULLWEIGHT=1.5.

LENGTH

includes length-of-month allowance in computing trading-day factors. If this option is omitted, length-of-month allowances are included with the seasonal factors.

NDEC= *n*

specifies the number of decimal places shown on the printed tables on the listing. This option has no effect on the precision of the variables values in the output data set.

PMFACTOR= *variable*

specifies a variable containing the prior monthly factors. Use this option if you have previous knowledge of monthly adjustment factors. The PMFACTOR= option can be used to:

- adjust the level of all or part of a series with discontinuities
- adjust for the influence of holidays that fall on different dates from year to year, such as the effect of Easter on certain retail sales
- adjust for unreasonable weather influence on series, such as housing starts
- adjust for changing starting dates of fiscal years (for budget series) or model years (for automobiles)
- adjust for temporary dislocating events, such as strikes

See "Prior Daily Weights and Trading-Day Regression" in the "Details" section later in this chapter for details and examples using the PMFACTOR= option.

PRINTOUT= STANDARD | LONG | FULL | NONE

specifies the tables to be printed by the procedure. If the PRINTOUT=STANDARD option is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed; however, charts are still printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also be used to specify particular monthly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= *mmmyyyy*

adjusts only the part of the input series starting with the specified month and year. When the DATE= option is not used, the START= option gives the year and month of the first input observation. For example, START=JAN1966. START= must be specified if DATE= is not given. If START= is specified (and no DATE= option is given), and an OUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for each observation. See the DATE= *variable* option for using the START= and END= options to subset a series.

SUMMARY

specifies that the data are already seasonally adjusted and the procedure is to produce summary measures. If the SUMMARY option is omitted, the X11 procedure performs seasonal adjustment of the input data before calculating summary measures.

TDCOMPUTE= *year*

uses the part of the input series beginning with January of the specified year to derive trading-day weights. If this option is omitted, the entire series is used.

TDREGR= NONE | PRINT | ADJUST | TEST

specifies the treatment of trading-day regression. The value NONE omits the computation of the trading-day regression. The value PRINT computes and prints the trading-day regressions but does not adjust the series. The value ADJUST computes and prints the trading-day regression and adjusts the irregular components to obtain preliminary weights. The value TEST adjusts the final series if the trading-day regression estimates explain significant variation on the basis of an *F* test (or residual trading-day variation if prior weights are used). The default is TDREGR=NONE.

See "Prior Daily Weights and Trading-Day Regression" in the "Details" section later in this chapter for details and examples using the TDREGR= option.

If ARIMA processing is requested, any value of TDREGR other than the default TDREGR=NONE will cause PROC X11 to perform an initial pass (see the "Details" section and the PRINTFP option).

The signifigance level reported Table C15 should be viewed with caution. The dependent variable in the trading day regression is the irregular component formed by an averaging operation. This induces a correlation in the dependent variable and hence in the residuals from which which the F-test is computed. Hence the distribution of the trading day regression F-statistics differs from an exact F; see Cleveland and Devlin, 1980 for details.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates in the first iteration. If the TRENDADJ option is omitted, the trend cycle is computed without modifications for extremes.

TRENDMA= 9 | 13 | 23.

specifies the number of terms in the moving average to be used by the procedure in estimating the variable trend cycle component. The value of the TRENDMA= option must be 9, 13, or 23. If the TRENDMA= option is omitted, the procedure selects an appropriate moving average. For information concerning the number of terms in the moving average, see U.S. Bureau of the Census (1967).

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The ZEROWEIGHT=value must be between .1 and 9.9 but must be greater than the FULLWEIGHT=value. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See Example 31.3 later in this chapter for an illustration of this use.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename=var1 var2 ... ;*

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

OUT= *SAS-data-set*

If OUT= is omitted, the SAS System names the new data set using the DATA*n* convention.

For each table to be included in the output data set, write the X11 table identification keyword, an equal sign, and a list of new variable names.

tablename = var1 var2 ...

The *tablename* keywords that can be used in the OUTPUT statement are listed in the "Printed Output" section on page 1899. The following is an example of a VAR and OUTPUT statement.

```
var z1 z2 z3;
output out=out_x11  b1=s  d11=w x y;
```

The variable s contains the table B1 values for the variable z1, while the table D11 values for variables z1, z2, and z3 are contained in variables w, x, and y respectively. As this example shows, the list of variables following a *tablename*= keyword can be shorter than the VAR variable list.

In addition to the variables named by *tablename*=*var1 var2* ... , the ID variables, and BY variables, the output data set contains a date identifier variable. If the DATE= option is given in the MONTHLY or QUARTERLY statement, the DATE= variable is the date identifier. If no DATE= is given, a variable named _DATE_ is the date identifier.

PDWEIGHTS Statement

PDWEIGHTS *day=w ... ;*

The PDWEIGHTS statement can be used to specify one to seven daily weights. The statement can only be used with monthly series using the multiplicative model. These weights are used to compute prior trading-day factors, which are then used to adjust the original series prior to the seasonal adjustment process. Only relative weights are needed; the X11 procedure adjusts the weights so that they sum to 7.0. The weights can also be corrected by the procedure on the basis of estimates of trading-day variation from the input data.

See "Prior Daily Weights and Trading-Day Regression" in the "Details" section later in this chapter for details and examples using the PDWEIGHTS statement.

Each *day*=*w* option specifies a weight (*w*) for the named day. The *day* can be any day, Sunday through Saturday. The *day* keyword can be the full spelling of the day, or the three letter abbreviation. For example, SATURDAY=1.0 and SAT=1.0 are both valid. The weights *w* must be a numeric value between 0.0 and 10.0.

The following is an example of a PDWEIGHTS statement.

```
   pdweights sun=.2 mon=.9 tue=1 wed=1 thu=1 fri=.8 sat=.3;
```

Any number of days can be specified with one PDWEIGHTS statement. The default weight value for any day that is not specified is 0. If you do not use a PDWEIGHTS statement, the program computes daily weights if TDREGR=ADJUST is specified. Refer to U.S. Bureau of the Census (1967) for details.

QUARTERLY Statement

QUARTERLY *options;*

The QUARTERLY statement must be used when the input data are quarterly time series. This statement includes options that determine the computations performed by the procedure and what is in the printed output. The DATE= option or the START= option must be used.

The following options can appear in the QUARTERLY statement.

ADDITIVE

performs additive adjustments. If this option is omitted, the procedure performs multiplicative adjustments.

CHARTS= STANDARD
CHARTS= FULL
CHARTS= NONE

specifies the charts to be produced by the procedure. The default value is CHARTS=STANDARD, which specifies four quarterly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE. The TABLES statement can also be used to specify particular charts to be printed. The presence of a TABLES statement overrides the default value of CHARTS=STANDARD, that is, if a TABLES statement is specified, and no CHARTS=option is specified, no charts (nor tables) are printed except those given in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you only wanted charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. This is accomplished by specifying the following statements.

```
quarterly date=date;
tables g1 g4;
```

DATE= *variable*

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested, and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have a series with 10 years of quarterly data (40 observations, no missing values) beginning in ’1970Q1’ and ending in ’1979Q4’, and you only want to seasonally adjust four years beginning in 1974Q1 and ending in 1977Q4. Specifying

```
quarterly date=variable start='1974q1' end='1977q4';
```

seasonally adjusts only this subset of the data. If, instead, you wanted to adjust the last six years of data, only the START= is needed:

```
quarterly date=variable start='1974q1';
```

END= *‘yyyyQq’*

specifies that only the part of the input series ending with the quarter and year given be adjusted (for example, END=’1973Q4’). The specification must be enclosed in quotes and *q* must be 1, 2, 3, or 4. See the DATE= *variable* option for using the START= and END= options to subset a series.

FULLWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is FULLWEIGHT=1.5.

NDEC= *n*

specifies the number of decimal places shown on the output tables. This option has no effect on the precision of the variables in the output data set.

PRINTOUT= STANDARD
PRINTOUT= LONG
PRINTOUT= FULL
PRINTOUT= NONE

specifies the tables to print. If PRINTOUT=STANDARD is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also specify particular quarterly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START= *'yyyyQq'*

adjusts only the part of the input series starting with the quarter and year given. When the DATE= option is not used, the START= option gives the year and quarter of the first input observation (for example, START='1967Q1'). The specification must be enclosed in quotes, and *q* must be 1, 2, 3, or 4. START= must be specified if the DATE= option is not given. If START= is specified (and no DATE= is given), and an OUTPUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for a given observation. See the DATE= option for using the START= and END= options to subset a series.

SUMMARY

specifies that the input is already seasonally adjusted and that the procedure is to produce summary measures. If this option is omitted, the procedure performs seasonal adjustment of the input data before calculating summary measures.

TRENDADJ

modifies extreme irregular values prior to computing the trend cycle estimates. If this option is omitted, the trend cycle is computed without modification for extremes.

ZEROWEIGHT= *value*

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. See Example 31.3 later in this chapter for an illustration of this use.

SSPAN Statement

SSPAN *options ;*

The SSPAN statement applies sliding spans analysis to determine the suitability of seasonal adjustment for an economic series.

The following options can appear in the SSPAN Statement:

NDEC= *n*
specifies the number of decimal places shown on selected Sliding Span reports. This option has no effect on the precision of the variables values in the OUTSPAN output data set.

CUTOFF= *value*
gives the percentage value for determining an excessive difference within a span for the seasonal factors, the seasonally adjusted series, and month-to-month and year-to-years differences in the seasonally adjusted series. The default value is 3.0. The use of the CUTOFF=value in determining the maximum percent difference (MPD) is described in "Computational Details" later in this section. Caution should be used in changing the default CUTOFF=value. The empirical threshold ranges found by the Census Bureau no longer apply when value is changed.

TDCUTOFF= *value*
gives the percentage value for determining an excessive difference within a span for the trading day factors. The default value is 2.0. The use of the TDCUTOFF=value in determining the maximum percent difference (MPD) is described in "Computational Details" later in this section. Caution should be used in changing the default TDCUTOFF=value. The empirical threshold ranges found by the Census Bureau no longer apply when value is changed.

NOPRINT
suppresses all sliding spans reports.

PRINT
prints the summary sliding spans reports S 0 - S 6.E.

PRINTALL
prints the summary sliding spans reports S 0 - S 6.E, along with detail reports S 7.A - S 7.E.

TABLES Statement

TABLES *tablenames;*

The TABLES statement prints the tables specified in addition to the tables that are printed as a result of the PRINTOUT= option in the MONTHLY or QUARTERLY statement. Table names are listed in Table 31.3 later in this chapter.

To print only selected tables, omit the PRINTOUT= option in the MONTHLY or QUARTERLY statement and list the tables to be printed on the TABLES statement. For example, to print only the final seasonal factors and final seasonally adjusted series, use the statement

```
tables d10 d11;
```

VAR Statement

VAR *variables;*

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the MONTHLY or QUARTERLY statement.

Details

Historical Development of X-11

This section briefly describes the historical development of the standard X-11 seasonal adjustment method and the later development of the X-11-ARIMA method. Most of the following discussion is based on a comprehensive article by Bell and Hillmer (1984), which describes the history of X-11 and the justification of using seasonal adjustment methods, such as X-11, given the current availability of time series software. For further discussions on statistical problems associated with the X-11 method, refer to Ghysels (1990).

Seasonal adjustment methods began development in the 1920s and 1930s before there were suitable analytic models available and before electronic computing devices were developed. The lack of any suitable model led to methods that worked the same for any series, that is, methods that were not model-based and that could be applied to any series. Experience with economic series had shown that a given mathematical form could adequately represent a time series only for a fixed length; as more data was added, the model became inadequate. This suggested an approach using moving averages.

The basic method was to break up an economic time series into long-term trend, long-term cyclical movements, seasonal movements, and irregular fluctuations.

Early investigators found that it was not possible to uniquely decompose the trend and cycle components. Thus, these two were grouped together; the resulting component is usually referred to as the "trend cycle component."

It was also found that estimating seasonal components in the presence of trend produced biased estimates of the seasonal components, but, at the same time, estimating trend in the presence of seasonality was difficult. This eventually lead to the iterative approach used in the X-11 method.

Two other problems were encountered by early investigators. First, some economic series appears to have changing or evolving seasonality. Secondly, moving averages were very sensitive to extreme values. The estimation method used in the X-11 method allows for evolving seasonal components. For the second problem, the X-11 method uses repeated adjustment of extreme values.

All of these problems encountered in the early investigation of seasonal adjustment methods suggested the use of moving averages in estimating components. Even with the use of moving averages instead of a model-based method, massive amounts of hand calculations were required. Only a small number of series could be adjusted, and little experimentation could be done to evaluate variations on the method.

With the advent of electronic computing in the 1950s, work on seasonal adjustment methods proceeded rapidly. These methods still used the framework previously described; variants of these basic methods could now be easily tested against a large number of series.

Much of the work was done by Julian Shiskin and others at the U.S. Bureau of the Census beginning in 1954 and culminated after a number of variants into the *X-11 Variant of the Census Method II Seasonal Adjustment Program*, which PROC X11 implements.

References for this work during this period include Shiskin and Eisenpress (1957), Shiskin (1958), and Marris (1960). The authoritative documentation for the X-11 Variant is in U.S. Bureau of the Census (1967). This document is not equivalent to a program specification; however the FORTRAN code implementing the X-11 Variant is in the public domain. A less detailed description of the X-11 Variant is given in U.S. Bureau of the Census (1969).

Development of the X-11-ARIMA Method

The X-11 method uses symmetric moving averages in estimating the various components. At the end of the series, however, these symmetric weights cannot be applied. Either asymmetric weights have to be used, or some method of extending the series must be found.

While various methods of extending a series have been proposed, the most important method to date has been the X-11-ARIMA method developed at Statistics Canada. This method uses Box-Jenkins ARIMA models to extend the series.

The Time Series Research and Analysis Division of Statistic Canada investigated 174 Canadian economic series and found five ARIMA models out of twelve that fit the majority of series well and reduced revisions for the most recent months. References giving details of various aspects of the X-11-ARIMA methodology include Dagum (1980, 1982a, 1982b, 1983, 1988), Laniel (1985), Lothian and Morry (1978a), and Huot,Chui, Higginson, and Gait (1986).

Differences Between X11ARIMA/88 and PROC X11

The original implementation of the X-11-ARIMA method was by Statistics Canada in 1980 (Dagum, 1980; X11ARIMA/80), with later changes and enhancements made in 1988 (Dagum, 1988; X11ARIMA/88). The calculations performed by PROC X11 differ from those in X11ARIMA/88, which will result in differences in the final component estimates provided by these implementations.

There are three areas where Statistic Canada made changes to the original X-11 seasonal adjustment method in developing X11ARIMA/80 (refer to Monsell, 1984). These are (a) selection of extreme values, (b) replacement of extreme values, and (c) generation of seasonal and trend cycle weights.

These changes have not been implemented in the current version of PROC X11. Thus the procedure produces identical results with previous versions of PROC X11 in the absence of an ARIMA statement.

Additional differences can result from the ARIMA estimation. X11ARIMA/88 uses Conditional Least Squares (CLS), while CLS, Unconditional Least Squares (ULS) and Maximum Likelihood (ML) are all available in PROC X11 by using the METHOD= option on the ARIMA statement. Generally, parameters estimates will differ for the different methods.

Implementation of the X-11 Seasonal Adjustment Method

The following steps describe the analysis of a monthly time series using multiplicative adjustments. Additional steps used by the X-11-ARIMA method are also indicated. Equivalent descriptions apply for an additive model by replacing *divide* by *subtract* where applicable.

In the multiplicative adjustment, the original series O_t is assumed to be of the form

$$O_t = C_t S_t I_t P_t D_t,$$

where C_t is the trend cycle component, S_t is the seasonal component, I_t is the irregular component, P_t is the prior monthly factors component and D_t is the trading-day component.

The trading-day component can be further factored as

$$D_t = D_{r,t} D_{tr,t},$$

where $D_{tr,t}$ are the trading-day factors derived from the prior daily weights, and $D_{r,t}$ are the residual trading-day factors estimated from the trading-day regression.

Additional Steps When Using the X-11-ARIMA Method

The X-11-ARIMA method consists of extending a given series by an ARIMA model and applying the usual X-11 seasonal adjustment method to this extended series. Thus in the simplest case in which there are no prior factors or calendar effects in the series, the ARIMA model selection, estimation and forecasting is first performed, and the resulting extended series goes through the standard X-11 steps described below.

If prior factor or calendar effects are present, they must be eliminated from the series before the ARIMA estimation is done because these effects are not stochastic.

Prior factors, if present, are removed first. Calendar effects represented by prior daily weights are then removed. If there are no further calendar effects, the adjusted series is extended by the ARIMA model, and this extended series goes through the standard X-11 steps without repeating the removal of prior factors and calendar effects from prior daily weights.

If further calendar effects are present, a trading-day regression must be performed. In this case it is necessary to go through an initial pass of the X-11 steps to obtain a final trading-day adjustment. In this initial pass, the series, adjusted for prior factors and prior daily weights, goes through the standard X-11 steps. At the conclusion of these steps, a final series adjusted for prior factors and all calendar effects is available. This adjusted series is then extended by the ARIMA model, and this extended series goes through the standard X-11 steps again, without repeating the removal of prior factors and calendar effects from prior daily weights and trading day regression.

The Standard X-11 Seasonal Adjustment Method

The following steps comprise the standard X-11 seasonal adjustment method. These steps are applied to the original data or the original data extended by an ARIMA model.

1. In step 1, the data are read, ignoring missing values until the first nonmissing value is found. If prior monthly factors are present, the procedure reads prior monthly P_t factors and divides them into the original series to obtain $O_t/P_t = C_t S_t I_t D_{tr,t} D_{r,t}$.

   Seven daily weights can be specified to develop monthly factors to adjust the series for trading-day variation, $D_{tr,t}$; these factors are then divided into the original or prior adjusted series to obtain $C_t S_t I_t D_{r,t}$.

2. In steps 2, 3, and 4, three iterations are performed, each of which provides estimates of the seasonal S_t, trading-day $D_{r,t}$, trend cycle C_t, and irregular components I_t. Each iteration refines estimates of the extreme values in the irregular components. After extreme values are identified and modified, final estimates of the seasonal component, seasonally adjusted series, trend cycle, and irregular components are produced. Step 2 consists of three substeps:

   (a) During the first iteration, a centered, 12-term moving average is applied to the original series O_t to provide a preliminary estimate $\hat{C}_t$ of the trend cycle curve C_t. This moving average combines 13 (a 2 term moving average of a 12-term moving average) consecutive monthly values, removing the S_t and I_t. Next, it obtains a preliminary estimate $\widehat{S_t I_t}$ by

   $$\widehat{S_t I_t} = \frac{O_t}{\hat{C}_t}$$

   (b) A moving average is then applied to the $\widehat{S_t I_t}$ to obtain an estimate $\hat{S}_t$ of the seasonal factors. $\widehat{S_t I_t}$ is then divided by this estimate to obtain an estimate $\hat{I}_t$ of the irregular component. Next, a moving standard deviation is calculated from the irregular component and is used in assigning a weight to each monthly value for measuring its degree of extremeness.

These weights are used to modify extreme values in $\widehat{S_t I_t}$. New seasonal factors are estimated by applying a moving average to the modified value of $\widehat{S_t I_t}$. A preliminary seasonally adjusted series is obtained by dividing the original series by these new seasonal factors. A second estimate of the trend cycle is obtained by applying a weighted moving average to this seasonally adjusted series.

(c) The same process is used to obtain second estimates of the seasonally adjusted series and improved estimates of the irregular component. This irregular component is again modified for extreme values and then used to provide estimates of trading-day factors and refined weights for the identification of extreme values.

3. Using the same computations, a second iteration is performed on the original series that has been adjusted by the trading-day factors and irregular weights developed in the first iteration. The second iteration produces final estimates of the trading-day factors and irregular weights.
4. A third and final iteration is performed using the original series that has been adjusted for trading-day factors and irregular weights computed during the second iteration. During the third iteration, PROC X11 develops final estimates of seasonal factors, the seasonally adjusted series, the trend cycle, and the irregular components. The procedure computes summary measures of variation and produces a moving average of the final adjusted series.

Sliding Spans Analysis

The motivation for sliding spans analysis is to answer the question "When is a economic series unsuitable for seasonal adjustment ?". There are a number of past attempts to answer this question: stable seasonality F-test; moving seasonality F-test, Q-statistics and others.

Sliding spans analysis attempts to quantify the stability of the seasonal adjustment process, and hence quantify the suitability of seasonal adjustment for a given series.

It is based on a very simple idea: for a stable series, deleting a small number of observations should not result in greatly different component estimates compared with the original, full series. Conversely, if deleting a small number of observations results in drastically different estimates, the series is unstable. For example, a drastic difference in the seasonal factors (Table D10) might result from a dominating irregular component, or sudden changes in the seasonally component. When the seasonal component estimates of a series is unstable in this manner, they have little meaning and the series is likely to be unsuitable for seasonal adjustment.

Sliding spans analysis, developed at the Statistical Research Division of the U.S. Census Bureau (see Findley, et al., 1990, and Findley and Monsell, 1986), performs a repeated seasonal adjustment on subsets or spans of the full series. In particular, an initial span of the data, typically eight years in length, is seasonally adjusted, and the tables C18, the trading day factors (if trading day regression performed), D10, the seasonal factors, and D11, the seasonally adjusted series are retained for further processing. Next, one year of data is deleted from the beginning of the initial span and one year of data is added. This new span is seasonally adjusted as before, with the same tables retained. This process continues until the end of the data is reached. The beginning and ending dates of the spans are such that the last observation in the original data is also the last observation in the last span. This is discussed in more detail below.

The following notation for the components or differences computed in the sliding spans analysis follows Findley et al., 1990. The meaning for the symbol X_t(k) is component X in month (or quarter) t, computed from data in the k-th span. These components are now defined.

Seasonal Factors (Table D10): S_t(k)

Trading Day Factor (Table C18): TD_t(k)

Seasonally Adjust Data (Table D11): SA_t(k)

Month-to-month changes in the Seasonally Adjust Data: MM_t(k)

Year-to-Year changes in the Seasonally Adjust Data: YY_t(k)

The key measure is the maximum percent difference across spans. For example, consider a series beginning in JAN72, ending in DEC84, and having four spans, each of length 8 years (see Figure 1. in Findley et al., 1990, page 346). Consider S_t(k) the seasonal factor (table D10) for month t for span k, and let N_t denote the number of spans containing month t, i.e.,

$$N_t = \{k : \ span\ k\ contains\ month\ t\}$$

In the middle years of the series there is overlap of all four spans and N_t will be 4. The last year of the series will have but one span, while the beginning can have 1 or 0 spans depending on the original length.

Since we are interested in how much the seasonal factors vary for a given month across the spans, a natural quantity to consider is

$$max_{k \epsilon N_t} S_t(k) - min_{k \epsilon N_t} S_t(k)$$

In the case of the multiplicative model, it is useful to compute a percent difference; define the maximum percent difference (MPD) at time t as

$$MPD_t = \frac{max_{k \epsilon N_t} S_t(k) - min_{k \epsilon N_t} S_t(k)}{min_{k \epsilon N_t} S_t(k)}$$

The seasonal factor for month t is then unreliable if MPD_t is large. While no exact significance level can be computed for this statistic, empirical levels have been established by considering over 500 economic series (see Findley, et al. 1990 and Findley and Monsell, 1986). For these series it was found that for four spans, stable series typically had less than 15% of the MPD values exceeding 3.0%, while in marginally stable series, between 15% and 25% of the MPD values exceeded 3.0%. A series in which 25% or more of the MPD values exceeded 3.0% is almost always unstable.

While these empirical values cannot be considered an exact significance level, they provide a useful empirical basis for deciding if a series is suitable for seasonal adjustment. These percentage values are shifted down when less than four spans are used.

Computation Details for Sliding Spans Analysis

Length and Number of Spans

The algorithm for determining the length and number of spans for a given series was developed at the U.S. Bureau of the Census, Statistical Research Division. A summary of this algorithm is as follows.

First, an initial length based on MACURVE specification is determined, then the maximum number of spans possible using this length is determined. If this maximum number exceed four, set the number of spans to four. If this maximum number is one or zero, there is not enough observations to perform the sliding spans analysis. In this case a note is written to the log and the sliding spans analysis is skipped for this variable.

If the maximum number of spans is two or three, the actual number of spans used is set equal to this maximum. Finally, the length is adjusted so that the spans begin in January (or the first quarter) of the beginning year of the span.

The remaining part of this section gives the computation formulas for the maximum percent difference (MPD) calculations along with the threshold regions.

Seasonal Factors (Table D10): $S_t(k)$

For the additive model, the MPD is defined as

$$max_{k \epsilon N_t} S_t(k) - min_{k \epsilon N_t} S_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{max_{k \epsilon N_t} S_t(k) - min_{k \epsilon N_t} S_t(k)}{min_{k \epsilon N_t} S_t(k)}$$

A series for which less than 15% of the MPD values of D10 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% unstable. Span reports S 2.A - S 2.C give the various breakdowns for the number of times the MPD exceeded these levels.

Trading Day Factor (Table C18): TD$_t$(k)

For the additive model, the MPD is defined as

$$max_{k\epsilon N_t} TD_t(k) - min_{k\epsilon N_t} TD_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{max_{k\epsilon N_t} TD_t(k) - min_{k\epsilon N_t} TD_t(k)}{min_{k\epsilon N_t} TD_t(k)}$$

The Census Bureau currently gives no recommendation concerning MPD thresholds for the Trading Day factors. Span reports S 3.A - S 3.C give the various breakdowns for MPD thresholds. When TDREGR=NONE is specified, no trading day computations are done, hence this table is skipped.

Seasonally Adjust Data (Table D11): SA$_t$(k)

For the additive model, the MPD is defined as

$$max_{k\epsilon N_t} SA_t(k) - min_{k\epsilon N_t} SA_t(k)$$

For the multiplicative model, the MPD is

$$MPD_t = \frac{max_{k\epsilon N_t} SA_t(k) - min_{k\epsilon N_t} SA_t(k)}{min_{k\epsilon N_t} SA_t(k)}$$

A series for which less than 15% of the MPD values of D11 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% unstable. Span reports S 4.A - S 4.C give the various breakdowns for the number of times the MPD exceeded these levels.

Month-to-Month Changes in the Seasonally Adjust Data: MM$_t$(k)

Some additional notation is needed for the month-to-month and year-to-year differences. Define N1$_t$ by

$$N1_t = \{k : \; span \; k \; contains \; month \; t \; and \; t-1\}$$

For the additive model the month-to-month change for span k is defined by

$$MM_t(k) = SA_t - SA_{t-1}$$

while for the multiplicative model

$$MM_t(k) = \frac{SA_t - SA_{t-1}}{SA_{t-1}},$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined by

$$MPD_t = max_{k \epsilon N1_t} MM_t(k) - min_{k \epsilon N1_t} MM_t(k)$$

The current recommendation of the Census Bureau is that if 35% or more of the MPD values of the month-to-month differences of D11 exceed 3.0% then the series is usually not stable. 40% exceeding this level clearly marks an unstable series. Span reports S 5.A.1 - S 5.C give the various breakdowns for number of times the MPD exceeds these levels.

Year-to-Year Changes in the Seasonally Adjust Data: YY$_t$(k)

First define $N12_t$ by

$$N12_t = \{k : \; span\ k\ contains\ month\ t\ and\ t-12\}$$

(appropriate changes in notation for a quarterly series are obvious.)

For the additive model the month-to-month change for span k is defined by

$$YY_t(k) = SA_t - SA_{t-12}$$

while for the multiplicative model

$$YY_t(k) = \frac{SA_t - SA_{t-12}}{SA_{t-12}},$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined by

$$MPD_t = max_{k \epsilon N1_t} YY_t(k) - min_{k \epsilon N1_t} YY_t(k)$$

The current recommendation of the Census Bureau is that if 10% or more of the MPD values of the month-to-month differences of D11 exceed 3.0% then the series is usually not stable. Span reports S 6.A - S 6.C give the various breakdowns for the number of times the MPD exceeds these levels.

Data Requirements

The input data set must contain either quarterly or monthly time series, and the data must be in chronological order. For the standard X-11 method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

For the X-11-ARIMA method, there must be at least five years of observations (20 for quarterly time series or 60 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

Missing Values

Missing values at the beginning of a series to be adjusted are skipped. Processing starts with the first nonmissing value and continues until the end of the series or until another missing value is found.

Missing values are not allowed for the DATE= variable. The procedure terminates if missing values are found for this variable.

Missing values found in the PMFACTOR= variable are replaced by 100 for the multiplicative model (default) and by 0 for the additive model.

Missing values can occur in the output data set. If the time series specified in the OUTPUT statement is not computed by the procedure, the values of the corresponding variable are missing. If the time series specified in the OUTPUT statement is a moving average, the values of the corresponding variable are missing for the first *n* and last *n* observations, where *n* depends on the length of the moving average. Additionally, if the time series specified is an irregular component modified for extremes, only the modified values are given, and the remaining values are missing.

Prior Daily Weights and Trading-Day Regression

Suppose that a detailed examination of retail sales at ZXY Company indicates that certain days of the week have higher sales. In particular, Thursday, Friday and Saturday have approximately double the number of sales as Monday, Tuesday, and Wednesday, and no sales occur on Sunday. This means that months with five Saturdays would have higher sales than months with only four Saturdays.

This phenomenon is called a calendar effect; it can be handled in PROC X11 by using the PDWEIGHTS (Prior Daily WEIGHTS) statement or the TDREGR=option (Trading-Day REGRession). The PDWEIGHTS statement and the TDREGR=option can be used separately or together.

If the relative weights are known (as in the preceding) it is appropriate to use the PDWEIGHTS statement. If further residual calendar variation is present TDREGR=ADJUST should also be used. If you know that a calendar effect is present, but know nothing about the relative weights, use TDREGR=ADJUST without a PDWEIGHTS statement.

In this example, it is assumed that the calendar variation is due to both prior daily weights and residual variation. Thus both a PDWEIGHTS statement and TDREGR= ADJUST are specified.

Note that only the relative weights are needed; in the actual computations, PROC X11 normalizes the weights to sum to 7.0. If a day of the week is not present in the PDWEIGHTS statement, it is given a value of zero. Thus "sun=0" is not needed.

```
proc x11 data=sales;
   monthly date=date tdregr=adjust;
   var sales;
   tables a1 a4 b15 b16 C14 C15 c18 d11;
   pdweights mon=1 tue=1 wed=1 thu=2 fri=2 sat=2;
```

```
      output out=x11out a1=a1 a4=a4 b1=b1 c14=c14
                        c16=c16 c18=c18 d11=d11;
   run;
```

Tables of interest include A1, A4, B15, B16, C14, C15, C18, and D11. Table A4 contains the adjustment factors derived from the prior daily weights, table C14 contains the extreme irregular values excluded from trading-day regression, table C15 contains the trading day-regression results, table C16 contains the monthly factors derived from the trading-day regression, table C18 contains the final trading-day factors derived from the combined daily weights. Finally, table D11 contains the final seasonally adjusted series.

Adjustment for Prior Factors

Suppose now that a strike at ZXY Company during July and August of 1988 caused sales to decrease an estimated 50%. Since this is a one-time event with a known cause, it is appropriate to prior adjust the data to reflect the effects of the strike. This is done in PROC X11 through the use of PMFACTOR= *varname* (Prior Monthly FACTOR) on the MONTHLY statement.

In the following example, the PMFACTOR variable is named PMF. Since the estimate of the decrease in sales is 50%, PMF has a value of 50.0 for the observations corresponding to July and August, 1988, and a value of 100.0 for the remaining observations.

This prior adjustment to SALES is performed to SALES by computing (SALES/PMF) * 100.0. A value of 100.0 for PMF leaves SALES unchanged, while a value of 50.0 for PMF doubles SALES. This value is the estimate of what SALES would have been without the strike. The following example shows how this prior adjustment is accomplished.

```
   data sales; set sales;
      if '01jul1988'd <= date <= '01aug1988'd then pmf = 50;
      else pmf = 100;
   run;

   proc x11 data=sales;
      monthly date=date pmfactor=pmf;
      var sales;
      tables a1 a2 a3 d11;
      output out=x11out a1=a1 a2=a2 a3=a3 d11=d11;
   run;
```

Table A2 contains the prior monthly factors (the values of PMF), and Table A3 contains the prior adjusted series.

The YRAHEADOUT Option

For monthly data, the YRAHEADOUT option affects only tables C16 (regression trading-day adjustment factors), C18 (trading-day factors from combined daily weights), and D10 (seasonal factors). For quarterly data, only D10 is affected. Variables for all other tables have missing values for the forecast observations. The forecast values for a table are included only if that table is specified in the OUTPUT statement.

Tables C16 and C18 are calendar effects that are extrapolated by calendar composition. These factors are independent of the data once trading-day weights have been calculated. Table D10 is extrapolated by a linear combination of past values. If N is the total number of nonmissing observations for the analysis variable, this linear combination is given by

$$D10_t = \frac{1}{2}(3 \times D10_{t-12} - D10_{t-24}), \quad t = N+1, .., N+12$$

If the input data are monthly time series, 12 extra observations are added to the end of the output data set. (If a BY statement is used, 12 extra observations are added to the end of each BY group.) If the input data is a quarterly time series, four extra observations are added to the end of the output data set. (If a BY statement is used, four extra observations are added to each BY group.)

The DATE= variable (or _DATE_) is extrapolated for the extra observations generated by the YRAHEADOUT option, while all other ID variables will have missing values.

If ARIMA processing is requested, and if both the OUTEXTRAP and YRAHEADOUT options are specified in the PROC X11 statement, an additional 12 (4) observations are added to the end of output data set for monthly (quarterly) data after the ARIMA forecasts, using the same linear combination of past values as before.

Effect of Backcast and Forecast Length

Based on a number of empirical studies, (Dagum 1982a, 1982b, 1982c, Dagum and Laniel, 1987) one year of forecasts minimized revisions when new data become available. Two and three years of forecasts showed only small gains.

Backcasting improves seasonal adjustment but introduces permanent revisions at the beginning of the series and also at the end for series of length 8, 9 or 10 years. For series shorter than 7 years, the advantages of backcasting outweigh the disadvantages (Dagum, 1988).

Other studies (Pierce, 1980, Bobbit and Otto, 1990, Buszuwski, 1987) suggest "full forecasting"; that is, using enough forecasts to allow symmetric weights for the seasonal moving averages for the most current data. For example, if a 3x9 seasonal moving average was specified for one or more months using the MACURVES statement, five years of forecasts would be required. This is because the seasonal moving averages are performed on calendar months separately, and the 3x9 is an eleven-term centered moving average, requiring five observations before and after the current observation. Thus

```
   macurves dec='3x9';
```

would require five additional December values to compute the seasonal moving average.

Details of Model Selection

If an ARIMA statement is present, but no MODEL= is given, PROC X11 estimates and forecasts five predefined models and selects the best. This section describes the details of the selection criteria and the selection process.

The five predefined models used by PROC X11 are the same as those used by X11ARIMA/88 from Statistics Canada. These particular models, shown in Table 31.1 were chosen on the basis of testing a large number of economics series (Dagum, 1988) and should provide reasonable forecasts for most economic series.

Table 31.1. Five Predefined Models

Model #	Specification	Multiplicative	Additive
1	(0,1,1)(0,1,1)s	log transform	no transform
2	(0,1,2)(0,1,1)s	log transform	no transform
3	(2,1,0)(0,1,1)s	log transform	no transform
4	(0,2,2)(0,1,1)s	log transform	no transform
5	(2,1,2)(0,1,1)s	no transform	no transform

The selection process proceeds as follows. The five models are estimated and one-step-ahead forecasts are produced in the order shown in Table 31.1. As each model is estimated the following three criteria are checked:

- The Mean Absolute Percent Error (MAPE) for the last three years of the series must be less than 15 %.
- The significance probability for the Box-Ljung Chi-square for up to lag 24 for monthly (8 for quarterly) must greater than 0.05.
- The over-differencing criteria must not exceed 0.9.

The description of these three criteria are given in "Criteria Details." The default values for these criteria are those used by X11ARIMA/88 from Statistics Canada; these defaults can be changed by the MAPECR=, CHICR= and OVDIFCR= options.

A model that fails any one of these three criteria is excluded from further consideration. In addition, if the ARIMA estimation fails for a given model, a warning is issued, and the model is excluded. The final set of all models considered are those that pass all three criteria and are estimated successfully. From this set, the model with the smallest MAPE for the last three years is chosen.

If all five models fail, ARIMA processing is skipped for the variable being processed, and the standard X-11 seasonal adjustment is performed. A note is written to the log with this information.

The chosen model is then used to forecast the series one or more years (determined by the FORECAST= option on the ARIMA statement). These forecasts are appended on the original data (or the prior and calendar-adjusted data).

If a BACKCAST= is specified, the chosen model form is used, but the parameters are reestimated using the reversed series. Using these parameters, the reversed series is forecasted for the number of years specified by the BACKCAST= option. These forecasts are then reversed and appended to the beginning of the original series, or the prior and calendar-adjusted series, to produce the backcasts.

Note that the final selection rule (the smallest MAPE using the last three years) emphasizes the quality of the forecasts at the end of the series. This is consistent with the purpose of the X-11-ARIMA methodology, namely, to improve the estimates of seasonal factors and thus minimize revisions to recent past data as new data become available.

Criteria Details

The Mean Absolute Percent Error (MAPE)

For the MAPE criteria testing, only the last three years of the original series (or prior and calendar adjusted series) is used in computing the MAPE.

Let y_t, *t*=1,..,*n* be the last three years of the series, and denote its one-step-ahead forecast by $\hat{y}_t$, where n=36 for a monthly series, and n=12 for a quarterly series.

With this notation, the MAPE criteria is computed as

$$MAPE = \frac{100}{n} \sum_{t=1}^{n} \frac{|y_t - \hat{y}_t|}{|y_t|}$$

Box-Ljung Chi-Square

The Box-Ljung Chi-Square is a lack of fit test using the model residuals. This test statistic is computed using the Ljung-Box formula

$$\chi_m^2 = n(n+2) \sum_{k=1}^{m} \frac{r_k^2}{(n-k)}$$

where *n* is the number of residuals that can be computed for the time series, and

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^{n} a_t^2}$$

where the a_t's are the residual sequence. This formula has been suggested by Ljung and Box as yielding a better fit to the asymptotic chi-square distribution. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978).

For monthly series, m=24, while for quarterly series, m=8.

Over-Differencing Test

From Table 31.1 you can se that all models have a single seasonal MA factor and at most two nonseasonal MA factors. Also, all models have seasonal and nonseasonal differencing. Consider model 2 applied to a monthly series y_t with $E(y_t) = \mu$:

$$(1 - B^1)(1 - B^{12})(y_t - \mu) = (1 - \theta_1 B - \theta_2 B^2)(1 - \theta_3 B^{12})a_t$$

If $\theta_3 = 1.0$, then the factors $(1 - \theta_3 B^{12})$ and $(1 - B^{12})$ will cancel, resulting in a lower-order model.

Similarly, if $\theta_1 + \theta_2 = 1.0$,

$$(1 - \theta_1 B - \theta_2 B^2) = (1 - B)(1 - \alpha B)$$

for some $\alpha \neq 0.0$. Again, this results in cancelation and a lower order model.

Since the parameters are not exact, it is not reasonable to require that

$$\theta_3 < 1.0 \text{ and } \theta_1 + \theta_2 < 1.0$$

Instead, an approximate test is performed by requiring that

$$\theta_3 \leq 0.9 \text{ and } \theta_1 + \theta_2 \leq 0.9$$

The default value of 0.9 can be changed by the OVDIFCR= option. Similar reasoning applies to the other models.

ARIMA Statement Options for the Five Predefined Models

The following table lists the five predefined models and gives the equivalent MODEL= parameters in a PROC X11 ARIMA statement.

In all models except the fifth, a log transformation is performed before the ARIMA estimation for the multiplicative case; no transformation is performed for the additive case. For the fifth model, no transformation is done for either case.

The multiplicative case is assumed in the following table. The indicated seasonality *s* in the specification is either 12 (monthly), or 4 (quarterly). The MODEL statement assumes a monthly series.

Table 31.2. ARIMA Statements Options for Predefined Models

Model	ARIMA Statement Options
(0,1,1)(0,1,1)s	MODEL=(Q=1 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,1,2)(0,1,1)s	MODEL=(Q=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(2,1,0)(0,1,1)s	MODEL=(P=2 SQ=1 DIF=1 SDIF=1) TRANSFORM=LOG
(0,2,2)(0,1,1)s	MODEL=(Q=2 SQ=1 DIF=2 SDIF=1) TRANSFORM=LOG
(2,1,2)(0,1,1)s	MODEL=(P=2 Q=2 SQ=1 DIF=1 SDIF=1)

OUT= Data Set

The OUT= data set specified in the OUTPUT statement contains the BY variables, if any; the ID variables, if any; and the DATE= variable if the DATE= option is given, or _DATE_ if the DATE= option is not specified.

In addition, the variables specified by the option

tablename =var1 var2 . . . varn

are placed in the OUT= data set. A list of tables available for monthly and quarterly series is given in Table 31.3.

The OUTSPAN Data Set

OUTSPAN= *SAS-data-set*

This option is specified on the PROC statement, and writes the sliding spans results to the specified output data set. The OUTSPAN data set contains the following variables.

- A1, a numeric variable that is a copy of the original series truncated to the current span. Note that overlapping spans will contain identical values for this variable.
- C18, a numeric variable that contains the Trading Day Factors for the seasonal adjustment for the current span.
- D10, a numeric variable that contains the Seasonal Factors for the seasonal adjustment for the current span.
- D11, a numeric variable that contains the Seasonally Adjusted Series for the current span.
- DATE, a numeric variable that contains the date within the current span.
- SPAN, a numeric variable that contains the current span. The first span is the earliest span, i.e., the one with the earliest begin date.
- VARNAME, a character variable containing the name of each variable in the VAR list. A separate sliding spans analysis is performed on each variable in the VAR list.

OUTSTB= Data Set

The output data set produced by the OUTSTB= option of the PROC X11 statement contains the information in the analysis of variance on table D8 (Final Unmodified

S-I Ratios). This analysis of variance, following table D8 in the printed output, tests for stable seasonality (refer to U.S. Bureau of the Census, 1967, Appendix A). The variables in this data are:

- VARNAME, a character variable containing the name of each variable in the VAR list.
- TABLE, a character variable specifying the table from which the analysis of variance is performed. When ARIMA processing is requested, and two passes of X11 are required (when TDREGR=PRINT, TEST, or ADJUST), Table D8 and the stable seasonality test are computed twice; once in the initial pass, then again in the final pass. Both of these computations are put in the OUTSTB data set and are identified by D18.1 or D18.2 respectively.
- SOURCE, a character variable corresponding to the "source" column in the Analysis of Variance table following Table D8.
- SS, a numeric variable containing the sum of squares associated with the corresponding source term.
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term.
- MS, a numeric variable containing the mean square associated with the corresponding source term. MS is missing for the source term "Total."
- F, a numeric variable containing the F statistic for the "Between" source term. F will be missing for all other source terms.
- PROBF, a numeric variable containing the significance level for the F statistic. PROBF is missing for the source term "Total" and "Error."

OUTTDR= Data Set

The trading-day regression results (tables B15 and C15) are written to the OUTTDR= data set, which contains the following variables:

- VARNAME, a character variable containing the name of the VAR variable being processed.
- TABLE, a character variable containing the name of the table. It can only have values B15 (Preliminary Trading-Day Regression) or C15 (Final Trading-Day Regression).
- _TYPE_, a character variable whose value distinguishes the three distinct table format types. These types are (a) the regression, (b) the listing of the standard error associated with length-of-month, and (c) the Analysis of Variance. The first seven observations in the OUTTDR data set correspond to the regression on days of the week, thus the _TYPE_ variable is given the value "REGRESS" (day-of-week regression coefficient). The next four observations correspond to 31, 30, 29, and 28 day months and are given the value _TYPE_ = LOM_STD (length-of-month standard errors). Finally the last three observations correspond to the Analysis of Variance table, and _TYPE_ = ANOVA.

- PARM, a character variable, further identifying the nature of the observation. PARM is set to blank for the three _TYPE_ = ANOVA observations.
- SOURCE, a character variable containing the source in the regression. This variable is missing for all _TYPE_ = REGRESS and LOM_STD.
- CWGT, a numeric variable containing the combined trading-day weight (prior weight + weight found from regression). The variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA .
- PRWGT, a numeric variable containing the prior weight. The prior weight is 1.0 if PDWEIGHTS are not specified. This variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA .
- COEFF, a numeric variable containing the calculated regression coefficient for the given day. This variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA .
- STDERR, a numeric variable containing the standard errors. For observations with _TYPE_ = REGRESS, this is the standard error corresponding to the regression coefficient. For observations with _TYPE_ = LOM_STD, this is standard error for the corresponding length-of-month. This variable is missing for all _TYPE_ = ANOVA .
- T1, a numeric variable containing the *t*-statistic corresponding to the test that the combined weight is different from the prior weight. This variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA .
- T2, a numeric variable containing the *t*-statistic corresponding to the test that the combined weight is different from 1.0 . This variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA.
- PROBT1, a numeric variable containing the significance level for *t*-statistic T1. The variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA.
- PROBT2, a numeric variable containing the significance level for *t*-statistic T2. The variable is missing for all _TYPE_ = LOM_STD and _TYPE_ = ANOVA .
- SS, a numeric variable containing the sum of squares associated with the corresponding source term. This variable is missing for all _TYPE_ = REGRESS and LOM_STD.
- DF, a numeric variable containing the degrees of freedom associated with the corresponding source term. This variable is missing for all _TYPE_ = REGRESS and LOM_STD.
- MS, a numeric variable containing the mean square associated with the corresponding source term. This variable is missing for the source term Total and for all _TYPE_ = REGRESS and LOM_STD.
- F, a numeric variable containing the F statistic for the Regression source term. The variable is missing for the source terms Total and Error, and for all _TYPE_ = REGRESS and LOM_STD.

- PROBF, a numeric variable containing the significance level for the F statistic. This variable is missing for the source term Total and Error and for all _TYPE_ = REGRESS and LOM_STD.

Printed Output

The output from PROC X11, both printed tables and the series written to the OUT= data set, depends on whether the data is monthly or quarterly. For the printed tables, the output depends further on the value of the PRINTOUT= option and the TABLE statement, along with other options specified.

The printed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X11 procedure are as follows.

A	prior adjustments (optional)
B	preliminary estimates of irregular component weights and regression trading-day factors
C	final estimates of irregular component weights and regression trading-day factors
D	final estimates of seasonal, trend cycle, and irregular components
E	analytical tables
F	summary measures
G	charts

Table 31.3 describes the individual tables and charts. Most tables apply both to quarterly and monthly series. Those that apply only to a monthly time series are indicated by an "M" in the notes section, while "P" indicates the table is not a time series, and is only printed, not output to the OUT= data set.

Table 31.3. Table Names and Descriptions

Table	Description	Notes
A1	original series	M
A2	prior monthly adjustment factors	M
A3	original series adjusted for prior monthly factors	M
A4	prior trading-day adjustments	M
A5	prior adjusted or original series	M
A13	ARIMA forecasts	
A14	ARIMA backcasts	
A15	prior adjusted or original series extended by arima backcasts, forecasts	
B1	prior adjusted or original series	
B2	trend cycle	
B3	unmodified seasonal-irregular (S-I) ratios	
B4	replacement values for extreme S-I ratios	
B5	seasonal factors	

Table 31.3. (continued)

Table	Description	Notes
B6	seasonally adjusted series	
B7	trend cycle	
B8	unmodified S-I ratios	
B9	replacement values for extreme S-I ratios	
B10	seasonal factors	
B11	seasonally adjusted series	
B13	irregular series	
B14	extreme irregular values excluded from trading-day regression	M
B15	preliminary trading-day regression	M,P
B16	trading-day adjustment factors	M
B17	preliminary weights for irregular components	
B18	trading-day factors derived from combined daily weights	M
B19	original series adjusted for trading-day and prior variation	M
C1	original series modified by preliminary weights and adjusted for trading-day and prior variation	
C2	trend cycle	
C4	modified S-I ratios	
C5	seasonal factors	
C6	seasonally adjusted series	
C7	trend cycle	
C9	modified S-I ratios	
C10	seasonal factors	
C11	seasonally adjusted series	
C13	irregular series	
C14	extreme irregular values excluded from trading-day regression	M
C15	final trading-day regression	M,P
C16	final trading-day adjustment factors derived from regression coefficients	M
C17	final weight for irregular components	
C18	final trading-day factors derived from combined daily weights	M
C19	original series adjusted for trading-day and prior variation	M
D1	original series modified for final weights and adjusted for trading-day and prior variation	
D2	trend cycle	
D4	modified S-I ratios	
D5	seasonal factors	
D6	seasonally adjusted series	
D7	trend cycle	
D8	final unmodified S-I ratios	
D9	final replacement values for extreme S-I ratios	
D10	final seasonal factors	
D11	final seasonally adjusted series	
D12	final trend cycle	
D13	final irregular series	
E1	original series with outliers replaced	

Table 31.3. (continued)

Table	Description	Notes
E2	modified seasonally adjusted series	
E3	modified irregular series	
E4	ratios of annual totals	P
E5	percent changes in original series	
E6	percent changes in final seasonally adjusted series	
F1	MCD moving average	
F2	summary measures	P
G1	chart of final seasonally adjusted series and trend cycle	P
G2	chart of S-I ratios with extremes, S-I ratios without extremes, and final seasonal factors	P
G3	chart of S-I ratios with extremes, S-I ratios without extremes, and final seasonal factors in calendar order	P
G4	chart of final irregular and final modified irregular series	P

The PRINTOUT= Option

The PRINTOUT= option controls printing for groups of tables. See the "TABLES Statement" in this chapter for details on specifying individual tables. The following list gives the tables printed for each value of the PRINTOUT= option.

STANDARD (26 tables)	A1-A4, B1, C13-C19, D8-D13, E1-E6, F1, F2.
LONG (40 tables)	A1-A5, A13-A15, B1, B2, B7, B10, B13-B15, C1, C7, C10, C13-C19, D1, D7-D11, D13, E1-E6, F1, F2.
FULL (62 tables)	A1-A5, A13-A15, B1-B11, B13-B19, C1-C11, C13-C19, D1, D2, D4-D12, E1-E6, F1, F2.

The actual number of tables printed depends on the options and statements specified. If a table is not computed, it is not printed. For example, if TDREGR=NONE is specified, none of the tables associated with the trading-day are printed.

The CHARTS= Option

Of the four charts listed in Table 31.3, G1 and G2 are printed by default (CHARTS=STANDARD). Charts G3 and G4 are printed when CHARTS=FULL is specified. See the "TABLES Statement" later in this chapter for details in specifying individual charts.

Stable, Moving and Combined Seasonality Tests on the Final Unmodified SI Ratios (Table D8)

Past releases of PROC X11 printed the "Stable Seasonality Test" after Table D8. Two additional tests have been added and are printed the just after the "Stable Seasonality Test". The motivation, interpretation, and statistical details of all these tests are now given.

Motivation

The seasonal component of this time series, S_t, is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality).

To determine if stable seasonality if present in a series, PROC X11 computes a one-way analysis of variance using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use since the removal of the trend-cycle is equivalent to detrending. PROC X11 prints this test, labeled "Stable Seasonality Test" immediately after the Table D8. This test has not changed from previous releases.

The X11 seasonal adjustment method allows for slowing evolving seasonality. PROC X11 now computes and prints a test for seasonality when it is evolving or moving. The test is a two-way analysis of variance using months (or quarters) and years. As in the "Stable Seasonality Test", this analysis of variance is performed on the Final Unmodified SI Ratios (Table D8). PROC X11 prints this test, labeled "Moving Seasonality Test" after the "Stable Seasonality Test".

The final new test that PROC X11 computes is a combined or joint test of both stable and moving seasonality. This test combines the two F-tests previously described, along with the Kruskal-Wallis Chi-squared test for the stable seasonality to determine "identifiable" seasonality. This test, labeled "Combined Test for the Presence of Identifiable Seasonality", is printed after the "Moving Seasonality Test".

Interpretation and Statistical Details

The "Stable Seasonality Test" is a one-way analysis of variance on the "Final Unmodified SI Ratios" with seasons (months or quarters) as the factor.

To determine if stable seasonality if present in a series, PROC X11 computes a one-way analysis of variance using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use since the removal of the similar to detrending.

A large F and small significance level is evidence that a significant amount of variation in the SI-ratios is due to months or quarters, which in turn is evidence of seasonality; the null hypothesis of no month/quarter effect is rejected.

Conversely, a small F and large significance level (close to 1.0) is evidence that variation due to month or quarter could be due random error and the null hypothesis of no month/quarter effect is not rejected. The interpretation and utility of seasonal adjustment is problematical under such conditions.

The F-test for moving seasonality is performed by a two-way analysis of variance. The two factors are seasons (months or quarters) and years. The years effect is tested separately; the null hypothesis is no effect due to years after accounting for variation due to months or quarters.)

The significance level reported in both the moving and stable seasonality test is only approximate. Table D8, the Final Unmodified SI Ratios is constructed from an averaging operation which induces a correlation in the residuals from which which the F-test is computed. Hence the computed F-statistic differs from an exact F; see Cleveland and Devlin, 1980 for details.

The test for identifiable seasonality is performed by combining the F-tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The description below is based on Dagum, (1980); for further details, see Lothian and Morry, 1978b.

Let F_s and F_m denote the F-value for the stable and moving seasonality tests respectively. The combined test is performed as follows.

1) If the null hypothesis in the moving seasonality tests is not rejected at the 0.10 % level (one thousandths percent), the seasonality is not identifiable.

2) If the null hypothesis in 1) is rejected, but the moving seasonality null hypothesis is not rejected at the 5.0% level, then compute the following quantities:

$$T_1 = \frac{7}{F_m - F_s},$$

$$T_2 = \frac{3F_m}{F_s}.$$

Let T denote the simple average of T_1 and T_2:

$$T = \frac{(T_1 + T_2)}{2};$$

if $T \geq 1.0$, the null hypothesis of identifiable seasonality *not* present is accepted.

3) If the moving seasonality f-test based on F_M passes, but one of the two statistics based on the T's fails, or the Kruskal-Wallis Chi-squared test fails at the 1% level, the then PROC X11 prints "Identifiable Seasonality Probably Present"

4) If the F_S, F_M and the Kruskal-Wallis Chi-squared test pass, then the null hypothesis (of identifiable seasonality *not* present if rejected, and PROC X11 prints "Identifiable Seasonality Present".

Tables Written to the OUT= data set

All tables that are time series can be written to the OUT= data set. However, depending on the specified options and statements, not all tables are computed. When a table is not computed, but is requested in the OUTPUT statement, the resulting variable has all missing values.

For example, if the PMFACTOR= option is not specified, table A2 is not computed, and requesting this table in the OUTPUT statement results in the corresponding variable having all missing values.

The trading-day regression results, tables B15 and C15, although not written to the OUT= data set, can be written to an output data set; see the "OUTTDR=" option for details.

Printed Output Generated by Sliding Spans Analysis

Table S 0.A

Table S 0.A gives the variable name, the length and number of spans, and the beginning and ending dates of each span.

Table S 0.B

Table S 0.B gives the summary of the two f-tests performed during the standard X11 seasonal adjustments for stable and moving seasonality on table D8, the final SI ratios. These tests are described in "Printed Output" in the "PROC X11" chapter.

Table S 1.A

Table S 1.A gives the range analysis of seasonal factors. This includes the means for each month (or quarter) within a span, the maximum percent difference across spans for each month and the average. The minimum and maximum within a span is also indicated.

For example, for a monthly series and an analysis with four spans, the January row would contain a column for each span, with the value representing the average seasonal factor (Table D10) over all January calendar months occurring within the span. Beside each span column is a character column with either a MIN, MAX or blank value, indicating which calendar month had the minimum and maximum value over that span.

Denote the average over the j-th calendar month in span k, k=1,..,4 by $\bar{S}_j$(k); then the maximum percent difference (MPD) for month j is defined by

$$MPD_j = \frac{max_{k=1,..,4}\bar{S}_j(k) - min_{k=1,..,4}\bar{S}_j(k)}{min_{k=1,..,4}\bar{S}_j(k)}$$

The last numeric column of Table S 1.A is the average value over all spans for each calendar month, with the minimum and maximum row flagged as in the span columns.

Table S 1.B

Table S 1.B gives a summary of range measures for each span. The first column, Range Means, is calculated by computing the maximum and minimum over all months or quarters in a span, the taking the difference. The next column is the range ratio means, which is simply the ratio of the previously described maximum and minimum. The next two columns are the minimum and maximum seasonal factors over the entire span, while the range sf column is the difference of these. Finally, the last column is the ratio of the Max SF and Min SF columns.

Breakdown Tables

Table S 2.A.1 begins the breakdown analysis for the various series considered in the sliding spans analysis. The key concept here is the MPD described in the Introduction and in "Computational Details" above. For a month or quarter that appears in two or more spans, the maximum percent difference is computed and tested against a cutoff level. If it exceeds this cutoff, it is counted as an instance of exceeding the level. It is of interest to see if such instances fall disproportionately in certain months and years. Tables S 2.A.1 - S 6.A.3 display this breakdown for all series considered.

Table S 2.A.1

Table S 2.A.1 gives the monthly (quarterly) breakdown for the seasonal factors (table D10). The first column identifies the month or quarter. The next column is the number of times the MPD for D10 exceeded 3.0%, followed by the total count. The last is the average maximum percentage difference for the corresponding month or quarter.

Table S 2.A.2

Table S 2.A.2 gives the same information as Table S 2.A.1, but on a yearly basis.

Table S 2.A.3

The description of Table S 2.A.3 requires the definition of "Sign Change" and "Turning Point".

First, some motivation. Recall that for a highly stable series, adding or deleting a small number of observations should not affect the estimation of the various components of a seasonal adjustment procedure.

Consider Table D10, the seasonal factors in a sliding spans analysis that uses 4 spans. For a given observation t, looking across the 4 spans, we can easily pick out large differences if they occur. More subtle differences can occur when estimates go from above to below (or vice versa) a base level. In the case of multiplicative model, the seasonal factors have a base level of 100.0. So it is useful to enumerate those instances where both a large change occurs (an MPD value exceeding 3.0%) and a change of sign (with respect to the base) occur.

Let B denote the base value (which in general depends on the component being considered and the model type, multiplicative or additive). If, for span 1, $S_t(1)$ is below B (i.e., $S_t(1)$-B is negative) and for some subsequent span k, $S_t(k)$ is above B (i.e., $S_t(k)$-B is positive), then an positive "Change in Sign" has occurred at observation t. Similarly, if, for span 1, $S_t(1)$ is above B, and for some subsequent span k, $S_t(k)$ is below B, then a negative "Change in Sign" has occurred. Both cases, positive or negative, constitute a "Change in Sign"; the actual direction indicated in tables S 7.A-S 7.E, which will be described below.

Another behavior of interest occurs when component estimates increase then decrease (or vice versa) across spans for a given observation. Using the example above, the seasonal factors at observation t could first increase, then decrease across the 4 spans.

This behavior, combined with an MPD exceeding the level is of interest in questions of stability.

Again, consider Table D10, the seasonal factors in a sliding spans analysis that uses 4 spans. For a given observation t, (containing at least three spans), note the level of D10 for the first span. Continue across the spans until a difference of 1.0% or greater occurs (or no more spans are left), noting whether the difference is up or down. If the difference is up, continue until a difference of 1.0% or greater occurs downward (or no more spans are left). If such an up-down combination occurs, the observation is counted as an up-down turning point. A similar description occurs for a down-up turning point. Tables S 7.A-S 7.E, described below, show the occurrence of turning points, indicating whether up-down or down-up. Note that it requires at least three spans to test for a turning point. Hence Tables S 2.A.3 - S 6.A.3 show a reduced number in the "Turning Point" row for the "Total Tested" column, and in Tables S 7.A - S 7.E, the turning points symbols can only occur where three or more spans overlap.

With these descriptions of sign change and turning point, we now describe Table S 2.A.3. The first column gives the type or category, the second gives the total number of observations falling into the category, the third column gives the total number tested, and the last column gives the percentage for the number found in the category.

The first category (row) of the table is for flagged observations, i.e., those observations where the MPD exceeded the appropriate cutoff level (3.0% is default for the seasonal factors.) The second category is for level changes, while the third category is for turning points. The fourth category is for flagged sign changes, i.e., for those observations that are sign changes, how many are also flagged. Note the total tested column for this category equals the number found for sign change, reflecting the definition of the fourth category.

The fifth column is for flagged turning points, i.e., for those observations that are turning points, how many are also flagged.

The footnote to Table S 2.A.3 gives the Census Bureau recommendation for thresholds, as described in "Computational Details" earlier in this section.

Table S 2.B

Table S 2.B gives the histogram of flagged for seasonal factors (Table D10) using the appropriate cutoff value (default 3.0%). This table looks at the spread of the number of times the MPD exceeded the corresponding level. The range is divided up into four intervals: 3.0%-4.0%, 4.0%-5.0%, 5.0%-6.0% and greater than 6.0%. The first column shows the symbol used in table S 7.A; the second column gives the range in interval notation, and the last column gives the number found in the corresponding interval. Note that the sum of the last column should agree with the "Number Found" column of the "Flagged MPD" row in Table S 2.A.3.

Table S 2.C

Table S 2.C gives selected percentiles for the MPD for the seasonal factors (Table D10).

Tables S 3.A.1 - S 3.A.3

These table relate to the Trading Day Factors (Table C18), and follow the same format as Tables S 2.A.1-S 2.A.3. The only difference between these tables and S 2.A.1-S 2.A.3 is the default cutoff value of 2.0% instead of the 3.0% used for the Seasonal Factors.

Tables S 3.B, S 3.C

These tables, applied to the Trading Day Factors (Table C18), are the same format as tables S 2.B - S 2.C. The default cutoff value is different, with corresponding differences in the intervals in S 3.B.

Tables S 4.A.1 - S 4.A.3

These table relate to the Seasonally Adjusted Series (Table D11), and follow the same format as Tables S 2.A.1-S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 4.B, S 4.C

These tables, applied to the Seasonally Adjusted Series (Table D11) are the same format as tables S 2.B - S 2.C.

Tables S 5.A.1 - S 5.A.3

These table relate to the Month-to-Month (or Quarterly-to-Quarterly) differences in the Seasonally Adjusted Series, and follow the same format as Tables S 2.A.1-S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 5.B, S 5.C

These tables, applied to the Month-to-Month (or Quarterly-to-Quarterly) differences in the Seasonally Adjusted Series, are the same format as tables S 2.B - S 2.C. The same default cutoff value of 3.0% is used.

Tables S 6.A.1 - S 6.A.3

These table relate to the Year-to-Year differences in the Seasonally Adjusted Series, and follow the same format as Tables S 2.A.1-S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 6.B, S 6.C

These tables, applied to the Year-to-Year differences in the Seasonally Adjusted Series, are the same format as tables S 2.B - S 2.C. The same default cutoff value of 3.0% is used.

Table S 7.A

Table S 7.A gives the entire listing of the Seasonal Factors (Table D10) for each span. The first column gives the date for each observation included in the spans. Note that the dates do not cover the entire original data set. Only those observations included in one or more spans are listed.

The next N columns (where N is the number of spans) are the individual spans starting at the earliest span. The span columns are labeled by their beginning and ending dates.

Following the last span is the "Sign Change" column. As explained in the description of Table S 2.A.3, a sign change occurs at a given observation when the seasonal factor estimates go from above to below, or below to above, a base level. For the seasonal factors, 100.0 is the base level for the multiplicative model, 0.0 for the additive model. A blank value indicates no sign change, a "U" indicates a movement "upwards" from the base level and a "D" indicates a movement "downwards" from the base level.

The next column is the "Turning Point" column. As explained in the description of Table S 2.A.3, a turning point occurs when there is an upward then downward movement, or downward then upward movement of sufficient magnitude. A blank value indicates no turning point, a "U-D" indicates a movement "upwards then downwards" and a "D-U" indicates a movement "downwards then upwards".

The next column is the maximum percent difference (MPD). This quantity, described in "Computational Details" above, is the main computation for sliding spans analysis. A measure of how extreme the MPD value is given in the last column, the "Level of Excess" column. The symbols used and their meaning is described in Table S 2.A.3. If a given observation has exceeded the cutoff, the level of excess column is blank.

Table S 7.B

Table S 7.B gives the entire listing of the Trading Day Factors (Table C18) for each span. The format of this table is exactly like Table S 7.A.

Table S 7.C

Table S 7.C gives the entire listing of the Seasonally Adjusted Data (Table D11) for each span. The format of this table is exactly like Table S 7.A except for the "Sign Change" column, which is not printed. The Seasonally Adjusted Data has the same units as the original data; there is no natural base level as in the case of a percentage. Hence the sign change is not appropriate for D11.

Table S 7.D

Table S 7.D gives the entire listing of the Month-to-Month (or Quarter-to-Quarter) Changes in Seasonally Adjusted Data for each span. The format of this table is exactly like Table S 7.A.

Table S 7.E

Table S 7.E gives the entire listing of the Year-to-Year Changes in Seasonally Adjusted Data for each span. The format of this table is exactly like Table S 7.A.

Printed Output from the ARIMA Statement

The information printed by default for the ARIMA model includes the parameter estimates, their approximate standard errors, t ratios, and variances, the standard deviation of the error term, and the AIC and SBC statistics for the model. In addition, a criteria summary for the chosen model is given that shows the values for each of the three test criteria and the corresponding critical values.

If the PRINTALL option is specified, a summary of the Nonlinear Estimation Optimization and a table of Box-Ljung Statistics is also produced. If the automatic model selection is used, this information is printed for each of the five predefined models. Lastly, a Model Selection Summary is printed, showing the final model chosen.

ODS Table Names

PROC X11 assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 8, “Using the Output Delivery System.”

Note: For monthly and quarterly tables use the ODSNAME MonthlyTables and QuarterlyTables; For brevity, only the MonthlyTables are listed here; the QuarterlyTables are simply duplicates. Printing of individual tables can be specified by using the TABLES table_name which is not listed here. Printing groups of tables is specified in the MONTHLY and QUARTERLY statements by specifying the option PRINTOUT=NONE|STANDARD|LONG|FULL. The default is PRINTOUT=STANDARD.

Examples

Example 31.1. Component Estimation - Monthly Data

This example computes and plots the final estimates of the individual components for a monthly series. In the first plot, Output 31.1.1 an overlaid plot of the original and seasonally adjusted data is produced. The trend in the data is more evident in the seasonally adjusted data than in the original data. This trend is even more clear in Output 31.1.3, the plot of Table D12, the trend cycle. Note that both the seasonal factors and the irregular factors vary around 100, while the trend cycle and the seasonally adjusted data are in the scale of the original data.

From Output 31.1.2 the seasonal component appears to be slowly increasing, while no apparent pattern exists for the irregular series in Output 31.1.4.

Example 31.3. Outlier Detection and Removal

PROC X11 can be used to detect and replace outliers in the irregular component of a monthly or quarterly series.

The weighting scheme used in measuring the "extremeness" of the irregulars is developed iteratively; thus the statistical properties of the outlier adjustment method are unknown.

In this example, the data is simulated by generating a trend plus a random error. Two periods in the series were made "extreme" by multiplying one generated value by 2.0 and another by 0.10. The additive model is appropriate based on the way the data was generated. Note that the trend in the generated data was modeled automatically by the trend cycle component estimation.

The detection of outliers is accomplished by considering table D9, the final replacement values for extreme S-I ratios. This table indicates which observations had irregular component values more than FULLWEIGHT= standard deviation units from 0.0 (1.0 for the multiplicative model). The default value of the FULLWEIGHT= option is 1.5; a larger value would result in fewer observations being declared extreme.

In this example, FULLWEIGHT=3.0 is used to isolate the extreme inflated and deflated values generated in the data step. The value of ZEROWEIGHT= must be greater than FULLWEIGHT; it is given a value of 3.5.

A plot of the original and modified series, Output 31.3.2, shows that the deviation from the trend line for the modified series is greatly reduced compared with the original series.

```
data a;
   retain seed 99831;
   do kk = 1 to 48;
      x = kk + 100 + rannor( seed );
      date = intnx( 'month', '01jan1970'd, kk-1 );
      if kk = 20 then x = 2 * x;
      else if kk = 30 then x = x / 10;
      output;
      end;

Chapter 32 The X12 Procedure

Overview

The X12 procedure, an adaptation of the U.S. Bureau of the Census X-12-ARIMA Seasonal Adjustment program (U.S. Bureau of the Census 2001c), seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X-12-ARIMA program combines the capabilities of the X-11 program (Shiskin, Young, and Musgrave 1967) and the X-11-ARIMA/88 program (Dagum 1988) and also introduces some new features (Findley et al. 1998). One of the main enhancements involves the use of a regARIMA model, a regression model with ARIMA (autoregressive integrated moving average) errors. Thus, the X-12-ARIMA program contains methods developed by both the U.S. Census Bureau and Statistics Canada. In addition, the X-12-ARIMA automatic modeling routine is based on the TRAMO (Time series Regression with ARIMA noise, Missing values, and Outliers) method (Gomez and Maravall 1997a;b). The four major components of the X-12-ARIMA program are regARIMA modeling, model diagnostics, seasonal adjustment using enhanced X-11 methodology, and post-adjustment diagnostics. Statistics Canada's X-11 method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, O_t, t = 1, $\ldots$,n, and separated from trend-cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, S_t, is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend-cycle component, C_t, includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, D_t, is the variation that can be attributed to the composition of the calendar. The irregular component, I_t, is the residual variation. Many economic time series are related in a multiplicative fashion ($O_t = S_t C_t D_t I_t$). Other economic series are related in an additive fashion ($O_t = S_t + C_t + D_t + I_t$). A seasonally adjusted time series, $C_t I_t$ or $C_t + I_t$, consists of only the trend-cycle and irregular components. For more details on seasonal adjustment with the X-11 method, refer to Ladiray and Quenneville (2001).

Experimental graphics are now available with the X12 procedure. For more information, see the "ODS Graphics" section on page 1951.

Getting Started

The most common use of the X12 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X12 to produce a seasonally adjusted series, C_tI_t, from an original series $O_t = S_tC_tD_tI_t$.

In the multiplicative model, the trend cycle component C_t keeps the same scale as the original series O_t, while S_t, D_t, and I_t vary around 1.0. In all displayed tables, these latter components are expressed as percentages and thus vary around 100.0 (in the additive case, they vary around 0.0). However, in the output data set, the data displayed as percentages will be expressed as the decimal equivalent and thus will vary around 1.0 in the multiplicative case.

The naming convention used in PROC X12 for the tables follows the convention used in the Census Bureau's X-12-ARIMA program; refer to *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b) and *X-12-ARIMA Quick Reference for Unix* (U.S. Bureau of the Census 2001a). Also see the "Displayed Output/ODS Table Names/OUTPUT Tablename Keywords" section on page 1949 later in this chapter. The table names are outlined in Table 32.7 on page 1950.

The tables corresponding to parts A through C are intermediate calculations. The final estimates of the individual components are found in the D tables: table D10 contains the final seasonal factors, table D12 contains the final trend cycle, and table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you need only to look at table D11, the final seasonally adjusted series. Tables in part E contain information regarding extreme values and changes in the original and seasonally adjusted series. The tables in part F are seasonal adjustment quality measures. Spectral analysis is performed in part G. For further information concerning the tables produced by the X11 statement, refer to Ladiray and Quenneville (2001).

Basic Seasonal Adjustment

Suppose that you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point, you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the PROC X12 statement and request seasonal adjustment in the X11 statement. The results of the seasonal adjustment are in table D11 (the final seasonally adjusted series) in the displayed output as shown in Figure 32.1.

```
data sales;
   set sashelp.air;
   sales = air;
```

```
      date = intnx( 'month', '01sep78'd, _n_-1 );
      format date monyy.;
   run ;

   proc x12 data=sales date=date;
      var sales;
      x11;
   run ;
```

```
                                 The X12 Procedure

                                     Min:   124.56  Max:   499.2
```

Figure 32.1. Basic Seasonal Adjustment

You can compare the original series (table A1) and the final seasonally adjusted series (table D11) by plotting them together as shown in Figure 32.2. These tables are requested in the OUTPUT statement and are written to the OUT= data set. Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

```
proc x12 data=sales date=date;
   var sales;
   x11;
   output out=out a1 d11;
run ;

axis1 label=none;
axis2 label=none;
symbol1 i=join v='star' c=red;
symbol2 i=join v='circle' c=blue;
legend1 label=none value=('original' 'adjusted');

proc gplot data=out;
   plot sales_A1    * date = 1
        sales_D11   * date = 2
      / overlay legend=legend1 haxis=axis1 vaxis=axis2;
run;
```

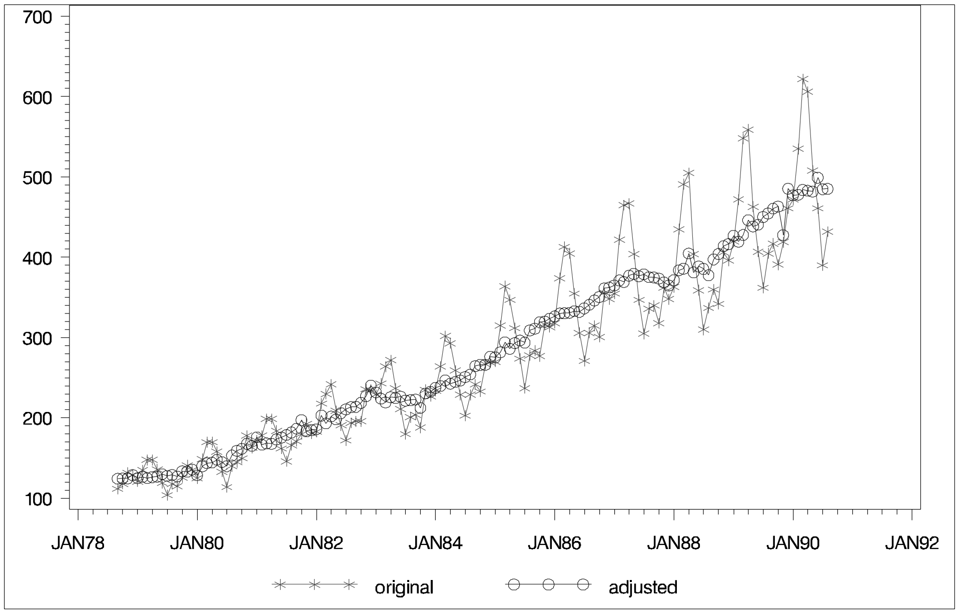

Figure 32.2. Plot of Original and Seasonally Adjusted Data

Syntax

The X12 procedure uses the following statements:

PROC X12 *options*;
  VAR *variables*;
  BY *variables*;
  ID *variables*;
  TRANSFORM *options*;
  IDENTIFY *options*;
  AUTOMDL *options*;
  OUTLIER *options*;
  REGRESSION *options*;
  ARIMA *options*;
  ESTIMATE *options*;
  X11 *options*;
  FORECAST *options*;
  OUTPUT *options*;

The PROC X12 statements perform basically the same function as the Census Bureau's X-12-ARIMA specs. *Specs* or specifications are used in X-12-ARIMA to control the computations and output. The PROC X12 statement performs some of the same functions as the Series spec in the Census Bureau's X-12-ARIMA software. The TRANSFORM, IDENTIFY, AUTOMDL, OUTLIER, REGRESSION, ARIMA, ESTIMATE, X11, and FORECAST statements are designed to perform the same functions as the corresponding X-12-ARIMA *specs*, although full compatibility is not yet available. The Census Bureau documentation *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b) can provide added insight to the functionality of these statements.

Functional Summary

The following table outlines the options available for the X12 procedure classified by function.

Description	Statement	Option
Data Set Options		
specify input data set	PROC X12	DATA=
write table values to an output data set	OUTPUT	OUT=
Printing Control Options		
suppress all printed output	PROC X12	NOPRINT

Description	Statement	Option
Date Information Options		
specify the date variable	PROC X12	DATE=
specify the date of the first observation	PROC X12	START=
specify the beginning date of the subset	PROC X12	SPAN=(mmmyy)
	PROC X12	SPAN=('yyQq')
specify the ending date of the subset	PROC X12	SPAN=(, mmmyy)
	PROC X12	SPAN=(, 'yyQq')
specify monthly time series	PROC X12	INTERVAL=MONTH
specify monthly time series	PROC X12	SEASONS=12
specify quarterly time series	PROC X12	INTERVAL=QTR
specify quarterly time series	PROC X12	SEASONS= 4
Declaring the Role of Variables		
specify BY-group processing	BY	
specify identifying variables	ID	
specify the variables to be seasonally adjusted	VAR	
Controlling the Table Computations		
transform or prior adjust the series	TRANSFORM	FUNCTION=
transform or prior adjust the series	TRANSFORM	POWER=
use differencing to identify the ARIMA part of the model	IDENTIFY	
use X-12-ARIMA TRAMO-based method to choose a model	AUTOMDL	
specify automatic outlier detection	OUTLIER	
specify regression information	REGRESSION	PREDEFINED=
specify the ARIMA part of the model	ARIMA	MODEL=
estimate the regARIMA model specified by the REGRESSION and ARIMA statements	ESTIMATE	
specify seasonal adjustment	X11	
specify the number of forecasts	FORECAST	LEAD=

PROC X12 Statement

PROC X12 *options;*

The PROC X12 statement provides information about the time series to be processed by PROC X12. Either the START= or the DATE= option must be specified.

The original series is displayed in table A1. If there are missing values in the original series, and a regARIMA model is specified or automatically selected, then table MV1 is displayed. Table MV1 contains the original series with missing values replaced by the predicted values from the fitted model. Table B1 will be displayed when the original data is altered, for example, through an ARIMA model estimation, prior adjustment factors, an irregular regression, or the series is extended with forecasts.

Although the X-12-ARIMA method will handle missing values, there are some restrictions. In order for Proc X12 to process the series, no month or quarter may contain missing values for all years. For instance, if the third quarter contained only missing values for all years, then processing will be skipped for that series. In addition, if more than half the values for a month or a quarter are missing, then a warning message will be displayed in the log file, and other errors may occur later in processing. If a series contains many missing values, the user should consider other methods of missing value replacement.

The following options can appear in the PROC X12 statement.

DATA= *SAS-data-set*
specifies the input SAS data set used. If this option is omitted, the most recently created SAS data set is used.

DATE= *variable*
DATEVAR= *variable*
specifies a variable that gives the date for each observation. Unless specified in the SPAN= option, the starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS datetime values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly in ascending order. If the INTERVAL= or SEASONS= option is specified, its values must agree with the values of the date variable. If neither the INTERVAL= or SEASONS= option is specified, then the procedure tries to determine the type of data from the values of the date variable. This variable is automatically added to the OUTPUT= data set if one is requested and is extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

START= *mmmyy*
START= *'yyQq'*
STARTDATE= *mmmyy*
STARTDATE= *'yyQq'*
gives the date of the first observation. Unless the SPAN= option is used, the starting and ending dates are the dates of the first and last observations, respectively. Either this option or the DATE= option is required. When using this option, use either the INTERVAL= or SEASONS= option to specify monthly or quarterly data. If neither the INTERVAL= or SEASONS= is present, monthly data are assumed. Note that for a quarterly date, the specification must be enclosed in quotes. A 4-digit year can be specified, but if a 2-digit year is given, the value specified in the YEARCUTOFF= SAS system option applies. When using this option with BY processing, the start date will be applied to the first observation in each BY group.

SPAN= (*mmmyy*,*mmmyy***)**
SPAN= (*'yyQq'*,*'yyQq'***)**
gives the dates of the first and last observations to define a subset for processing. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(,*mmmyy*). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set is assumed. A 4-digit year can be specified, but if a 2-digit year is given, the value specified in the YEARCUTOFF= SAS system option applies.

INTERVAL= *interval*

specifies the frequency of the input time series. If the input data consist of quarterly observations, then INTERVAL=QTR should be used. If the input data consist of monthly observations, then INTERVAL=MONTH should be used. If the INTERVAL= option is not specified and SEASONS=4, then INTERVAL=QTR is assumed; likewise, SEASONS=12 implies INTERVAL=MONTH. If both are used, the values should not be conflicting. If neither the INTERVAL= nor SEASONS= option is specified and the START= option is specified, then the data are assumed to be monthly. If a date variable is specified using the DATE= option, it is not necessary to specify the INTERVAL= or SEASONS= option; however, if specified, the values of the INTERVAL= or SEASONS= option should not be in conflict with the values of the date variable.

SEASONS= *period*

specifies the number of observations in a seasonal cycle. If the SEASONS= option is not specified and INTERVAL=QTR, then SEASONS=4 is assumed. If the SEASONS= option is not specified and INTERVAL=MONTH, then SEASONS=12 is assumed. If the SEASONS= option is specified, its value should not conflict with the values of the INTERVAL= option or the values of the date variable. See the preceding descriptions for the START=, DATE=, and INTERVAL= options for more details.

NOTRIMMISS

By default leading and trailing missing values are trimmed from the series. NOTRIMMISS suppresses the default. If NOTRIMMISS is used, Proc X12 will automatically generate missing value regressors for any missing value within the span of the series, including leading and trailing missing values.

NOPRINT

suppresses any printed output.

BY Statement

BY *variables;*

A BY statement can be used with PROC X12 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

ID Statement

ID *variables;*

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the Proc X12 statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from forecasting) are extrapolated, while all other ID variables are missing.

ARIMA Statement

ARIMA *options;*

The ARIMA statement specifies the ARIMA part of the regARIMA model. This statement defines a pure ARIMA model if the regression statement is omitted. The ARIMA part of the model can include multiplicative seasonal factors.

The following option can appear in the ARIMA statement.

MODEL= ((*p d q* **)(** *P D Q* **)** *s* **)**

specifies the ARIMA model. The format follows standard Box-Jenkins notation (Box, Jenkins, and Reinsel 1994). The nonseasonal AR and MA orders are given by *p* and *q*, respectively, while the seasonal AR and MA orders are given by *P* and *Q*. The number of differences and seasonal differences are given by *d* and *D*, respectively. The notation (*p d q*) and (*P D Q*) can also be specified as (*p*, *d*, *q*) and (*P*, *D*, *Q*). The maximum lag of any AR or MA parameter is 36. The maximum value of a difference order, *d* or *D*, is 144. All values for *p*, *d*, *q*, *P*, *D*, and *Q* should be nonnegative integers. The lag corresponding to seasonality is *s*. *s* should be a positive integer. If *s* is omitted, it is set equal to the value used in the PROC X12 SEASONS= statement.

For example,

```
proc x12 data=ICMETI seasons=12 start=jan1968;
   arima model=((2,1,1)(1,1,0));
```

specifies an ARIMA (2,1,1)(1,1,0)12 model.

ESTIMATE Statement

ESTIMATE *options;*

The ESTIMATE statement estimates the regARIMA model specified by the REGRESSION and ARIMA statements. Estimation output includes point estimates and standard errors for all estimated AR, MA, and regression parameters; the maximum likelihood estimate of the variance σ^2; *t* statistics for individual regression parameters; χ^2 statistics for assessing the joint significance of the parameters associated with certain regression effects (if included in the model); and likelihood-based model selection statistics (if the exact likelihood function is used). The regression effects for which χ^2 statistics are produced are fixed seasonal effects.

Tables displayed in association with estimation are Exact ARMA Likelihood Estimation Iteration Tolerances, Average absolute percentage error in within-sample forecasts:, ARMA Iteration History, AR/MA Roots, Exact ARMA Likelihood Estimation Iteration Summary, Regression Model Parameter Estimates, Chi-squared Tests for Groups of Regressors, Exact ARMA Maximum Likelihood Estimation, and Estimation Summary.

The following options can appear in the ESTIMATE statement.

MAXITER= *value*

Specifies the maximum number allowed of ARMA iterations (nonlinear iterations for estimating the AR and MA parameters). For models with regression variables, this limit applies to the total number of ARMA iterations over all IGLS iterations. For models without regression variables, this is the maximum number of iterations allowed for the single set of ARMA iterations The default is MAXITER=200.

TOL= *value*

Specifies the convergence tolerance for the nonlinear estimation. Absolute changes in the log-likelihood are compared to TOL to check convergence of the estimation iterations. For models with regression variables, TOL is used to check convergence of the IGLS iterations (where the regression parameters are reestimated for each new set of AR and MA parameters). For models without regression variables there are no IGLS iterations, and TOL is then used to check convergence of the nonlinear iterations used to estimate the AR and MA parameters. The default value is TOL=0.00001.

ITPRINT

Specifies that the Iterations History table will be displayed. This includes detailed output for estimation iterations, including log-likelihood values and parameters, and counts of function evaluations and iterations. It is useful to examine the Iterations History table when errors occur within estimation iterations. By default, only successful iterations are displayed, unless PRINTERR is specified. An unsuccessful iteration is an iteration which is restarted due to a problem such as a root inside the unit circle. Successful iterations will have a status of 0. If restarted iterations are displayed, a note at the end of the table will give definitions for status codes that indicate a restarted iteration. For restarted iterations, the number of function evaluations and the number of iterations will be -1, which will be displayed as missing. If regression parameters are included in the model, then both IGLS and ARMA iterations will be included in the table. The number of function evaluations is a cumulative total.

PRINTERR

Use of PRINTERR either causes restarted iterations to be included in the Iterations History table (if ITPRINT is specified), or creates the Restarted Iterations table (if ITPRINT is not specified). Whether or not PRINTERR is specified, a WARNING message will be printed to the log file if any iteration is restarted during estimation.

FORECAST Statement

FORECAST *options;*

The FORECAST statement is used to forecast the time series using the estimated model. The output contains point forecast and forecast statistics for the transformed and original series.

The following option can appear in the FORECAST statement.

LEAD= *value*

Specifies the number of periods ahead to forecast. The default is the number of periods in a year (4 or 12), and the maximum is 60.

Forecasts and Standard Errors Tables are displayed in association with the FORECAST statement. Confidence limits are also included. If the data is transformed, then two tables will be displayed, one table for the original data, and one table for the transformed data.

IDENTIFY Statement

IDENTIFY *options;*

The IDENTIFY statement must be used to produce plots of the sample Autocorrelation Functions (ACFs) and Partial Autocorrelation Functions (PACFs) for identifying the ARIMA part of a regARIMA model. Sample ACFs and PACFs are produced for all combinations of the nonseasonal and seasonal differences of the data specified by the DIFF and SDIFF options. If the REGRESSION statement is present, the ACFs and PACFs are calculated for the specified differences of a series of regression residuals. If the REGRESSION statement is not present, the ACFs and PACFs are calculated for the specified differences of the original data.

Tables printed in association with identification are “Autocorrelation of Model Residuals” and “Partial Autocorrelation of Model Residuals”. If the REGRESSION statement is present, then the “Regression Model Parameter Estimates” table will also be available.

The following options can appear in the IDENTIFY statement.

DIFF= *(order, order, order)*
specifies orders of nonseasonal differencing. The value 0 specifies no differencing, the value 1 specifies one nonseasonal difference $(1 - B)$, the value 2 specifies two nonseasonal differences $(1 - B)^2$, and so forth. The ACFs and PACFs are produced for all orders of nonseasonal differencing specified, in combination with all orders of seasonal differencing specified in the SDIFF= option. The default is DIFF=(0). You can specify up to three values for nonseasonal differences.

SDIFF= *(order, order, order)*
specifies orders of seasonal differencing. The value 0 specifies no seasonal differencing, the value 1 specifies one seasonal difference $(1 - B^s)$, the value 2 specifies two seasonal differences $(1 - B^s)^2$, and so forth. Here the value for *s* will correspond to the value of the SEASONS= option in the PROC X12 statement. The value of SEASONS= is supplied explicitly or is implicitly supplied through the INTERVAL= option or the values of the DATE= variable. The ACFs and PACFs are produced for all orders of seasonal differencing specified, in combination with all orders of nonseasonal differencing specified in the DIFF= option. The default is SDIFF=(0). You can specify up to three values for seasonal differences.

For example,

