The following SAS statements produce a conditional logistic regression analysis of the data. The variable `Time` is the response, and `Low` is the censoring variable. Note that the data set is created so that all the cases have the same event time, and the controls have later censored times. The matching variable `Age` is used in the `STRATA` statement so each unique age value defines a stratum. The variables `LWT`, `Smoke`, `HT`, and `UI` are specified as explanatory variables. The `TIES=DISCRETE` option requests the discrete logistic model.

```
proc phreg data=LBW;
  model Time*Low(0)= LWT Smoke HT UI / ties=discrete;
  strata Age;
run;
```

The procedure displays a summary of the number of event and censored observations for each stratum. These are the number of cases and controls for each matched set shown in [Output 54.3.1](#).

Output 54.3.1. Summary of Number of Case and Controls

15	30	7	1	6	85.71
16	31	5	1	4	80.00
17	32	6	1	5	83.33

Total		174	54	120	68.97

Results of the conditional logistic regression analysis are shown in [Output 54.3.2](#). Based on the Wald test for individual variables, the variables LWT, Smoke, and HT are statistically significant while UI is marginal.

The hazards ratios, computed by exponentiating the parameter estimates, are useful in interpreting the results of the analysis. If the hazards ratio of a prognostic factor is larger than 1, an increment in the factor increases the hazard rate. If the hazards ratio is less than 1, an increment in the factor decreases the hazard rate. Results indicate that women were more likely to have low birth-weight babies if they were underweight in the last menstrual cycle, were hypertensive, smoked during pregnancy, or suffered uterine irritability.

Output 54.3.2. Conditional Logistic Regression Analysis for the Low Birth-Weight Study

HT	1	1.75143	0.73932	5.6120	0.0178	5.763
UI	1	0.88341	0.48032	3.3827	0.0659	2.419

For matched case-control studies with one case per matched set (1:n matching), the likelihood function for the conditional logistic regression reduces to that of the Cox model for the continuous time scale. For this situation, you can use the default TIES=BRESLOW.

Example 54.4. Model Using Time-Dependent Explanatory Variables

Time-dependent variables can be used to model the effects of subjects transferring from one treatment group to another. One example of the need for such strategies is the Stanford heart transplant program. Patients are accepted if physicians judge them suitable for heart transplant. Then, when a donor becomes available, physicians choose transplant recipients according to various medical criteria. A patient's status can be changed during the study from waiting for a transplant to being a transplant recipient. Transplant status can be defined by the time-dependent covariate function $z = z(t)$ as

$$z(t) = \begin{cases} 0 & \text{if the patient has not received the transplant at time } t \\ 1 & \text{if the patient has received the transplant at time } t \end{cases}$$

The Stanford heart transplant data that appear in Crowley and Hu (1977) consist of 103 patients, 69 of whom received transplants. The data are saved in a SAS data set called `Heart`. For each patient in the program, there is a birth date (`Bir_Date`), a date of acceptance (`Acc_Date`), and a date last seen (`Ter_Date`). The survival time (`Time`) in days is defined as $\text{Time} = \text{Ter_Date} - \text{Acc_Date}$. The survival time is said to be uncensored (`Status=1`) or censored (`Status=0`), depending on whether `Ter_Date` is the date of death or the closing date of the study. The age in years at acceptance into the program is $\text{Acc_Age} = (\text{Acc_Date} - \text{Bir_Date}) / 365$. Previous open-heart surgery for each patient is indicated by the variable `PrevSurg`. For each transplant recipient, there is a date of transplant (`Xpl_Date`) and three measures (`NMismatch`, `Antigen`, `Mismatch`) of tissue-type mismatching. The waiting period (`WaitTime`) in days for a transplant recipient is calculated as $\text{WaitTime} = \text{Xpl_Date} - \text{Acc_Date}$, and the age in years at transplant is $\text{Xpl_Age} = (\text{Xpl_Date} - \text{Bir_Date}) / 365$. For those who do not receive heart transplants, the `WaitTime`, `Xpl_Age`, `NMismatch`, `Antigen`, and `Mismatch` variables contain missing values.

The input data contains dates that have a two-digit year representation. The SAS option `YEARCUTOFF=1900` is specified to ensure that a two-digit year `xx` is year 19xx.

The code is as follows:

```

options yearcutoff=1900;

data Heart;
  input ID
        @5  Bir_Date mmddyy8.
        @14 Acc_Date mmddyy8.

Crowley and Hu (1977) have presented a number of analyses to assess the effects of various explanatory variables on the survival of patients. This example fits two of the models that they have considered.

The first model consists of two explanatory variables—the transplant status and the age at acceptance. The transplant status (`XStatus`) is a time-dependent variable defined by the programming statements between the `MODEL` statement and the `RUN` statement. The `XStatus` variable takes the value 1 or 0 at time t (measured from the date of acceptance), depending on whether or not the patient has received a transplant at that time. Note that the value of `XStatus` changes for subjects in each risk set (subjects still alive just before each distinct event time); therefore, the variable cannot be created in the `DATA` step. The variable `Acc_Age`, which is not time-dependent, accounts for the possibility that pretransplant risks vary with age.