```
identify diff=(1) sdiff=(0, 1);
```

produces ACFs and PACFs for two models: $(1 - B)$ and $(1 - B)(1 - B^s)$.

PRINTREG
causes the "Regression Model Parameter Estimates" table to be printed if the REGRESSION statement is present. By default, the table is not printed.

AUTOMDL Statement

AUTOMDL *options;*

The AUTOMDL statement is used to invoke the automatic model selection procedure of the X-12-ARIMA method. This method is based largely on the TRAMO (Time series Regression with ARIMA noise, Missing values, and Outliers) method by Gomez and Maravall (1997a;b). If the AUTOMDL statement is used without the OUTLIER statement, then only missing values will be identified. If the AUTOMDL and the OUTLIER statements are used, then both missing values and outliers will be identified. If both the AUTOMDL statement and the ARIMA statement are present, the ARIMA statement will be ignored. The ARIMA statement specifies the model, while the AUTOMDL statement allows the X12 procedure to select the model.

When AUTOMDL is specified, the X12 procedure will compare a model selected using a TRAMO method to a default model. The TRAMO method is implemented first, and involves two parts: identifying the orders of differencing and identifying the ARIMA model. The table "ARIMA Estimates for Unit Root Identification" provides details regarding the identification of the orders of differencing, while "Results of Unit Root Test for Identifying Orders of Differencing" shows the orders of differencing selected by TRAMO. The table "Models estimated by Automatic ARIMA Model Selection procedure" provides details regarding the TRAMO automatic model selection, and the table "Best Five ARIMA Models Chosen by Automatic Modeling" ranks the best five models estimated using the TRAMO method. The next available table, "Comparison of Automatically Selected Model and Default Model," compares the model selected by the TRAMO method to a default model. At this point, if the Default Model is selected over the TRAMO model, Proc X12 will display a note. No note will be displayed if the TRAMO model is selected. Proc X12 will then perform checks for unit roots, overdifferencing, and insignificant ARMA coefficients. If the model is changed due to any of these tests, a note will be displayed. The last table, "Final Automatic Model Selection," shows the results of automatic model selection.

The following options can appear in the AUTOMDL statement.

MAXORDER= *(nonseasonal order, seasonal order)*
specifies the maximum orders of nonseasonal and seasonal ARMA polynomials for the automatic ARIMA model identification procedure. The maximum order for the nonseasonal ARMA parameters should be between 1 and 4; the maximum order for the seasonal ARMA should be 1 or 2.

DIFFORDER= *(nonseasonal order, seasonal order)*
specifies the fixed orders of differencing to be used in the automatic ARIMA model identification procedure. When DIFFORDER is used, only the AR and MA orders are automatically identified. Acceptable values for the regular differencing orders are 0, 1 and 2; acceptable values for the seasonal differencing orders are 0 and 1. If the MAXDIFF option is also specified, the DIFFORDER option will be ignored.

There are no default values for DIFFORDER. If neither the DIFFORDER nor the MAXDIFF option is specified, the default is MAXDIFF=(2,1).

MAXDIFF= *(nonseasonal order, seasonal order)*

specifies the maximum orders of regular and seasonal differencing for the automatic identification of differencing orders. When MAXDIFF is specified, the differencing orders will first be identified, and then the AR and MA orders will be identified. Acceptable values for the regular differencing orders are 1 and 2; the only acceptable value for the seasonal differencing orders is 1. If the DIFFORDER option is also specified, the DIFFORDER option will be ignored. If neither option is specified, the default is MAXDIFF=(2,1).

PRINT= UNITROOTTEST
PRINT= AUTOCHOICE
PRINT= UNITROOTTESTMDL
PRINT= AUTOCHOICEMDL
PRINT= BEST5MODEL

lists the tables to be displayed in the output. AUTOCHOICE is displayed by default. The default tables are titled “Comparison of Automatically Selected Model and Default Model” and “Final Automatic Model Selection.” “Comparison of Automatically Selected Model and Default Model” compares a default model to the model chosen by the TRAMO-based automatic modeling method. “Final Automatic Model Selection” indicates which model has been chosen automatically.

Unless the nonseasonal and seasonal differences are specified using the DIFFORDER option, AUTOMDL automatically identifies the orders of differencing. PRINT=UNITROOTTEST causes the table titled “Results of Unit Root Test for Identifying Orders of Differencing” to be printed; this table displays the orders which were automatically selected by AUTOMDL.

PRINT=UNITROOTMDL displays the table titled “ARIMA Estimates for Unit Root Identification.” This table summarizes the various models that were considered by the TRAMO automatic selection method while identifying the orders of differencing and the statistics associated with those models. The unit root identification method will first attempt to obtain the coefficients using the Hannan-Rissanen method. If Hannan-Rissanen estimation cannot be performed, the algorithm will attempt to obtain the coefficients using conditional likelihood estimation.

PRINT=AUTOCHOICEMDL displays the table “Models Estimated by Automatic ARIMA Model Selection Procedure.” This table summarizes the various models that were considered by the TRAMO automatic model selection method and their measures of fit.

PRINT=BEST5MODEL displays the table “Best Five ARIMA Models Chosen by Automatic Modeling.” This table ranks the five best models that were considered by the TRAMO automatic modeling method.

BALANCED
specifies that the automatic model procedure will have a preference for balanced models (sum of AR, differencing, and seasonal differencing orders = sum of MA and seasonal MA orders). Specifying BALANCED gives the same preference as the TRAMO program. If BALANCED is not specified, all models will be given equal consideration.

HRINITIAL
specifies that Hannan-Rissanen estimation is done before exact maximum likelihood estimation to provide initial values. If HRINITIAL is specified, then models for which the Hannan-Rissanen estimation has an unacceptable coefficient will be rejected.

ACCEPTDEFAULT
specifies that the default model is chosen if its Ljung-Box Q is acceptable.

LJUNGBOXLIMIT= *value*
specifies acceptance criteria for confidence coefficient of the Ljung-Box Q statistic. If the Ljung-Box Q for a final model is greater than this value, the model is rejected, the outlier critical value is reduced, and outlier identification is redone with the reduced value (see reducecv option). The value specified must be greater than 0.0 and less than 1.0. The default value is 0.95.

REDUCECV= *value*
specifies the percentage that the outlier critical value will be reduced when a final model is found to have an unacceptable confidence coefficient for the Ljung-Box Q statistic. This value should be between 0 and 1. The default value is 0.14286.

ARMACV= *value*
specifies the threshold value for *t*-statistics of ARMA coefficients for tests of model parsimony. Insignificant ARMA coefficients whose *t*-values have an absolute value less than this value will be set to zero. An ARMA coefficient is considered to be insignificant if it is below 0.15 for 150 or less observations and below 0.1 for more than 150 observations. This value is also used as the critical value for testing for adding a constant to the regression model. A constant regressor will be added if the *t*-statistic is below the critical value. Note that if a constant regressor is added to the model, and then the ARIMA model changes, then the *t*-statistic will also change. This value should be greater than zero. The default value is 1.0.

OUTPUT Statement

OUTPUT OUT= *SAS-data-set tablename1 tablename2 ... ;*

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

OUT= *SAS-data-set*
If the OUT= option is omitted, the SAS System names the new data set using the default DATA*n* convention.

For each table to be included in the output data set, you must specify the X12 *tablename* keyword. The keyword corresponds to the title label used by the Census Bureau

X12-ARIMA software. Currently available tables are A1, A2, A6, A8, A8AO, A8LS, A8TC, B1, C17, C20, D1, D7, D8, D9, D10, D10D, D11, D12, D13, D16, D16B, D18, E5, E6, E7, and MV1. If no table is specified, table A1 will be output to the dataset by default.

The tablename keywords that can be used in the OUTPUT statement are listed in the "Displayed Output/ODS Table Names/OUTPUT Tablename Keywords" section on page 1949. The following is an example of a VAR statement and an OUTPUT statement:

```
var sales costs;
output out=out_x12  b1 d11;
```

Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name. The variable sales_B1 contains the table B1 values for the variable sales, the variable costs_B1 contains the table B1 values for costs, while the table D11 values for sales are contained in the variable sales_D11, and the variable costs_D11 contains the table D11 values for costs. If necessary, the variable name is shortened so that the table name can be added. Currently, you cannot specify the output variable names. If DATE= is specified in the PROC X12 statement, then that variable is included in the output data set. Otherwise, a variable named _DATE_ is the date identifier.

OUTLIER Statement

OUTLIER *options;*

The OUTLIER statement specifies that the X12 procedure perform automatic detection of additive (point) outliers, temporary change outliers, level shifts, or any combination of the three using the specified model. After outliers are identified, the appropriate regression variables are incorporated into the model as "Automatically Identified Outliers," and the model is reestimated. This procedure is repeated until no additional outliers are found.

The OUTLIER statement also identifies potential outliers and lists them in the table "Potential Outliers" in the displayed output. Potential outliers are identified by decreasing the critical value by 0.5.

In the output, the default initial critical values used for outlier detection in a given analysis are displayed in the table "Critical Values to Use in Outlier Detection." Outliers that are detected and incorporated into the model are displayed in the output in the table "Regression Model Parameter Estimates," where the regression variable is listed as "Automatically Identified."

The following options can appear in the OUTLIER statement.

TYPE= NONE
TYPE= *(outlier types)*

lists the outlier types to be detected by the automatic outlier identification method. TYPE=NONE turns off outlier detection. The valid outlier types are AO, LS, and TC. The default is TYPE=(AO LS).

CV= *value*

specifies an initial critical value to use for detection of all types of outliers. The absolute value of the *t*-statistic associated with an outlier parameter estimate is compared with the critical value to determine the significance of the outlier. If the CV= option is not specified, then the default initial critical value is computed using a formula presented by Ljung (1993), which is based on the number of observations or model span used in the analysis. Table 32.1 gives default critical values for various series lengths. Raising the critical value decreases the sensitivity of the outlier detection routine, and may reduce the number of observations treated as outliers. The automatic model identification process may lower the critical value by a certain percentage, if the automatic model identification process fails to identify an acceptable model.

Table 32.1. Default Critical Values for Outlier Identification

Number of Observations	Outlier Critical Value
1	1.96
2	2.24
3	2.44
4	2.62
5	2.74
6	2.84
7	2.92
8	2.99
9	3.04
10	3.09
11	3.13
12	3.16
24	3.42
36	3.55
48	3.63
72	3.73
96	3.80
120	3.85
144	3.89
168	3.92
192	3.95
216	3.97
240	3.99
264	4.01
288	4.03
312	4.04
336	4.05
360	4.07

AOCV= *value*

specifies a critical value to use for additive (point) outliers. If AOCV is specified, this value will override any default critical value for AO outliers. See the CV= option for more details.

LSCV= *value*

specifies a critical value to use for level shift outliers. If LSCV is specified, this value will override any default critical value for LS outliers. See the CV= option for more details.

TCCV= *value*

specifies a critical value to use for temporary change outliers. If TCCV is specified, this value will override any default critical value for TC outliers. See the CV= option for more details.

REGRESSION Statement

REGRESSION *options;*

The REGRESSION statement includes regression variables in a regARIMA model or specifies regression variables whose effects are to be removed by the IDENTIFY statement to aid in ARIMA model identification. Predefined regression variables are selected with the PREDEFINED option. The currently available predefined variables are listed below. Table A6 provides information related to trading-day effects. Tables A8, A8AO, A8LS, and A8TC provide information related to outlier factors. You should note that missing values in the span of an input series automatically create missing value regressors. See the NOTRIMMISS option of the Proc X12 statement and the "Missing Values" section on page 1949 later in this chapter for further details regarding missing values. Combining your model with additional predefined regression variables may result in a singularity problem. If a singularity occurs, then you may need to alter either the model or the choices of the predefined regressors in order to successfully perform the regression.

In order to seasonally adjust a series using a regARIMA model, the factors derived from the regression coefficients must be the same type as factors generated by the seasonal adjustment procedure, so that combined adjustment factors can be derived and adjustment diagnostics can be generated. If the regARIMA model is applied to a log-transformed series, the regression factors are expressed in the form of ratios, which match seasonal factors generated by the multiplicative (or log-additive) adjustment modes. Conversely, if the regARIMA model is fit to the original series, the regression factors are measured on the same scale as the original series, which match seasonal factors generated by the additive adjustment mode. You should note that the default transformation (no transformation) and the default seasonal adjustment mode (multiplicative) are in conflict. Thus when specifying both the REGRESSION and X11 statements, it is necessary to also specify either a transform (using the TRANSFORM statement) or a mode (using the MODE= option of the X11 statement) in order to seasonally adjust the data using the regARIMA model.

According to Ladiray and Quenneville (2001), "X-12-ARIMA is based on the same principle [as the X-11 method] but proposes, in addition, a complete module, called

Reg-ARIMA, that allows for the initial series to be corrected for all sorts of undesirable effects. These effects are estimated using regression models with ARIMA errors (Findley et al. [23]).” In order to correct the series for effects in this manner, the REGRESSION statement must be specified. The effects which may be corrected in this manner are listed in the PREDEFINED= option below.

The following options can appear in the REGRESSION statement.

PREDEFINED= CONSTANT
PREDEFINED= LOM
PREDEFINED= LOMSTOCK
PREDEFINED= LOQ
PREDEFINED= LPYEAR
PREDEFINED= SEASONAL
PREDEFINED= TD
PREDEFINED= TDNOLPYEAR
PREDEFINED= TD1COEF
PREDEFINED= TD1NOLPYEAR

lists the predefined regression variables to be included in the model. Data values for these variables are calculated by the program, mostly as functions of the calendar. Table 32.2 gives definitions for the available predefined variables. The values LOM and LOQ are actually equivalent: the actual regression is controlled by the PROC X12 SEASONS= option. Multiple predefined regression variables can be used. The syntax for using both a length-of-month and a seasonal regression could be in one of the following forms:

```
regression predefined=lom seasonal;

regression predefined=(lom seasonal);

regression predefined=lom predefined=seasonal;
```

Certain restrictions apply when using more than one predefined regression variable. Only one of TD, TDNOLPYEAR, TD1COEF, or TD1NOLPYEAR may be specified. LPYEAR cannot be used with TD, TD1COEF, LOM, LOMSTOCK, or LOQ. LOM or LOQ cannot be used with TD or TD1COEF.

Table 32.2. Predefined Regression Variables in X-12-ARIMA

Regression Effect	**Variable Definitions**
Table 32.2. (continued)	
Trend Constant CONSTANT	$(1-B)^{-d}(1-B^s)^{-D}I(t \geq 1)$, where $I(t \geq 1) = \begin{cases} 1 & \text{for } t \geq 1 \\ 0 & \text{for } t < 1 \end{cases}$
Length-of-Month (monthly flow) LOM	$m_t - \bar{m}$ where m_t = length of month t (in days) and $\bar{m} = 30.4375$ (average length of month)
Stock Length-of-Month LOMSTOCK	$SLOM_t = \begin{cases} m_t - \bar{m} - \mu(l) & \text{for t = 1} \\ SLOM_{t-1} + m_t - \bar{m} & \text{otherwise} \end{cases}$ where $\bar{m}$ and m_t are defined in LOM and $\mu(l) = \begin{cases} 0.375 & \text{when 1st February in series is a leap year} \\ 0.125 & \text{when 2nd February in series is a leap year} \\ -0.125 & \text{when 3rd February in series is a leap year} \\ -0.375 & \text{when 4th February in series is a leap year} \end{cases}$
Length-of-Quarter (quarterly flow) LOQ	$q_t - \bar{q}$ where q_t = length of quarter t (in days) and $\bar{q} = 91.3125$ (average length of quarter)
Leap Year (monthly and quarterly flow) LPYEAR	$LY_t = \begin{cases} 0.75 & \text{in leap year February (first quarter)} \\ -0.25 & \text{in other Februaries (first quarter)} \\ 0 & \text{otherwise} \end{cases}$
Fixed Seasonal SEASONAL	$M_{1,t} = \begin{cases} 1 & \text{in January} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$,..., $M_{11,t} = \begin{cases} 1 & \text{in November} \\ -1 & \text{in December} \\ 0 & \text{otherwise} \end{cases}$
Trading Day TD, TDNOLPYEAR	$T_{1,t} = (no.of Mondays) - (no.of Sundays)$, ..., $T_{6,t} = (no.of Saturdays) - (no.of Sundays)$
One Coefficient Trading Day TD1COEF, TD1NOLPYEAR	$(no.of weekdays) - \frac{5}{2}(no.of Saturdays and Sundays)$

TRANSFORM Statement

TRANSFORM *options;*

The TRANSFORM statement transforms or adjusts the series prior to estimating a regARIMA model. With this statement, the series can be Box-Cox (power) transformed. The Prior Adjustment Factors table is associated with the TRANSFORM statement.

Only one of the following options can appear in the TRANSFORM statement.

POWER= *value*

Transform the input series Y_t using a Box-Cox power transformation,

$$Y_t \rightarrow y_t = \begin{cases} log(Y_t) & \lambda = 0 \\ \lambda^2 + (Y_t^\lambda - 1)/\lambda & \lambda \neq 0 \end{cases}$$

The power λ must be specified (for example, POWER= .33). The default is no transformation ($\lambda = 1$); that is, POWER= 1. The log transformation (POWER= 0), square root transformation (POWER= .5), and the inverse transformation (POWER= -1) are equivalent to the corresponding FUNCTION= option.

Table 32.3. Power Values Related to the Census Bureau Function Argument

function=	**transformation**	**range for Y_t**	**equivalent power argument**
none	Y_t	all values	$power = 1$
log	$log(Y_t)$	$Y_t > 0$ for all t	$power = 0$
sqrt	$2(\sqrt{Y_t} - 0.875)$	$Y_t \geq 0$ for all t	$power = 0.5$
inverse	$2 - \frac{1}{Y_t}$	$Y_t \neq 0$ for all t	$power = -1$
logistic	$log(\frac{Y_t}{1-Y_t})$	$0 < Y_t < 1$ for all t	*none equivalent*

FUNCTION=NONE
FUNCTION=LOG
FUNCTION=SQRT
FUNCTION=INVERSE
FUNCTION=LOGISTIC
FUNCTION=AUTO

The transformation used by FUNCTION=NONE, LOG, SQRT, INVERSE, and LOGISTIC is related to the POWER= option as shown in Table 32.3. FUNCTION=AUTO uses an AIC-based selection to decide between a log transformation and no transformation. The default is FUNCTION=NONE.

However, the FUNCTION= and POWER= options are not completely equivalent. In some cases, using the FUNCTION= option causes the program to automatically select other options. For instance, FUNCTION=NONE causes the default mode to be MODE=ADD in the X11 statement. Also, the choice of transformation invoked by the FUNCTION=AUTO option may impact the default mode of the X11 statement.

Note that there are restrictions on the value used in the POWER and FUNCTION options when preadjustment factors for seasonal adjustment are generated from a regARIMA model. When seasonal adjustment is requested with the X11 statement, any value of the POWER option can be used for the purpose of forecasting the series with a regARIMA model. However, this is not the case when factors generated from the regression coefficients are used to adjust either the original series or the final seasonally adjusted series. In this case, the only accepted transformations are the log transformation, which can be specified as POWER = 0 (for multiplicative or log-additive seasonal adjustments) and no transformation, which can be specified as POWER = 1 (for additive seasonal adjustments). If no seasonal adjustment is performed, any POWER transformation can be used. The above restrictions also apply to FUNCTION=NONE and FUNCTION=LOG.

VAR Statement

VAR *variables;*

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the PROC X12 statement.

X11 Statement

X11 *options;*

The X11 statement is an optional statement for invoking seasonal adjustment by an enhanced version of the methodology of the Census Bureau X-11 and X-11Q programs. You can control the type of seasonal adjustment decomposition calculated with the MODE= option. The output includes the final tables and diagnostics for the X-11 seasonal adjustment method listed below in Table 32.4.

Table 32.4. Tables Related to X11 Seasonal Adjustment

Table Name	Description
B1	original series, adjusted for prior effects and forecast extended
C17	final weights for the irregular component
C20	final extreme value adjustment factors
D1	modified original data, D iteration
D7	preliminary trend cycle, D iteration
D8	final unmodified SI ratios (differences)
D8A	*F* tests for stable and moving seasonality, D8
D9	final replacement values for extreme SI ratios (differences), D iteration
D9A	moving seasonality ratios for each period
D10	final seasonal factors
D10D	final seasonal difference
D11	final seasonally adjusted series
D11A	final seasonally adjusted series with forced yearly totals
D11R	rounded final seasonally adjusted series (with forced yearly totals)
D12	final trend-cycle
D13	final irregular component
D16	combined seasonal and trading day factors
D16B	final adjustment differences
D18	combined calendar adjustment factors
E4	ratio of yearly totals of original and seasonally adjusted series
E5	percent changes (differences) in original series
E6	percent changes (differences) in seasonally adjusted series
E6A	percent changes (differences) in seasonally adjusted series with forced yearly totals (D11.A)
E6R	percent changes (differences) in rounded seasonally adjusted series (D11.R)
E7	percent changes (differences) in final trend component series
F2A - F2I	X11 diagnostic summary
F3	monitoring and quality assessment statistics
F4	day of the week trading day component factors
G	spectral plots

For more details on the X-11 seasonal adjustment diagnostics, refer to Shiskin, Young, and Musgrave (1967), Lothian and Morry (1978), and Ladiray and Quenneville (2001).

The following options can appear in the X11 statement.

MODE= ADD
MODE= MULT
MODE= LOGADD
MODE= PSEUDOADD

determines the mode of the seasonal adjustment decomposition to be performed. There are four choices: multiplicative (MODE=MULT), additive (MODE=ADD), pseudo-additive (MODE=PSEUDOADD), and log-additive (MODE=LOGADD) decomposition. If this option is omitted, the procedure performs multiplicative adjustments. Table 32.5 shows the values of the MODE= option and the corresponding models for the original (O) and the seasonally adjusted (SA) series.

Table 32.5. Modes of Seasonal Adjustment and Their Models

Value of Mode Option	Name	Model for O	Model for SA
mult	Multiplicative	$O = C \times S \times I$	$SA = C \times I$
add	Additive	$O = C + S + I$	$SA = C + I$
pseudoadd	Pseudo-Additive	$O = C \times [S + I - 1]$	$SA = C \times I$
logadd	Log-Additive	$Log(O) = C + S + I$	$SA = exp(C + I)$

OUTFCST
OUTFORECAST

determines if forecasts will be included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecasted values will be included in the output data set for tables A6, A8, A16, B1, D10, D10D, D16, D16B, and D18. The default is not to include forecasts.

SEASONALMA=S3X1
SEASONALMA=S3X3
SEASONALMA=S3X5
SEASONALMA=S3X9
SEASONALMA=S3X15
SEASONALMA=STABLE
SEASONALMA=X11DEFAULT
SEASONALMA=MSR

specifies which seasonal moving average (also called seasonal “filter”) will be used to estimate the seasonal factors. These seasonal moving averages are $n \times m$ *moving averages*, meaning that an n-term simple average is taken of a sequence of consecutive m-term simple averages. X11DEFAULT is the method used by the U.S. Census Bureau’s X-11-ARIMA program. The default for PROC X12 is SEASONALMA=MSR, which is the methodology of Statistic Canada’s X-11-ARIMA/88 program. Table 32.6 describes the seasonal filter options available.

The following seasonal filters can be selected for the entire series:

Table 32.6. X-12-ARIMA Seasonal Filter Options and Descriptions

Filter Name	Description of Filter
S3X1	A 3×1 moving average.
S3X3	A 3×3 moving average.
S3X5	A 3×5 moving average.
S3X9	A 3×9 moving average.
S3X15	A 3×15 moving average.
STABLE	Stable seasonal filter. As single seasonal factor for each calendar month or quarter is generated by calculating the simple average of all the values for each month or quarter (taken after detrending and outlier adjustment).
X11DEFAULT	A 3×3 moving average is used to calculate the initial seasonal factors in each iteration, and a 3×5 moving average to calculate the final seasonal factors.
MSR	Choose filter automatically using moving seasonality ratio of X-11-ARIMA/88 (Dagum 1988).

TRENDMA= *value*

specifies which Henderson moving average will be used to estimate the final trend-cycle. Any odd number greater than one and less than or equal to 101 can be specified. Example: trendma=23. If no selection is made the program will select a trend moving average based on statistical characteristics of the data. For monthly series, either a 9-, 13-, or 23-term Henderson moving average will be selected. For quarterly series, the program will choose either a 5- or a 7-term Henderson moving average.

FINAL= AO
FINAL= LS
FINAL= TC
FINAL= ALL

Lists the types of prior adjustment factors, obtained from the regression and outlier statements, that are to be removed from the final seasonally adjusted series. Additive outliers (FINAL=AO), level change and ramp outliers (FINAL=LS), and temporary change (FINAL=TC) can be removed. If this option is not specified, the final seasonally adjusted series will contain these effects.

FORCE= TOTALS
FORCE= ROUND
FORCE= BOTH

specifies that the seasonally adjusted series be modified to (a) force the yearly totals of the seasonally adjusted series and the original series be the same (FORCE=TOTALS), (b) adjust the seasonally adjusted values for each calendar year so that the sum of the rounded seasonally adjusted series for any year will equal the rounded annual total (FORCE=ROUND), or (c) first force the yearly totals, then round the adjusted series (FORCE=BOTH). When FORCE=TOTALS, the differences between the annual totals is distributed over the seasonally adjusted values in a way that approximately preserves the month-to-month (or quarter-to-quarter) movements of the original series. For more details refer to Huot (1975) and Cholette (1979). This forcing procedure is not recommended if the seasonal pattern is changing or if trading day adjustment is performed. Forcing the seasonally adjusted totals to be the same as the original series annual totals can degrade the quality of the seasonal adjustment, especially when the seasonal pattern is undergoing change. It is not natural if trading day adjustment is performed because the aggregate trading day effect over a year is variable and moderately different from zero.

Details

Missing Values

PROC X12 can process a series with missing values. Missing values in a series are considered to be one of two types. One type of missing value is a leading or trailing missing value; these values occur before the first non-missing value or after the last non-missing value in the span of a series. The span of a series may either be determined explicitly by the SPAN= option of the PROC X12 statement or implicitly by the START= or DATE= options. By default leading and trailing missing values are ignored. The second type of missing value is an embedded missing value; these missing values occur between the first non-missing value and the last non-missing value in the span of the series. Embedded missing values are processed using X-12-ARIMA's missing value method described below. The NOTRIMMISS option of the PROC X12 statement causes leading and trailing missing values to also be processed using the X-12-ARIMA missing value method.

When the X-12-ARIMA method encounters a missing value, it inserts an additive outlier for that observation into the set of regression variables for the model of the series and then replaces the missing observation with a value large enough to be considered an outlier during model estimation. After the regARIMA model is estimated, the X-12-ARIMA method adjusts the original series using factors generated from these missing value outlier regressors. The adjusted values are estimates of the missing values, and the adjusted series is displayed in Table MV1.

Computations

For more details on the computations used in PROC X12, refer to *X-12-ARIMA Reference Manual* (U.S. Bureau of the Census 2001b).

For more details on the X-11 method of decomposition, refer to *Seasonal Adjustment with the X-11 Method* (Ladiray and Quenneville 2001).

Displayed Output/ODS Table Names/OUTPUT Tablename Keywords

The options specified in PROC X12 control both the tables produced by the procedure and the tables available for output to the OUT= data set specified in the OUTPUT statement.

The displayed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X12 procedure are as follows:

A	prior adjustments and regARIMA components (optional)
B	preliminary estimates of irregular component weights and trading-day regression factors (X-11 method)
C	final estimates of irregular component weights and trading-day regression factors
D	final estimates of seasonal, trend cycle, and irregular components
E	analytical tables
F	summary measures
G	charts

Table 32.7 describes the individual tables and charts. “P” indicates that the table is displayed only and is not available for output to the OUT= data set. Data from displayed tables can be extracted into data sets using the Output Delivery System (ODS). Refer to Chapter 6, “Using the Output Delivery System,” in the *SAS/ETS User’s Guide*. “O” indicates that the table is available only using the OUTPUT statement. The actual number of tables displayed depends on the options and statements specified. If a table is not computed, it is not displayed.

Table 32.7. Table Names and Descriptions

Table	**Description**	**Notes**
A1	original series	
A2	prior-adjustment factors	
RegParameterEstimates	regression model parameter estimates	P
ACF	autocorrelation factors	P
PACF	partial autocorrelation factors	P
ARMAIterationTolerances	exact ARMA likelihood estimation iteration tolerances	P
IterHistory	ARMA iteration history	P
ARMAIterationSummary	exact ARMA likelihood estimation iteration summary	P
RegressorGroupChiSq	chi-squared tests for groups of regressors	P
ARMAParameterEstimates	exact ARMA maximum likelihood estimation	P
AvgFcstErr	average absolute percentage error in within(out)-sample fore(back)casts:	P
Roots	(non)seasonal (AR)MA roots	P
MLESummary	estimation summary	P
ForecastCL	forecasts, standard errors, and confidence limits	P
MV1	original series adjusted for missing value regressors	
A6	regARIMA trading day component	
A8	regARIMA combined outlier component	
A8AO	regARIMA AO outlier component	
A8LS	regARIMA level change outlier component	
A8TC	regARIMA temporary change outlier component	
B1	prior adjusted or original series	
C17	final weight for irregular components	
C20	final extreme value adjustment factors	O
D1	modified original data, D iteration	O
D7	preliminary trend cycle, D iteration	O

Table 32.7. (continued)

Table	Description	Notes
D8	final unmodified S-I ratios	
D8A	seasonality tests	P
D9	final replacement values for extreme S-I ratios	
D9A	moving seasonality ratio	P
D10	final seasonal factors	
D10D	final seasonal difference	
D11	final seasonally adjusted series	
D11A	final seasonally adjusted series with forced yearly totals	
D11R	rounded final seasonally adjusted series (with forced yearly totals)	
D12	final trend cycle	
D13	final irregular series	
D16	combined adjustment factors	
D16B	final adjustment differences	
D18	combined calendar adjustment factors	
E4	ratios of annual totals	P
E5	percent changes in original series	
E6	percent changes in final seasonally adjusted series	
E6A	percent changes (differences) in seasonally adjusted series with forced yearly totals (D11.A)	
E6R	percent changes (differences) in rounded seasonally adjusted series (D11.R)	
E7	differences in final trend cycle	
F2A-I	summary measures	P
F3	quality assessment statistics	P
F4	Day of the Week Trading Day Component Factors	P
G	spectral analysis	P

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the X12 procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 9, “Statistical Graphics Using ODS.”

The graphics available through ODS GRAPHICS are ACF plots, PACF plots, and spectral graphs. ACF and PACF plots are not available unless the IDENTIFY statement is used. A spectral plot of the original series is always available; however additional spectral plots are provided when the X11 statement is used. When the ODS GRAPHICS statement is not used, the plots are integrated into the ACF, PACF and spectral tables as a column of the table.

ODS Graph Names

PROC X12 assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 32.8.

Table 32.8. ODS Graphics Produced by PROC X12

ODS Graph Name	Plot Description
ACFPlot	Autocorrelation of Model Residuals
PACFPlot	Partial Autocorrelation of Model Residuals
SpectralPlot	Spectral Plot of Original or Adjusted Series

Examples

Example 32.1. Model Identification

An example of the statements typically invoked when using PROC X12 for model identification might follow the same format as the following example. This example invokes the X12 procedure and uses the TRANSFORM and IDENTIFY statements. It specifies the time series data, takes the logarithm of the series (TRANSFORM statement), and generates ACFs and PACFs for the specified levels of differencing (IDENTIFY statement). The ACFs and PACFs for Nonseasonal Order=1 and Seasonal Order=1 are shown in Output 32.1.1, Output 32.1.2, Output 32.1.3 and Output 32.1.4. The data set is the same as in the section "Basic Seasonal Adjustment" on page 1926.

The graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the X12 procedure, see the "ODS Graphics" section on page 1951.

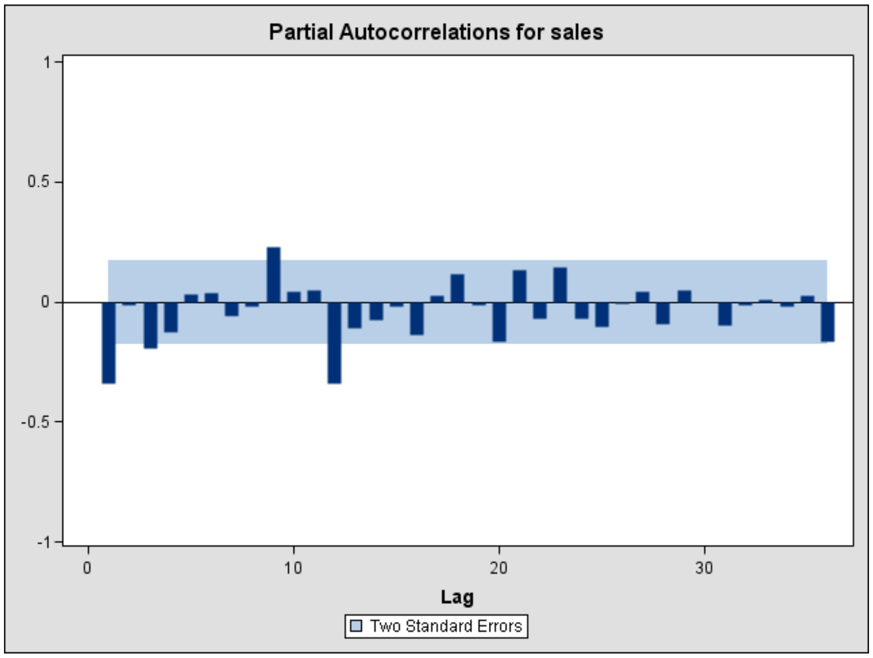
Output 32.1.4. Plot for PACFs (Nonseasonal Order=1 Seasonal Order=1) (Experimental)



Example 32.2. Model Estimation

After studying the output from Example 32.1 and identifying the ARIMA part of the model as, for example, (0 1 1)(0 1 1) 12, you can replace the IDENTIFY statement with the ARIMA and ESTIMATE statements. The parameter estimates and estimation summary statistics are shown in Output 32.2.1.

```
proc x12 data=sales date=date;
   var sales;
   transform power=0;
   arima model=( (0,1,1)(0,1,1) );
   estimate;
run ;
```

Example 32.3. Seasonal Adjustment

Assuming that the model in Example 32.2 is satisfactory, a seasonal adjustment utilizing forecast extension can be performed by adding the X11 statement to the procedure. By default, the data is forecast one year ahead at the end of the series. Table D8.A is shown in Output 32.3.1.

```
ods output D8A#1=SalesD8A_1;
ods output D8A#2=SalesD8A_2;
ods output D8A#3=SalesD8A_3;
ods output D8A#4=SalesD8A_4;
```

```
proc x12 data=sales date=date;
   var sales;
   transform power=0;
   arima model=( (0,1,1)(0,1,1) );
   estimate;
   x11;
run ;

proc print data=SalesD8A_1;
   title 'Stable Seasonality Test';
run;

proc print data=SalesD8A_2;
   title 'Nonparametric Stable Seasonality Test';
run;

proc print data=SalesD8A_3;
   title 'Moving Seasonality Test';
run;

proc print data=SalesD8A_4;
   title 'Combined Seasonality Test';
run;
```

Output 32.3.1. Table D8.A as Displayed

```
                                The X12 Procedure

                      Table D 8.A:  F-tests for seasonality
                                For variable sales

            **Moving seasonality present at the one percent level.

           COMBINED TEST FOR THE PRESENCE OF IDENTIFIABLE SEASONALITY

                      IDENTIFIABLE SEASONALITY    PRESENT
```

The four ODS statements in the preceding example direct output from the D8A tables into four data sets: SalesD8A_1, SalesD8A_2, SalesD8A_3, and SalesD8A_4. It is best to direct the output to four different data sets because the four tables associated with table D8A have varying formats. The ODS data sets are shown below in Output 32.3.2.

Output 32.3.2. Table D8.A as Output in a Data Set Using ODS

Example 32.4. regARIMA Automatic Model Selection

This example demonstrates two of the new features available through the X-12-ARIMA method that are not available using the previous X-11 and X-11-ARIMA methods: regARIMA modeling and TRAMO-based automatic model selection. Assume that the same data set is used as in the previous examples.

```
ods select X12.ModelEstimation.AutoModel.UnitRootTestModel
           X12.ModelEstimation.AutoModel.UnitRootTest
           X12.ModelEstimation.AutoModel.AutoChoiceModel
           X12.ModelEstimation.AutoModel.Best5Model
           X12.ModelEstimation.AutoModel.AutomaticModelChoice
           X12.ModelEstimation.AutoModel.FinalModelChoice
           X12.ModelEstimation.AutoModel.AutomdlNote;
proc x12 data=sales date=date;
   var sales;
   transform function=log;
   regression predefined=td;
   automdl print=unitroottest unitroottestmdl autochoicemdl best5model;
   estimate;
   x11;
   output out=out a1 a2 a6 b1 c17 c20 d1 d7 d8 d9 d10
                  d11 d12 d13 d16 d18;
   run;
```

The Automatic Model Selection output is shown in Output 32.4.1 and Output 32.4.2. The first table in Output 32.4.1, "ARIMA Estimate for Unit Root Identification", gives details of the method that TRAMO uses to automatically select the orders of differencing. The second table, "Results of Unit Root Test for Identifying Orders of Differencing", shows that a regular difference order of 1 and a seasonal difference order of 1 has been determined by TRAMO. The third table, "Models estimated by Automatic ARIMA Model Selection procedure", shows all the models examined by the TRAMO-based method.

In Output 32.4.2, the first table, "Best Five ARIMA Models Chosen by Automatic Modeling", shows the top five models in order of rank and their BIC2 statistic. The second table, "Comparison of Automatically Selected Model and Default Model", compares the model selected by the TRAMO model to the default X-12-ARIMA model. The third table, "Final Automatic Model Selection", shows which model was actually selected.

Output 32.4.1. Output from the Automdl Statement

```

Table 32.9 and Output 32.4.3 illustrate the regARIMA modeling method. Table 32.9 shows the relationship between the output variables in PROC X12 that results from a regARIMA model. Note that some of these formulas apply only to this example. Output 32.4.3 shows the values of these variables for the first 24 observations in the example.

Table 32.9. regARIMA Output Variables and Descriptions

Table	Title	Type	Formula
A 1	Time series data (for the span analyzed)	data	Input.
A 2	Prior-adjustment factors Leap year (from trading day regression) adjustments.	factor	Calculated from regression.
A 6	RegARIMA trading day component Leap year prior adjustments included from Table A2.	factor	Calculated from regression.
B 1	Original series (prior adjusted) (adjusted for regARIMA factors)	data	$B1 = A1/A6$ * * because only TD specified.
C 17	Final weights for irregular component	factor	Calculated using moving standard deviation.
C 20	Final extreme value adjustment factors	factor	Calculated using C16 and C17.
D 1	Modified original data, D iteration	data	$D1 = B1/C20$ ** $D1 = C19/C20$ ** C19=B1 in this example.
D 7	Preliminary trend cycle, D iteration	data	Calculated using Henderson moving average.
D 8	Final unmodified SI ratios	factor	$D8 = B1/D7$ *** $D8 = C19/D7$ *** TD specified in regression.
D 9	Final replacement values for SI ratios	factor	If C17 shows extreme values, $D9 = D1/D7$; $D9 =$. otherwise.
D 10	Final seasonal factors	factor	Calculated using moving averages.
D 11	Final seasonally adjusted data (also adjusted for trading day)	data	$D11 = B1/D10$ **** $D11 = C19/D10$ **** $B1 = C19$ for this example.
D 12	Final trend cycle	data	Calculated using Henderson moving average.
D 13	Final irregular component	factor	$D13 = D11/D12$
D 16	Combined adjustment factors (includes seasonal, trading day factors)	factor	$D16 = A1/D11$
D 18	Combined calendar adjustment factors (includes trading day factors)	factor	$D18 = D16/D10$ $D18 = A6$ ***** ***** regression TD is the only calendar adjustment factor in this example.

Example 32.5. Automatic Outlier Detection

This example demonstrates using the OUTLIER statement to automatically detect and remove outliers from a time series to be seasonally adjusted. The data set is the same as in the section "Basic Seasonal Adjustment" on page 1926 and the previous examples. Adding the OUTLIER statement to Example 32.3 requests that outliers be detected using the default critical value as described in the section "OUTLIER Statement" on page 1939. The tables associated with outlier detection for this example are shown in Output 32.5.1. The first table shows the critical values; the second table shows that a single potential outlier was identified; the third table shows the estimates for the ARMA parameters. Since no outliers are included in the regression model, the Regression Model Parameter Estimates table is not displayed. Because only a potential outlier was identified, and not an actual outlier, in this case the A1 series and the B1 series are identical.

```
proc x12 data=sales date=date;
   var sales;
   transform function=log;
   arima model=( (0,1,1)(0,1,1) );
   outlier;
   estimate;
   x11;
   output out=nooutlier a1 b1 d10;
   run ;
```

Output 32.5.1. Proc X12 Output when Potential Outliers are Identified

```
                              The X12 Procedure

                   Critical Values to use in Outlier Detection
                             For variable sales

                         Begin                   SEP1978
                         End                     AUG1990
                         Observations                144
                         Method                  Add One
                         AO Critical Value      3.889838
                         LS Critical Value      3.889838

 NOTE:  The following time series values might later be identified as outliers
 when data are added or revised.  They were not identified as outliers in this
  run either because their test t-statistics were slightly below the critical
value or because they were eliminated during the backward deletion step of the
        identification procedure, when a non-robust t-statistic is used.

                             Potential Outliers
                             For variable sales
                   Type of                 t Value    t Value

Nonseasonal MA               1       0.40181       0.07887       5.09      <.0001
Seasonal MA                 12       0.55695       0.07626       7.30      <.0001
```

In the next example, reducing the critical value to 3.3 causes the outlier identification routine to more agressively identify outliers as shown in Output 32.5.2. The first table shows the critical values. The second table shows that three additive outliers and a level shift have been included in the regression model. The third table shows how the inclusion of outliers in the model affects the ARMA parameters.

```
proc x12 data=sales date=date;
   var sales;
   transform function=log;
   arima model=((0,1,1) (0,1,1));
   outlier cv=3.3;
   estimate;
   x11;
   output out=outlier a1 a8  a8ao a8ls b1 d10;
run;
```

```

The first 65 observations of the A1, A8, A8AO, A8LS, B1 and D10 series are displayed in Output 32.5.3. The user can confirm the relationships,

$$A8 = A8AO \times A8LS$$

$$B1 = A1/A8$$

The seasonal factors are in series D10.

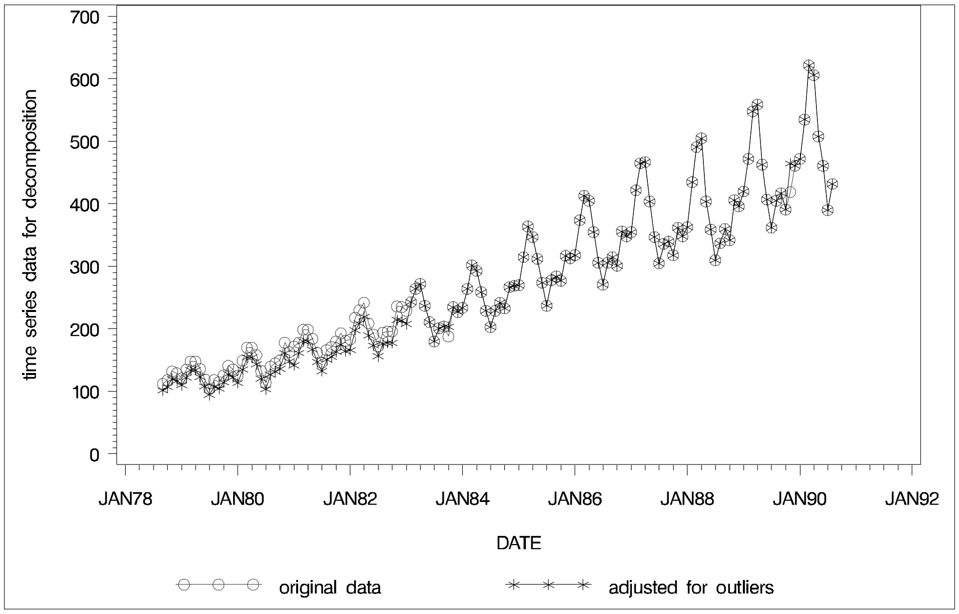
  . . . output observations omitted . . .
```

From the two previous examples, you can examine how outlier detection affects the seasonally adjusted series. Output 32.5.4 shows a plot of A1 versus B1 in the series where outliers are detected. B1 has been adjusted for the additive outliers and the level shift. Output 32.5.5 compares the seasonal factors (table D10) of the series unadjusted for outliers to the series adjusted for outliers. The seasonal factors are based on the B1 series.

```
axis2 label=(angle=90  'time series data for decomposition');
symbol1 i=join v='star' c=black;
symbol2 i=join v='circle' c=red;
legend1 label=none value=('original data' 'adjusted for outliers');

proc gplot data=outlier;
      plot sales_A1    * date = 2
           sales_B1    * date = 1 / overlay legend=legend1 vaxis=axis2;
run;
```

Output 32.5.4. Original Series and Outlier Adjusted Series

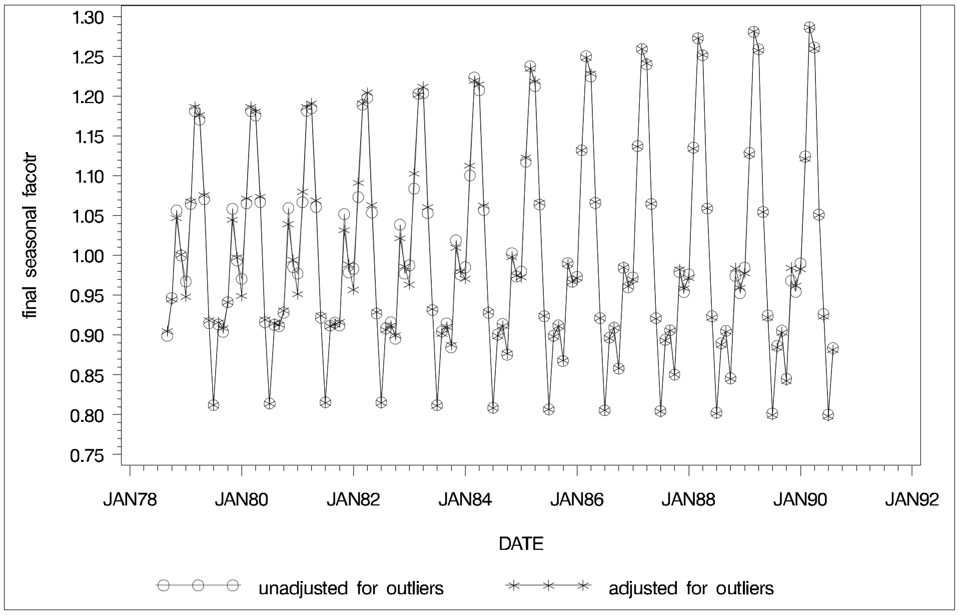


```
data both;
  merge nooutlier(rename=(sales_D10=unadj_D10)) outlier;
run;

axis2 label=(angle=90  'final seasonal facotr');
symbol1 i=join v='star' c=blue;
symbol2 i=join v='circle' c=red;
legend1 label=none value=('unadjusted for outliers' 'adjusted for outliers');

proc gplot data=both;
      plot unadj_D10    * date = 2
           sales_D10    * date = 1 / overlay legend=legend1 vaxis=axis2;
run;
```

Output 32.5.5. Seasonal Factors Based on Original and Outlier Adjusted Series



Example 32.6. Illustration of ODS Graphics (Experimental)

This example illustrates the use of experimental ODS graphics. Using the same data set as in the section "Basic Seasonal Adjustment" on page 1926 and the previous examples, a Spectral Plot of the original series is displayed in Output 32.6.1.

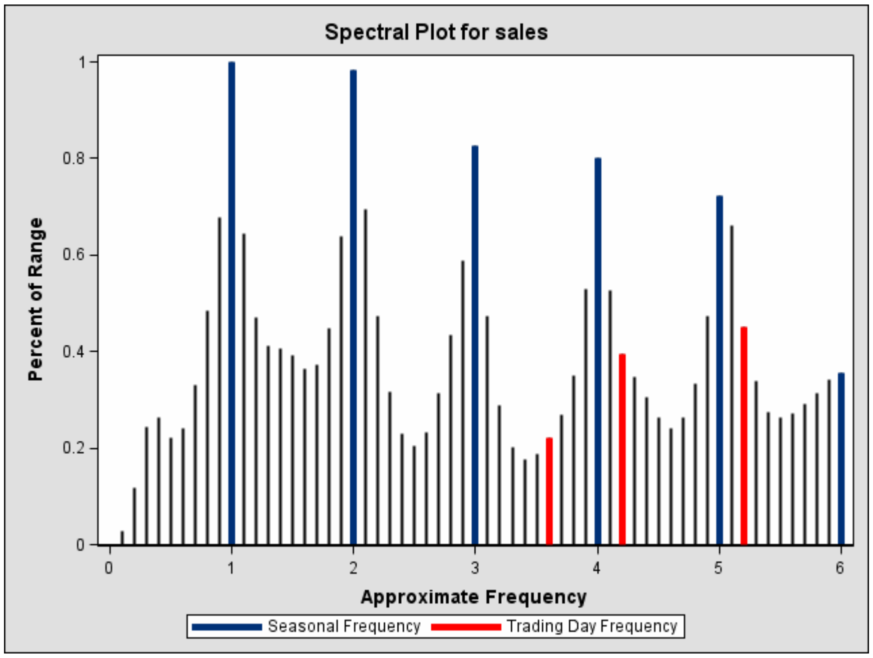
The graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 9, "Statistical Graphics Using ODS." For specific information about the graphics available in the X12 procedure, see the "ODS Graphics" section on page 1951.

```
ods html;
ods graphics on;

proc x12 data=sales date=date;
   var sales;
run ;

ods graphics off;
ods html close;
```

Output 32.6.1. Spectral Plot for Original Data (Experimental)



Acknowledgments

The X-12-ARIMA procedure was developed by the Time Series Staff of the Statistical Research Division, U.S. Bureau of the Census.

Brian Monsell is the primary programmer for the U.S. Census Bureau's X-12-ARIMA procedure and has been very helpful in the development of PROC X12.

The version of PROC X12 documented here was produced by converting the U.S. Census Bureau's FORTRAN code to the SAS development language and adding typical SAS procedure syntax. This conversion work was performed by SAS Institute, which resulted in the X12 procedure. Although several features were added during the conversion, credit for the statistical aspects and general methodology of the X12 procedure belongs to the U.S. Bureau of the Census.

The X-12-ARIMA seasonal adjustment program contains components developed from Statistics Canada's X-11-ARIMA program.

The X-12-ARIMA automatic modeling method is based on the work of Gomez and Maravall (1997a;b).

Chapter 33
Overview of the Time Series Forecasting System

Introduction

The Time Series Forecasting system forecasts future values of time series variables by extrapolating trends and patterns in the past values of the series or by extrapolating the effect of other variables on the series. The system provides convenient point-and-click windows to drive the time series analysis and forecasting tools of SAS/ETS software.

You can use the system in a fully automatic mode, or you can use the system's diagnostic features and time series modeling tools interactively to develop forecasting models customized to best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The following is a brief summary of the features of the Time Series Forecasting system. With the system you can

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits, as well as autocorrelations and results of white noise and stationarity tests. Any of these plots can be zoomed and can represent raw or transformed series.
- use hold-out samples to select the best forecasting method
- compare goodness-of-fit measures for any two forecasting models side by side or list all models sorted by a particular fit statistic
- view the predictions and errors for each model in a spreadsheet or compare the fit of any two models in a spreadsheet
- examine the fitted parameters of each forecasting model and their statistical significance
- control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models

- customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection
- save your work in a project catalog
- print an audit trail of the forecasting process
- show source statements for PROC ARIMA code
- save and print system output including spreadsheets and graphs

Using The Time Series Forecasting System

Chapters starting from Chapter 34 through Chapter 38 contain a series of example sessions that show the major features of the system. Chapters from Chapter 39 through Chapter 41 serve as reference and provide more details on how the system operates. The reference chapters contain a complete list of Forecasting system features.

To get started using the Time Series Forecasting system, it is a good idea to work through a few of the example sessions. Start with Chapter 34, "Getting Started with Time Series Forecasting," and use the system to reproduce the steps shown in the examples. Continue with the other chapters when you feel comfortable using the system.

The example sessions make use of time series data sets contained in the SASHELP library: `air, citimon, citiqtr, citiyr, citiwk, citiday, gnp, retail, usecon`, and `workers`. You can use these data sets to work through the example sessions or to experiment further with the Forecasting system.

Once you are familiar with how the system operates, start working with your own data to build your own forecasting models. When you have questions, consult the reference chapters mentioned above for more information about particular features.

The Time Series Forecasting system forecasts *time series*, that is, variables comprised of ordered observations taken at regular intervals over time. Since the Forecasting system is a part of the SAS software system, time series values must be stored as variables in a SAS data set or data view, with the observations representing the time periods. The data may also be stored in an external spreadsheet or data base if you license SAS/ACCESS software.

The Time Series Forecasting System chapters refer to *series* and *variables*. Since time series are stored as variables in SAS data sets or data views, these terms are used interchangeably. However, the term *series* is preferred when attention is focused on the sequence of data values, and the term *variable* is preferred when attention is focused on the data set.

Information Available on the World Wide Web

Visit the Time Series Forecasting Web site, support.sas.com/rnd/app/ets/forecasting.html, for up-to-date supplemental information. While using the forecasting system, click or select *SAS on the Web* and *Time Series Forecasting System* under the *Help* menu. The site contains:

- an overview of the Time Series Forecasting System
- information and examples on running the system in batch
- information and examples on creating forecasting reports for the Web
- documentation for the *Forecast Command Builder*, a utility for creating, saving, and running sets of forecasting jobs
- SCL source code for the *Forecast Command Builder*

SAS Software Products Needed

The Time Series Forecasting system is part of SAS/ETS software. To use it, you must have a license for SAS/ETS. To use the graphical display features of the system, you must also license SAS/GRAPH software.

Chapter 34
Getting Started

Chapter Contents

Chapter 34 Getting Started with Time Series Forecasting

This chapter outlines the forecasting process and introduces the major windows of the system through three example sessions.

The first example, beginning with the section "The Time Series Forecasting Window", shows how to use the system for fully automated forecasting of a set of time series. This example also introduces the system's features for viewing data and forecasts through tables and interactive graphs. It also shows how to save and restore forecasting work in SAS catalogs.

The second example, beginning with the section "Develop Models Window", introduces the features for developing the best forecasting models for individual time series. The chapter concludes with an example showing how to create dating variables for your data in the form expected by the system.

After working through the examples in this chapter, you should be able to

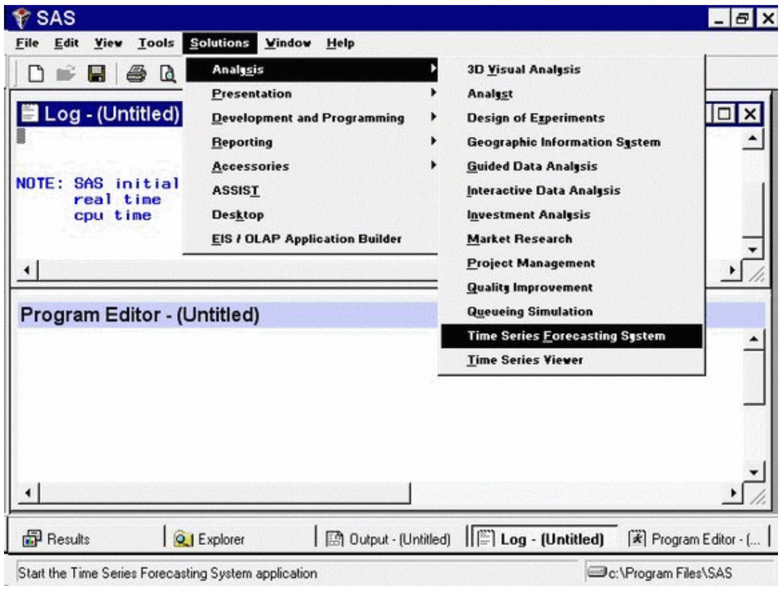
- select a data set of time series to work with and specify its periodicity and time ID variable
- use the automatic forecasting model selection feature to create forecasting models for the variables in a data set
- produce and save forecasts of variables in a data set
- examine your data and forecasts as tables of values and through interactive graphs
- save and restore your forecasting models using project files in a SAS catalog and edit project information
- use some of the model development features to fit and select forecasting models for individual time series variables.

This chapter introduces these topics and will help you get started using the system. Later chapters present these topics in greater detail and document more advanced features and options.

The Time Series Forecasting Window

There are several ways to get to the Time Series Forecasting System. If you prefer to use commands, invoke the system by entering `forecast` on the command line. You can optionally specify additional information on the command line; see Chapter 39, "Command Reference," for details.

If you are using the SAS Windowing Environment with pull-down menus, select the Solutions menu from the menu bar, select the Analysis item, and then select `Time Series Forecasting System`, as shown in Figure 34.1.



```
NOTE: SAS initial
      real time
      cpu time
```

Start the Time Series Forecasting System application

Figure 34.1. Time Series Forecasting System Menu Selection

You can invoke the Forecasting System from the SAS Explorer window by opening an existing forecasting project. By default these projects are stored in the FMSPROJ catalog in the SASUSER library. Select SASUSER in the Explorer to display its contents. Then select FMSPROJ. This catalog is created the first time you use the Forecasting System. If you have saved projects, they appear in the Explorer with the forecasting graph icon, as shown in Figure 34.2. Double-click one of the projects, or select it with the right mouse button and then select Open from the pop-up menu, as shown in the figure. This brings up the Forecasting System and opens the selected project.

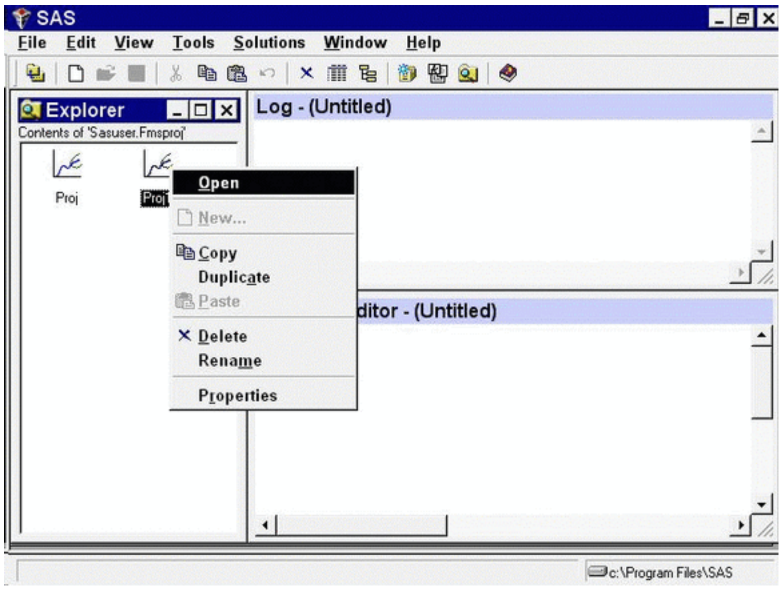


Figure 34.2. Opening a Project from the Explorer

To invoke the Forecasting System in the SAS Desktop environment, select the Solutions menu from the menu bar, select `Desktop`, and then open the Analysis folder. You can run the Time Series Forecasting System or the Time Series Viewer directly, or you can drag and drop. Figure 34.3 illustrates dragging a data set (known as a table in the Desktop environment) and dropping it on the Forecasting icon. In this example, the tables reside in a user-defined folder called *Time Series Data*.

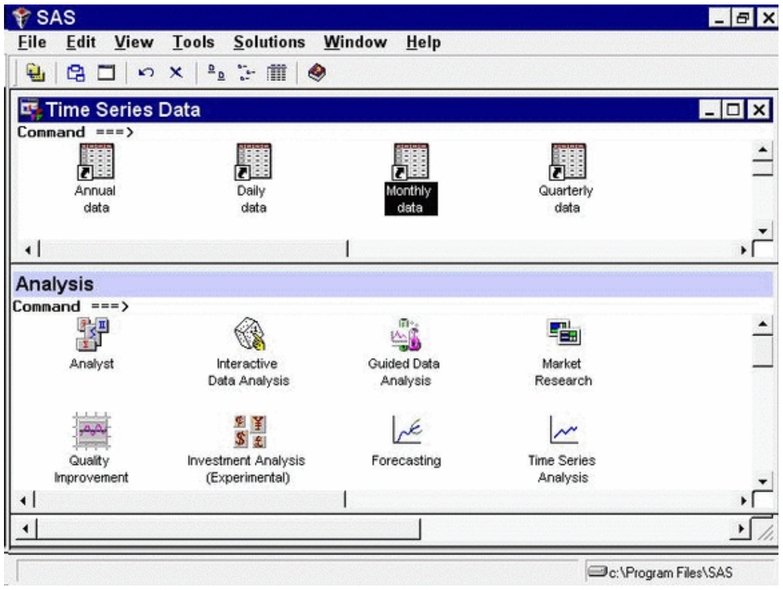

Figure 34.3. Drag and Drop Using the SAS Desktop

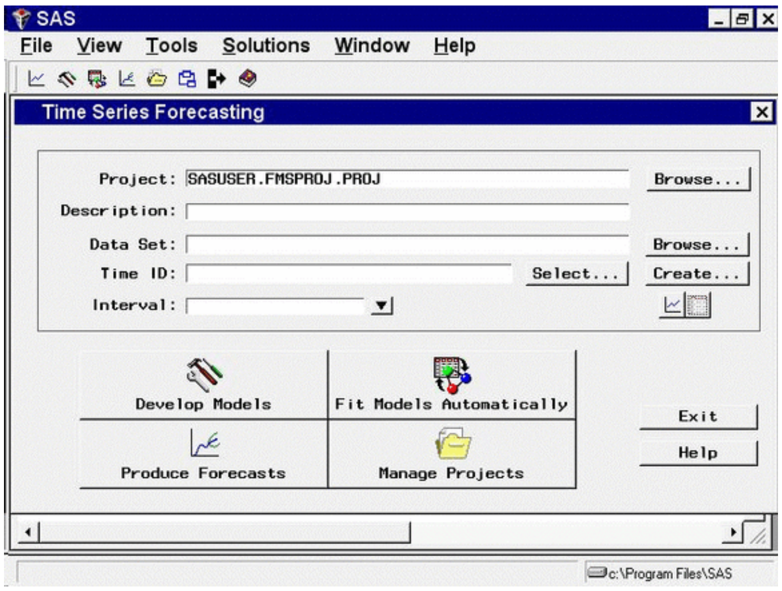
If you are using SAS/ASSIST software, select the Planning button and then select `Forecasting` from the pop-up menu.

Any of these methods takes you to the Time Series Forecasting window, as shown in Figure 34.4.



Project: SASUSER.FMSPROJ.PROJ
Description:
Data Set:
Time ID:
Interval:

Figure 34.4. Time Series Forecasting Window

At the top of the window is a data selection area for specifying a project file and the input data set containing historical data (the known past values) for the time series variables that you want to forecast. This area also contains buttons for bringing up viewers to explore your input data either graphically, one series at a time, or as a table, one data set at a time.

The Project and Description fields are used to specify a project file for saving and restoring forecasting models created by the system. Using project files is discussed later, and we will ignore these fields for now.

The lower part of the window contains six buttons:

`Develop Models`
: brings up the Develop Models window, which you use to develop and fit forecasting models interactively for individual time series.

`Fit Models Automatically`
: brings up the Automatic Model Fitting window, which you use to search automatically for the best forecasting model for multiple series in the input data set.

`Produce Forecasts`
: brings up the Produce Forecasts window, which you use to compute forecasts for all the variables in the input data set for which forecasting models have been fit.

`Manage Projects`
: brings up the Manage Forecasting Project window, which lists the time series for which you have fit forecasting models. You can drill down on a series to see the models that have been fit. You can delete series or models from the project, re-evaluate or refit models, and explore models and forecasts graphically or in tabular form.

`Exit`
: exits the Forecasting System.

`Help`
: displays information about the Forecasting System.

Outline of the Forecasting Process

The examples shown in the following sections illustrate the basic process you will use with the Forecasting System.

Specify the Input Data Set

Suppose you have a number of *time series*, variables recorded over time, for which you want to forecast future values. The past values of these time series are stored as variables in a SAS data set or data view. The observations of this data set correspond to regular time periods, such as days, weeks, or months. The first step in the forecasting process is to tell the system to use this data set by setting the Data Set field.

If your time series are not in a SAS data set, you must provide a way for the SAS System to access the data. You can use SAS features to read your data into a SAS data set; refer to *SAS Language Reference*. You can use a SAS/ACCESS product to establish a view of data in a database management system; refer to SAS/ACCESS documentation. You can use PROC SQL to create a SAS data view. You can use PROC DATASOURCE to read data from files supplied by supported data vendors; refer to Chapter 14, "The DATASOURCE Procedure," for more details.

Provide a Valid Time ID Variable

To use the Forecasting System, your data set must be dated: the data set must contain a *time ID variable* that gives the date of each observation. The time ID variable must represent the observation dates with *SAS date values* or with *SAS datetime values* (for hourly data or other frequencies less than a day), or you can use a simple time index.

When SAS date values are used, the ID variable contains dates within the time periods corresponding to the observations. For example, for monthly data, the values for the time ID variable may be the date of the first day of the month corresponding to each observation, or the time ID variable may contain the date of the last day in the month. (Any date within the period will serve as the time ID for the observation.)

If your data set already contains a valid time ID variable with SAS date or datetime values, the next step is to specify this time ID variable in the Time ID field. If the time ID variable is named DATE, the system fills in the Time ID field automatically.

If your data set does not contain a time ID, you must add a valid time ID variable before beginning the forecasting process. The Forecasting System provides features that make this easy to do. See Chapter 35, "Creating Time ID Variables," for details.

Select and Fit a Forecasting Model for each Series

If you are using the automated model selection feature, the system performs this step for you and chooses a forecasting model for each series automatically. All you need to do is select the Fit Models Automatically button and then select the variables to fit models for.

If you want more control over forecasting model selection, you can select the Develop Models button, select the series you want to forecast, and use the Develop Models window to specify a forecasting model. As part of this process, you may use the Time Series Viewer and Model Viewer graphical tools. Once you have selected a model for the first series, you can select a different series to work with and repeat the model development process until you have created forecasting models for all the series you want to forecast.

The system provides many features to help you choose the best forecasting model for each series. The features of the Develop Models window and graphical viewer tools are introduced in later sections.

Produce the Forecasts

Once a forecasting model has been fit for each series, select the Produce Forecasts button and use the Produce Forecasts window to compute forecast values and store them in a SAS data set.

Save Your Work

If you want only a single forecast, your task is now complete. But you may want to produce updated forecasts later, as more data becomes available. In this case, you want to save the forecasting models you have created, so that you will not need to repeat the model selection and fitting process.

To save your work, fill in the Project field with the name of a SAS catalog member in which the system will store the model information when you exit the system. Later, you will select the same catalog member name when you first enter the Forecasting System, and the model information will be reloaded.

Note that any number of people can work with the same project file. If you are working on a forecasting project as part of a team, you should take care to avoid conflicting updates to the project file by different team members.

Summary

This is the basic outline of how the Forecasting System works. The system offers many other features and options that you may need to use (for example, the time range of the data used to fit models and how far into the future to forecast). These options will become apparent as you work with the Forecasting System.

As an introductory example, the following sections use the Automatic Model Fitting and Produce Forecasts windows to perform automated forecasting of the series in an example data set.

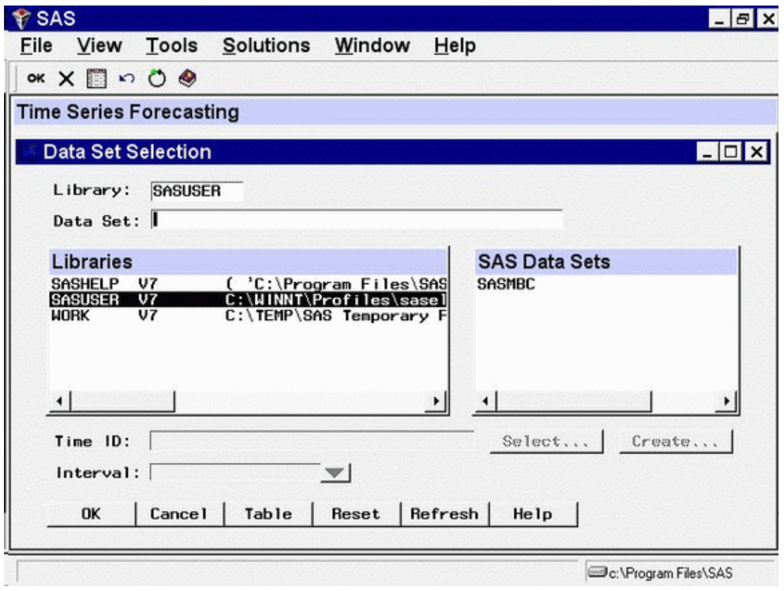
The Input Data Set

As the first step, you must specify the input data set.

The Data Set field in the Time Series Forecasting window gives the name of the input data set containing the time series to forecast. Initially, this field is blank. You can specify the input data set by typing the data set name in this field. Alternatively, you can select the Browse button at the right of the Data Set field to select the data set from a list, as shown in the following section.

The Data Set Selection Window

Select the Browse button to the right of the Data Set field. This brings up the Data Set Selection window, as shown in Figure 34.5.



Library: SASUSER
Data Set:

Libraries

```
SASHELP  V7     ( 'C:\Program Files\SAS
SASUSER  V7     C:\WINNT\Profiles\sasel

```

SAS Data Sets

```
SASMBC
```

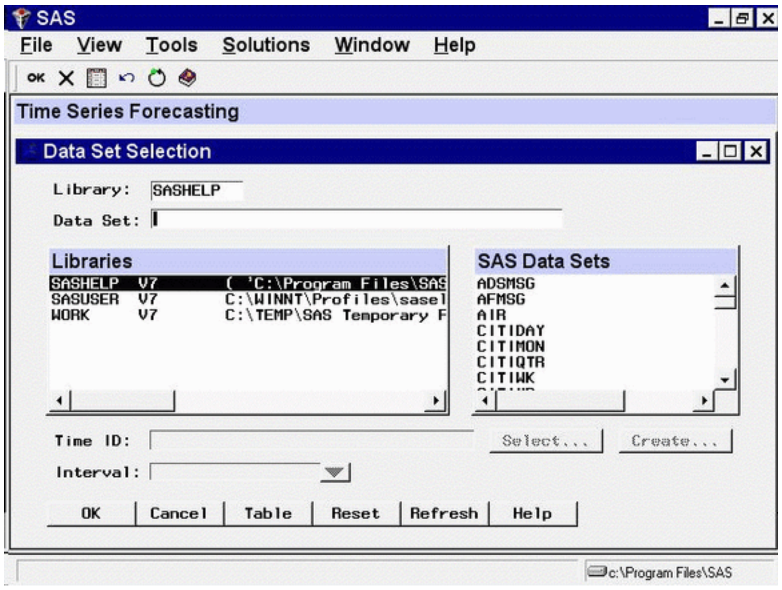
Time ID:
Interval:

c:\Program Files\SAS

Figure 34.5. Data Set Selection Window

The `Libraries` list shows the SAS librefs that are currently allocated in your SAS session. Initially, the SASUSER library is selected, and the `SAS Data Sets` list shows the data sets available in your SASUSER library.

In the `Libraries` list, select the row that starts with SASHELP. The Data Set Selection window now lists the data sets in the SASHELP library, as shown in Figure 34.6.



```
Library:  SASHELP
Data Set:

Libraries
SASHELP   V7      ( 'C:\Program Files\SAS
SASUSER   V7      C:\WINNT\Profiles\sasel

```

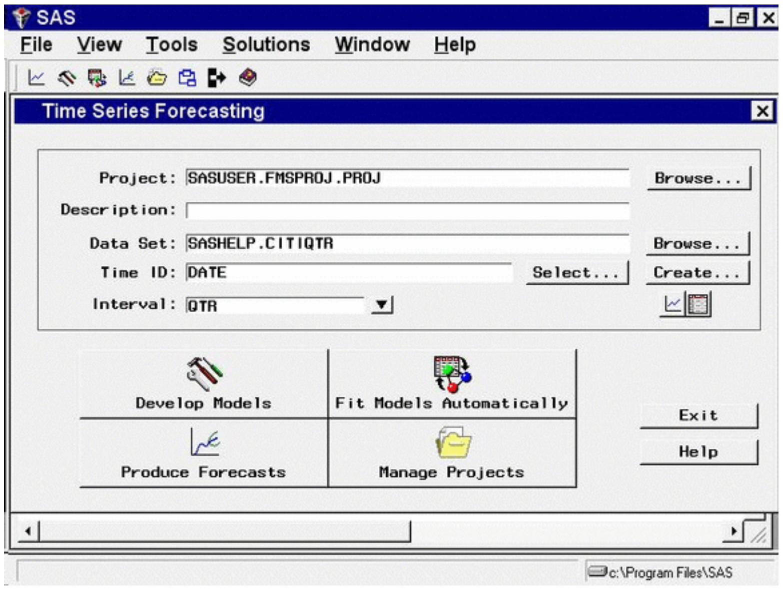
Figure 34.7. CITIQTR Data Set Selected

Note that the Time ID field is now set to DATE and the Interval field is set to QTR. These fields are explained in the following section.

Now select the OK button to complete selection of the CITIQTR data set. This closes the Data Set Selection window and returns to the Time Series Forecasting window, as shown in Figure 34.8.



Project: SASUSER.FMSPROJ.PROJ
Description:
Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR

Figure 34.8. Time Series Forecasting Window

Time Series Data Sets, ID variables, and Time Intervals

Before you continue with the example, it is worthwhile to consider how the system determined the values for the Time ID and Interval fields in the Data Set Selection window.

The Forecasting System requires that the input data set contain time series observations, with one observation for each time period. The observations must be sorted in increasing time order, and there must be no gaps in the sequence of observations. The time period of each observation must be identified by an ID variable, which is shown in the Time ID field.

If the data set contains a variable named DATE, TIME, or DATETIME, the system assumes that that variable is the SAS date or datetime valued ID variable, and the Time ID field is filled in automatically. The time ID variable for the SASHELP.CITIQTR data set is named DATE, and therefore the system set the Time ID field to DATE.

If the time ID variable for a data set is not named DATE, TIME, or DATETIME, you must specify the time ID variable name. You can specify the time ID variable either by typing the ID variable name in the Time ID field or by clicking the Select button.

If your data set does not contain a time ID variable with SAS date values, you can add a time ID variable using one of the windows described in Chapter 35, “Creating Time ID Variables.”

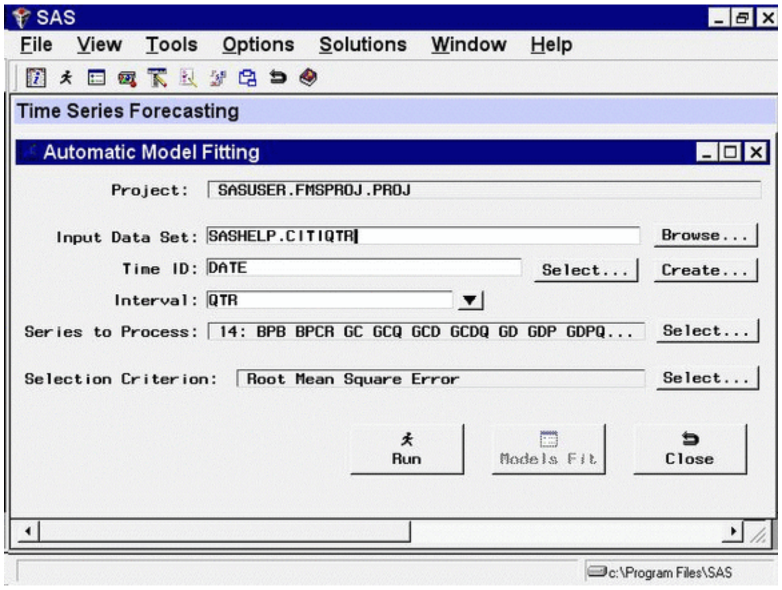
Once the time ID variable is known, the Forecasting System examines the ID values to determine the time interval between observations. The data set SASHELP.CITIQTR contains quarterly observations. Therefore, the system determined that the data have a quarterly interval, and set the Interval field to QTR.

If the system cannot determine the data frequency from the values of the time ID variable, you must specify the time interval between observations. You can specify the time interval using the `Interval` combo box. In addition to the interval names provided in the pop-up list, you can type in more complex interval names to specify an interval that is a multiple of other intervals or that has date values in the middle of the interval (such as monthly data with time ID values falling on the 10th day of the month).

See Chapter 2, "Working with Time Series Data," and Chapter 3, "Date Intervals, Formats, and Functions," for more information on time intervals, SAS date values, and ID variables for time series data sets.

Automatic Model Fitting Window

Before you can produce forecasts, you must fit forecasting models to the time series. Select the Fit Models Automatically button. This brings up the Automatic Model Fitting window, as shown in Figure 34.9.



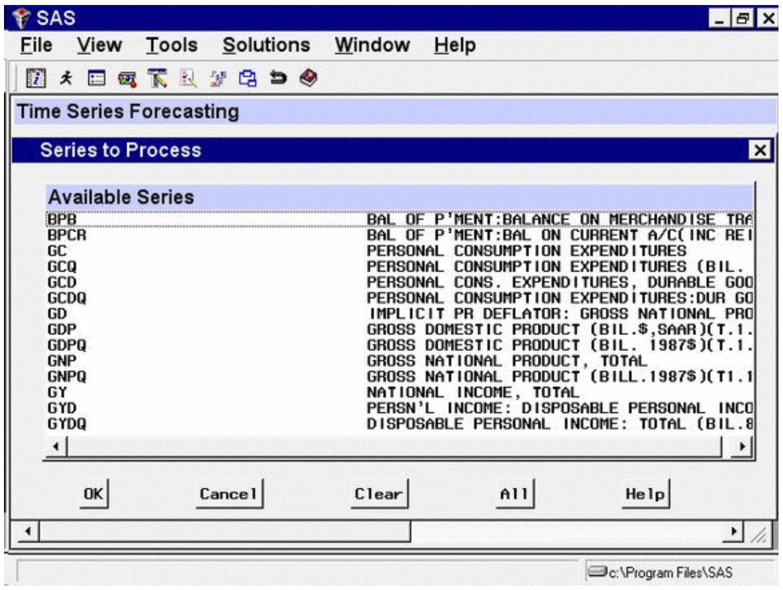
Project: SASUSER.FMSPROJ.PROJ
Input Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR
Series to Process: 14: BPB BPCR GC GCQ GCD GCDQ GD GDP GDPQ...
Selection Criterion: Root Mean Square Error

Figure 34.9. Automatic Model Fitting Window

The first part of the Automatic Model Fitting window confirms the project filename and the input data set name.

The Series to Process field shows the number and lists the names of the variables in the input data set to which the Automatic Model Fitting process will be applied. By default, all numeric variables (except the time ID variable) are processed. However, you can specify that models be generated for only a select subset of these variables.

Click the Select button to the right of the Series to Process field. This brings up the Series to Process window, as shown in Figure 34.10.



```
BPB     BAL OF P'MENT:BALANCE ON MERCHANDISE TRA
BPCR    BAL OF P'MENT:BAL ON CURRENT A/C( INC REI

GY      NATIONAL INCOME, TOTAL
GYD     PERSN'L INCOME: DISPOSABLE PERSONAL INCO
GYDQ    DISPOSABLE PERSONAL INCOME: TOTAL (BIL.8
```

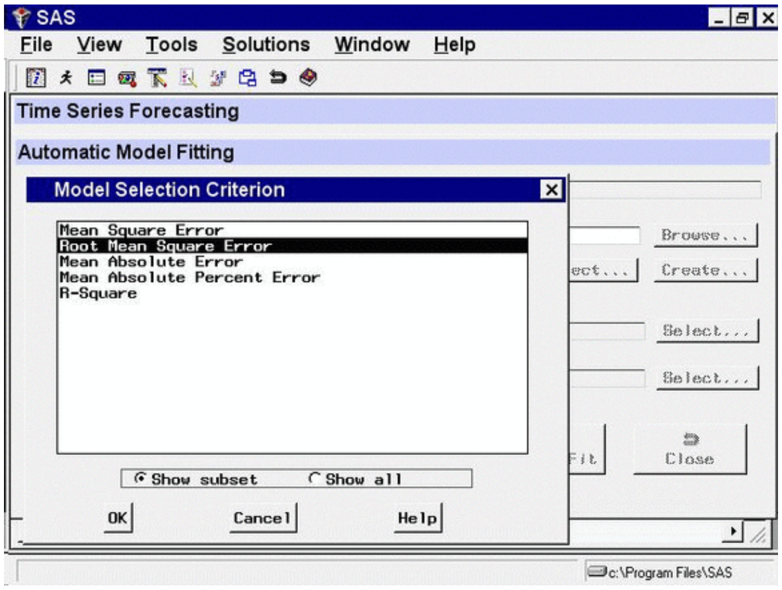
Figure 34.11. Selecting Series for Automatic Model Fitting

Now select the OK button. This returns you to the Automatic Model Fitting window. The Series to Process field now shows the selected variables.

The Selection Criterion field shows the goodness-of-fit measure that the Forecasting System will use to select the best fitting model for each series. By default, the selection criterion is the root mean square error. To illustrate how you can control the selection criterion, this example will use the mean absolute percent error to select the best fitting models.

Click the Select button to the right of the Selection Criterion field. This brings up a list of statistics of fit, as shown in Figure 34.12.

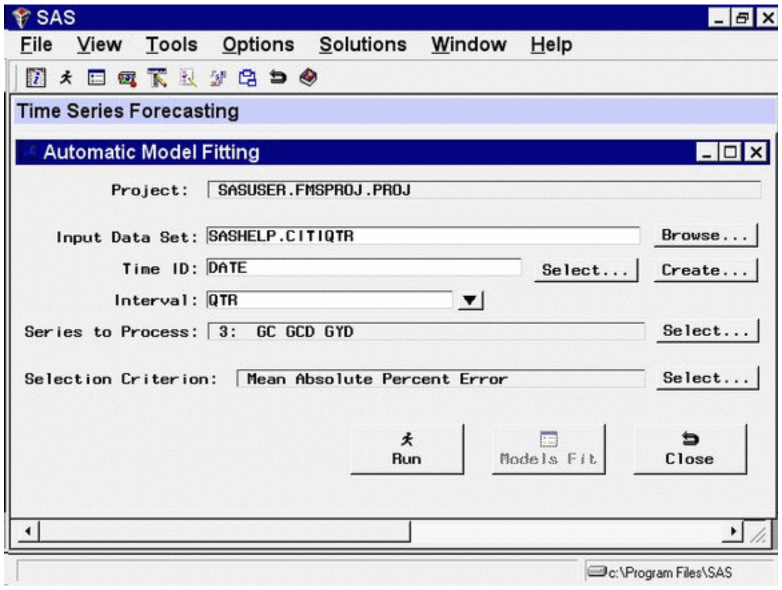


Mean Square Error
Root Mean Square Error
Mean Absolute Error
Mean Absolute Percent Error
R-Square

[✓ Show subset] Show all

Figure 34.12. Choosing the Model Selection Criterion

Select *Mean Absolute Percent Error* and then select the OK button. The Automatic Model Fitting window now appears as shown in Figure 34.13.

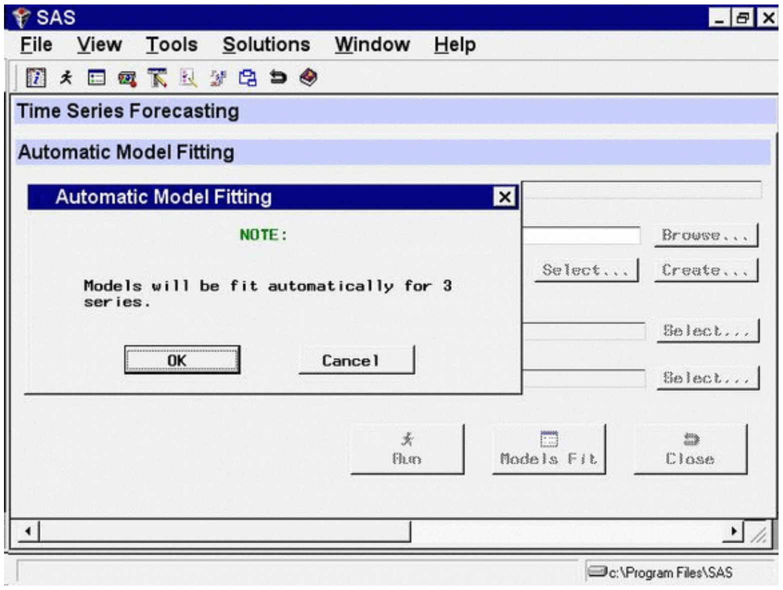


Project: SASUSER.FMSPROJ.PROJ
Input Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR
Series to Process: 3: GC GCD GYD
Selection Criterion: Mean Absolute Percent Error

Figure 34.13. Automatic Model Fitting Window

Now that all the options are set appropriately, select the Run button.

The Forecasting System now displays a notice, shown in Figure 34.14, confirming that models will be fit for 3 series using the automatic forecasting model search feature. This prompt is displayed because it is possible to fit models for a large number of series at once, which may take a lot of time, and so the system gives you a chance to cancel if you accidentally ask to fit models for more series than you intended. Select the OK button.

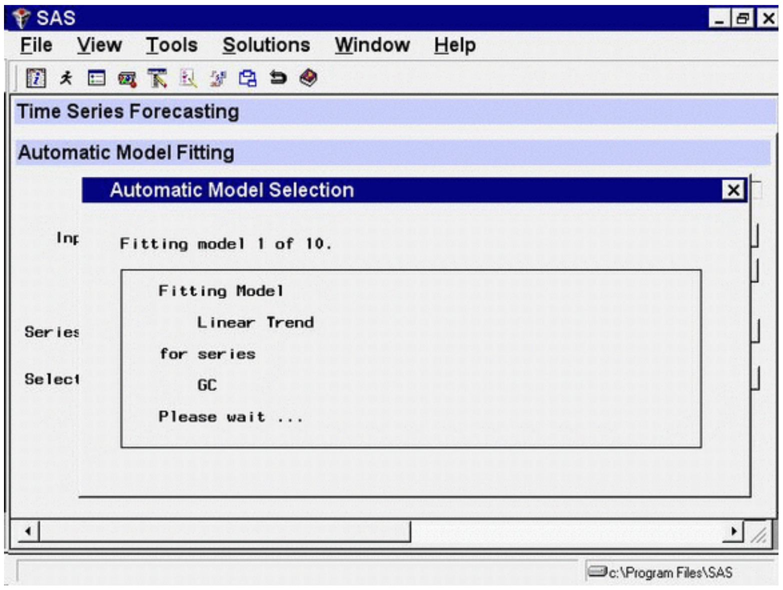


NOTE:

Models will be fit automatically for 3 series.

Figure 34.14. Automatic Model Fitting Note

The system now fits several forecasting models to each of the three series you selected. While the models are being fit, the Forecasting System displays notices indicating what it is doing so that you can observe its progress, as shown in Figure 34.15.



Fitting model 1 of 10.

Figure 34.16. Automatic Model Fitting Results

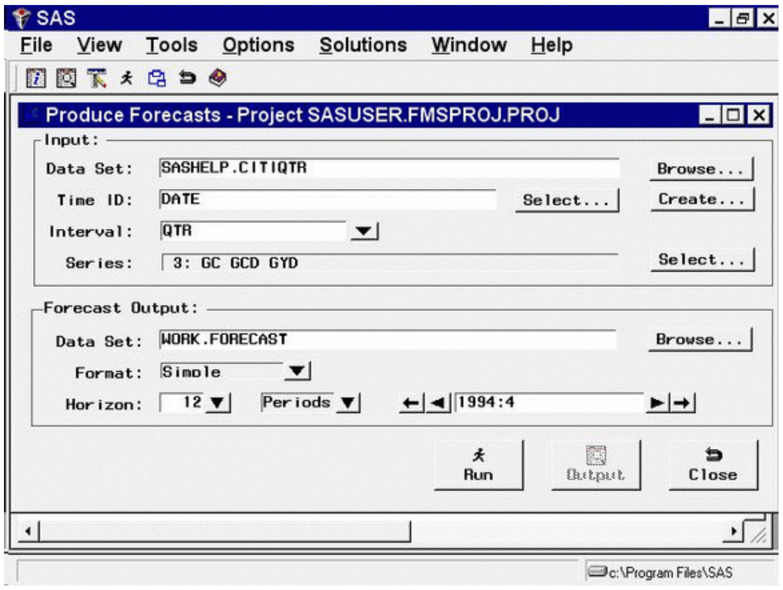
This resizable window shows the list of series names and descriptive labels for the forecasting models chosen for them, as well as the values of the model selection criterion and other statistics of fit. Select the Close button.

This returns you to the Automatic Model Fitting window. You can now fit models for other series in this data set or change to a different data set and fit models for series in the new data set.

Select the Close button to return to the Time Series Forecasting window.

Produce Forecasts Window

Now that you have forecasting models for these three series, you are ready to produce forecasts. Select the Produce Forecasts button. This brings up the Produce Forecasts window, as shown in Figure 34.17.



Produce Forecasts - Project SASUSER.FMSPROJ.PROJ

Input:
Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR
Series: 3: GC GCD GYD

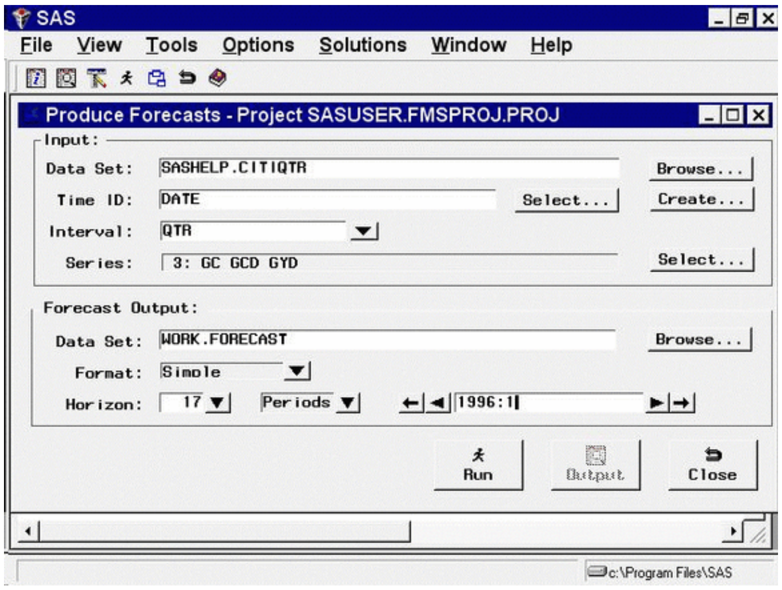
Forecast Output:
Data Set: WORK.FORECAST
Format: Simple
Horizon: 12 Periods 1994:4

Figure 34.17. Produce Forecasts Window

The Produce Forecasts window shows the input data set information and indicates the variables in the input data set for which forecasting models exist. Forecasts will be produced for these series. If you want to produce forecasts for only some of these series, use the control arrow at the right of the Series field to select the series to forecast. The Data Set field in the `Forecast Output` box contains the name of the SAS data set in which the system will store the forecasts. The default output data set is WORK.FORECAST.

You can set the forecast horizon using the controls on the line labeled `Horizon`. The default horizon is 12 periods. You can change it using number of periods, number of years, or the date of the last forecast period. Position the cursor in the date field and change the forecast ending date to 1 January 1996 by typing `jan1996` and pressing the ENTER key.

The window now appears as shown in Figure 34.18.



Produce Forecasts - Project SASUSER.FMSPROJ.PROJ

Input:
Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR
Series: 3: GC GCD GYD

Forecast Output:
Data Set: WORK.FORECAST
Format: Simple
Horizon: 17 Periods 1996:1

Figure 34.18. Produce Forecasts Window

Now select the Run button to produce the forecasts. The system indicates that the forecasts have been stored in the output data set. Select `OK` to dismiss the notice.

The Forecast Data Set

The Forecasting System can save the forecasts to a SAS data set in three different formats. Depending on your needs, you may find one of these output formats more convenient. The output data set format is controlled by the `Format` combo box. You can select the following output formats. The simple format is the default.

`Simple`	The data set contains time ID variables and the forecast variables, and it contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.
`Interleaved`	The data set contains time ID variables, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.
`Concatenated`	The data set contains the variable SERIES, time ID variables, and the variables ACTUAL, PREDICT, ERROR, UPPER, LOWER, and STD. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

Simple Format Forecast Data Set

To see the simple format forecast data set that the system created, select the Output button. This brings up a Viewtable window to display the data set, as shown in Figure 34.19.

	Date of Observation	YEAR	QTR	GC	GCD	GYD
1	1980:1	1980	1	1702	218.7000	1894
2	1980:2	1980	2	1705	198.2000	1901
3	1980:3	1980	3	1762	211.3000	1966
4	1980:4	1980	4	1824	221.8000	2051
5	1981:1	1981	1	1876	230.8000	2107
6	1981:2	1981	2	1909	225.5000	2142
7	1981:3	1981	3	1952	236.3000	2209
8	1981:4	1981	4	1968	221.4000	2241
9	1982:1	1982	1	2005	230.9000	2259
10	1982:2	1982	2	2029	232.9000	2303
11	1982:3	1982	3	2073	235.2000	2343
12	1982:4	1982	4	2129	246.9000	2374
13	1983:1	1983	1	2163	251.2000	2406
14	1983:2	1983	2	2232	270.1000	2457
15	1983:3	1983	3	2289	281.0000	2518
16	1983:4	1983	4	2347	297.7000	2594
17	1984:1	1984	1	[illegible]	[illegible]	[illegible]

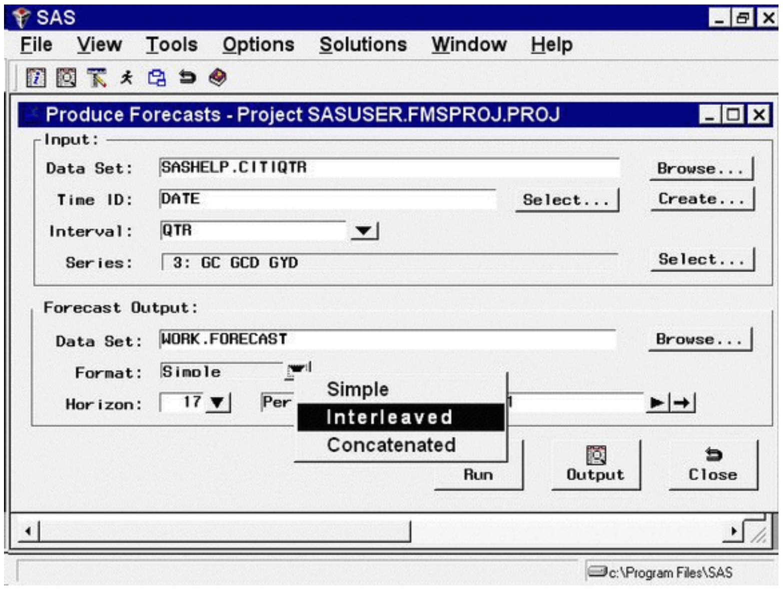
Figure 34.19. Forecast Data Set – Simple Format

Figure 34.19 shows the default simple format. This form of the forecast data set contains time ID variables and the variables that you forecast. The forecast variables contain actual values or predicted values, depending on whether the date of the observation is within the range of data supplied in the input data set.

Select `File` and `Close` to close the Viewtable window.

Interleaved Format Forecast Data Set

From the Produce Forecasts window, use the combo box to select the `Interleaved` format, as shown in Figure 34.20.



Data Set: SASHELP.CITIQTR
Time ID: DATE
Interval: QTR
Series: 3: GC GCD GYD

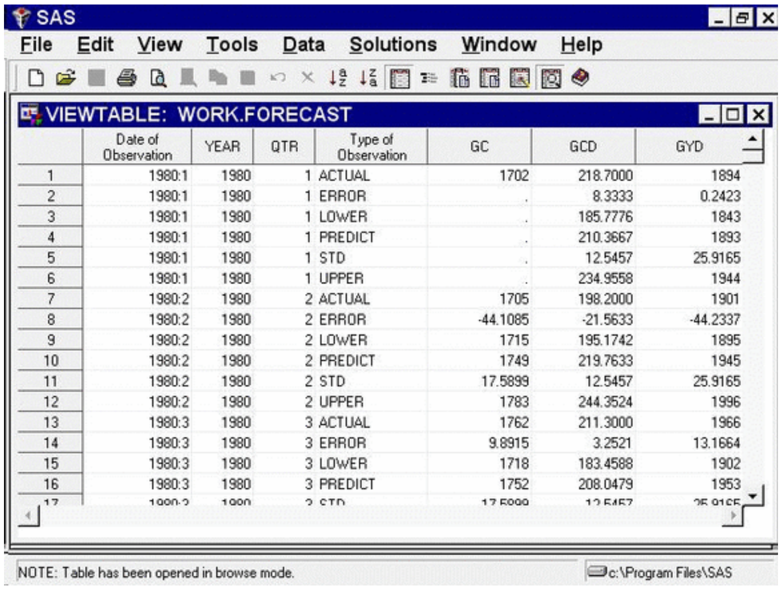
Data Set: WORK.FORECAST
Format: Simple
Horizon: 17 Per

Figure 34.20. Forecast Data Set Options

Now select the Run button again. The system presents a warning notice reminding you that the data set WORK.FORECAST already exists and asking if you want to replace it. Select `Replace`.

The forecasts are stored in the data set WORK.FORECAST again, this time in the *Interleaved* format. Dismiss the notice that the forecast was stored.

Now select the Output button again. This brings up a Viewtable window to display the data set, as shown in Figure 34.21.



VIEWTABLE: WORK.FORECAST

Figure 34.21. Forecast Data Set – Interleaved Format

In the interleaved format, there are several output observations for each input observation, identified by the TYPE variable. The values of the forecast variables for observations with different TYPE values are as follows.

`ACTUAL`	actual values copied from the input data set.
`ERROR`	the difference between the actual and predicted values.
`LOWER`	the lower confidence limits.
`PREDICT`	the predicted values from the forecasting model. These are within-sample, one-step-ahead predictions for observations within the historical period, or multistep predictions for observations within the forecast period.
`STD`	the estimated standard deviations of the prediction errors.
`UPPER`	the upper confidence limits.

Select `File` and `Close` to close the Viewtable window.

Concatenated Format Forecast Data Set

Use the combo box to select the `Concatenated` format. Re-create the forecast data set again, and then select the Output button.

The Viewtable window showing the concatenated format of the forecast data set appears, as shown in Figure 34.22.

	series	Date of Observation	YEAR	QTR	Actual value	Predicted value	Prediction error	Upper 95% Confidence Limit	Lower 95% Confidence Limit	Prediction standard error

Figure 34.22. Forecast Data Set – Concatenated Format

This completes the example of how to use the Produce Forecasts window. Select `File` and `Close` to close the Viewtable window. Select the Close button to return to the Time Series Forecasting window.

Forecasting Projects

The system collects all the forecasting models you create, together with the options you set, into a package called a *forecasting project*. You can save this information in a SAS catalog entry and restore your work in later forecasting sessions. You can store any number of forecasting projects under different catalog entry names.

To see how this works, select the Manage Projects button. This brings up the Manage Forecasting Project window, as shown in Figure 34.23.

Project Name: SASUSER.FMSPROJ.PROJ

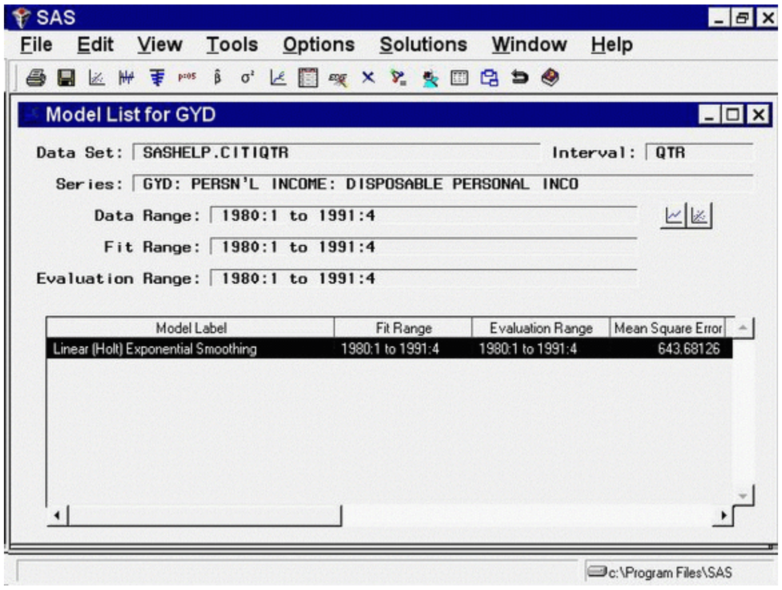
Description:

Series Name	Series Frequency	Input Data Set Name	Forecasting Model
GC	QTR	SASHELP.CITIQTR	Random Walk with Drift
GCD	QTR	SASHELP.CITIQTR	Linear (Holt) Exponential Smoothing
GYD	QTR	SASHELP.CITIQTR	Linear (Holt) Exponential Smoothing

Figure 34.23. Manage Forecasting Project Window

The table in this window lists the series for which forecasting models have been fit, and it shows for each series the forecasting model used to produce the forecasts. This window provides several features that allow you to manage the information in your forecasting project.

You can select a row of the table to drill down to the list of models fit to the series. Select the GYD row of the table, either by double-clicking with the mouse or by clicking once to highlight the table row and then selecting `List Models` from the toolbar or from the Tools pull-down menu. This brings up the Model List window for this series, as shown in Figure 34.24.



Data Set: SASHELP.CITIQTR Interval: QTR

Series: GYD: PERSN'L INCOME: DISPOSABLE PERSONAL INCO

Data Range: 1980:1 to 1991:4

Fit Range: 1980:1 to 1991:4

Evaluation Range: 1980:1 to 1991:4

Model Label	Fit Range	Evaluation Range	Mean Square Error
Linear (Holt) Exponential Smoothing	1980:1 to 1991:4	1980:1 to 1991:4	643.68126

Figure 34.24. Model List Window

Because the Automatic Model Fitting Process process kept only the best fitting model, only one model appears in the model list. You can fit and retain any number of models for each series, and all the models fit and kept will appear in the series' model list.

Select `Close` from the toolbar or from the File pull-down menu to return to the Manage Forecasting Project window.

Saving and Restoring Project Information

To illustrate how you can save your work between sessions, in this section you will exit and then re-enter the Forecasting System.

From the Manage Forecasting Project window, select `File` and `Save as`. This brings up the Forecasting Project to Save window. In the Project Name field type the name WORK.TEST.TESTPROJ. In the Description field, type "Test of forecasting project file". The window should now appear as shown in Figure 34.25.

Time ID: DATE
Interval: QTR

Figure 34.28. Time Series Forecasting Window after Loading Project

If you now select the Manage Projects button, you will see the list of series and forecasting models you created in the previous forecasting session.

Sharing Projects

If you plan to work with others on a forecasting project, you may need to consider how project information can be shared. The series, models, and results of your project are stored in a forecasting project (fmsproj) catalog entry in the location you specify, as illustrated in the previous section. You need only read access to the catalog to work with it, but you must have write access to save the project. Multiple users cannot open a project for update at the same time, but they can do so at different times if they all have write access to the catalog where it is stored.

Project options settings such as the *model selection criterion* and *number of models to keep* are stored in an slist catalog entry in the SASUSER or TSFSUSER library. Write access to this catalog is required. If you have only read access to the SASUSER library, you can use the -RSASUSER option when starting SAS. You will be prompted for a location for the TSFSUSER library, if it is not already assigned. If you want to use TSFSUSER routinely, assign it before you start the Time Series Forecasting System. Select New from the SAS Explorer file menu. In the New Library window, type TSFSUSER for the name. Click the browse button and select the directory or folder you want to use. Turn on the *enable at startup* option so this library will be assigned automatically in subsequent sessions.

The SASUSER library is typically used for private settings saved by individual users. This is the default location for project options. If a work group shares a single options catalog (SASUSER or TSFSUSER points to the same location for all users), then only one user can use the system at a time.

Develop Models Window

In the first forecasting example, you used the Automatic Model Fitting window to fit and select the forecasting model for each series automatically. In addition to this automatic forecasting process, you can also work with time series one at a time to fit forecasting models and apply your own judgment to choose the best forecasting model for each series.

Using the Automatic Model Fitting feature, the system acts like a "black box." This section goes inside the black box to look at the kinds of forecasting methods that the system provides and introduces some of the tools the system offers to help you find the best forecasting model.

Introduction

From the Time Series Forecasting window, select the Browse button to the right of the Data Set field to bring up the Data Set Selection window. Select the USECON data set from the SASHELP library. This data set contains monthly data on the U.S. economy.

Select OK to close the selection window. Now select the Develop Models button. This brings up the Series Selection window, as shown in Figure 34.29. You can enlarge this window for easier viewing of lists of data sets and series.

	No models	

Figure 34.30. Develop Models Window

The Data Set, Interval, and Series fields in the upper part of the Develop Models window indicate the series with which you are currently working. You can change the settings of these fields by selecting the Browse button.

The Data Range, Fit Range, and Evaluation Range fields show the time period over which data are available for the current series, and what parts of that time period will be used to fit forecasting models to the series and to evaluate how well the models fit the data. You can change the settings of these fields by selecting the Set Ranges button.

The bottom part of the Develop Models window consists of a table of forecasting models fit to the series. Initially, the list is empty, as indicated by the message "No models." You can fit any number of forecasting models to each series and designate which one you want to use to produce forecasts.

Graphical tools are available for exploring time series and fitted models. The two icons below the Browse button access the `Time Series Viewer` and the Model Viewer.

Select the left icon. This brings up the Time Series Viewer window, as shown in Figure 34.31.

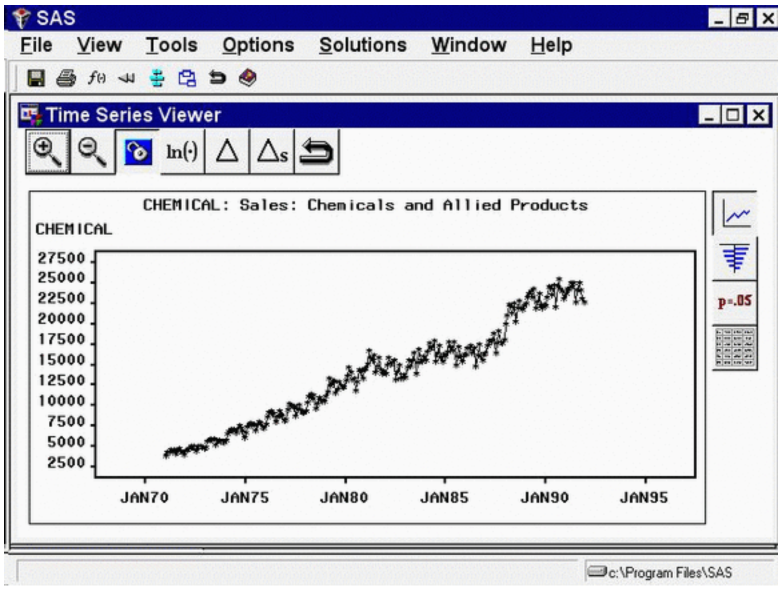

Figure 34.31. Chemical and Allied Product Series

The Time Series Viewer displays a plot of the CHEMICAL series. The Time Series Viewer offers many useful features, which are explored in later sections.

The Time Series Viewer appears in a separate resizable window. You can switch back and forth between the Time Series Viewer window and other windows. For now, return to the Develop Models window. You can close the Time Series Viewer window or leave it open. (To close the Time Series Viewer window, select `Close` from the toolbar or from the File pull-down menu.)

Fitting Models

To bring up a menu of model fitting choices, select `Edit` from the menu bar and then select `Fit Model`, or select `Fit Models from List` in the tool-bar, or simply select a blank line in the table as shown in Figure 34.32.

Figure 34.32. Menu of Model Fitting Choices

The Forecasting System provides several ways to specify forecasting models. The eight choices given by the menu shown in Figure 34.32 are as follows:

`Fit Models Automatically`
: performs for the current series the same automatic model selection process that the Automatic Model Fitting window applies to a set of series.

`Fit Models from List`
: presents a list of commonly used forecasting models for convenient point-and-click selection.

`Fit Smoothing Model`
: displays the Smoothing Model Specification window, which enables you to specify several kinds of exponential smoothing and Winters method forecasting models.

`Fit ARIMA Model`
: displays the ARIMA Model Specification window, which enables you to specify many kinds of autoregressive integrated moving average (ARIMA) models, including seasonal ARIMA models and ARIMA models with regressors, transfer functions, and other predictors.

`Fit Factored ARIMA Model`
: displays the Factored ARIMA Model Specification window, which enables you to specify more general ARIMA models, including subset models and models with unusual and/or multiple seasonal cycles. It also supports regressors, transfer functions, and other predictors.

`Fit Custom Model`
: displays the Custom Model Specification window, which enables you to construct a forecasting model by specifying separate options for transforming the data, modeling the trend, modeling seasonality, modeling autocorrelation of the errors, and modeling the effect of regressors and other independent predictors.

`Combine Forecasts`
: displays the Forecast Combination Model Specification window, which enables you to specify models that produce forecasts by combining, or averaging, the forecasts from other models. (This option is not available unless you have fit at least two models.)

`Use External Forecasts`
: displays the External Forecast Model Specification window, which enables you to use judgmental or externally produced forecasts that have been saved in a separate series in the data set.

All of the forecasting models used by the system are ultimately specified through one of the four windows: Smoothing Method Specification, ARIMA Model Specification, Factored ARIMA Model Specification, or Custom Model Specification. You can specify the same models with either the ARIMA Model Specification window or the Custom Model Specification window, but the Custom Model Specification window may provide a more natural way to specify models for those who are less familiar with the Box-Jenkins style of time series model specification.

The Automatic Model feature, the Models to Fit window, and the Forecast Combination Model Specification window all deal with lists of forecasting models previously defined through the Smoothing Model, ARIMA Model, or Custom Model specification windows. These windows are discussed in detail in later sections.

To get started using the Develop Models window, select the Fit Models from List item from the menu shown in Figure 34.32. This brings up the Models to Fit window, as shown in Figure 34.33.

Forecast Model	Model Title	Root Mean Square Error
☐	Linear Trend	1203.2
☑	Double (Brown) Exponential Smoothing	868.69919

Figure 34.35. Fitted Models List

Model List and Statistics of Fit

In the model list, the *Model Title* column shows the descriptive labels for the two fitted models, in this case Linear Trend and Double Exponential Smoothing.

The column labeled *Root Mean Square Error* (or labeled *Mean Absolute Percent Error* if you continued from the example in the previous section) shows the goodness-of-fit criterion used to decide which model fits better. By default, the criterion used is the root mean square error, but you can choose a different measure of fit. The linear trend model has a root mean square error of 1203, while the double exponential smoothing model fits better, with a RMSE of only 869.

The left column labeled *Forecast Model* consists of check boxes that indicate which one of the models in the list has been selected as the model to use to produce the forecasts for the series. When new models are fit and added to the model list, the system sets the Forecast Model flags to designate the one model with the best fit–as measured by the selected goodness-of-fit statistic–as the forecast model. (In the case of ties, the first model with the best fit is selected.)

Because the Double Exponential Smoothing model has the smaller RMSE of the two models in the list, its Forecast Model check box is set. If you would rather produce forecasts using the Linear Trend model, choose it by selecting the corresponding check box in the Forecast Model column.

To use a different goodness-of-fit criterion, select the button with the current criterion name on it (Root Mean Square Error or Mean Absolute Percent Error). This brings up the Model Selection Criterion window, as shown in Figure 34.36.

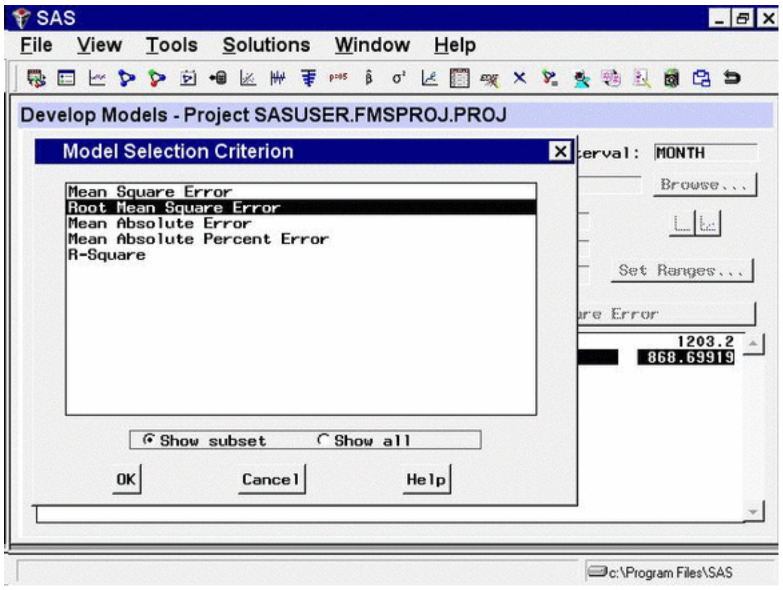

Figure 34.36. Model Selection Criterion Window

The system provides many measures of fit that you can use as the model selection criterion. To avoid confusion, only the most popular of the available fit statistics are shown in this window by default. To display the complete list, you can select the `Show all` option. You can control the subset of statistics listed in this window through the Statistics of Fit item in the Options menu on the Develop Models window.

Initially, Root Mean Square Error is selected. Select R-Square and then select the OK button. This changes the fit statistic displayed in the model list, as shown in Figure 34.37.

Figure 34.40. Model Viewer: Prediction Errors Plot

If the model being viewed includes a transformation, prediction errors are defined as the difference between the transformed series actual values and model predictions. You can choose to graph instead the difference between the untransformed series values and untransformed model predictions, which are called *model residuals*. You can also graph normalized prediction errors or normalized model residuals. Use the Residual Plot Options submenu under the Options pull-down menu.

Autocorrelation Plots

Select the third icon from the top in the vertical tool-bar. This switches the Viewer to display a plot of autocorrelations of the model prediction errors at different lags, as shown in Figure 34.41. Autocorrelations, partial autocorrelations, and inverse autocorrelations are displayed, with lines overlaid at plus and minus two standard errors. You can switch the graphs so that the bars represent significance probabilities by selecting the Correlation Probabilities item on the tool-bar or from the View pull-down menu. For more information on the meaning and use of autocorrelation plots, refer to Chapter 11, "The ARIMA Procedure."

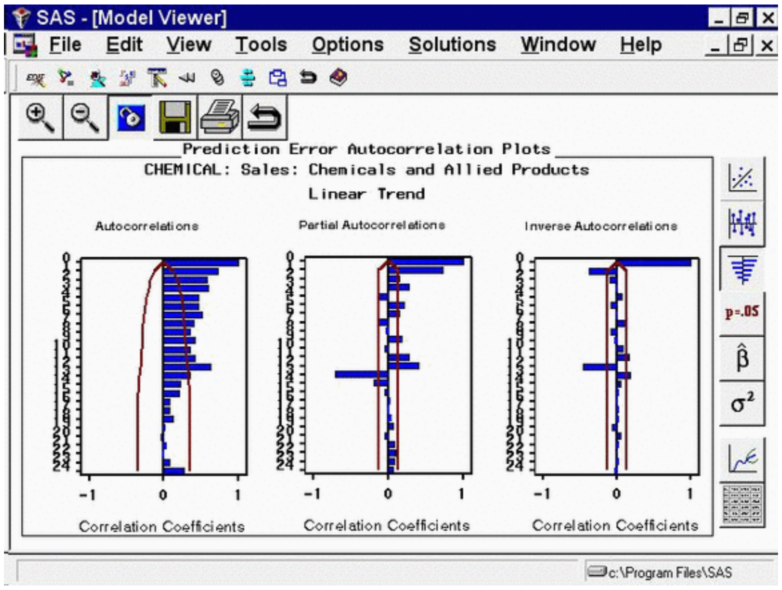

Figure 34.41. Model Viewer: Autocorrelations Plot

White Noise and Stationarity Plots

Select the fourth icon from the top in the vertical tool-bar. This switches the Viewer to display a plot of white noise and stationarity tests on the model prediction errors, as shown in Figure 34.42.

p=.05
c:\Program Files\SAS

Figure 34.42. Model Viewer: White Noise and Stationarity Plot

The white noise test bar chart shows significance probabilities of the Ljung-Box Chi Square statistic. Each bar shows the probability computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the prediction errors represent white noise. In this example they are all significant beyond the .001 probability level, so that we reject the null hypothesis. In other words, the high level of significance at all lags makes it clear that the linear trend model is inadequate for this series.

The second bar chart shows significance probabilities of the Augmented Dickey-Fuller test for unit roots. For example, the bar at lag three indicates a probability of .0014, so that we reject the null hypothesis that the series is nonstationary. The third bar chart is similar to the second except that it represents the seasonal lags. Since this series has a yearly seasonal cycle, the bars represent yearly intervals.

You can select any of the bars to display an interpretation. Select the fourth bar of the middle chart. This displays the `Recommendation for Current View`, as shown in Figure 34.43. This window gives an interpretation of the test represented by the bar that was selected; it is significant, therefore a stationary series is likely. It also gives a recommendation: You do not need to perform a simple difference to make the series stationary.

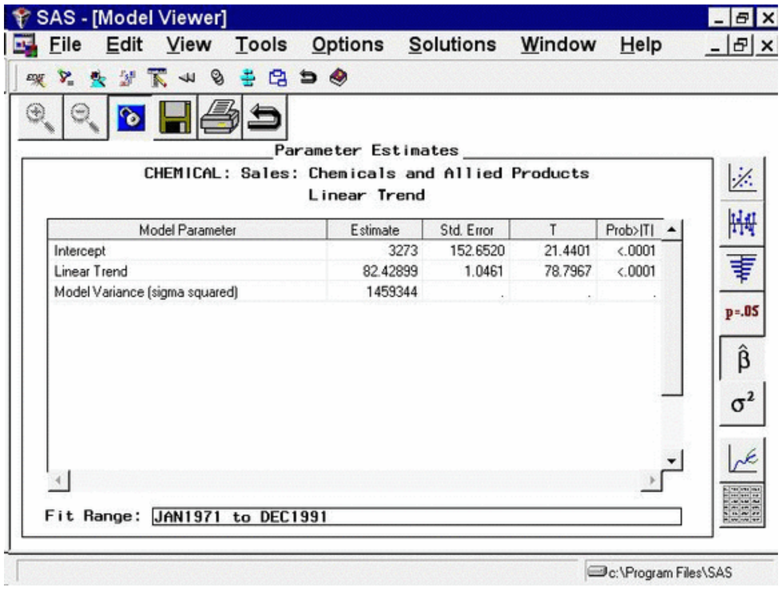
Parameter Estimates Table

Select the fifth icon from the top in the vertical tool-bar to the right of the graph. This switches the Viewer to display a table of parameter estimates for the fitted model, as shown in Figure 34.44.



Parameter Estimates

CHEMICAL: Sales: Chemicals and Allied Products
Linear Trend

Model Parameter	Estimate	Std. Error	T	Prob>|T|
Intercept	3273	152.6520	21.4401	<.0001
Linear Trend	82.42899	1.0461	78.7967	<.0001
Model Variance (sigma squared)	1459344	.	.	.

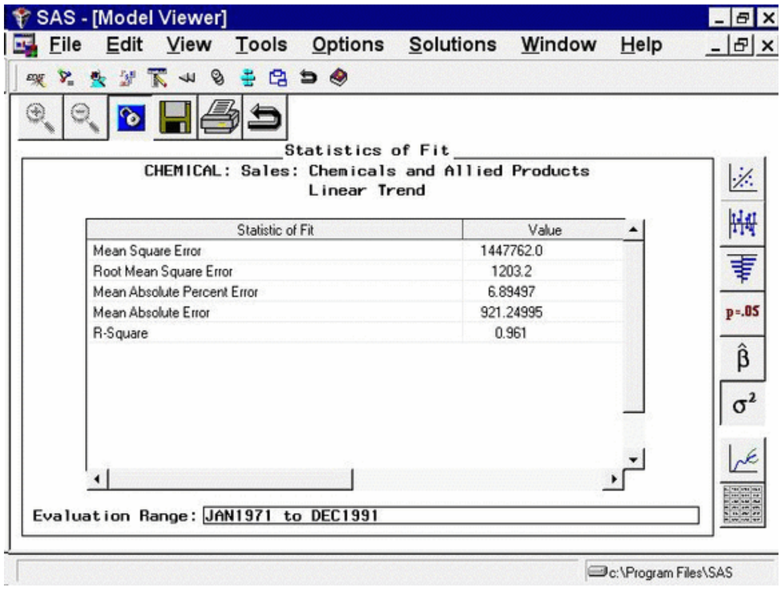
Fit Range: JAN1971 to DEC1991

Figure 34.44. Model Viewer: Parameter Estimates Table

For the linear trend model, the parameters are the intercept and slope coefficients. The table shows the values of the fitted coefficients together with standard errors and *t*-tests for the statistical significance of the estimates. The model residual variance is also shown.

Statistics of Fit Table

Select the sixth icon from the top in the vertical tool-bar to the right of the table. This switches the Viewer to display a table of statistics of fit computed from the model prediction errors, as shown in Figure 34.45. The list of statistics displayed is controlled by selecting `Statistics of Fit` from the Options pull-down menu.



Statistics of Fit
CHEMICAL: Sales: Chemicals and Allied Products
Linear Trend

Statistic of Fit	Value
Mean Square Error	1447762.0
Root Mean Square Error	1203.2
Mean Absolute Percent Error	6.89497
Mean Absolute Error	921.24995
R-Square	0.961

Evaluation Range: JAN1971 to DEC1991

Figure 34.45. Model Viewer: Statistics of Fit Table

Changing to a Different Model

Select the first icon in the vertical tool-bar to the right of the table to return the display to the predicted and actual values plots (Figure 34.39).

Now return to the Develop Models window, but do not close the Model Viewer window. You can use the Next Viewer icon in the tool-bar or your system's window manager controls to switch windows. You can resize the windows to make them both visible.

Select the Double Exponential Smoothing model so that this line of the model list is highlighted. The Model Viewer window is now updated to display a plot of the predicted values for the Double Exponential Smoothing model, as shown in Figure 34.46. The Model Viewer is automatically updated to display the currently selected model, unless you specify `Unlink` (the third icon in the window's horizontal tool-bar).

To view the full data set, use the vertical and horizontal scroll bars on the data table or enlarge the window.

Closing the Model Viewer

Other features of the Model Viewer and Develop Models window are discussed later in this book. For now, close the Model Viewer window and return to the Time Series Forecasting window.

To close the Model Viewer window, select `Close` from the window's horizontal tool-bar or from the File pull-down menu.

Chapter 35
Creating Time ID Variables

Chapter Contents

Chapter 35

Creating Time ID Variables

The Forecasting System requires that the input data set contain a time ID variable. If the data you want to forecast are not in this form, you can use features of the Forecasting System to help you add time ID variables to your data set. This chapter shows examples of how to use these features.

Creating a Time ID Value from a Starting Date and Frequency

As a first example of adding a time ID variable, you will use the SAS data set created by the following statements. (Or use your own data set if you prefer.)

```
data no_id;
  input y @@;
datalines;
  10 15 20 25 30 35 40 45
  50 55 60 65 70 75 80 85
run;
```

Submit these SAS statements to create the data set NO_ID. This data set contains the single variable Y. Assume that Y is a quarterly series and starts in the first quarter of 1991.

In the `Time Series Forecasting` window, use the Browse button to the right of the `Data set` field to bring up the `Data Set Selection` window. Select the WORK library and then select the NO_ID data set.

You must create a time ID variable for the data set. Click the Create button to the right of the Time ID field. This brings up a menu of choices for creating the Time ID variable, as shown in Figure 35.1.

Help
Create...
c:\Program Files\SAS

Figure 35.2. Time ID Creation from Starting Date Window

Enter the starting date, 1991:1, in the `Starting Date` field.

Select the `Interval` combo box arrow and select QTR from the pop-up menu. The Interval value QTR means that the time interval between successive observations is a quarter of a year; that is, the data frequency is quarterly.

Now select the `OK` button. The system prompts you for the name of the new data set. If you want to create a new copy of the input data set with the DATE variable added, you should enter a name for the new data set. If you want to replace the NO_ID data set with the new copy containing DATE, just select the `OK` button without changing the name.

For this example, change the `New name` field to WITH_ID and select the `OK` button. The data set WITH_ID is created containing the series Y from NO_ID and the added ID variable DATE. The system returns to the `Data Set Selection` window, which now appears as shown in Figure 35.3.

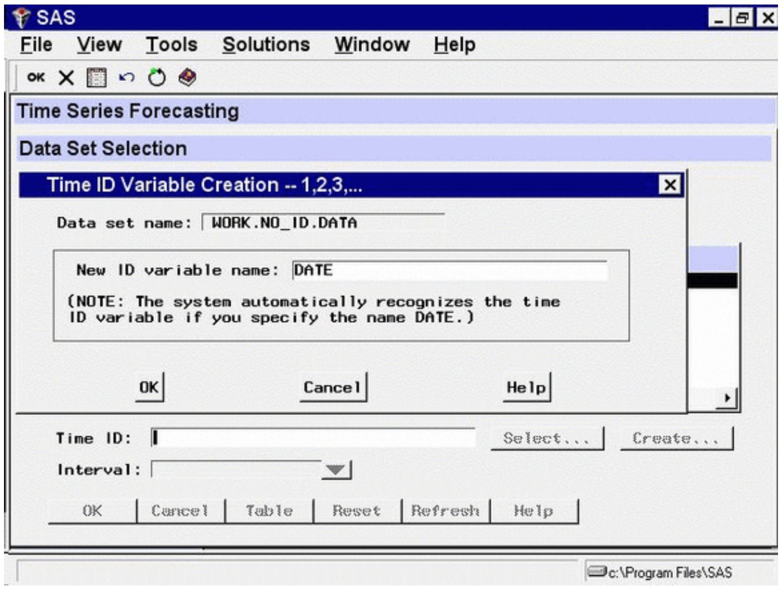
NOTE: Table has been opened in browse mode.
c:\Program Files\SAS

Figure 35.4. Viewtable Display of Data Set with Time ID Added

Using Observation Numbers as the Time ID

Normally, the time ID variable will contain date values. If you do not want to have dates associated with your forecasts, you can also use observation numbers as time ID variables. However, you still must have an ID variable. This can be illustrated by adding an observation index time ID variable to the data set NO_ID.

In the Data Set Selection window, select the data set NO_ID again. Select the Create button to the right of the `Time ID` field. Select the fourth choice, `Create from observation numbers`, from the pop-up menu. This brings up the `Time ID Variable Creation` window shown in Figure 35.5.



Data set name: WORK.NO_ID.DATA

New ID variable name: DATE

(NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.)

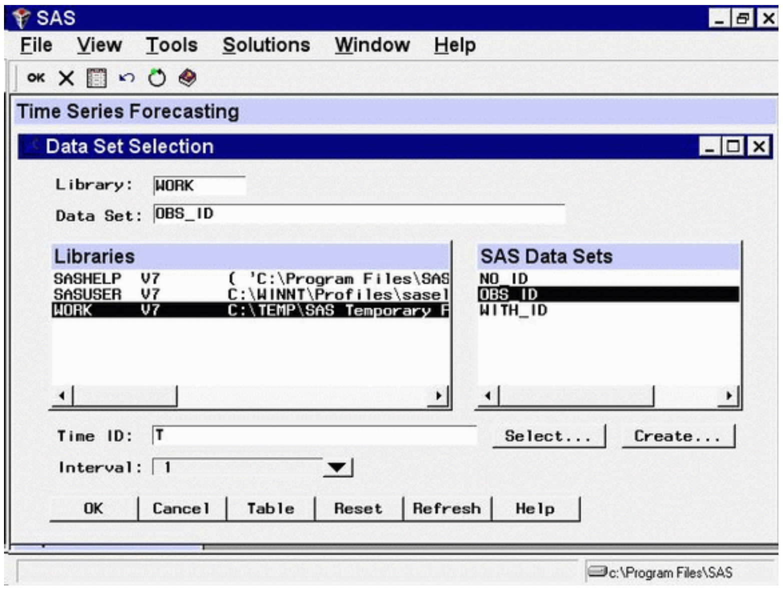
Time ID:

Interval:

Figure 35.5. Create Time ID Variable Window

Select the `OK` button. This brings up the `New Data Set Name` window. Enter "OBS_ID" in the `New data set name` field. Enter "T" in the `New ID variable name` field.

Now select the `OK` button. The new data set OBS_ID is created, and the system returns to the `Data Set Selection` window, which now appears as shown in Figure 35.6.



Library: WORK

Data Set: OBS_ID

```

Figure 35.7. VIEWTABLE of Data Set with Observation Index ID

Select `File` and `Close` to close the VIEWTABLE window. Select the `OK` button from the `Data Set Selection` window to return to the `Time Series Forecasting` window.

Creating a Time ID from Other Dating Variables

Your data set may contain ID variables that date the observations in a different way than the SAS date valued ID variable expected by the forecasting system. For example, for monthly data, the data set may contain the ID variables YEAR and MONTH, which together date the observations.

In these cases, you can use the Forecasting System's Create Time ID features to compute a time ID variable with SAS date values from the existing dating variables. As an example of this, you will use the SAS data set read in by the following SAS statements:

```
data id_parts;
  input yr qtr y;
datalines;
 91 1 10
 91 2 15
 91 3 20
 91 4 25
 92 1 30
 92 2 35
 92 3 40
 92 4 45
 93 1 50
 93 2 55
 93 3 60
 93 4 65
 94 1 70
 94 2 75
 94 3 80
 94 4 85
run;
```

Submit these SAS statements to create the data set ID_PARTS. This data set contains the three variables YR, QTR, and Y. YR and QTR are ID variables that together date the observations, but each variable provides only part of the date information. Because the forecasting system requires a single dating variable containing SAS date values, you need to combine YR and QTR to create a single variable DATE.

Type ID_PARTS in the `Data Set` field and press the ENTER key. (You could also use the Browse button to bring up the Data Set Selection window, as in the previous example, and complete this example from there.)

Select the Create button at the right of the `Time ID` field. This brings up the menu of Create Time ID choices, as shown in Figure 35.8.

Now select the `OK` button. This brings up the `New Data Set Name` window. Change the `New data set name` field to NEWDATE, and then select the `OK` button.

The data set NEWDATE is created, and the system returns to the `Time Series Forecasting` window with NEWDATE as the selected Data Set. The Time ID field is set to DATE, and the Interval field is set to QTR.

Chapter 36
Specifying Forecasting Models

Chapter Contents

Chapter 36
Specifying Forecasting Models

This chapter explores the tools available through the Develop Models window for investigating the properties of time series and for specifying and fitting models. The first section shows you how to diagnose time series properties in order to determine the class of models appropriate for forecasting series with such properties. Later sections show you how to specify and fit different kinds of forecasting models.

Series Diagnostics

The series diagnostics tool helps you determine the kinds of forecasting models that are appropriate for the data series so that you can limit the search for the best forecasting model. The series diagnostics address these three questions: Is a log transformation needed to stabilize the variance? Is a time trend present in the data? Is there a seasonal pattern to the data?

The automatic model fitting process, which you used in the previous chapter through the Automatic Model Fitting window, performs series diagnostics and selects trial models from a list according to the results. You can also look at the diagnostic information and make your own decisions as to the kinds of models appropriate for the series. The following example illustrates the series diagnostics features.

Select "Develop Models" from the Time Series Forecasting window. Select the library SASHELP, the data set CITIMON, and the series RCARD. This series represents domestic retail sales of passenger cars. To look at this series, select "View Series" from the Develop Models window. This brings up the Time Series Viewer window, as shown in Figure 36.1.

Series: RCARD: RETAIL SALES: NEW PASSENGER CARS, DOMEST

Series Characteristics:

Log Transform: Yes No [✓ Maybe]

Trend: Yes No [✓ Maybe]

Seasonality: Yes No [✓ Maybe]

Figure 36.3. Series Diagnostics Window

Each of the three series characteristics–need for log transformation, presence of a trend, and seasonality–has a set of radio buttons for `Yes`, `No`, and `Maybe`. `Yes` indicates that the series has the characteristic and that forecasting models fit to the series should be able to model and predict this behavior. `No` indicates that you do not need to consider forecasting models designed to predict series with this characteristic.

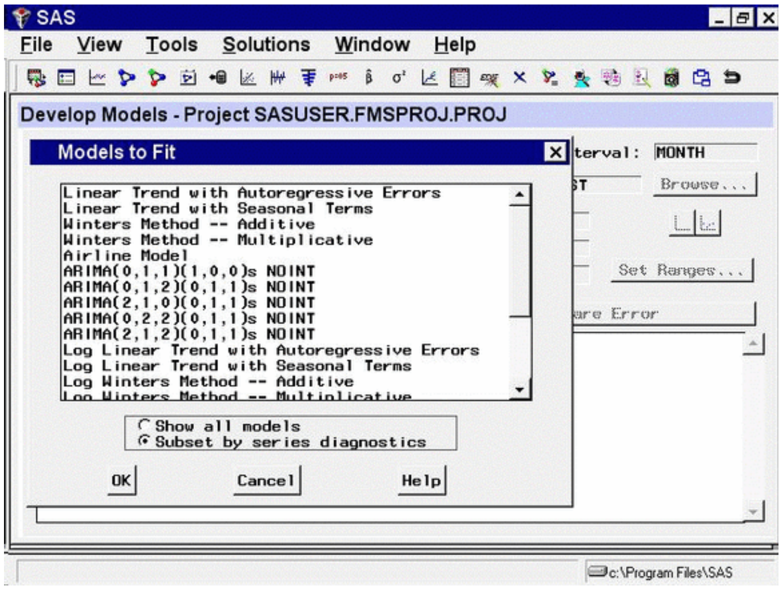
`Maybe` indicates that models with and without the characteristic should be considered. Initially, all these values are set to `Maybe.`

To have the system diagnose the series characteristics, select the Automatic Series Diagnostics button. This runs the diagnostic routines described in Chapter 41, "Forecasting Process Details," and sets the radio buttons according to the results. In this example, `Trend` and `Seasonality` are changed from `Maybe` to `Yes`, while `Log Transform` remains set to `Maybe`.

These diagnostic criteria affect the models displayed when you use the Models to Fit window or the Automatic Model Selection model-fitting options described in the following section. You can set the criteria manually, according to your judgment, by selecting any of the radio buttons, whether you have used the Automatic Series Diagnostics button or not. For this exercise, leave them as set by the automatic diagnostics. Select the OK button to close the Series Diagnostics window.

Models to Fit Window

As you saw in the previous chapter, you can select models from a list. Invoke the Models to Fit window by clicking the middle of the table and selecting "Fit Models from List" from the pop-up menu. This can also be selected from the tool bar or the Fit Model submenu of the Edit pull-down menu. The Models to Fit window comes up, as shown in Figure 36.4.



```

Figure 36.6. Develop Models Window Showing Model Fit

You can edit the model list that appears in the Models to Fit window by selecting "Options" and "Model Selection List" from the menu bar or by selecting the Edit Model List tool bar icon. You can then delete models you are not interested in from the default list and add models using any of the model specification methods described in this chapter. When you save your project, the edited model selection list is saved in the project file. In this way, you can use the Select from List item and the Automatic Model Selection item to select models from a customized search set.

Automatic Model Selection

Automatic model selection is equivalent to choosing Select from List, as you did in the preceding section, fitting all the models in the subset list and then deleting all except the best fitting of the models. If series diagnostics have not yet been done, they are performed automatically to determine the model subset to fit. If you set the series diagnostics for log, trend, or seasonal criteria manually using the radio buttons, these choices are honored by the automatic fitting process.

Using automatic selection, the system does not pause to warn you of model fitting errors, such as failure of the estimates to converge (you can track these using the audit trail feature).

By default, only the best fitting model is kept. However, you can control the number of automatically fit models retained in the Develop Models list, and the following example shows how to do this.

From the menu bar, choose “Options” and “Automatic Fit.” This brings up the Automatic Model Selection Options window. Click the `Models to Keep` combo box arrow, and select “All models”, as shown in Figure 36.7. Now select “OK”.

Damping: Optimize
Season: Optimize
Bounds: Zero-One/Additive

Log Linear Trend with Seasonal Terms 1.00002

Figure 36.10. Smoothing Model Specification Window

The Smoothing Model Specification window consists of several parts. At the top is the series name and a field for the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The `Smoothing Methods` box lists the different methods available. Below the `Smoothing Methods` box is the Transformation field, which is used to apply the smoothing method to transformed series values.

The `Smoothing Weights` box specifies how the smoothing weights are determined. By default, the smoothing weights are automatically set to optimize the fit of the model to the data. See Chapter 41, “Forecasting Process Details,” for more information about how the smoothing weights are fit.

Under smoothing methods, select “Winters Method - Additive.” Notice the smoothing weights box to the right. The third item, `Damping`, is grayed out, while the other items, `Level`, `Trend`, and `Season`, show the word `Optimize`. This tells you that these three smoothing weights are applicable to the smoothing method that you selected and that the system is currently set to optimize these weights for you.

Next, specify a transformation using the `Transformation` combo box. A menu of transformation choices pops up, as shown in Figure 36.11.

Transformation:

Log Linear Trend with Seas 1.00002

Figure 36.11. Transformation Options

You can specify a logarithmic, logistic, square root, or Box-Cox transformation. For this example, select “Square Root” from the pop-up menu. The Transformation field is now set to Square Root.

This means that the system will first take the square roots of the series values, apply the additive version of the Winters method to the square root series, and then produce the predictions for the original series by squaring the Winters method predictions (and multiplying by a variance factor if the Mean Prediction option is set in the Forecast Options window). See Chapter 41, “Forecasting Process Details,” for more information on predictions from transformed models.

The Smoothing Model Specification window should now appear as shown in Figure 36.12. Select the OK button to fit the model. The model is added to the table of fitted models in the Develop Models window.

Moving Average: Q=	0

Transformation: None

Intercept: [✓ Yes] No

Figure 36.13. ARIMA Model Specification Window

This ARIMA Model Specification window is structured according to the Box and Jenkins approach to time series modeling. You can specify the same time series models with the Custom Model Specification window and the ARIMA Model

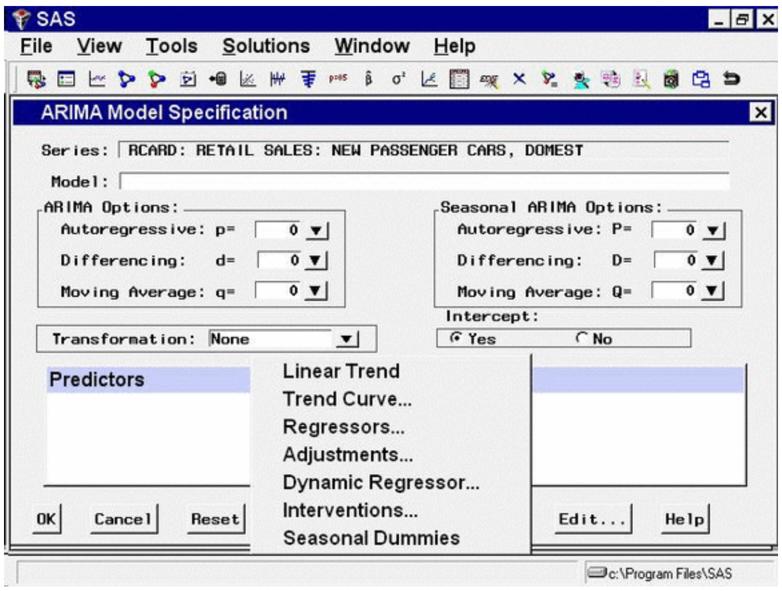
Specification window, but the windows are structured differently, and you may find one more convenient than the other.

At the top of the ARIMA Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

Using the ARIMA Model Specification window, you can specify autoregressive (p), differencing (d), and moving average (q) orders for both simple and seasonal factors. You can specify transformations with the `Transformation` combo box. You can also specify whether an intercept is included in the ARIMA model.

In addition to specifying seasonal and nonseasonal ARIMA processes, you can also specify predictor variables and other terms as inputs to the model. ARIMA models with inputs are sometimes called ARIMAX models or Box-Tiao models. Another term for this kind of model is *dynamic regression*.

In the lower part of the ARIMA model specification window is the list of *predictors* to the model (initially empty). You can specify predictors using the Add button. This brings up a menu of different kinds of independent effects, as shown in Figure 36.14.



ARIMA Model Specification

Series: RCARD: RETAIL SALES: NEW PASSENGER CARS, DOMEST

Model:

ARIMA Options:
Autoregressive: p= 0
Differencing: d= 0
Moving Average: q= 0

Seasonal ARIMA Options:
Autoregressive: P= 0
Differencing: D= 0
Moving Average: Q= 0

Intercept: [✓ Yes] No

Transformation: None

Predictors

Figure 36.14. Add Predictors Menu

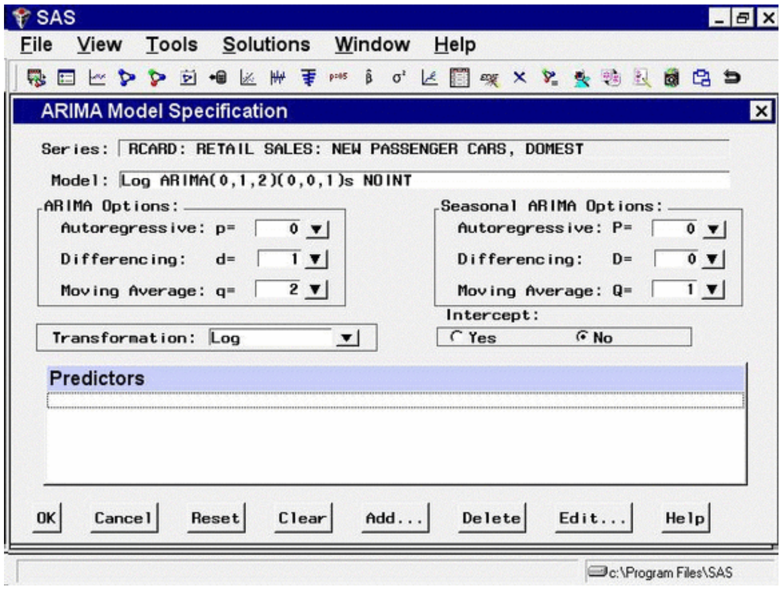
The kinds of predictor effects allowed include time trends, regressors, adjustments, dynamic regression (transfer functions), intervention effects, and seasonal dummy variables. How to use different kinds of predictors is explained in Chapter 38, "Using Predictor Variables."

As an example, in the `ARIMA Options` box, set the order of differencing `d` to `1` and the moving average order `q` to `2`. You can either type in these values or click the combo box arrows and select them from pop-up lists.

These selections specify an ARIMA(0,1,2) or IMA(1,2) model. (Refer to Chapter 11, "The ARIMA Procedure," for more information on the notation used for ARIMA models.) Notice that the model label at the top is now `IMA(1,2) NOINT`, meaning that the data are differenced once and a second-order moving average term is included with no intercept.

In the `Seasonal ARIMA Options` box, set the seasonal moving average order `Q` to `1`. This adds a first-order moving average term at the seasonal (12 month) lag. Finally, select "Log" in the Transformation combo box.

The model label is now `Log ARIMA(0,1,2)(0,0,1)s NOINT`, and the window appears as shown in Figure 36.15.



Series: RCARD: RETAIL SALES: NEW PASSENGER CARS, DOMEST
Model: Log ARIMA(0,1,2)(0,0,1)s NOINT
ARIMA Options:
Autoregressive: p= 0
Differencing: d= 1

Autoregressive: p=
Differencing: d=
Moving Average: q=
Intercept: [✓ Yes] No
Transformation: None
Estimation Method: Maximum Likelihood

Figure 36.16. Factored ARIMA Model Specification Window

The Factored ARIMA Model Specification window is similar to the ARIMA Model Specification window, and has the same features, but uses a more general specification of the autoregressive (p), differencing (d), and moving average (q) terms. To specify these terms, select the corresponding Set button, as shown in Figure 36.16. For example, to specify autoregressive terms, select the first Set button. This brings up the AR Polynomial Specification Window, shown in Figure 36.17.

List of Polynomials
(1, 3)
(6, 12)

Figure 36.17. AR Polynomial Specification Window

To add AR polynomial terms, select the New button. This brings up the Polynomial Specification Window, shown in Figure 36.18. Specify the first lag you want to include using the `Lag` spin box, then select the Add button. Repeat this process, adding each lag you want to include in the current list. All lags must be specified. For example, if you add only lag 3, the model contains only lag 3, not 1 through 3.

As an example, add lags 1 and 3, then select the OK button. The AR Polynomial Specification Window now shows (1,3) in the list of polynomials. Now select "New" again. Add lags 6 and 12 and select "OK". Now the AR Polynomial Specification Window shows (1,3) and (6,12) as shown in Figure 36.17. Select "OK" to close this window. The Factored ARIMA Model Specification Window now shows the factored model `p=(1,3)(6,12)`. Use the same technique to specify the q terms, or moving average part of the model. There is no limit to the number of lags or the number of factors you can include in the model.

Figure 36.18. Polynomial Specification Window

To specify differencing lags, select the middle Set button to bring up the Differencing Specification window. Specify lags using the spin box and add them to the list with the Add button. When you select "OK" to close the window, the differencing lags appear after `d=` in the Factored ARIMA Specification Window, within a single pair of parentheses.

You can use the Factored ARIMA Model Specification Window to specify any model that you can specify with the ARIMA Model and Custom Model windows, but the notation is more similar to that of the ARIMA Procedure (Chapter 11, "The ARIMA Procedure,"). Consider as an example the classic Airline model fit to the International Airline Travel series, `SASHELP.AIR`. This is a factored model with one moving average term at lag one and one moving average term at the seasonal lag, with first order differencing at the simple and seasonal lags. Using the ARIMA Model Specification Window, you specify the value 1 for the q and d terms and also for the Q and D terms, which represent the seasonal lags. For monthly data, the seasonal lags represent lag 12, since a yearly seasonal cycle is assumed.

By contrast, the Factored ARIMA Model Specification Window makes no assumptions about seasonal cycles. The Airline model is written as `IMA d=(1,12) q=(1)(12) NOINT`. To specify the differencing terms, add the values 1 and 12 in the Differencing Specification Window and select “OK”. Then select “New” in the MA Polynomial Specification Window, add the value 1, and select “OK”. To add the factored term, select “New” again, add the value 12, and select “OK”. Remember to select “No” in the Intercept radio box, since it is not selected by default. Select “OK” to close the Factored ARIMA Model Specification Window and fit the model.

You can show that the results are the same as they are when you specify the model using the ARIMA Model Specification Window and when you select Airline Model from the default model list. If you are familiar with the ARIMA Procedure (Chapter 11, “The ARIMA Procedure,”), you may wish to turn on the `Show Source Statements` option before fitting the model, then examine the procedure source statements in the log window after fitting the model.

The strength of the Factored ARIMA Specification approach lies in its ability to contruct unusual ARIMA models, such as:

Subset models
: These are models of order n, where fewer than n lags are specified. For example, an AR order 3 model might include lags 1 and 3 but not lag 2.

Unusual seasonal cycles
: For example, a monthly series might cycle two or four times per year instead of just once.

Multiple cycles
: For example, a daily sales series might peak on a certain day each week and also once a year at the Christmas season. Given sufficient data, you can fit a three-factor model, such as `IMA d=(1) q=(1)(7)(365)`.

Models with high order lags take longer to fit, and often fail to converge. To save time, select the Conditional Least Squares or Unconditional Least Squares estimation method (see Figure 36.16). Once you have narrowed down the list of candidate models, change to the Maximum Likelihood estimation method.

Custom Model Specification Window

To fit a custom time series model not already provided in the Models to Fit window, select the Custom Model item from the pop-up menu, toolbar, or Edit pull-down menu. This brings up the Custom Model Specification window, as shown in Figure 36.19.

Figure 36.19. Custom Model Specification Window

You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you may find one more convenient than the other.

At the top of the Custom Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Custom Model Specification window consists of four fields: `Transformation`, `Trend Model`, `Seasonal Model`, and `Error Model`. These fields allow you to specify the model in four parts. Each part specifies how a different aspect of the pattern of the time series is modeled and predicted.

The `Predictors` list at the bottom of the Custom Model Specification window allows you to include different kinds of predictor variables in the forecasting model. The Predictors feature for the Custom Model Specification window is like the Predictors feature for the ARIMA Model Specification window, except that time trend predictors are provided through the Trend Model field and seasonal dummy variable predictors are provided through the Seasonal Model field.

To illustrate how to use the Custom Model Specification window, the following example specifies the same model you fit using the ARIMA Model Specification window.

First, specify the data transformation to use. Select "Log" using the Transformation combo box.

Second, specify how to model the trend in the series. Select `First Difference` in the `Trend Model` combo box, as shown in Figure 36.20.

Now that you have seen how the Custom Model Specification window works, select "Cancel" to exit the window without fitting the model. This should return you to the Develop Models window.

Editing the Model Selection List

Now that you know how to specify new models that are not included in the system default model selection list, you can edit the model selection list to add models that you expect to use in the future or to delete models that you do not expect to use. When you save the forecasting project to a SAS catalog, the edited model selection list is saved with the project file, and the list is restored when you load the project.

There are two reasons why you would add a model to the model selection list. First, by adding the model to the list, you will be able to fit the model to different time series by selecting it through the `Fit Models from List` action. You do not need to specify the model again every time you use it.

Second, once the model is added to the model selection list, it is available to the automatic model selection process. The model will then be considered automatically whenever you use the automatic model selection feature for any series.

To edit the model selection list, select "Model Selection List" from the Options pull-down menu as shown in Figure 36.25, or select the Edit Model List toolbar icon.

✓      Square Root Simple Exponential Smoothing
```

Figure 36.28. Model Added to Selection List

If you want to delete one or more models from the list, select the model labels to highlight them in the list. Click a second time to unselect a selected model. Then select “Delete” from the Edit pull-down menu, or the corresponding toolbar icon. As an example, delete the `Square Root Simple Exponential Smoothing` model that you just added.

The Model Selection List editor window gives you a lot of flexibility for managing multiple model lists, as explained in the section “Model Selection List Editor Window” on page 2171. For example, you can create your own model lists from scratch or modify or combine previously saved model lists and those provided with the software, and you can save them and designate one as the default for future projects.

Now select “Close” from the File menu (or the Close icon) to close the Model Selection List editor window.

Forecast Combination Model Specification Window

Once you have fit several forecasting models to a series, you face the question of which model to use to produce the final forecasts. One possible answer is to combine or average the forecasts from several models. Combining the predictions from several different forecasting methods is a popular approach to forecasting.

The way that you produce forecast combinations with the Time Series Forecasting System is to use the Forecast Combination Model Specification window to specify a new forecasting model that performs the averaging of forecasts from the models you want to combine. This new model is added to the list of fitted models just like other models. You can then use the Model Viewer window features and Model Fit Comparison window features to examine the fit of the combined model.

To specify a forecast combination model, select “Combine Forecasts” from the pop-up menu or tool-bar, or select “Edit” amd “Fit Model” from the menu bar. This brings up the Forecast Combination Model Specification window, as shown in Figure 36.29.

.	Log Linear Trend with Seasonal Terms	1.00002

Figure 36.29. Forecast Combination Window

At the top of the Forecast Combination window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Forecast Combination window consists of the list of models that you have fit to the series. This table shows the label and goodness-of-fit measure for each model and the combining weight assigned to the model.

The `Weight` column controls how much weight is given to each model in the combined forecasts. A missing weight means that the model is not used. Initially, all the models have missing Weight values.

You can enter the weight values you want to use in the Weight column. Alternatively, you can select models from the Model Description column, and Weight values for the models you select are set automatically. To remove a model from the combination, select it again. This resets its weight value to missing.

At the bottom of the Forecast Combination window are two buttons: `Normalize Weights` and `Fit Regression Weights.` The Normalize Weights button adjusts the nonmissing Weight values so that they sum to one. The Fit Regression Weights button uses linear regression to compute the weight values that produce the combination of model predictions with the best fit to the series.

If no models are selected, the Fit Regression Weights button fits weights for all the models in the list. You can compute regression weights for only some of the models by first selecting the models you want to combine and then selecting Fit Regression Weights. In this case, only the nonmissing Weight values are replaced with regression weights.

As an example of how to combine forecasting models, select all the models in the list. After you have finished selecting the models, all the models in the list should now have equal Weight values, which implies a simple average of the forecasts.

Now select the Fit Regression Weights button. The system performs a linear regression of the series on the predictions from the models with nonmissing Weight values and replaces the Weight values with the estimated regression coefficients. These are the combining weights that produce the smallest mean square prediction error within the sample.

The Forecast Combination window should now appear as shown in Figure 36.30. (Note that some of the regression weight values are negative.)

Figure 36.31. Develop Models Window Showing All Models Fit

Notice that the combined model has a smaller root mean square error than any one of the models included in the combination. The confidence limits for forecast combinations are produced by taking a weighted average of the mean square prediction errors for the component forecasts, ignoring the covariance between the prediction errors.

Incorporating Forecasts from Other Sources

You may have forecasts from other sources that you want to include in the forecasting process. Examples of other forecasts you might want to use are "best guess" forecasts based on personal judgments, forecasts produced by government agencies or commercial forecasting services, planning scenarios, and reference or "base line" projections. Because such forecasts are produced externally to the Time Series Forecasting System, they are referred to as external forecasts.

You can include external forecasts in combination models to produce compromise forecasts that split the difference between the external forecast and forecasting models that you fit. You can use external forecasts to compare them to the forecasts from models that are fit by the system.

To include external forecasts in the Time Series Forecasting process, you must first supply the external forecast as a variable in the input data set. You then specify a special kind of forecasting "model" whose predictions are identical to the external forecast recorded in the data set.

As an example, suppose you have 12 months of sales data and 5 months of sales forecasts based on a consensus opinion of the sales staff. The following statements create a SAS data set containing made-up numbers for this situation.

```
data widgets;
   input date monyy5. sales staff;
   format date monyy5.;
   label sales = "Widget Sales"
         staff = "Sales Staff Consensus Forecast";
   datalines;
jun94  142.1     .
jul94  139.6     .
aug94  145.0     .
sep94  150.2     .
oct94  151.1     .

Figure 36.35. Model for External Forecast

You can now use this model for comparison with the predictions from other forecasting models that you fit, or you can include it in a forecast combination model.

Note that no fitting is actually performed for an external forecast model. The predictions of the external forecast model are simply the values of the external forecast series read from the input data set. The goodness-of-fit statistics for such models will depend on the values that the external forecast series contains for observations within the period of fit. In this case, no STAFF values are given for past periods, and therefore the fit statistics for the model are missing.

Chapter 37
Choosing the Best Model

Chapter Contents

Chapter 37
Choosing the Best Forecasting Model

The Time Series Forecasting System provides a variety of tools for identifying potential forecasting models and for choosing the best fitting model. It allows you to decide how much control you want to have over the process, from a hands-on approach to one that is completely automated. This chapter begins with an exploration of the tools available through the Series Viewer and Model Viewer. It presents an example of identifying models graphically and exercising your knowledge of model properties. The remainder of the chapter shows you how to compare models by using a variety of statistics and by controlling the fit and evaluation time ranges. It concludes by showing you how to refit existing models and how to compare models using hold-out samples.

Time Series Viewer Features

The `Time Series Viewer` is a graphical tool for viewing and analyzing time series. It can be used separately from the `Time Series Forecasting System` using the TSVIEW command or by selecting `Time Series Viewer` from the `Analysis` pull-down menu under `Solutions`.

In this chapter you will use the Time Series Viewer to examine plots of your series before fitting models. Begin this example by invoking the forecasting system and selecting the `View Series Graphically` button, as shown in Figure 37.1, or the `View Series` toolbar icon.

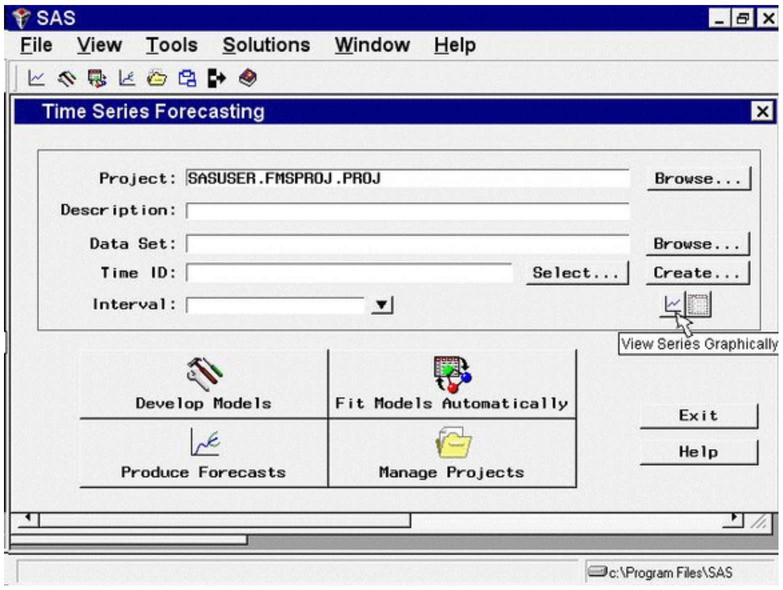

Figure 37.1. Invoking the Time Series Viewer

From the Series Selection window, select SASHELP as the library, WORKERS as the data set, and MASONRY as the time series, and then click the `Graph` button.

The Time Series Viewer displays a plot of the series, as shown in Figure 37.2.

Figure 37.3. Selecting an Area for Zoom

The zoomed plot should appear as shown in Figure 37.4.

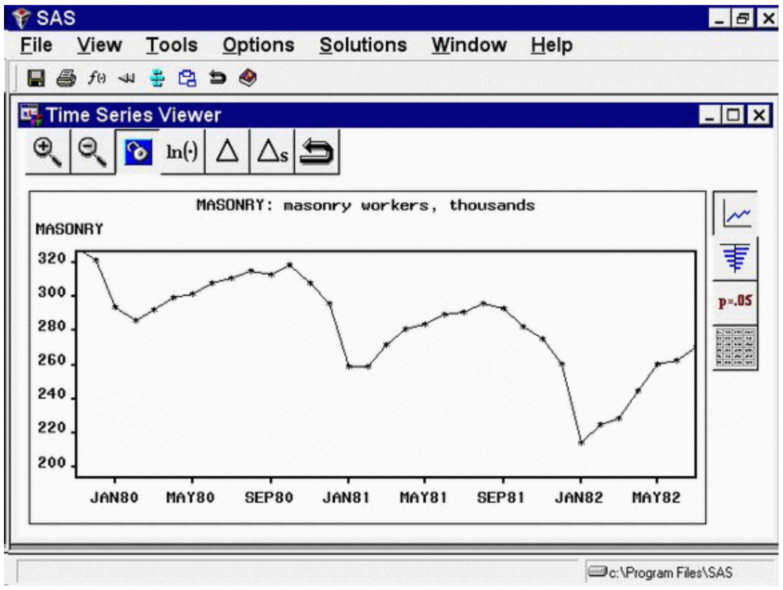

Figure 37.4. Zoomed Plot

You can repeat the process to zoom in still further. To return to the previous view, select the Zoom Out icon, the second icon on the window's horizontal toolbar.

The third icon on the horizontal toolbar is used to link or unlink the viewer window. By default, the viewer is linked, meaning that it is automatically updated to reflect selection of a different time series. To see this, return to the Series Selection window by clicking on it or using the Window pull-down menu or `Next Viewer` toolbar icon. Select the Electric series in the `Time Series Variables` list box. Notice that the Time Series Viewer window is updated to show a plot of the ELECTRIC series. Select the `Link/unlink` icon if you prefer to unlink the viewer so that it is not automatically updated in this way. Successive selections toggle between the linked and unlinked state. A note on the message line informs you of the state of the Time Series Viewer window.

When a Time Series Viewer window is linked, selecting `View Series` again will make the linked Viewer window active. When no Time Series Viewer window is linked, selecting `View Series` brings up an additional Time Series Viewer window. You can bring up as many Time Series Viewer windows as you want.

Having seen the plot in Figure 37.2, you might suspect that the series is nonstationary and seasonal. You can gain further insight into this by examining the sample autocorrelation function (ACF), partial autocorrelation function (PACF), and inverse autocorrelation function (IACF) plots. To switch the display to the autocorrelation plots, select the second icon from the top on the vertical toolbar at the right side of the Time Series Viewer. The plot appears as shown in Figure 37.5.

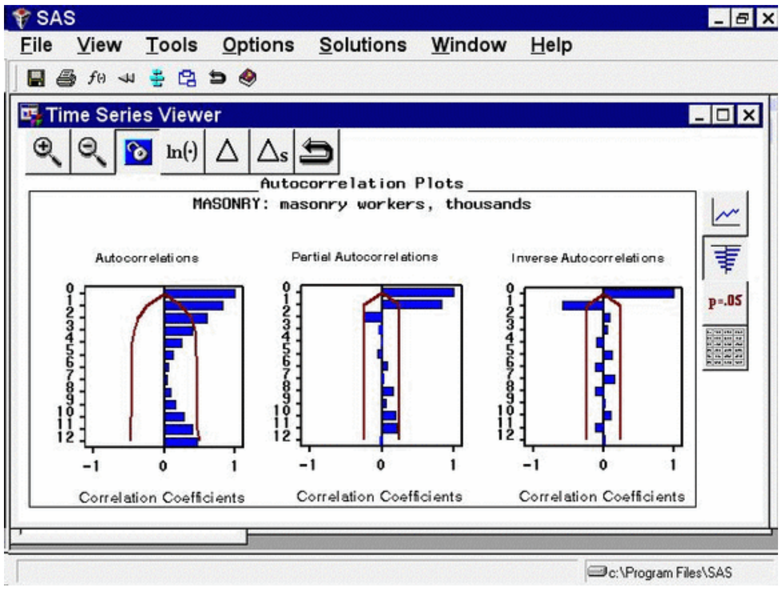

Figure 37.5. Sample Autocorrelation Plots

Each bar represents the value of the correlation coefficient at the given lag. The overlaid lines represent confidence limits computed at plus and minus two standard errors. You can switch the graphs to show significance probabilities by selecting `Correlation Probabilities` under the `Options` pull-down menu, or by selecting the `Toggle ACF Probabilities` toolbar icon.

The slow decline of the ACF suggests that first differencing may be warranted. To see the effect of first differencing, select the simple difference icon, the fifth icon from the left on the window's horizontal toolbar. The plot now appears as shown in Figure 37.6.

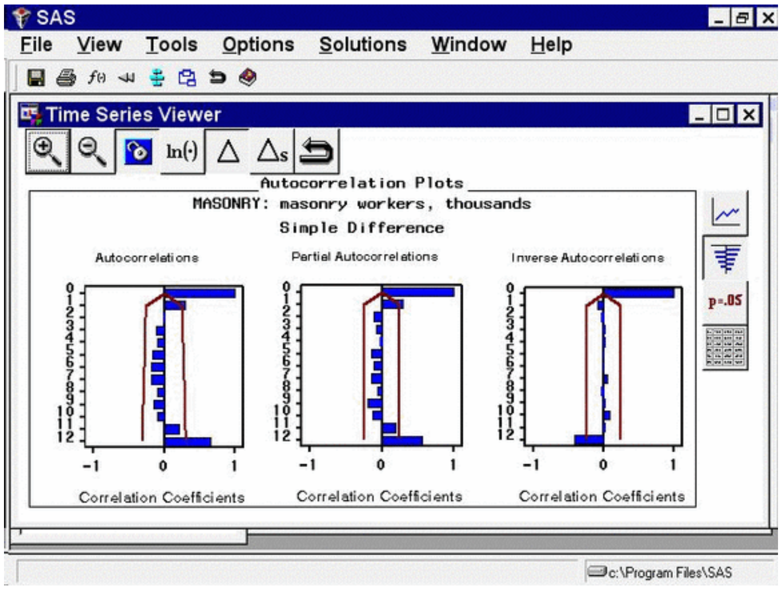

Figure 37.6. ACF Plots with First Difference Applied

Since the ACF still displays slow decline at seasonal lags, seasonal differencing is appropriate (in addition to the first differencing already applied). Select the `Seasonal Difference` icon, the sixth icon from the left on the horizontal toolbar. The plot now appears as shown in Figure 37.7.

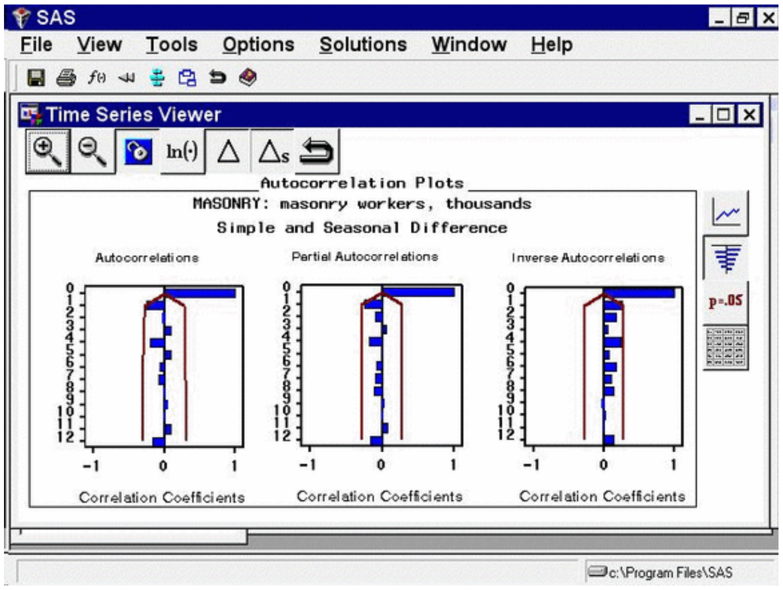

Figure 37.7. ACF Plot with Simple and Seasonal Differencing

Model Viewer Prediction Error Analysis

Leave the Time Series Viewer open for the remainder of this exercise. Drag it out of the way or push it to the background so that you can return to the Time Series Forecasting window. Select `Develop Models`, then click an empty part of the table to bring up the pop-up menu, and select `Fit ARIMA Model`. Define the ARIMA(0,1,0)(0,1,0)s model by selecting `1` for differencing under ARIMA Options, `1` for differencing under Seasonal ARIMA Options, and `No` for `Intercept`, as shown in Figure 37.8.

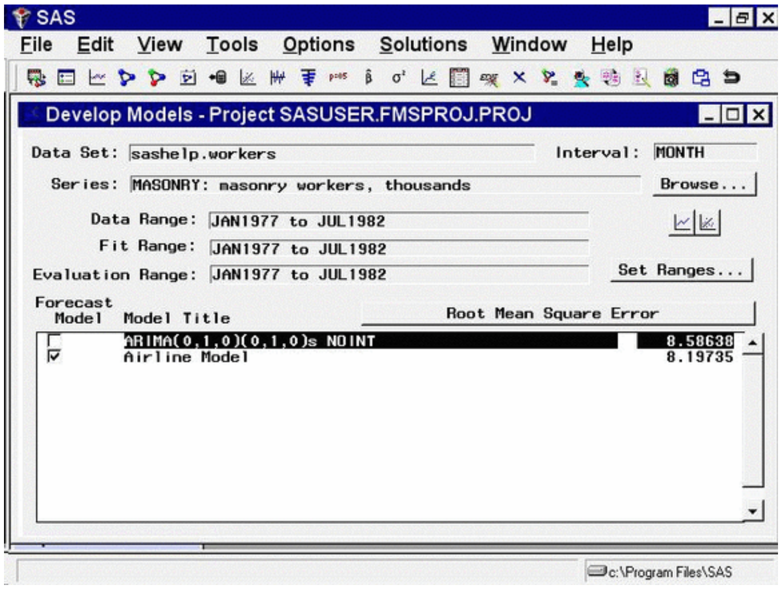
Intercept: Yes [✓ No]

Figure 37.8. Specifying the ARIMA(0,1,0)(0,1,0)s Model

When you select the `OK` button, the model is fit and you are returned to the Develop Models window. Click on an empty part of the table and choose `Fit Models from List` from the pop-up menu. Select `Airline Model` from the window. (Airline Model is a common name for the ARIMA(0,1,1)(0,1,1)s model, which is often used for seasonal data with a linear trend.) Select the `OK` button. Once the model has been fit, the table shows the two models and their root mean square errors. Notice that the Airline Model provides only a slight improvement over the differencing model, ARIMA(0,1,0)(0,1,0)s. Select the first row to highlight the differencing model, as shown in Figure 37.9.



SAS
File Edit View Tools Options Solutions Window Help
Develop Models - Project SASUSER.FMSPROJ.PROJ

Set Ranges...
c:\Program Files\SAS

Data Set: sashelp.workers Interval: MONTH
Series: MASONRY: masonry workers, thousands
Data Range: JAN1977 to JUL1982
Fit Range: JAN1977 to JUL1982
Evaluation Range: JAN1977 to JUL1982

Forecast Model	Model Title	Root Mean Square Error
☐	ARIMA(0,1,0)(0,1,0)s NOINT	8.58638
✓	Airline Model	8.19735

Figure 37.9. Selecting a Model

Now select the `View Selected Model Graphically` button, below the `Browse` button at the right side of the Develop Models window. The `Model Viewer` window appears, showing the actual data and model predictions for the MASONRY series. (Note that predicted values are missing for the first 13 observations due to simple and seasonal differencing.)

To examine the ACF plot for the model prediction errors, select the third icon from the top on the vertical toolbar. For this model, the prediction error ACF is the same as the ACF of the original data with first differencing and seasonal differencing applied. This differencing is apparent if you bring the Time Series Viewer back into view for comparison.

Return to the Develop Models Window by clicking on it or using the window pull-down menu or the Next Viewer toolbar icon. Select the second row of the table in the Develop Models window to highlight the Airline Model. The Model Viewer is automatically updated to show the prediction error ACF of the newly selected model, as shown in Figure 37.10.

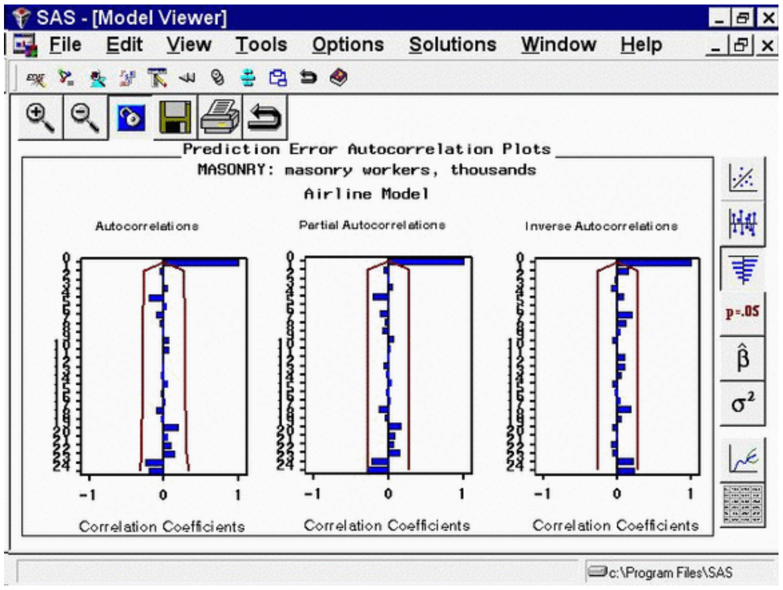

Figure 37.10. Prediction Error ACF Plot for the Airline Model

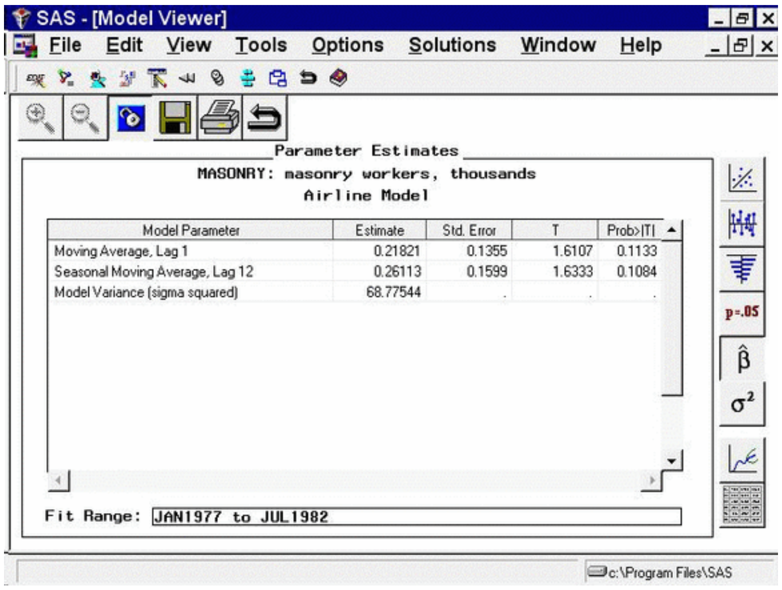
Another helpful tool available within the Model Viewer is the parameter estimates table. Select the fifth icon from the top of the vertical toolbar. The table gives the parameter estimates for the two moving average terms in the Airline Model, as well as the model residual variance, as shown in Figure 37.11.



Parameter Estimates

MASONRY: masonry workers, thousands
Airline Model

Model Parameter	Estimate	Std. Error	T	Prob>|T|
Moving Average, Lag 1	0.21821	0.1355	1.6107	0.1133
Seasonal Moving Average, Lag 12	0.26113	0.1599	1.6333	0.1084
Model Variance (sigma squared)	68.77544	.	.	.

Fit Range: JAN1977 to JUL1982

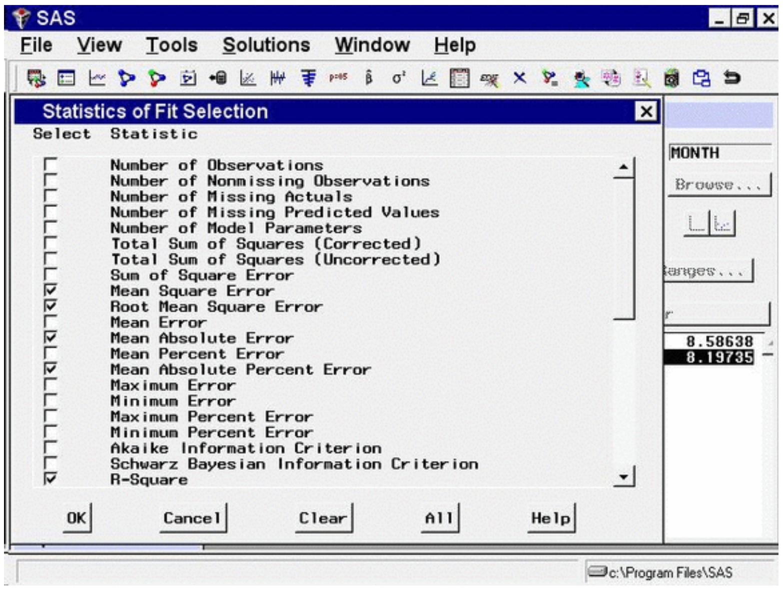
Figure 37.11. Parameter Estimates for the Airline Model

You can adjust the column widths in the table by dragging the vertical borders of the column titles with the mouse. Notice that neither of the parameter estimates is significantly different from zero at the .05 level of significance, since `Prob>|t|` is greater than .05. This suggests that the Airline Model should be discarded in favor of the more parsimonious differencing model, which has no parameters to estimate.

The Model Selection Criterion

Return to the Develop Models window (Figure 37.9) and notice the Root Mean Square Error button at the right side of the table banner. This is the model selection criterion–the statistic used by the system to select the best fitting model. So far in this example you have fit two models and have left the default criterion, root mean square error (RMSE), in effect. Because the Airline Model has the smaller value of this criterion, and because smaller values of the RMSE indicate better fit, the system has chosen this model as the forecasting model, indicated by the check box in the `Forecast Model` column.

The statistics available as model selection criteria are a subset of the statistics available for informational purposes. To access the entire set, select `Options` from the menu bar, and then select `Statistics of Fit`. The `Statistics of Fit Selection` window appears, as shown in Figure 37.12.



Select	Statistic
☐	Number of Observations
☐	Number of Nonmissing Observations
☐	Number of Missing Actuals
☐	Number of Missing Predicted Values
☐	Number of Model Parameters
☐	Total Sum of Squares (Corrected)
☐	Total Sum of Squares (Uncorrected)
☐	Sum of Square Error
☑	Mean Square Error
☑	Root Mean Square Error
☐	Mean Error
☑	Mean Absolute Error
☐	Mean Percent Error
☑	Mean Absolute Percent Error
☐	Maximum Error
☐	Minimum Error
☐	Maximum Percent Error
☐	Minimum Percent Error
☐	Akaike Information Criterion
☐	Schwarz Bayesian Information Criterion
☑	R-Square

Figure 37.12. Statistics of Fit

By default, five of the more well known statistics are selected. You can select and deselect statistics by clicking the check boxes in the left column. For this exercise, select `All`, and notice that all the check boxes become checked. Select the `OK` button to close the window. Now if you choose `Statistics of Fit` in the `Model Viewer` window, all of the statistics will be shown for the selected model.

To change the model selection criterion, click the `Root Mean Square Error` button or select `Options` from the menu bar and then select `Model Selection Criterion.` Notice that most of the statistics of fit are shown, but those which are not relevant to model selection, such as number of observations, are not shown. Select `Schwarz Bayesian Information Criterion` and click `OK`. Since this statistic puts a high penalty on models with larger numbers of parameters, the ARIMA(0,1,0)(0,1,0)s model comes out with the better fit.

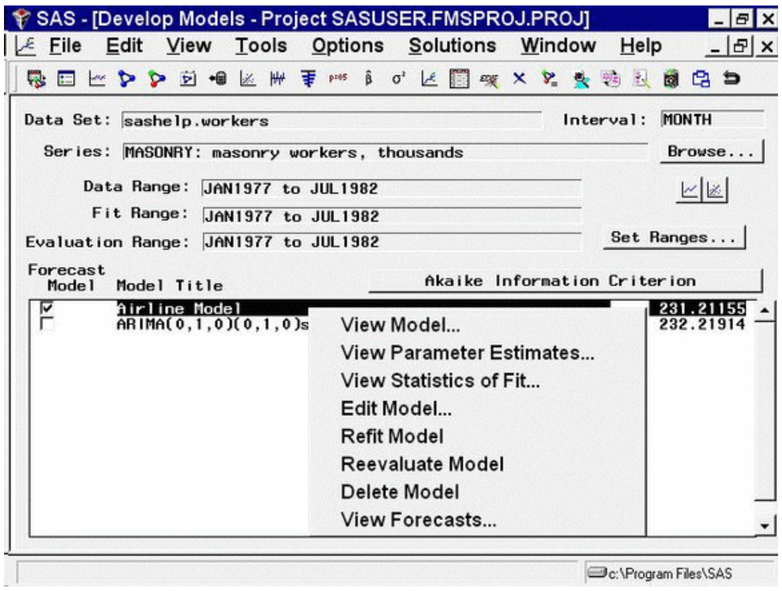
Notice that changing the selection criterion does not automatically select the model that is best according to that criterion. You can always choose the model you want to use for forecasts by selecting its check box in the `Forecast Model` column.

Now bring up the Model Selection Criterion window again and select `Akaike Information Criterion`. This statistic puts a lesser penalty on number of parameters, and the Airline Model comes out as the better fitting model.

Sorting and Selecting Models

Select `Sort Models` on the `Tools` pull-down menu or from the toolbar. This sorts the current list of fitted models by the current selection criterion. Although some selection criteria assign larger values to better fitting models (for example, R-square) while others assign smaller values to better fitting models, Sort Models always orders models with the best fitting model–in this case, the Airline Model–at the top of the list.

When you select a model in the table, its name and criterion value become highlighted, and actions that apply to that model become available. If your system supports a right mouse button, you can click it to invoke a pop-up menu, as shown in Figure 37.13.



Data Set: sashelp.workers   Interval: MONTH

Series: MASONRY: masonry workers, thousands

Data Range: JAN1977 to JUL1982

Fit Range: JAN1977 to JUL1982

Evaluation Range: JAN1977 to JUL1982

Forecast Model	Model Title	Akaike Information Criterion
✓	Airline Model	231.21155
	ARIMA(0,1,0)(0,1,0)s	232.21914

Figure 37.13. Right Mouse Button Pop-up Menu

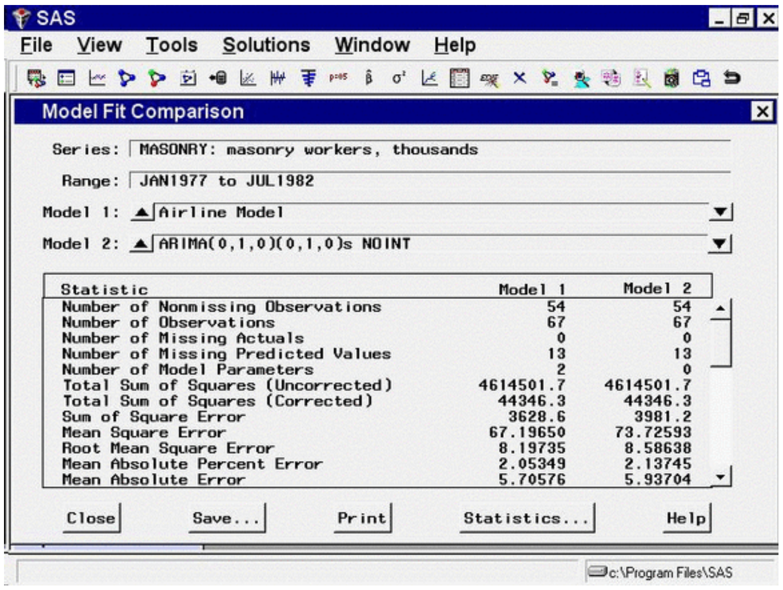
Whether or not you have a right mouse button, the same choices are available under `Edit` and `View` from the menu bar. If the model viewer has been invoked, it is automatically updated to show the selected model, unless you have unlinked the viewer using the `Link/Unlink` toolbar button.

Select the highlighted model in the table again. Notice that it is no longer highlighted. When no models are highlighted, the right mouse button pop-up menu changes, and items on the menu bar that apply to a selected model become grayed out. For example, you can choose `Edit` from the menu bar, but you can't choose the `Edit Model` or `Delete Model` selections unless you have highlighted a model in the table.

When you select the check box in the `Forecast Model` column of the table, the model in that row becomes the forecasting model. This is the model that will be used the next time forecasts are generated by choosing `View Forecasts`, or by using the `Produce Forecasts` window. Note that this forecasting model flag is automatically set when you use `Fit Automatic Model` or when you fit an individual model that fits better, using the current selection criterion, than the current forecasting model.

Comparing Models

Select `Tools` and `Compare Models` from the menu bar. This displays the `Model Fit Comparison` table, as shown in Figure 37.14.