```

proc phreg data= Heart;
  model Time*Status(0)= XStatus Acc_Age;
  if (WaitTime = . or Time < WaitTime) then XStatus=0.;
  else XStatus= 1.0;
run;

```

Results of this analysis are shown in [Output 54.4.1](#). Transplantation appears to be associated with a slight decrease in risk, although the effect is not significant ($p = 0.8432$). The age at acceptance as a pretransplant risk factor adds significantly to the model ($p = 0.0294$). The risk increases significantly with age at acceptance.

```

The second model consists of three explanatory variables—the transplant status, the transplant age, and the mismatch score. Four transplant recipients who were not typed have no `Mismatch` values; they are excluded from the analysis by the use of a `WHERE` clause. The transplant age (`XAge`) and the mismatch score (`XScore`) are also time-dependent and are defined in a fashion similar to that of `XStatus`. While the patient is waiting for a transplant, `XAge` and `XScore` have a value of 0. After the patient has migrated to the recipient population, `XAge` takes on the value of `Xpl_Age` (transplant age for the recipient), and `XScore` takes on the value of `Mismatch` (a measure of the degree of dissimilarity between donor and recipient).

```
proc phreg data= Heart;
  model Time*Status(0)= XStatus XAge XScore;
  where NotTyped ^= 'y';
  if (WaitTime = . or Time < WaitTime) then do;
    XStatus=0.;
    XAge=0.;
    XScore= 0.;
  end;
  else do;
    XStatus= 1.0;
    XAge= Xpl_Age;
    XScore= Mismatch;
  end;
run;
```

Results of the analysis are shown in [Output 54.4.2](#). Note that only 99 patients are included in this analysis, instead of 103 patients as in the previous analysis, since four transplant recipients who were not typed are excluded. The variable `XAge` is statistically significant ($p = 0.0146$) with a hazards ratio exceeding 1. Therefore, patients who had a transplant at younger ages lived longer than those who received a transplant later in their lives. The variable `XScore` has only minimal effect on the survival ($p = 0.1129$).

Example 54.5. Time-Dependent Repeated Measurements of a Covariate

Repeated determinations may be made during the course of a study of variables thought to be related to survival. Consider an experiment to study the dosing effect of a tumor-promoting agent. Forty-five rodents initially exposed to a carcinogen were randomly assigned to three dose groups. After the first death of an animal, the rodents were examined every week for the number of papillomas. Investigators were interested in determining the effects of dose on the carcinoma incidence after

adjusting for the number of papillomas.

The input data set TUMOR consists of the following 19 variables:

- ID (subject identification)
- Time (survival time of the subject)
- Dead (censoring status where 1=dead and 0=censored)
- Dose (dose of the tumor-promoting agent)
- P1–P15 (number of papillomas at the 15 times that animals died. These 15 death times are weeks 27, 34, 37, 41, 43, 45, 46, 47, 49, 50, 51, 53, 65, 67, and 71. For instance, subject 1 died at week 47; it had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. For an animal that died before week 71, the number of papillomas is missing for those times beyond its death.)

The following SAS statements create the data set TUMOR:

```

data Tumor;
  infile datalines missover;
  input ID Time Dead Dose P1-P15;
  label ID='Subject ID';
  datalines;

;

```

The number of papillomas (NPap) for each animal in the study was measured repeatedly over time. One way of handling time-dependent repeated measurements in the PHREG procedure is to use programming statements to capture the appropriate covariate values of the subjects in each risk set. In this example, NPap is a time-dependent explanatory variable with values that are calculated by means of the programming statements shown in the following SAS statements:

```

proc phreg data=Tumor;
  model Time*Dead(0)=Dose NPap;
  array pp{*} P1-P14;
  array tt{*} t1-t15;
  t1 = 27;
  t2 = 34;
  t3 = 37;
  t4 = 41;
  t5 = 43;
  t6 = 45;
  t7 = 46;
  t8 = 47;
  t9 = 49;
  t10= 50;
  t11= 51;
  t12= 53;
  t13= 65;
  t14= 67;
  t15= 71;
  if Time < tt[1] then NPap=0;
  else if time >= tt[15] then NPap=P15;
  else do i=1 to dim(pp);
    if tt[i] <= Time < tt[i+1] then NPap= pp[i];
  end;
run;

```

At each death time, the NPap value of each subject in the risk set is recalculated to reflect the actual number of papillomas at the given death time. For instance, subject one in the data set