Series: MASONRY: masonry workers, thousands

Mean Absolute Percent Error                    2.05349      2.13745
Mean Absolute Error                            5.70576      5.93704
```

Figure 37.14. Model Comparison Window

The two models you have fit are shown as `Model 1` and `Model 2.` When there are more than two models, you can bring any two of them into the table by selecting the up and down arrows. In this way, it is easy to do pairwise comparisons on any number of models, looking at as many statistics of fit as you like. Since you previously chose to display all statistics of fit, all of them are shown in the comparison table. Use the vertical scroll bar to move through the list.

After you have examined the model comparison table, select the `Close` button to return to the `Develop Models` window.

Controlling the Period of Evaluation and Fit

Notice the three time ranges shown on the `Develop Models` window (Figure 37.9). The data range shows the beginning and ending dates of the MASONRY time series. The period of fit shows the beginning and ending dates of data used to fit the models. The period of evaluation shows the beginning and ending dates of data used to compute statistics of fit. By default, the fit and evaluate ranges are the same as the data range. To change these ranges, select the `Set Ranges` button, or select `Options` and `Time Ranges` from the menu bar. This brings up the `Time Ranges Specification` window, as shown in Figure 37.15.

Data Set: sashelp.workers
Interval: MONTH
Series: MASONRY: masonry workers, thousands

Time Ranges:

	From		To
Data Range:	JAN1977		JUL1982
Period of Fit:	JAN1977		JUL1982
Period of Evaluation:	JAN1977		JUL1982
Forecast Horizon:	12	Periods	JUL1983
Hold-out Sample:	0	Periods	

Figure 37.15. Time Ranges Specification Window

For this example, suppose the early data in the series is unreliable, and you want to use the range June 1978 to the latest available for both model fitting and model evaluation. You can either type in JUN1978 in the `From` column for `Period of Fit` and `Period of Evaluation`, or you can advance these dates by clicking the right pointing arrows. The outer arrow advances the date by a large amount (in this case, by a year), and the inner arrow advances it by a single period (in this case, by a month). Once you have changed the `Period of Fit` and the `Period of Evaluation` to JUN1978 in the `From` column, select the `OK` button to return to the `Develop Models` window. Notice that these time ranges are updated at the top of the window, but the models already fit have not been affected. Your changes to the time ranges affect *subsequently fit* models.

Refitting and Reevaluating Models

If you fit the ARIMA(0,1,0)(0,1,0)s and Airline models again in the same way as before, they will be added to the model list, with the same names but with different values of the model selection criterion. Parameter estimates will be different, due to the new fit range, and statistics of fit will be different, due to the new evaluation range.

For this exercise, instead of specifying the models again, refit the existing models by selecting `Edit` from the menu bar and then selecting `Refit Models` and `All Models.` After the models have been refit, you should see the same two models listed in the table but with slightly different values for the selection criterion. The ARIMA (0,1,0)(0,1,0)s and Airline models have now been fit to the MASONRY series using data from June 1978 to July 1982, since this is the period of fit you specified. The statistics of fit have been computed for the period of evaluation, which was the same as the period of fit. If you had specified a period of evaluation different from the period of fit, the statistics would have been computed accordingly.

In practice, another common reason for refitting models is the availability of new data. For example, when data for a new month become available for a monthly series, you might add them to the input data set, then invoke the forecasting system, open the project containing models fit previously, and refit the models prior to generating new forecasts. Unless you specify the period of fit and period of evaluation in the `Time Ranges Specification` window, they default to the full data range of the series found in the input data set at the time of refitting.

If you prefer to apply previously fit models to revised data without refitting, use `Reevaluate Models` instead of `Refit Models`. This recomputes the statistics of fit using the current evaluation range, but does not re-estimate the model parameters.

Using Hold-out Samples

One important application of model fitting where the period of fit is different from the period of evaluation is the use of hold-out samples. With this technique of model evaluation, the period of fit ends at a time point before the end of the data series, and the remainder of the data are held out as a nonoverlapping period of evaluation. With respect to the period of fit, the hold-out sample is a period in the future, used to compare the forecasting accuracy of models fit to past data.

For this exercise, use a hold-out sample of 12 months. Bring up the `Time Ranges Specification` window again by selecting the `Set Ranges` button. Set `Hold-out Sample` to 12 using the combo box, as shown in Figure 37.16. You can also type in a value. To specify a hold-out sample period in different units, you can use the `Periods` combo box. In this case, it will allow you to select years as the unit, instead of periods.

Figure 37.16. Specifying the Hold-out Sample Size

Notice that setting the holdout sample to 12 automatically sets the fit range to JUN1978–JUL1981 and the evaluation range to AUG1981–JUL1982. If you had set the period of fit and period of evaluation to these ranges, the hold-out sample would have been automatically set to 12 periods.

Select the `OK` button to return to the `Develop Models` window. Now refit the models again. Select `Tools` and `Compare Models` to compare the models now that they have been fit to the period June 1978 through July 1981 and evaluated for the hold-out sample period August 1981 through July 1982. Note that the fit statistics for the hold-out sample are based on one-step-ahead forecasts. (See *Statistics of Fit* in Chapter 41, "Forecasting Process Details,").

As shown in Figure 37.17, the ARIMA (0,1,0)(0,1,0)s model now seems to provide a better fit to the data than does the Airline model. It should be noted that the results can be quite different if you choose a different size hold-out sample.

Chapter 38
Using Predictor Variables

Chapter Contents

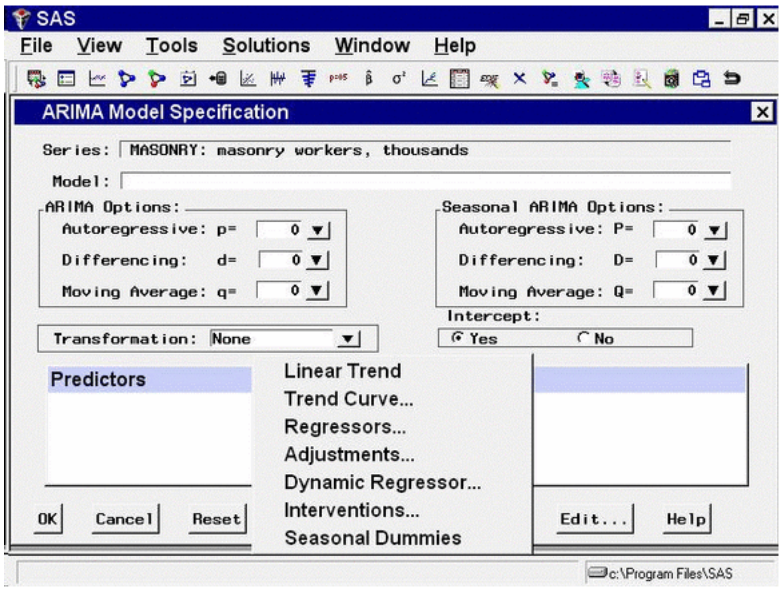
Chapter 38
Using Predictor Variables

Forecasting models predict the future values of a series using two sources of information: the past values of the series and the values of other time series variables. Other variables used to predict a series are called *predictor variables*.

Predictor variables that are used to predict the dependent series may be variables in the input data set, such as regressors and adjustment variables, or they can be special variables computed by the system as functions of time, such as trend curves, intervention variables, and seasonal dummies.

You can specify seven different types of predictors in forecasting models using the ARIMA Model or Custom Model Specification windows. You cannot specify predictor variables with the Smoothing Model Specification window.

Figure 38.1 shows the menu of options for adding predictors to an ARIMA model that is brought up by the Add button. The Add menu for the Custom Model Specification menu is similar.



Series: MASONRY: masonry workers, thousands
Model:
ARIMA Options:
Autoregressive: p= 0
Differencing: d= 0
Moving Average: q= 0
Seasonal ARIMA Options:
Autoregressive: P= 0
Differencing: D= 0
Moving Average: Q= 0
Transformation: None
Intercept: [✓ Yes] No

Figure 38.1. Add Predictors Menu

These types of predictors are as follows.

Linear Trend	adds a variable that indexes time as a predictor series. A straight line time trend is fit to the series by regression when you specify a linear trend.
Trend Curve	provides a menu of various functions of time that you can add to the model to fit nonlinear time trends. The Linear Trend option is a special case of the Trend Curve option for which the trend curve is a straight line.

Regressors	allows you to predict the series by regressing it on other variables in the data set.
Adjustments	allows you to specify other variables in the data set that supply adjustments to the forecast.
Dynamic Regressor	allows you to select a predictor variable from the input data set and specify a complex model for the way that the predictor variable affects the dependent series.
Interventions	allows you to model the effect of special events that "intervene" to change the pattern of the dependent series. Examples of intervention effects are strikes, tax increases, and special sales promotions.
Seasonal Dummies	adds seasonal indicator or "dummy" variables as regressors to model seasonal effects.

You can add any number of predictors to a forecasting model, and you can combine predictor variables with other model options.

The following sections explain these seven kinds of predictors in greater detail and provide examples of their use. The examples illustrate these different kinds of predictors using series in the SASHELP.USECON data set.

Select the `Develop Models` button from the main window. Select the data set SASHELP.USECON and select the series PETROL. Then select the `View Series Graphically` button from the Develop Models window. The plot of the example series PETROL appears as shown in Figure 38.2.

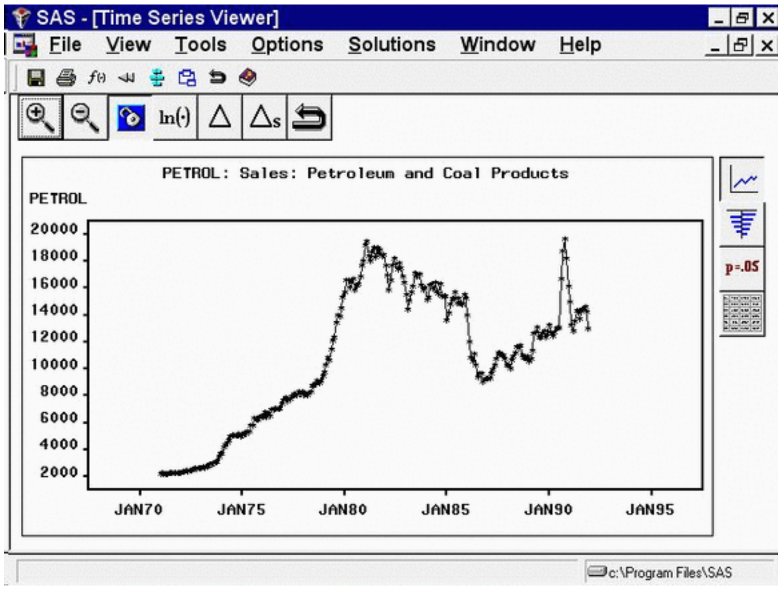


Figure 38.2. Sales of Petroleum and Coal

Linear Trend

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Linear Trend` from the menu (shown in Figure 38.1).

A linear trend is added to the Predictors list, as shown in Figure 38.3.

Intercept: [✓ Yes] No

Predictors
Trend Curve _LINEAR_: Linear Trend

Figure 38.3. Linear Trend Predictor Specified

The description for the linear trend item shown in the Predictors list has the following meaning. The first part of the description, Trend Curve, describes the type of predictor. The second part, _LINEAR_, gives the variable name of the predictor series. In this case, the variable is a time index that the system computes. This variable will be included in the output forecast data set. The final part, Linear Trend, describes the predictor.

Notice that the model you have specified consists only of the time index regressor _LINEAR_ and an intercept. Although this window is normally used to specify ARIMA models, in this case no ARIMA model options are specified, and the model is a simple regression on time.

Select the `OK` button. The Linear Trend model is fit and added to the model list in the Develop Models window.

Now bring up the Model Viewer using the `View Model Graphically` icon or the `Model Predictions` item under the `View` pull-down menu or toolbar. This displays a plot of the model predictions and actual series values, as shown in Figure 38.4. The predicted values lie along the least squares trend line.

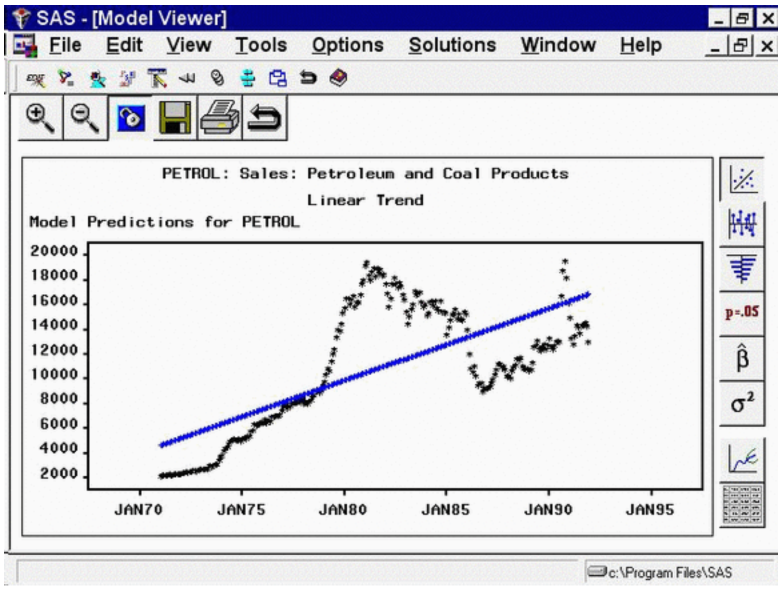

Figure 38.4. Linear Trend Model

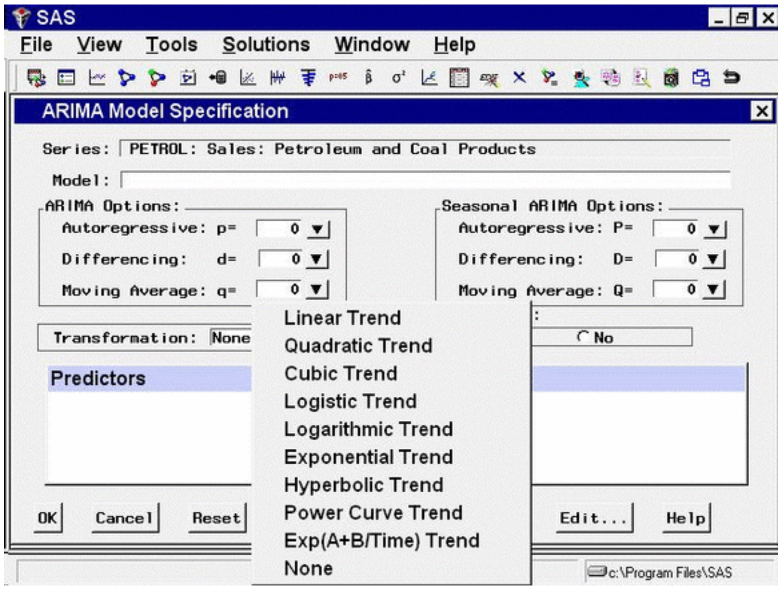
Time Trend Curves

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select Add and then select `Trend Curve` from the menu (shown in Figure 38.1). A menu of different kinds of trend curves is displayed, as shown in Figure 38.5.



Series: PETROL: Sales: Petroleum and Coal Products

Model:

ARIMA Options:
- Autoregressive: p= 0

Model Predictions for PETROL

Figure 38.7. Quadratic Trend Model

This curve does not fit the PETROL series very well, but the View Model plot illustrates how time trend models work. You may want to experiment with different trend models to see what the different trend curves look like.

Some of the trend curves require transforming the dependent series. When you specify one of these curves, a notice is displayed reminding you that a transformation is needed, and the Transformation field is automatically filled in. Therefore, you cannot control the Transformation specification when some kinds of trend curves are specified.

See the section "Time Trend Curves" in Chapter 41, “Forecasting Process Details,” for more information about the different trend curves.

Regressors

From the Develop Models window, select `Fit ARIMA Model`. From the ARIMA Model Specification window, select `Add` and then select `Regressors` from the menu (shown in Figure 38.1). This displays the `Regressors Selection` window, as shown in Figure 38.8. This window allows you to select any number of other series in the input data set as regressors to predict the dependent series.

Predictors

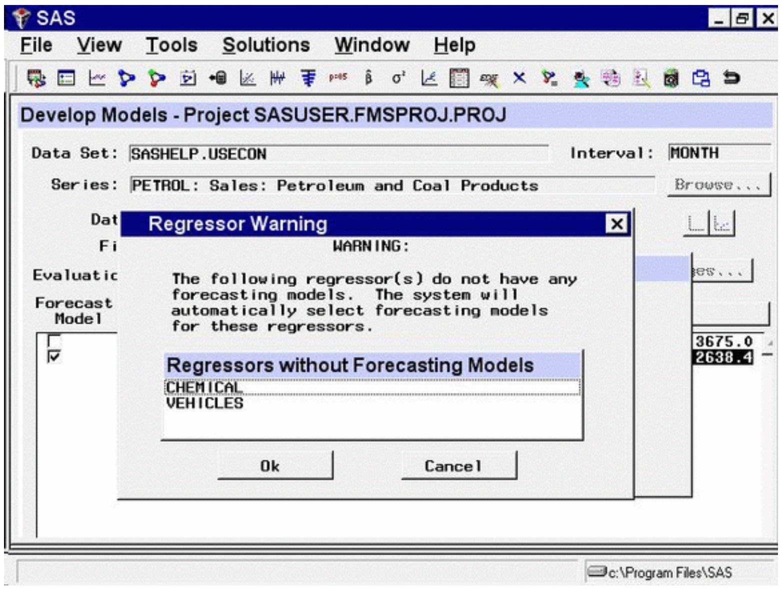
```
Regressor        CHEMICAL: Sales: Chemicals and Allied Products
Regressor        VEHICLES: Sales: Motor Vehicles and Parts
```

Figure 38.9. Regressors Selected

You must have forecasts of the future values of the regressor variables in order to use them as predictors. To do this, you can specify a forecasting model for each regressor, have the system automatically select forecasting models for the regressors, or supply predicted future values for the regressors in the input data set.

Even if you have supplied future values for a regressor variable, the system requires a forecasting model for the regressor. Future values that you supply in the input data set will take precedence over predicted values from the regressor's forecasting model when the system computes the forecasts for the dependent series.

Select the `OK` button. The system starts to fit the regression model but then stops and displays a warning that the regressors that you selected do not have forecasting models, as shown in Figure 38.10.



Develop Models - Project SASUSER.FMSPROJ.PROJ

Data Set: SASHELP.USECON Interval: MONTH

Series: PETROL: Sales: Petroleum and Coal Products

Regressor Warning

WARNING:

The following regressor(s) do not have any forecasting models. The system will automatically select forecasting models for these regressors.

Regressors without Forecasting Models

CHEMICAL
VEHICLES

Figure 38.10. Regressors Needing Models Warning

If you want the system to create forecasting models automatically for the regressor variables using the automatic model selection process, select the `OK` button. If not, you can select the `Cancel` button to abort fitting the regression model.

For this example, select the `OK` button. The system now performs the automatic model selection process for CHEMICAL and VEHICLES. The selected forecasting models for CHEMICAL and VEHICLES are added to the model lists for those series. If you switch the current time series in the Develop Models window to CHEMICAL or VEHICLES, you will see the model that the system selected for that series.

Once forecasting models have been fit for all regressors, the system proceeds to fit the regression model for PETROL. The fitted regression model is added to the model list displayed in the Develop Models window.

Adjustments

An *adjustment* predictor is a variable in the input data set that is used to adjust the forecast values produced by the forecasting model. Unlike a regressor, an adjustment variable does not have a regression coefficient. No model fitting is performed for adjustments. Nonmissing values of the adjustment series are simply added to the model prediction for the corresponding period. Missing adjustment values are ignored. If you supply adjustment values for observations within the period of fit, the adjustment values are subtracted from the actual values, and the model is fit to these adjusted values.

To add adjustments, select `Add` and then select `Adjustments` from the pop-up menu (shown in Figure 38.1). This displays the `Adjustments Selection` window. The Adjustments Selection window functions the same as the Regressor Selection window (which is shown in Figure 38.8). You can select any number of adjustment variables as predictors.

Unlike regressors, adjustments do not require forecasting models for the adjustment variables. If a variable that is used as an adjustment does have a forecasting model fit to it, the adjustment variable's forecasting model is ignored when the variable is used as an adjustment.

You can use forecast adjustments to account for expected future events that have no precedent in the past and so cannot be modeled by regression. For example, suppose you are trying to forecast the sales of a product, and you know that a special promotional campaign for the product is planned during part of the period you want to forecast. If such sales promotion programs have been frequent in the past, then you can record the past and expected future level of promotional efforts in a variable in the data set and use that variable as a regressor in the forecasting model.

However, if this is the first sales promotion of its kind for this product, you have no way to estimate the effect of the promotion from past data. In this case, the best you can do is to make an educated guess at the effect the promotion will have and add that guess to what your forecasting model would predict in the absence of the special sales campaign.

Adjustments are also useful for making judgmental alterations to forecasts. For example, suppose you have produced forecast sales data for the next 12 months. Your supervisor believes that the forecasts are too optimistic near the end and asks you to prepare a forecast graph in which the numbers that you have forecast are reduced by 1000 in the last three months. You can accomplish this task by editing the input data set so that it contains observations for the actual data range of sales plus 12 additional observations for the forecast period, and a new variable called, for example, ADJUSTMENT. The variable ADJUSTMENT contains the value 1000 for the last three observations, and is missing for all other observations. You fit the same model previously selected for forecasting using the `ARIMA Model Specification` or `Custom Model Specification` window, but with an adjustment added using the variable ADJUSTMENT. Now when you graph the forecasts using the Model Viewer, the last three periods of the forecast are reduced by 1000. The confidence limits are unchanged, which helps draw attention to the fact that the adjustments to the forecast deviate from what would be expected statistically.

Dynamic Regressor

Selecting `Dynamic Regressor` from the `Add Predictors` menu (shown in Figure 38.1) allows you to specify a complex time series model of the way that a predictor variable influences the series that you are forecasting.

When you specify a predictor variable as a simple regressor, only the current period value of the predictor effects the forecast for the period. By specifying the predictor with the Dynamic Regression option, you can use past values of the predictor series, and you can model effects that take place gradually.

Dynamic regression models are an advanced feature that you are unlikely to find useful unless you have studied the theory of statistical time series analysis. You may want to skip this section if you are not trained in time series modeling.

The term *dynamic regression* was introduced by Pankratz (1991) and refers to what Box and Jenkins (1976) named *transfer function models*. In dynamic regression, you have a time series model, similar to an ARIMA model, that predicts how changes in the predictor series affect the dependent series over time.

The dynamic regression model relates the predictor variable to the expected value of the dependent series in the same way that an ARIMA model relates the fluctuations of the dependent series about its conditional mean to the random error term (which is also called the innovation series). Refer to "*Forecasting with Dynamic Regression Models*" (Pankratz, 1991) and) "*Time Series Analysis: Forecasting and Control*" (Box and Jenkins, 1976 for more information on dynamic regression or transfer function models. See also Chapter 11, "The ARIMA Procedure."

From the Develop Models window, select `Fit ARIMA Model.` From the ARIMA Model Specification window, select `Add` and then select `Linear Trend` from the menu (shown in Figure 38.1).

Now select `Add` and select `Dynamic Regressor`. This displays the `Dynamic Regressors Selection` window, as shown in Figure 38.11.

Denominator Factors:

Simple Order: 0

Seasonal Order: 0

Figure 38.12. Dynamic Regression Specification Window

This window consists of four parts. The `Input Transformations` fields allow you to transform or lag the predictor variable. For example, you might use the lagged logarithm of the variable as the predictor series.

The `Order of Differencing` fields allow you to specify simple and seasonal differencing of the predictor series. For example, you might use changes in the predictor variable instead of the variable itself as the predictor series.

The `Numerator Factors` and `Denominator Factors` fields allow you to specify the orders of simple and seasonal numerator and denominator factors of the transfer function.

Simple regression is a special case of dynamic regression in which the dynamic regression model consists of only a single regression coefficient for the current value of the predictor series. If you select the `OK` button without specifying any options in the Dynamic Regression Specification window, a simple regressor will be added to the model.

For this example, use the `Simple Order` combo box for `Denominator Factors` and set its value to 1. The window now appears as shown in Figure 38.13.

Figure 38.14. Dynamic Regression Model

This model is a multiple regression of PETROL on a time trend variable and an infinite distributed lag of VEHICLES. Select the `OK` button to fit the model.

As with simple regressors, if VEHICLES does not already have a forecasting model, an automatic model selection process is performed to find a forecasting model for VEHICLES before the dynamic regression model for PETROL is fit.

Interventions

An *intervention* is a special indicator variable, computed automatically by the system, that identifies time periods affected by unusual events that influence or intervene in the normal path of the time series you are forecasting. When you add an intervention predictor, the indicator variable of the intervention is used as a regressor, and the impact of the intervention event is estimated by regression analysis.

To add an intervention to the Predictors list, you must use the Intervention Specification window to specify the time or times that the intervening event took place and to specify the type of intervention. You can add interventions either through the `Interventions` item of the `Add` action or by selecting `Tools` from the menu bar and then selecting `Define Interventions.`

Intervention specifications are associated with the series. You can specify any number of interventions for each series, and once you define interventions you can select them for inclusion in forecasting models. If you select the `Include Interventions` option in the `Options` pull-down menu, any interventions that you have previously specified for a series are automatically added as predictors to forecasting models for the series.

From the Develop Models window, invoke the series viewer by selecting the `View Series Graphically` icon or `Series` under the `View` pull-down menu. This displays the Time Series Viewer, as was shown in Figure 38.2.

Note that the trend in the PETROL series shows several clear changes in direction. The upward trend in the first part of the series reverses in 1981. There is a sharp drop in the series towards the end of 1985, after which the trend is again upwardly sloped. Finally, in 1991 the series takes a sharp upward excursion but quickly returns to the trend line.

You may have no idea what events caused these changes in the trend of the series, but you can use these patterns to illustrate the use of intervention predictors. To do this, you fit a linear trend model to the series, but modify that trend line by adding intervention effects to model the changes in trend you observe in the series plot.

The Intervention Specification Window

From the Develop Models window, select `Fit ARIMA` model. From the ARIMA Model Specification window, select `Add` and then select `Linear Trend` from the menu (shown in Figure 38.1).

Select `Add` again and then select `Interventions.` If you have any interventions already defined for the series, this selection displays the `Interventions for Series` window. However, since you have not previously defined any interventions, this list is empty. Therefore, the system assumes that you want to add an intervention and displays the `Intervention Specification` window instead, as shown in Figure 38.15.

MAR71	2165.0000
APR71	2223.0000
MAY71	2190.0000
JUN71	2288.0000
JUL71	2250.0000
AUG71	2251.0000
SEP71	2281.0000
OCT71	2320.0000

Figure 38.15. Interventions Specification Window

The top of the Intervention Specification window shows the current series and the label for the new intervention (initially blank). At the right side of the window is a scrollable table showing the values of the series. This table helps you locate the dates of the events you want to model.

At the left of the window is an area titled `Intervention Specification` that contains the options for defining the intervention predictor. The `Date` field specifies the time that the intervention occurs. You can type a date value in the `Date` field, or you can set the Date value by selecting a row from the table of series values at the right side of the window.

The area titled `Type of Intervention` controls the kind of indicator variable constructed to model the intervention effect. You can specify the following kinds of interventions:

Point	is used to indicate an event that occurs in a single time period. An example of a point event is a strike that shuts down production for part of a time period. The value of the intervention's indicator variable is zero except for the date specified.
Step	is used to indicate a continuing event that changes the level of the series. An example of a step event is a change in the law, such as a tax rate increase. The value of the intervention's indicator variable is zero before the date specified and 1 thereafter.
Ramp	is used to indicate a continuing event that changes the trend of the series. The value of the intervention's indicator variable is zero before the date specified, and it increases linearly with time thereafter.

The areas titled `Effect Time Window` and `Effect Decay Pattern` specify how to model the effect that the intervention has on the dependent series. These options are not used for simple interventions, they will be discussed later in this chapter.

Specifying a Trend Change Intervention

In the Time Series Viewer window position the mouse over the highest point in 1981 and select the point. This displays the data value, 19425, and date, February 1981, of that point in the upper-right corner of the Time Series Viewer, as shown in Figure 38.16.

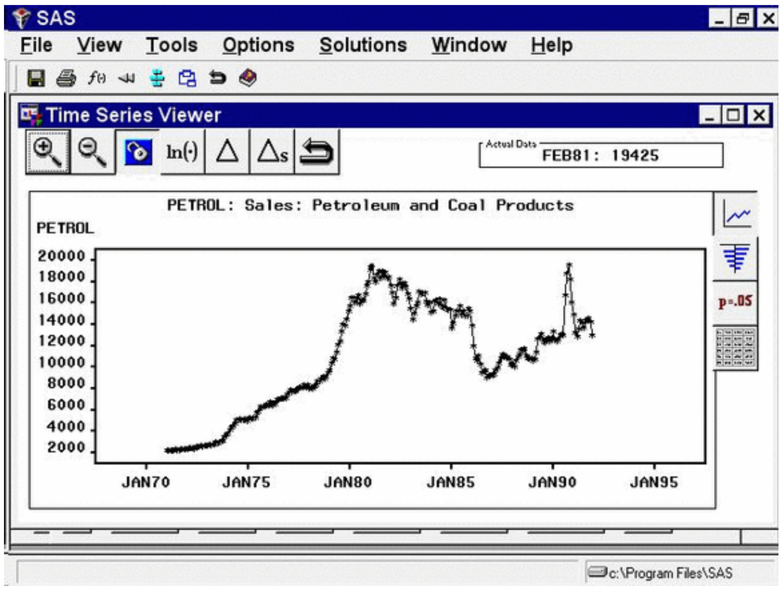

Figure 38.16. Identifying the Turning Point

Now that you know the date that the trend reversal occurred, enter that date in the `Date` field of the Intervention Specification window. Select `Ramp` as the type of intervention. The window should now appear as shown in Figure 38.17.

Figure 38.18. Interventions for Series Window

This window allows you to select interventions for inclusion in the forecasting model. Since you need to define other interventions, select the `Add` button. This returns you to the Intervention Specification window (shown in Figure 38.15).

Specifying a Level Change Intervention

Now add an intervention to account for the drop in the series in late 1985. You can locate the date of this event by selecting points in the Time Series Viewer plot or by scrolling through the data values table in the Interventions Specification window. Use the latter method so that you can see how this works.

Scrolling through the table, you see that the drop was from 15262 in December 1985, to 13937 in January 1986, to 12002 in February, to 10834 in March. Since the drop took place over several periods, you could use another ramp type intervention. However, this example represents the drop as a sudden event using a step intervention and uses February 1986 as the approximate time of the drop.

Select the table row for February 1986 to set the `Date` field. Select `Step` as the intervention type. The window should now appear as shown in Figure 38.19.

Figure 38.19. Step Intervention Specified

Select the `OK` button to add this intervention to the list for the series.

Since the trend reverses again after the drop, add a ramp intervention for the same date as the step intervention. Select `Add` from the Interventions for Series window. Enter FEB86 in the `Date` field, select `Ramp,` and then select the `OK` button.

Modeling Complex Intervention Effects

You have now defined three interventions to model the changes in trend and level. The excursion near the end of the series remains to be dealt with.

Select `Add` from the Interventions for Series window. Scroll through the data values and select the date on which the excursion began, August 1990. Leave the intervention type as Point.

The pattern of the series from August 1990 through January 1991 is more complex than a simple shift in level or trend. For this pattern, you need a complex intervention model for an event that causes a sharp rise followed by a rapid return to the previous trend line. To specify this model, use the `Effect Time Window` and `Effect Decay Rate` options.

The `Effect Time Window` option controls the number of lags of the intervention's indicator variable used to model the effect of the intervention on the dependent series. For a simple intervention, the number of lags is zero, which means that the effect of the intervention is modeled by fitting a single regression coefficient to the intervention's indicator variable.

When you set the number of lags greater than zero, regression coefficients are fit to lags of the indicator variable. This allows you to model interventions whose effects take place gradually, or to model rebound effects. For example, severe weather may reduce production during one period but cause an increase in production in the following period as producers struggle to catch up. You could model this using a point intervention with an effect time window of 1 lag. This would fit two coefficients for the intervention, one for the immediate effect and one for the delayed effect.

The `Effect Decay Pattern` option controls how the effect of the intervention dissipates over time. `None` specifies that there is no gradual decay: for point interventions, the effect ends immediately; for step and ramp interventions, the effect continues indefinitely. `Exp` specifies that the effect declines at an exponential rate. `Wave` specifies that the effect declines like an exponentially damped sine wave (or as the sum of two exponentials, depending on the fit to the data).

If you are familiar with time series analysis, these options may be clearer if you note that together the Effect Time Window and Effect Decay Pattern options define the numerator and denominator orders of a transfer function or dynamic regression model for the indicator variable of the intervention. See the section "Dynamic Regressor" later in this chapter for more information.

For this example, select 2 lags as the value of the Event Time Window option, and select `Exp` as the Effect Decay Pattern option. The window should now appear as shown in Figure 38.20.

Figure 38.23. Linear Trend with Interventions Model

You may wish to use the Zoom In feature to take a closer look at how the complex intervention effect fits the excursion in the series starting in August 1990.

Limitations of Intervention Predictors

Note that the model you have just fit is intended only to illustrate the specification of interventions. It is not intended as an example of good forecasting practice.

The use of continuing (step and ramp type) interventions as predictors has some limitations that you should consider. If you model a change in trend with a simple ramp intervention, then the trend in the data before the date of the intervention has no influence on the forecasts. Likewise, when you use a step intervention, the average level of the series before the intervention has no influence on the forecasts.

Only the final trend and level at the end of the series are extrapolated into the forecast period. If a linear trend is the only pattern of interest, then instead of specifying step or ramp interventions, it would be simpler to adjust the period of fit so that the model ignores the data before the final trend or level change.

Step and ramp interventions are valuable when there are other patterns in the data–such as seasonality, autocorrelated errors, and error variance–that are stable across the changes in level or trend. Step and ramp interventions allow you to fit seasonal and error autocorrelation patterns to the whole series while fitting the trend only to the latter part of the series.

Point interventions are a useful tool for dealing with outliers in the data. A point intervention will fit the series value at the specified date exactly, and it has the effect of removing that point from the analysis. When you specify an effect time window, a point intervention will exactly fit as many additional points as the number of lags specified.

Seasonal Dummies

A *Seasonal Dummies* predictor is a special feature that adds to the model seasonal indicator or "dummy" variables to serve as regressors for seasonal effects.

From the Develop Models window, select `Fit ARIMA Model.` From the ARIMA Model Specification window, select `Add` and then select `Seasonal Dummies` from the menu (shown in Figure 38.1).

A Seasonal Dummies input is added to the Predictors list, as shown in Figure 38.24.

Predictors
Dummy Vars SDUMMY: Seasonal Dummies

Figure 38.24. Seasonal Dummies Specified

Select the OK button. A model consisting of an intercept and 11 seasonal dummy variables is fit and added to the model list in the Develop Models window. This is effectively a mean model with a separate mean for each month.

Now return to the Model Viewer, which displays a plot of the model predictions and actual series values, as shown in Figure 38.25. This is obviously a poor model for this series, but it serves to illustrate how seasonal dummy variables work.

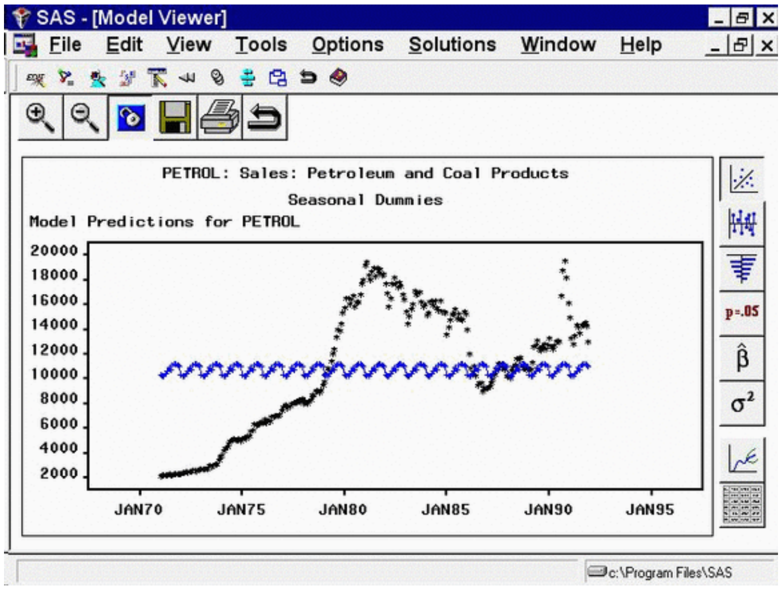

Figure 38.25. Seasonal Dummies Model

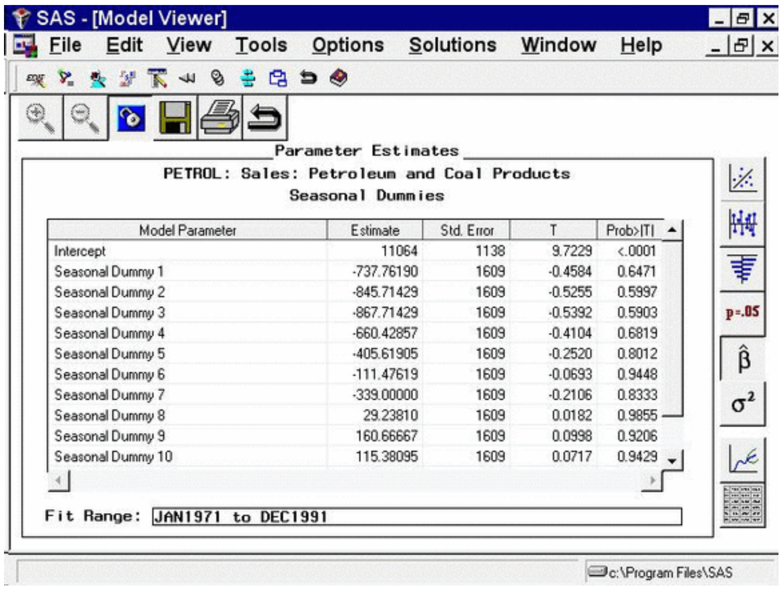
Now select the parameter estimates icon, the fifth from the top on the vertical toolbar. This displays the `Parameter Estimates` table, as shown in Figure 38.26.



Parameter Estimates

PETROL: Sales: Petroleum and Coal Products

Seasonal Dummies

Model Parameter	Estimate	Std. Error	T	Prob>|T|
Intercept	11064	1138	9.7229	<.0001
Seasonal Dummy 1	-737.76190	1609	-0.4584	0.6471
Seasonal Dummy 2	-845.71429	1609	-0.5255	0.5997
Seasonal Dummy 3	-867.71429	1609	-0.5392	0.5903
Seasonal Dummy 4	-660.42857	1609	-0.4104	0.6819
Seasonal Dummy 5	-405.61905	1609	-0.2520	0.8012
Seasonal Dummy 6	-111.47619	1609	-0.0693	0.9448
Seasonal Dummy 7	-339.00000	1609	-0.2106	0.8333
Seasonal Dummy 8	29.23810	1609	0.0182	0.9855
Seasonal Dummy 9	160.66667	1609	0.0998	0.9206
Seasonal Dummy 10	115.38095	1609	0.0717	0.9429

Fit Range: JAN1971 to DEC1991

Figure 38.26. Parameter Estimates for Seasonal Dummies Model

Since the data for this example are monthly, the Seasonal Dummies option added 11 seasonal dummy variables. These include a dummy regressor variable that is 1.0 for January and 0 for other months, a regressor that is 1.0 only for February, and so forth through November.

Because the model includes an intercept, no dummy variable is added for December. The December effect is measured by the intercept, while the effect of other seasons is measured by the difference between the intercept and the estimated regression coefficient for the season's dummy variable.

The same principle applies for other data frequencies: the "Seasonal Dummy 1" parameter will always refer to the first period in the seasonal cycle; and, when an intercept is present in the model, there will be no seasonal dummy parameter for the last period in the seasonal cycle.

Chapter 39
Command Reference

Chapter Contents

Chapter 39
Command Reference

TSVIEW Command and Macro

The TSVIEW command invokes the Time Series Viewer. This is a component of the Time Series Forecasting System that can also be used as a stand-alone graphical viewer for any time series data set or view. See “Time Series Viewer Window” in Chapter 40, “Window Reference,” for more information.

The TSVIEW command must be given from the command line or an SCL program. If you need to submit from the program editor, use the %TSVIEW macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the TSVIEW command or %TSVIEW macro is issued without arguments, the Series Selection window appears to enable you to select an input data set and series. This is equivalent to selecting “Time Series Viewer” from the Analysis submenu of the Solutions pull-down menu. By specifying the DATA= and VAR= arguments, you can bring up the Time Series Viewer window directly. The ID= and INTERVAL= arguments are useful when the system cannot determine them automatically from the data.

Syntax

The TSVIEW command has the following form:

TSVIEW *[options]*

The %TSVIEW macro has the following form:

%TSVIEW *[(option, ..., option)] ;*

The following options can be specified for the command and the macro.

DATA= *data set name*
Specifies the name of the SAS data set containing the input data.

VAR= *time series variable name*
Specifies the series variable name. It must be a numeric variable contained in the data set.

ID= *time id variable name*
Specifies the time ID variable name for the data set. If the ID= option is not specified, the system will attempt to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option.

INTERVAL= *interval name*
Specifies the time ID interval between observations in the data set.

Examples

TSVIEW Command

```
tsview data=sashelp.air var=air
tsview data=dept.prod var=units id=period interval=qtr
```

%TSVIEW Macro

```
%tsview( data=sashelp.air, var=air);
%tsview( data=dept.prod, var=units, id=period, interval=qtr);
```

FORECAST Command and Macro

The FORECAST command invokes the Time Series Forecasting System. The command must be given from the command line or an SCL program. If you need to submit from the program editor, use the %FORECAST macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the FORECAST command or %FORECAST macro is issued without arguments, the Time Series Forecasting window appears. This is equivalent to selecting "Time Series Forecasting System" from the `Analysis` submenu of the Solutions pulldown menu.

Using the arguments, it is possible to do the following:

- Bring up the system with information already filled into some of the fields
- Bring up the system starting at a different window than the default Time Series Forecasting window
- Run the system in unattended mode so that a task such as creating a forecast data set is accomplished without any user interaction. By submitting such commands repeatedly from a SAS/AF or SAS/EIS application, it is possible to do "batch" processing for many data sets or by-group processing for many subsets of a data set. You can create a project in unattended mode and later open it for inspection interactively. You can also create a project interactively in order to set options, fit a model, or edit the list of models, and then use this project later in unattended mode.

The `Forecast Command Builder`, a point-and-click SAS/AF application, makes it easy to specify, run, save, and rerun forecasting jobs using the FORECAST command. To use it, enter the following on the command line (not the program editor):

`%FCB`

or

`AF C=SASHELP.FORCAST.FORCCMD.FRAME`.

Syntax

The FORECAST command has the following form:

FORECAST *[options]*

The %FORECAST macro has the following form:

%FORECAST *[(option, ..., option)] ;*

The following options can be specified for the command and the macro.

PROJECT= *project name*
Specifies the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system.

DATA= *data set name*
Specifies the name of the SAS data set containing the input data.

VAR= *time series variable name*
Specifies the series variable name. It must be a numeric variable contained in the data set.

ID= *time id variable name*
Specifies the time ID variable name for the data set. If the ID= option is not specified, the system will attempt to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option. However, it is recommended that you specify the time ID variable whenever you are using the ENTRY= argument.

INTERVAL= *interval name*
Specifies the time ID interval between observations in the data set. Commonly used intervals are `year`, `semiyear`, `qtr`, `month`, `semimonth`, `week`, `weekday`, `day`, `hour`, `minute`, and `second`. See Chapter 3, "Date Intervals, Formats, and Functions," for information on more complex interval specifications. If the INTERVAL= option is not specified, the system will attempt to determine the interval based on the time ID variable. However, it is recommended that you specify the interval whenever you are using the ENTRY= argument.

STAT= *statistic*
Specifies the name of the goodness-of-fit statistic to be used as the model selection criterion. The default is RMSE. Valid names are

`sse`	Sum of Square Error
`mse`	Mean Square Error
`rmse`	Root Mean Square Error
`mae`	Mean Absolute Error
`mape`	Mean Absolute Percent Error
`aic`	Akaike Information Criterion
`sbc`	Schwarz Bayesian Information Criterion

`rsquare`	R-Square
`adjrsq`	Adjusted R-Square
`rwrsq`	Random Walk R-Square
`arsq`	Amemiya's Adjusted R-Square
`apc`	Amemiya's Prediction Criterion

CLIMIT= *integer*
An integer specifying the level of the confidence limits to be computed for the forecast. This integer represents a percentage; for example, 925 indicates 92.5% confidence limits. The default is 95, that is, 95% confidence limits.

HORIZON= *integer*
Specifies the number of periods into the future for which forecasts will be computed. The default is 12 periods. The maximum is 9999.

ENTRY= *name*
The name of an entry point into the system. Valid names are

`main`	Starts the system at the Time Series Forecasting window (default).
`devmod`	Starts the system at the Develop Models window.
`viewmod`	Starts the system at the Model Viewer window. Specify a project containing a forecasting model using the PROJECT= option. If a project containing a model is not specified, the message "No forecasting model to view" appears.
`viewser`	Starts the system at the Time Series Viewer window.
`autofit`	Runs the system in unattended mode, fitting a forecasting model automatically and saving it in a project. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used.
`forecast`	Runs the system in unattended mode to generate a forecast data set. The name of this data set is specified by the OUT= parameter. If OUT= is not specified, a window appears to prompt for the name and label of the output data set. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used. If the project does not exist or does not contain a forecasting model for the specified series, automatic model fitting is performed and the forecast is computed using the automatically selected model. If the project exists and contains a forecasting model for the specified series, the forecast is computed using this model. If the series covers a different time range than it did when the project was created, use the REFIT or REEVAL keyword to reset the time ranges.

OUT= *argument*
The one or two-level name of a SAS data set in which forecasts will be saved. Use in conjunction with ENTRY=FORECAST. If omitted, the system prompts for the name of the forecast data set.

KEEP= *argument*

Specifies the number of models to keep in the project when automatic model fitting is performed. This corresponds to “Models to Keep” in the Automatic Model Selection Options window. A value greater than 9 indicates that all models will be kept. The default is 1.

DIAG= YES|NO

DIAG= YES causes the automatic model selection process to search only over those models that are consistent with the series diagnostics. DIAG= NO causes the automatic model selection process to search over all models in the selection list, without regard for the series diagnostics. This corresponds to `Models to Fit` in the Automatic Model Selection Options window. The default is YES.

REFIT *keyword*

Macro usage: REFIT= . Refits a previously saved forecasting model using the current fit range; the is, it re-estimates the model parameters. Refitting also causes the model to be reevaluated (statistics of fit recomputed), and it causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). This keyword has no effect if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REFIT keyword if you have added new data to the input series and you want to refit the forecasting model and update the forecast using the new time ranges. Be sure to use the same project, data set, and series names that you used previously.

REEVAL *keyword*

Macro usage: REEVAL= . Re-evaluates a previously saved forecasting model using the current evaluation range; that is, it recomputes the statistics of fit. Re-evaluating also causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). It does not refit the model parameters. This keyword has no effect if you also specify REFIT, or if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REEVAL keyword if you have added new data to the input series and want to update your forecast using a previously fit forecasting model and the same project, data set, and series names that you used previously.

Examples

FORECAST Command

The following command brings up the Time Series Forecasting window with the data set name and series name filled in. The time ID variable is also filled in since the data set contains the variable DATE. The interval is filled in because the system recognizes that the observations are monthly.

```
forecast data=sashelp.air var=air
```

The following command brings up the Time Series Forecasting window with the project, data set name, series, time ID, and interval fields filled in, assuming that the project SAMPROJ was previously saved either interactively or using unattended mode as depicted below. Previously fit models will appear when the Develop Models or Manage Projects window is opened.

```
forecast project=samproj
```

The following command runs the system in unattended mode, fitting a model automatically, storing it in the project SAMPROJ in the default catalog SASUSER.FMSPROJ, and placing the forecasts in the data set WORK.SAMPOUT.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=forecast out=sampout
```

The following command assumes that a new month's data have been added to the data set from the previous example and that an updated forecast is needed using the previously fit model. Time ranges are automatically updated to include the new data since the REEVAL keyword is included. Substitute REFIT for REEVAL if you want the system to re-estimate the model parameters.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=forecast out=sampout reeval
```

The following command brings up the model viewer using the project created in the previous example and using 99 percent confidence limits in the forecast graph.

```
forecast data=sashelp.workers var=electric id=date interval=month
project=samproj entry=viewmod climit=99
```

The final example illustrates using unattended mode with an existing project that has been defined interactively. In this example, the goal is to add a model to the model selection list, and to specify that all models in that list be fit and that all models which are fit successfully be retained.

First bring up the Time Series Forecasting window and specify a new project name, WORKPROJ. Then select `Develop Models`, choosing SASHELP.WORKERS as the data set and MASONRY as the series. Now select "Model Selection List" from the Options pull-down menu. In the Model Selection List window, click `Actions`, then `Add`, and then `ARIMA Model`. Define the model `ARIMA(0,1,0)(0,1,0)s NOINT` by setting the differencing value to 1 under both `ARIMA Options` and `Seasonal ARIMA Options`. Select "OK" to save the model and `OK` to close the Model Selection List window. Now select "Automatic Fit" from the Options pull-down menu. In the Automatic Model Selection Options window, select "All autofit models in selection list" in the Models to fit radio box, select "All models" from the `Models to keep` combo box, and then click `OK` to close the window. Select "Save Project" from the File pull-down menu, and then close the Develop Models window and the Time Series Forecasting window. You now have a project with a new model added to the selection list, options set for automatic model fitting, and one series selected but no models fit.

Now enter the command:

```
forecast data=sashelp.workers var=electric id=date interval=month
project=workproj entry=forecast out=workforc
```

The system runs in unattended mode to update the project and create the forecast data set WORKFORC. Check the messages in the Log window to find out if the run was successful and which model was selected for forecasting. To see the forecast data set, issue the command `viewtable WORKFORC`. To see the contents of the project, bring up the Time Series Forecasting window, open the project WORKPROJ, and select “Manage Projects”. You will see that the variable ELECTRIC was added to the project and has a forecasting model. Select this row in the table and then select `List Models` from the Tools pull-down menu. You will see that all of the models in the selection list which fit successfully are there, including the new model you added to the selection list.

%FORECAST Macro

This example demonstrates the use of the %FORECAST macro to start the Time Series Forecasting System from a SAS program submitted from the Editor window. The SQL procedure is used to create a view of a subset of a products data set. Then the %FORECAST macro is used to produce forecasts.

```
proc sql;
create view selprod as
select * from products
where type eq ’A’
order by date;

%forecast(data=selprod, var=amount, id=date, interval=day,
     entry=forecast, out=typea, proj=proda, refit= );
```

Chapter 40
Window Reference

Chapter Contents

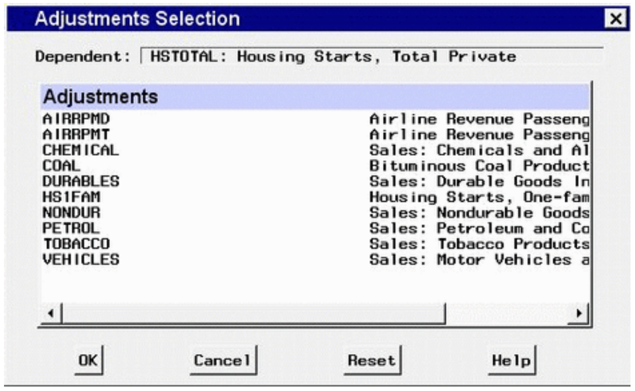
Chapter 40
Window Reference

Overview

This chapter provides a reference to the various windows of the Time Series Forecasting system. The windows are presented in alphabetical order by name. Each section describes the purpose of the window, how to bring it up, and its controls, fields, and menus. For windows which have their own pull-down menus, there is a description of each menu item under the heading “Menu Bar”. These windows also have a tool bar with icons duplicating the more commonly used menu items. Each icon has a *screen tip*: A brief description which appears when you place the mouse cursor over the icon. If you don’t see the screen tips, bring up the SAS Preferences window, under the Options submenu of the Tools pull-down menu. Select the View tab and make sure the “Screen tips” check box is checked.

Adjustments Selection Window

Use the Adjustments Selection window to select input variables for use as adjustments to the forecasts and add them to the Predictors list. Invoke this window from the pop-up menu which appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window. For more information, see the “Adjustments” section in Chapter 38, “Using Predictor Variables.”



Dependent: HSTOTAL: Housing Starts, Total Private

Adjustments	
AIRRPMD	Airline Revenue Passeng
AIRRPMT	Airline Revenue Passeng
CHEMICAL	Sales: Chemicals and Al
COAL	Bituminous Coal Product
DURABLES	Sales: Durable Goods In
HS1FAM	Housing Starts, One-fam
NONDUR	Sales: Nondurable Goods
PETROL	Sales: Petroleum and Co
TOBACCO	Sales: Tobacco Products
VEHICLES	Sales: Motor Vehicles a

Controls and Fields

`Dependent`
: is the name and variable label of the current series.

`Adjustments`
: is a table listing the names and labels in the input data set available for selection as adjustments. The variables you select are highlighted. Selecting a highlighted row again deselects that variable.

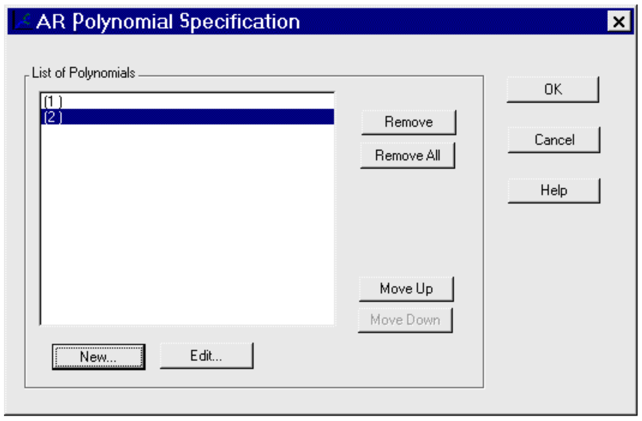
`OK`
: closes the Adjustments Selection window and adds the selected variables as adjustments in the model.

`Cancel`
: closes the window without adding any adjustments.

`Reset`
: resets all selections to their initial values upon entry to the window.

AR/MA Polynomial Specification Window

Use these windows to specify the autoregressive and moving average terms in a factored ARIMA model. Access the AR Polynomial Specification window from the Set button next to the Autoregressive term in the Factored ARIMA Model Specification window. Access the MA Polynomial Specification window from the Set button next to the Moving Average term.



Controls and Fields

`List of Polynomials`

Lists the polynomials which have been specified. Each polynomial is represented by a comma-delimited list of lag values enclosed in parentheses.

`New`
: Brings up the Polynomial Specification window to add a new polynomial to the model.

`Edit`
: Brings up the Polynomial Specification window to edit a polynomial which has been selected. If no polynomial is selected, this button is grayed.

`Remove`
: Removes a selected polynomial from the list. been selected. If none are selected, this button is grayed.

`Remove All`
: Clears the list of polynomials.

`Move Up`
: Moves a selected polynomial up one position in the list. If no polynomial is selected, or the first one is selected, this button is grayed.

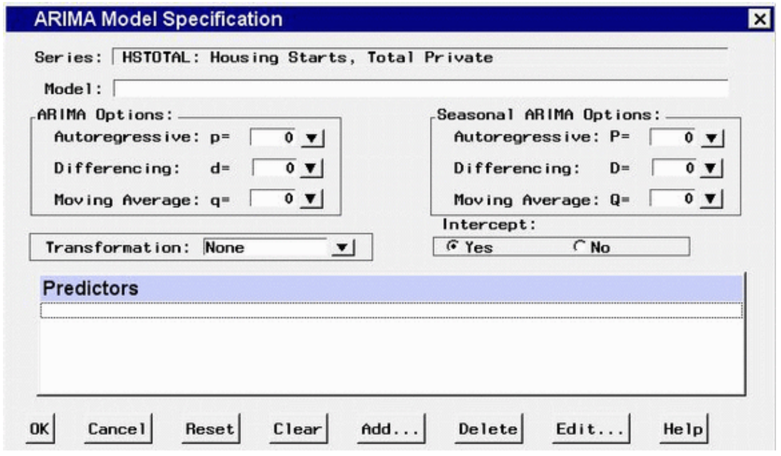
`Move Down`
: Moves a selected polynomial down one position in the list. If no polynomial is selected, or the last one is selected, this button is grayed.

`OK`
: Closes the window and returns the specified list of polynomials to the Factored ARIMA Model Specification window.

`Cancel`
: Closes the window and discards any changes made to the list of polynomials.

ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.



ARIMA Model Specification

Series: HSTOTAL: Housing Starts, Total Private

Model:

ARIMA Options:
Autoregressive: p= 0
Differencing: d= 0
Moving Average: q= 0

Seasonal ARIMA Options:
Autoregressive: P= 0
Differencing: D= 0
Moving Average: Q= 0

Intercept: [✓ Yes] No

Transformation: None

Predictors

Controls and Fields

`Series`
: is the name and variable label of the current series.

`Model`
: is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

`ARIMA Options`
: Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a popup list.

`Autoregressive`
defines the order of the autoregressive part of the model.

`Differencing`
defines the order of simple differencing, for example, first difference or second difference.

`Moving Average`
defines the order of the moving average part of the model.

`Seasonal ARIMA Options`
Use these combo boxes to specify the orders of the seasonal part of the ARIMA model. You can either type in a value or click the combo box arrow to select from a popup list.

`Autoregressive`
defines the order of the seasonal autoregressive part of the model.

`Differencing`
defines the order of seasonal differencing, for example, first difference or second difference at the seasonal lags.

`Moving Average`
defines the order of the seasonal moving average part of the model.

`Transformation`
defines the series transformation for the model. When a transformation is specified, the ARIMA model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the ARIMA model predictions. The available transformations are: `Log`, `Logistic`, `Square Root`, `Box-Cox`, and `None`.

`Intercept`
The options `Yes` and `No` enable you to specify whether a mean or intercept parameter is included in the ARIMA model. By default, the Intercept option is set to No when the model includes differencing and Yes when there is no differencing.

`Predictors`
This table lists the predictor effects included as inputs in the model.

`OK`
closes the ARIMA Model Specification window and fits the model.

`Cancel`
closes the ARIMA Model Specification window without fitting the model. Any options you specified are lost.

`Reset`
resets all options to their initial values upon entry to the ARIMA Model Specification window. This may be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

`Clear`
resets all options to their default values.

`Add`
brings up a menu of types of predictors to add to the Predictors list.

`Delete`
: deletes the selected (highlighted) entry from the Predictors list.

`Edit`
: edits the selected (highlighted) entry in the Predictors list.

Mouse Button Actions

You can select or deselect entries in the Predictors list by positioning the mouse cursor over the entry and clicking the left mouse button. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you position the mouse cursor over the Predictors list and click the right mouse button, the system displays the following menu of actions encompassing the features of the Add, Delete, and Edit buttons.

`Add Linear Trend`
: adds a Linear Trend item to the Predictors list.

`Add Trend Curve`
: brings up a menu of different time trend curves and adds the curve you select to the Predictors list. Certain trend curve specifications also set the Transformation field.

`Add Regressors`
: brings up the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

`Add Adjustments`
: brings up the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

`Add Dynamic Regressor`
: brings up the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

`Add Interventions`
: brings up the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

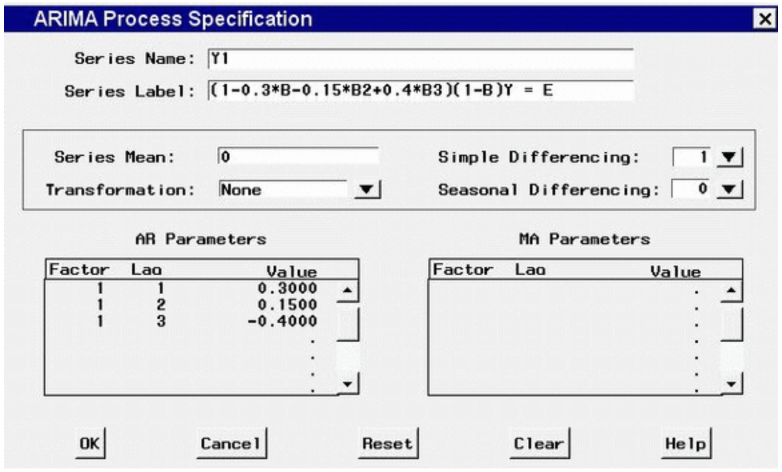
`Add Seasonal Dummies`
: adds a Seasonal Dummies predictor item to the Predictors list.

`Edit Predictor`
: edits the selected (highlighted) entry in the Predictors list.

`Delete Predictors`
: deletes the selected (highlighted) entry from the Predictors list.

ARIMA Process Specification Window

Use the ARIMA Process Specification window to define ARIMA processes for simulation. Invoke this window from the Add Series button in the Time Series Simulation window.



Series Name: Y1
Series Label: (1-0.3*B-0.15*B2+0.4*B3)(1-B)Y = E

Series Mean: 0
Transformation: None
Simple Differencing: 1
Seasonal Differencing: 0

AR Parameters

Factor	Lag	Value
1	1	0.3000
1	2	0.1500
1	3	-0.4000

MA Parameters

Factor	Lag	Value

Controls and Fields

`Series Name`
: is the variable name for the series to be simulated.

`Series Label`
: is the variable label for the series to be simulated.

`Series Mean`
: is the mean of the simulated series.

`Transformation`
: defines the series transformation.

`Simple Differencing`
: is the order of simple differencing for the series.

`Seasonal Differencing`
: is the order of seasonal differencing for the series.

`AR Parameters`
: is a table of Autoregressive terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the AR part of the process you want to simulate. For a non-factored AR model, make the Factor values the same for all terms. For a factored AR model, use different Factor values to group the terms into the factors.

`MA Parameters`
: is a table of Moving Average terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the MA part of the process you want to simulate. For a non-factored MA model, make the Factor values the same for all terms. For a factored MA model, use different Factor values to group the terms into the factors.

`OK`
: closes the ARIMA Process Specification window and adds the specified process to the Series to Generate list in the Time Series Simulation window.

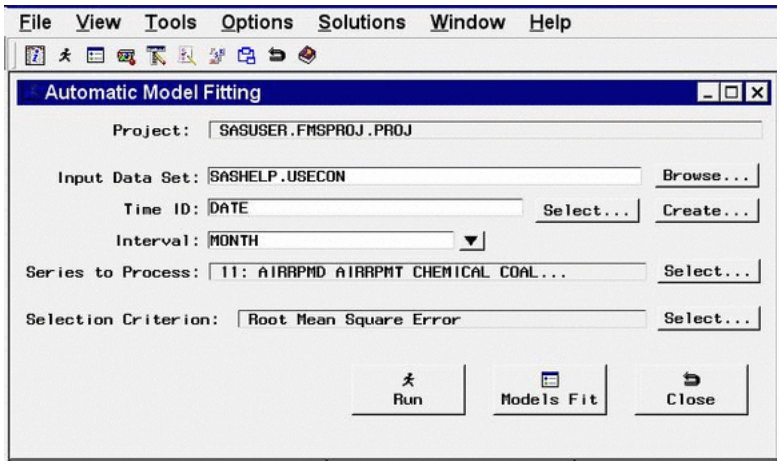
`Cancel`
: closes the window without adding to the Series to Generate list. Any options you specified are lost.

`Reset`
: resets all the fields to their initial values upon entry to the window.

`Clear`
: resets all the fields to their default values.

Automatic Model Fitting Window

Use the Automatic Model Fitting window to perform automatic model selection on all series or selected series in an input data set. Invoke this window using the Fit Models Automatically button on the Time Series Forecasting window. Note that you can also perform automatic model fitting, one series at a time, from the Develop Models window.



Project: SASUSER.FMSPROJ.PROJ

Input Data Set: SASHELP.USECON

Time ID: DATE

Interval: MONTH

Series to Process: 11: AIRRPMD AIRRPMT CHEMICAL COAL...

Selection Criterion: Root Mean Square Error

Controls and Fields

`Project`
: the name of the SAS catalog entry in which the results of the model search process are stored.

`Input Data Set`
: is the name of the current input data set. You can type in a one or two level data set name here.

`Browse button`
: brings up the Data Set Selection window for selecting an input data set.

`Time ID`
: is the name of the ID variable for the input data set. You can type in the variable name here, or use the Select or Create button.

time ID `Select` button
: brings up the Time ID Variable Specification window.

time ID `Create` button
: brings up a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

`Interval`
: is the time interval between observations (data frequency) in the current input data set. You can type in an interval name or select one using the combo box popup menu.

`Series to Process`
: indicates the number and names of time series variables for which forecasting model selection will be applied.

Series to Process `Select` button
: brings up the Series to Process window to let you select the series for which you want to fit models.

`Selection Criterion`
: shows the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Selection Criterion `Select` button
: brings up the Model Selection Criterion window to enable you to select the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

`Run` button
: begins the automatic model fitting process.

`Models Fit` button
: invokes the Automatic Model Fitting Results window to display the models fit during the current invocation of the Automatic Model Fitting window. The results appear automatically when model fitting is complete, but this button enables you to redisplay the results window.

`Close` button
: Closes the Automatic Model Fitting window.

Menu Bar

`File`

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Close`
: Closes the Automatic Model Fitting window.

`View`

`Input Data Set`
: brings up a Viewtable window to browse the current input data set.

`Models Fit`
: brings up Automatic Model Fitting Results window to show the forecasting models fit during the current invocation of the Automatic Model Fitting window. This is the same as the Models Fit button.

`Tools`

`Fit Models`
: performs the automatic model selection process for the selected series. This is the same as the Run button.

`Options`

`Default Time Ranges`
: brings up the Default Time Ranges window to enable you to control how the system sets the time ranges for series.

`Model Selection List`
: Brings up the Model Selection List editor window. Use this action to control the forecasting models considered by the automatic model selection process and displayed in the Models to Fit window.

`Model Selection Criterion`
: brings up the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as the Selection Criterion Select button.

`Statistics of Fit`
: brings up the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion menu.

`Forecast Options`
: brings up the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

`Forecast Data Set`
: see Produce Forecasts window.

`Alignment of Dates`

`Beginning`
: aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

`Middle`
: aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

`End`
: aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

`Automatic Fit`
: brings up the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

`Tool Bar Type`

`Image Only`
: displays the tool bar items as icons without text.

`Label Only`
: displays the tool bar items as text without icon images.

`Both`
: displays the tool bar items with both text and icon images.

`Include Interventions`
: controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

`Print Audit Trail`
: prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

`Show Source Statements`
: controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Automatic Model Fitting Results Window

This resizable window displays the models fit by the most recent invocation of the Automatic Model Fitting window. It appears automatically after Automatic Model Fitting runs, and can be brought up repeatedly from that window using the Models Fit button or by selecting Models Fit from the View pull-down menu. Once you exit the Automatic Model Fitting window, the Automatic Model Fitting Results window cannot be opened again until you fit additional models using Automatic Model Fitting.

Series Name	Model Label	Root Mean Square Error
AIRRPMD	Log ARIMA(2,1,2)(0,1,1)s NOINT	0.63290
AIRRPMD	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.63390
AIRRPMT	Log ARIMA(0,1,2)(0,1,1)s NOINT	0.74226
AIRRPMT	Log ARIMA(2,1,0)(0,1,1)s NOINT	0.74883
CHEMICAL	Log ARIMA(2,1,2)(0,1,1)s NOINT	386.25
CHEMICAL	Log Winters Method -- Additive	397.96
COAL	Linear Trend with Autoregressive Errors	6972.17
COAL	Winters Method -- Additive	7244.40
DURABLES	Log Winters Method -- Multiplicative	2157.29
DURABLES	Log Winters Method -- Additive	2161.37
HS1FAM	Log Seasonal Exponential Smoothing	7.22149

Table Contents

The results table displays the series name in the first column and the model label in the second column. If you have chosen to retain more than one model using the Automatic Model Selection Options window, more than one row appears in the table for each series; that is, there is a row for each model fit. If you have already fit models to the same series before invoking the Automatic Model Fitting window, those models do not appear here, since the Automatic Model Fitting Results window is intended to show the results of the current operation of Automatic Model Fitting. To see all models which have been fit, use the Manage Projects window.

The third column of the table shows the values of the current model selection criterion statistic. Additional columns show the values of other fit statistics. The set of statistics shown are selectable using the Statistics of Fit Selection window.

The table can be sorted by any column other than Series Name by clicking on the column heading.

Controls and Fields

`Graph`
: brings up the Model Viewer window on the model currently selected in the table.

`Stats`
: brings up the Statistics of Fit Selection window. This controls the set of

goodness-of-fit statistics displayed in the table and in other parts of the Time Series Forecasting System.

`Compare`
: brings up the Model Fit Comparison window for the series currently selected in the table. This button is grayed out if the currently selected row in the table represents a series for which fewer than two models have been fit.

`Save`
: brings up an output data set dialog, enabling you to specify a SAS data set to which the contents of the table will be saved. Note that this operation saves what you see in the table. If you want to save the models themselves for use in a future session, use the Manage Projects window.

`Print`
: prints the contents of the table.

`Close`
: closes the window and returns to the Automatic Model Fitting window.

Menu Bar

`File`

`Save`
: brings up an output data set dialog, enabling you to specify a SAS data set to which the contents of the table will be saved. This is the same as the Save button.

`Print`
: prints the contents of the table. This is the same as the Print button.

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Close`
: closes the window and returns to the Automatic Model Fitting window.

`View`

`Model Predictions`
: brings up the Model Viewer to display a predicted and actual plot for the currently highlighted model.

`Prediction Errors`
: brings up the Model Viewer to display the prediction errors for the currently highlighted model.

`Prediction Error Autocorrelations`
: brings up the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

`Prediction Error Tests`
: brings up the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

`Parameter Estimates`
: brings up the Model Viewer to display the parameter estimates table for the currently highlighted model.

`Statistics of Fit`
: brings up the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

`Forecast Graph`
: brings up the Model Viewer to graph the forecasts for the currently highlighted model.

`Forecast Table`
: brings up the Model Viewer to display forecasts for the currently highlighted model in a table.

`Tools`

`Compare Models`
: brings up the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This item is grayed out until you select a series in the table for which the automatic model fitting run selected two or more models.

`Options`

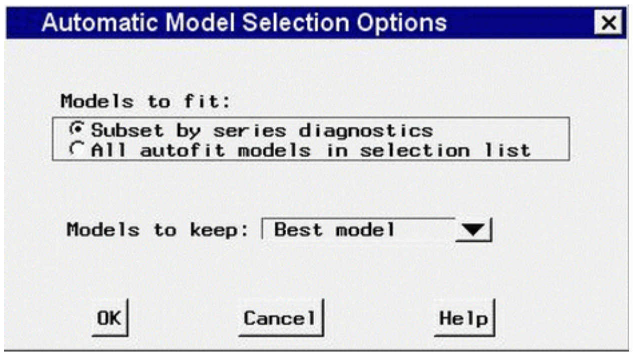
`Statistics of Fit`
: brings up the Statistics of Fit Selection window. This is the same as the Stats button.

`Column Labels`
: selects long or short column labels for the table. Long column labels are used by default.

`ID Columns`
: freezes or unfreezes the series and model columns. By default they are frozen so that they remain visible when you scroll the table horizontally to view other columns.

Automatic Model Selection Options Window

Use the Automatic Model Selection Options window to control the automatic selection process. This window is available from the Automatic Fit item of the Options pull-down menu in the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.



Automatic Model Selection Options

Models to fit:
[✓ Subset by series diagnostics]
All autofit models in selection list

Models to keep: Best model

Controls and Fields

`Models to fit`

`Subset by series diagnostics`
when selected, causes the automatic model selection process to search only over those models consistent with the series diagnostics.

`All models in selection list`
when selected, causes the automatic model selection process to search over all models in the search list, without regard for the series diagnostics.

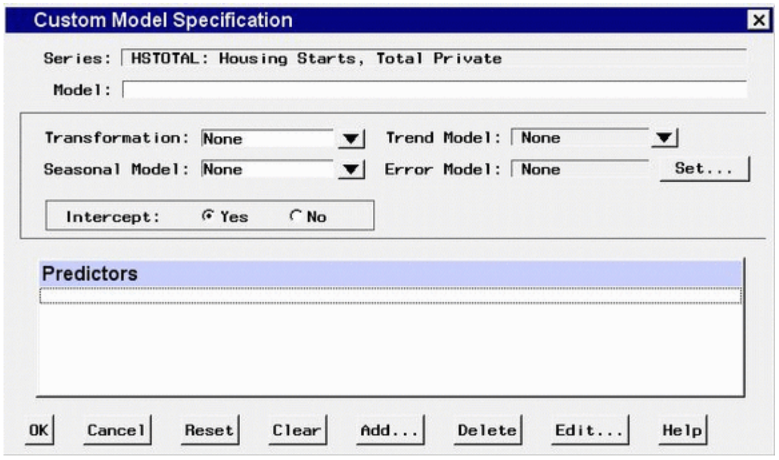
`Models to keep`
specifies how many of the models tried by the automatic model selection process are retained and added to the model list for the series. You can specify the best fitting model only, the best *n* models, where *n* can be 1 through 9, or all models tried.

`OK`
closes the window and saves the automatic model selection options you specified.

`Cancel`
closes the window without changing the automatic model selection options.

Custom Model Specification Window

Use the Custom Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models window, where it is invoked from the Fit Model item under the Edit pull-down menu, or from the pop-up menu when you click an empty area of the model table.



Controls and Fields

`Series`
: is the name and variable label of the current series.

`Model`
: is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

`Transformation`
: defines the series transformation for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the resulting forecasts. The available transformations are

  `Log`
  : specifies a logarithmic transformation.

  `Logistic`
  : specifies a logistic transformation.

  `Square Root`
  : specifies a square root transformation.

  `Box-Cox`
  : specifies a Box-Cox transform and brings up a window to specify the Box-Cox λ parameter.

  `None`
  : specifies no series transformation.

`Trend Model`
: controls the model options to model and forecast the series trend. Select from

  `Linear Trend`
  : adds a Linear Trend item to the Predictors list.

`Trend Curve`
: brings of a menu of different time trend curves and adds the curve you select to the Predictors list.

`First Difference`
: specifies differencing the series.

`Second Difference`
: specifies second-order differencing of the series.

`None`
: specifies no model for the series trend.

`Seasonal Model`
: controls the model options to model and forecast the series seasonality. Select from:

`Seasonal ARIMA`
: brings up the Seasonal ARIMA Model Options window to enable you to specify an ARIMA model for the seasonal pattern in the series.

`Seasonal Difference`
: specifies differencing the series at the seasonal lag.

`Seasonal Dummy Regressors`
: adds a Seasonal Dummies predictor item to the Predictors list.

`None`
: specifies no seasonal model.

`Error Model`
: displays the current settings of the autoregressive and moving average terms, if any, for modeling the prediction error autocorrelation pattern in the series.

`Set` button
: brings up the Error Model Options window to let you set the autoregressive and moving average terms for modeling the prediction error autocorrelation pattern in the series.

`Intercept`
: The options “Yes” and “No” enable you to specify whether a mean or intercept parameter is included in the model. By default, the Intercept option is set to No when the model includes differencing and set to Yes when there is no differencing.

`Predictors`
: is a list of the predictor effects included as inputs in the model.

`OK`
: closes the Custom Model Specification window and fits the model.

`Cancel`
: closes the Custom Model Specification window without fitting the model. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the Custom Model

Specification window. This may be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

`Clear`
: resets all options to their default values.

`Add`
: brings up a menu of types of predictors to add to the Predictors list. Select from:

  `Linear Trend`
  : adds a Linear Trend item to the Predictors list.

  `Trend Curve`
  : brings up a menu of different time trend curves and adds the curve you select to the Predictors list.

  `Regressors`
  : brings up the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

  `Adjustments`
  : brings up the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

  `Dynamic Regressor`
  : brings up the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

  `Interventions`
  : brings up the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

  `Seasonal Dummies`
  : adds a Seasonal Dummies predictor item to the Predictors list. This is grayed out if the series interval is not one which has a seasonal cycle.

`Delete`
: deletes the selected (highlighted) entry from the Predictors list.

`Edit`
: edits the selected (highlighted) entry in the Predictors list.

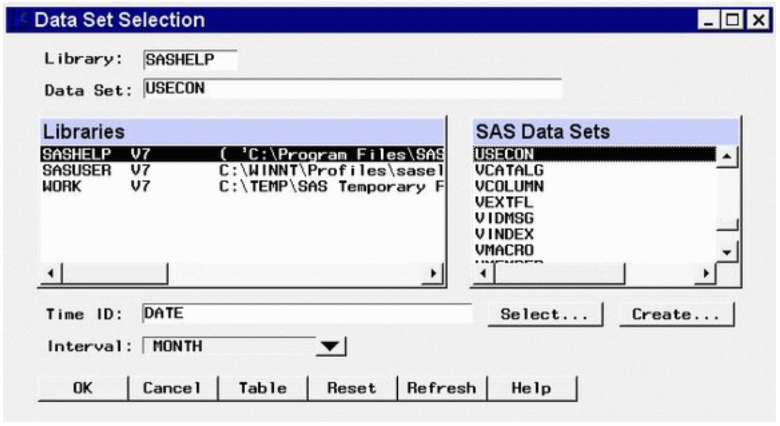
Mouse Button Actions

You can select or deselect entries in the Predictors list by positioning the mouse cursor over the entry and clicking the left mouse button. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you position the mouse cursor over the Predictors list and press the right mouse button, the system displays a menu of actions encompassing the features of the Add, Delete, and Edit buttons.

Data Set Selection Window

Use this resizable window to select a data set to process by specifying a library and a SAS data set or view. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set.



Library: SASHELP
Data Set: USECON

```
SASHELP   V7       ( 'C:\Program Files\SAS
SASUSER   V7       C:\WINNT\Profiles\sasel
WORK      V7       C:\TEMP\SAS Temporary F
```

```
USECON
VCATALG
VCOLUMN
VEXTFL
VIDMSG
VINDEX
VMACRO
```

Time ID: DATE
Interval: MONTH

Access this window using the Browse button to the right of the Data Set field in the Time Series Forecasting, Automatic Model Fitting, and Produce Forecasts windows. It functions in the same way as the Series Selection window, except that it does not allow you to select or view a time series variable.

Controls and Fields

`Library`
: is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname. See also Libraries under Selection Lists.

`Data Set`
: is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted.

`Time ID`
: is the name of the ID variable for the selected input data set. To specify the ID variable, you can type the ID variable name in this field or select the control arrows to the right of the field.

Time ID `Select` button
: brings up the Time ID Variable Specification window.

Time ID `Create` button
: brings up a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

`Interval`
: is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically identified by the system, you can type in the interval name or select it from a list by clicking the combo box arrow. For more information on intervals, see Chapter 3, "Date Intervals, Formats, and Functions," in this book.

`OK`
: closes the Data Set Selection window and makes the selected data set the current input data set.

`Cancel`
: closes the window without applying any selections made.

`Table`
: brings up a Viewtable window for browsing the selected data set.

`Reset`
: resets the fields to their initial values upon entry to the window.

`Refresh`
: updates all fields and lists on the window. If you assign a new libname without exiting the Data Set Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname.

Selection Lists

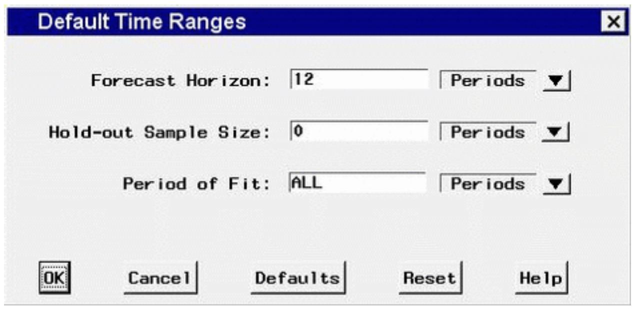
`Libraries`
: displays a list of currently assigned libnames. You can select a libname by clicking it with the left mouse button, which is equivalent to typing its name in the Library field.

  If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select "New" from the File pull-down menu, then select "Library" and "OK". This brings up the New Library window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

`SAS Data Sets`
: displays a list of the SAS data sets (data files or data views) contained in the selected library. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Data set field. You can double-click on a data set name to select it and exit the window.

Default Time Ranges Window

Use the Default Time Ranges window to control how the period of fit and evaluation and the forecasting horizon are determined for each series when you do not explicitly set these ranges for a particular series. Invoke this window from the Options pull-down menu of the Develop Models, Automatic Model Fitting, Produce Forecasts, and Manage Forecasting Project windows. The settings you make in this window affect subsequently selected series: They do not alter the time ranges of series you have already selected.



Default Time Ranges

Forecast Horizon: 12 Periods

Hold-out Sample Size: 0 Periods

Period of Fit: ALL Periods

Controls and Fields

`Forecast Horizon`
: specifies the forecast horizon as either a number of periods or years from the last nonmissing data value or as a fixed date. You can type a number or date value in this field. Date value must be entered in a form recognized by a SAS date informat. (Refer to "SAS Language Reference" for information on SAS date informats.)

`Forecast Horizon Units`
: indicates whether the value in the forecast horizon field represents periods or years or a date. Click the arrow and choose one of these three options from the popup list.

`Hold-out Sample Size`
: specifies that a number of observations, number of years, or percent of the data at the end of the data range be used for the period of evaluation with the remainder of data used as the period of fit.

`Hold-out Sample Size Units`
: indicates whether the hold-out sample size represents periods or years or percent of data range.

`Period of Fit`
: specifies how much of the data range for a series is to be used as the period of fit for models fit to the series. ALL indicates that all the available data is used. You can specify a number of periods, number of years, or a fixed date, depending on the value of the units field to the right. When you specify a date, the start of the period of fit is the specified date or the first nonmissing series value, whichever is more recent. Date value must be entered in a form recognized by a SAS date informat. (Refer to "SAS Language Reference" for information on SAS date informats.) When you specify the number of periods or years, the start of the period of fit is computed as the date that number of periods or years from the end of the data.

`Period of Fit Units`
: indicates whether the period of fit value represents periods or years or a date.

`OK`
: closes the window and stores the specified changes.

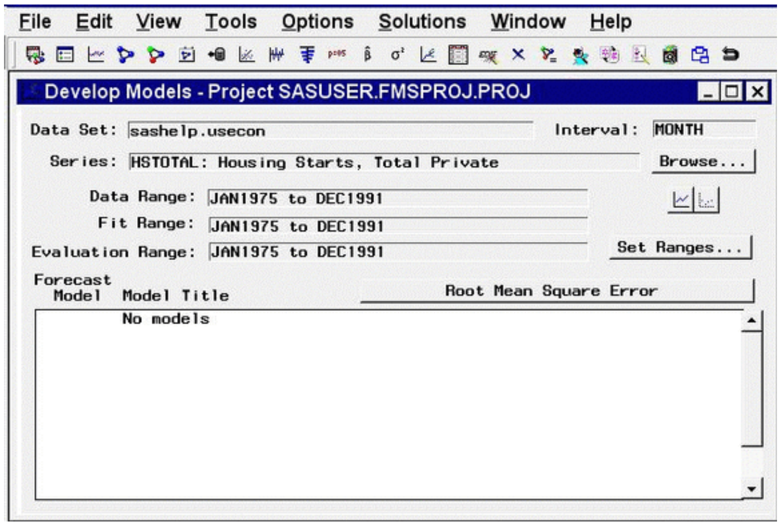
`Cancel`
: closes the window without saving changes. Any options you specified are lost.

`Defaults`
: resets all options to their default values.

`Reset`
: resets the options to their initial values upon entry to the window.

Develop Models Window

This resizable window provides access to all of the Forecasting System's interactive model fitting and graphical tools. Use it to fit forecasting models to an individual time series and choose the best model to use to produce the final forecasts of the series. Invoke this window using the Develop Models button on the Time Series Forecasting window.



File Edit View Tools Options Solutions Window Help
Develop Models - Project SASUSER.FMSPROJ.PROJ
Browse...
Set Ranges...

Data Set: sashelp.usecon
Interval: MONTH
Series: HSTOTAL: Housing Starts, Total Private
Data Range: JAN1975 to DEC1991
Fit Range: JAN1975 to DEC1991
Evaluation Range: JAN1975 to DEC1991

Forecast Model	Model Title	Root Mean Square Error
	No models	

Controls and Fields

`Data Set`
: is the name of the current input data set.

`Interval`
: is the time interval (data frequency) for the input data set.

`Series`
: is the variable name and label of the current time series.

`Browse` button
: brings up the Series Selection window to enable you to change the current input data set or series.

`Data Range`
: is the date of the first and last nonmissing data values available for the current series in the input data set.

`Fit Range`
: is the current period of fit setting. This is the range of data that will be used to fit models to the series.

`Evaluation Range`
: is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series.

`Set Ranges` button
: brings up the Time Ranges Specification window to enable you to change the fit range or evaluation range. Note: A new fit range is applied when new models are fit or when existing models are refit. A new evaluation range is applied when new models are fit or when existing models are refit or reevaluated. Changing the ranges does not automatically refit or reevaluate any models in the table: Use the Refit Models or Reevaluate Models items under the Edit pull-down menu.

`View Series Graphically` icon
: brings up the Time Series Viewer window to display plots of the current series.

`View Selected Model Graphically` icon
: brings up the Model Viewer to display graphs and tables for the currently highlighted model.

`Forecast Model`
: is the column of the model table that contains check boxes to select which model is used to produce the final forecasts for the current series.

`Model Title`
: is the column of the model table that contains the descriptive labels of the forecasting models fit to the current series.

`Root Mean Square Error` (or other statistic name) button
: is the button above the right side of the table. It displays the name of the current model selection criterion: A statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button brings up the Model Selection Criterion window to let you to select a different statistic. When you select a statistic, the model table the Develop Models window is updated to show current values of that statistic.

Menu Bar

`File`

`New Project`
: brings up a dialog which lets you create a new project, assign it a name and description, and make it the active project.

`Open Project`
: brings up a dialog which lets you select and load a previously saved project.

`Save Project`
: saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

`Save Project as`
: saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

`Clear Project`
: clears the system, deleting all the models for all series.

`Save Forecast`
: writes forecasts from the currently highlighted model to an output data set.

`Save Forecast As`
: prompts for an output data set name and saves the forecasts from the currently highlighted model.

`Output Forecast Data Set`
: brings up a dialog for specifying the default data set used when you select "Save Forecast".

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Close`
: closes the Develop Models window and returns to the main window.

`Edit`

`Fit Model`

`Automatic Fit`
: invokes the automatic model selection process.

`Select From List`
: brings up the Models to Fit window.

`Smoothing Model`
: brings up the Smoothing Model Specification window.

`ARIMA Model`
: brings up the ARIMA Model Specification window.

`Custom Model`
: brings up the Custom Model Specification window.

`Combine Forecasts`
: brings up the Forecast Combination Model Specification window.

`External Forecasts`
: brings up the External Forecast Model Specification window.

`Edit Model`
: enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

`Delete Model`
: deletes the currently highlighted model from the model table.

`Refit Models`

`All Models`
: refits all models in the table using data within the current fit range.

`Selected Model`
: refits the currently highlighted model using data within the current fit range.

`Reevaluate Models`

`All Models`
: recomputes statistics of fit for all models in the table using data within the current evaluation range.

`Selected Model`
: recomputes statistics of fit for the currently highlighted model using data within the current evaluation range.

`View`

`Project`
: brings up the Manage Forecasting Project window.

`Data Set`
: brings up a Viewtable window to display the current input data set.

`Series`
: brings up the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

`Model Predictions`
: brings up the Model Viewer to display a predicted versus actual plot for the currently highlighted model. This is the same as the View Selected Model Graphically icon.

`Prediction Errors`
: brings up the Model Viewer to display the prediction errors for the currently highlighted model.

`Prediction Error Autocorrelations`
: brings up the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

`Prediction Error Tests`
: brings up the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

`Parameter Estimates`
: brings up the Model Viewer to display the parameter estimates table for the currently highlighted model.

`Statistics of Fit`
: brings up the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

`Forecast Graph`
: brings up the Model Viewer to graph the forecasts for the currently highlighted model.

`Forecast Table`
: brings up the Model Viewer to display forecasts for the currently highlighted model in a table.

`Tools`

`Diagnose Series`
: brings up the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

`Define Interventions`
: brings up the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

`Sort Models`
: sorts the models in the table by the values of the currently displayed fit statistic.

`Compare Models`
: brings up the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This is grayed out if there are fewer than two models in the table.

`Generate Data`
: brings up the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

`Options`

`Time Ranges`
: brings up the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon. This action is the same as the Set Ranges button.

`Default Time Ranges`
: brings up the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made using this window do not affect series you are already working with, they take effect when you select a new series.

`Model Selection List`
: brings up the Model Selection List editor window. Use this action to edit

the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

`Model Selection Criterion`
brings up the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This action is the same as clicking the button above the table which displays the name of the current model selection criterion.

`Statistics of Fit`
brings up the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

`Forecast Options`
brings up the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

`Alignment of Dates`

`Beginning`
aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

`Middle`
aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

`End`
aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

`Automatic Fit`
brings up the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

`Include Interventions`
controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Models to Fit window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows. A check mark or filled check box next to this item indicates that the option is turned on.

`Print Audit Trail`
prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

`Show Source Statements`
: Controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions for the Model Table

When the cursor is over the description of a model in the table, the left mouse button selects (highlights) or deselects that model. On some computer systems, you can double-click to bring up the Model Viewer window for the selected model.

When the cursor is over an empty part of the model table, the left mouse button brings up a menu of model fitting choices. These choices are the same as those in the Fit Model submenu of the of the Edit pull-down menu.

Right Mouse Button Actions for the Model Table

When a model in the table is selected, the right mouse brings up a menu of actions that apply to the highlighted model. The actions available in this menu are as follows.

`View Model`
: brings up the Model Viewer for the selected model. This action is the same as the View Model Graphically icon.

`View Parameter Estimates`
: brings up the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as the Parameter Estimates item in the View pull-down menu.

`View Statistics of Fit`
: brings up the Model Viewer to display a table of goodness-of-fit statistics for the currently highlighted model. This is the same as the Statistics of Fit item in the View pull-down menu.

`Edit Model`
: enables you to modify the specification of the currently highlighted model in the table and fit the modified model. This is the same as the Edit Model item in the Edit pull-down menu.

`Refit Model`
: refits the highlighted model using data within the current fit range. This is the same as the Selected Model item under the Refit Models submenu of the Edit pull-down.

`Reevaluate Model`
: reevaluates the highlighted model using data within the evaluation fit range. This is the same as the Selected Model item under the Reevaluate Models submenu of the Edit pull-down.

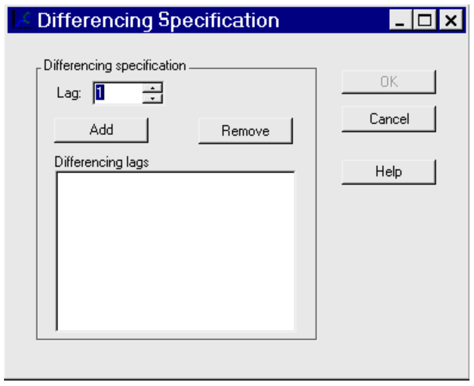
`Delete Model`
: deletes the currently highlighted model from the model table. This is the same as the Delete Model item under the Edit pull-down menu.

`View Forecasts`
: brings up the Model Viewer to display the forecasts for the currently highlighted model. This is the same as the Forecast Graph item under the View pull-down menu.

When the model list is empty or when no model is selected, the right mouse button brings up the same menu of model fitting actions as the left mouse button.

Differencing Specification Window

Use the Differencing Specification window to specify the list of differencing lags `d=(lag, ..., lag)` in a factored ARIMA model. To specify a first difference, add the value 1 (`d=(1)`. To specify a second difference (difference twice at lag 1), add the value 1 again `d=(1,1)`. For first differencing at lags 1 and 12, use the values 1 and 12 (`d=(1,12)`.



Controls and Fields

`Lag`
: specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows. Duplicates are allowed.

`Add`
: Adds the value in the `Lag` spin box to the list of differencing lags.

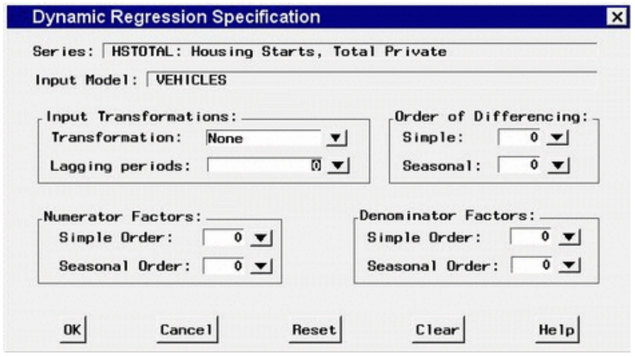
`Remove`
: Deletes a selected lag from the list of differencing lags.

`OK`
: Closes the window and returns the specified list to the Factored ARIMA Model Specification window.

`Cancel`
: Closes the window and discards any lags added to the list.

Dynamic Regression Specification Window

Use the Dynamic Regression Specification window to specify a dynamic regression or transfer function model for the effect of the predictor variable. It is invoked from the Dynamic Regressors Selection window.



Series: HSTOTAL: Housing Starts, Total Private
Input Model: VEHICLES
Input Transformations:
Transformation: None
Lagging periods: 0
Order of Differencing:
Simple: 0
Seasonal: 0
Numerator Factors:
Simple Order: 0
Seasonal Order: 0
Denominator Factors:
Simple Order: 0
Seasonal Order: 0

Controls and Fields

`Series`
: is the name and variable label of the current series.

`Input Model`
: is a descriptive label for the dynamic regression model. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify. When no options are specified, the label is the name and variable label of the predictor variable.

`Input Transformation`
: displays the transformation specified for the predictor variable. When a transformation is specified, the transfer function model is fit to the transformed input variable.

`Lagging periods`
: is the pure delay in the effect of the predictor, *l*.

`Simple Order of Differencing`
: is the order of differencing, *d*. Set this field to 1 to use the changes in the predictor variable.

`Seasonal Order of Differencing`
: is the order of seasonal differencing, *D*. Set this field to 1 to difference the predictor variable at the seasonal lags, for example, to use the year-over-year or week-over-week changes in the predictor variable.

`Simple Order Numerator Factors`
: is the order of the numerator factor of the transfer function, *p*.

`Seasonal Order Numerator Factors`
: is the order of the seasonal numerator factor of the transfer function, *P*.

`Simple Order Denominator Factors`
: is the order of the denominator factor of the transfer function, *q*.

`Seasonal Order Denominator Factors`
: is the order of the seasonal denominator factor of the transfer function, *Q*.

`OK`
: closes the window and adds the dynamic regression model specified to the model predictors list.

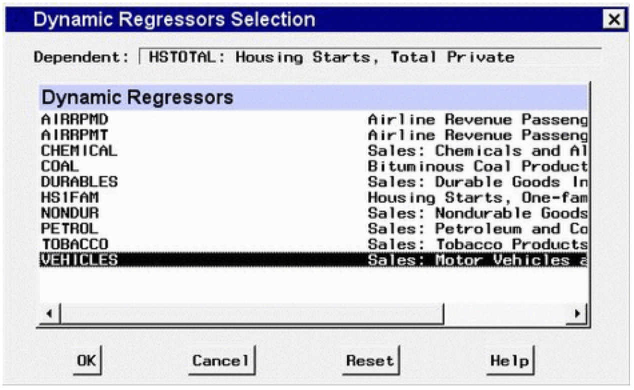
`Cancel`
: closes the window without adding the dynamic regression model. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the window. This may be useful when editing a predictor specification; otherwise, Reset has the same function as Clear.

`Clear`
: resets all options to their default values.

Dynamic Regressors Selection Window

Use the Dynamic Regressors Selection window to select an input variable as a dynamic regressor. Access this window from the pop-up menu which appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.



Dynamic Regressors Selection

Dependent: HSTOTAL: Housing Starts, Total Private

```
Dynamic Regressors
AIRRPMD                                Airline Revenue Passeng
AIRRPMT                                Airline Revenue Passeng
CHEMICAL                               Sales: Chemicals and Al
COAL                                   Bituminous Coal Product
DURABLES                               Sales: Durable Goods In
HS1FAM                                 Housing Starts, One-fam
NONDUR                                 Sales: Nondurable Goods
PETROL                                 Sales: Petroleum and Co
TOBACCO                                Sales: Tobacco Products
VEHICLES                               Sales: Motor Vehicles a
```

Controls and Fields

`Dependent`
: is the name and variable label of the current series.

`Dynamic Regressors`
: is a table listing the variables in the input data set. Select one variable in this list as the predictor series.

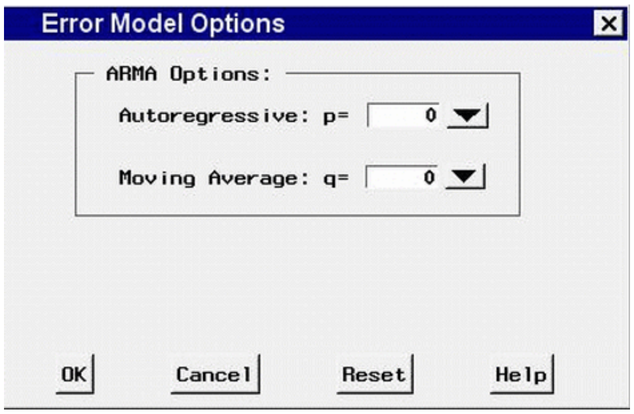
`OK`
: brings up the Dynamic Regression Specification window for you to specify the form of the dynamic regression for the selected predictor series, and then closes the Dynamic Regressors Selection window and adds the specified dynamic regression to the model predictors list.

`Cancel`
: closes the window without adding the dynamic regression model. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the window.

Error Model Options Window

Use the Error Model Options window to specify the the autoregressive and moving average orders for the residual autocorrelation part of a model defined using the Custom Model Specification window. Access it using the Set button of that window.



Controls and Fields

`ARIMA Options`
: Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a popup list.

  `Autoregressive`
  : defines the order of the autoregressive part of the model.

  `Moving Average`
  : defines the order of the moving average term.

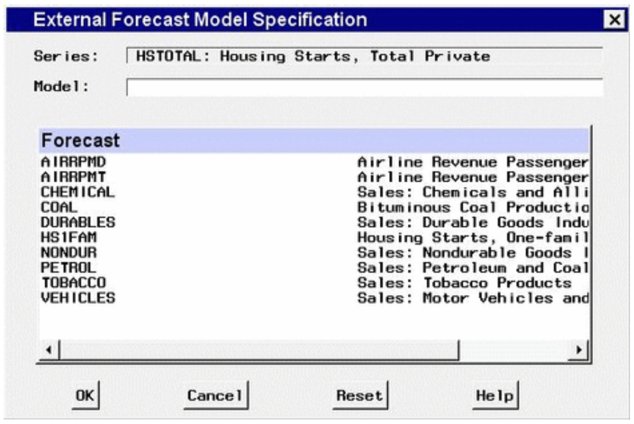
`OK`
: closes the Error Model Options window and returns to the Custom Model Specification window.

`Cancel`
: closes the Error Model Options window and returns to the Custom Model Specification window, discarding any changes made.

`Reset`
: resets all options to their initial values upon entry to the window.

External Forecast Model Specification Window

Use the External Forecast Model Specification window to add to the current project forecasts produced externally to the Time Series Forecasting System. To add an external forecast, select a variable from the selection list and choose the OK button. The name of the selected variable will be added to the list of models fit, and the values of this variable will be used as the forecast. For more information, see "Incorporating Forecasts from Other Sources" in the "Specifying Forecasting Models" chapter.



Series: HSTOTAL: Housing Starts, Total Private

Model:

Forecast	
AIRRPMD	Airline Revenue Passenger
AIRRPMT	Airline Revenue Passenger
CHEMICAL	Sales: Chemicals and Alli
COAL	Bituminous Coal Productio
DURABLES	Sales: Durable Goods Indu
HS1FAM	Housing Starts, One-famil
NONDUR	Sales: Nondurable Goods I
PETROL	Sales: Petroleum and Coal
TOBACCO	Sales: Tobacco Products
VEHICLES	Sales: Motor Vehicles and

Controls and Fields

`OK`
: Closes the window and adds the external forecast to the project.

`Cancel`
: Closes the window without adding an external forecast to the project.

`Reset`
: Deselects any selection made in the selection list.

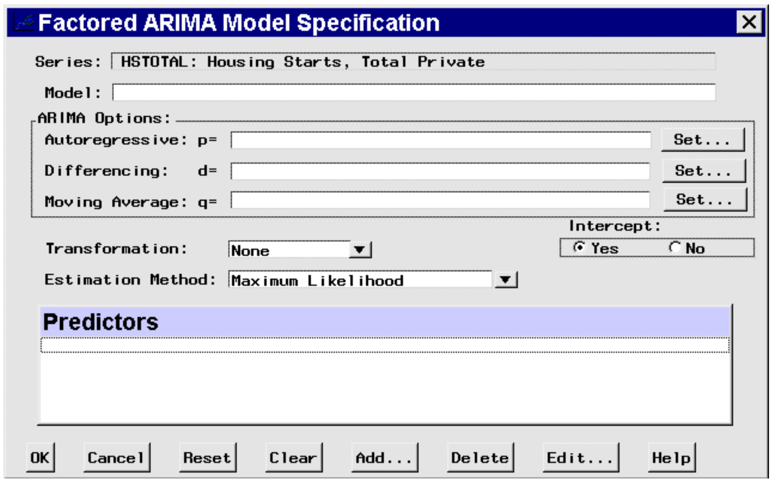
Factored ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify an ARIMA model using the notation:

```
p = (lag, ..., lag) ...  (lag, ..., lag)
d = (lag, ..., lag)
q = (lag, ..., lag) ...  (lag, ..., lag)
```

where p, d, and q represent autoregressive, differencing, and moving average terms, respectively.

Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit in the menu bar, or from the pop-up menu when you click an empty area of the model table.



Factored ARIMA Model Specification

Series: HSTOTAL: Housing Starts, Total Private

Model:

ARIMA Options:

Autoregressive: p=

Differencing: d=

Moving Average: q=

Intercept: [✓ Yes] No

Transformation: None

Estimation Method: Maximum Likelihood

Predictors

The Factored ARIMA Model Specification window is identical to the ARIMA Model Specification window, except that the p, d, and q terms are specified in a more general and less limited way. Only those controls and fields which differ from the ARIMA Model Specification window are described here.

Controls and Fields

`Model`

is a descriptive label for the model. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the p, d, and q terms that you specify. For example, if you specify `p=(1,2,3), d=(1), q=(12)` and no intercept, the model label is `ARIMA p=(1,2,3) d=(1) q=(12) NOINT`. For monthly data, this is equivalent to the model `ARIMA(3,1,0)(0,0,1)s NOINT` as specified in the ARIMA Model Specification window or the Custom Model Specification window.

`ARIMA Options`

Specifies the ARIMA model in terms of the autoregressive lags (p), differencing lags (d), and moving average lags (q).

`Autoregressive`

defines the autoregressive part of the model. Select the Set button to bring up the AR Polynomial Specification window, where you can add any set of autoregressive lags grouped into any number of factors.

`Differencing`

specifies differencing to be applied to the input data. Select the Set button to bring up the Differencing Specification window, where you can specify any set of differncing lags.

`Moving Average`

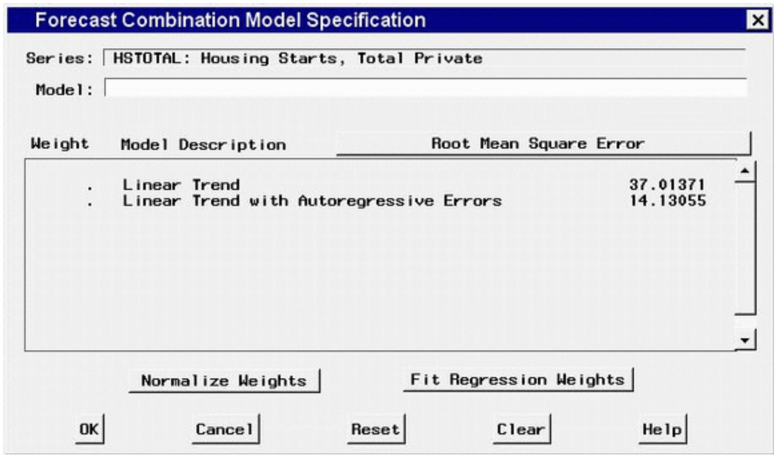
defines the moving average part of the model. Select the Set button to bring up the MA Polynomial Specification window, where you can add any set of moving average lags grouped into any number of factors.

`Estimation Method`

specifies the method used to estimate the model parameters. The Conditional Least Squares and Unconditional Least Squares methods generally require fewer computing resources and are more likely to succeed in fitting complex models. The Maximum Likelihood method requires more resources but provides a better fit in some cases. See also Estimation Details in Chapter 11, “The ARIMA Procedure.”

Forecast Combination Model Specification Window

Use the Forecast Combination Model Specification window to produce forecasts by averaging the forecasts of two or more forecasting models. The specified combination of models is added to the model list for the series. Access this window from the Develop Models window whenever two or more models have been fit to the current series. It is invoked by selecting Combine Forecasts from the Fit Model submenu of the Edit pull-down, or from the pop-up menu which appears when you click an empty part of the model table.



```
Series: HSTOTAL: Housing Starts, Total Private
Model:

Weight   Model Description                            Root Mean Square Error
  .      Linear Trend                                          37.01371
  .      Linear Trend with Autoregressive Errors               14.13055
```

Controls and Fields

`Series`

is the name and variable label of the current series.

`Model`

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

`Weight`

is a column of the forecasting model table that contains the weight values for each model. The forecasts for the combined model are computed as a weighted average of the predictions from the models in the table using these weights. Models with missing weight values are not included in the forecast combination. You can type weight values in these fields or you can use other features of the window to set the weights.

`Model Description`

is a column of the forecasting model table that contains the descriptive labels of the forecasting models fit to the current series that are available for combination.

`Root Mean Square Error` (or other statistic name) button
: is the button above the right side of the table. It displays the name of the current model selection criterion: A statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button brings up the Model Selection Criterion window to enable you to select a different statistic.

`Normalize Weights` button
: replaces each nonmissing value in the Weights column with the current value divided by the sum of the weights. The resulting weights are proportional to original weights and sum to 1.

`Fit Regression Weights` button
: computes weight values for the models in the table by regressing the series on the predictions from the models. The values in the Weights column are replaced by the estimated coefficients produced by this linear regression. If some weight values are nonmissing and some are missing, only models with nonmissing weight values are included in the regression. If all weights are missing, all models are used.

`OK`
: closes the Forecast Combination Model Specification window and fits the model.

`Cancel`
: closes the Forecast Combination Model Specification window without fitting the model. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the Forecast Combination Model Specification window. This may be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

`Clear`
: resets all options to their default values.

Mouse Button Actions

You can select or deselect models for inclusion in the combination model by positioning the mouse cursor over the model description and pressing the left mouse button. When you select a model in this way, the weights are automatically updated.

The newly selected model is given a weight equal to the average weight of the previously selected models, and all the nonmissing weights are normalized to sum to 1. When you use the mouse to remove a model from the combination, the weight of the deselected model is set to missing and the remaining nonmissing weights are normalized to sum to 1.

Forecasting Project File Selection Window

Use the Forecasting Project File Selection window to locate and load a previously stored forecasting project. Access it from the project Browse button of the Manage Forecasting Project window or the Time Series Forecasting window or from the Open Project item under the File pull-down of the Develop Models window.

Selection Lists

`Libraries`
: is a list of currently assigned libraries. When you select a library from this list, the catalogs in that library are shown in the catalog selection list.

`Catalogs`
: is a list of catalogs contained in the currently selected library. When you select a catalog from this list, any forecasting project entries stored in that catalog are shown in the projects selection list.

`Projects`
: is a list of forecasting project entries contained in the currently selected catalog.

Controls and Fields

`OK`
: closes the window and opens the selected project.

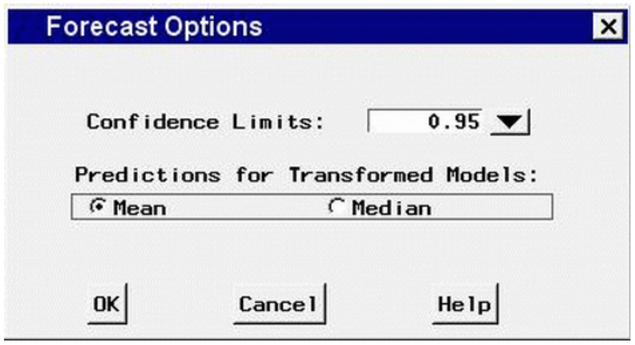
`Cancel`
: closes the window without selecting a project.

`Delete`
: deletes the selected project file.

`Reset`
: restores selections to those which were set before the window was opened.

Forecast Options Window

Use the Forecast Options window to set options to control how forecasts and confidence limits are computed. It is available from the Forecast Options item in the Options pull-down menu of the Develop Models window, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.



Controls and Fields

`Confidence Limits`
: specifies the size of the confidence limits for the forecast values. For example, a value of .95 specifies 95% confidence intervals. You can type in a number or select from the popup list.

`Predictions for transformed models`
: These two options control how forecast values are computed for models that employ a series transformation. See the section "Predictions for Transformed Models" in Chapter 41, “Forecasting Process Details,” , for more information. The values are as follows.

  `Mean`
  : specifies that forecast values be predictions of the conditional mean of the series.

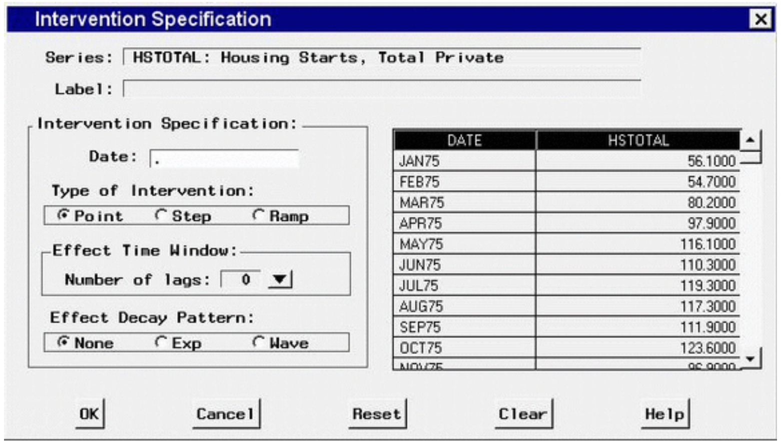
  `Median`
  : specifies that forecast values be predictions of the conditional median of the series.

`OK`
: closes the window and saves the option settings you specified.

`Cancel`
: closes the window without changing the forecast options. Any options you specified are lost.

Intervention Specification Window

Use the Intervention Specification window to specify intervention effects to model the impact on the series of unusual events. Access it from the Intervention for Series window. For more information, see “Interventions” in the “Using Predictor Variables” section.



Series: HSTOTAL: Housing Starts, Total Private

Label:

Intervention Specification:

Date: .

Type of Intervention: [✓ Point] Step Ramp

Effect Time Window:

Number of lags: 0

Effect Decay Pattern: [✓ None] Exp Wave

DATE	HSTOTAL
JAN75	56.1000
FEB75	54.7000
MAR75	80.2000
APR75	97.9000
MAY75	116.1000
JUN75	110.3000
JUL75	119.3000
AUG75	117.3000
SEP75	111.9000
OCT75	123.6000

Controls and Fields

`Series`
: is the name and variable label of the current series.

`Label`
: is a descriptive label for the intervention effect that you specify. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify.

`Date`
: is the date that the intervention occurs. You can type a date value in this field, or you can set the date by selecting a row of the data table on the right side of the window.

`Type of Intervention`

- `Point`
  specifies that the intervention variable is zero except for the specified date.
- `Step`
  specifies that the intervention variable is zero before the specified date and a constant 1.0 after the date.
- `Ramp`
  specifies that the intervention variable is an increasing linear function of time after the date of the intervention and zero before the intervention date.

`Number of lags`
: specifies the numerator order for the transfer function model for the intervention effect. Select a value from the popup list.

`Effect Decay Pattern`
: specifies the denominator order for the transfer function model for the intervention effect. The value "Exp" specifies a single lag denominator factor; the value "Wave" specifies a two lag denominator factor.

`OK`
: closes the window and adds the intervention effect specified to the series interventions list.

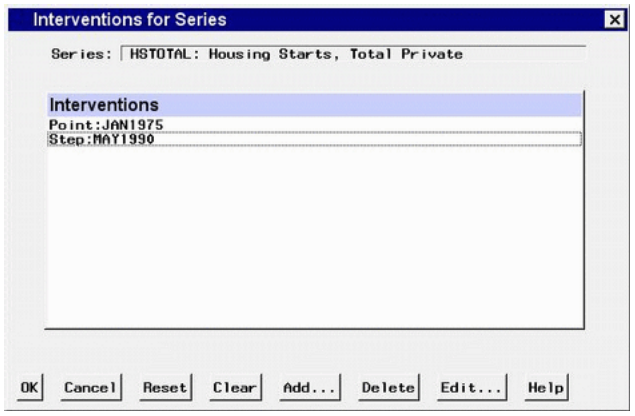
`Cancel`
: closes the window without adding the intervention. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the window. This may be useful when editing an intervention specification; otherwise, Reset has the same function as Clear.

`Clear`
: resets all options to their default values.

Interventions for Series Window

Use the Interventions for Series window to create and edit a list of intervention effects to model the impact on the series of unusual events and to select intervention effects as predictors for forecasting models. Access it from the Add button pop-up menu of the ARIMA Model Specification or Custom Model Specification window, or by selecting Define Interventions from the Tools pull-down in the Develop Models window. For more information, see “Interventions” in Chapter 38, “Using Predictor Variables.”



Interventions for Series

Series: HSTOTAL: Housing Starts, Total Private

Interventions
Point:JAN1975
Step:MAY1990

Controls and Fields

`Series`
: is the name and variable label of the current series.

`OK`
: closes the window. If you access this window from the ARIMA Model Specification window or the Custom Model Specification window, any interventions which are selected (highlighted) in the list are added to the model. If you access this window from the Tools pull-down menu, all interventions in the list are saved for the current series.

`Cancel`
: closes the window without returning a selection or changing the interventions list. Any options you specified are lost.

`Reset`
: resets the list as it was on entry to the window.

`Clear`
: deletes all interventions from the list.

`Add`
: brings up the Intervention Specification window to specify a new intervention effect and add it to the list.

`Delete`
: deletes the currently selected (highlighted) entries from the list.

`Edit`
: brings up the Intervention Specification window to edit the currently selected (highlighted) intervention.

Mouse Button Actions

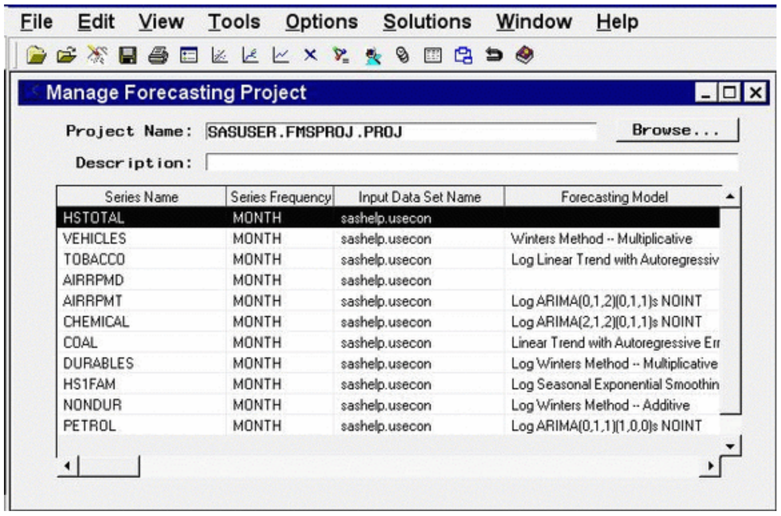
To select or deselect interventions, position the mouse cursor over the intervention's label in the Interventions list and press the left mouse button.

When you position the mouse cursor in the Interventions list and press the right mouse button, a menu containing the actions Add, Delete, and Edit appears. These actions are the same as the Add, Delete, and Edit buttons.

Double-clicking on an intervention in the list invokes an Edit action for that intervention specification.

Manage Forecasting Project Window

Use this resizable window to work with collections of series, models, and options called *projects*. It consists of project name and description fields and a table of information about all the series for which you have fit forecasting models. Access it using the Manage Projects button on the Time Series Forecasting window.



Project Name: SASUSER.FMSPROJ.PROJ
Description:

Series Name	Series Frequency	Input Data Set Name	Forecasting Model
HSTOTAL	MONTH	sashelp.usecon	
VEHICLES	MONTH	sashelp.usecon	Winters Method -- Multiplicative
TOBACCO	MONTH	sashelp.usecon	Log Linear Trend with Autoregressiv
AIRRPMD	MONTH	sashelp.usecon	
AIRRPMT	MONTH	sashelp.usecon	Log ARIMA(0,1,2)(0,1,1)s NOINT
CHEMICAL	MONTH	sashelp.usecon	Log ARIMA(2,1,2)(0,1,1)s NOINT
COAL	MONTH	sashelp.usecon	Linear Trend with Autoregressive Err
DURABLES	MONTH	sashelp.usecon	Log Winters Method -- Multiplicative
HS1FAM	MONTH	sashelp.usecon	Log Seasonal Exponential Smoothin
NONDUR	MONTH	sashelp.usecon	Log Winters Method -- Additive
PETROL	MONTH	sashelp.usecon	Log ARIMA(0,1,1)(1,0,0)s NOINT

Controls and Fields

`Project Name`
: is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by selecting the Browse button to the right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one level name, it is assumed to be the name of a project in the "fmsproj" catalog in the "sasuser" library. For example, typing `samproj` is equivalent to typing `sasuser.fmsproj.samproj`.

project `Browse` button
: brings up the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored project files.

`Description`
: is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field if you save the project.

Series List Table

The table of series for which forecasting models have been fit contains the following columns.

`Series Name`
: is the name of the time series variable represented in the given row of the table.

`Series Frequency`
: is the time interval (data frequency) for the time series.

`Input Data Set Name`
: is the input data set that provided the data for the series.

`Forecasting Model`
: is the descriptive label for the forecasting model selected for the series.

`Statistic Name`
: is the statistic of fit for the forecasting model selected for the series.

`Number of Models`
: is the total number of forecasting models fit to the series. If there is more than one model for a series, use the Model List window to see a list of models.

`Series Label`
: is the variable label for the series.

`Time ID Variable Name`
: is the time ID variable for the input data set for the series.

`Series Data Range`
: is the time range of the nonmissing values of the series.

`Model Fit Range`
: is the period of fit used for the series.

`Model Evaluation Range`
is the evaluation period used for the series.

`Forecast Range`
is the forecast period set for the series.

Menu Bar

`File`

`New`
brings up a dialog which lets you create a new project, assign it a name and description, and make it the active project.

`Open`
brings up a dialog which lets you select and load a previously saved project.

`Close`
closes the Manage Forecasting Project window and returns to the main window.

`Save`
saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

`Save As`
saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

`Save to Data Set`
saves the current project file information in a SAS data set. The contents of the data set are the same as the information displayed in the series list table.

`Delete`
deletes the current project file.

`Import Data`
is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print`
prints the current project file information.

`Print Setup`
brings up the Print Setup window, which allows you to access your operating system print setup.

`Edit`

`Delete Series`
deletes all models for the selected (highlighted) row of the table and removes the series from the project.

`Clear`
: resets the system, deleting all series and models from the project.

`Reset`
: restores the Manage Forecasting Project window to its initial state.

`View`

`Data Set`
: brings up a Viewtable window to display the input data set for the selected (highlighted) series.

`Series`
: brings up the Time Series Viewer window to display plots of the selected (highlighted) series.

`Model`
: brings up the Model Viewer window to show the current forecasting model for the selected series.

`Forecast`
: brings up the Model Viewer to display plots of the forecasts produced by the forecasting model for the selected (highlighted) series.

`Tools`

`Diagnose Series`
: brings up the Series Diagnostics window to perform the automatic series diagnostic process to determine the kinds of forecasting models appropriate for the selected (highlighted) series.

`List Models`
: brings up the Model List window for the selected (highlighted) series, which displays a list of all the models that you fit for the series. This action is the same as double-clicking the mouse on the table row.

`Generate Data`
: brings up the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

`Refit Models`

`All Series`
: refits all the models for all the series in the project using data within the current fit range.

`Selected Series`
: refits all the models for the currently highlighted series using data within the current fit range.

`Reevaluate Models`

`All Series`
: reevaluates all the models for all the series in the project using data within the current evaluation fit range.

`Selected Series`
: reevaluates all the models for the currently highlighted series using data within the current evaluation range.

`Options`

`Time Ranges`
: brings up the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon.

`Default Time Ranges`
: brings up the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made using this window do not affect series you are already working with–they take effect when you select a new series.

`Model Selection List`
: brings up the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

`Statistics of Fit`
: brings up the Statistics of Fit Selection window, which controls which of the available statistics will be displayed.

`Forecast Options`
: brings up the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

`Column Labels`
: enables you to set long or short column labels. Long labels are used by default.

`Include Interventions`
: controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Model Selection List editor window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows.

`Print Audit Trail`
: prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

`Show Source Statements`
: controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions

If you select a series in the table by positioning the cursor over the table row and clicking with the left mouse button once, that row of the table is highlighted. Menu bar actions such as Delete Series will apply to the highlighted row of the table.

If you select a series in the table by positioning the cursor over the table row and double-clicking with the left mouse button, the system brings up the Model List window for that series, which displays a list of all the models that you fit for the series. This is the same as the List Models action under Tools in the menu bar.

Right Mouse Button Actions

Clicking the right mouse button invokes a pop-up menu of actions applicable to the highlighted series. The actions in this menu are as follows.

`Delete Series`
: deletes the highlighted series and its models from the project. This is the same as Delete Series in the Edit pull-down menu.

`Refit All Models`
: refits all models attached to the highlighted series using data within the current fit range. This is the same as the Selected Series item under Refit Models in the Tools pull-down menu.

`Reevaluate All Models`
: reevaluates all models attached to the highlighted series using data within the current evaluation range. This is the same as the Selected Series item under Reevaluate Models in the Tools pull-down menu.

`List Models`
: invokes the Model List window. This is the same as List Models under the Tools pull-down menu.

`View Series`
: brings up the Time Series Viewer window to display plots of the highlighted series. This is the same as “Series” in the View pull-down menu.

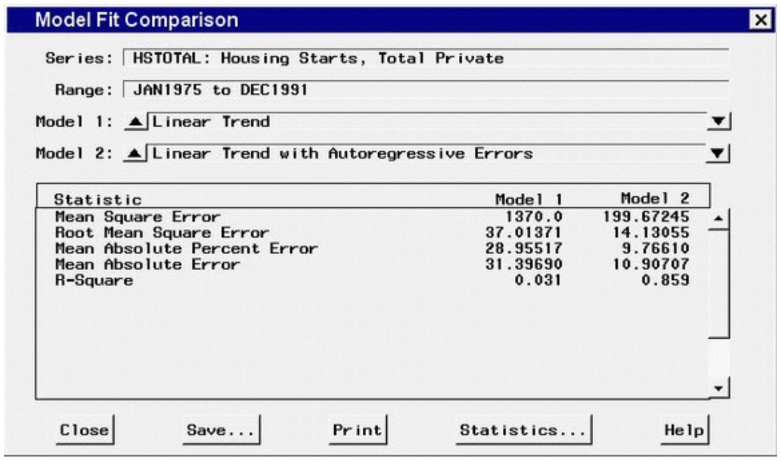
`View Forecasting Model`
: invokes the Model Viewer window to display the forecasting model for the highlighted series. This is the same as “Model” in the View pull-down menu.

`View Forecast`
: brings up the Model Viewer window to display the forecasts for the highlighted series. This is the same as “Forecast” in the View pull-down menu.

`Refresh`
: updates information shown in the Manage Forecasting Project window.

Model Fit Comparison Window

Use the Model Fit Comparison window to compare goodness-of-fit statistics for any two models fit to the current series. Access it from the Tools pull-down menu of the Develop Models window and the Automatic Model Fitting Results window whenever two or more models have been fit to the series.



Series: HSTOTAL: Housing Starts, Total Private

Range: JAN1975 to DEC1991

Model 1: Linear Trend

Model 2: Linear Trend with Autoregressive Errors

```
Statistic                                Model 1      Model 2
Mean Square Error                         1370.0    199.67245
Root Mean Square Error                  37.01371     14.13055
Mean Absolute Percent Error             28.95517      9.76610
Mean Absolute Error                     31.39690     10.90707
R-Square                                   0.031        0.859
```

Controls and Fields

`Series`
: identifies the current time series variable.

`Range`
: displays the starting and ending dates of the series data range.

`Model 1`
: shows the model currently identified as Model 1.

`Model 1 upward arrow button`
: enables you to change the model identified as Model 1 if it is not already the first model in the list of models associated with the series. Select this button to cycle upward through the list of models.

`Model 1 downward arrow button`
: enables you to change the model identified as Model 1 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

`Model 2`
: shows the model currently identified as Model 2.

`Model 2 upward arrow button`
: enables you to change the model identified as Model 2 if it is not already the first model in the list of models associated with the series. Select this button to cycle upward through the list of models.

`Model 2 downward arrow button`
: enables you to change the model identified as Model 2 if it is not already the last model in the list of models. Select this button to cycle downward through the list of models.

`Close`
: closes the Model Fit Comparison window.

`Save`
: brings up a dialog for specifying the name and label of a SAS data set to which the statistics will be saved. The data set will contain all available statistics and their values for Model 1 and Model 2, as well as a flag variable that is set to 1 for those statistics that were displayed.

`Print`

prints the contents of the table to the SAS Output window. If you find that the contents do not appear immediately in the Output window, you will need to set scrolling options. Select “Preferences” under the Options submenu of the Tools pull-down. In the Preferences window, select the Advanced tab, then set output scroll lines to a number greater than zero.

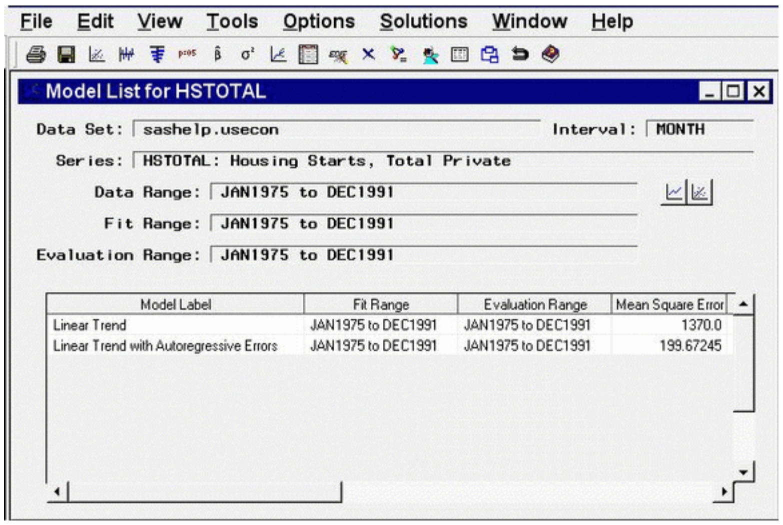
If you want to route the contents to a printer, go to the Output window and select “Print” from the File pull-down menu.

`Statistics`

brings up the Statistics of Fit Selection window for controlling which statistics are displayed.

Model List Window

This resizable window shows all of the models that have been fit to a particular series in a project. Access it from the Manage Forecasting Project window by selecting a series in the series list table and choosing “List Models” from the Tools pull-down menu or by double-clicking the series.



Data Set: sashelp.usecon Interval: MONTH

Series: HSTOTAL: Housing Starts, Total Private

Data Range: JAN1975 to DEC1991

Fit Range: JAN1975 to DEC1991

Evaluation Range: JAN1975 to DEC1991

Model Label	Fit Range	Evaluation Range	Mean Square Error
Linear Trend	JAN1975 to DEC1991	JAN1975 to DEC1991	1370.0
Linear Trend with Autoregressive Errors	JAN1975 to DEC1991	JAN1975 to DEC1991	199.67245

Controls and Fields

`Data Set`

is the name of the current input data set.

`Interval`

is the time interval (data frequency) for the input data set.

`Series`

is the variable name and label of the current time series.

`Data Range`

is the date of the first and last nonmissing data values available for the current series in the input data set.

`Fit Range`

is the current period of fit setting. This is the range of data that will be used to fit models to the series. It may be different from the fit ranges shown in the table, which were in effect when the models were fit.

`Evaluation Range`
: is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series. It may be different from the evaluation ranges shown in the table, which were in effect when the models were fit.

`View Series Graphically` icon
: brings up the Time Series Viewer window to display plots of the current series.

`View Model Graphically` icon
: brings up the Model Viewer to display graphs and tables for the currently highlighted model.

Model List Table

The table of models fit to the series contains columns showing the model label, the fit range and evaluation range used to fit the models, and all of the currently selected fit statistics. You can change the selection of fit statistics using the Statistics of Fit Selection window.

Click on column headings to sort the table by a particular column. If a model is highlighted, clicking with the right mouse button invokes a pop-up menu providing actions applicable to the highlighted model. It includes the following items.

`View Model`
: brings up the Model Viewer on the selected model. This is the same as "Model Predictions" under the View pull-down menu.

`View Parameter Estimates`
: brings up the Model Viewer to display the parameter estimates table for the currently highlighted model. This is the same as "Parameter Estimates" under the View pull-down menu.

`View Statistics of Fit`
: brings up the Model Viewer to display the statistics of fit table for the currently highlighted model. This is the same as "Statistics of FIt" under the View pull-down menu.

`Edit Model`
: brings up the appropriate model specification window for changing the attributes of the highlighted model and fitting the modified model.

`Refit Model`
: refits the highlighted model using the current fit range.

`Reevaluate Model`
: reevaluates the highlighted model using the current evaluation range.

`Delete Model`
: deletes the highlighted model from the project.

`View Forecasts`
: brings up the Model Viewer to show the forecasts for the highlighted model. This is the same as "Forecast Graph" under the View pull-down menu.

Menu Bar

`File`

`Save`
: brings up a dialog which lets you save the contents of the table to a specified SAS data set.

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print`
: sends the contents of the table to a printer as defined through Print Setup.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Close`
: closes the window and returns to the Manage Forecasting Projects window.

`Edit`

`Edit Model`
: enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

`Refit Model`
: refits the currently highlighted model using data within the current fit range.

`Reevaluate Model`
: recomputes statistics of fit for the currently highlighted model using data within the current evaluation range.

`Delete Model`
: deletes the currently highlighted model from the model table.

`Reset`
: restores the contents of the Model List window to the state initially displayed.

`View`

`Series`
: brings up the Time Series Viewer window to display plots of the current series. This is the same as the View Series Graphically icon.

`Model Predictions`
: brings up the Model Viewer to display a predicted and actual plot for the currently highlighted model. This is the same as the View Model Graphically icon.

`Prediction Errors`
: brings up the Model Viewer to display the prediction errors for the currently highlighted model.

`Prediction Error Autocorrelations`
: brings up the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

`Prediction Error Tests`
: brings up the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

`Parameter Estimates`
: brings up the Model Viewer to display the parameter estimates table for the currently highlighted model.

`Statistics of Fit`
: brings up the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

`Forecast Graph`
: brings up the Model Viewer to graph the forecasts for the currently highlighted model.

`Forecast Table`
: brings up the Model Viewer to display forecasts for the currently highlighted model in a table.

`Options`

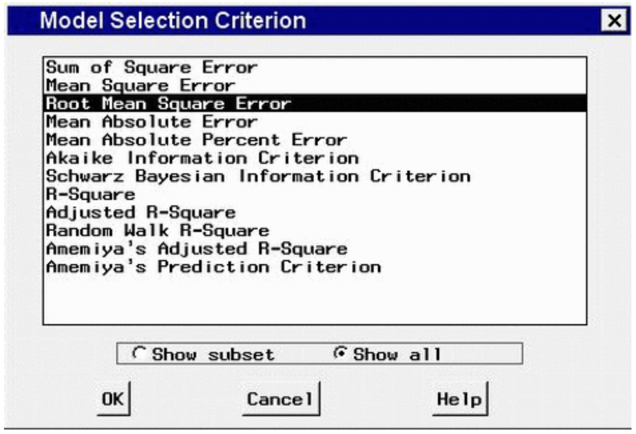
`Statistics of Fit`
: brings up the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

`Column Labels`
: enables you to set long or short column labels. Long labels are used by default.

Model Selection Criterion Window

Use the Model Selection Criterion window to select the model selection criterion statistic used by the automatic selection process to determine the best fitting forecasting model. Model selection criterion statistics are a subset of those shown in the Statistics of Fit Selection window, since some statistics of fit, such as number of observations, are not useful for model selection.

This window is available from the Model Selection Criterion item of the Options pull-down menu of the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.



Model Selection Criterion
Sum of Square Error
Mean Square Error
Root Mean Square Error
Mean Absolute Error
Mean Absolute Percent Error
Akaike Information Criterion
Schwarz Bayesian Information Criterion
R-Square
Adjusted R-Square
Random Walk R-Square
Amemiya's Adjusted R-Square
Amemiya's Prediction Criterion
Show subset
Show all
OK
Cancel
Help

Show subset [✓ Show all]

Controls and Fields

`Show subset`
: when selected, lists only those model selection criterion statistics which are selected in the Statistics of Fit Selection window.

`Show all`
: when selected, lists all available model selection criterion statistics.

`OK`
: closes the window and sets the model selection criterion to the statistic you specified.

`Cancel`
: closes the window without changing the model selection criterion.

Model Selection List Editor Window

Use the Model Selection List Editor window to edit the model selection list, including adding your own custom models, and to specify which models in the list are to be used in the automatic fitting process. Access it from the Options pull-down menu in the Develop Models, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

The window initially displays the current model list for your project. You can modify this set of models in several ways:

- Open one or more alternate model lists to replace or append to the current model list. These can be either model lists included with the software or model lists previously saved by you or other users.
- Turn the autofit option on or off for individual models. Those which are not flagged for autofit will be available using the Models to Fit window but not using automatic model fitting.
- Delete models from the list which are not needed for your project.
- Reorder the models in the list.

- Edit models in the list.
- Create a new empty list.
- Add new models to the list.

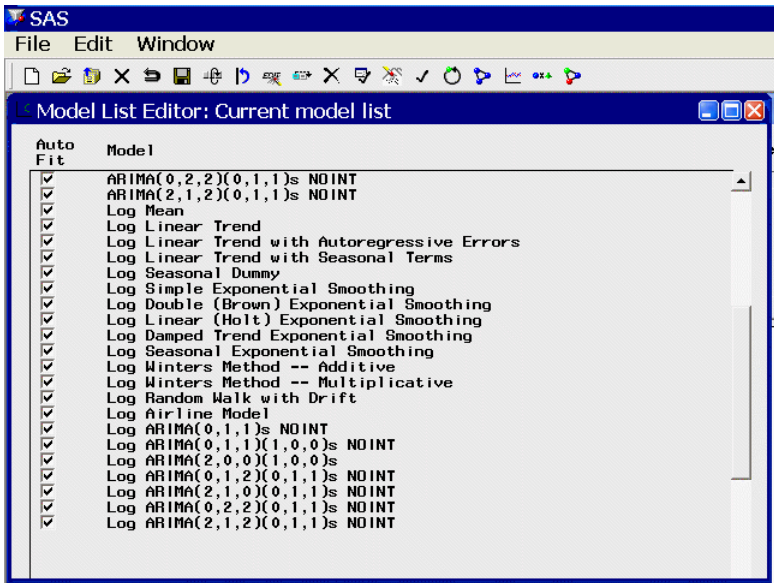
Having modified the current model list, you can save it for future use in several ways:

- Save it in a catalog so it can be opened later in the Model Selection List Editor.
- Save it as the user default to be used automatically when new projects are created.
- Select *close* to close the Model Selection List Editor and attach the modified model selection list to the current project.
- Select *cancel* to close the Model Selection List Editor without changing the current project's model selection list.

Since model selection lists are not bound to specific data sources, care must be taken when including data-specific features such as interventions and regressors. When you add an ARIMA, Factored ARIMA, or Custom model to the list, you can add regressors by selecting from the variables in the current data set. If there is no current data set, you will be prompted to specify a data set so you can select regressors from the series it contains.

If you use a model list having models with a particular regressor name on a data set which does not contain a series of that name, model fitting will fail. However, you can make global changes to the regressor names in the model list using *Set regressor names*. For example, you might use the list of dynamic regression models found in the sashelp.forcast catalog. It uses the regressor name "price." If your regessor series is named "x," you can specify "price" as the current regressor name and "x" as the "change to" name. The change will be applied to all models in the list containing the specified regressor name.

Interventions cannot be defined for models defined from the Model Selection List Editor. However, you can define interventions using the Intervention Specification Window and apply them to your models by turning on the Include Interventions option.



```

☑     Log ARIMA(0,1,1)(1,0,0)s NOINT
☑     Log ARIMA(2,0,0)(1,0,0)s
☑     Log ARIMA(0,1,2)(0,1,1)s NOINT
☑     Log ARIMA(2,1,0)(0,1,1)s NOINT
☑     Log ARIMA(0,2,2)(0,1,1)s NOINT
☑     Log ARIMA(2,1,2)(0,1,1)s NOINT
```

Auto Fit

The auto fit column of check boxes enables you to eliminate some of the models from being used in the automatic fitting process without having to delete them from the list. By default, all models are checked, meaning that they are all used for automatic fitting.

Model

This column displays the descriptions of all models in the model selection list. You can select one or more models by clicking them with the left mouse button. Selected models are highlighted and become the object of the actions Edit, Move, and Delete.

Menu Bar

`File`

`New`
: creates a new empty model selection list.

`Open`
: brings up a dialog for selecting one or more existing model selection lists to open. If you select multiple lists, they are all opened at once as a concatenated list. This helps you build large specialized model lists quickly by mixing and matching various existing lists such as the various ARIMA model lists included in SASHELP.FORCAST. By default, the lists you open replace the current model list. Select the “append” radio button if you want to append them to the current model list.

`Open System Default`
: opens the default model list supplied with the product.

`Cancel`
: exits the window without applying any changes to the current project's model selection list.

`Close`
: closes the window and applies any changes made to the project's model selection list.

`Save`
: brings up a dialog for saving the edited model selection list in a catalog of your choice.

`Save as User Default`
: saves your edited model list as a default list for new projects. The location of this saved list is shown on the message line. When you create new projects, the system searches for this model list and uses it if it is found. If it is not found, the system uses the original default model list supplied with the product.

`Edit`

`Reset`
: restores the list to its initial state when the window was invoked.

`Add Model`
: enables you to add new models to the selection list. You can use the Smoothing Model Specification window, the ARIMA Model Specification window, the Factored ARIMA Model Specification window, or the Custom Model Specification window.

`Edit Selected`
: brings up the appropriate model specification window for changing the attributes of the highlighted model and adding the modified model to the selection list. The original model is not deleted.

`Move Selected`
: enables you to reorder the models in the list. Select one or more models, then select Move Selected from the menu or toolbar. A note appears on the message line: "Select the row after which the selected models are to be moved." Then select any unhighlighted row in the table. The selected models will be moved after this row.

`Delete`
: deletes any highlighted models from the list. This item is not available if no models are selected.

`Set Regressor Names`
: brings up a dialog for changing all occurrences of a given regressor name in the models of the current model selection list to a name that you specify.

`Select All`
: selects all models in the list.

`Clear Selections`
: deselects all models in the list.

`Select All for Autofit`
: checks the autofit check boxes of all models in the list.

`Clear Autofit Selections`
deselects the autofit check boxes of all models in the list.

Mouse Button Actions

Selecting any model description in the table with the left mouse button selects (highlights) that model. Selecting the same model again deselects it. Multiple selections are allowed.

Selecting the auto fit check box in any row toggles the associated model's eligibility for use in automatic model fitting.

Selecting the right mouse button brings up a pop-up menu.

Model Viewer Window

This resizable window provides plots and tables of actual values, model predictions, forecasts, and related statistics. The various plots and tables available are referred to as *views*. The following "View Selection Icons" section explains how to change the view.

You can access Model Viewer in a number of ways, including the View Model Graphically icon of the Develop Models and Model List windows, the Graph button of the Automatic Model Fitting Results window, and the Model item under the View pull-down in the Manage Forecasting Project window. In addition, you can go directly to a selected view in the Model Viewer window by selecting Model Predictions, Prediction Errors, Statistics of Fit, Prediction Error Autocorrelations, Prediction Error Tests, Parameter Estimates, Forecast Graph, or Forecast Table from the View pull-down menu or corresponding toolbar icon or popup menu item in the Develop Models, Model List, or Automatic Model Fitting Results windows.

The state of the Model Viewer window is controlled by the current model and the currently selected view. You can resize this window, and you can use other windows without closing the Model Viewer window. By default, the Model

Viewer window is automatically updated to display the new model when you switch to working with another model (that is, when you highlight a different model). You can unlink the Model Viewer window from the current model selection by selecting the Link/Unlink icon from the window's horizontal tool bar. See "Link/Unlink" under "Tool Bar Icons".

For more information, see "Model Viewer" in the "Getting Started" section.

Tool Bar Icons

The Model Viewer window contains a horizontal row of icons called the Tool Bar. Corresponding menu items appear under various pull-down menus. The function of each icon is explained in the following list.

`Zoom in`
: In the Model Predictions, Prediction Errors, and Forecast Graph views, the Zoom In action changes the mouse cursor into cross hairs that you can use with the left mouse button to define a region of the graph to zoom in on. In the Prediction Error Autocorrelations and Prediction Error Tests views, Zoom In reduces the number of lags displayed.

`Zoom out`
: reverses the previous Zoom In action.

`Link/Unlink viewer`
: disconnects or connects the Model Viewer window to the model table (Develop Models window, Model List window, or Automatic Model Fitting Results window). When the viewer is linked, selecting another model in the model table causes the model viewer to be updated to show the selected model. When the Viewer is unlinked, selecting another model does not affect the viewer. This feature is useful for comparing two or more models graphically. You can display a model of interest in the Model Viewer, unlink it, then select another model and bring up another Model Viewer window for that model. Position the viewer windows side by side for convenient comparisons of models, or use the Next Viewer icon or F12 function key to switch between them.

`Save`
: saves the contents of the Model Viewer window. By default, an html page is created. This enables you to display graphs and tables using the Results Viewer or publish them on the Web or your intranet. See also "Save Graph As" and "Save Data As" under "Menu Bar" below.

`Print`
: prints the contents of the viewer window.

`Close`
: closes the Model Viewer window and returns to the window from which it was invoked.

View Selection Icons

At the right hand side of the Model Viewer window is a vertical tool bar to select the view, that is, the kind of plot or table that the viewer displays. Corresponding menu items appear under View in the menu bar. The function of each icon is explained in the following list.

`Model Predictions`
: displays a plot of actual series values and model predictions over time. Click on individual points in the graph to get a display of the type (actual or predicted), ID value, and data value in the upper right corner of the window.

`Prediction Errors`
: displays a plot of model prediction errors (residuals) over time. Click individual points in the graph to get a display of the prediction error value in the upper right corner of the window.

`Prediction Error Autocorrelations`
: displays horizontal bar charts of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the model prediction errors. Overlaid line plots represent confidence limits computed at plus and minus two standard errors. Click on any of the bars to display its value.

`Prediction Error Tests`
: displays horizontal bar charts representing results of white noise and stationarity tests on the model prediction errors. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click on any of the bars to display an interpretation.

  The second bar chart shows tests of stationarity of the model prediction errors, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click on any of the bars to display an interpretation.

`Parameter Estimates`
: displays a table showing model parameter estimates along with standard errors and *t*-tests for the null hypothesis that the parameter is zero.

`Statistics of Fit`
: displays a table of statistics of fit for the selected model. The set of statistics shown can be changed using the Statistics of Fit item under Options in the menu bar.

`Forecast Graph`
: displays a plot of actual and predicted values for the series data range, followed by a horizontal reference line and forecasted values with confidence limits. Click on individual points in the graph to get a display of the type, date/time, and value of the data point in the upper right corner of the window.

`Forecast Table`
: displays a data table with columns containing the date/time, actual, predicted, error (residual), lower confidence limit, and upper confidence limit values, together with any predictor series.

Menu Bar

`File`

`Save Graph`
: saves the plot displayed in viewer window as a SAS/GRAPH grseg catalog entry. When the current view is a table, this menu item is not available. See also "Save" under "Tool Bar Icons". If a graphics catalog entry name has not already been specified, this action functions like "Save Graph As".

`Save Graph As`
: saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an html page is created, with the graph embedded as a gif image.

`Save Data`
: saves the data displayed in the viewer window in a SAS data set, where applicable.

`Save Data As`
: saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an html page is created, with the data displayed as a table.

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Graph`
: prints the contents of the viewer window if the current view is a graph. This is the same as the Print tool bar icon. If the current view is a table, this menu item is not available.

`Print Data`
: prints the data displayed in the viewer window, where applicable.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Print Preview`
: brings up a preview window to show how your plots will appear when printed.

`Close`
: closes the Model Viewer window and returns to the window from which it was invoked.

`Edit`

`Edit Model`
: enables you to modify the specification of the current model and to fit the modified model, which is then displayed in the viewer.

`Refit Model`
: refits the current model using data within the current fit range. This action also causes the ranges to be reset if the data range has changed.

`Reevaluate Model`
: reevaluates the current model using data within the current evaluation range. This action also causes the ranges to be reset if the data range has changed.

`View`

See the "View Selection Icons" section. It describes each of the items available under "View", except "Zoom Way Out".

`Zoom Way Out`
: zooms the plot out as far as it will go, undoing all prior zoom in operations.

`Tools`

`Link Viewer`
: See "Link/Unlink" under "Tool Bar Icons".

`Options`

`Time Ranges`
: brings up the Time Ranges Specification window to enable you to change the period of fit, period of evaluation, or forecast horizon to be applied to subsequently fit models.

`Statistics of Fit`
: brings up the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the statistics of fit table and available for selection in the Model Selection Criterion menu.

`Forecast Options`
: brings up the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

`Residual Plot Options`
: Provides a choice of four methods of computing prediction errors for models which include a data transformation.

  `Prediction Errors`
  : computes the difference between the transformed series actual values and model predictions.

  `Normalized Prediction Errors`
  : computes prediction errors in normalized form.

  `Model Residuals`
  : computes the difference between the untransformed series values and the untransformed model predictions.

`Normalized Model Residuals`
computes model residuals in normalized form.

`Number of Lags`
brings up a window to enable you to specify the number of lags shown in the Prediction Error Autocorrelations and Prediction Error Tests views. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

`Correlation Probabilities`
controls whether the bar charts in the Prediction Error Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

`Include Interventions`
controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

`Print Audit Trail`
prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

`Show Source Statements`
controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Mouse Button Actions

You can examine the data values of individual points in the Model Predictions, Model Prediction Errors, and Forecast Graph views of the Model Viewer by positioning the mouse cursor over the point and clicking the left mouse button. The date/time and data values as well as the type (actual, predicted, and so forth) are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

Similarly, you can display values in the Prediction Error Autocorrelations view by clicking on any of the bars. Clicking on bars in the Prediction Error Tests view displays a Recommendation for Current View window which explains the test represented by the bar.

When you select the Zoom In action in the Predicted Values, Model Prediction Errors, and Forecasted Values views, you can use the mouse to define a region of the graph to zoom. Position the mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

Models to Fit Window

Use the Models to Fit window to fit models by choosing them from the current model selection list. Access it using “Fit Models from List” under the Fit Model submenu of the Edit pull-down in the Develop Models window, or the pop-up menu which appears when you click an empty area of the model table in the Develop Models window. If you want to alter the list of models which appears here, use the Model Selection List editor window.

Help

To select a model to be fit, use the left mouse button. To select more than one model to fit, drag with the mouse, or select the first model, then press the shift key while selecting the last model. For noncontiguous selections, press the control key while selecting with the mouse. To begin fitting the models, double-click the last selection or select the OK button.

If series diagnostics have been performed, the radio box is ungrayed. If the Subset by series diagnostics radio button is selected, only those models in the selection list that fit the diagnostic criteria will be shown for selection. If you wish to choose models that do not fit the diagnostic criteria, select the Show all models button.

Controls and Fields

`Show all models`

when selected, lists all available models, regardless of the setting of the series diagnostics options.

`Subset by series diagnostics`

when selected, lists only the available models that are consistent with the series diagnostics options.

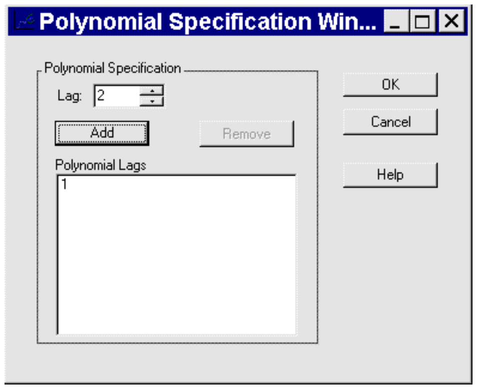
`OK`

closes the Models to Fit window and fits the selected models.

`Cancel`
: closes the window without fitting any models. Any selections you made are lost.

Polynomial Specification Window

Use the Polynomial Specification window to add a polynomial to an ARIMA model. The set of lags defined here become a polynomial factor, denoted by a list of lags in parentheses, when you select “OK”. If you accessed this window from the AR Polynomial Specification window it is added to the autoregressive part of the model. If you accessed it from the MA Polynomial Specification window it is added to the moving average part of the model.



Controls and Fields

`Lag`
: specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows.

`Add`
: adds the value in the Lag spin box to the list of polynomial lags. Duplicate values are not allowed.

`Remove`
: deletes a selected lag from the list of polynomial lags.

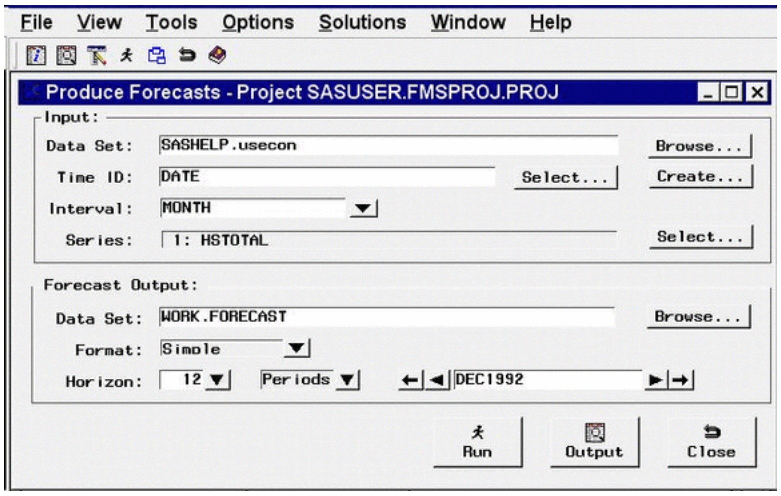
`Polynomial Lags`
: is a list of unique integers representing lags to be added to the model.

`OK`
: closes the window and returns the specified polynomial to the AR or MA polynomial specification window.

`Cancel`
: closes the window and discards any polynomial lags added to the list.

Produce Forecasts Window

Use the Produce Forecasts window to produce forecasts for the series in the current input data set for which you have fit forecasting models. Access it using the Produce Forecasts button of the Time Series Forecasting window.



Produce Forecasts - Project SASUSER.FMSPROJ.PROJ

Input:

Data Set: SASHELP.usecon

Time ID: DATE

Interval: MONTH

Series: 1: HSTOTAL

Forecast Output:

Data Set: WORK.FORECAST

Format: Simple

Horizon: 12 Periods DEC1992

Controls and Fields

Input `Data Set`

is the name of the current input data set. To specify the input data set, you can type a one or two level SAS data set name in this field or select the Browse button to the right of the field.

Input data set `Browse` button

brings up the Data Set Selection window to enable you to select the input data set.

`Time ID`

is the name of the time ID variable for the input data set. To specify this variable, you can type the ID variable name in this field or use the Select button.

Time ID `Select` button

brings up the Time ID Variable Specification window.

`Create` button

brings up a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

`Interval`

is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in by the system, you can type in an interval name here, or select one from the popup list.

`Series`

indicates the number and names of time series variables for which forecasts will be produced.

Series `Select` button

brings up the Series to Process window to let you select the series for which you want to produce forecasts.

Forecast Output `Data Set`

is the name of the output data set that will contain the forecasts. Type the name of the output data set in this field or click the Browse button.

Forecast Output `Browse` button
: brings up a dialog to let you locate an existing data set to which to save the forecasts.

`Format`
: Lets you select one of three formats for the forecast data set:

  `Simple`
  : specifies the simple format for the output data set. The data set contains the time ID variable and the forecast variables and contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.

  `Interleaved`
  : specifies the interleaved format for the output data set. The data set contains the time ID variable, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.

  `Concatenated`
  : specifies the concatenated format for the output data set. The data set contains the variable SERIES, the time ID variable, and the variables ACTUAL, PREDICT, ERROR, LOWER, and UPPER. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

`Horizon`
: is the number of periods or years to forecast beyond the end of the input data range. To specify the forecast horizon, you can type a value in this field or select one from the popup list.

`Horizon periods`
: selects the units to apply to the horizon. By default, the horizon value represents number of periods. For example, if the interval is month, the horizon represents the number of months to forecast. Depending on the interval, you can also select weeks or years, so that the horizon is measured in those units.

`Horizon date`
: is the ending date of the forecast horizon. You can type in a date using a form recognized by a SAS date informat, or you can increment or decrement the date shown using the left and right arrows. The outer arrows change the date by a larger amount than the inner arrows. The date field and the horizon field reset each other, so you can use either one to specify the forecasting horizon.

`Run` button
: produces forecasts for the selected series and stores the forecasts in the specified output SAS data set.

`Output` button
: brings up a Viewtable window to display the output data set. This button becomes ungrayed once the forecasts have been written to the data set.

`Close` button
: closes the Produce Forecasts window and returns to the Time Series Forecasting window.

Menu Bar

`File`

`Import Data`
: is available if you license SAS/Access software. It brings up an Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Close`
: closes the Produce Forecasts window and returns to the Time Series Forecasting window.

`View`

`Input Data Set`
: brings up a Viewtable window to browse the current input data set.

`Output Data Set`
: brings up a Viewtable window to browse the output data set. This is the same as the Output button.

`Tools`

`Produce Forecasts`
: produces forecasts for the selected series and stores the forecasts in the specified output SAS data set. This is the same as the Run button.

`Options`

`Default Time Ranges`
: brings up the Default Time Ranges window to enable you to control how the system sets the time ranges when new series are selected.

`Model Selection List`
: brings up the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

`Model Selection Criterion`
: brings up the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model.

`Statistics of Fit`
: brings up the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion window.

`Forecast Options`
: brings up the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

`Forecast Data Set`
: lets you select one of three formats for the forecast data set. See the description under "format".

`Alignment of Dates`

`Beginning`
: aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

`Middle`
: aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

`End`
: aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

`Automatic Fit`
: brings up the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

`Set Toolbar Type`

`Image Only`
: displays the tool bar items as icons without text.

`Label Only`
: displays the tool bar items as text without icon images.

`Both`
: displays the tool bar items as both text and icon images.

`Include Interventions`
: controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

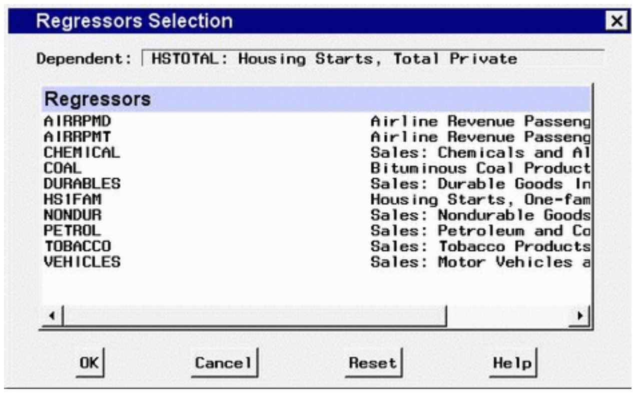
`Print Audit Trail`
: prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

`Show Source Statements`
: controls whether SAS statements submitted by the forecasting system are

printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Regressors Selection Window

Use the Regressors Selection window to select one or more time series variables in the input data set to include as regressors in the forecasting model to predict the dependent series. Access it from the pop-up menu which appears when you select the Add button of the ARIMA Model Specification window or Custom Model Specification window.



Dependent: HSTOTAL: Housing Starts, Total Private

Regressors	
AIRRPMD	Airline Revenue Passeng
AIRRPMT	Airline Revenue Passeng
CHEMICAL	Sales: Chemicals and Al
COAL	Bituminous Coal Product
DURABLES	Sales: Durable Goods In
HS1FAM	Housing Starts, One-fam
NONDUR	Sales: Nondurable Goods
PETROL	Sales: Petroleum and Co
TOBACCO	Sales: Tobacco Products
VEHICLES	Sales: Motor Vehicles a

Controls and Fields

`Dependent`
: is the name and variable label of the current series.

`Regressors`
: is a table listing the names and labels of the variables in the input data set available for selection as regressors. The variables that you select are highlighted. Selecting a highlighted row again deselects that variable.

`OK`
: closes the Regressors Selection window and adds the selected variables as regressors in the model.

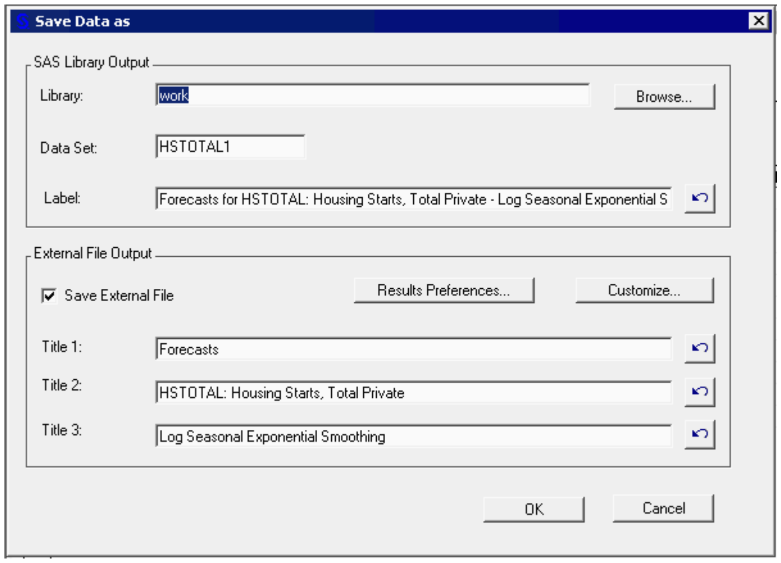
`Cancel`
: closes the window without adding any regressors. Any selections you made are lost.

`Reset`
: resets all options to their initial values upon entry to the window.

Save Data As

Use Save Data As from the Time Series Viewer Window or the Model Viewer Window to save data displayed in a table to a SAS data set or external file.

Use Save Forecast As from the Develop Models Window to save forecasts and related data including the series name, model, and interval. It supports append mode, enabling you to accumulate the forecasts of multiple series in a single data set.



Save Data as

SAS Library Output

Library: work

Data Set: HSTOTAL1

Label: Forecasts for HSTOTAL: Housing Starts, Total Private - Log Seasonal Exponential S

External File Output

[✓] Save External File

Title 1: Forecasts

Title 2: HSTOTAL: Housing Starts, Total Private

Title 3: Log Seasonal Exponential Smoothing

To save your data in a SAS data set, provide a library name or assign one using the Browse button, then provide a data set name or accept the default. Enter a descriptive label for the data set in the Label field. Click OK to save the data set. If you specify an existing data set, it will be overwritten, except in the case of Save Forecast As, described above.

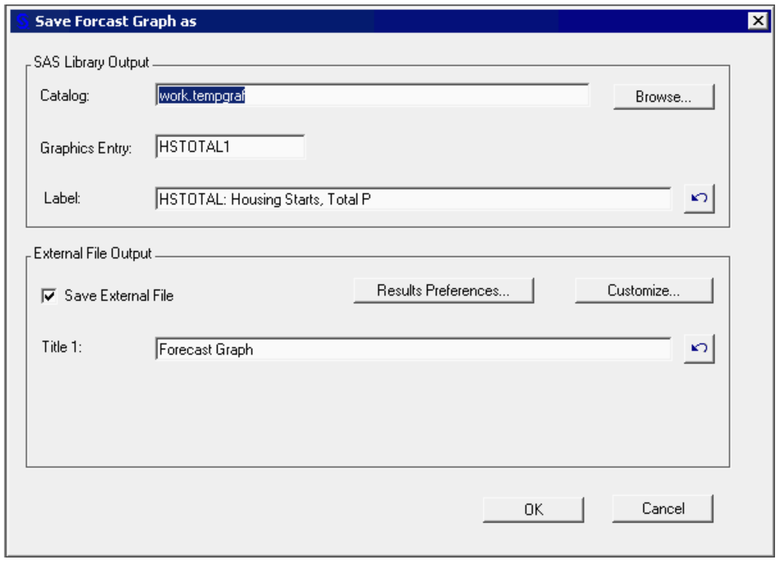
External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating html tables for Web reporting. You can build a set of Web pages quickly and use the ODS Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

If you have previously saved data of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro containing ODS statements. You will notice that the default macro simply runs the PRINT procedure. A custom macro can be used to add PRINT procedure and/or ODS statements to customize the type and organization of output files produced.

Save Graph As

Use Save Graph As from the Time Series Viewer Window or the Model Viewer Window to save any of the graphs in a catalog or external file.



Save Forcast Graph as

SAS Library Output

Catalog: work.tempgraf

Graphics Entry: HSTOTAL1

Label: HSTOTAL: Housing Starts, Total P

External File Output

[✓] Save External File

Title 1: Forecast Graph

To save your graph as a grseg catalog entry, enter a two level name for the catalog or select Browse to bring up an Open dialog. Use it to select an existing library or assign a new one and then select a catalog to contain the graph. Click the Open button to open the catalog and close the dialog. Then enter a graphics entry name (eight characters or less) and a label or accept the defaults and click the OK button to save the graph.

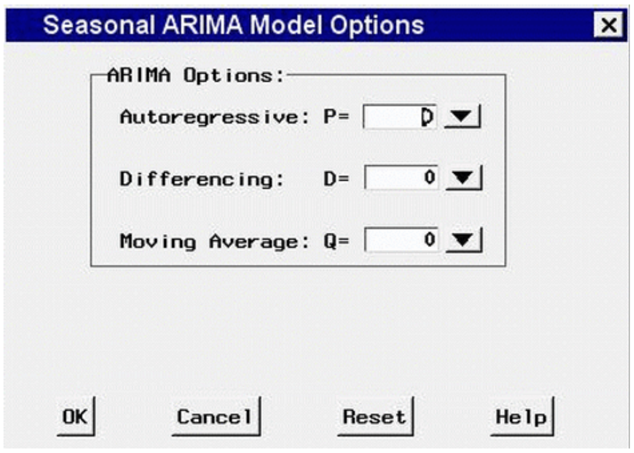
External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating gif images and html for Web reporting. You can build a set of Web pages containing graphs and use the Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, then select the Results tab in the Preferences dialog.

If you have previously saved graphs of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro containing ODS statements. You will notice that the default macro simply runs the GREPLAY procedure. Users familiar with ODS may wish to add statements to the macro to customize the type and organization of output files produced.

Seasonal ARIMA Model Options Window

Use the Seasonal ARIMA Model Options window to specify the the autoregressive, differencing, and moving average orders for the seasonal part of a model defined using the Custom Model Specification window. Access it by selecting "Seasonal ARIMA..." from the Seasonal Model combo box of that window.



Controls and Fields

`ARIMA Options`

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a popup list.

`Autoregressive`

defines the order of the seasonal autoregressive part of the model.

`Differencing`

defines the order of seasonal differencing.

`Moving Average`

defines the order of the seasonal moving average term.

`OK`

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window.

`Cancel`

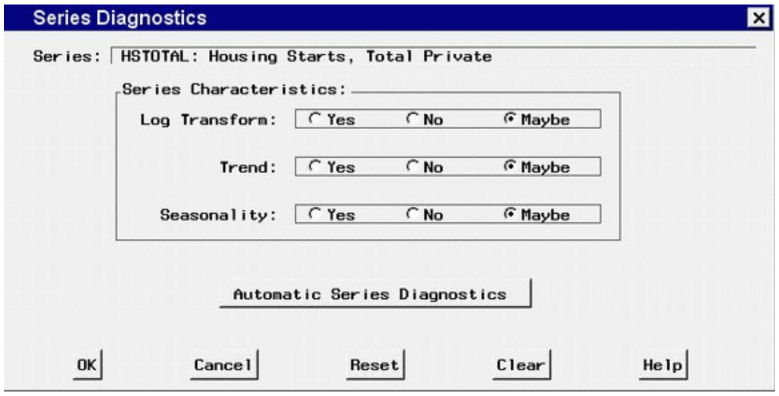
closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window, discarding any changes made.

`Reset`

resets all options to their initial values upon entry to the window.

Series Diagnostics Window

Use the Series Diagnostics window to set options to limit the kinds of forecasting models considered for the series according to series characteristics. Access it by selecting "Diagnose Series" from the Tools pull-down menu in the Develop Models, Manage Project, and Time Series Viewer window menu bars. You can let the system diagnose the series' characteristics automatically or you can specify series characteristics according to your judgment using the radio buttons.



Series Diagnostics

Series: HSTOTAL: Housing Starts, Total Private

Series Characteristics:

Log Transform: Yes No [✓ Maybe]

Trend: Yes No [✓ Maybe]

Seasonality: Yes No [✓ Maybe]

For each of the options Log Transform, Trend, and Seasonality, the value "Yes" means that only models appropriate for series with that characteristic should be considered. The value "No" means that only models appropriate for series without that characteristic should be considered. The value "Maybe" means that models should be considered without regard for that characteristic.

Controls and Fields

`Series`
: is the name and variable label of the current series.

`Series Characteristics`

  `Log Transform`
  : specifies whether forecasting models with or without a logarithmic series transformation are appropriate for the series.

  `Trend`
  : specifies whether forecasting models with or without a trend component are appropriate for the series.

  `Seasonality`
  : specifies whether forecasting models with or without a seasonal component are appropriate for the series.

`Automatic Series Diagnostics`
: performs the automatic series diagnostic process. The options Log Transform, Trend, and Seasonality are set according to the results of statistical tests.

`OK`
: closes the Series Diagnostics window.

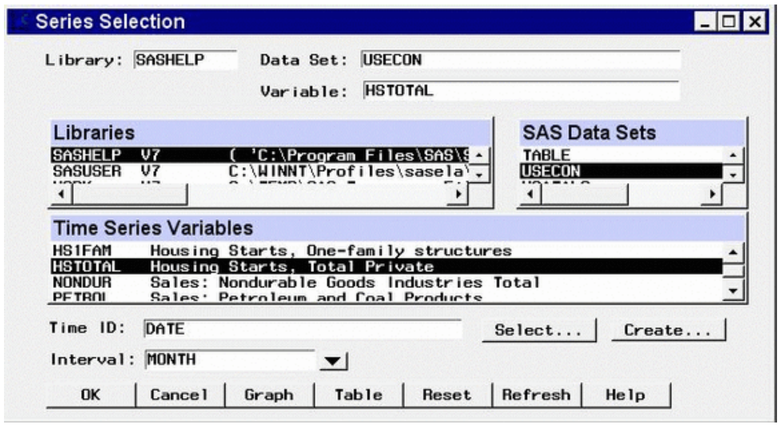
`Cancel`
: closes the Series Diagnostics window without changing the series diagnostics options. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the Series Diagnostics window.

`Clear`
: resets all options to their default values.

Series Selection Window

Use this resizable window to select a time series variable by specifying a library, a SAS data set or view, and a variable. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set or view plots of the series from this window.



Library: SASHELP
Data Set: USECON
Variable: HSTOTAL

```
SASHELP  V7        ( 'C:\Program Files\SAS\S
SASUSER  V7        C:\WINNT\Profiles\sasela\
```

```
TABLE
USECON
```

```
HS1FAM    Housing Starts, One-family structures
HSTOTAL   Housing Starts, Total Private
NONDUR    Sales: Nondurable Goods Industries Total
PETROL    Sales: Petroleum and Coal Products
```

Time ID: DATE
Interval: MONTH

This window appears automatically when you select the View Series Graphically or Develop Models buttons in the Time Series Forecasting window and no series has been selected, and when you bring up the Time Series Viewer as a stand-alone tool. It is also invoked using the Browse button in the Develop Models window.

The system requires that series names be unique for each frequency (interval) within the forecasting project. If you select a series from the current input data set that already exists in the project with the same interval but a different input data set name, the system warns you and gives you the option to cancel the selection, to refit all models associated with the series using the data from the current input data set, to delete the models for the series, or to inherit the existing models.

Controls and Fields

`Library`
: is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field and press Return. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname.

`Data Set`
: is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and

will be highlighted, and the Time Series Variables list will be populated with the numeric variables in the data set.

`Variable`
: is the name of a numeric variable contained in the selected data set. You can type the variable name in this field or you can select the variable with the mouse from the Time Series Variables list.

`Time ID`
: is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or click the Select button.

`Select` button
: brings up the Time ID Variable Specification window to let you select an existing variable in the data set as the Time ID.

`Create` button
: brings up a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

`Interval`
: is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically filled in by the system, you can type in an interval name or select one from the popup list. For more information on intervals, see Chapter 3, "Date Intervals, Formats, and Functions," in this book.

`OK`
: This button is present when you have selected "Develop Models" from the Time Series Forecasting window. It closes the Series Selection window and makes the selected series the current series.

`Close`
: If you have selected the View Series Graphically icon from the Time Series Forecasting window, this button returns you to that window. If you have selected a series, it remains selected as the current series.

  If you are using the Time Series Viewer as a stand-alone application, this button closes the application.

`Cancel`
: This button is present when you have selected "Develop Models" from the Time Series Forecasting window. It closes the Series Selection window without applying any selections made.

`Reset`
: resets the fields to their initial values at entry to the window.

`Table`
: brings up a Viewtable window for browsing the selected data set. This can assist you in locating the variable containing data you are looking for.

`Graph`
: brings up the Time Series Viewer window to display the selected time series variable. You can switch to a different series in the Series Selection window without closing the Time Series Viewer window. Position the windows so

they are both visible, or use the Next Viewer tool bar icon or F12 function key to switch between windows.

`Refresh`
: updates all fields and lists on the window. If you assign a new libname without exiting the Series Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname. Also use the Refresh action to update the variables list if the input data set is changed.

Selection Lists

`Libraries`
: displays a list of currently assigned libnames. You can select a libname by clicking it with the left mouse button, which is equivalent to typing its name in the Library field. If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File pull-down menu, then select “Library” and “OK”. This brings up the New Library dialog window. You also assign a libname by submitting a libname statement from the Editor window. Select the Refresh button to make the new libname available in the libraries list.

`SAS Data Sets`
: displays a list of the SAS data sets (data files or data views) located under the selected libname. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Data Set field.

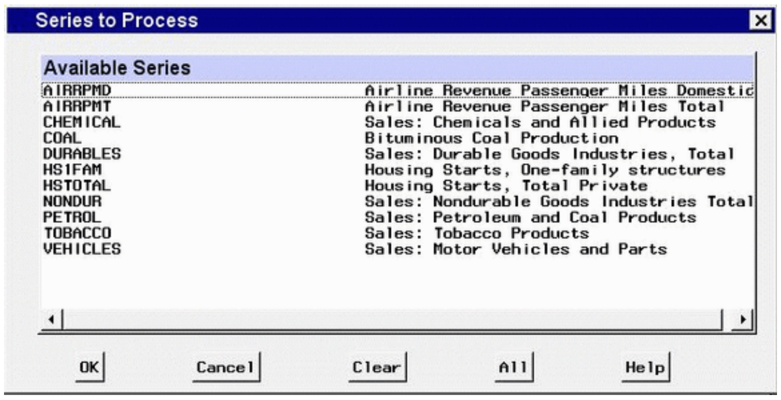
`Time Series Variables`
: displays a list of numeric variables contained within the selected data set. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Variable field. You can double-click on a series to select it and exit the window.

Series to Process Window

Use the Series to Process window to select series for model fitting or forecasting. Access it using the Select button in the Automatic Model Fitting and Produce Forecasts windows. Hold down the shift key or drag with the left mouse button for multiple selections. Use the control key for noncontiguous multiple selections. Once you make selections and select OK, the number of selected series and their names are listed in the Series to Process field of the calling window (with ellipses if not all the names will fit).

When invoked from Automatic Model Fitting, the Series to Process window shows all the numeric variables in the input data set except the time id variable. These are the series which are currently available for model fitting.

When invoked from Produce Forecasts, the Series to Process window shows all the series in the input data set for which models have been fit. These are the series which are currently available for forecasting.



AIRRPMD	Airline Revenue Passenger Miles Domestic
AIRRPMT	Airline Revenue Passenger Miles Total
CHEMICAL	Sales: Chemicals and Allied Products
COAL	Bituminous Coal Production
DURABLES	Sales: Durable Goods Industries, Total
HS1FAM	Housing Starts, One-family structures
HSTOTAL	Housing Starts, Total Private
NONDUR	Sales: Nondurable Goods Industries Total
PETROL	Sales: Petroleum and Coal Products
TOBACCO	Sales: Tobacco Products
VEHICLES	Sales: Motor Vehicles and Parts

Controls and Fields

`OK`
: closes the window and applies the series selection(s) which have been made. At least one series must be selected to close the window.

`Cancel`
: closes the window, ignoring series selections which have been made, if any.

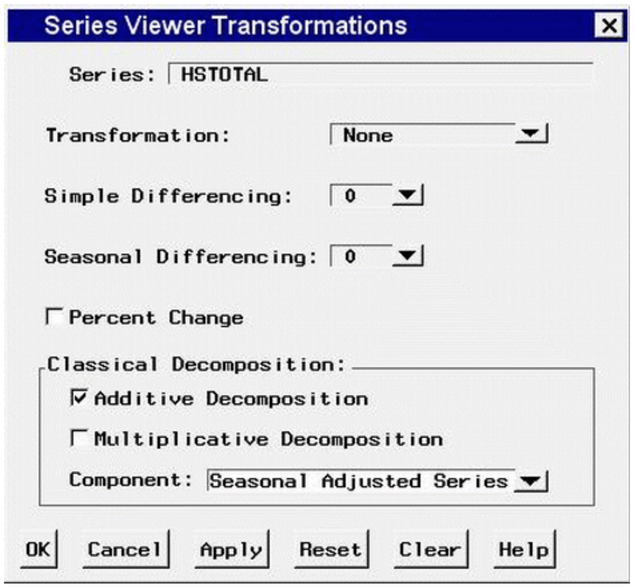
`Clear`
: deselects all series in the selection list.

`All`
: selects all series in the selection list.

Series Viewer Transformations Window

Use the Series Viewer Transformations window to view plots of transformations of the current series in the Time Series Viewer window. It provides a larger set of transformations than those available from the viewer window's tool bar. It is invoked using "Other Transformations" under the Tools pull-down menu of the Time Series Viewer window. The options that you specify in this window are applied to the series displayed in the Time Series Viewer window when you select "OK" or "Apply".

Use the Apply button if you want to make repeated transformations to a series without having to close and reopen the Series Viewer Transformations window each time.



Series Viewer Transformations

Series: HSTOTAL

Transformation: None

Simple Differencing: 0

Seasonal Differencing: 0

☐ Percent Change

Classical Decomposition:

☑ Additive Decomposition

☐ Multiplicative Decomposition

Component: Seasonal Adjusted Series

Controls and Fields

`Series`
: is the variable name for the current time series.

`Transformation`
: is the transformation applied to the time series displayed in the Time Series Viewer window. Select Log, Logistic, Square Root, Box-Cox, or none from the popup list.

`Simple Differencing`
: is the order of differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 5 from the popup list.

`Seasonal Differencing`
: is the order of seasonal differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 3 from the popup list.

`Percent Change`
: is a check box that if selected displays the series in terms of percent change from the previous period.

`Additive Decomposition`
: is a check box which produces a display of a selected series component derived using additive decomposition.

`Multiplicative Decomposition`
: is a check box which produces a display of a selected series component derived using multiplicative decomposition.

`Component`
: selects a series component to display when either additive or multiplicative decomposition is turned on. You can display the seasonally adjusted component, the trend-cycle component, the seasonal component, or the irregular component, that is, the residual which remains after removal of the

other components. The heading in the viewer window shows which component is currently displayed.

`OK`
: applies the transformation options you selected to the series displayed in the Time Series Viewer window and closes the Series Viewer Transformations window.

`Cancel`
: closes the Series Viewer Transformations window without changing the series displayed by the Time Series Viewer window.

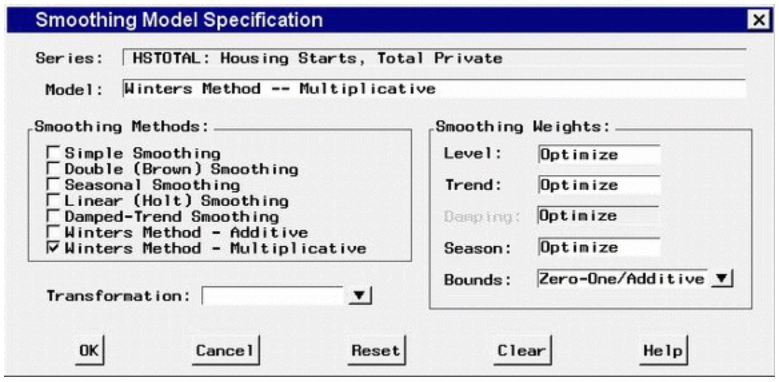
`Apply`
: applies the transformation options you selected to the series displayed in the Time Series Viewer window without closing the Series Viewer Transformations window.

`Reset`
: resets the transformation options to their initial values upon entry to the Series Viewer Transformations window.

`Clear`
: resets the transformation options to their default values (no transformations).

Smoothing Model Specification Window

Use the Smoothing Model Specification window to specify and fit exponential smoothing and Winters method models. Access it from the Develop Models window using the Fit Model submenu of the Edit pull-down or from the pop-up menu when you click an empty area of the model table.



Series: HSTOTAL: Housing Starts, Total Private
Model: Winters Method -- Multiplicative

Smoothing Methods:
- [ ] Simple Smoothing
- [ ] Double (Brown) Smoothing
- [ ] Seasonal Smoothing
- [ ] Linear (Holt) Smoothing
- [ ] Damped-Trend Smoothing
- [ ] Winters Method - Additive
- [✓] Winters Method - Multiplicative

Transformation:

Smoothing Weights:
Level: Optimize
Trend: Optimize
Damping: Optimize
Season: Optimize
Bounds: Zero-One/Additive

Controls and Fields

`Series`
: is the name and variable label of the current series.

`Model`
: is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

`Smoothing Methods`

`Simple Smoothing`
: specifies simple (single) exponential smoothing.

`Double (Brown) Smoothing`
: specifies double exponential smoothing using Brown's one parameter model (single exponential smoothing applied twice).

`Seasonal Smoothing`
: specifies seasonal exponential smoothing. (This is like Winters method with the trend term omitted.)

`Linear (Holt) Smoothing`
: specifies exponential smoothing of both the series level and trend (Holt's two parameter model).

`Damped-Trend Smoothing`
: specifies exponential smoothing of both the series level and trend with a trend damping weight.

`Winters Method - Additive`
: specifies Winters method with additive seasonal factors.

`Winters Method - Multiplicative`
: specifies Winters method with multiplicative seasonal factors.

`Smoothing Weights`
: displays the values used for the smoothing weights. By default, the Smoothing Weights fields are set to "optimize", which means that the system will compute the weight values that best fit the data. You can also type smoothing weight values in these fields.

`Level`
: is the smoothing weight used for the level of the series.

`Trend`
: is the smoothing weight used for the trend of the series.

`Damping`
: is the smoothing weight used by the damped-trend method to damp the forecasted trend towards zero as the forecast horizon increases.

`Season`
: is the smoothing weight used for the seasonal factors in Winters method and seasonal exponential smoothing.

`Transformation`
: displays the series transformation specified for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the model predictions. Select `Log`, `Logistic`, `Square Root`, `Box-Cox`, or `None` from the popup list.

`Bounds`
: displays the constraints imposed on the fitted smoothing weights. Select one of the following from the popup list:

`Zero-One/Additive`
: sets the smoothing weight optimization region to the the intersection of the region bounded by the intervals from zero (0.001) to one (0.999) and the additive invertible region. This is the default.

`Zero-One Boundaries`
: sets the smoothing weight optimization region to the region bounded by the intervals from zero (0.001) to one (0.999).

`Additive Invertible`
: sets the smoothing weight optimization region to the additive invertible region.

`Unrestricted`
: sets the smoothing weight optimization region to be unbounded.

`Custom`
: brings up the `Smoothing Weights` window to enable you to customize the constraints for smoothing weights optimization.

`OK`
: closes the Smoothing Model Specification window and fits the model you specified.

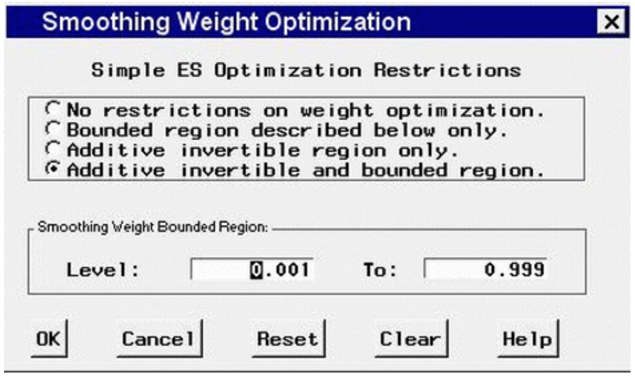
`Cancel`
: closes the Smoothing Model Specification window without fitting the model. Any options you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the window. This may be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

`Clear`
: resets all options to their default values.

Smoothing Weight Optimization Window

Use the Smoothing Weight Optimization window to specify constraints for the automatic fitting of smoothing weights for exponential smoothing and Winters method models. Access it from the Smoothing Models Specification window when you select “Custom” in the “Bounds” combo box.



Simple ES Optimization Restrictions

- No restrictions on weight optimization.
- Bounded region described below only.
- Additive invertible region only.
- [✓ Additive invertible and bounded region.]

Smoothing Weight Bounded Region:

Level: 0.001 To: 0.999

Controls and Fields

`No restrictions`
: when selected, specifies unrestricted smoothing weights.

`Bounded region`
: when selected, restricts the fitted smoothing weights to be within the bounds that you specify with the “Smoothing Weight Bounded Region” options.

`Additive invertible region`
: when selected, restricts the fitted smoothing weights to be within the additive invertible region of the parameter space of the ARIMA model equivalent to the smoothing model. (See the section "Smoothing Models" in Chapter 41, “Forecasting Process Details,” for details.)

`Additive invertible and bounded region`
: when selected, restricts the fitted smoothing weights to be both within the additive invertible region and within bounds that you specify.

`Smoothing Weight Bounded Region`
: is a group of numeric entry fields that enable you to specify lower and upper limits on the fitted value of each smoothing weight. The fields that appear in this part of the window depend on the kind of smoothing model that you specified.

`OK`
: closes the window and sets the Bounds options that you specified.

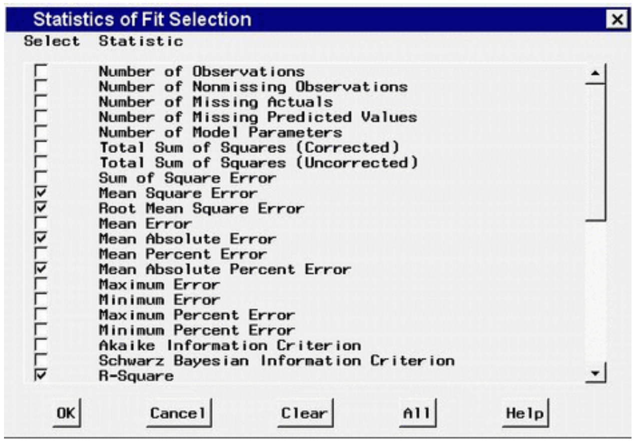
`Cancel`
: closes the window without changing the Bounds option. Any values you specified are lost.

`Reset`
: resets all options to their initial values upon entry to the window.

`Clear`
: resets all options to their default values.

Statistics of Fit Selection Window

Use the Statistics of Fit Selection window to specify which of the available goodness-of-fit statistic are reported for models you fit and are available for selection as the model selection criterion used by the automatic selection process. This window is available under the Options pull-down menu in the Develop Models, Automatic Model Fitting, Produce Forecasts, and Model List windows, and from the Statistics button of the Model Fit Comparison window and Automatic Model Fitting results windows.



Select	Statistic
☐	Number of Observations
☐	Number of Nonmissing Observations
☐	Number of Missing Actuals
☐	Number of Missing Predicted Values
☐	Number of Model Parameters
☐	Total Sum of Squares (Corrected)
☐	Total Sum of Squares (Uncorrected)
☐	Sum of Square Error
✓	Mean Square Error
✓	Root Mean Square Error
☐	Mean Error
✓	Mean Absolute Error
☐	Mean Percent Error
✓	Mean Absolute Percent Error
☐	Maximum Error
☐	Minimum Error
☐	Maximum Percent Error
☐	Minimum Percent Error
☐	Akaike Information Criterion
☐	Schwarz Bayesian Information Criterion
✓	R-Square

Controls and Fields

`Available Statistics Table`
: list the available statistics. Select a row of the table to select or deselect the statistic shown in that row.

`OK`
: closes the window and applies the selections made.

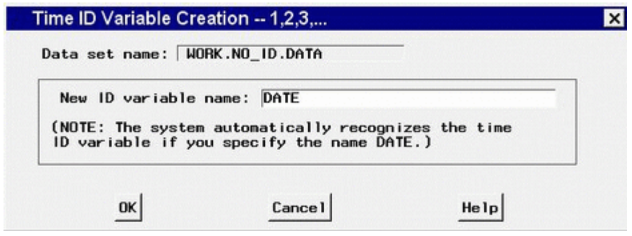
`Cancel`
: closes the window without applying any selections.

`Clear`
: deselects all statistics.

`All`
: selects all statistics.

Time ID Creation – 1,2,3 Window

Use the Time ID Creation – 1,2,3 window to add a time ID variable to an input data set with observation numbers as the ID values. The interval for the series will be 1. Use this approach if the data frequency does not match any of the system's date or date-time intervals, or if other methods of assigning a time ID do not work. To access this window, select "Create from observation numbers" from the the Create popup list in any window where you can select a Time ID variable. For more information, see Chapter 3, "Date Intervals, Formats, and Functions," in this book.



Data set name: WORK.NO_ID.DATA

New ID variable name: DATE

(NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.)

Controls and Fields

`Data set name`
: is the name of the input data set.

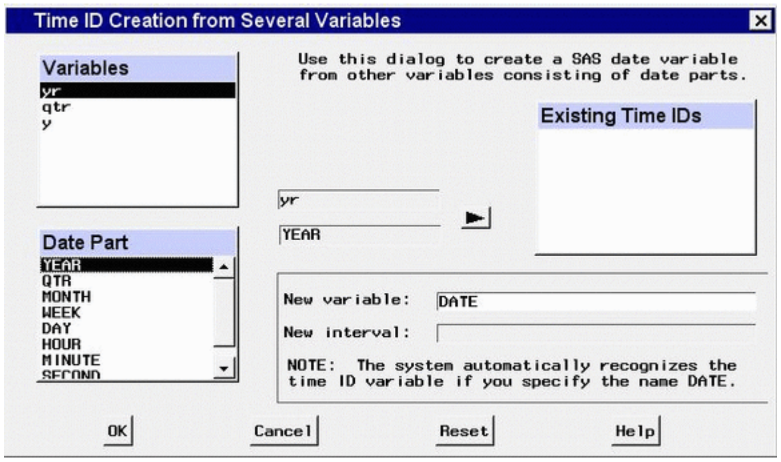
`New ID variable name`
: is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

`OK`
: closes the window and proceeds to the next step in the time ID creation process.

`Cancel`
: closes the window without creating a Time ID variable Any options you specified are lost.

Time ID Creation from Several Variables Window

Use the Time ID Creation from Several Variables window to add a SAS date valued time ID variable to an input data set when the input data set already contains several dating variables, such as day, month, and year. To access this window, select "Create from existing variables" from the Create popup list in any window where you can select a Time ID variable. For more information, see "Creating Time ID Variables" in this book.



Use this dialog to create a SAS date variable from other variables consisting of date parts.

yr

YEAR

New variable: DATE

New interval:

NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.

Controls and Fields

`Variables`
: is a list of variables in the input data set. Select existing ID variables from this list.

`Date Part`
: is a list of date parts that you can specify for the selected ID variable. For each ID variable that you select from the Variables list, select the Date Part value that describes what the values of the ID variable represent.

`arrow button`
: Use this button to move the selected existing ID variable and date part specification to the "Existing Time IDs" list. Once you have done this, you can select another ID variable from the Variables list.

`New variable`
: is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

`New interval`
: is the time interval between observations in the input data set implied by the date part ID variables you have selected.

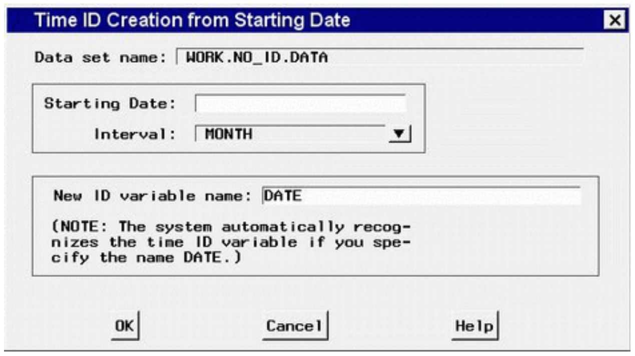
`OK`
: closes the window and proceeds to the next step in the time ID creation process.

`Cancel`
: closes the window without creating a time ID. Any options you specified are lost.

`Reset`
: resets the options to their initial values upon entry to the window.

Time ID Creation from Starting Date Window

Use the Time ID Creation from Starting Date window to add a SAS date valued time ID variable to an input data set. This is a convenient way to add a time ID of any interval as long as you know the starting date of the series. To access this window, select “Create from starting date and frequency” from the Create popup list in any window where you can select a Time ID variable. For more information, see “Creating Time ID Variables” in this book.



Time ID Creation from Starting Date

Data set name: WORK.NO_ID.DATA

Starting Date:

Interval: MONTH

New ID variable name: DATE

(NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.)

Controls and Fields

`Data set name`
: is the name of the input data set.

`Starting Date`
: is the starting date for the time series in the data set. Enter a date value in this field, using a form recognizable by a SAS date informat, for example, 1998:1, feb1997, or 03mar1998.

`Interval`
: is the time interval between observations in the data set. Select an interval from the popup list.

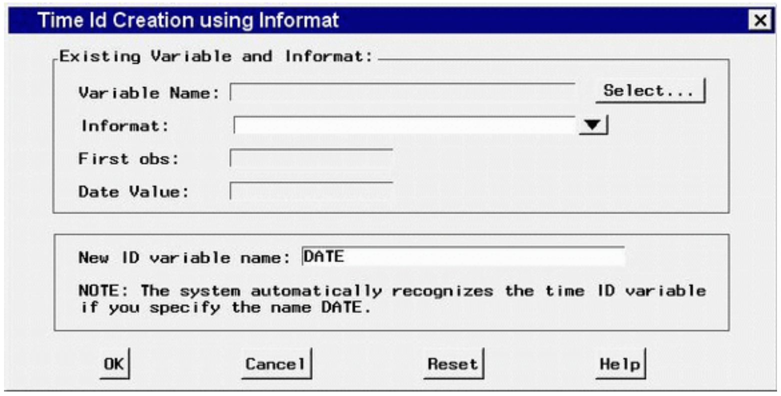
`New ID variable name`
: is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

`OK`
: closes the window and proceeds to the next step in the time ID creation process.

`Cancel`
: closes the window without changing the input data set. Any options you specified are lost.

Time ID Creation using Informat Window

Use the Time ID Creation using Informat window to add a SAS date valued time ID variable to an input data set. Use this window if your data set contains a date variable which is stored as a character string. Using the appropriate SAS date informat, the date string is read in and used to create a date or date-time variable. To access this window, select “Create from existing variable/informat” from the Create popup list in any window where you can select a Time ID variable.



Time Id Creation using Informat

Existing Variable and Informat:

Variable Name:

Informat:

First obs:

Date Value:

New ID variable name: DATE

NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.

Controls and Fields

`Variable Name`
: is the name of an existing ID variable in the input data set. Click the Select button to select a variable.

`Select button`
: brings up a list of variables in the input data set for you to select from.

`Informat`
: is a SAS date or datetime informat for reading date or datetime value from the values of the specified existing ID variable. You can type in an informat or select one from the popup list.

`First Obs`
: is the value of the variable you selected from the first observation in the data set, displayed here for convenience.

`Date Value`
: is the SAS date or datetime value read from the first observation value using the informat that you specified.

`New ID variable name`
: is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

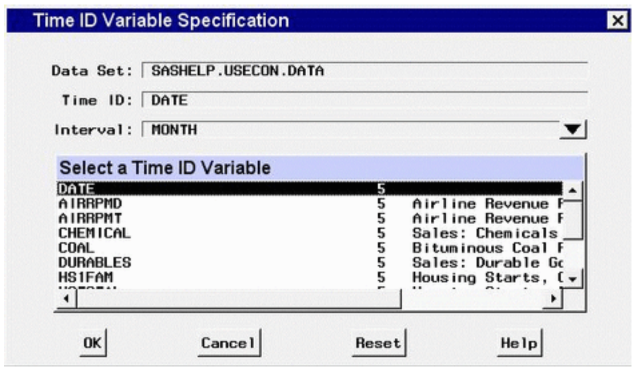
`OK`
: closes the window and proceeds to the next step in the time ID creation process.

`Cancel`
: closes the window without changing the input data set. Any options you specified are lost.

`Reset`
: resets the options to their initial values upon entry to the window.

Time ID Variable Specification Window

Use the Time ID Variable Specification window to specify a variable in the input data set which contains the SAS date or datetime value of each observation. You do not need to use this window if your time ID variable is named `date`, `time`, or `datetime`, since these are picked up automatically. Invoke the window from the Select button to the right of the Time ID field in the Data Set Selection, Automatic Model Fitting, Produce Forecasts, Series Selection, and Time Series Forecasting windows.



Data Set: SASHELP.USECON.DATA
Time ID: DATE
Interval: MONTH

Select a Time ID Variable

```
DATE                    5
AIRRPMD                 5   Airline Revenue F
AIRRPMT                 5   Airline Revenue F
CHEMICAL                5   Sales: Chemicals
COAL                    5   Bituminous Coal F
DURABLES                5   Sales: Durable Gc
HS1FAM                  5   Housing Starts, (
```

Controls and Fields

`Data Set`
: is the name of the current input data set.

`Time ID`
: is the name of the currently selected Time ID variable, if any.

`Interval`
: is the time interval between observations (data frequency) in the input data set.

`Select a Time ID Variable`
: is a selection list of variables in the input set. Select one variable to assign it as the Time ID variable.

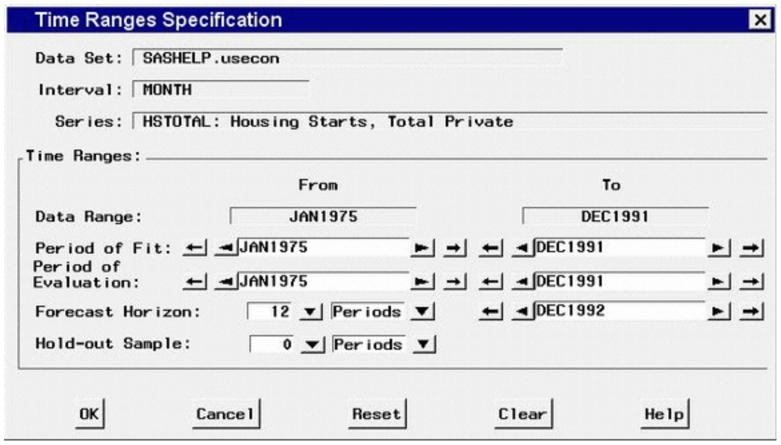
`OK`
: closes the window and retains the selection made, if it is a valid time ID.

`Cancel`
: closes the window and ignores any selection made.

`Reset`
: restores the time ID variable to the one assigned when the window was initially opened, if any.

Time Ranges Specification Window

Use the Time Ranges Specification window to control the period of fit and evaluation and the forecasting horizon. Invoke this window from the Options menu in the Develop Models, Manage Forecasting Project, and Model Viewer windows or the Set Ranges button in the Develop Models window.



Data Set: SASHELP.usecon
Interval: MONTH
Series: HSTOTAL: Housing Starts, Total Private

Time Ranges:

	From		To	
Data Range:	JAN1975		DEC1991	
Period of Fit:	JAN1975		DEC1991	
Period of Evaluation:	JAN1975		DEC1991	
Forecast Horizon:	12	Periods	DEC1992	
Hold-out Sample:	0	Periods		

Controls and Fields

`Data Set`
: is the name of the current input data set.

`Interval`
: is the time interval (data frequency) for the input data set.

`Series`
: is the variable name and label of the current time series.

`Data Range`
: gives the date of the first and last nonmissing data values available for the current series in the input data set.

`Period of Fit`
: gives the starting and ending dates of the period of fit. This is the time range used for estimating model parameters. By default, it is the same as the data range. You can type dates in these fields, or you can use the arrow buttons to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (Refer to "SAS Language Reference" for information on SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

`Period of Evaluation`
: gives the starting and ending dates of the period of evaluation. This is the time range used for evaluating models in terms of statistics of fit. By default, it is the same as the data range. You can type dates in these fields, or you can use the control arrows to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (Refer to "SAS Language Reference" for information on SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

`Forecast Horizon`
: is the forecasting horizon expressed as a number of forecast periods or number of years (or number of weeks for daily data). You can type a number or select one from the popup list. The ending date for the forecast period is automatically updated when you change the number of forecasts periods.

`Forecast Horizon - Units`
: indicates whether the Forecast Horizon value represents periods or years (or weeks for daily data).

`Forecast Horizon Date Value`
: is the date of the last forecast observation. You can type a date in this field, or you can use the arrow buttons to the left and right of the date field to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (Refer to "SAS Language Reference" for information on SAS date informats.) The Forecast Horizon is automatically updated when you change the ending date for the forecast period.

`Hold-out Sample`
: specifies that a number of observations or years (or weeks) of data at the end of the data range are used for the period of evaluation with the remainder of data used as the period of fit. You can type a number in this field or select one from the popup list. When the hold-out sample value is changed, the Period of Fit and Period of Evaluation ranges are changed to reflect the hold-out sample specification.

`Hold-out Sample - Units`
: indicates whether the hold-out sample field represents periods or years (or weeks for daily data).

`OK`
: closes the window and stores the specified changes.

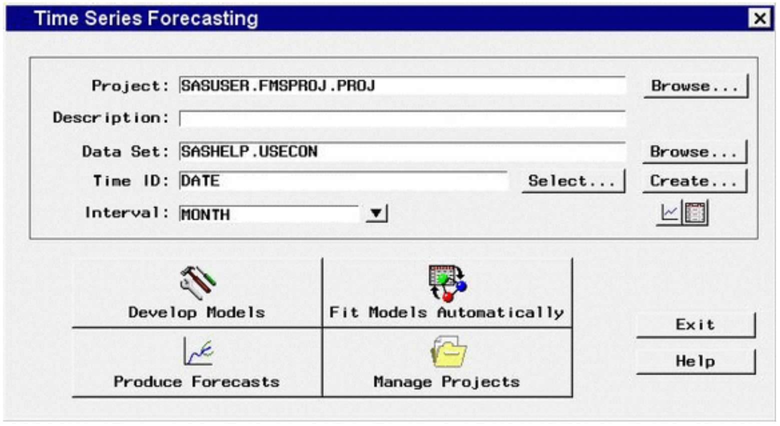
`Cancel`
: closes the window without saving changes. Any options you specified are lost.

`Reset`
: resets the options to their initial values upon entry to the window.

`Clear`
: resets all options to their default values.

Time Series Forecasting Window

The Time Series Forecasting window is the main application window which appears when you invoke the Time Series Forecasting System. It allows you to specify a project file and an input data set and provides access to the other windows described in this chapter.



Project: SASUSER.FMSPROJ.PROJ
Description:
Data Set: SASHELP.USECON
Time ID: DATE
Interval: MONTH

Controls and Fields

`Project`
: is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by selecting the Browse button to right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one level name, the catalog name is assumed to be `fmsproj` and the library is assumed to be `sasuser`. For example, `samproj` is equivalent to `sasuser.fmsproj.samproj`.

Project `Browse` button
: brings up the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored projects.

`Description`
: is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field.

`Data Set`
: is the name of the current input data set. To specify the input data set, you can type the data set name in this field or use the Browse button to the right of the field.

Data set `Browse` button
: brings up the Data Set Selection window to enable you to select the input data set.

`Time ID`
: is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or use the Select

button. If the time ID variable is named `date`, `time`, or `datetime`, it is automatically picked up by the system.

`Select` button
: brings up the Time ID Variable Specification window.

`Create` button
: brings up a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

`Interval`
: is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in, you can type an interval name or select one from the popup list. For more information on intervals, see "Time Series Data Sets, ID variables, and Time Intervals" in this book.

`View Series Graphically` icon
: brings up the Time Series Viewer window to display plots of series in the current input data set.

`View Data as a Table`
: brings up a Viewtable window for browsing the selected input data set.

`Develop Models`
: brings up the Develop Models window to enable you to fit forecasting models to individual time series and choose the best models to use to produce the final forecasts of each series.

`Fit Models Automatically`
: brings up the Automatic Model Fitting window for applying the automatic model selection process to all series or to selected series in an input data set.

`Produce Forecast`
: brings up the Produce Forecasts window for producing forecasts for the series in the current input data set for which you have fit forecasting models.

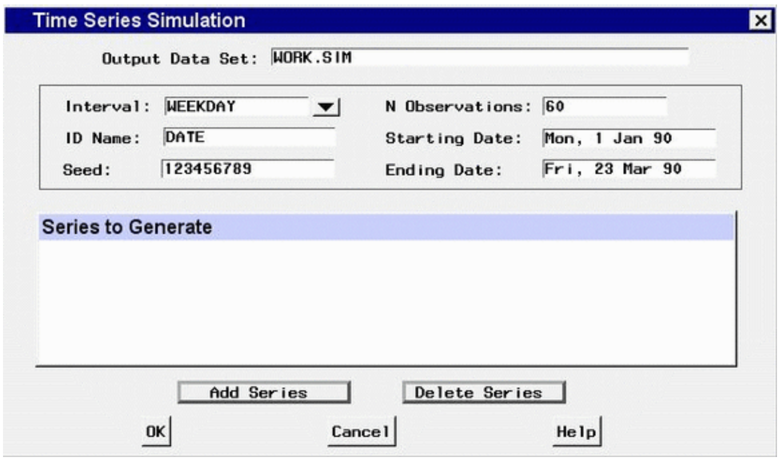
`Manage Projects`
: brings up the Manage Forecasting Project window for viewing or editing information stored in projects.

`Exit`
: closes the Time Series Forecasting system.

`Help`
: accesses the help system.

Time Series Simulation Window

Use the Time Series Simulation window to create a data set of simulated series generated by ARIMA processes. Access this window from the Tools pull-down menu in the Develop Models and Manage Forecasting Project windows.



Time Series Simulation

Output Data Set: WORK.SIM

Interval: WEEKDAY
ID Name: DATE
Seed: 123456789
N Observations: 60
Starting Date: Mon, 1 Jan 90
Ending Date: Fri, 23 Mar 90

Controls and Fields

`Output Data Set`
: is the name of the data set to be created. Type in a one or two level SAS data set name.

`Interval`
: is the time interval between observations (data frequency) in the simulated data set. Type in an interval name or select one from the popup list.

`Seed`
: is the seed for the random number generator used to produce the simulated time series.

`N Observations`
: is the number of time periods to simulate.

`Starting Date`
: is the starting date for the simulated observations. Type in a date in a form recognizable by a SAS data informat, for example, 1998:1, feb1997, or 03mar1998.

`Ending Date`
: is the ending date for the simulated observations. Type in a date in a form recognizable by a SAS data informat.

`Series to Generate`
: is the list of variable names and ARIMA processes to simulate.

`Add Series`
: brings up the ARIMA Process Specification window to enable you to add entries to the Series to Generate list.

`Delete Series`
: deletes selected (highlighted) entries from the Series to Generate list.

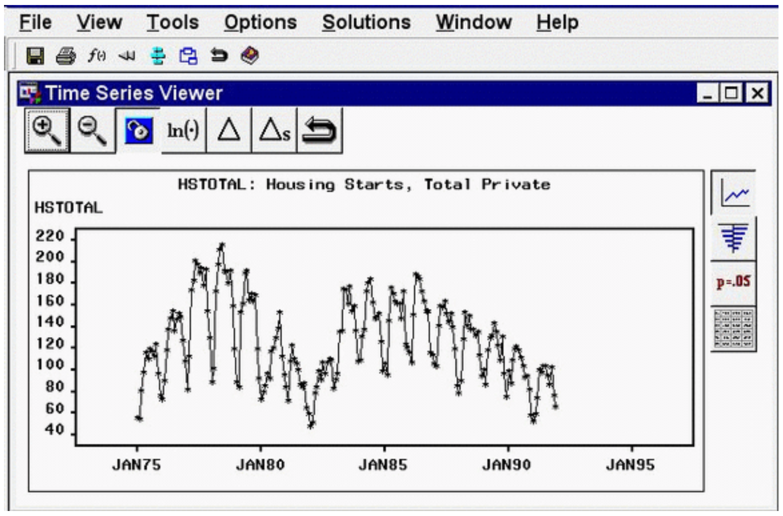
`OK`
: closes the Time Series Simulation window and performs the specified simulations and creates the specified data set.

`Cancel`
closes the window without creating a simulated data set. Any options you specified are lost.

Time Series Viewer Window

Use the Time Series Viewer window to explore time series data using plots, transformations, statistical tests, and tables. It is available as a stand-alone application and as part of the Time Series Forecasting System. To use it as a stand-alone application, select it from the Analysis submenu of the Solutions pull-down menu, or use the `tsview` command (see Chapter 39, "Command Reference," in this book). To use it within the Time Series Forecasting System, select the View Series Graphically icon in the Time Series Forecasting, Develop Models, or Model List window, or select "Series" from the View pull-down menu of the Develop Models, Manage Project, or Model List window.

The various plots and tables available are referred to as *views*. The following "View Selection Icons" section explains how to change the view.



The state of the Time Series Viewer window is controlled by the current series, the current series transformation specification, and the currently selected view. You can resize this window, and you can use other windows without closing the Time Series Viewer window. You can explore a number of series conveniently by keeping the Series Selection window open. Each time you make a selection, the viewer window is updated to show the selected series. Keep both windows visible, or switch between them using the Next Viewer tool bar icon or the F12 function key.

You can bring up multiple Time Series Viewer windows. This enables you to "freeze" a plot so you can come back to it later, or compare two plots side by side on your screen. To do this, unlink the viewer using the Link/Unlink icon on the window's tool bar or the corresponding item in the Tools pull-down menu. While the viewer window remains unlinked, it is not updated when other selections are made in the Series Selection window. Instead, when you select a series and click the Graph button, a new Time Series Viewer window is invoked. You can continue this process to bring up as many viewer windows as you want. The Next Viewer icon and corresponding F12 function key are useful for navigating between windows when they are not simultaneously visible on your screen.

A wide range of series transformations is available. Basic transformations are available from the window’s horizontal tool bar, and others are available by selecting “Other Transformations” from the Tools pull-down menu.

Horizontal Tool Bar

The Time Series Viewer window contains a horizontal tool bar with the following icons:

`Zoom in`
: changes the mouse cursor into cross hairs that you can use with the left mouse button to drag out a region of the time series plot to zoom in on. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom In reduces the number of lags displayed.

`Zoom out`
: reverses the previous Zoom In action and expands the time range of the plot to show more of the series. In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom Out increases the number of lags displayed.

`Link/Unlink viewer`
: disconnects or connects the Time Series Viewer window to the window in which the series was selected. When the Viewer is linked, it always shows the current series. If you select another series, linked Viewers are updated. Unlinking a Viewer freezes its current state, and changing the current series has no effect on the Viewer’s display. The View Series action creates a new Series Viewer window if there is no linked Viewer. By using the unlink feature, you can bring up several Time Series Viewer windows and display several different series simultaneously.

`Log Transform`
: applies a log transform to the current view. This can be combined with other transformations: The current transformations are shown in the title.

`Difference`
: applies a simple difference to the current view. This can be combined with other transformations: The current transformations are shown in the title.

`Seasonal Difference`
: applies a seasonal difference to the current view. For example, if the data are monthly, the seasonal cycle is one year. Each value has subtracted from it the value from one year previous. This can be combined with other transformations: The current transformations are shown in the title.

`Close`
: closes the Time Series Viewer window and returns to the window from which it was invoked.

Vertical Toolbar View Selection Icons

At the right-hand side of the Time Series Viewer window is a vertical tool bar used to select the kind of plot or table that the Viewer displays.

`Series`
: displays a plot of series values over time.

`Autocorrelations`
: displays plots of the sample autocorrelations, partial autocorrelation, and inverse autocorrelation functions for the series, with lines overlaid at plus and minus two standard errors.

`White Noise and Stationarity Tests`
: displays horizontal bar charts representing results of white noise and stationarity tests. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click on any of the bars to display an interpretation.

  The second bar chart shows tests of stationarity, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click on any of the bars to display an interpretation.

`Data Table`
: displays a data table containing the values in the input data set.

Menu Bar

`File`

  `Save Graph`
  : saves the current plot as a SAS/GRAPH grseg catalog entry in a default or most recently specified catalog. This item is grayed out in the Data Table view.

  `Save Graph as`
  : saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an html page is created, with the graph embedded as a gif image. This item is grayed out in the Data Table view.

  `Save Data`
  : saves the data displayed in the viewer window to an output SAS data set. This item is grayed out in the Series view.

  `Save Data as`
  : saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an html page is created, with the data displayed as a table.

  `Import Data`
  : is available if you license SAS/Access software. It brings up an

Import Wizard which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

`Export Data`
: is available if you license SAS/Access software. It brings up an Export Wizard which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

`Print Graph`
: prints the plot displayed in the viewer window. This item is grayed out in the Data Table view.

`Print Data`
: prints the data displayed in the viewer window. This item is grayed out in the Series view.

`Print Setup`
: brings up the Print Setup window, which allows you to access your operating system print setup.

`Print Preview`
: brings up a preview window to show how your plots will look when printed.

`Close`
: closes the Time Series Viewer window and returns to the window from which it was invoked.

`View`

`Series`
: displays a plot of series values over time. This is the same as the Series icon in the vertical tool bar.

`Autocorrelations`
: displays plots of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the series. This is the same as the Autocorrelations icon in the vertical tool bar.

`White Noise and Stationarity Tests`
: displays horizontal bar charts representing results of white noise and stationarity tests. This is the same as the White Noise and Stationarity Tests icon in the vertical tool bar.

`Data Table`
: displays a data table containing the values in the input data set. This is the same as the Data Table icon in the vertical tool bar.

`Zoom In`
: zooms the display. This is the same as the Zoom In icon in the window's horizontal tool bar.

`Zoom Out`
: undoes the last zoom in action. This is the same as the Zoom Out icon in the window's horizontal tool bar.

`Zoom Way Out`
: reverses all previous Zoom In actions and expands the time range of the plot to show all of the series, or shows the maximum number of

lags in the Autocorrelations View or the White Noise and Stationarity Tests view.

`Tools`

`Log Transform`
: applies a log transformation. This is the same as the Log Transform icon in the window's horizontal tool bar.

`Difference`
: applies simple differencing. This is the same as the Difference icon in the window's horizontal tool bar.

`Seasonal Difference`
: applies seasonal differencing. This is the same as the Seasonal Difference icon in the window's horizontal tool bar.

`Other Transformations`
: brings up the Series Viewer Transformations window to enable you to apply a wide range of transformations.

`Diagnose Series`
: brings up the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

`Define Interventions`
: brings up the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

`Link Viewer`
: connects or disconnects the Time Series Viewer window to the window from which series are selected. This is the same as the Link item in the window's horizontal tool bar.

`Options`

`Number of Lags`
: brings up a window to let you specify the number of lags shown in the Autocorrelations view and the White Noise and Stationarity Tests view. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

`Correlation Probabilities`
: controls whether the bar charts in the Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Mouse Button Actions

You can examine the data value and date of individual points in the Series view by positioning the mouse cursor over the point and clicking the left mouse button. The date and value are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

You can examine the values of the bars and confidence limits at different lags in the Autocorrelations view by clicking on individual bars in the vertical bar charts.

You can display an interpretation of the tests in the White Noise and Stationarity Tests view by clicking on the bars.

When you select the Zoom In action, you can use the mouse to define a region of the graph to take a closer look at. Position the mouse cursor at one corner of the region, press the left mouse button, and move the mouse cursor to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

Chapter 41
Forecasting Details

Chapter Contents

Chapter 41
Forecasting Process Details

This chapter provides computational details on several aspects of the Time Series Forecasting System.

Forecasting Process Summary

This section summarizes the forecasting process.

Parameter Estimation

The parameter estimation process for ARIMA and smoothing models is described graphically in Figure 41.1.

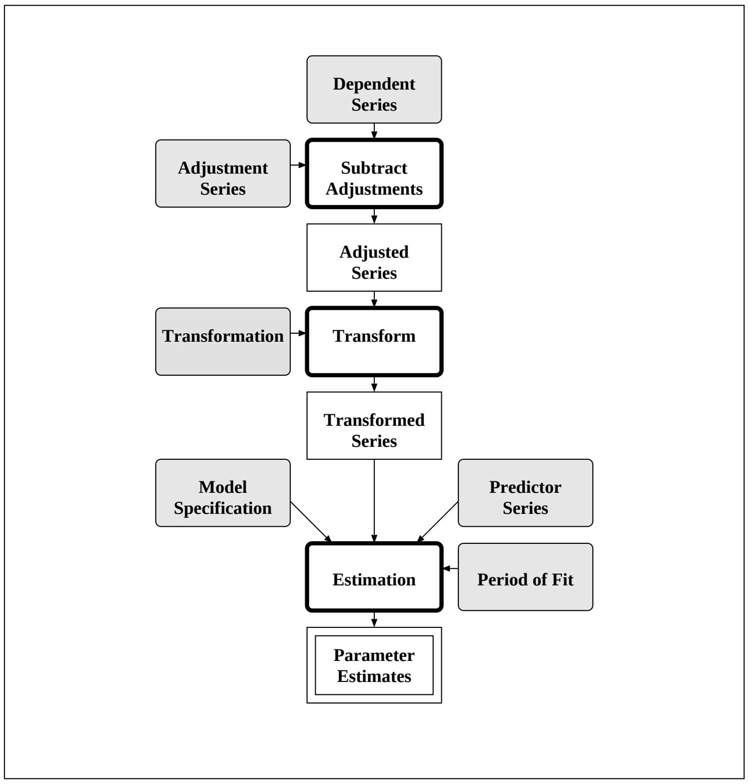


Figure 41.1. Model Fitting Flow Diagram

The specification of smoothing and ARIMA models is described in Chapter 36, “Specifying Forecasting Models.” Computational details for these kinds of models are provided in the following sections "Smoothing Models" and "ARIMA Models." The results of the parameter estimation process are displayed in the Parameter Estimates table of the Model Viewer window along with the estimate of the model variance and the final smoothing state.

Model Evaluation

The model evaluation process is described graphically in Figure 41.2.

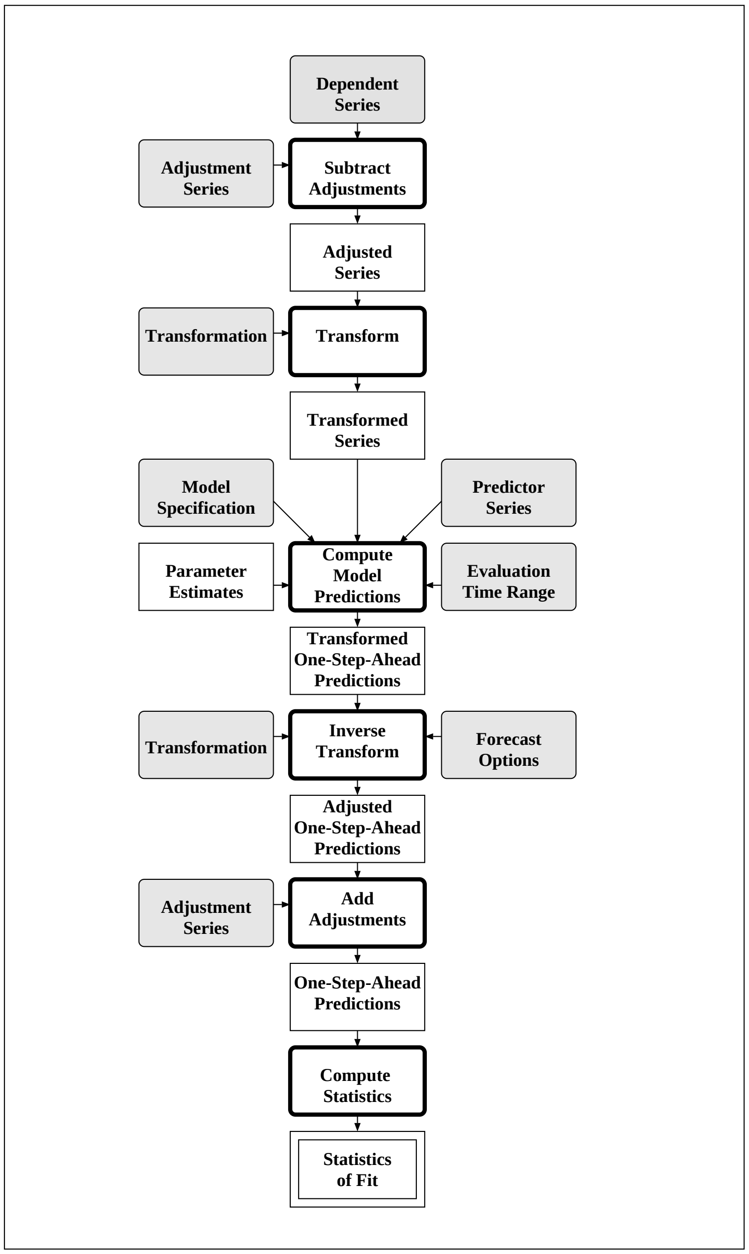

Figure 41.2. Model Evaluation Flow Diagram

Model evaluation is based on the one-step-ahead prediction errors for observations within the period of evaluation. The one-step-ahead predictions are generated from the model specification and parameter estimates. The predictions are inverse transformed (median or mean) and adjustments are removed. The prediction errors (the difference of the dependent series and the predictions) are used to compute the statistics of fit, which are described in the following section "Diagnostic Tests and Statistics of Fit." The results generated by the evaluation process are displayed in the Statistics of Fit table of the Model Viewer window.

Forecasting

The forecasting generation process is described graphically in Figure 41.3.

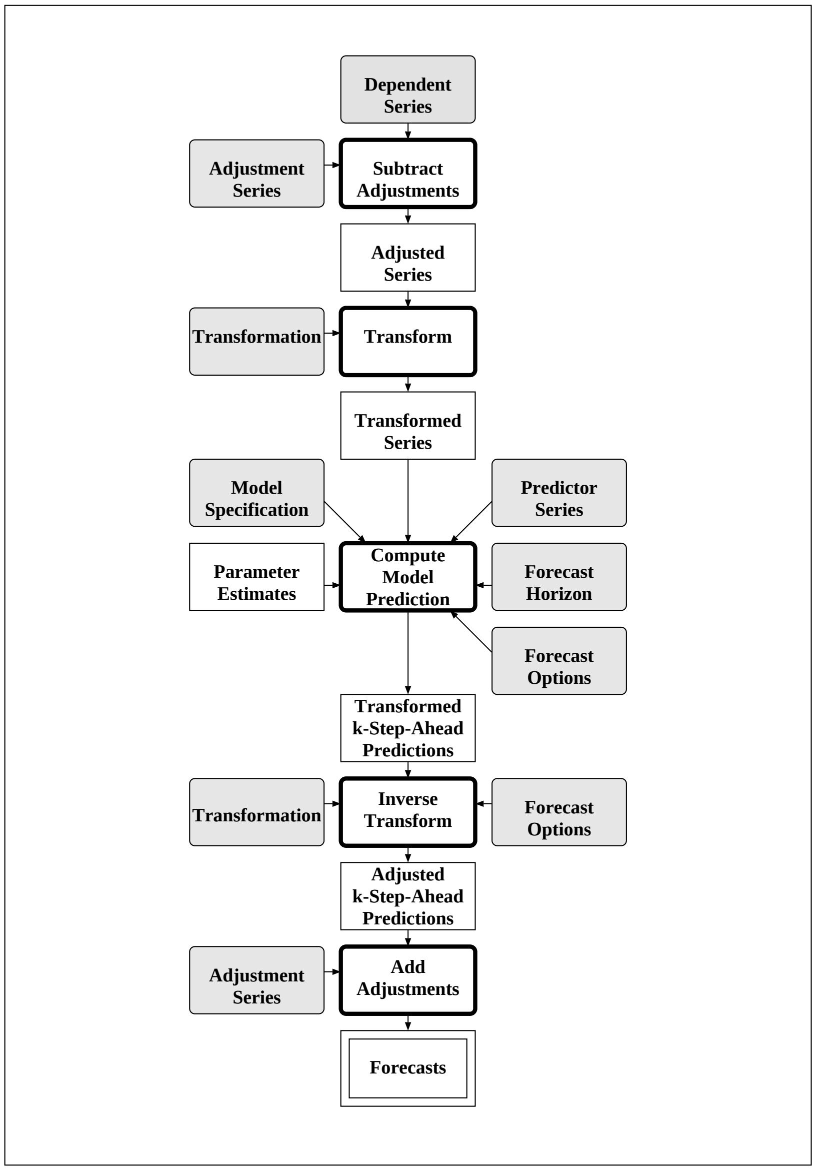

Figure 41.3. Forecasting Flow Diagram

The forecasting process is similar to the model evaluation process described in the preceding section, except that *k*-step-ahead predictions are made from the end of the data through the specified forecast horizon, and prediction standard errors and confidence limits are calculated. The forecasts and confidence limits are displayed in the Forecast plot or table of the Model Viewer window.

Forecast Combination Models

This section discusses the computation of predicted values and confidence limits for forecast combination models. See Chapter 36, "Specifying Forecasting Models," for information on how to specify forecast combination models and their combining weights.

Given the response time series $\{y_t : 1 \leq t \leq n\}$ with previously generated forecasts for the *m* component models, a combined forecast is created from the component forecasts as follows:

Predictions:	$\hat{y}_t = \sum_{i=1}^{m} w_i \hat{y}_{i,t}$
Prediction Errors:	$\hat{e}_t = y_t - \hat{y}_t$

where $\hat{y}_{i,t}$ are the forecasts of the component models and w_i are the combining weights.

The estimate of the root mean square prediction error and forecast confidence limits for the combined forecast are computed by assuming independence of the prediction errors of the component forecasts, as follows:

Standard Errors:	$\hat{\sigma}_t = \sqrt{\sum_{i=1}^{m} w_i^2 \hat{\sigma}_{i,t}^2}$
Confidence Limits:	$\pm \hat{\sigma}_t \mathrm{Z}_{\alpha/2}$

where $\hat{\sigma}_{i,t}$ are the estimated root mean square prediction errors for the component models, α is the confidence limit width, $1 - \alpha$ is the confidence level, and $\mathrm{Z}_{\alpha/2}$ is the $\frac{\alpha}{2}$ quantile of the standard normal distribution.

Since, in practice, there may be positive correlation between the prediction errors of the component forecasts, these confidence limits may be too narrow.

External or User-Supplied Forecasts

This section discusses the computation of predicted values and confidence limits for external forecast models.

Given a response time series y_t and external forecast series $\hat{y}_t$, the prediction errors are computed as $\hat{e}_t = y_t - \hat{y}_t$ for those *t* for which both y_t and $\hat{y}_t$ are nonmissing. The mean square error (MSE) is computed from the prediction errors.

The variance of the *k*-step-ahead prediction errors is set to *k* times the MSE. From these variances, the standard errors and confidence limits are computed in the usual way. If the supplied predictions contain so many missing values within the time range of the response series that the MSE estimate cannot be computed, the confidence limits, standard errors, and statistics of fit are set to missing.

Adjustments

Adjustment predictors are subtracted from the response time series prior to model parameter estimation, evaluation, and forecasting. After the predictions of the adjusted response time series are obtained from the forecasting model, the adjustments are added back to produce the forecasts.

If y_t is the response time series and $X_{i,t}$, $1 \leq i \leq m$ are *m* adjustment predictor series, then the adjusted response series w_t is

$$w_t = y_t - \sum_{i=1}^{m} X_{i,t}$$

Parameter estimation for the model is performed using the adjusted response time series w_t. The forecasts $\hat{w}_t$ of w_t are adjusted to obtain the forecasts $\hat{y}_t$ of y_t.

$$\hat{y}_t = \hat{w}_t + \sum_{i=1}^{m} X_{i,t}$$

Missing values in an adjustment series are ignored in these computations.

Series Transformations

For pure ARIMA models, transforming the response time series may aid in obtaining stationary noise series. For general ARIMA models with inputs, transforming the response time series or one or more of the input time series may provide a better model fit. Similarly, the fit of smoothing models may improve when the response series is transformed.

There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log — is the logarithmic transformation.

$$w_t = \ln(\mathrm{y_t})$$

Logistic — is the logistic transformation.

$$w_t = \ln(\mathrm{cy_t}/(1 - \mathrm{cy_t}))$$

where the scaling factor c is

$$c = (1 - 10^{-6})10^{-\mathrm{ceil}(\log_{10}(\max(\mathrm{y_t})))}$$

and $\mathrm{ceil}(\mathrm{x})$ is the smallest integer greater than or equal to *x*.

Square Root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^\lambda - 1}{\lambda}, & \lambda \neq 0 \\ \ln(\mathrm{y_t}), & \lambda = 0 \end{cases}$$

Parameter estimation is performed using the transformed series. The transformed model predictions and confidence limits are then obtained from the transformed time-series and these parameter estimates.

The transformed model predictions $\hat{w}_t$ are used to obtain either the minimum mean absolute error (MMAE) or minimum mean squared error (MMSE) predictions $\hat{y}_t$, depending on the setting of the forecast options. The model is then evaluated based on the residuals of the original time series and these predictions. The transformed model confidence limits are inverse-transformed to obtain the forecast confidence limits.

Predictions for Transformed Models

Since the transformations described in the previous section are monotonic, applying the inverse-transformation to the transformed model predictions results in the *median* of the conditional probability density function at each point in time. This is the minimum mean absolute error (MMAE) prediction.

If $w_t = \mathrm{F(y_t)}$ is the transform with inverse-transform $y_t = \mathrm{F^{-1}(w_t)}$, then

$$\mathrm{median(\hat{y}_t) = F^{-1}(E\left[w_t\right]) = F^{-1}(\hat{w}_t)}$$

The minimum mean squared error (MMSE) predictions are the *mean* of the conditional probability density function at each point in time. Assuming that the prediction errors are normally distributed with variance σ_t^2, the MMSE predictions for each of the transformations are as follows:

Log is the conditional expectation of inverse-logarithmic transformation.

$$\hat{y}_t = E[e^{w_t}] = \exp\left(\mathrm{\hat{w}_t} + \sigma_\mathrm{t}^2/2\right)$$

Logistic is the conditional expectation of inverse-logistic transformation.

$$\hat{y}_t = E\left[\frac{1}{c(1+exp(-w_t))}\right]$$

where the scaling factor $c = (1 - e^{-6})10^{-\mathrm{ceil}(\log_{10}(\max(\mathrm{y_t})))}$.

Square Root is the conditional expectation of the inverse-square root transformation.

$$\hat{y}_t = E\left[w_t^2\right] = \hat{w}_t^2 + \sigma_t^2$$

Box Cox is the conditional expectation of the inverse Box-Cox transformation.

$$\hat{y}_t = \begin{cases} E\left[(\lambda w_t + 1)^{1/\lambda}\right], & \lambda{\neq}0 \\ E\left[e^{w_t}\right] = \exp(\hat{\mathrm{w}}_{\mathrm{t}} + \frac{1}{2}\sigma_{\mathrm{t}}^2), & \lambda = 0 \end{cases}$$

The expectations of the inverse logistic and Box-Cox ($\lambda{\neq}0$) transformations do not generally have explicit solutions and are computed using numerical integration.

Smoothing Models

This section details the computations performed for the exponential smoothing and Winters method forecasting models.

Smoothing Model Calculations

The descriptions and properties of various smoothing methods can be found in Gardner (1985), Chatfield (1978), and Bowerman and O'Connell (1979). The following section summarizes the smoothing model computations.

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the underlying model assumed by the smoothing models has the following (additive seasonal) form:

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

where

μ_t	represents the time-varying mean term.
β_t	represents the time-varying slope.
$s_p(t)$	represents the time-varying seasonal contribution for one of the p seasons
ϵ_t	are disturbances.

For smoothing models without trend terms, $\beta_t = 0$; and for smoothing models without seasonal terms, $s_p(t) = 0$. Each smoothing model is described in the following sections.

At each time t, the smoothing models estimate the time-varying components described above with the *smoothing state*. After initialization, the smoothing state is updated for each observation using the *smoothing equations*. The smoothing state at the last nonmissing observation is used for predictions.

Smoothing State and Smoothing Equations

Depending on the smoothing model, the *smoothing state* at time t will consist of the following:

L_t is a smoothed level that estimates μ_t.

T_t is a smoothed trend that estimates β_t.

S_{t-j}, $j = 0, \ldots, p-1$, are seasonal factors that estimate $s_p(t)$.

The smoothing process starts with an initial estimate of the smoothing state, which is subsequently updated for each observation using the *smoothing equations*.

The smoothing equations determine how the smoothing state changes as time progresses. Knowledge of the smoothing state at time $t-1$ and that of the time-series value at time t uniquely determine the smoothing state at time t. The *smoothing weights* determine the contribution of the previous smoothing state to the current smoothing state. The smoothing equations for each smoothing model are listed in the following sections.

Smoothing State Initialization

Given a time series $\{Y_t : 1 \leq t \leq n\}$, the smoothing process first computes the smoothing state for time $t = 1$. However, this computation requires an initial estimate of the smoothing state at time $t = 0$, even though no data exists at or before time $t = 0$.

An appropriate choice for the initial smoothing state is made by backcasting from time $t = n$ to $t = 1$ to obtain a prediction at $t = 0$. The initialization for the backcast is obtained by regression with constant and linear terms and seasonal dummies (additive or multiplicative) as appropriate for the smoothing model. For models with linear or seasonal terms, the estimates obtained by the regression are used for initial smoothed trend and seasonal factors; however, the initial smoothed level for backcasting is always set to the last observation, Y_n.

The smoothing state at time $t = 0$ obtained from the backcast is used to initialize the smoothing process from time $t = 1$ to $t = n$ (refer to Chatfield and Yar 1988).

For models with seasonal terms, the smoothing state is normalized so that the seasonal factors S_{t-j} for $j = 0, \ldots, p-1$ sum to zero for models that assume additive seasonality and average to one for models (such as Winters method) that assume multiplicative seasonality.

Missing Values

When a missing value is encountered at time t, the smoothed values are updated using the *error-correction form* of the smoothing equations with the one-step-ahead prediction error, e_t, set to zero. The missing value is estimated using the one-step-ahead prediction at time $t-1$, that is $\hat{Y}_{t-1}(1)$ (refer to Aldrin 1989). The error-correction forms of each of the smoothing models are listed in the following sections.

Predictions and Prediction Errors

Predictions are made based on the last known smoothing state. Predictions made at time t for k steps ahead are denoted $\hat{Y}_t(k)$ and the associated prediction errors are denoted $e_t(k) = Y_{t+k} - \hat{Y}_t(k)$. The *prediction equation* for each smoothing model is listed in the following sections.

The *one-step-ahead predictions* refer to predictions made at time $t - 1$ for one time unit into the future, that is, $\hat{Y}_{t-1}(1)$, and the *one-step-ahead prediction errors* are more simply denoted $e_t = e_{t-1}(1) = Y_t - \hat{Y}_{t-1}(1)$. The one-step-ahead prediction errors are also the model residuals, and the sum of squares of the one-step-ahead prediction errors is the objective function used in smoothing weight optimization.

The *variance of the prediction errors* are used to calculate the confidence limits (refer to Sweet 1985, McKenzie 1986, Yar and Chatfield 1990, and Chatfield and Yar 1991). The equations for the variance of the prediction errors for each smoothing model are listed in the following sections.

Note: $var(\epsilon_t)$ is estimated by the mean square of the one-step-ahead prediction errors.

Smoothing Weights

Depending on the smoothing model, the smoothing weights consist of the following:

α	is a level smoothing weight.
γ	is a trend smoothing weight.
δ	is a seasonal smoothing weight.
ϕ	is a trend damping weight.

Larger smoothing weights (less damping) permit the more recent data to have a greater influence on the predictions. Smaller smoothing weights (more damping) give less weight to recent data.

Specifying the Smoothing Weights

Typically the smoothing weights are chosen to be from zero to one. (This is intuitive because the weights associated with the past smoothing state and the value of current observation would normally sum to one.) However, each smoothing model (except Winters Method – Multiplicative Version) has an ARIMA equivalent. Weights chosen to be within the ARIMA additive-invertible region will guarantee stable predictions (refer to Archibald 1990 and Gardner 1985). The ARIMA equivalent and the additive-invertible region for each smoothing model are listed in the following sections.

Optimizing the Smoothing Weights

Smoothing weights are determined so as to minimize the sum of squared one-step-ahead prediction errors. The optimization is initialized by choosing from a predetermined grid the initial smoothing weights that result in the smallest sum of squared, one-step-ahead prediction errors. The optimization process is highly dependent on this initialization. It is possible that the optimization process will fail due to the inability to obtain stable initial values for the smoothing weights (refer to Greene 1993 and Judge et al 1980), and it is possible for the optimization to result in a local minima.

The optimization process can result in weights to be chosen outside both the zero-to-one range and the ARIMA additive-invertible region. By restricting weight optimization to additive-invertible region, you can obtain a local minimum with stable predictions. Likewise, weight optimization can be restricted to the zero-to-one range or other ranges. It is also possible to fix certain weights to a specific value and optimize the remaining weights.

Standard Errors

The standard errors associated with the smoothing weights are calculated from the Hessian matrix of the sum of squared, one-step-ahead prediction errors with respect to the smoothing weights used in the optimization process.

Weights Near Zero or One

Sometimes the optimization process results in weights near zero or one.

For Simple or Double (Brown) Exponential Smoothing, a level weight near zero implies that simple differencing of the time series may be appropriate.

For Linear (Holt) Exponential Smoothing, a level weight near zero implies that the smoothed trend is constant and that an ARIMA model with deterministic trend may be a more appropriate model.

For Damped-Trend Linear Exponential Smoothing, a damping weight near one implies that Linear (Holt) Exponential Smoothing may be a more appropriate model.

For Winters Method and Seasonal Exponential Smoothing, a seasonal weight near one implies that a nonseasonal model may be more appropriate and a seasonal weight near zero implies that deterministic seasonal factors may be present.

Equations for the Smoothing Models

Simple Exponential Smoothing

The model equation for simple exponential smoothing is

$$Y_t = \mu_t + \epsilon_t$$

The smoothing equation is

$$L_t = \alpha Y_t + (1 - \alpha) L_{t-1}$$

The error-correction form of the smoothing equation is

$$L_t = L_{t-1} + \alpha e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t$$

The ARIMA model equivalency to simple exponential smoothing is the ARIMA(0,1,1) model

$$(1 - B)Y_t = (1 - \theta B)\epsilon_t$$

$$\theta = 1 - \alpha$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \alpha \epsilon_{t-j}$$

For simple exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} \alpha^2 \right] = var(\epsilon_t)(1 + (k-1)\alpha^2)$$

Double (Brown) Exponential Smoothing

The model equation for double exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha Y_t + (1 - \alpha)L_{t-1}$$

$$T_t = \alpha(L_t - L_{t-1}) + (1 - \alpha)T_{t-1}$$

This method may be equivalently described in terms of two successive applications of simple exponential smoothing:

$$S_t^{[1]} = \alpha Y_t + (1 - \alpha)S_{t-1}^{[1]}$$

$$S_t^{[2]} = \alpha S_t^{[1]} + (1-\alpha) S_{t-1}^{[2]}$$

where $S_t^{[1]}$ are the smoothed values of Y_t, and $S_t^{[2]}$ are the smoothed values of $S_t^{[1]}$. The prediction equation then takes the form:

$$\hat{Y}_t(k) = (2 + \alpha k/(1-\alpha)) S_t^{[1]} - (1 + \alpha k/(1-\alpha)) S_t^{[2]}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t$$

$$T_t = T_{t-1} + \alpha^2 e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t + ((k-1) + 1/\alpha) T_t$$

The ARIMA model equivalency to double exponential smoothing is the ARIMA(0,2,2) model

$$(1-B)^2 Y_t = (1-\theta B)^2 \epsilon_t$$

$$\theta = 1 - \alpha$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (2\alpha + (j-1)\alpha^2) \epsilon_{t-j}$$

For double exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t) \left[1 + \sum_{j=1}^{k-1} (2\alpha + (j-1)\alpha^2)^2 \right]$$

Linear (Holt) Exponential Smoothing

The model equation for linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha Y_t + (1 - \alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t$$

$$T_t = T_{t-1} + \alpha\gamma e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t$$

The ARIMA model equivalency to linear exponential smoothing is the ARIMA(0,2,2) model

$$(1 - B)^2 Y_t = (1 - \theta_1 B - \theta_2 B^2)\epsilon_t$$

$$\theta_1 = 2 - \alpha - \alpha\gamma$$

$$\theta_2 = \alpha - 1$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + j\alpha\gamma)\epsilon_{t-j}$$

For linear exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

$$\{0 < \gamma < 4/\alpha - 2\}$$

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t)\left[1 + \sum_{j=1}^{k-1} (\alpha + j\alpha\gamma)^2\right]$$

Damped-Trend Linear Exponential Smoothing

The model equation for damped-trend linear exponential smoothing is

$$Y_t = \mu_t + \beta_t t + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha Y_t + (1-\alpha)(L_{t-1} + \phi T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1-\gamma)\phi T_{t-1}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \phi T_{t-1} + \alpha e_t$$

$$T_t = \phi T_{t-1} + \alpha\gamma e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t + \sum_{i=1}^{k} \phi^i T_t$$

The ARIMA model equivalency to damped-trend linear exponential smoothing is the ARIMA(1,1,2) model

$$(1-\phi B)(1-B)Y_t = (1-\theta_1 B - \theta_2 B^2)\epsilon_t$$

$$\theta_1 = 1 + \phi - \alpha - \alpha\gamma\phi$$

$$\theta_2 = (\alpha - 1)\phi$$

The moving-average form of the equation (assuming $|\phi| < 1$) is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + \alpha\gamma\phi(\phi^j - 1)/(\phi - 1))\epsilon_{t-j}$$

For damped-trend linear exponential smoothing, the additive-invertible region is

$$\{0 < \alpha < 2\}$$

$$\{0 < \phi\gamma < 4/\alpha - 2\}$$

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t)\left[1 + \sum_{j=1}^{k-1} (\alpha + \alpha\gamma\phi(\phi^j - 1)/(\phi - 1))^2\right]$$

Seasonal Exponential Smoothing

The model equation for seasonal exponential smoothing is

$$Y_t = \mu_t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t - S_{t-p}) + (1 - \alpha)L_{t-1}$$

$$S_t = \delta(Y_t - L_t) + (1 - \delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + \alpha e_t$$

$$S_t = S_{t-p} + \delta(1 - \alpha)e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t + S_{t-p+k}$$

The ARIMA model equivalency to seasonal exponential smoothing is the ARIMA(0,1,p+1)(0,1,0)$_p$ model

$$(1 - B)(1 - B^p)Y_t = (1 - \theta_1 B - \theta_2 B^p - \theta_3 B^{p+1})\epsilon_t$$

$$\theta_1 = 1 - \alpha$$

$$\theta_2 = 1 - \delta(1 - \alpha)$$

$$\theta_3 = (1 - \alpha)(\delta - 1)$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j}$$

$$\psi_j = \begin{cases} \alpha & \text{for } j \bmod p \neq 0 \\ \alpha + \delta(1-\alpha) & \text{for } j \bmod p = 0 \end{cases}$$

For seasonal exponential smoothing, the additive-invertible region is

$$\{\max(-p\alpha, 0) < \delta(1-\alpha) < (2-\alpha)\}$$

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t)\left[1 + \sum_{j=1}^{k-1} \psi_j^2\right]$$

Winters Method – Additive Version

The model equation for the additive version of Winters method is

$$Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t - S_{t-p}) + (1-\alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1-\gamma)T_{t-1}$$

$$S_t = \delta(Y_t - L_t) + (1-\delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t$$

$$T_t = T_{t-1} + \alpha\gamma e_t$$

$$S_t = S_{t-p} + \delta(1-\alpha)e_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = L_t + kT_t + S_{t-p+k}$$

The ARIMA model equivalency to the additive version of Winters method is the ARIMA(0,1,p+1)(0,1,0)$_p$ model

$$(1-B)(1-B^p)Y_t = \left[1 - \sum_{i=1}^{p+1} \theta_i B^i\right] \epsilon_t$$

$$\theta_j = \begin{cases} 1-\alpha-\alpha\gamma & j=1 \\ -\alpha\gamma & 2 \le j \le p-1 \\ 1-\alpha\gamma-\delta(1-\alpha) & j=p \\ (1-\alpha)(\delta-1) & j=p+1 \end{cases}$$

The moving-average form of the equation is

$$Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j}$$

$$\psi_j = \begin{cases} \alpha + j\alpha\gamma & \text{for } j \text{ mod } p \neq 0 \\ \alpha + j\alpha\gamma + \delta(1-\alpha), & \text{for } j \text{ mod } p = 0 \end{cases}$$

For the additive version of Winters method (see Archibald 1990), the additive-invertible region is

$$\{\max(-\mathrm{p}\alpha, 0) < \delta(1-\alpha) < (2-\alpha)\}$$

$$\{0 < \alpha\gamma < 2 - \alpha - \delta(1-\alpha)(1-cos(\vartheta)\}$$

where ϑ is the smallest nonnegative solution to the equations listed in Archibald (1990).

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t)\left[1 + \sum_{j=1}^{k-1} \psi_j^2\right]$$

Winters Method – Multiplicative Version

In order to use the multiplicative version of Winters method, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of Winters method is

$$Y_t = (\mu_t + \beta_t t)s_p(t) + \epsilon_t$$

The smoothing equations are

$$L_t = \alpha(Y_t/S_{t-p}) + (1-\alpha)(L_{t-1} + T_{t-1})$$

$$T_t = \gamma(L_t - L_{t-1}) + (1-\gamma)T_{t-1}$$

$$S_t = \delta(Y_t/L_t) + (1-\delta)S_{t-p}$$

The error-correction form of the smoothing equations is

$$L_t = L_{t-1} + T_{t-1} + \alpha e_t/S_{t-p}$$

$$T_t = T_{t-1} + \alpha\gamma e_t/S_{t-p}$$

$$S_t = S_{t-p} + \delta(1-\alpha)e_t/L_t$$

(Note: For missing values, $e_t = 0$.)

The *k*-step prediction equation is

$$\hat{Y}_t(k) = (L_t + kT_t)S_{t-p+k}$$

The multiplicative version of Winters method does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of Winters method described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

$$var(e_t(k)) = var(\epsilon_t)\left[\sum_{i=0}^{\infty}\sum_{j=0}^{p-1}(\psi_{j+ip}S_{t+k}/S_{t+k-j})^2\right]$$

where ψ_j are as described for the additive version of Winters method, and $\psi_j = 0$ for $j \geq k$.

ARIMA Models

Auto**R**egressive **I**ntegrated **M**oving-**A**verage, or *ARIMA*, models predict values of a dependent time series with a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series (predictor time series).

The Time Series Forecasting System uses the ARIMA procedure of SAS/ETS software to fit and forecast ARIMA models. The maximum likelihood method is used for parameter estimation. Refer to Chapter 11, "The ARIMA Procedure," for details of ARIMA model estimation and forecasting.

This section summarizes the notation used for ARIMA models.

Notation for ARIMA Models

A dependent time series that is modeled as a linear combination of its own past values and past values of an error series is known as a (pure) ARIMA model.

Nonseasonal ARIMA Model Notation

The order of an ARIMA model is usually denoted by the notation ARIMA(*p*,*d*,*q*), where

p	is the order of the autoregressive part.
d	is the order of the differencing (rarely should $d > 2$ be needed).
q	is the order of the moving-average process.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA model is written as

$$(1-B)^d Y_t = \mu + \frac{\theta(B)}{\phi(B)} a_t$$

where

t	indexes time
μ	is the mean term
B	is the backshift operator; that is, $BX_t = X_{t-1}$
$\phi(B)$	is the autoregressive operator, represented as a polynomial in the back shift operator: $\phi(B) = 1 - \phi_1 B - \ldots - \phi_p B^p$
$\theta(B)$	is the moving-average operator, represented as a polynomial in the back shift operator: $\theta(B) = 1 - \theta_1 B - \ldots - \theta_q B^q$
a_t	is the independent disturbance, also called the random error.

For example, the mathematical form of the ARIMA(1,1,2) model is

$$(1-B)Y_t = \mu + \frac{(1 - \theta_1 B - \theta_2 B^2)}{(1 - \phi_1 B)} a_t$$

Seasonal ARIMA Model Notation

Seasonal ARIMA models are expressed in factored form by the notation ARIMA(p,d,q)(P,D,Q)$_s$, where

P	is the order of the seasonal autoregressive part
D	is the order of the seasonal differencing (rarely should D > 1 be needed)
Q	is the order of the seasonal moving-average process
s	is the length of the seasonal cycle.

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA seasonal model is written as

$$(1-B)^d(1-B^s)^D Y_t = \mu + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)} a_t$$

where

$\phi_s(B^s)$	is the seasonal autoregressive operator, represented as a polynomial in the back shift operator: $\phi_s(B^s) = 1 - \phi_{s,1}B^s - \ldots - \phi_{s,P}B^{sP}$
$\theta_s(B^s)$	is the seasonal moving-average operator, represented as a polynomial in the back shift operator: $\theta_s(B^s) = 1 - \theta_{s,1}B^s - \ldots - \theta_{s,Q}B^{sQ}$

For example, the mathematical form of the ARIMA(1,0,1)(1,1,2)$_{12}$ model is

$$(1-B^{12})Y_t = \mu + \frac{(1-\theta_1 B)(1-\theta_{s,1}B^{12} - \theta_{s,2}B^{24})}{(1-\phi_1 B)(1-\phi_{s,1}B^{12})} a_t$$

Abbreviated Notation for ARIMA Models

If the differencing order, autoregressive order, or moving-average order is zero, the notation is further abbreviated as

I(d)(D)$_s$	integrated model or ARIMA(0,d,0)(0,D,0)
AR(p)(P)$_s$	autoregressive model or ARIMA(p,0,0)(P,0,0)
IAR(p,d)(P,D)$_s$	integrated autoregressive model or ARIMA(p,d,0)(P,D,0)$_s$
MA(q)(Q)$_s$	moving average model or ARIMA(0,0,q)(0,0,Q)$_s$
IMA(d,q)(D,Q)$_s$	integrated moving average model or ARIMA(0,d,q)(0,D,Q)$_s$
ARMA(p,q)(P,Q)$_s$	autoregressive moving-average model or ARIMA(p,0,q)(P,0,Q)$_s$.

Notation for Transfer Functions

A transfer function can be used to filter a predictor time series to form a dynamic regression model.

Let Y_t be the dependent series, and let X_t be the predictor series, and let $\Psi(B)$ be a linear filter or transfer function for the effect of X_t on Y_t. The ARIMA model is then

$$(1-B)^d(1-B^s)^D Y_t = \mu + \Psi(B)(1-B)^d(1-B^s)^D X_t + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)}a_t$$

This model is called a *dynamic regression* of Y_t on X_t.

Nonseasonal Transfer Function Notation

Given the *i*th predictor time series $\{X_{i,t} : 1 \leq t \leq n\}$, the transfer function is written as [Dif(d_i)Lag(k_i)N(q_i)/ D(p_i)] where

d_i	is the simple order of the differencing for the *i*th predictor time series, $(1-B)^{d_i}X_{i,t}$ (rarely should d_i > 2 be needed).
k_i	is the pure time delay (lag) for the effect of the *i*th predictor time series, $X_{i,t}B^{k_i} = X_{i,t-k_i}$.
p_i	is the simple order of the denominator for the *i*th predictor time series.
q_i	is the simple order of the numerator for the *i*th predictor time series.

The mathematical notation used to describe a transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)}{\delta_i(B)}(1-B)^{d_i}B^{k_i}$$

where

B	is the backshift operator; that is, $BX_t = X_{t-1}$.
$\delta_i(B)$	is the denominator polynomial of the transfer function for the *i*th predictor time series: $\delta_i(B) = 1 - \delta_{i,1}B - \ldots - \delta_{i,p_i}B^{p_i}$.
$\omega_i(B)$	is the numerator polynomial of the transfer function for the *i*th predictor time series: $\omega_i(B) = 1 - \omega_{i,1}B - \ldots - \omega_{i,q_i}B^{q_i}$.

The numerator factors for a transfer function for a predictor series are like the MA part of the ARMA model for the noise series. The denominator factors for a transfer function for a predictor series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

For example, the transfer function for the *i*th predictor time series with

$k_i = 3$	time lag is 3
$d_i = 1$	simple order of differencing is one
$p_i = 1$	simple order of the denominator is one
$q_i = 2$	simple order of the numerator is two

would be written as [Dif(1)Lag(3)N(2)/D(1)]. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = \frac{(1-\omega_{i,1}B-\omega_{i,2}B^2)}{(1-\delta_{i,1}B)}(1-B)B^3$$

Seasonal Transfer Function Notation

The general transfer function notation for the *i*th predictor time series $X_{i,t}$ with seasonal factors is [Dif(d_i)(D_i)$_s$ Lag(k_i) N(q_i)(Q_i)$_s$/ D(p_i)(P_i)$_s$] where

D_i	is the seasonal order of the differencing for the *i*th predictor time series (rarely should $D_i > 1$ be needed).
P_i	is the seasonal order of the denominator for the *i*th predictor time series (rarely should $P_i > 2$ be needed).
Q_i	is the seasonal order of the numerator for the *i*th predictor time series, (rarely should $Q_i > 2$ be needed).
s	is the length of the seasonal cycle.

The mathematical notation used to describe a seasonal transfer function is

$$\Psi_i(B) = \frac{\omega_i(B)\omega_{s,i}(B^s)}{\delta_i(B)\delta_{s,i}(B^s)}(1-B)^{d_i}(1-B^s)^{D_i}B^{k_i}$$

where

$\delta_{s,i}(B^s)$	is the denominator seasonal polynomial of the transfer function for the *i*th predictor time series: $\delta_{s,i}(B) = 1-\delta_{s,i,1}B - \ldots - \delta_{s,i,P_i}B^{sP_i}$
$\omega_{s,i}(B^s)$	is the numerator seasonal polynomial of the transfer function for the *i*th predictor time series: $\omega_{s,i}(B) = 1-\omega_{s,i,1}B - \ldots - \omega_{s,i,Q_i}B^{sQ_i}$

For example, the transfer function for the *i*th predictor time series $X_{i,t}$ whose seasonal cycle $s = 12$ with

$d_i = 2$	simple order of differencing is two
$D_i = 1$	seasonal order of differencing is one
$q_i = 2$	simple order of the numerator is two

$Q_i = 1$	seasonal order of the numerator is one

would be written as [Dif(2)(1)$_s$ N(2)(1)$_s$]. The mathematical notation for the transfer function in this example is

$$\Psi_i(B) = (1 - \omega_{i,1}B - \omega_{i,2}B^2)(1 - \omega_{s,i,1}B^{12})(1-B)^2(1-B^{12})$$

Note: In this case, [Dif(2)(1)$_s$ N(2)(1)$_s$] = [Dif(2)(1)$_s$Lag(0)N(2)(1)$_s$/D(0)(0)$_s$].

Predictor Series

This section discusses time trend curves, seasonal dummies, interventions, and adjustments.

Time Trend Curves

When you specify a time trend curve as a predictor in a forecasting model, the system computes a predictor series that is a deterministic function of time. This variable is then included in the model as a regressor, and the trend curve is fit to the dependent series by linear regression, in addition to other predictor series.

Some kinds of nonlinear trend curves are fit by transforming the dependent series. For example, the exponential trend curve is actually a linear time trend fit to the logarithm of the series. For these trend curve specifications, the series transformation option is set automatically, and you cannot independently control both the time trend curve and transformation option.

The computed time trend variable is included in the output data set in a variable named in accordance with the trend curve type. Let *t* represent the observation count from the start of the period of fit for the model, and let X_t represent the value of the time trend variable at observation *t* within the period of fit. The names and definitions of these variables are as follows. (Note: These deterministic variables are reserved variable names.)

Linear Trend	Variable name _LINEAR_, with $X_t = t - c$.
Quadratic Trend	Variable name _QUAD_, with $X_t = (t-c)^2$. Note that a quadratic trend implies a linear trend as a special case and results in two regressors: _QUAD_ and _LINEAR_.
Cubic Trend	Variable name _CUBE_, with $X_t = (t-c)^3$. Note that a cubic trend implies a quadratic trend as a special case and results in three regressors: _CUBE_, _QUAD_, and _LINEAR_.
Logistic Trend	Variable name _LOGIT_, with $X_t = t$. The model is a linear time trend applied to the logistic transform of the dependent series. Thus, specifying a logistic trend is equivalent to specifying the Logistic series transformation and

	a linear time trend. A logistic trend predictor can be used only in conjunction with the logistic transformation, which is set automatically when you specify logistic trend.
Logarithmic Trend	Variable name _LOG_, with $X_t = ln(t)$.
Exponential Trend	Variable name _EXP_, with $X_t = t$. The model is a linear time trend applied to the logarithms of the dependent series. Thus, specifying an exponential trend is equivalent to specifying the log series transformation and a linear time trend. An exponential trend predictor can be used only in conjunction with the log transformation, which is set automatically when you specify exponential trend.
Hyperbolic Trend	Variable name _HYP_, with $X_t = 1/t$.
Power Curve Trend	Variable name _POW_, with $X_t = ln(t)$. The model is a logarithmic time trend applied to the logarithms of the dependent series. Thus, specifying a power curve is equivalent to specifying the log series transformation and a logarithmic time trend. A power curve predictor can be used only in conjunction with the log transformation, which is set automatically when you specify a power curve trend.
EXP(A+B/TIME) Trend	Variable name _ERT_, with $X_t = 1/t$. The model is a hyperbolic time trend applied to the logarithms of the dependent series. Thus, specifying this trend curve is equivalent to specifying the log series transformation and a hyperbolic time trend. This trend curve can be used only in conjunction with the log transformation, which is set automatically when you specify this trend.

Intervention Effects

Interventions are used for modeling events that occur at specific times. That is, they are known changes that affect the dependent series or outliers.

The *i*th intervention series is included in the output data set with variable name _INTV*i*_, which is a reserved variable name.

Point Interventions

The point intervention is a one-time event. The *i*th intervention series $X_{i,t}$ has a point intervention at time t_{int} when the series is nonzero only at time t_{int}, that is,

$$X_{i,t} = \begin{cases} 1, & t = t_{int} \\ 0, & otherwise \end{cases}$$

Step Interventions

Step interventions are continuing, and the input time series flags periods after the intervention. For a step intervention, before time t_{int}, the *i*th intervention series $X_{i,t}$ is zero and then steps to a constant level thereafter, that is,

$$X_{i,t} = \begin{cases} 1, & t \geq t_{int} \\ 0, & otherwise \end{cases}$$

Ramp Interventions

A ramp intervention is a continuing intervention that increases linearly after the intervention time. For a ramp intervention, before time t_{int}, the *i*th intervention series $X_{i,t}$ is zero and increases linearly thereafter, that is, proportional to time.

$$X_{i,t} = \begin{cases} t - t_{int}, & t \geq t_{int} \\ 0, & otherwise \end{cases}$$

Intervention Effect

Given the *i*th intervention series $X_{i,t}$, you can define how the intervention takes effect by filters (transfer functions) of the form

$$\Psi_i(B) = \frac{1 - \omega_{i,1}B - \ldots - \omega_{i,q_i}B^{q_i}}{1 - \delta_{i,1}B - \ldots - \delta_{i,p_i}B^{p_i}}$$

where B is the backshift operator $By_t = y_{t-1}$.

The denominator of the transfer function determines the decay pattern of the intervention effect, whereas the numerator terms determine the size of the intervention effect time window.

For example, the following intervention effects are associated with the respective transfer functions.

Immediately	$\Psi_i(B) = 1$
Gradually	$\Psi_i(B) = 1/(1 - \delta_{i,1}B)$
1 Lag window	$\Psi_i(B) = 1 - \omega_{i,1}B$
3 Lag window	$\Psi_i(B) = 1 - \omega_{i,1}B - \omega_{i,2}B^2 - \omega_{i,3}B^3$

Intervention Notation

The notation used to describe intervention effects has the form *type*:t_{int}(q_i)/(p_i), where *type* is point, step, or ramp; t_{int} is the time of the intervention (for example, OCT87); q_i is the transfer function numerator order; and p_i is the transfer function denominator order. If $q_i = 0$, the part "(q_i)" is omitted; if $p_i = 0$, the part "/(p_i)" is omitted.

In the Intervention Specification window, the `Number of Lags` option specifies the transfer function numerator order q_i, and the `Effect Decay Pattern` option specifies the transfer function denominator order p_i. In the `Effect Decay Pattern options`, values and resulting p_i are: `None`, $p_i = 0$; `Exp`, $p_i = 1$; `Wave`, $p_i = 2$.

For example, a step intervention with date 08MAR90 and effect pattern `Exp` is denoted "Step:08MAR90/(1)" and has a transfer function filter $\Psi_i(B) = 1/(1 - \delta_1 B)$. A ramp intervention immediately applied on 08MAR90 is denoted "Ramp:08MAR90" and has a transfer function filter $\Psi_i(B) = 1$.

Seasonal Dummy Inputs

For a seasonal cycle of length *s*, the seasonal dummy regressors include $\{X_{i,t} : 1 \leq i \leq (s-1), 1 \leq t \leq n\}$ for models that include an intercept term and $\{X_{i,t} : 1 \leq i \leq s, 1 \leq t \leq n\}$ for models that exclude an intercept term. Each element of a seasonal dummy regressor is either zero or one, based on the following rule:

$$X_{i,t} = \begin{cases} 1, & \text{when } i = t \bmod s \\ 0, & otherwise \end{cases}$$

Note that if the model includes an intercept term, the number of seasonal dummy regressors is one less than *s* to ensure that the linear system is full rank.

The seasonal dummy variables are included in the output data set with variable names prefixed with "SDUMMY*i*" and sequentially numbered. They are reserved variable names.

Series Diagnostic Tests

This section describes the diagnostic tests that are used to determine the kinds of forecasting models appropriate for a series.

The series diagnostics are a set of heuristics that provide recommendations on whether or not the forecasting model should contain a log transform, trend terms, and seasonal terms. These recommendations are used by the automatic model selection process to restrict the model search to a subset of the model selection list. (You can disable this behavior using the Automatic Model Selection Options window.)

The tests that are used by the series diagnostics will not always produce the correct classification of the series. They are intended to accelerate the process of searching for a good forecasting model for the series, but you should not rely on them if finding the very best model is important to you.

If you have information about the appropriate kinds of forecasting models (perhaps from studying the plots and autocorrelations shown in the Series Viewer window), you can set the series diagnostic flags in the Series Diagnostics window. Select the YES, NO, or MAYBE values for the `Log Transform`, `Trend`, and `Seasonality` options in the Series Diagnostics window as you think appropriate.

The series diagnostics tests are intended as a heuristic tool only, and no statistical validity is claimed for them. These tests may be modified and enhanced in future releases of the Time Series Forecasting System. The testing strategy is as follows:

1. **Log transform test.** The log test fits a high order autoregressive model to the series and to the log of the series and compares goodness-of-fit measures for the prediction errors of the two models. If this test finds that log transforming the series is suitable, the `Log Transform` option is set to YES, and the subsequent diagnostic tests are performed on the log transformed series.
2. **Trend test.** The resultant series is tested for presence of a trend using an augmented Dickey-Fuller test and a random walk with drift test. If either test finds that the series appears to have a trend, the `Trend` option is set to YES, and the subsequent diagnostic tests are performed on the differenced series.
3. **Seasonality test.** The resultant series is tested for seasonality. A seasonal dummy model with AR(1) errors is fit and the joint significance of the seasonal dummy estimates is tested. If the seasonal dummies are significant, the AIC statistic for this model is compared to the AIC for and AR(1) model without seasonal dummies. If the AIC for the seasonal model is lower than that of the nonseasonal model, the `Seasonal` option is set to YES.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well different models fit the data. The statistics of fit for the various forecasting models can be viewed or stored in a data set using the Model Viewer window.

Statistics of fit are computed using the actual and forecasted values for observations in the period of evaluation. One-step forecasted values are used whenever possible, including the case when a hold-out sample contains no missing values. If a one-step forecast for an observation cannot be computed due to missing values for previous series observations, a multi-step forecast is computed, using the minimum number of steps as the previous nonmissing values in the data range permit.

The various statistics of fit reported are as follows. In these formula, n is the number of nonmissing observations and k is the number of fitted parameters in the model.

Number of Nonmissing Observations.
The number of nonmissing observations used to fit the model.

Number of Observations.
The total number of observations used to fit the model, including both missing and nonmissing observations.

Number of Missing Actuals.
The number of missing actual values.

Number of Missing Predicted Values.
The number of missing predicted values.

Number of Model Parameters.
The number of parameters fit to the data. For combined forecast, this is the number of forecast components.

Total Sum of Squares (Uncorrected).
The total sum of squares for the series, SST, uncorrected for the mean: $\sum_{t=1}^{n} y_t^2$.

Total Sum of Squares (Corrected).
The total sum of squares for the series, SST, corrected for the mean: $\sum_{t=1}^{n} (y_t - \overline{y})^2$, where $\overline{y}$ is the series mean.

Sum of Square Errors.
The sum of the squared prediction errors, SSE. $SSE = \sum_{t=1}^{n} (y_t - \hat{y}_t)^2$, where $\hat{y}$ is the one-step predicted value.

Mean Square Error.
The mean squared prediction error, MSE, calculated from the one-step-ahead forecasts. $MSE = \frac{1}{n}SSE$. This formula enables you to evaluate small holdout samples.

Root Mean Square Error.
The root mean square error (RMSE), $\sqrt{MSE}$.

Mean Absolute Percent Error.
The mean absolute percent prediction error (MAPE), $\frac{100}{n} \sum_{t=1}^{n} |(y_t - \hat{y}_t)/y_t|$.
The summation ignores observations where $y_t = 0$.

Mean Absolute Error.
The mean absolute prediction error, $\frac{1}{n} \sum_{t=1}^{n} |y_t - \hat{y}_t|$.

R-Square.
The R^2 statistic, $R^2 = 1 - SSE/SST$. If the model fits the series badly, the model error sum of squares, *SSE*, may be larger than *SST* and the R^2 statistic will be negative.

Adjusted R-Square.
The adjusted R^2 statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$.

Amemiya's Adjusted R-Square.
Amemiya's adjusted R^2, $1 - (\frac{n+k}{n-k})(1 - R^2)$.

Random Walk R-Square.
The random walk R^2 statistic (Harvey's R^2 statistic using the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^{n} (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^{n} (y_t - y_{t-1})$.

Akaike's Information Criterion.
Akaike's information criterion (AIC), $n \ln(MSE) + 2k$.

Schwarz Bayesian Information Criterion.
Schwarz Bayesian information criterion (SBC or BIC),
$n \ln(MSE) + k \ln(n)$.

Amemiya's Prediction Criterion.
Amemiya's prediction criterion, $\frac{1}{n}SST(\frac{n+k}{n-k})(1 - R^2) = (\frac{n+k}{n-k})\frac{1}{n}SSE$.

Maximum Error.
The largest prediction error.

Minimum Error.
The smallest prediction error.

Maximum Percent Error.
The largest percent prediction error, $100\max((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Minimum Percent Error.
The smallest percent prediction error, $100\min((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

Mean Error.
The mean prediction error, $\frac{1}{n}\sum_{t=1}^{n}(y_t - \hat{y}_t)$.

Mean Percent Error.
The mean percent prediction error, $\frac{100}{n}\sum_{t=1}^{n}\frac{(y_t - \hat{y}_t)}{y_t}$. The summation ignores observations where $y_t = 0$.

Chapter 42
Overview

Chapter Contents

Chapter 42
Overview

About Investment Analysis

The Investment Analysis system is an interactive environment for the time-value of money of a variety of investments:

- Loans
- Savings
- Depreciations
- Bonds
- Generic cashflows

Various analyses are provided to help analyze the value of investment alternatives: time value, periodic equivalent, internal rate of return, benefit-cost ratio, and breakeven analysis.

These analyses can help answer a number of questions you may have about your investments:

- Which option is more profitable or less costly?
- Is it better to buy or rent?
- Are the extra fees for refinancing at a lower interest rate justified?
- What is the balance of this account after saving this amount periodically for so many years?
- How much is legally tax-deductible?
- Is this a reasonable price?

Investment Analysis can be beneficial to users in many industries for a variety of decisions:

- manufacturing: cost justification of automation or any capital investment, replacement analysis of major equipment, or economic comparison of alternative designs
- government: setting funds for services
- finance: investment analysis and portfolio management for fixed-income securities

Starting Investment Analysis

There are two ways to invoke Investment Analysis from the main SAS window. One way is to select **Solutions** → **Analysis** → **Investment Analysis** from the main SAS menu, as displayed in Figure 42.1.

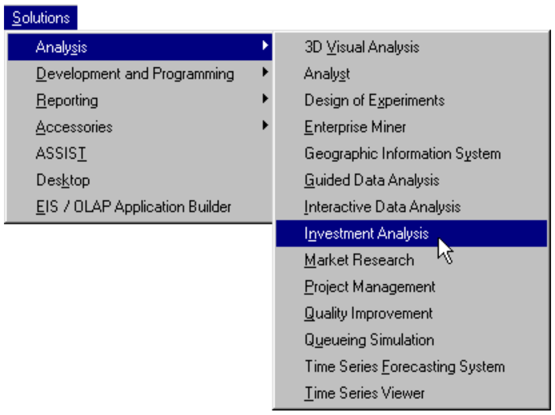

Figure 42.1. Initializing Investment Analysis with the Menu Bar

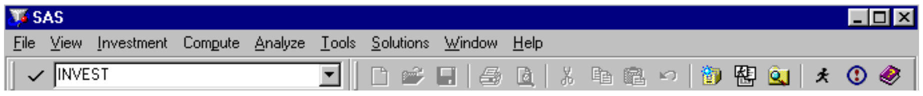
The other way is to type **INVEST** into the toolbar's command prompt, as displayed in Figure 42.2.



SAS
File View Investment Compute Analyze Tools Solutions Window Help
INVEST

Figure 42.2. Initializing Investment Analysis with the Toolbar

Getting Help

You can get help in Investment Analysis in three ways. One way is to use the Help Menu, as displayed in Figure 42.3. This is the right-most menu item on the menu bar.

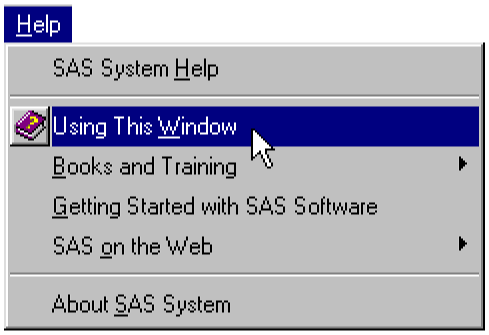


Figure 42.3. The Help Menu

Help buttons, as in Figure 42.4, provide another way to access help. Most dialog boxes provide help buttons in their lower-right corners.

Figure 42.4. A Help Button

Also, the toolbar has a button (see Figure 42.5) that invokes the help system. This is the right-most icon on the toolbar.

Figure 42.5. The Help Icon

Each of these methods invokes a browser that gives specific help for the active window.

Using Help

The chapters pertaining to Investment Analysis in this document typically have a section that introduces you to a menu and summarizes the options available through the menu. Such chapters then have sections titled Task and Dialog Box Guides. The Task section provides a description of how to perform many useful tasks. The Dialog Box Guide lists all dialog boxes pertinent to those tasks and gives a brief description of each element of each dialog box.

Software Requirements

The Investment Analysis Application is available in Version 9 of the SAS System for the following platforms:

- OS/390,
- Windows NT/2000/XP,
- OpenVMS Alpha,
- Compaq's Digital UNIX,
- HP 64,
- Solaris 64,
- AIX 64,
- RedHat Linux on Intel,
- HP/UX for Itanium Platform Family, and
- Windows for IPF.

Investment Analysis uses the following SAS software:

- Base SAS,
- SAS/ETS, and
- SAS/GRAPH (optional, to view bond pricing and breakeven graphs).

Chapter 43
Portfolios

Chapter Contents

Chapter 43
Portfolios

The File Menu

Investment Analysis stores portfolios as catalog entries. Portfolios contain a collection of investments, providing a structure to collect investments with a common purpose or goal (like a retirement or building fund portfolio). It may be advantageous also to collect investments into a common portfolio if they are competing investments you wish to perform a comparative analysis upon. Within this structure you can perform computations and analyses on a collection of investments in a portfolio, just as you would perform them on a single investment.

Investment Analysis provides many tools to aid in your manipulation of portfolios through the **File** menu, shown in Figure 43.1.

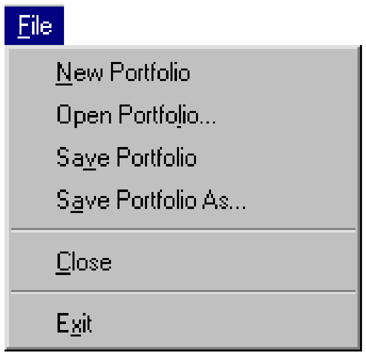

Figure 43.1. File Menu

The **File** menu offers the following items.

New Portfolio creates an empty portfolio with a new name.

Open Portfolio... opens the standard SAS Open dialog box where you select a portfolio to open.

Save Portfolio saves the current portfolio to its current name.

Save Portfolio As... opens the standard SAS Save As dialog box where you supply a new portfolio name for the current portfolio.

Close closes Investment Analysis.

Exit closes SAS (Windows only).

Tasks

Creating a New Portfolio

From the Investment Analysis dialog box, select **File** → **New Portfolio**.

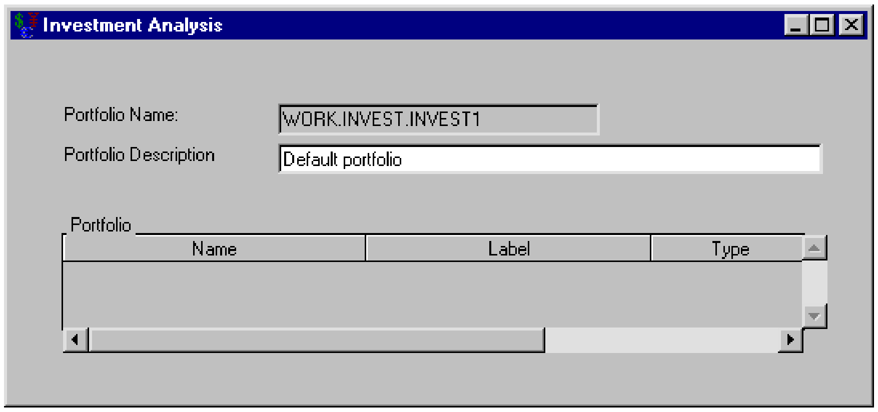

Figure 43.2. Creating a New Portfolio

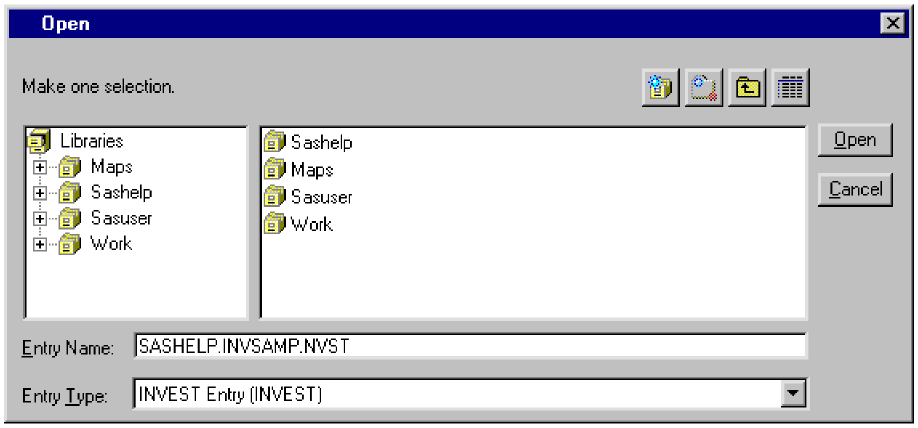
The **Portfolio Name** will be WORK.INVEST.INVEST1 as displayed in Figure 43.7, unless you have saved a portfolio to that name in the past. In that case some other unused portfolio name is given to the new portfolio.

Saving a Portfolio

From the Investment Analysis dialog box, select **File** → **Save Portfolio**. The portfolio is saved to a catalog-entry with the name in the **Portfolio Name** box.

Opening an Existing Portfolio

From the Investment Analysis dialog box, select **File** → **Open Portfolio...**. This opens the standard SAS Open dialog box. You enter the name of a SAS portfolio to open in the **Entry Name** box. For example, enter SASHELP.INVSAMP.NVST as displayed in Figure 43.3.

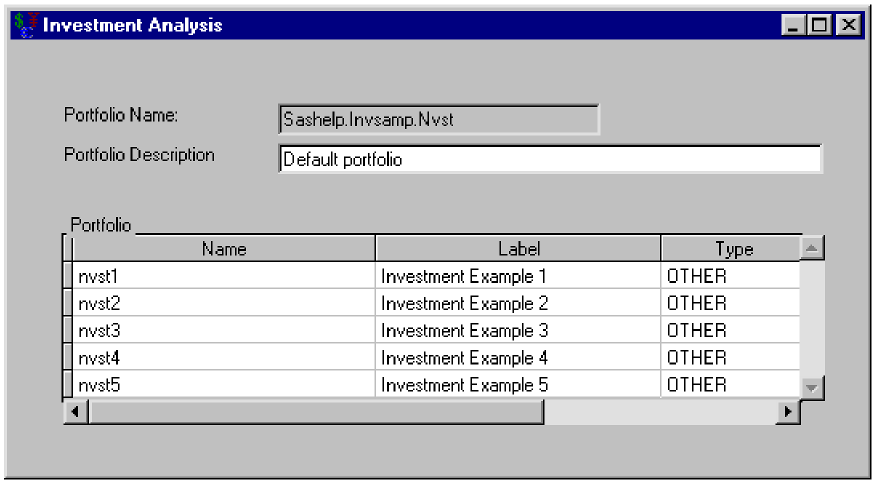


Entry Name: SASHELP.INVSAMP.NVST

Entry Type: INVEST Entry (INVEST)

Figure 43.3. Opening an Existing Portfolio

Click **Open** to load the portfolio. The portfolio should look like Figure 43.4.



Portfolio Name: Sashelp.Invsamp.Nvst

Portfolio Description: Default portfolio

Portfolio

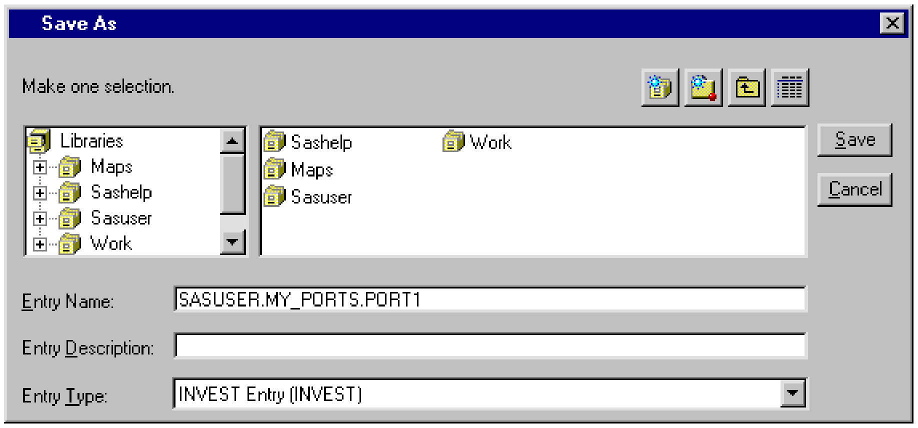
Name	Label	Type
nvst1	Investment Example 1	OTHER
nvst2	Investment Example 2	OTHER
nvst3	Investment Example 3	OTHER
nvst4	Investment Example 4	OTHER
nvst5	Investment Example 5	OTHER

Figure 43.4. The Opened Portfolio

Saving a Portfolio to a Different Name

From the Investment Analysis dialog box, select **File** → **Save Portfolio As...**.

This opens the standard SAS Save As dialog box. You can enter the name of a SAS portfolio into the **Entry Name** box. For example, enter SASUSER.MY_PORTS.PORT1 as in Figure 43.5.



Entry Name: SASUSER.MY_PORTS.PORT1

Entry Description:

Entry Type: INVEST Entry (INVEST)

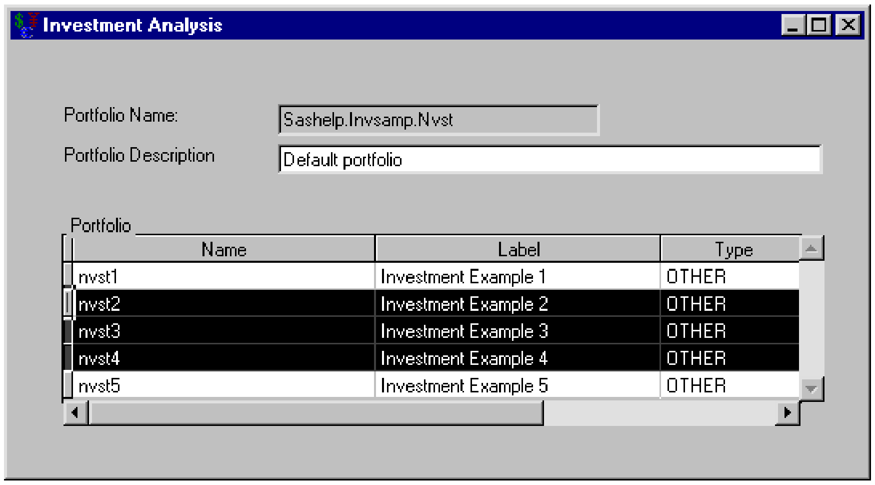
Figure 43.5. Saving a Portfolio to a Different Name

Click **Save** to save the portfolio.

Selecting Investments within a Portfolio

To select a single investment in an opened portfolio, click the investment in the Portfolio area within the Investment Analysis dialog box.

To select a list of adjacent investments, do the following: click the first investment, hold down SHIFT, and click the final investment. Once the list of investment is selected, you may release the SHIFT key. The selected investments will appear highlighted as in Figure 43.6.



Investment Analysis

Portfolio Name: Sashelp.Invsamp.Nvst

Portfolio Description: Default portfolio

Portfolio

Name	Label	Type
nvst1	Investment Example 1	OTHER
nvst2	Investment Example 2	OTHER
nvst3	Investment Example 3	OTHER
nvst4	Investment Example 4	OTHER

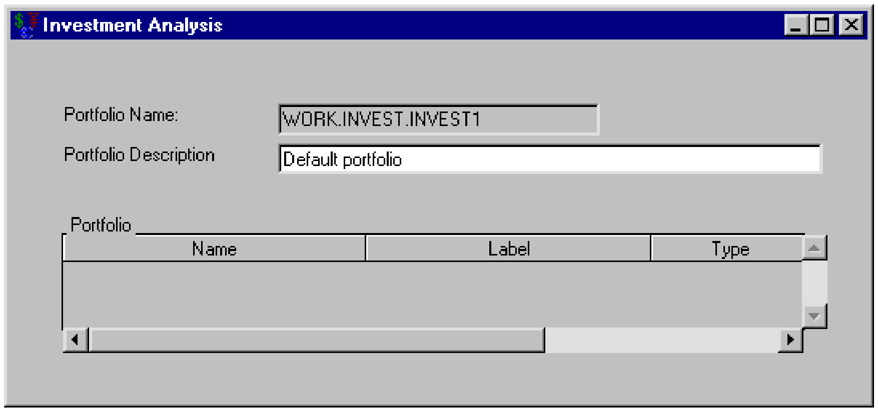
Dialog and Utility Guide

Investment Analysis



Investment Analysis

Portfolio Name: WORK.INVEST.INVEST1

Portfolio Description: Default portfolio

Portfolio

Name	Label	Type

Figure 43.7. Investment Analysis Dialog Box

Investment Portfolio Name holds the name of the portfolio. It is of the form library.catalog_entry.portfolio. The default portfolio name is work.invest.invest1, as in Figure 43.7.

Portfolio Description provides a more descriptive explanation of the portfolio's contents. You can edit this description any time this dialog box is active.

The **Portfolio** area contains the list of investments comprising the particular portfolio. Each investment in the **Portfolio** area displays the following attributes:

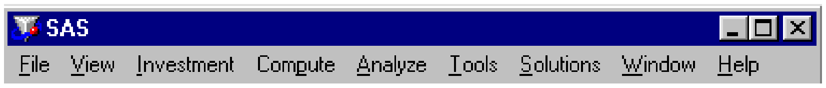
Name is the name of the investment. It must be a valid SAS name. It is used to distinguish investments when performing analyses and computations.

Label is a place where you can provide a more descriptive explanation of the investment.

Type is the type of investment, which is fixed when you create the investment. It will be one of the following: LOAN, SAVINGS, DEPRECIATION, BOND, or OTHER.

Additional tools to aid in the management of your portfolio are available by selecting from the menu bar and by right-clicking within the **Portfolio** area.

Menu Bar Options



SAS
File View Investment Compute Analyze Tools Solutions Window Help

Figure 43.8. The Menu Bar

The menu bar (shown in Figure 43.8) provides many tools to aid in the management of portfolios and the investments that comprise them. The following menu items provide functionality particular to Investment Analysis:

File opens and saves portfolios.

Investment creates new investments within the portfolio.

Compute performs constant dollar, after tax, and currency conversion computations on generic cashflows.

Analyze analyzes investments to aid in decision-making.

Tools sets default values of inflation and income tax rates.

Right-Clicking within the Portfolio Area

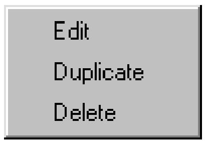


Figure 43.9. Right-Clicking

After selecting an investment, right-clicking in the **Portfolio** area pops up a menu (see Figure 43.9) that offers the following options:

Edit opens the selected investment within the portfolio.

Duplicate creates a duplicate of the selected investment within the portfolio.

Delete removes the selected investment from the portfolio.

If you wish to perform one of these actions on a collection of investments, you must select a collection of investments (as described in the section “Selecting Investments within a Portfolio” on page 2264) before right-clicking.

Chapter 44
Investments

Chapter Contents

Chapter 44
Investments

The Investment Menu

Because there are many types of investments, a tool that manages and analyzes collections of investments must be robust and flexible. Providing specifications for four specific investment types and one generic type, Investment Analysis can model almost any real-world investment.

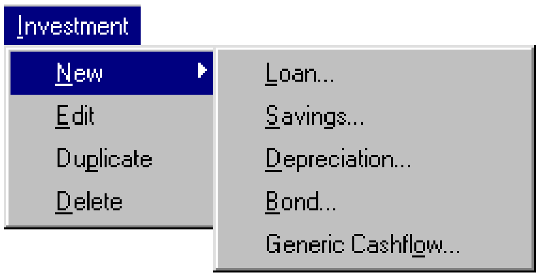

Figure 44.1. Investment Menu

The **Investment** menu, shown in Figure 44.1, offers the following items:

New → **Loan...** opens the Loan dialog box. Loans are useful for acquiring capital to pursue various interests. Available terms include rate adjustments for variable rate loans, initialization costs, prepayments, and balloon payments.

New → **Savings...** opens the Savings dialog box. Savings are necessary when planning for the future, whether for business or personal purposes. Account summary calculations available per deposit include starting balance, deposits, interest earned, and ending balance.

New → **Depreciation...** opens the Depreciation dialog box. Depreciations are relevant in tax calculation. The available depreciation methods are Straight Line, Sum-of-years Digits, Depreciation Table, and Declining Balance. Depreciation Tables are necessary when depreciation calculations must conform to set yearly percentages. Declining Balance with conversion to Straight Line is also provided.

New → **Bond...** opens the Bond dialog box. Bonds have widely varying terms depending on the issuer. As bond issuers frequently auction their bonds, the ability to price a bond between the issue date and maturity date is desirable. Fixed-coupon bonds may be analyzed for the following: price versus yield-to-maturity, duration, and convexity. These are available at different times in the bond's life.

New → **Generic Cashflow...** opens the Generic Cashflow dialog box. Generic cashflows are the most flexible investments. Only a sequence of date-amount pairs is necessary for specification. You can enter date-amount pairs and load values from

SAS data sets to specify any type of investment. You can generate uniform, arithmetic, and geometric cashflows with ease. SAS's forecasting ability is available to forecast future cashflows as well. The new graphical display aids in visualization of the cashflow and enables the user to change the frequency of the cashflow view to aggregate and disaggregate the view.

Edit opens the specification dialog box for an investment selected within the portfolio.

Duplicate creates a duplicate of an investment selected within the portfolio.

Delete removes an investment selected from the portfolio.

If you wish to edit, duplicate, or delete a collection of investments, you must select a collection of investments as described in "Selecting Investments within a Portfolio" on page 2264 before performing the menu-option.

Tasks

Loan Tasks

Suppose you want to buy a home that costs $100,000. You can make a down payment of $20,000. Hence, you need a loan of $80,000. You are able to acquire a 30-year loan at 7% interest starting January 1, 2000. Let's use Investment Analysis to specify and analyze this loan.

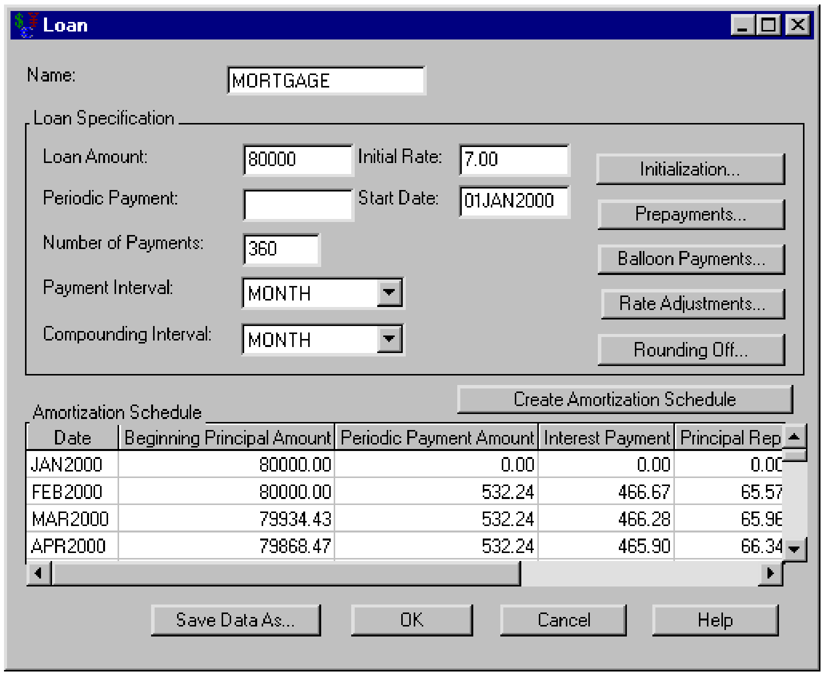
From the Investment Analysis dialog box, select **Investment** → **New** → **Loan...** from the menu bar to open the Loan dialog box.

Specifying Loan Terms to Create an Amortization Schedule

You must specify the loan before generating the amortization table. To specify the loan, follow these steps:

1. Enter **MORTGAGE** for the **Name**.
2. Enter 80000 for the **Loan Amount**.
3. Enter 7 for the **Initial Rate**.
4. Enter 360 for the **Number of Payments**.
5. Enter 01JAN2000 for the **Start Date**.

Once you have specified the loan, click **Create Amortization Schedule** to generate the amortization schedule displayed in Figure 44.2.



Loan

Name: MORTGAGE

Loan Specification

Loan Amount: 80000

Initial Rate: 7.00

Periodic Payment:

Start Date: 01JAN2000

Number of Payments: 360

Payment Interval: MONTH

Compounding Interval: MONTH

Amortization Schedule

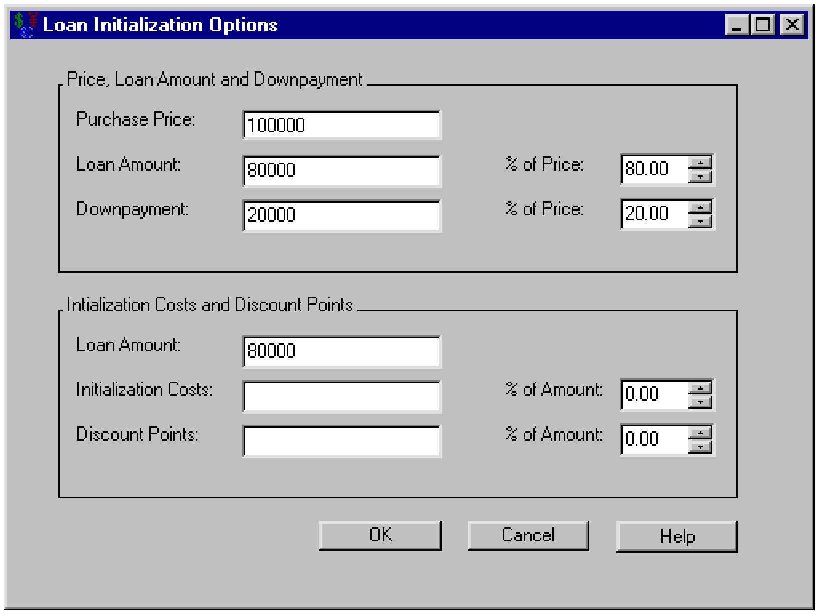
Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	532.24	466.67	65.57
MAR2000	79934.43	532.24	466.28	65.96
APR2000	79868.47	532.24	465.90	66.34

Figure 44.2. Creating an Amortization Schedule

Storing Other Loan Terms

Let's include information concerning the purchase price and downpayment. These terms are not necessary to specify the loan, but it may be advantageous to store such information with the loan.

Consider the loan described in "Loan Tasks" on page 2272. From the Loan dialog box (Figure 44.2) click **Initialization...** to open the Loan Initialization Options dialog box. Here you can specify the down payment, initialization costs, and discount points. To specify the down payment, enter 100000 for the **Purchase Price**, as shown in Figure 44.3.



Price, Loan Amount and Downpayment

Purchase Price:	100000		
Loan Amount:	80000	% of Price:	80.00
Downpayment:	20000	% of Price:	20.00

Intialization Costs and Discount Points

Loan Amount:	80000		
Initialization Costs:		% of Amount:	0.00
Discount Points:		% of Amount:	0.00

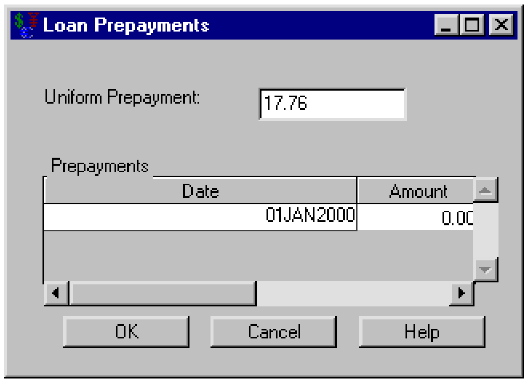
Figure 44.3. Including the Purchase Price

Click **OK** to return to the Loan dialog box.

Adding Prepayments

Now let's observe the effect of prepayments on the loan. Consider the loan described in "Loan Tasks" on page 2272. You must pay a minimum of $532.24 each month to keep up with payments. However, let's say you dislike entering this amount in your checkbook. You would rather pay $550.00 to keep the arithmetic simpler. This would constitute a uniform prepayment of $17.76 each month.

From the Loan dialog box, click **Prepayments...** that opens the Loan Prepayments dialog box shown in Figure 44.4.



Uniform Prepayment: 17.76

Prepayments

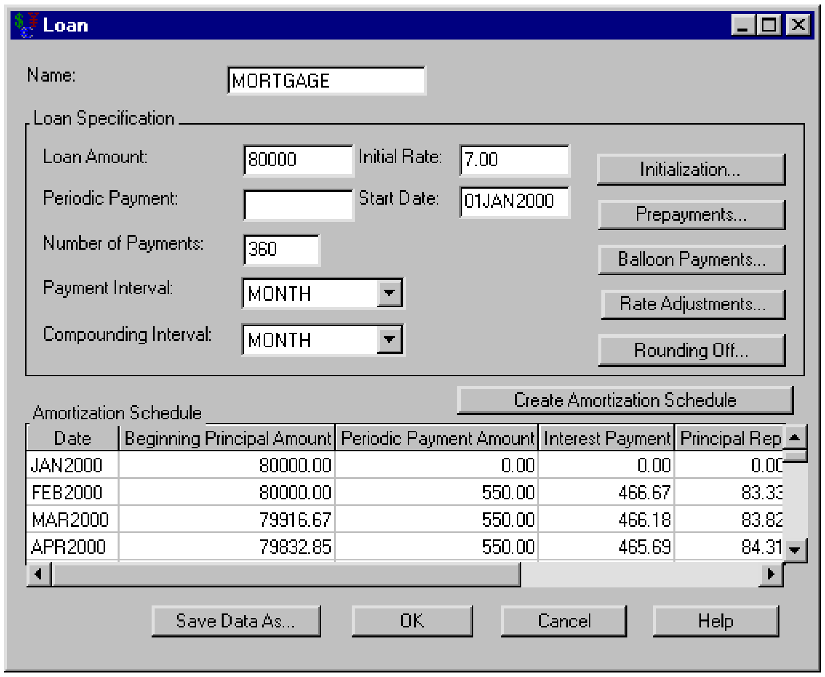
Date	Amount
01JAN2000	0.00

Figure 44.4. Specifying the Loan Prepayments

You can specify an arbitrary sequence of prepayments in the **Prepayments** area. If you want a uniform prepayment, clear the **Prepayments** area and enter the uniform payment amount in the **Uniform Prepayment** box. That amount will be added to each payment until the loan is paid off.

To specify this uniform prepayment, follow these steps:

1. Enter 17.76 for the **Uniform Prepayment**.
2. Click **OK** to return to the Loan dialog box.
3. Click **Create Amortization Schedule**, and the amortization schedule updates, as displayed in Figure 44.5.



Name: MORTGAGE

Loan Amount: 80000
Initial Rate: 7.00
Periodic Payment:
Start Date: 01JAN2000
Number of Payments: 360
Payment Interval: MONTH
Compounding Interval: MONTH

Amortization Schedule

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Rep
JAN2000	80000.00	0.00	0.00	0.00
FEB2000	80000.00	550.00	466.67	83.33
MAR2000	79916.67	550.00	466.18	83.82
APR2000	79832.85	550.00	465.69	84.31

Figure 44.5. The Amortization Schedule with Loan Prepayments

The last payment is on January 2030 without prepayments and February 2027 with prepayment; you would pay the loan off almost three years earlier with the $17.76 prepayments.

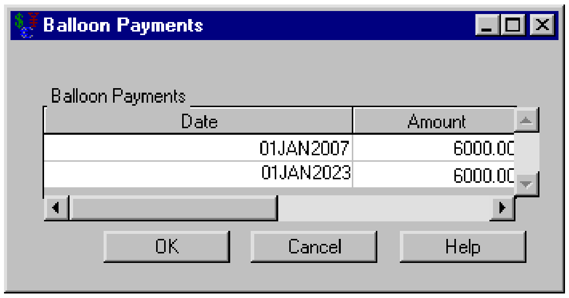
To continue this example you must remove the prepayments from the loan specification, following these steps:

1. Return to the Prepayments dialog box from the Loan dialog box by clicking **Prepayments...**.
2. Enter 0 for **Uniform Prepayment**.
3. Click **OK** to return to the Loan dialog box.

Adding Balloon Payments

Consider the loan described in "Loan Tasks" on page 2272. Suppose you cannot afford the payments of $532.24 each month. To lessen your monthly payment you could pay balloon payments of $6,000 at the end of 2007 and 2023. You wonder how this would affect your monthly payment. (Note that Investment Analysis does not allow both balloon payments and rate adjustments to be specified for a loan.)

From the Loan dialog box, click **Balloon Payments...**, which opens the Balloon Payments dialog box shown in Figure 44.6.



Balloon Payments

Date	Amount
01JAN2007	6000.0C
01JAN2023	6000.0C

Figure 44.6. Defining Loan Balloon Payments

You can specify an arbitrary sequence of balloon payments by adding date-amount pairs to the **Balloon Payments** area.

To specify these balloon payments, follow these steps:

1. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
2. Set the pair's **Date** to 01JAN2007.
3. Set its **Amount** to 6000.
4. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **New**.
5. Set the new pair's **Date** to 01JAN2023.
6. Set its **Amount** to 6000.

Click **OK** to return to the Loan dialog box. Click **Create Amortization Schedule**, and the amortization schedule updates. Your monthly payment is now $500.30, a difference of approximately $32 each month.

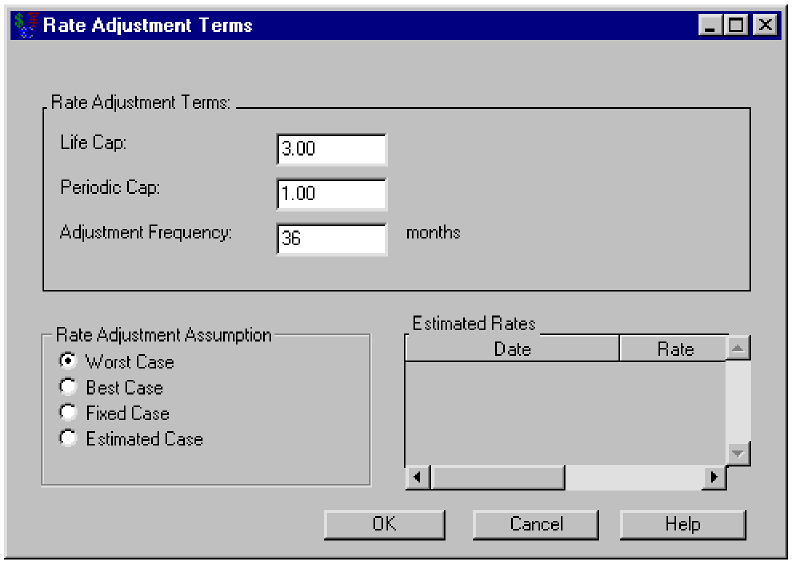
To continue this example you must remove the balloon payments from the loan specification, following these steps:

1. Return to the Balloon Payments dialog box.
2. Right-click within the **Balloon Payment** area (which pops up a menu) and release on **Clear**.
3. Click **OK** to return to the Loan dialog box.

Handling Rate Adjustments

Consider the loan described in "Loan Tasks" on page 2272. Another option for lowering your payments is to get a variable rate loan. You can acquire a three-year-ARM at 6% with a periodic cap of 1% with a maximum of 9%. (Note that Investment Analysis does not allow both rate adjustments and balloon payments to be specified for a loan.)

From the Loan dialog box, click **Rate Adjustments...** to open the Rate Adjustment Terms dialog box shown in Figure 44.7.



Rate Adjustment Terms

Rate Adjustment Terms:

Life Cap: 3.00

Periodic Cap: 1.00

Adjustment Frequency: 36 months

Rate Adjustment Assumption

[✓ Worst Case]
Best Case
Fixed Case
Estimated Case

Estimated Rates

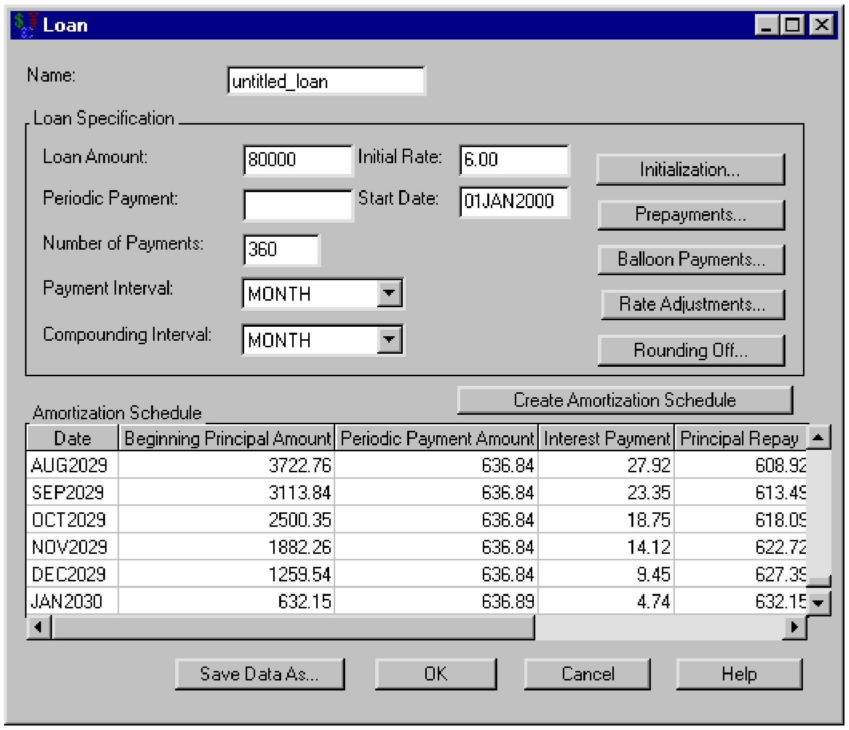
Date	Rate

Figure 44.7. Setting the Rate Adjustments

To specify these loan adjustment terms, follow these steps:

1. Enter 3 for the **Life Cap**. The **Life Cap** is the maximum deviation from the **Initial Rate**.
2. Enter 1 for the **Periodic Cap**.
3. Enter 36 for the **Adjustment Frequency**.
4. Confirm that **Worst Case** is selected in the Rate Adjustment Assumption area.
5. Click **OK** to return to the Loan dialog box.
6. Enter 6 for the **Initial Rate**.

Click **Create Amortization Schedule**, and the amortization schedule updates. Your monthly payment drops to $479.64 each month. However, if the worst-case scenario plays out, the payments will increase to $636.84 in nine years. Figure 44.8 displays amortization table information for the final few months under this scenario.



Name: untitled_loan

Loan Specification

Loan Amount:	80000	Initial Rate:	6.00
Periodic Payment:		Start Date:	01JAN2000
Number of Payments:	360		
Payment Interval:	MONTH		
Compounding Interval:	MONTH		

Amortization Schedule

Date	Beginning Principal Amount	Periodic Payment Amount	Interest Payment	Principal Repay
AUG2029	3722.76	636.84	27.92	608.92
SEP2029	3113.84	636.84	23.35	613.49
OCT2029	2500.35	636.84	18.75	618.09
NOV2029	1882.26	636.84	14.12	622.72
DEC2029	1259.54	636.84	9.45	627.39
JAN2030	632.15	636.89	4.74	632.15

Figure 44.8. The Amortization Schedule with Rate Adjustments

Click **OK** to return to the Investment Analysis dialog box.

Specifying Savings Terms to Create an Account Summary

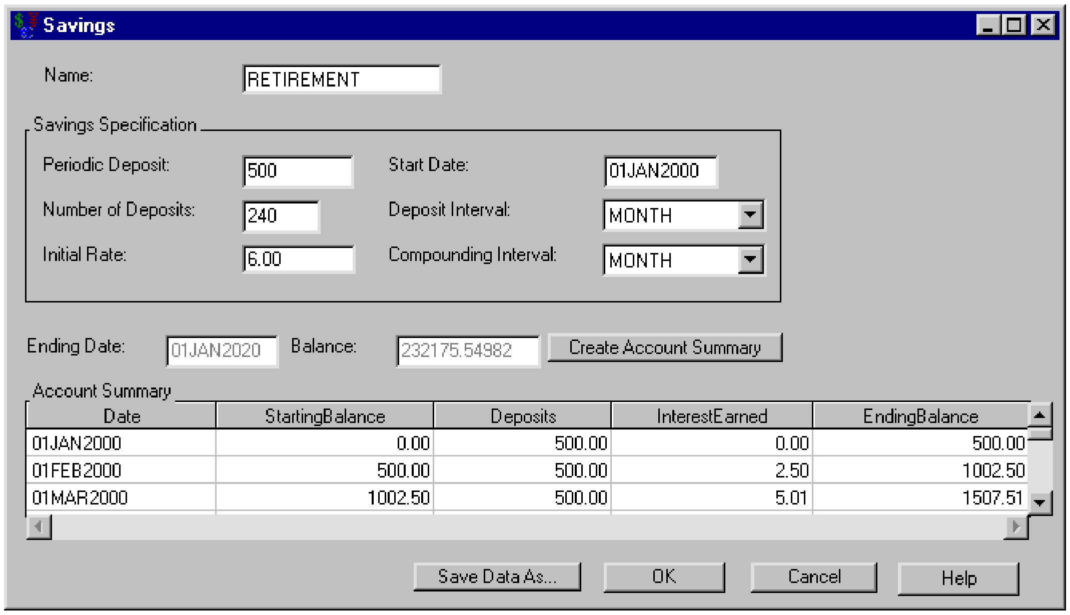
Suppose you put $500 each month into an account that earns 6% interest for 20 years. What is the balance of the account after those 20 years?

From the Investment Analysis dialog box, select **Investment** → **New** → **Savings...** from the menu bar to open the Savings dialog box.

To specify the savings, follow these steps:

1. Enter **RETIREMENT** for the **Name**.
2. Enter 500 for the **Periodic Deposit**.
3. Enter 240 for the **Number of Deposits**.
4. Enter 6 for the **Initial Rate**.

You must specify the savings before generating the account summary. Once you have specified the savings, click **Create Account Summary** to compute the ending date and balance and to generate the account summary displayed in Figure 44.9.



Name: RETIREMENT

Savings Specification

Periodic Deposit:	500	Start Date:	01JAN2000
Number of Deposits:	240	Deposit Interval:	MONTH
Initial Rate:	6.00	Compounding Interval:	MONTH

Ending Date: 01JAN2020 Balance: 232175.54982

Account Summary

Date	StartingBalance	Deposits	InterestEarned	EndingBalance
01JAN2000	0.00	500.00	0.00	500.00
01FEB2000	500.00	500.00	2.50	1002.50
01MAR2000	1002.50	500.00	5.01	1507.51

Figure 44.9. Creating an Account Summary

Click **OK** to return to the Investment Analysis dialog box.

Depreciation Tasks

Commercial assets are considered to lose value as time passes. For tax purposes, you want to quantify this loss. This investment structure helps calculate appropriate values.

Suppose you buy a boat that costs $50,000 for commercial fishing that is considered to have a ten-year useful life. How would you depreciate it?

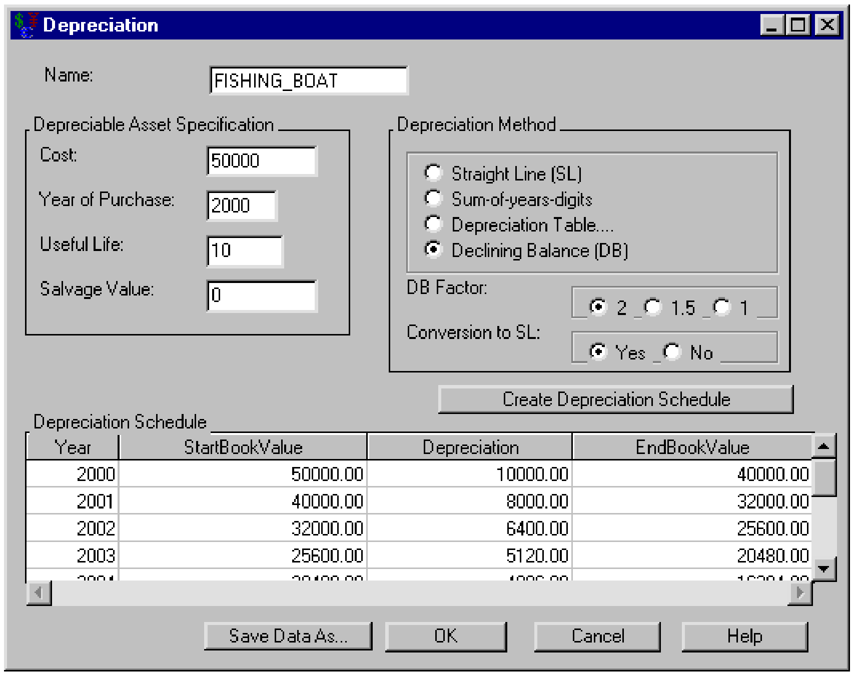
From the Investment Analysis dialog box, select **Investment** → **New** → **Depreciation...** from the menu bar to open the Depreciation dialog box.

Specifying Depreciation Terms to Create a Depreciation Table

To specify the depreciation, follow these steps:

1. Enter **FISHING_BOAT** for the **Name**.
2. Enter 50000 for the **Cost**.
3. Enter 2000 for the **Year of Purchase**.
4. Enter 10 for the **Useful Life**.
5. Enter 0 for the **Salvage Value**.

You must specify the depreciation before generating the depreciation schedule. Once you have specified the depreciation, click **Create Depreciation Schedule** to generate a deprecation schedule like the one displayed in Figure 44.10.



Name: FISHING_BOAT

Depreciable Asset Specification

Cost:	50000
Year of Purchase:	2000
Useful Life:	10
Salvage Value:	0

Depreciation Method

- Straight Line (SL)
- Sum-of-years-digits
- Depreciation Table....
- [✓ Declining Balance (DB)]

DB Factor: [✓ 2] 1.5 1

Conversion to SL: [✓ Yes] No

Depreciation Schedule

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	10000.00	40000.00
2001	40000.00	8000.00	32000.00
2002	32000.00	6400.00	25600.00
2003	25600.00	5120.00	20480.00

Figure 44.10. Creating a Depreciation Schedule

The default deprecation method is Declining Balance (with Conversion to Straight Line). Try the following methods to see how they each affect the schedule:

- Straight Line
- Sum-of-years Digits
- Declining Balance (without conversion to Straight Line)

It might be useful to compare the value of the boat at 5 years for each method.

A description of these methods is available in "Depreciation Methods" on page 2346.

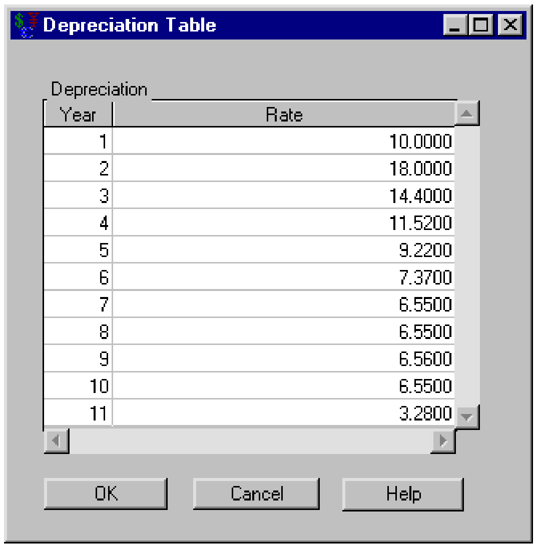
Using the Depreciation Table

Sometimes you want to force the depreciation rates to be certain percentages each year. This option is particularly useful for calculating Modified Accelerated Cost Recovery System (MACRS) Depreciations. The United States' Tax Reform Act of 1986 set depreciation rates for an asset based on an assumed lifetime for that asset. Since these lists of rates are important to many people, Investment Analysis provides SAS Datasets for situations with yearly rates (using the "half-year convention"). Find them at SASHELP.MACRS* where * refers to the class of the property. For example, use SASHELP.MACRS15 for a fifteen-year property. (When using the MACRS with the Tax Reform Act tables, you must set the **Salvage Value** to zero.)

Suppose you want to compute the depreciation schedule for the commercial fishing boat described in "Depreciation Tasks" on page 2279. The boat is a ten-year property according to the Tax Reform Act of 1986.

To employ the MACRS depreciation from the Depreciation dialog box, follow these steps:

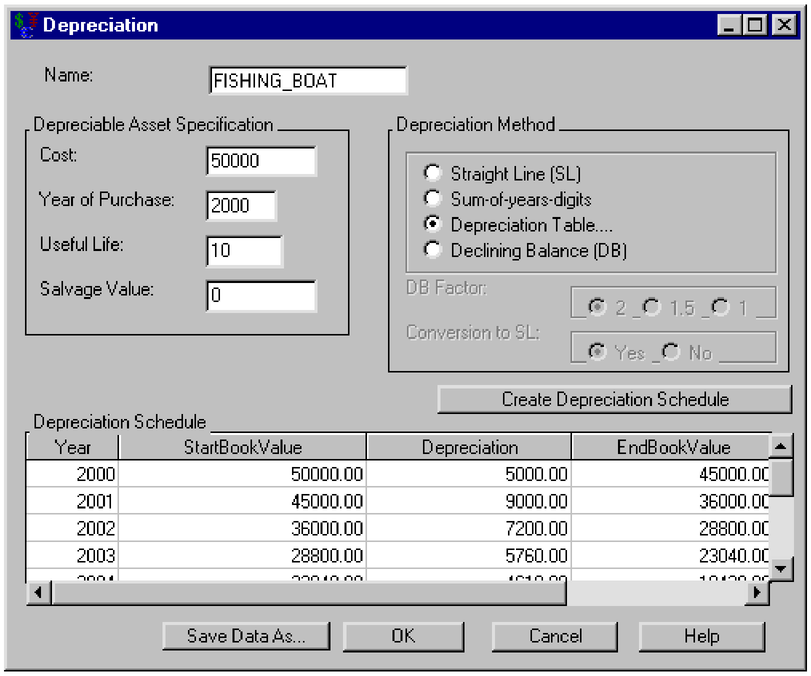
1. Click **Depreciation Table...** within the **Deprecation Method** area. This opens the Depreciation Table dialog box.
2. Right-click within the **Depreciation** area (which pops up a menu) and select **Load**.
3. Enter SASHELP.MACRS10 for the **Dataset Name**. The dialog box should look like Figure 44.11.



Year	Rate
1	10.0000
2	18.0000
3	14.4000
4	11.5200
5	9.2200
6	7.3700
7	6.5500
8	6.5500
9	6.5600
10	6.5500
11	3.2800

Figure 44.11. MACRS Percentages for a Ten-Year Property

Click **OK** to return to the Depreciation dialog box. Click **Create Depreciation Schedule** and the depreciation schedule fills (see Figure 44.12).



Name: FISHING_BOAT

Depreciable Asset Specification

Cost: 50000

Year of Purchase: 2000

Useful Life: 10

Salvage Value: 0

Depreciation Method

Straight Line (SL) Sum-of-years-digits [✓ Depreciation Table....] Declining Balance (DB)

DB Factor: [✓ 2] 1.5 1

Conversion to SL: [✓ Yes] No

Depreciation Schedule

Year	StartBookValue	Depreciation	EndBookValue
2000	50000.00	5000.00	45000.00
2001	45000.00	9000.00	36000.00
2002	36000.00	7200.00	28800.00
2003	28800.00	5760.00	23040.00

Figure 44.12. Depreciation Table with MACRS10

Note there are eleven entries in this depreciation table. This is because of the half-year convention that enables you to deduct one half of a year the first year which leaves a half year to deduct after the useful life is over.

Click **OK** to return to the Investment Analysis dialog box.

Bond Tasks

Suppose someone offers to sell you a 20-year utility bond. It was issued six years ago. It has a $1,000 face value and pays semi-year coupons at 2%. You can purchase it for $780. Would you be satisfied with this bond if you expect an 8% MARR?

From the Investment Analysis dialog box, select **Investment** → **New** → **Bond...** from the menu bar to open the Bond dialog box.

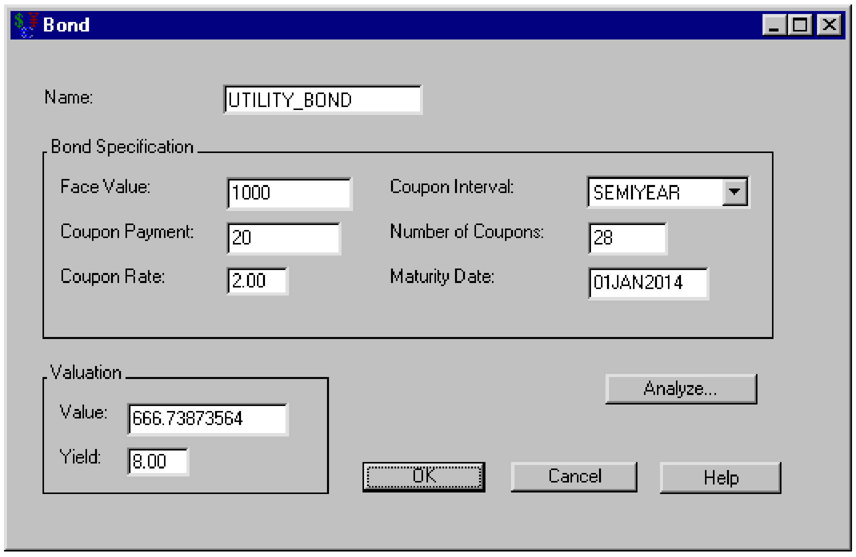
Specifying Bond Terms

To specify the bond, follow these steps:

1. Enter **UTILITY_BOND** for the **Name**.
2. Enter 1000 for the **Face Value**.
3. Enter 2 for the **Coupon Rate**. The **Coupon Payment** updates to 20.
4. Select SEMIYEAR for **Coupon Interval**.
5. Enter 28 for the **Number of Coupons**. As 14 years remain before the bond matures, the bond still has 28 semiyear coupons to pay. The **Maturity Date** updates.

Computing the Price from Yield

Enter 8 for **Yield** within the **Valuation** area. You see the bond's value would be $666.72 as in Figure 44.13.



Name: UTILITY_BOND

Bond Specification

Face Value:	1000	Coupon Interval:	SEMIYEAR
Coupon Payment:	20	Number of Coupons:	28
Coupon Rate:	2.00	Maturity Date:	01JAN2014

Valuation

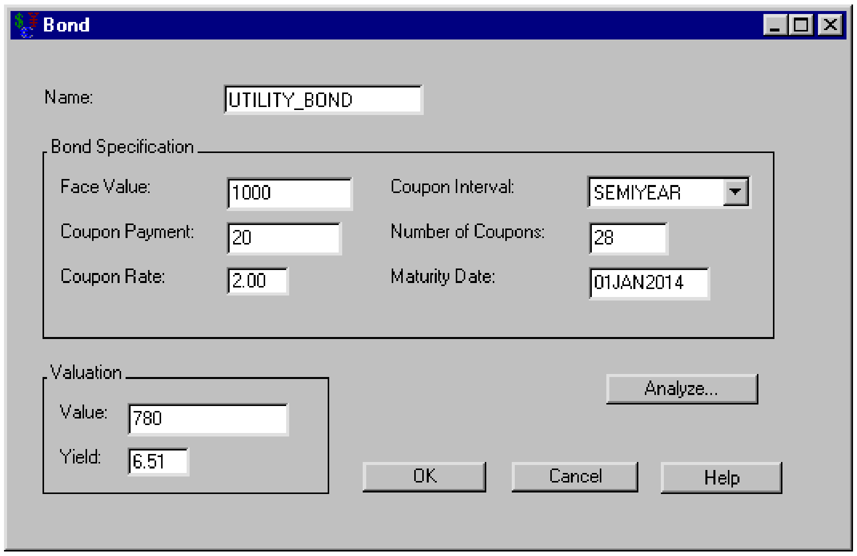
Value: 666.73873564

Yield: 8.00

Figure 44.13. Bond Value

Computing the Yield from Price

Now enter 780 for **Value** within the **Valuation** area. You see the yield is only 6.5%, as in Figure 44.14. This is not acceptable if you desire an 8% MARR.



Name: UTILITY_BOND

Bond Specification

Face Value:	1000	Coupon Interval:	SEMIYEAR
Coupon Payment:	20	Number of Coupons:	28
Coupon Rate:	2.00	Maturity Date:	01JAN2014

Valuation

Value: 780

Yield: 6.51

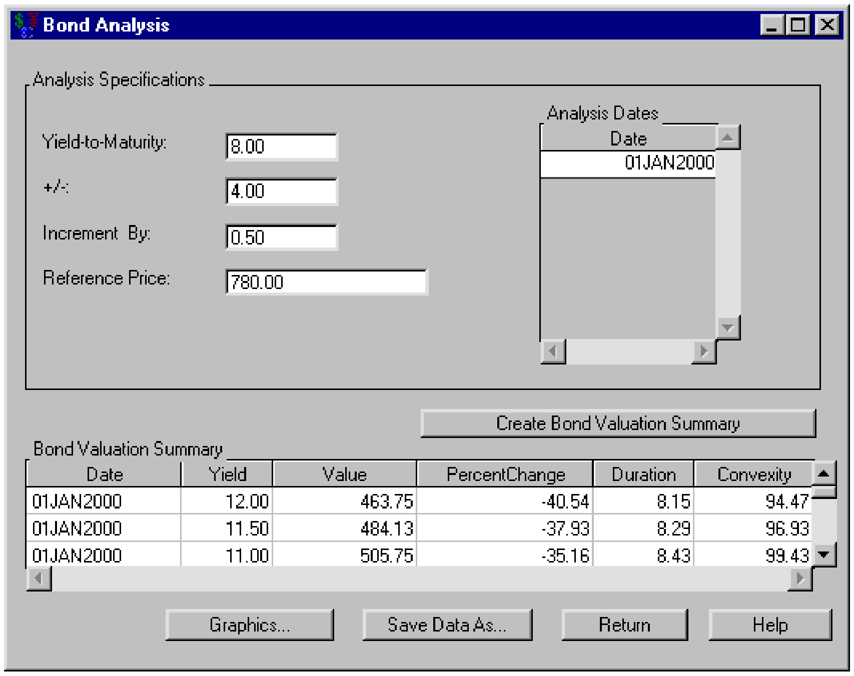
Figure 44.14. Bond Yield

Performing Bond Analysis

To perform bond-pricing analysis, follow these steps:

1. Click **Analyze...** to open the Bond Analysis dialog box.
2. Enter 8.0 as the **Yield to Maturity**.
3. Enter 4.0 as the +/-.
4. Enter 0.5 as the **Increment by**.
5. Enter 780 as the **Reference Price**.
6. Click **Create Bond Valuation Summary**.

The **Bond Valuation Summary** area fills and shows you the different values for various yields as in Figure 44.15.



Yield-to-Maturity: 8.00
+/-: 4.00
Increment By: 0.50
Reference Price: 780.00

Date
01JAN2000

Date	Yield	Value	PercentChange	Duration	Convexity
01JAN2000	12.00	463.75	-40.54	8.15	94.47
01JAN2000	11.50	484.13	-37.93	8.29	96.93
01JAN2000	11.00	505.75	-35.16	8.43	99.43

Figure 44.15. Bond Price Analysis

Creating a Price versus Yield-to-Maturity Graph

Click **Graphics...** to open the Bond Price dialog box. This contains the price versus yield-to-maturity graph shown in Figure 44.16.

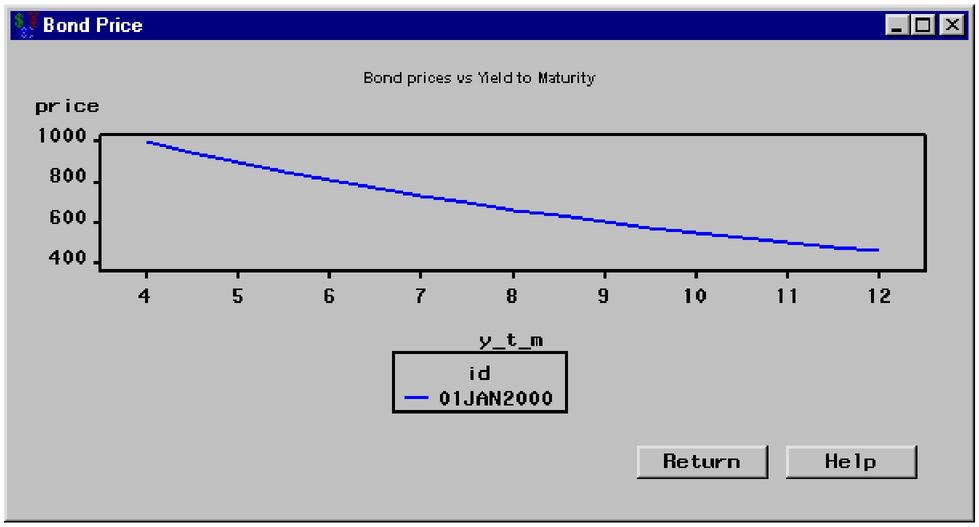


Figure 44.16. Bond Price Graph

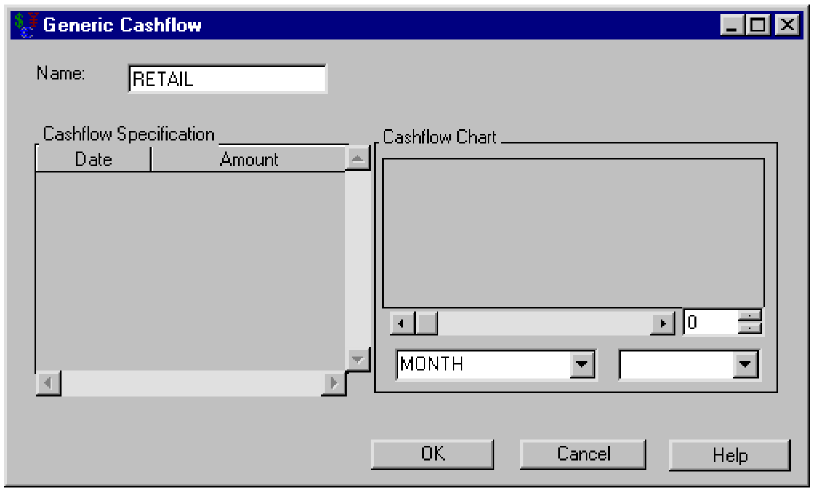
Click **Return** to return to the Bond Analysis dialog box. Click **OK** to return to the Bond dialog box. Click **OK** to return to the Investment Analysis dialog box.

Generic Cashflow Tasks

To specify a generic cashflow, you merely define any sequence of date-amount pairs. The flexibility of generic cashflows enables the user to represent economic alternatives/investments that do not fit into loan, savings, depreciation, or bond specifications.

From the Investment Analysis dialog box, select **Investment** → **New** → **Generic Cashflow...** from the menu bar to open the **Generic Cashflow** dialog box. Enter RETAIL for the **Name** as in Figure 44.17.



Name: RETAIL

Figure 44.17. Introducing the Generic Cashflow

Right-Clicking within the Cashflow Specification Area

Right-clicking within Generic Cashflow's **Cashflow Specification** area reveals the pop-up menu displayed in Figure 44.18. The menu provides many useful tools to assist you in creating these date-amount pairs.

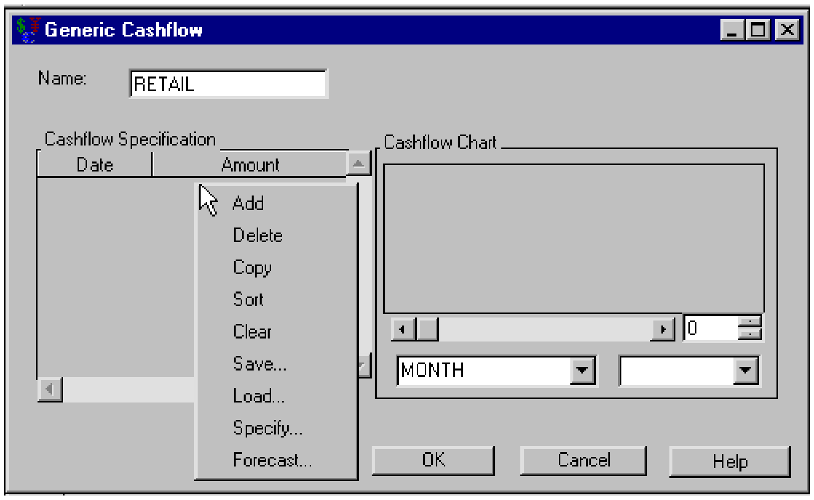


Figure 44.18. Right-Clicking within the Cashflow Specification Area

The following sections describe how to use most of these right-click options. The **Specify...** and **Forecast...** options are described in "Including a Generated Cashflow" and "Including a Forecasted Cashflow".

Adding a New Date-Amount Pair

To add a new date-amount pair manually, follow these steps:

1. Right-click in the **Cashflow Specification** area as shown in Figure 44.18, and release on **Add**.
2. Enter 01JAN01 for the date.
3. Enter 100 for the amount.

Copying a Date-Amount Pair

To copy a selected date-amount pair, follow these steps:

1. Select the pair you just created.
2. Right-click in the **Cashflow Specification** area as shown in Figure 44.18, but this time release on **Copy**.

Sorting All of the Date-Amount Pairs

Change the second date to 01JAN00. Now the dates are unsorted. Right-click in the **Cashflow Specification** area as shown in Figure 44.18, and release on **Sort**.

Deleting a Date-Amount Pair

To delete a selected date-amount pair, follow these steps:

1. Select a date-amount pair.
2. Right-click in the **Cashflow Specification** area as shown in Figure 44.18, and release on **Delete**.

Clearing All of the Date-Amount Pairs

To clear all date-amount pairs, right-click in the **Cashflow Specification** area as shown in Figure 44.18, and release on **Clear**.

Loading Date-Amount Pairs from a Dataset

To load date-amount pairs from a SAS data set into the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Load...**. This opens the Load Dataset dialog box.
2. Enter SASHELP.RETAIL for **Dataset Name**.
3. Click **OK** to return to the Generic Cashflow dialog box.

If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no **Date** variable, it loads the first available date or datetime-formatted variable. Investment Analysis then searches the SAS data set for an **Amount** variable to use. If none exists, it takes the first numeric variable that is not used by the **Date** variable.

Saving Date-Amount Pairs to a Dataset

To save date-amount pairs from the **Cashflow Specification** area to a SAS data set, follow these steps:

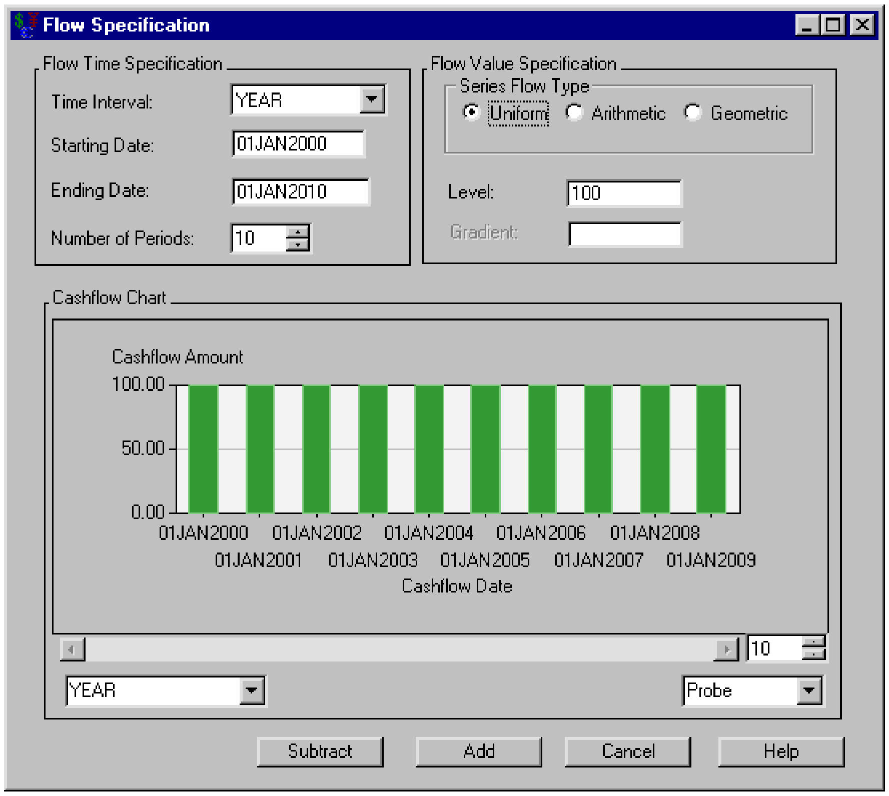
1. Right-click in the **Cashflow Specification** area and release on **Save...**. This opens the Save Dataset dialog box.
2. Enter the name of the SAS data set for **Dataset Name**.
3. Click **OK** to return to the Generic Cashflow dialog box.

Including a Generated Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Specify...**. This opens the Flow Specification dialog box.
2. Select **YEAR** for the **Time Interval**.
3. Enter today’s date for the **Starting Date**.

4. Enter 10 for the **Number of Periods**. The **Ending Date** updates.
5. Enter 100 for the level. You can visualize the specification in the Cashflow Chart area (see Figure 44.19).
6. Click **Add** to add the specified cashflow to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.



Flow Specification

Flow Time Specification

Time Interval: YEAR

Starting Date: 01JAN2000

Ending Date: 01JAN2010

Number of Periods: 10

Flow Value Specification

Series Flow Type: [✓ Uniform] Arithmetic Geometric

Level: 100

Gradient:

Figure 44.19. Uniform Cashflow Specification

Clicking **Subtract** will subtract the current cashflow from the Generic Cashflow dialog box as it returns you to the Generic Cashflow dialog box.

You can generate arithmetic and geometric specifications by clicking them within the **Series Flow Type** area. However, you must enter a value for the **Gradient**. In both cases the **Level** value is the value of the list at the **Starting Date**. With an arithmetic flow type, entries increment by the value **Gradient** each **Time Interval**. With a geometric flow type, entries increase by the factor **Gradient** each **Time Interval**. Figure 44.20 displays an arithmetic cashflow with a **Level** of 100 and a **Gradient** of 12.

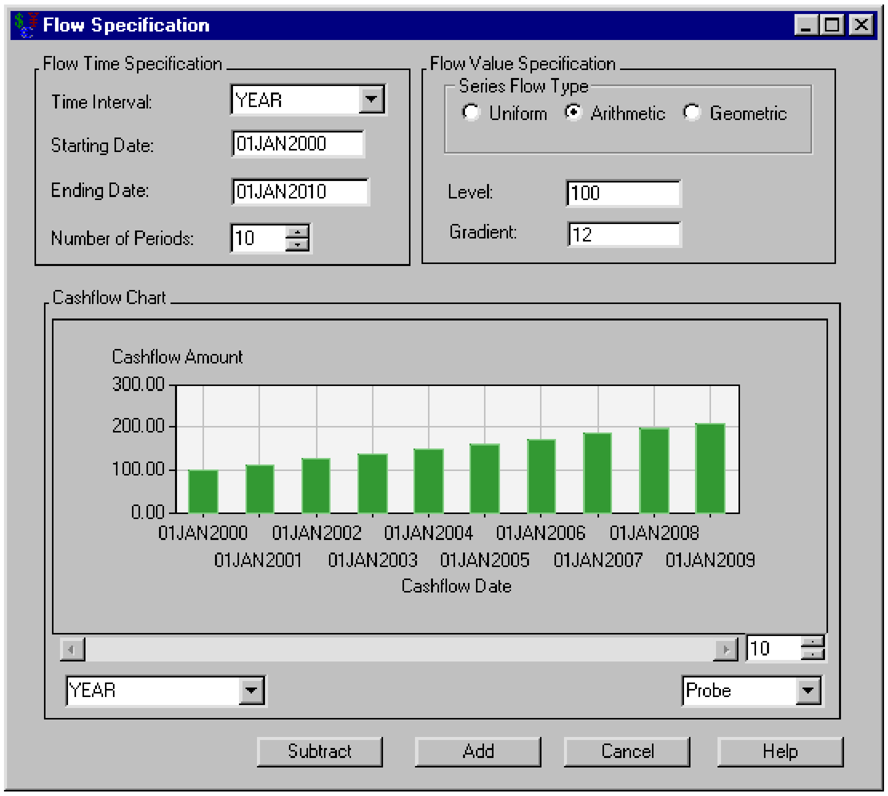


Figure 44.20. Arithmetic Cashflow Specification

Including a Forecasted Cashflow

To generate date-amount pairs for the **Cashflow Specification** area, follow these steps:

1. Right-click in the **Cashflow Specification** area and release on **Forecast...**. This opens the **Forecast Specification** dialog box.
2. Enter SASHELP.RETAIL as the **Data Set**.
3. Select SALES for the **Analysis Variable**.
4. Click **Compute Forecast** to generate the forecast. You can visualize the forecast in the Cashflow Chart area (see Figure 44.21).
5. Click **Add** to add the forecast to the list in the Generic Cashflow dialog box. Clicking **Add** also returns you to the Generic Cashflow dialog box.

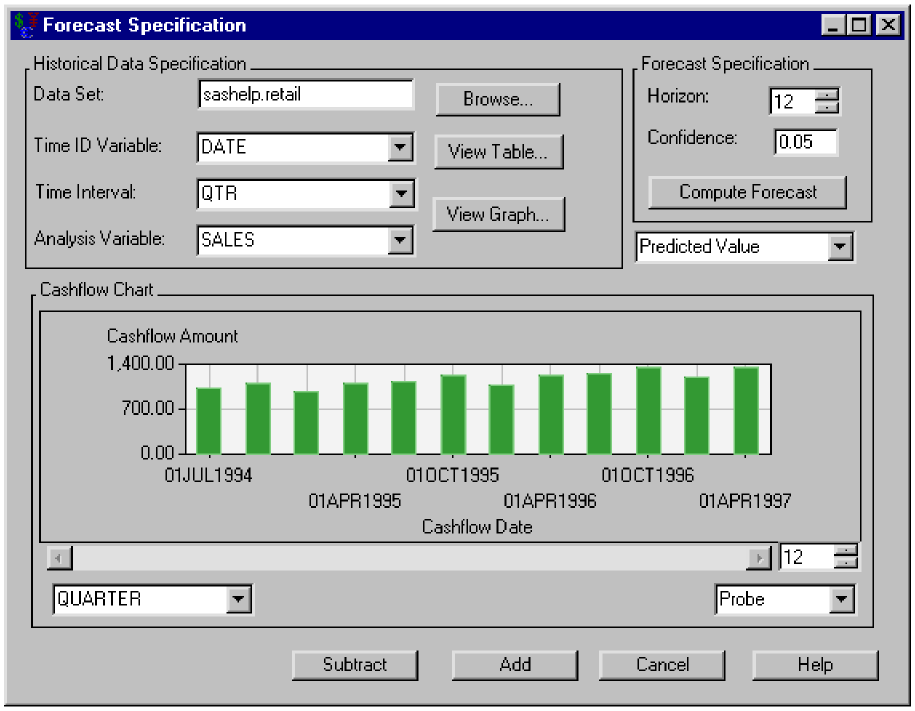

Figure 44.21. Cashflow Forecast

Clicking **Subtract** will subtract the current forecast from the Generic Cashflow dialog box as it returns you to the Generic Cashflow dialog box.

To review the values from the SAS data set you forecast, click **View Table...** or **View Graph...**.

You can adjust the following values for the SAS data set you forecast: **Time ID Variable**, **Time Interval**, and **Analysis Variable**.

You can adjust the following values for the forecast: the **Horizon**, the **Confidence**, and choice of predicted value, lower confidence limit, and upper confidence limit.

Using the Cashflow Chart

Three dialog boxes contain the Cashflow Chart to aide in your visualization of cashflows: Generic Cashflow, Flow Specification, and Forecast Specification. Within this chart, you possess the following tools:

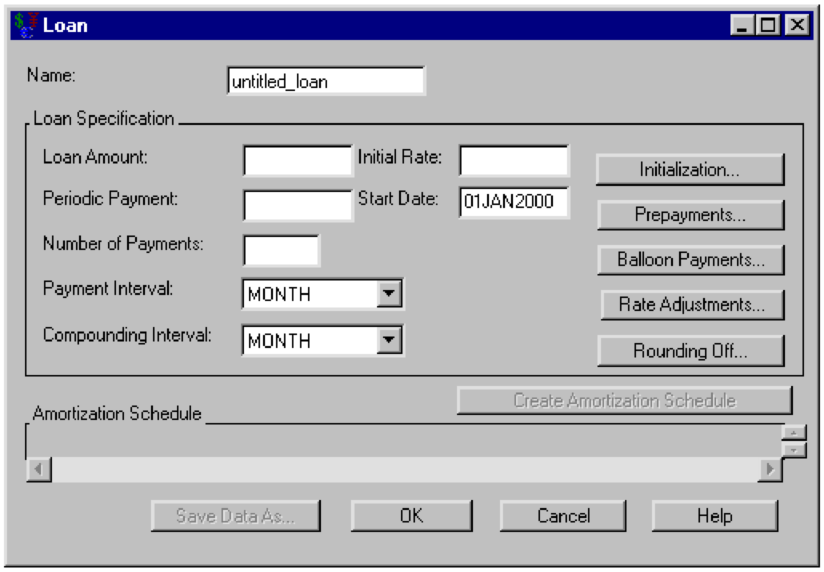
You can click on a bar in the plot and view its **Cashflow Date** and **Cashflow Amount**.

You can change the aggregation period of the view with the box in the lower left corner of the Cashflow Chart. You can take the quarterly sales figures from the previous example, select YEAR as the value for this box, and view the annual sales figures. You can change the number in the box to the right of the horizontal scroll bar to alter the number of entries you wish to view. The number in that box must be no greater than the number of entries in the cashflow list. Lessening this number has the effect of zooming in upon a portion of the cashflow. When the number is less than the number of entries in the cashflow list, you can use the scroll bar at the bottom of the chart to scroll through the chart.

Dialog Box Guide

Loan

Selecting **Investment** → **New** → **Loan...** from the Investment Analysis dialog box's menu bar opens the Loan dialog box displayed in Figure 44.22.



Name: untitled_loan

Start Date: 01JAN2000

Payment Interval: MONTH

Compounding Interval: MONTH

Figure 44.22. Loan Dialog Box

The following items are displayed:

Name holds the name you assign to the loan. You can set the name here or within the **Portfolio** area of the Investment Analysis dialog box. This must be a valid SAS name.

The **Loan Specification** area gives access to the values that define the loan.

Loan Amount holds the borrowed amount.

Periodic Payment holds the value of the periodic payments.

Number of Payments holds the number of payments in loan terms.

Payment Interval holds the frequency of the **Periodic Payment**.

Compounding Interval holds the compounding frequency.

Initial Rate holds the interest rate (a nominal percentage between 0 and 120) you pay on the loan.

Start Date holds the SAS date when the loan is initialized. The first payment is due one **Payment Interval** after this time.

Initialization... opens the Loan Initialization Options dialog box where you can define initialization costs and down-payments relevant to the loan.

Prepayments... opens the Loan Prepayments dialog box where you can specify the SAS dates and amounts of any prepayments.

Balloon Payments... opens the Balloon Payments dialog box where you can specify the SAS dates and amounts of any balloon payments.

Rate Adjustments... opens the Rate Adjustment Terms dialog box where you can specify terms for a variable-rate loan.

Rounding Off... opens the Rounding Off dialog box where you can select the number of decimal places for calculations.

Create Amortization Schedule becomes available when you adequately define the loan within the **Loan Specification** area. Clicking it generates the amortization schedule.

Amortization Schedule fills when you click **Create Amortization Schedule**. The schedule contains a row for the loan's start-date and each payment-date with information about the following:

Date is a SAS date, either the loan's start-date or a payment-date.

Beginning Principal Amount is the balance at that date.

Periodic Payment Amount is the expected payment at that date.

Interest Payment is zero for the loan's start-date; otherwise it holds the interest since the previous date.

Principal Repayment is the amount of the payment that went toward the principal.

Ending Principal is the balance at the end of the payment interval.

Print becomes available when you generate the amortization schedule. Clicking it sends the contents of the amortization schedule to the SAS session print device.

Save Data As... becomes available when you generate the amortization schedule. Clicking it opens the Save Output Dataset dialog box where you can save the amortization table (or portions thereof) as a SAS Dataset.

OK returns you to the Investment Analysis dialog box. If this is a new loan specification, clicking **OK** appends the current loan specification to the portfolio. If this is an existing loan specification, clicking **OK** returns the altered loan specification to the portfolio.

Cancel returns you to the Investment Analysis dialog box. If this is a new loan specification, clicking **Cancel** discards the current loan specification. If this is an existing loan specification, clicking **Cancel** discards the current editions.

Loan Initialization Options

Clicking **Initialization...** in the Loan dialog box opens the Loan Initialization Options dialog box displayed in Figure 44.23.

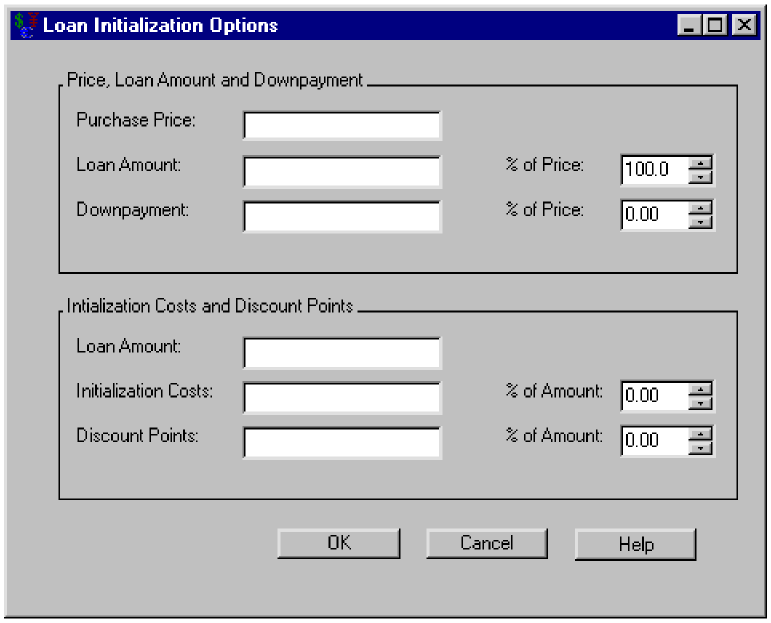


Figure 44.23. Loan Initialization Options Dialog Box

The following items are displayed:

The **Price, Loan Amount and Downpayment** area

> **Purchase Price** holds the actual price of the asset. This value equals the loan amount plus the downpayment.
>
> **Loan Amount** holds the loan amount.
>
> **% of Price** (to the right of **Loan Amount**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Loan Amount**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.
>
> **Downpayment** holds any downpayment paid for the asset.
>
> **% of Price** (to the right of **Downpayment**) updates when you enter the **Purchase Price** and either the **Loan Amount** or **Downpayment**. This holds the percentage of the **Purchase Price** that comprises the **Downpayment**. Setting the percentage manually causes the **Loan Amount** and **Downpayment** to update.

Initialization Costs and Discount Points area

Loan Amount holds a copy of the **Loan Amount** above.

Initialization Costs holds the value of any initialization costs.

% of Amount (to the right of **Initialization Costs**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Initialization Costs**. Setting the percentage manually causes the **Initialization Costs** to update.

Discount Points holds the value of any discount points.

% of Amount (to the right of **Discount Points**) updates when you enter the **Purchase Price** and either the **Initialization Costs** or **Discount Points**. This holds the percentage of the **Loan Amount** that comprises the **Discount Points**. Setting the percentage manually causes the **Discount Points** to update.

OK returns you to the Loan dialog box, saving the information that is entered.

Cancel returns you to the Loan dialog box, discarding any editions since you opened the dialog box.

Loan Prepayments

Clicking **Prepayments...** in the Loan dialog box opens the Loan Prepayments dialog box displayed in Figure 44.24.

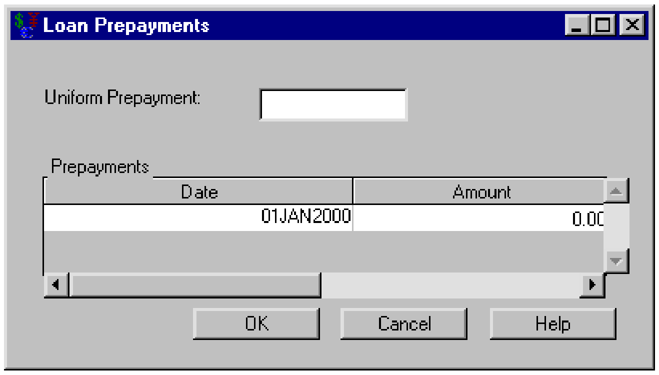

Figure 44.24. Loan Prepayments Dialog Box

The following items are displayed:

Uniform Prepayment holds the value of a regular prepayment concurrent to the usual periodic payment.

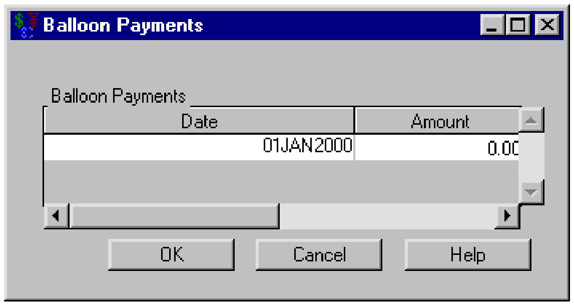
Prepayments holds a list of date-amount pairs to accommodate any prepayments. Right-clicking within the **Prepayments** area reveals many helpful tools for managing date-amount pairs.

OK returns you to the Loan dialog box, storing the information entered on the prepayments.

Cancel returns you to the Loan dialog box, discarding any prepayments entered since you opened the dialog box.

Balloon Payments

Clicking **Balloon Payments...** in the Loan dialog box opens the Balloon Payments dialog box displayed in Figure 44.25.



Date	Amount
01JAN2000	0.00

Figure 44.25. Balloon Payments Dialog Box

The following items are displayed:

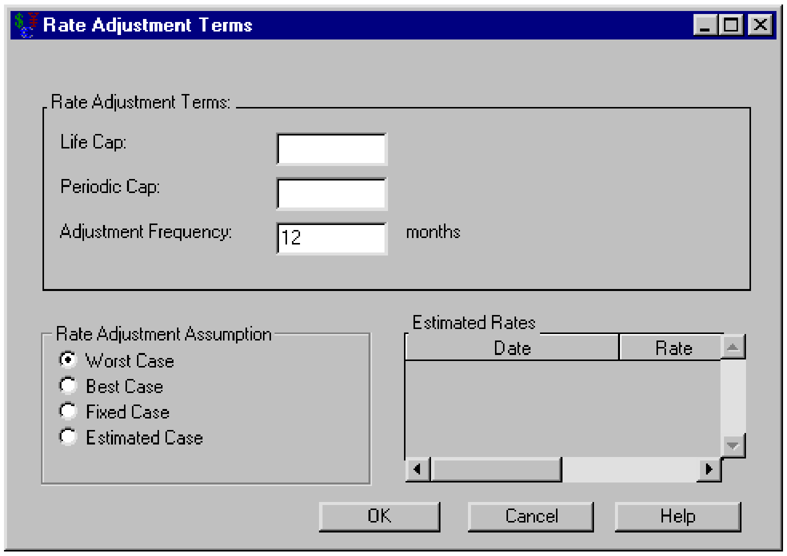
Balloon Payments holds a list of date-amount pairs to accommodate any balloon payments. Right-clicking within the **Balloon Payments** area reveals many helpful tools for managing date-amount pairs.

OK returns you to the Loan dialog box, storing the information entered on the balloon payments.

Cancel returns you to the Loan dialog box, discarding any balloon payments entered since you opened the dialog box.

Rate Adjustment Terms

Clicking **Rate Adjustments...** in the Loan dialog box opens the Rate Adjustment Terms dialog box displayed in Figure 44.26.



Rate Adjustment Terms

Rate Adjustment Terms:

Life Cap:

Periodic Cap:

Adjustment Frequency: 12 months

Rate Adjustment Assumption

[✓ Worst Case]
Best Case
Fixed Case
Estimated Case

Estimated Rates

Date	Rate

Figure 44.26. Rate Adjustment Terms Dialog Box

The following items are displayed:

The **Rate Adjustment Terms** area

> **Life Cap** holds the maximum deviation from the **Initial Rate** allowed over the life of the loan.
>
> **Periodic Cap** holds the maximum adjustment allowed per adjustment.
>
> **Adjustment Frequency** holds how often (in months) the lender can adjust the interest rate.

The **Rate Adjustment Assumption** determines the scenario the adjustments will take.

> **Worst Case** uses information from the **Rate Adjustment Terms** area to forecast a worst-case scenario.
>
> **Best Case** uses information from the **Rate Adjustment Terms** area to forecast a best-case scenario.
>
> **Fixed Case** specifies a fixed-rate loan.
>
> **Estimated Case** uses information from the **Rate Adjustment Terms** and **Estimated Rate** area to forecast a best-case scenario.

Estimated Rates holds a list of date-rate pairs, where each date is a SAS date and the rate is a nominal percentage between 0 and 120. The **Estimated Case** assumption uses these rates for its calculations. Right-clicking within the **Estimated Rates** area reveals many helpful tools for managing date-rate pairs.

OK returns you to the Loan dialog box, taking rate adjustment information into account.

Cancel returns you to the Loan dialog box, discarding any rate adjustment information provided since opening the dialog box.

Rounding Off

Clicking **Rounding Off...** in the Loan dialog box opens the Rounding Off dialog box displayed in Figure 44.27.

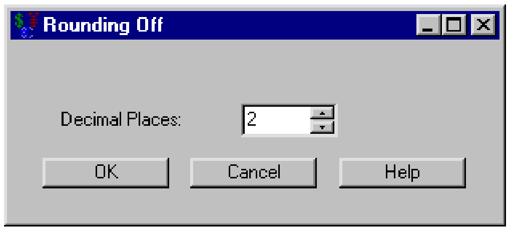


Figure 44.27. Rounding Off Dialog Box

The following items are displayed:

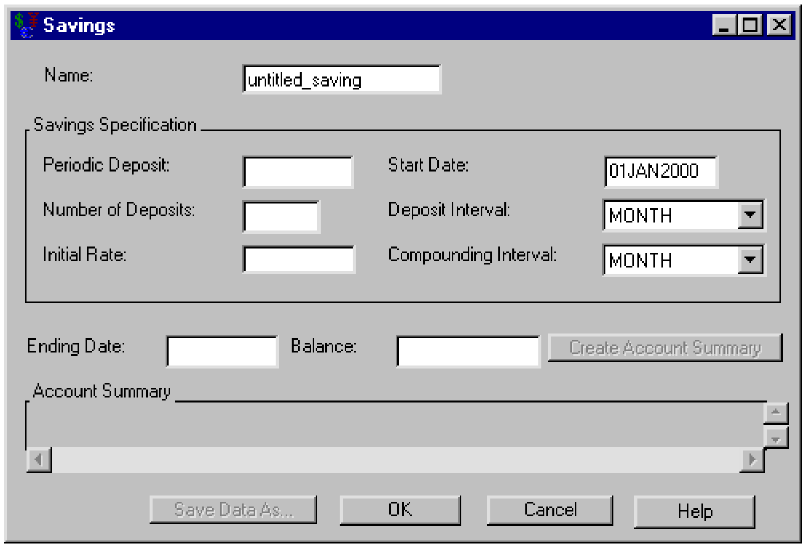
Decimal Places fixes the number of decimal places your results will display.

OK returns you to the Loan dialog box. Numeric values will then be represented with the number of decimals specified in **Decimal Places**.

Cancel returns you to the Loan dialog box. Numeric values will be represented with the number of decimals specified prior to opening this dialog box.

Savings

Selecting **Investment** → **New** → **Savings...** from the Investment Analysis dialog box's menu bar opens the Savings dialog box displayed in Figure 44.28.



Name: untitled_saving

Periodic Deposit:

Number of Deposits:

Initial Rate:

Start Date: 01JAN2000

Deposit Interval: MONTH

Compounding Interval: MONTH

Ending Date:

Balance:

Figure 44.28. Savings Dialog Box

The following items are displayed:

Name holds the name you assign to the savings. You can set the name here or within the **Portfolio** area of the Investment Analysis dialog box. This must be a valid SAS name.

The **Savings Specification** area

> **Periodic Deposit** holds the value of your regular deposits.
>
> **Number of Deposits** holds the number of deposits into the account.
>
> **Initial Rate** holds the interest rate (a nominal percentage between 0 and 120) the savings account earns.
>
> **Start Date** holds the SAS date when deposits begin.
>
> **Deposit Interval** holds the frequency of your **Periodic Deposit**.
>
> **Compounding Interval** holds how often the interest compounds.

Create Account Summary becomes available when you adequately define the savings within the **Savings Specification** area. Clicking it generates the account summary.

Account Summary fills when you click **Create Account Summary**. The schedule contains a row for each deposit-date with information about the following:

> **Date** is the SAS date of a deposit.
>
> **Starting Balance** is the balance at that date.
>
> **Deposits** is the deposit at that date.
>
> **Interest Earned** is the interest earned since the previous date.

Ending Balance is the balance after the payment.

Print becomes available when you generate an account summary. Clicking it sends the contents of the account summary to the SAS session print device.

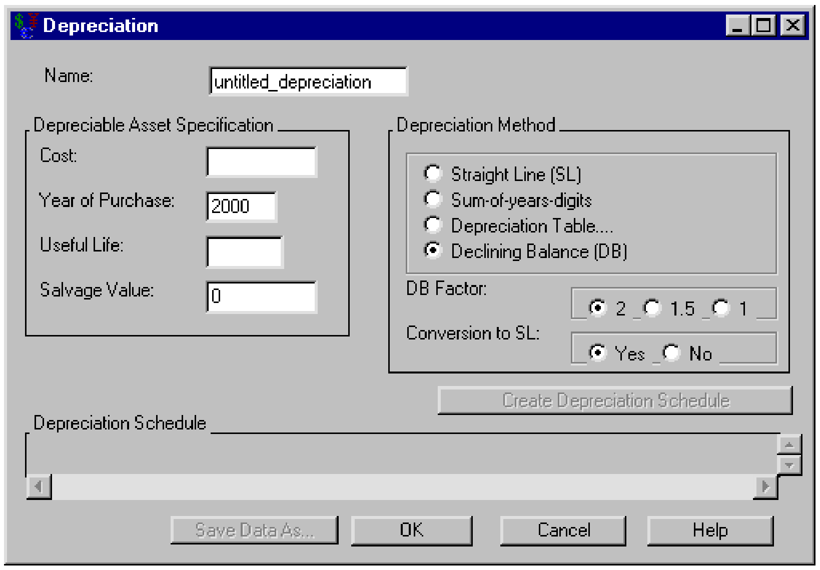
Save Data As... becomes available when you generate an account summary. Clicking it opens the Save Output Dataset dialog box where you can save the account summary (or portions thereof) as a SAS Dataset.

OK returns you to the Investment Analysis dialog box. If this is a new savings, clicking **OK** appends the current savings specification to the portfolio. If this is an existing savings specification, clicking **OK** returns the altered savings to the portfolio.

Cancel returns you to the Investment Analysis dialog box. If this is a new savings, clicking **Cancel** discards the current savings specification. If this is an existing savings, clicking **Cancel** discards the current editions.

Depreciation

Selecting **Investment** → **New** → **Depreciation...** from the Investment Analysis dialog box's menu bar opens the Depreciation dialog box displayed in Figure 44.29.



Depreciation

Name: untitled_depreciation

Depreciable Asset Specification
Cost:
Year of Purchase: 2000
Useful Life:
Salvage Value: 0

Depreciation Method
Straight Line (SL)
Sum-of-years-digits
Depreciation Table....
[✓ Declining Balance (DB)]

DB Factor: [✓ 2] 1.5 1
Conversion to SL: [✓ Yes] No

Figure 44.29. Depreciation Dialog Box

The following items are displayed:

Name holds the name you assign to the depreciation. You can set the name here or within the **Portfolio** area of the Investment Analysis dialog box. This must be a valid SAS name.

Depreciable Asset Specification

Cost holds the asset's original cost.

Year of Purchase holds the asset's year of purchase.

Useful Life holds the asset's useful life (in years).

Salvage Value holds the asset's value at the end of its **Useful Life**.

The **Depreciation Method** area holds the depreciation methods available:

- Straight Line
- Sum-of-years Digits
- Depreciation Table...
- Declining Balance
  - DB Factor: choice of 2, 1.5, or 1
  - Conversion to SL: choice of Yes or No

Create Depreciation Schedule becomes available when you adequately define the depreciation within the **Depreciation Asset Specification** area. Clicking the **Create Depreciation Schedule** button then fills the **Depreciation Schedule** area.

Depreciation Schedule fills when you click **Create Depreciation Schedule**. The schedule contains a row for each year. Each row holds:

Year is a year

Start Book Value is the starting book value for that year

Depreciation is the depreciation value for that year

End Book Value is the ending book value for that year

Print becomes available when you generate the depreciation schedule. Clicking it sends the contents of the depreciation schedule to the SAS session print device.

Save Data As... becomes available when you generate the depreciation schedule. Clicking it opens the Save Output Dataset dialog box where you can save the depreciation table (or portions thereof) as a SAS Dataset.

OK returns you to the Investment Analysis dialog box. If this is a new depreciation specification, clicking **OK** appends the current depreciation specification to the portfolio. If this is an existing depreciation specification, clicking **OK** returns the altered depreciation specification to the portfolio.

Cancel returns you to the Investment Analysis dialog box. If this is a new depreciation specification, clicking **Cancel** discards the current depreciation specification. If this is an existing depreciation specification, clicking **Cancel** discards the current editions.

Depreciation Table

Clicking **Depreciation Table...** from **Depreciation Method** area of the Depreciation dialog box opens the Depreciation Table dialog box displayed in Figure 44.30.

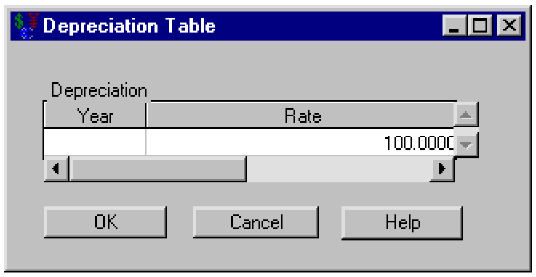


Figure 44.30. Depreciation Table Dialog Box

The following items are displayed:

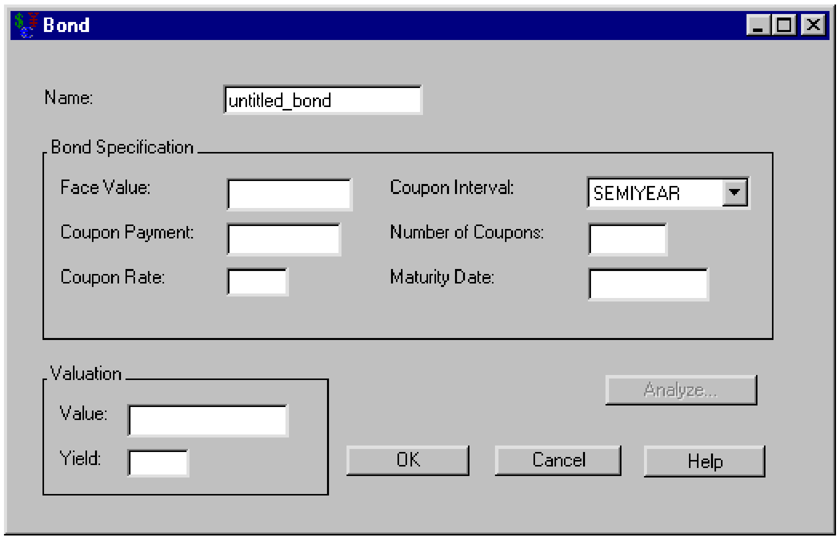
The **Depreciation** area holds a list of year-rate pairs where the rate is an annual depreciation rate (a percentage between 0% and 100%). Right-clicking within the **Depreciation** area reveals many helpful tools for managing year-rate pairs.

OK returns you to the Depreciation dialog box with the current list of depreciation rates from the **Depreciation** area.

Cancel returns you to the Depreciation dialog box, discarding any editions to the **Depreciation** area since you opened the dialog box.

Bond

Selecting **Investment** → **New** → **Bond...** from the Investment Analysis dialog box's menu bar opens the Bond dialog box displayed in Figure 44.31.



Name: untitled_bond

Bond Specification

Face Value:
Coupon Payment:
Coupon Rate:
Coupon Interval: SEMIYEAR
Number of Coupons:
Maturity Date:

Valuation

Value:
Yield:

Figure 44.31. Bond

The following items are displayed:

Name holds the name you assign to the bond. You can set the name here or within the **Portfolio** area of the Investment Analysis dialog box. This must be a valid SAS name.

Bond Specification

> **Face Value** holds the bond's value at maturity.
>
> **Coupon Payment** holds the amount of money you receive periodically as the bond matures.
>
> **Coupon Rate** holds the rate (a nominal percentage between 0% and 120%) of the **Face Value** that defines the **Coupon Payment**.
>
> **Coupon Interval** holds how often the bond pays its coupons.
>
> **Number of Coupons** holds the number of coupons before maturity.
>
> **Maturity Date** holds the SAS date when you can redeem the bond for its **Face Value**.

The **Valuation** area becomes available when you adequately define the bond within the **Bond Specification** area. Entering either the **Value** or the **Yield** causes the calculation of the other. If you respecify the bond after performing a calculation here, you must reenter the **Value** or **Yield** value to update the calculation.

> **Value** holds the bond's value if expecting the specified **Yield**.
>
> **Yield** holds the bond's yield if the bond is valued at the amount of **Value**.

You must specify the bond before analyzing it. Once you have specified the bond, clicking **Analyze...** opens the Bond Analysis dialog box where you can compare various values and yields.

OK returns you to the Investment Analysis dialog box. If this is a new bond specification, clicking **OK** appends the current bond specification to the portfolio. If this is an existing bond specification, clicking **OK** returns the altered bond specification to the portfolio.

Cancel returns you to the Investment Analysis dialog box. If this is a new bond specification, clicking **Cancel** discards the current bond specification. If this is an existing bond specification, clicking **Cancel** discards the current editions.

Bond Analysis

Clicking **Analyze...** from the Bond dialog box opens the Bond Analysis dialog box displayed in Figure 44.32.

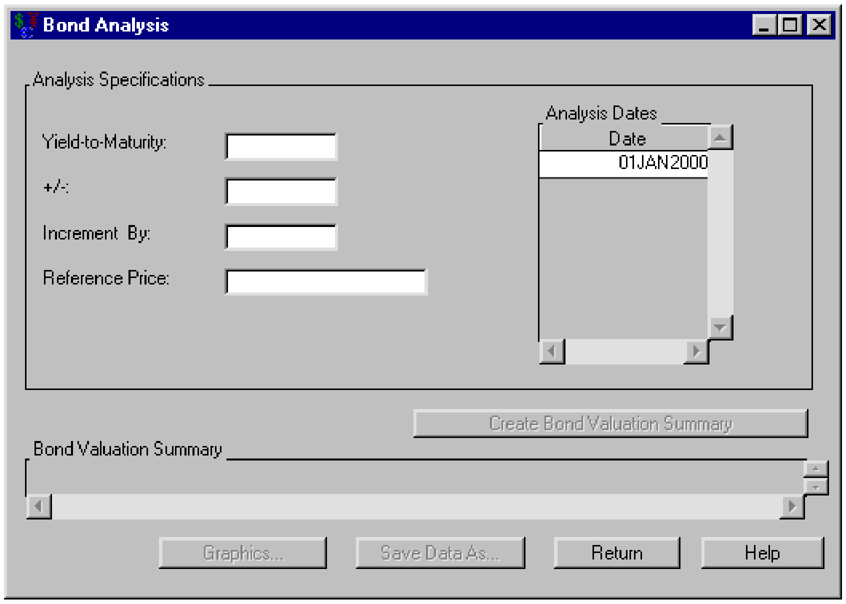


Figure 44.32. Bond Analysis

The following items are displayed:

Analysis Specifications

Yield-to-maturity holds the percentage yield upon which to center the analysis.

+/- holds the maximum deviation percentage from the **Yield-to-maturity** to consider.

Increment by holds the percentage increment by which the analysis is calculated.

Reference Price holds the reference price.

Analysis Dates holds a list of SAS dates for which you perform the bond analysis.

You must specify the analysis before valuing the bond for the various yields. Once you adequately specify the analysis, click **Create Bond Valuation Summary** to generate the bond valuation summary.

Bond Valuation Summary fills when you click **Create Bond Valuation Summary**. The schedule contains a row for each rate with information concerning the following:

Date is the SAS date when the **Value** gives the particular **Yield**.

Yield is the percent yield that corresponds to the **Value** at the given **Date**.

Value is the value of the bond at **Date** for the given **Yield**.

Percent Change is the percent change if the **Reference Price** is specified.

Duration is the duration.

Convexity is the convexity.

Graphics... opens the Bond Price graph representing the price versus yield-to-maturity.

Print becomes available when you generate the **Bond Valuation Summary**. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you fill the **Bond Valuation Summary** area. Clicking it opens the Save Output Dataset dialog box where you can save the valuation summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Bond dialog box.

Bond Price

Clicking **Graphics...** from the Bond dialog box opens the Bond Price dialog box displayed in Figure 44.33.

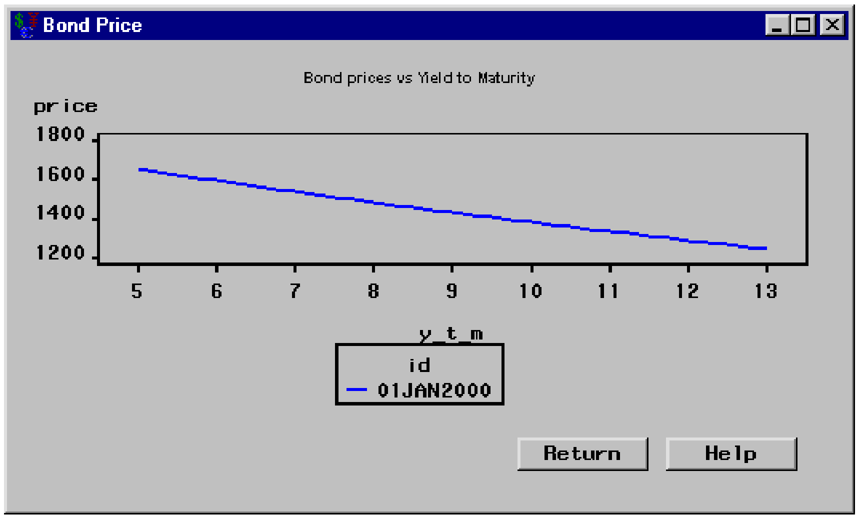

Figure 44.33. Bond Price Graph

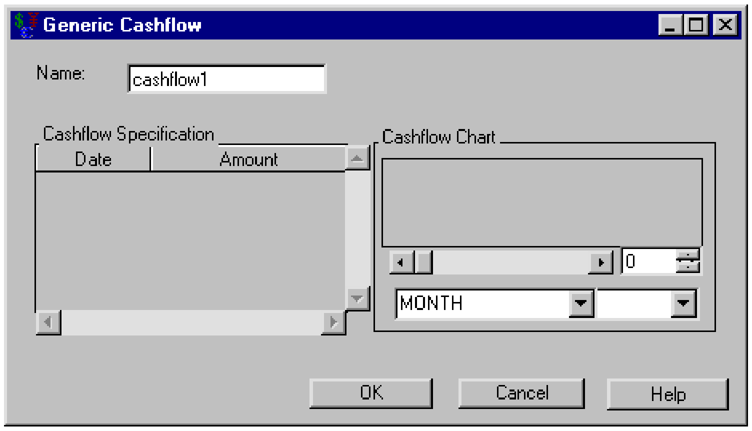
It possesses the following item:

Return takes you back to the Bond Analysis dialog box.

Generic Cashflow

Selecting **Investment** → **New** → **Generic Cashflow...** from the Investment Analysis dialog box's menu bar opens the Generic Cashflow dialog box displayed in Figure 44.34.



Name: cashflow1

Figure 44.34. Generic Cashflow

The following items are displayed:

Name holds the name you assign to the generic cashflow. You can set the name here or within the **Portfolio** area of the Investment Analysis dialog box. This must be a valid SAS name.

Cashflow Specification holds date-amount pairs corresponding to deposits and withdrawals (or benefits and costs) for the cashflow. Each date is a SAS date. Right-clicking within the **Cashflow Specification** area reveals many helpful tools for managing date-amount pairs.

The **Cashflow Chart** fills with a graph representing the cashflow when the **Cashflow Specification** area is nonempty. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency for drilling purposes.

OK returns you to the Investment Analysis dialog box. If this is a new generic cashflow specification, clicking **OK** appends the current cashflow specification to the portfolio. If this is an existing cashflow specification, clicking **OK** returns the altered cashflow specification to the portfolio.

Cancel returns you to the Investment Analysis dialog box. If this is a new cashflow specification, clicking **Cancel** discards the current cashflow specification. If this is an existing cashflow specification, clicking **Cancel** discards the current editions.

Right-Clicking within Generic Cashflow's Cashflow Specification Area

Right-click within the **Cashflow Specification** area of the Generic Cashflow dialog box pops up the menu displayed in Figure 44.35.

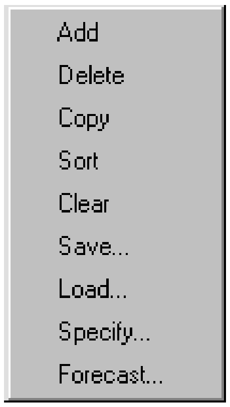


Figure 44.35. Right-Clicking

Add creates a blank pair.

Delete removes the currently highlighted pair.

Copy duplicates the currently selected pair.

Sort arranges the entered pairs in chronological order.

Clear empties the area of all pairs.

Save... opens the Save Dataset dialog box where you can save the entered pairs as a SAS Dataset for later use.

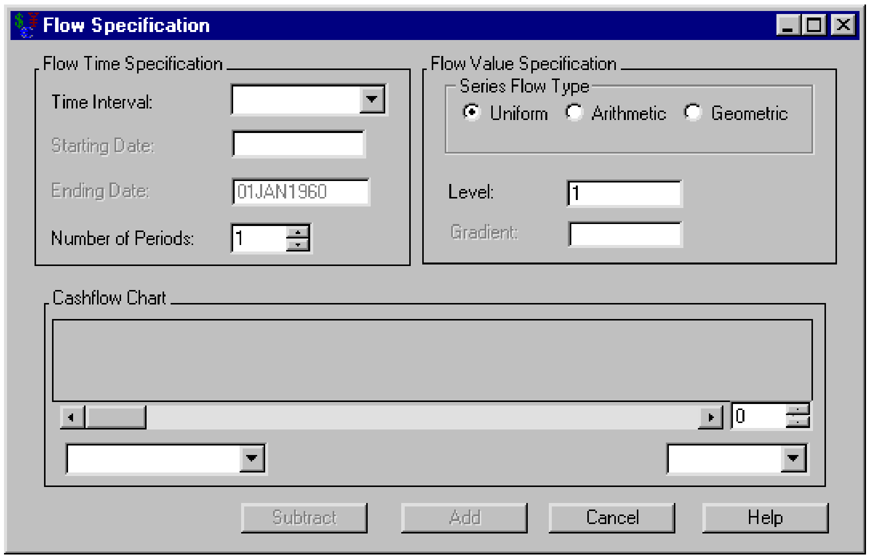
Load... opens the Load Dataset dialog box where you select a SAS Dataset to populate the area.

Specify... opens the Flow Specification dialog box where you can generate date-rate pairs to include in your cashflow.

Forecast... opens the Forecast Specification dialog box where you can generate the forecast of a SAS data set to include in your cashflow.

If you wish to perform one of these actions on a collection of pairs, you must select a collection of pairs before right-clicking. To select an adjacent list of pairs, do the following: click the first pair, hold down SHIFT, and click the final pair. Once the list of pairs is selected, you may release the SHIFT key.

Flow Specification



Flow Specification

Flow Time Specification
Time Interval:
Starting Date:
Ending Date: 01JAN1960
Number of Periods: 1

Flow Value Specification
Series Flow Type
[✓ Uniform] Arithmetic Geometric
Level: 1
Gradient:

Cashflow Chart
0

Figure 44.36. Flow Specification

The following items are displayed:

Flow Time Specification

Time Interval holds the uniform frequency of the entries.

You can set the **Starting Date** when you set the **Time Interval**. It holds the SAS date the entries will start.

You can set the **Ending Date** when you set the **Time Interval**. It holds the SAS date the entries will end.

Number of Periods holds the number of entries.

Flow Value Specification

Series Flow Type describes the movement the entries can assume:

- **Uniform** assumes all entries are equal.
- **Arithmetic** assumes the entries begin at **Level** and increase by the value of **Gradient** per entry.
- **Geometric** assumes the entries begin at **Level** and increase by a factor of **Gradient** per entry.

Level holds the starting amount for all **Flow Type**s.

You can set the **Gradient** when you select either **Arithmetic** or **Geometric Gradient**. It holds the arithmetic and geometric gradients, respectively, for the **Arithmetic** and **Geometric Flow Type**s.

The **Cashflow Chart** fills with a graph displaying the dates and values of the entries when the cashflow entries are adequately defined. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency for drilling purposes.

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the Generic Cashflow dialog box subtracting the entries from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the Generic Cashflow dialog box adding the entries to the current cashflow.

Cancel returns you to Generic Cashflow dialog box without editing the cashflow.

Figure 44.37. Forecast Specification

The following items are displayed:

Historical Data Specification

Data Set holds the name of the SAS data set to forecast.

Browse... opens the standard SAS **Open** dialog box to help select a SAS data set to forecast.

Time ID Variable holds the time ID variable to forecast over.

Time Interval fixes the time interval for the **Time ID Variable**.

Analysis Variable holds the data variable upon which to forecast.

View Table... opens a table that displays in a list the contents of the specified SAS data set.

View Graph... opens the Time Series Viewer that graphically displays the contents of the specified SAS data set.

Forecast Specification

Horizon holds the number of periods into the future you wish to forecast.

Confidence holds the confidence limit for applicable forecasts.

Compute Forecast fills the **Cashflow Chart** with the forecast.

The following box holds the type of forecast you wish to generate:

- Predicted Value

- Lower Confidence Limit
- Upper Confidence Limit

The **Cashflow Chart** fills when you click **Compute Forecast**. The box to the right of the scroll bar controls the number of entries with which to fill the graph. If the number in this box is less than the total number of entries, you can use the scroll bar to view different segments of the cashflow. The left box below the scroll bar holds the frequency for drilling purposes.

Subtract becomes available when the collection of entries is adequately specified. Clicking **Subtract** then returns you to the Generic Cashflow dialog box subtracting the forecast from the current cashflow.

Add becomes available when the collection of entries is adequately specified. Clicking **Add** then returns you to the Generic Cashflow adding the forecast to the current cashflow.

Cancel returns to Generic Cashflow dialog box without editing the cashflow.

Chapter 45
Computations

Chapter Contents

Chapter 45
Computations

The Compute Menu

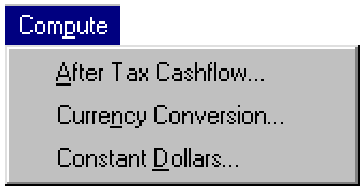

Figure 45.1. The Compute Menu

The **Compute** menu, shown in Figure 45.1, offers the following options that apply to generic cashflows.

After Tax Cashflow opens the After Tax Cashflow Calculation dialog box. Computing an after tax cashflow is useful when taxes affect investment alternatives differently. Comparing after tax cashflows provides a more accurate determination of the cashflows' profitabilities. You can set default values for income tax rates by selecting **Tools** → **Define Rate** → **Income Tax Rate...** from the Investment Analysis dialog box. This opens the Income Tax Specification dialog box where you can enter the tax rates.

Currency Conversion opens the Currency Conversion dialog box. Currency conversion is necessary when investments are in different currencies. For data concerning currency conversion rates, see http://dsbb.imf.org/, the International Monetary Fund's Dissemination Standards Bulletin Board.

Constant Dollars opens the Constant Dollar Calculation dialog box. A constant dollar (inflation adjusted monetary value) calculation takes cashflow and inflation information and discounts the cashflow to a level where the buying power of the monetary unit is "constant" over time. Groups quantify inflation (in the form of price indices and inflation rates) for countries and industries by averaging the growth of prices for various products and sectors of the economy. For data concerning price indices, see the United States Department of Labor at http://www.dol.gov/ and the International Monetary Fund's Dissemination Standards Bulletin Board at http://dsbb.imf.org/. You can set default values for inflation rates by clicking **Tools** → **Define Rate** → **Inflation...** from the Investment Analysis dialog box. This opens the Inflation Specification dialog box where you can enter the inflation rates.

Tasks

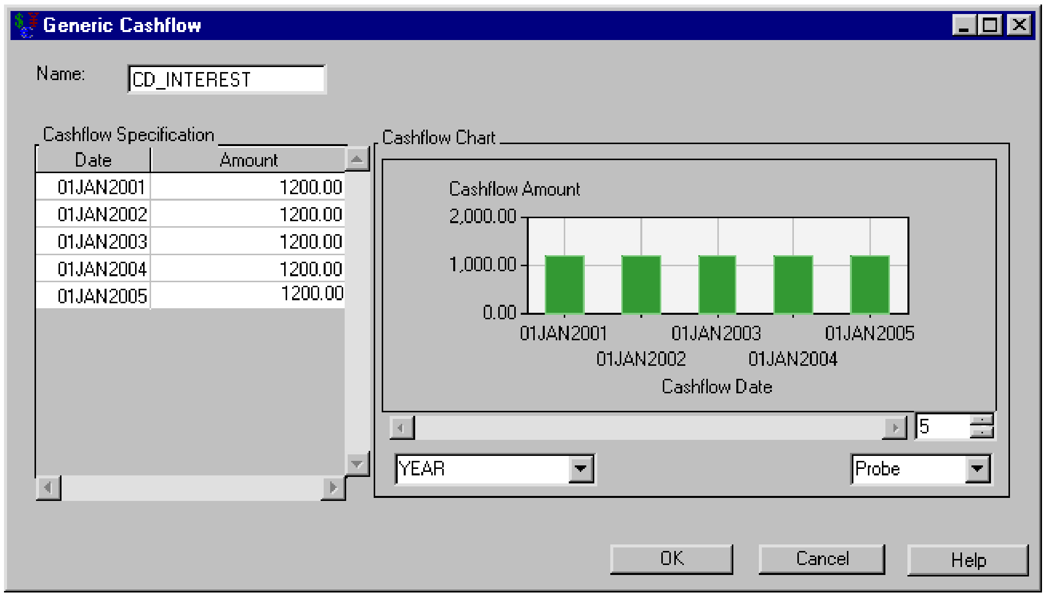
The next few sections show how to perform computations for the following situation. Suppose you buy a $10,000 certificate of deposit that pays 12% interest a year for five years. Your earnings are taxed at a rate of 30% federally and 7% locally. Also, you want to transfer all the money to an account in England. British pounds convert to American dollars at an exchange rate of $1.00 to £0.60. The inflation rate in England is 3%. The instructions in this example assume familiarity with the following:

- The right-clicking options of the **Cashflow Specification** area in the Generic Cashflow dialog box (described in "Right-Clicking within Generic Cashflow's Cashflow Specification Area" on page 2306.)
- The **Save Data As...** button located in many dialog boxes (described in "Saving Output to SAS Datasets" on page 2343.)

Taxing a Cashflow

Consider the example described in "The Compute Menu" on page 2313. To create the earnings, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow** to create a generic cashflow.
2. Enter CD_INTEREST for the **Name**.
3. Enter 1200 for each of the five years starting one year from today as displayed in Figure 45.2.
4. Click **OK** to return to the Investment Analysis dialog box.



Name: CD_INTEREST

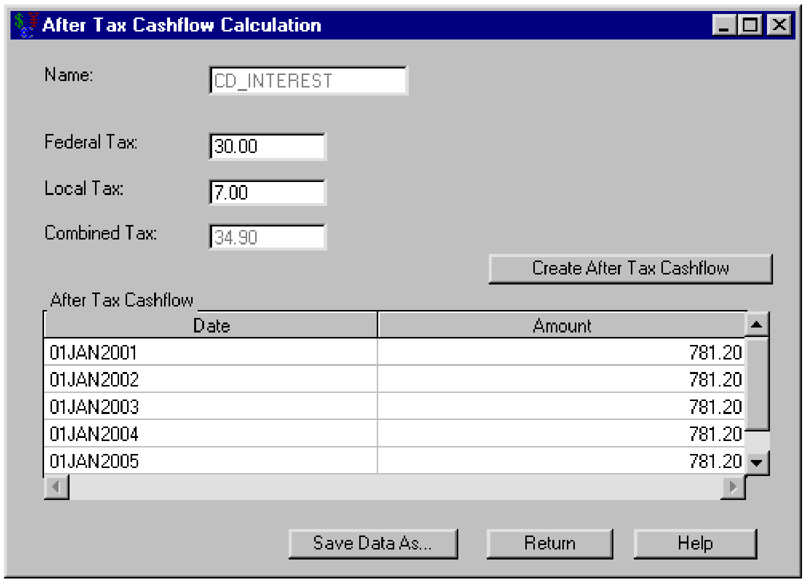
Cashflow Specification

Date	Amount
01JAN2001	1200.00
01JAN2002	1200.00
01JAN2003	1200.00
01JAN2004	1200.00
01JAN2005	1200.00

Figure 45.2. Computing the Interest on the CD

To compute the tax on the earnings, follow these steps:

1. Select CD_INTEREST from the **Portfolio** area.
2. Select **Compute** → **After Tax Cashflow** from the pull-down menu.
3. Enter 30 for **Federal Tax**.
4. Enter 7 for **Local Tax**. Note that **Combined Tax** updates.
5. Click **Create After Tax Cashflow** and the **After Tax Cashflow** area fills, as displayed in Figure 45.3.



Name: CD_INTEREST

Federal Tax: 30.00

Local Tax: 7.00

Combined Tax: 34.90

After Tax Cashflow

Date	Amount
01JAN2001	781.20
01JAN2002	781.20
01JAN2003	781.20
01JAN2004	781.20
01JAN2005	781.20

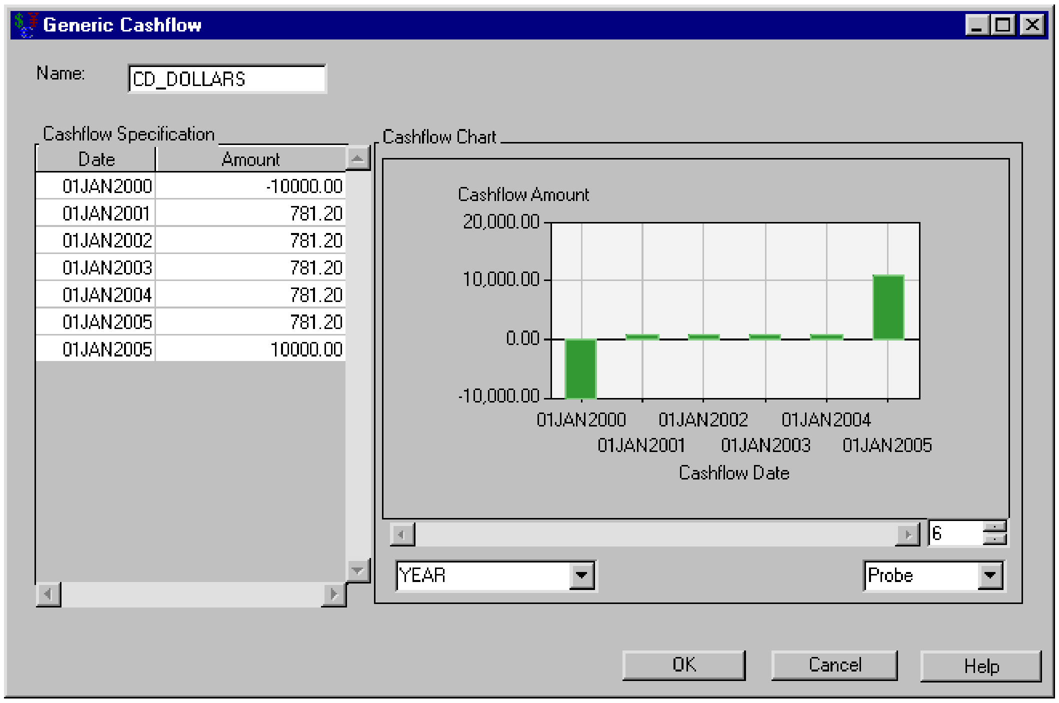
Figure 45.3. Computing the Interest After Taxes

Save the taxed earnings to a SAS data set named WORK.CD_AFTERTAX. Click **Return** to return to the Investment Analysis dialog box.

Converting Currency

Consider the example described in "The Compute Menu" on page 2313. To create the cashflow to convert, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow...** to open a new generic cashflow.
2. Enter CD_DOLLARS for the **Name**.
3. Load WORK.CD_AFTERTAX into its **Cashflow Specification**.
4. Add -10,000 for today and +10,000 for five years from today to the cashflow as displayed in Figure 45.4.
5. Sort the transactions by date to aid your reading.
6. Click **OK** to return to the Investment Analysis dialog box.



Name: CD_DOLLARS

Cashflow Specification

Date	Amount
01JAN2000	-10000.00
01JAN2001	781.20
01JAN2002	781.20
01JAN2003	781.20

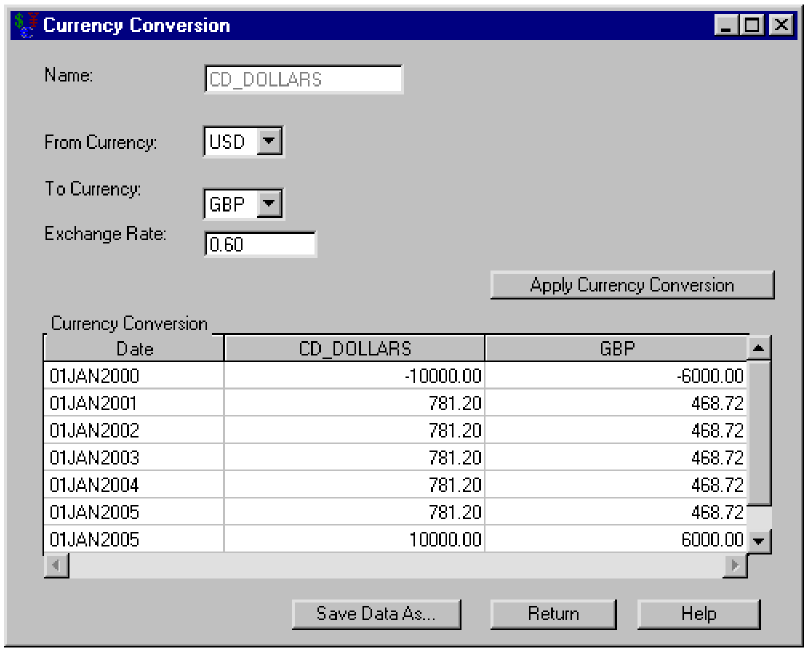
Figure 45.4. The CD in Dollars

To convert from British pounds to American dollars, follow these steps:

1. Select CD_DOLLARS from the portfolio.
2. Select **Compute** → **Currency Conversion** from the pull-down menu. This opens the Currency Conversion dialog box.
3. Select USD for the **From Currency**.
4. Select GBP for the **To Currency**.
5. Enter 0.60 for the **Exchange Rate**.
6. Click **Apply Currency Conversion** to fill the **Currency Conversion** area as displayed in Figure 45.5.



Name: CD_DOLLARS

From Currency: USD

To Currency: GBP

Exchange Rate: 0.60

Currency Conversion

Date	CD_DOLLARS	GBP
01JAN2000	-10000.00	-6000.00
01JAN2001	781.20	468.72
01JAN2002	781.20	468.72
01JAN2003	781.20	468.72
01JAN2004	781.20	468.72
01JAN2005	781.20	468.72
01JAN2005	10000.00	6000.00

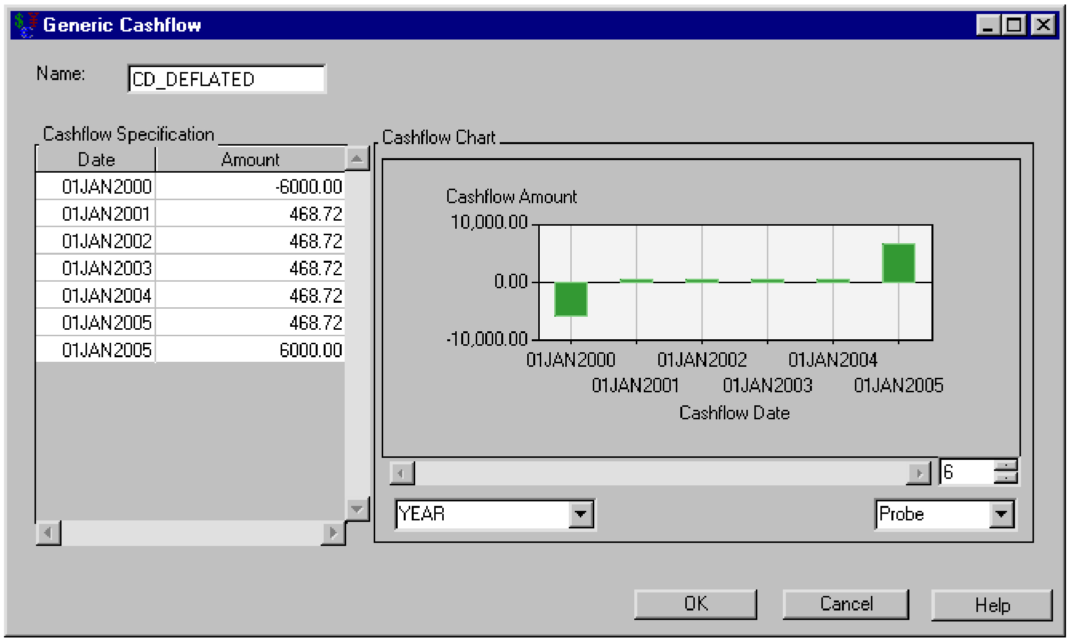
Figure 45.5. Converting the CD to Pounds

Save the converted values to a SAS data set named WORK.CD_POUNDS. Click **Return** to return to the Investment Analysis dialog box.

Inflating Cashflows

Consider the example described in "The Compute Menu" on page 2313. To create the cashflow to deflate, follow these steps:

1. Select **Investment** → **New** → **Generic Cashflow...** to open a new generic cashflow.
2. Enter CD_DEFLATED for **Name**.
3. Load WORK.CD_POUNDS into its **Cashflow Specification** (see Figure 45.6).
4. Click **OK** to return to the Investment Analysis dialog box.



Name: CD_DEFLATED

Cashflow Specification

Date	Amount
01JAN2000	-6000.00
01JAN2001	468.72
01JAN2002	468.72
01JAN2003	468.72

01JAN2005	5175.65

Figure 45.7. CD Values after Deflation

You can save the deflated cashflow to a SAS data set for use in an internal rate of return analysis or breakeven analysis.

Click **Return** to return to the Investment Analysis dialog box.

Dialog Box Guide

After Tax Cashflow Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an after tax calculation, select **Compute** → **After Tax...** from the Investment Analysis dialog box's menu bar. This opens the After Tax Cashflow Calculation dialog box displayed in Figure 45.8.

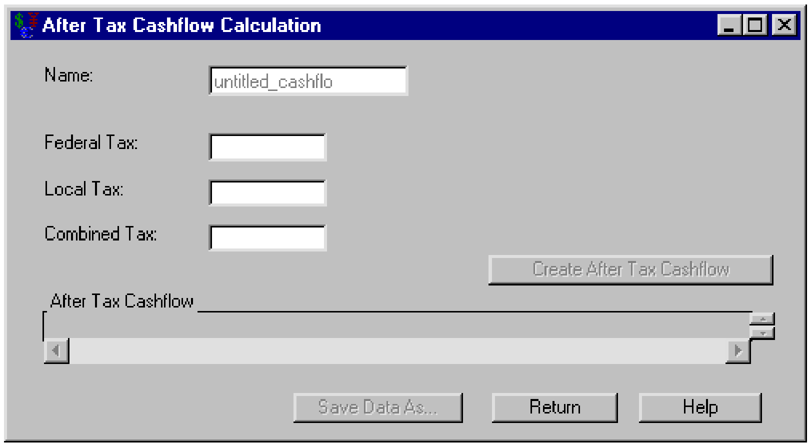

Figure 45.8. After Tax Cashflow Calculation Dialog Box

The following items are displayed:

Name holds the name of the investment for which you are computing the after tax cashflow.

Federal Tax holds the federal tax rate (a percentage between 0% and 100%).

Local Tax holds the local tax rate (a percentage between 0% and 100%).

Combined Tax holds the effective tax rate from federal and local income taxes.

Create After Tax Cashflow becomes available when **Combined Tax** is non-empty. Clicking **Create After Tax Cashflow** then fills the **After Tax Cashflow** area.

After Tax Cashflow fills when you click **Create After Tax Cashflow**. It holds a list of date-amount pairs where the amount is the amount retained after taxes for that date.

Print becomes available when you fill the after tax cashflow. Clicking it sends the contents of the after tax cashflow to the SAS session print device.

Save Data As... becomes available when you fill the after tax cashflow. Clicking it opens the Save Output Dataset dialog box where you can save the resulting cashflow (or portions thereof) as a SAS Dataset.

Return returns you to the Investment Analysis dialog box.

Currency Conversion

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a currency conversion, select **Compute** → **Currency Conversion...** from the Investment Analysis dialog box's menu bar. This opens the Currency Conversion dialog box displayed in Figure 45.9.

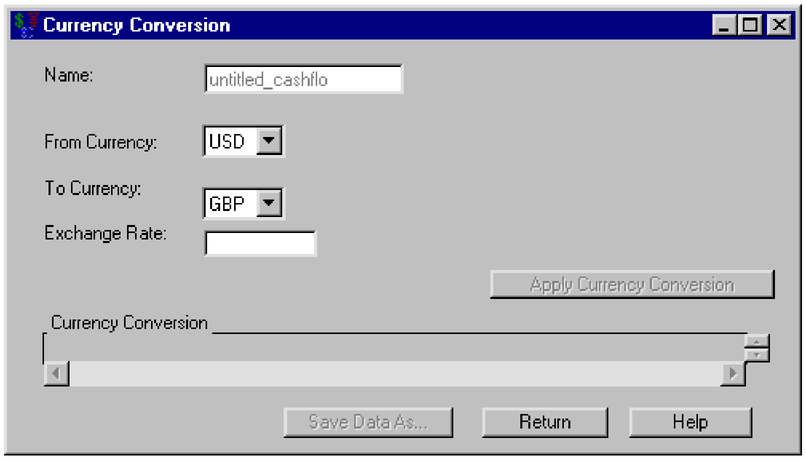

Figure 45.9. Currency Conversion Dialog Box

The following items are displayed:

Name holds the name of the investment to which you are applying the currency conversion.

From Currency holds the name of the currency the cashflow currently represents.

To Currency holds the name of the currency to which you wish to convert.

Exchange Rate holds the rate of exchange between the **From Currency** and the **To Currency**.

Apply Currency Conversion becomes available when you fill **Exchange Rate**. Clicking **Apply Currency Conversion** fills the **Currency Conversion** area.

Currency Conversion fills when you click **Apply Currency Conversion**. The schedule contains a row for each cashflow item with the following information:

- **Date** is a SAS date within the cashflow.
- The **From Currency** value is the amount in the original currency at that date.
- The **To Currency** value is the amount in the new currency at that date.

Print becomes available when you fill the **Currency Conversion** area. Clicking it sends the contents of the conversion table to the SAS session print device.

Save Data As... becomes available when you fill the **Currency Conversion** area. Clicking it opens the Save Output Dataset dialog box where you can save the conversion table (or portions thereof) as a SAS Dataset.

Return returns you to the Investment Analysis dialog box.

Constant Dollar Calculation

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a constant dollar calculation, select **Compute** → **Constant Dollars...** from the Investment Analysis dialog box's menu bar. This opens the Constant Dollar Calculation dialog box displayed in Figure 45.10.

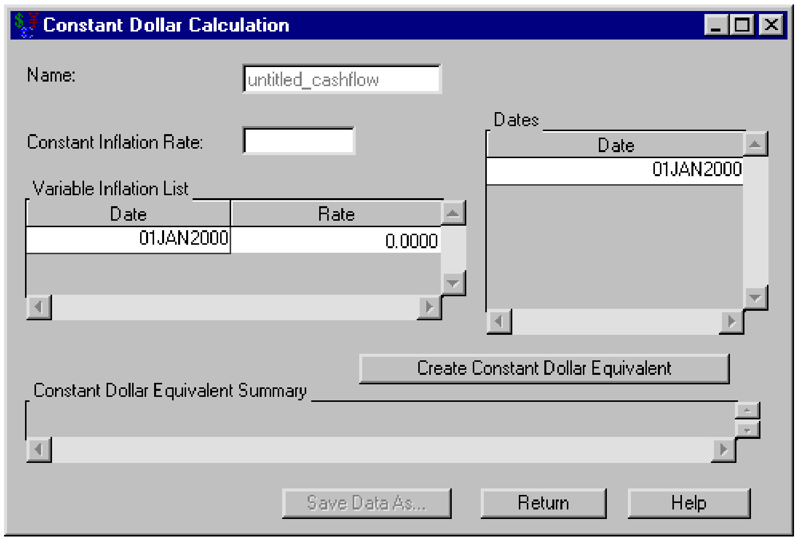

Figure 45.10. Constant Dollar Calculation Dialog Box

The following items are displayed:

Name holds the name of the investment for which you are computing the constant dollars value.

Constant Inflation Rate holds the constant inflation rate (a percentage between 0% and 120%). This value is used if the **Variable Inflation List** area is empty.

Variable Inflation List holds date-rate pairs that describe how inflation varies over time. Each date is a SAS date, and the rate is a percentage between 0% and 120%. Each date refers to when that inflation rate begins. Right-clicking within the **Variable Inflation** area reveals many helpful tools for managing date-rate pairs. If you assume a fixed inflation rate, just insert that rate in **Constant Rate**.

Dates holds the SAS date(s) at which you wish to compute the constant dollar equivalent. Right-clicking within the **Dates** area reveals many helpful tools for managing date lists.

Create Constant Dollar Equivalent becomes available when you enter inflation rate information. Clicking it fills the constant dollar equivalent summary with the computed constant dollar values.

Constant Dollar Equivalent Summary fills with a summary when you click **Create Constant Dollar Equivalent**. The first column lists the dates of the generic cashflow. The second column contains the constant dollar equivalent of the original generic cashflow item of that date.

Print becomes available when you fill the constant dollar equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you fill the constant dollar equivalent summary. Clicking it opens the Save Output Dataset dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return returns you to the Investment Analysis dialog box.

Chapter 46
Analyses

Chapter Contents

Chapter 46
Analyses

The Analyze Menu

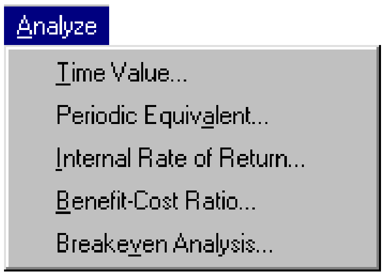

Figure 46.1. Analyze Menu

The **Analyze** menu, shown in Figure 46.1, offers the following options for use on applicable investments.

Time Value opens the Time Value Analysis dialog box. Time value analysis involves moving money through time across a defined MARR so that you can compare value at a consistent date. The MARR can be constant or variable over time.

Periodic Equivalent opens the Uniform Periodic Equivalent dialog box. Uniform periodic equivalent analysis determines the payment needed to convert a cashflow to uniform amounts over time, given a periodicity, a number of periods, and a MARR. This option helps when making comparisons where one alternative is uniform (such as renting) and another is not (such as buying).

Internal Rate of Return opens the Internal Rate of Return dialog box. The internal rate of return of a cashflow is the interest rate that makes the time value equal to 0. This calculation assumes uniform periodicity of the cashflow. It is particularly applicable where the choice of MARR would be difficult.

Benefit-Cost Ratio opens the Benefit-Cost Ratio Analysis dialog box. The benefit-cost ratio divides the time value of the benefits by the time value of the costs. For example, governments often use this analysis when deciding whether to commit to a public works project.

Breakeven Analysis opens the Breakeven Analysis dialog box. Breakeven analysis computes time values at various MARRs to compare, which can be advantageous when it is difficult to determine a MARR. This analysis can help you determine how the cashflow's profitability varies with your choice of MARR. A graph displaying the relationships between time value and MARR is also available.

Tasks

Performing Time Value Analysis

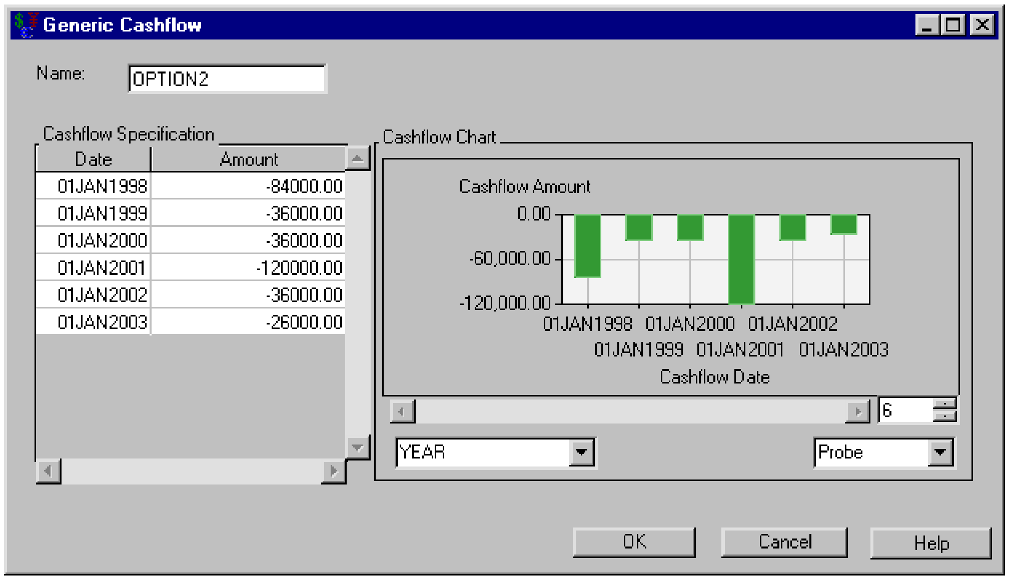
Suppose a rock quarry needs equipment to use the next five years. It has two alternatives:

- A box loader and conveyer system that has a one-time cost of $264,000.
- A two-shovel loader which costs $84,000 but has a yearly operating cost of $36,000. This loader has a service life of three years, which necessitates the purchase of a new loader for the final two years of the rock quarry project. Assume the second loader also costs $84,000 and its salvage value after its two-year service is $10,000. A SAS data set that describes this is available at SASHELP.ROCKPIT.

You expect a 13% MARR. Which is the better alternative?

To create the cashflows, follow these steps:

1. Create a cashflow with the single amount -264,000. Date the amount 01JAN1998 to be consistent with the SAS data set you load.
2. Load SASHELP.ROCKPIT into a second cashflow, as displayed in Figure 46.2.



Name: OPTION2

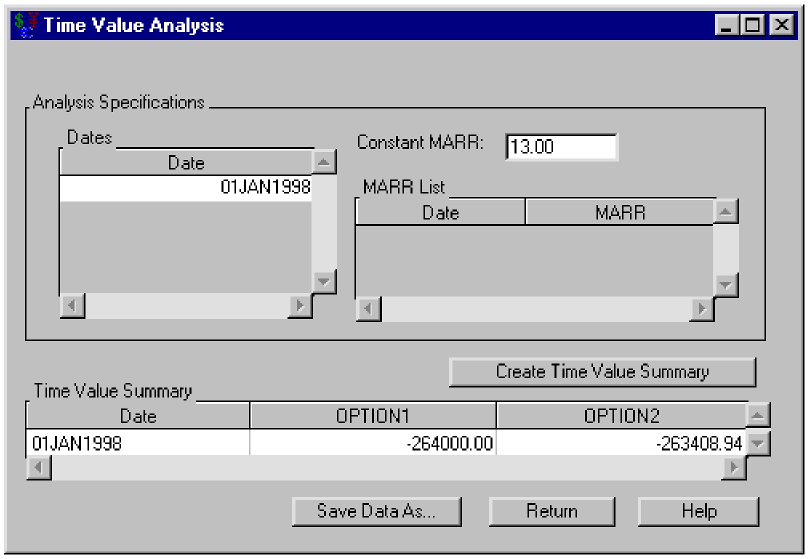
Date	Amount
01JAN1998	-84000.00
01JAN1999	-36000.00
01JAN2000	-36000.00
01JAN2001	-120000.00
01JAN2002	-36000.00
01JAN2003	-26000.00

Figure 46.2. The contents of SASHELP.ROCKPIT

To compute the time values of these investments, follow these steps:

1. Select both cashflows.

2. Select **Analyze** → **Time Value...**. This opens the Time Value Analysis dialog box.
3. Enter the date 01JAN1998 into the **Dates** area.
4. Enter 13 for the **Constant MARR**.
5. Click **Create Time Value Summary**.



Constant MARR: 13.00

Date
01JAN1998

MARR List

Date	MARR

Time Value Summary

Date	OPTION1	OPTION2
01JAN1998	-264000.00	-263408.94

Figure 46.3. Performing the Time Value Analysis

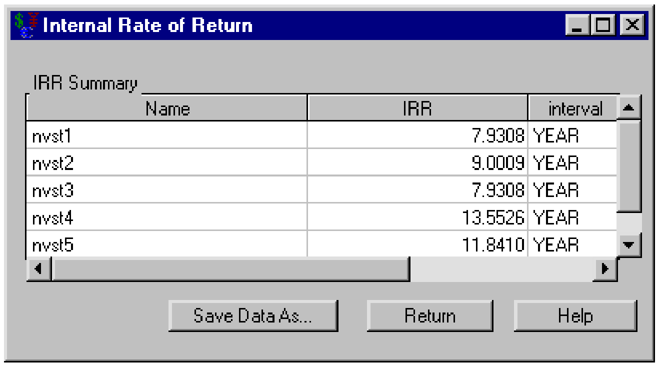
As shown in Figure 46.3, option 1 has a time value of -$264,000.00 naturally on 01JAN1998. However, option 2 has a time value of -$263,408.94, which is slightly less expensive.

Computing an Internal Rate of Return

You are choosing between five investments. A portfolio containing these investments is available at SASHELP.INVSAMP.NVST. Which investments are acceptable if you expect a MARR of 9%?

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments. Note that Internal Rate of Return computations assume regular periodicity of the cashflow. To compute the internal rates of return, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Internal Rate of Return...**.



IRR Summary

Name	IRR	interval
nvst1	7.9308	YEAR
nvst2	9.0009	YEAR
nvst3	7.9308	YEAR
nvst4	13.5526	YEAR
nvst5	11.8410	YEAR

Figure 46.4. Computing an Internal Rate of Return

The results displayed in Figure 46.4 indicate that the internal rates of return for investments 2, 4, and 5 are greater than 9%. Hence, each of these is acceptable.

Performing a Benefit-Cost Ratio Analysis

Suppose a municipality has excess funds to invest. It is choosing between the same investments described in the previous example. Government agencies often compute benefit-cost ratios to decide which investment to pursue. Which is best in this case?

Open the portfolio SASHELP.INVSAMP.NVST and compare the investments.

To compute the benefit-cost ratios, follow these steps:

1. Select all five investments.
2. Select **Analyze** → **Benefit-Cost Ratio...**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 9 for **Constant MARR**.
5. Click **Create Benefit-Cost Ratio Summary** to fill the **Benefit-Cost Ratio Summary** area.

The results displayed in Figure 46.5 indicate that investments 2, 4, and 5 have ratios greater than 1. Therefore, each is profitable with a MARR of 9%.

Figure 46.5. Performing a Benefit-Cost Ratio Analysis

Computing a Uniform Periodic Equivalent

Suppose you need a warehouse for ten years. You have two options:

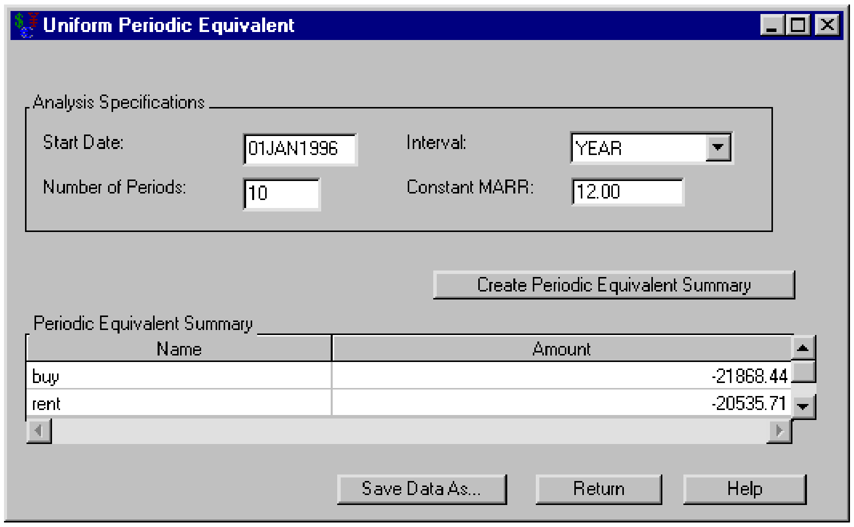
- Pay rent for ten years at $23,000 per year.
- Build a two-stage facility that you will maintain and which you intend to sell at the end of those ten years.

Datasets describing these scenarios are available in the portfolio SASHELP.INVSAMP.BUYRENT. Which option is more financially sound if you desire a 12% MARR?

Open the portfolio SASHELP.INVSAMP.BUYRENT and compare the options.

To perform the periodic equivalent, follow these steps:

1. Load the portfolio SASHELP.INVSAMP.BUYRENT.
2. Select both cashflows.
3. Select **Analyze** → **Periodic Equivalent...**.
   This opens the Uniform Periodic Equivalent dialog box.
4. Enter 01JAN1996 for the **Start Date**.
5. Enter 10 for the **Number of Periods**.
6. Select YEAR for the **Interval**.
7. Enter 12 for the **Constant MARR**.
8. Click **Create Time Value Summary**.



Uniform Periodic Equivalent
Create Periodic Equivalent Summary
Save Data As...

Analysis Specifications

Start Date:	01JAN1996	Interval:	YEAR
Number of Periods:	10	Constant MARR:	12.00

Periodic Equivalent Summary

Name	Amount
buy	-21868.44
rent	-20535.71

Figure 46.6. Computing a Uniform Periodic Equivalent

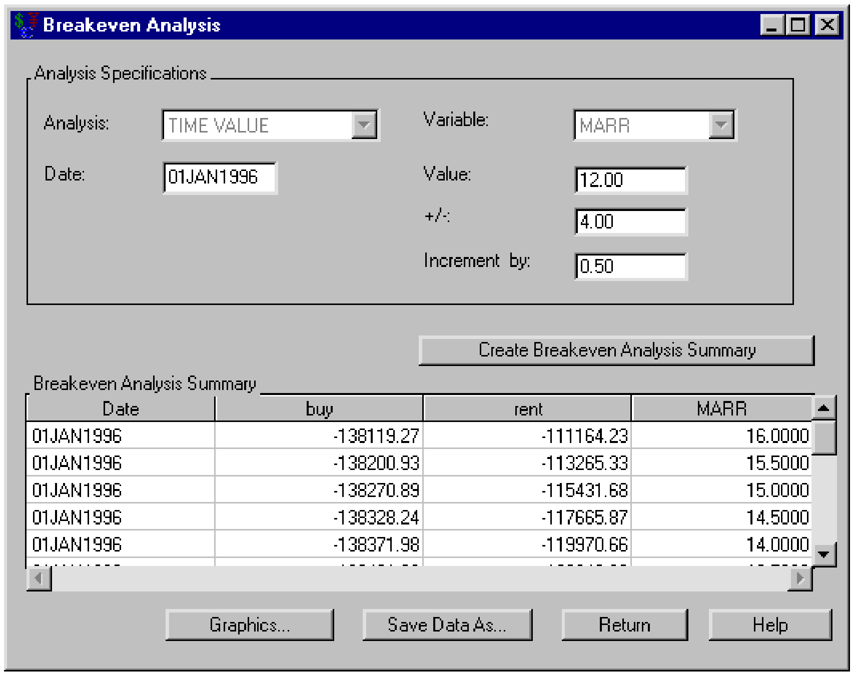
Figure 46.6 indicates that to rent costs about $1,300 less each year. Hence, renting is more financially sound. Notice the periodic equivalent for renting is not $23,000. This is because the the $23,000 per year does not account for the MARR.

Performing a Breakeven Analysis

In the previous example you computed the uniform periodic equivalent for a rent-buy scenario. Now let's perform a breakeven analysis to see how the MARR affects the time values.

To perform the breakeven analysis, follow these steps:

1. Select both options.
2. Select **Analyze** → **Breakeven Analysis...**.
3. Enter 01JAN1996 for the **Date**.
4. Enter 12.0 for **Value**.
5. Enter 4.0 for **(+/-)**.
6. Enter 0.5 for **Increment by**.
7. Click **Create Breakeven Analysis Summary** to fill the **Breakeven Analysis Summary** area as displayed in Figure 46.7.



Analysis Specifications

Analysis:	TIME VALUE	Variable:	MARR
Date:	01JAN1996	Value:	12.00

Create Breakeven Analysis Summary

Breakeven Analysis Summary

Date	buy	rent	MARR
01JAN1996	-138119.27	-111164.23	16.0000
01JAN1996	-138200.93	-113265.33	15.5000
01JAN1996	-138270.89	-115431.68	15.0000
01JAN1996	-138328.24	-117665.87	14.5000
01JAN1996	-138371.98	-119970.66	14.0000

Figure 46.7. Performing a Breakeven Analysis

Click **Graphics...** to view a plot displaying the relationship between time value and MARR.

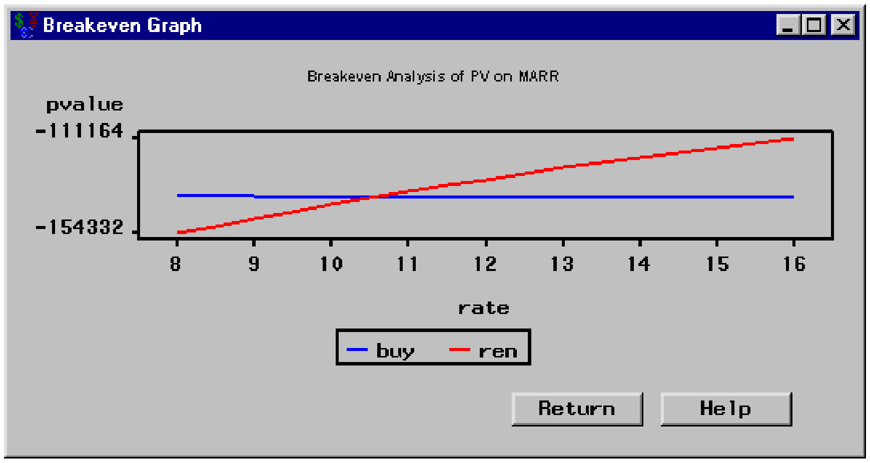

Figure 46.8. Viewing a Breakeven Graph

As shown in Figure 46.8 renting is better if you want a MARR of 12%. However, if your MARR should drop to 10.5%, buying would be better.

With a single investment, knowing where the graph has a time value of 0 tells the MARR when a venture switches from being profitable to a loss. With multiple investments, knowing where the graphs for the various investments cross each other tells at what MARR a particular investment becomes more profitable than another.

Dialog Box Guide

Time Value Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an time value analysis, select **Analyze** → **Time Value...** from the Investment Analysis dialog box's menu bar. This opens the Time Value Analysis dialog box displayed in Figure 46.9.

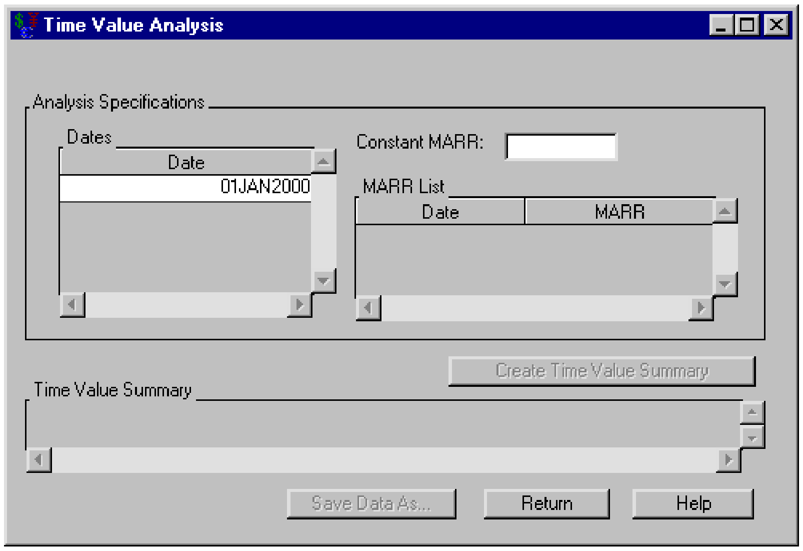

Figure 46.9. Time Value Analysis Dialog Box

The following items are displayed:

Analysis Specifications

Dates holds the list of dates as of which to perform the time value analysis. Right-clicking within the **Dates** area reveals many helpful tools for managing date lists.

Constant MARR holds the desired MARR for the time value analysis. This value is used if the **MARR List** area is empty.

MARR List holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. Right-clicking within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Time Value Summary becomes available when you adequately specify the analysis within the **Analysis Specifications** area. Clicking **Create Time Value Summary** then fills the **Time Value Summary** area.

Time Value Summary fills when you click **Create Time Value Summary**. The table contains a row for each date in the **Dates** area. The remainder of each row holds the time values at that date, one value for each investment selected.

Print becomes available when you fill the time value summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you fill the time value summary. Clicking it opens the Save Output Dataset dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Investment Analysis dialog box.

Uniform Periodic Equivalent

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a uniform periodic equivalent, select **Analyze** → **Periodic Equivalent...** from the Investment Analysis dialog box's menu bar. This opens the Uniform Periodic Equivalent dialog box displayed in Figure 46.10.

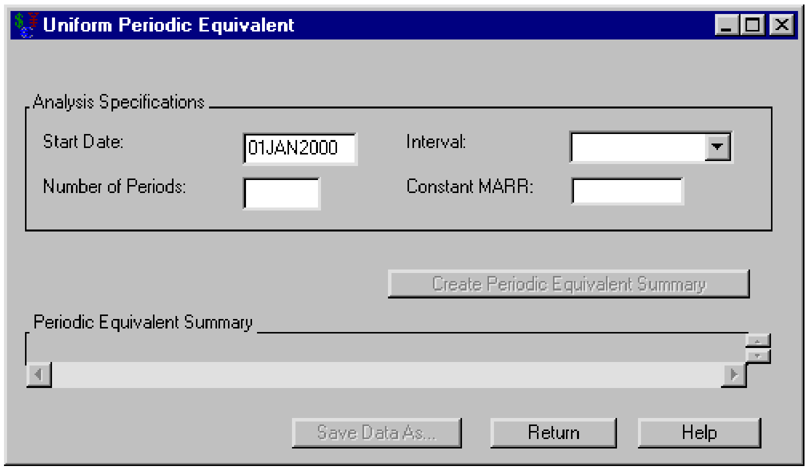

Figure 46.10. Uniform Periodic Equivalent Dialog Box

The following items are displayed:

Analysis Specifications

Start Date holds the date the uniform periodic equivalents begin.

Number of Periods holds the number of uniform periodic equivalents.

Interval holds how often the uniform periodic equivalents occur.

Constant MARR holds the Minimum Attractive Rate of Return.

Create Periodic Equivalent Summary becomes available when you adequately fill the **Analysis Specification** area. Clicking **Create Periodic Equivalent Summary** then fills the periodic equivalent summary.

Periodic Equivalent Summary fills with two columns when you click **Create Periodic Equivalent Summary**. The first column lists the investments selected. The second column lists the computed periodic equivalent amount.

Print becomes available when you fill the periodic equivalent summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you generate the periodic equivalent summary. Clicking it opens the Save Output Dataset dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Investment Analysis dialog box.

Internal Rate of Return

Having selected a generic cashflow from the Investment Analysis dialog box, to perform an internal rate of return calculation, select **Analyze** $\rightarrow$ **Internal Rate of Return...** from the Investment Analysis dialog box's menu bar. This opens the Internal Rate of Return dialog box displayed in Figure 46.11.

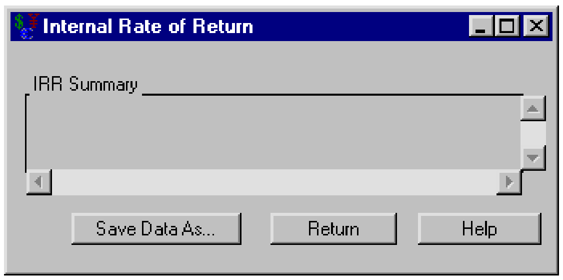

Figure 46.11. Internal Rate of Return Dialog Box

The following items are displayed:

IRR Summary contains a row for each deposit. Each row holds:

> **Name** holds the name of the investment.
>
> **IRR** holds the internal rate of return for that investment.
>
> **interval** holds the interest rate interval for that **IRR**.

Print becomes available when you fill the IRR summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... Clicking it opens the Save Output Dataset dialog box where you can save the IRR summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Investment Analysis dialog box.

Benefit-Cost Ratio Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to compute a benefit-cost ratio, select **Analyze** → **Benefit-Cost Ratio...** from the Investment Analysis dialog box's menu bar. This opens the Benefit-Cost Ratio Analysis dialog box displayed in Figure 46.12.

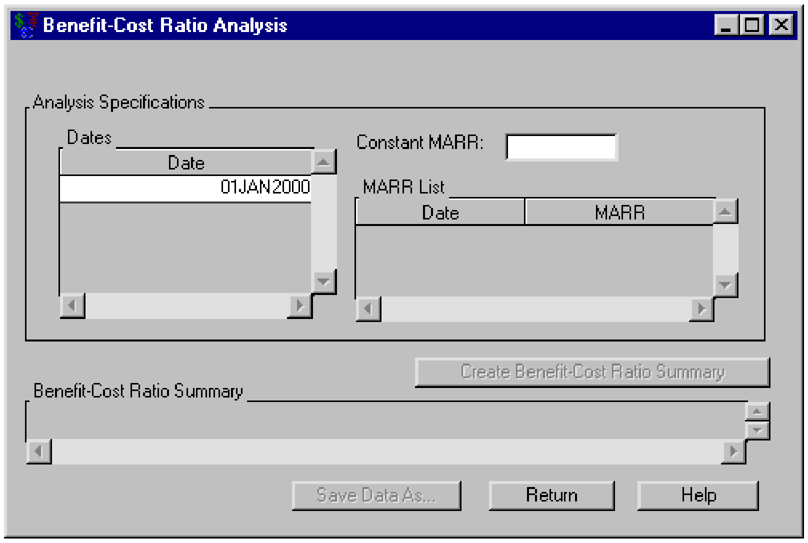

Figure 46.12. Benefit-Cost Ratio Analysis Dialog Box

The following items are displayed:

Analysis Specifications

> **Dates** holds the dates as of which to compute the Benefit-Cost ratios.
>
> **Constant MARR** holds the desired MARR. This value is used if the **MARR List** area is empty.
>
> **MARR List** holds date-rate pairs that express your desired MARR as it changes over time. Each date refers to when that expected MARR begins. Right-clicking within the **MARR List** area reveals many helpful tools for managing date-rate pairs.

Create Benefit-Cost Ratio Summary becomes available when you adequately specify the analysis. Clicking **Create Benefit-Cost Ratio Summary** fills the benefit-cost ratio summary.

Benefit-Cost Ratio Summary fills when you click **Exchange the Rates**. The area contains a row for each date in the **Dates** area. The remainder of each row holds the benefit-cost ratios at that date, one value for each investment selected.

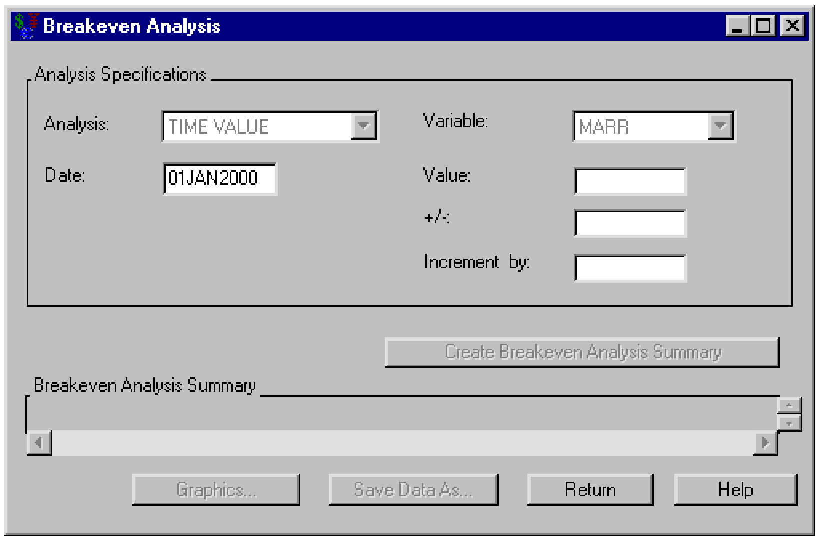
Print becomes available when you fill the benefit-cost ratio summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you generate the benefit-cost ratio summary. Clicking it opens the Save Output Dataset dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Investment Analysis dialog box.

Breakeven Analysis

Having selected a generic cashflow from the Investment Analysis dialog box, to perform a breakeven analysis, select **Analyze** → **Breakeven Analysis...** from the Investment Analysis dialog box's menu bar. This opens the Breakeven Analysis dialog box displayed in Figure 46.13.



Analysis: TIME VALUE
Date: 01JAN2000
Variable: MARR
Value:
+/-:
Increment by:

Figure 46.13. Breakeven Analysis Dialog Box

The following items are displayed:

Analysis Specification

Analysis holds the analysis type. Only Time Value is currently available.

Date holds the date for which you perform this analysis.

Variable holds the variable upon which the breakeven analysis will vary. Only MARR is currently available.

Value holds the desired rate upon which to center the analysis.

+/- holds the maximum deviation from the **Value** to consider.

Increment by holds the increment by which the analysis is calculated.

Create Breakeven Analysis Summary becomes available when you adequately specify the analysis. Clicking **Create Breakeven Analysis Summary** then fills the **Breakeven Analysis Summary** area.

Breakeven Analysis Summary fills when you click **Create Breakeven Analysis Summary**. The schedule contains a row for each MARR and date.

Graphics... becomes available when you fill the **Breakeven Analysis Summary** area. Clicking it opens the Breakeven Graph graph representing the time value versus MARR.

Print becomes available when you fill the breakeven analysis summary. Clicking it sends the contents of the summary to the SAS session print device.

Save Data As... becomes available when you generate the breakeven analysis summary. Clicking it opens the Save Output Dataset dialog box where you can save the summary (or portions thereof) as a SAS Dataset.

Return takes you back to the Investment Analysis dialog box.

Breakeven Graph

Suppose you perform a breakeven analysis in the Breakeven Analysis dialog box. Once you create the breakeven analysis summary, you can click the **Graphics...** button to open the Breakeven Graph dialog box displayed in Figure 46.14.

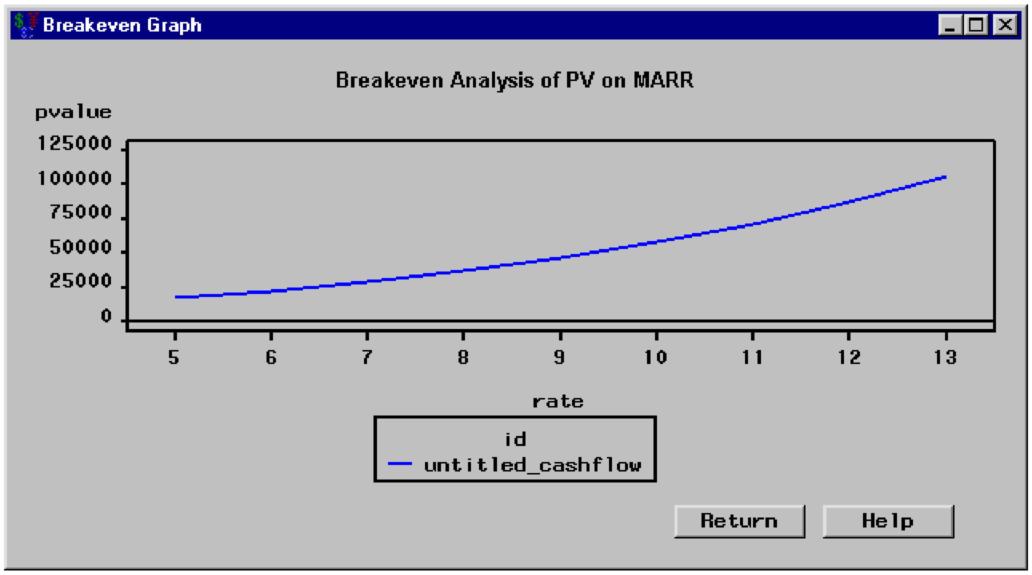


Figure 46.14. Breakeven Graph Dialog Box

Investments and Datasets

Investment Analysis provides tools to assist you in moving data between SAS data sets and lists you can use within Investment Analysis.

Saving Output to SAS Datasets

Many investment specifications have a button that reads **Save Data As...**. Clicking that button opens the Save Output Dataset dialog box (see Figure 47.1). This dialog box enables you to save all or part of the area generated by the specification.

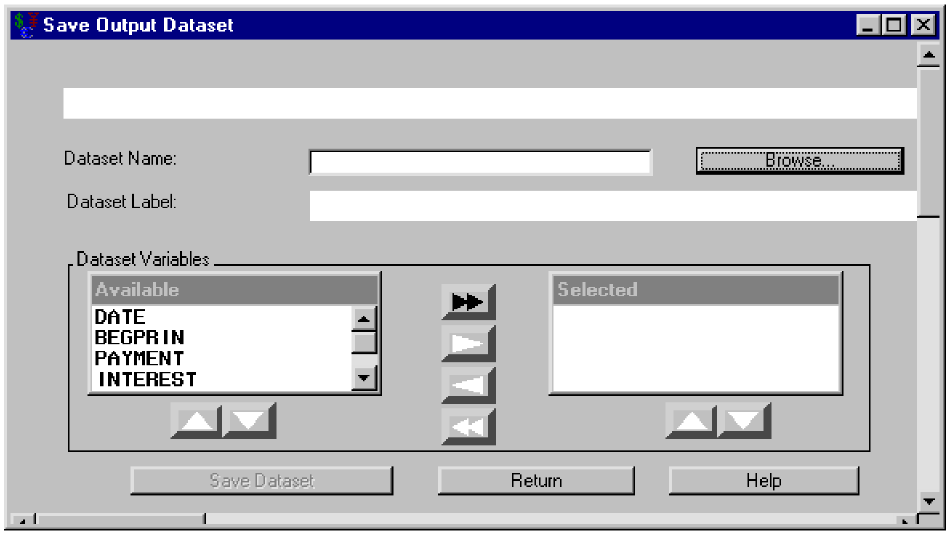

Figure 47.1. Saving to a Dataset

The following items are displayed:

Dataset Name holds the SAS data set name to which you wish to save.

Browse... opens the standard SAS **Open** dialog box, which enables you to select an existing SAS data set to overwrite.

Dataset Label holds the SAS data set's label.

Dataset Variables organizes variables. The variables listed in the **Selected** area will be included in the SAS data set.

- You can select variables one at a time, by clicking the single right-arrow after each selection to move it to the **Selected** area.

- If the desired SAS data set has many variables you wish to save, it may be simpler to follow these steps:
    1. Click the double right arrow to select all available variables.
    2. Remove any unwanted variable by selecting it from the **Selected** area and clicking the single left arrow.
- The double left arrow removes all selected variables from the proposed SAS data set.
- The up and down arrows below the **Available** and **Selected** boxes enable you to scroll up and down the list of variables in their respective boxes.

Save Dataset attempts to save the SAS data set. If the SAS data set name exists, you are asked if you want to replace the existing SAS data set, append to the existing SAS data set, or cancel the current save attempt. You then return to this dialog box ready to create another SAS data set to save.

Return takes you back to the specification dialog box.

Loading a SAS Dataset into a List

Right-click in the area you wish to load the list and release on **Load...**. This opens the Load Dataset dialog box (see Figure 47.2).

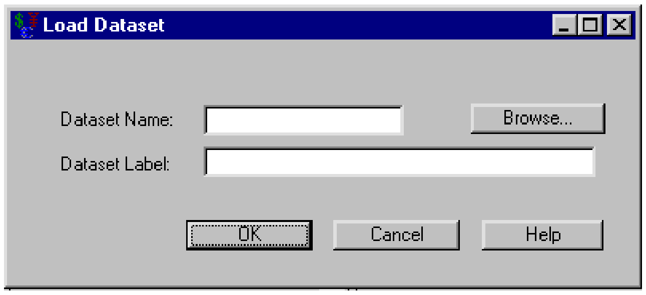

Figure 47.2. Load Dataset Dialog Box

The following items are displayed:

Dataset Name holds the name of the SAS data set you wish to load.

Browse... opens the standard SAS **Open** dialog box, which aids in finding a SAS data set to load. If there is a **Date** variable in the SAS data set, Investment Analysis loads it into the list. If there is no **Date** variable, it loads the first available time-formatted variable. If an amount or rate variable is needed, Investment Analysis searches the SAS data set for a **Amount** or **Rate** variable to use. Otherwise it takes the first numeric variable that is not used by the **Date** variable.

Dataset Label holds a SAS data set label.

OK attempts to load the SAS data set specified in **Dataset Name**. If the specified SAS data set exists, clicking **OK** returns you to the calling dialog box with the selected

SAS data set filling the list. If the specified SAS data set does not exist and you click **OK**, you receive an error message and no SAS data set is loaded.

Cancel returns you to the calling dialog box without loading a SAS data set. To load values from a SAS data set into a list, follow these steps:

Saving Data from a List to a SAS Dataset

Right-click in the area you wish to hold the list, and release on **Save...**. This opens the Save Dataset dialog box.

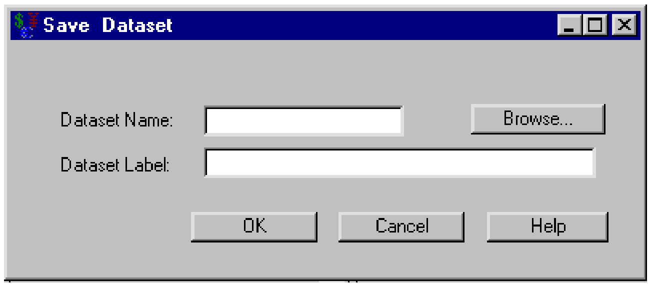

Figure 47.3. Save Dataset Dialog Box

The following items are displayed:

Dataset Name holds the SAS data set name to which you wish to save.

Browse... opens the standard SAS **Save As** dialog box, which enables you to find an existing SAS data set to overwrite.

Dataset Label holds a user-defined description to be saved as the label of the SAS data set.

OK saves the current data to the SAS data set specified in **Data set Name**. If the specified SAS data set does not already exist, clicking **OK** saves the SAS data set and returns you to the calling dialog box. If the specified SAS data set does already exist, clicking **OK** warns you and enables you to replace the old SAS data set with the new SAS data set or cancel the save attempt.

Cancel aborts the save process. Clicking **Cancel** returns you to the calling dialog box without attempting to save.

Right Mouse Button Options

A pop-up menu often appears when you right-click within table editors. The menus offer tools to aid in the management of the table's entries. Most table editors provide the following options.

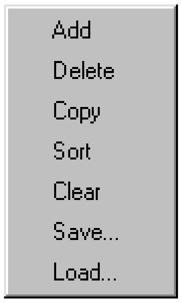

Figure 47.4. Right-Clicking Options

Add creates a blank row.

Delete removes any currently selected row.

Copy duplicates the currently selected row.

Sort arranges the rows in chronological order according to the date variable.

Clear empties the table of all rows.

Save... opens the Save Dataset dialog box where you can save the all rows to a SAS Dataset for later use.

Load... opens the Load Dataset dialog box where you select a SAS Dataset to fill the rows.

If you wish to perform one of these actions on a collection of rows, you must select a collection of rows before right-clicking. To select an adjacent list of rows, do the following: click the first pair, hold down SHIFT, and click the final pair. Once the list of rows is selected, you may release the SHIFT key.

Depreciation Methods

Suppose an asset's price is $20,000 and it has a salvage value of $5,000 in five years. The following sections describe various methods to quantify the depreciation.

Straight Line (SL)

This method assumes a constant depreciation value per year.

Assuming the price of a depreciating asset is P and its salvage value after N years is S,

$$\text{Annual Depreciation} = \frac{P-S}{N}$$

For our example, the annual depreciation would be

$$\frac{\$20,000 - \$5,000}{5} = \$3,000$$

Sum-of-years Digits

An asset often loses more of its value early in its lifetime. A method that exhibits this dynamic is desirable.

Assume an asset depreciates from price P to salvage value S in N years. First compute the value: sum-of-years = $1 + 2 + \cdots + N$. The depreciation for the years after the asset's purchase is:

Table 47.1. Sum-of-years General Example

year number	annual depreciation
first	$\frac{N}{\mathrm{sum-of-years}}(P-S)$
second	$\frac{N-1}{\mathrm{sum-of-years}}(P-S)$
third	$\frac{N-2}{\mathrm{sum-of-years}}(P-S)$
$\vdots$	$\vdots$
final	$\frac{1}{\mathrm{sum-of-years}}(P-S)$

For the ith year of the asset's use this equation generalizes to

$$\text{Annual Depreciation} = \frac{N+1-i}{\mathrm{sum-of-years}}(P-S)$$

For our example, $N = 5$ and the sum of years is $1+2+3+4+5 = 15$. The depreciation during the first year is

$$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$$

Table 47.2 describes how Declining Balance would depreciate the asset.

Table 47.2. Sum-of-years Example

Year	Depreciation	Year-end Value
1	$(\$20,000 - \$5,000)\frac{5}{15} = \$5,000$	$\$15,000.00$
2	$(\$20,000 - \$5,000)\frac{4}{15} = \$4,000$	$\$11,000.00$
3	$(\$20,000 - \$5,000)\frac{3}{15} = \$3,000$	$\$8,000.00$
4	$(\$20,000 - \$5,000)\frac{2}{15} = \$2,000$	$\$6,000.00$
5	$(\$20,000 - \$5,000)\frac{1}{15} = \$1,000$	$\$5,000.00$

And as expected, the value after N years is S.

$$\begin{aligned}
\text{Value after 5 years} &= P \text{ - (5 years' depreciation)} \\
&= P \text{ - } \Big(\tfrac{5}{10}(P-S) + \tfrac{4}{10}(P-S) + \tfrac{3}{10}(P-S) + \\
&\qquad \tfrac{2}{10}(P-S) + \tfrac{1}{10}(P-S)\Big) \\
&= P - (P-S) \\
&= S
\end{aligned}$$

Declining Balance (DB)

Recall that the Straight Line method assumes a constant depreciation value. Conversely, the Declining Balance method assumes a constant depreciation rate per year. And like the Sum-of-years method, more depreciation tends to occur earlier in the asset's life.

Assume the price of a depreciating asset is P and its salvage value after N years is S. You could assume the asset depreciates by a factor of $\frac{1}{N}$ (or a rate o f $\frac{100}{N}\%$). This method is known as Single Declining Balance. In an equation this looks like:

$$\text{Annual Depreciation} = \tfrac{1}{N}\ \text{Previous year's value}$$

So for our example, the depreciation during the first year is

$$\frac{\$20,000}{5} = \$4,000$$

Table 47.3 describes how Declining Balance would depreciate the asset.

Table 47.3. Declining Balance Example

Year	Depreciation	Year-end Value
1	$\frac{\$20{,}000.00}{5} = \$4,000.00$	$\$16,000.00$
2	$\frac{\$16{,}000.00}{5} = \$3,200.00$	$\$12,800.00$
3	$\frac{\$12{,}800.00}{5} = \$2,560.00$	$\$10,240.00$
4	$\frac{\$10{,}240.00}{5} = \$2,560.00$	$\$8,192.00$
5	$\frac{\$12{,}800.00}{5} = \$2,560.00$	$\$6,553.60$

DB Factor

You could also accelerate the depreciation by increasing the factor (and hence the rate) at which depreciation occurs. Other commonly accepted depreciation rates are $\frac{200}{N}\%$ (called Double Declining Balance as the depreciation factor becomes $\frac{2}{N}$) and $\frac{150}{N}\%$. Investment Analysis enables you to choose between these three types for Declining Balance: 2 (with $\frac{200}{N}\%$ depreciation), 1.5 (with $\frac{150}{N}\%$), and 1 (with $\frac{100}{N}\%$).

Declining Balance and the Salvage Value

The Declining Balance method assumes that depreciation is faster earlier in an asset's life; this is what you wanted. But notice the final value is greater than the salvage value. Even if the salvage value were greater than $6,553.60, the final year-end value would not change. The salvage value never enters the calculation, so there is no way for the salvage value to force the depreciation to assume its value. Newnan and Lavelle (1998) describe two ways to adapt the Declining Balance method to assume the salvage value at the final time. One way is as follows:

Suppose you call the depreciated value after i years $V(i)$. This sets $V(0) = P$ and $V(N) = S$.

- If $V(N) > S$ according to the usual calculation for $V(N)$, redefine $V(N)$ to equal S.
- If $V(i) < S$ according to the usual calculation for $V(i)$ for some i (and hence for all subsequent $V(i)$ values), you can redefine all such $V(i)$ to equal S.

This alteration to Declining Balance forces the depreciated value of the asset after N years to be S and keeps $V(i)$ no less than S.

Conversion to SL

The second (and preferred) way to force Declining Balance to assume the salvage value is by Conversion to Straight Line. If $V(N) > S$, the first way redefines $V(N)$ to equal S; you can think of this as converting to the Straight Line method for the last timestep.

If the $V(N)$ value supplied by DB is appreciably larger than S, then the depreciation in the final year would be unrealistically large. An alternate way is to compute the DB and SL step at each timestep and take whichever step gives a larger depreciation (unless DB drops below the salvage value).

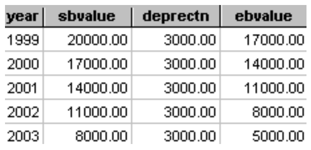
Once SL assumes a larger depreciation, it continues to be larger over the life of the asset. This forces the value at the final time to equal the salvage value as SL forces this. As an algorithm, this looks like

```
V(0) = P;
for i=1 to N
   if DB step > SL step from (i,V(i))
      take a DB step to make V(i);
   else
      break;
for j = i to N
   take a SL step to make V(j);
```

The MACRS discussed in Depreciation Table... is actually a variation on the Declining Balance with conversion to Straight Line method.

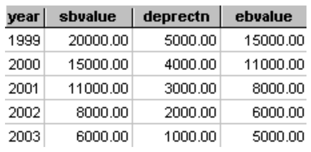
Comparison of Depreciation Methods

Figure 47.5 through Figure 47.8 display the depreciation for four depreciation methods. This example also assumes the asset has an initial value of $20,000 and depreciates to $5,000 in five years.



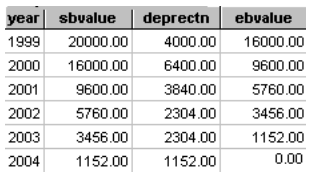
year	sbvalue	deprectn	ebvalue
1999	20000.00	3000.00	17000.00
2000	17000.00	3000.00	14000.00
2001	14000.00	3000.00	11000.00
2002	11000.00	3000.00	8000.00
2003	8000.00	3000.00	5000.00

Figure 47.5. Straight Line



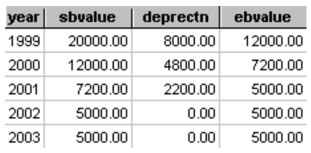
year	sbvalue	deprectn	ebvalue
1999	20000.00	5000.00	15000.00
2000	15000.00	4000.00	11000.00
2001	11000.00	3000.00	8000.00
2002	8000.00	2000.00	6000.00
2003	6000.00	1000.00	5000.00

Figure 47.6. Sum-of-years Digits



year	sbvalue	deprectn	ebvalue
1999	20000.00	4000.00	16000.00
2000	16000.00	6400.00	9600.00
2001	9600.00	3840.00	5760.00
2002	5760.00	2304.00	3456.00
2003	3456.00	2304.00	1152.00
2004	1152.00	1152.00	0.00

Figure 47.7. Depreciation Table



year	sbvalue	deprectn	ebvalue
1999	20000.00	8000.00	12000.00
2000	12000.00	4800.00	7200.00
2001	7200.00	2200.00	5000.00
2002	5000.00	0.00	5000.00
2003	5000.00	0.00	5000.00

Figure 47.8. Declining Balance

- Under Depreciation Table, realize a 5-year class MACRS Depreciation actually lasts 6 years.
- The Declining Balance method is Double Declining Balance with conversion to Straight Line.

For further reference, consider Newnan and Lavelle (1998). They offer explanations and graphs for the individual depreciation methods. They also analyze the differences between the various methods.

Rate Information

The Tools Menu

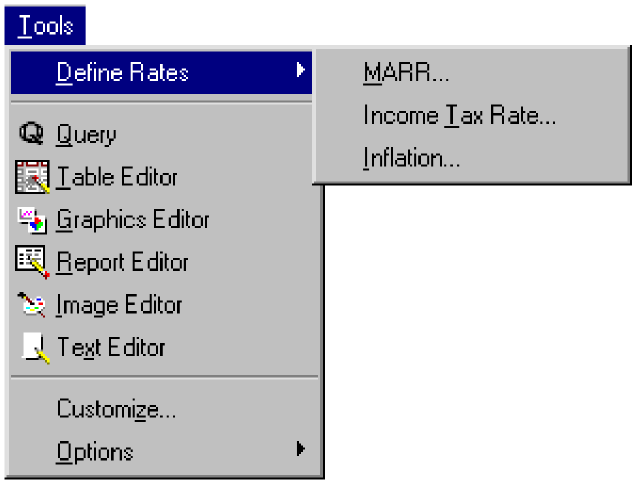


Figure 47.9. The Tools Menu

The **Tools** → **Define Rates** menu offers the following options.

MARR... opens the Minumum Attractive Rate of Return (MARR) dialog box.

Income Tax Rate... opens the Income Tax Specification dialog box.

Inflation... opens the Inflation Specification dialog box.

Dialog Box Guide

Minimum Attractive Rate of Return (MARR)

Selecting **Tools** → **Define Rates** → **MARR** from the Investment Analysis dialog box menu bar opens the MARR dialog box displayed in Figure 47.10.

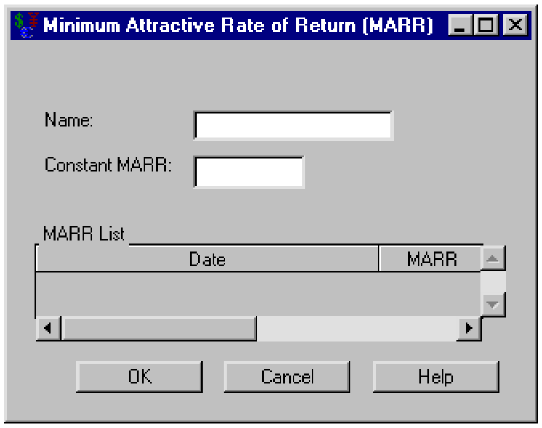

Figure 47.10. MARR Dialog Box

Name holds the name you assign to the MARR specification. This must be a valid SAS name.

Constant MARR holds the numeric value you choose to be the constant MARR. This value is used if the **MARR List** table editor is empty.

MARR List holds date-MARR pairs where the date refers to when the particular MARR value begins. Each date is a SAS date.

OK returns you to the Investment Analysis dialog box. Pressing it causes the preceding MARR specification to be assumed when you do not specify MARR rates in a dialog box that needs MARR rates.

Cancel returns you to the Investment Analysis dialog box, discarding any work done in the MARR dialog box.

Income Tax Specification

Selecting **Tools** → **Define Rates** → **Income Tax Rate** from the Investment Analysis dialog box menu bar opens the Income Tax Specification dialog box displayed in Figure 47.11.

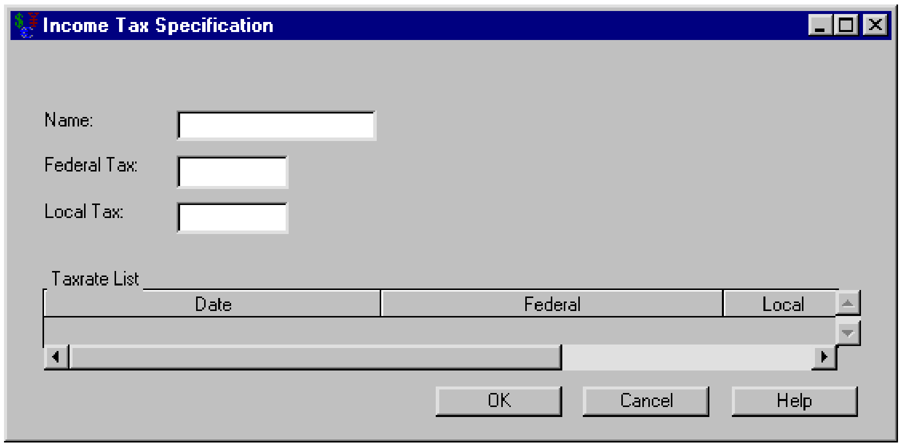

Figure 47.11. Income Tax Specification Dialog Box

Name holds the name you assign to the Income Tax specification. This must be a valid SAS name.

Federal Tax holds the numeric value you desire to be the constant Federal Tax.

Local Tax holds the numeric value you desire to be the constant Local Tax.

Taxrate List holds date-Income Tax triples where the date refers to when the particular Income Tax value begins. Each date is a SAS date, and the value is a percentage between 0% and 100%.

OK returns you to the Investment Analysis dialog box. Clicking it causes the preceding income tax specification to be the default income tax rates when using the After Tax Cashflow Calculation dialog box.

Cancel returns you to the Investment Analysis dialog box, discarding any editions since this dialog box was opened.

Inflation Specification

Selecting **Tools** → **Define Rates** → **Inflation** from the Investment Analysis dialog box menu bar opens the Inflation Specification dialog box displayed in Figure 47.12.

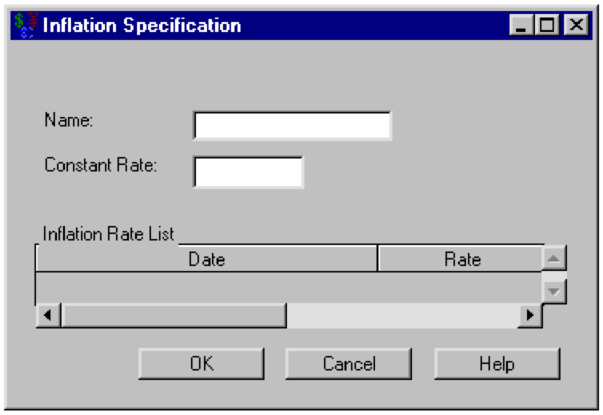

Figure 47.12. Inflation Specification Dialog Box

Name holds the name you assign to the Inflation specification. This must be a valid SAS name.

Constant Rate holds the numeric value you desire to be the constant inflation rate. This value is used if the **Inflation Rate List** table editor is empty.

Inflation Rate List holds date-rate pairs where the date refers to when the particular inflation rate begins. Each date is a SAS date and the rate is a percentage between 0% and 120%.

OK returns you to the Investment Analysis dialog box. Pressing it causes the preceding inflation specification to be assumed when you use the Constant Dollar Calculation dialog box and do not specify inflation rates.

Cancel returns you to the Investment Analysis dialog box, discarding any editions since this dialog box was opened.
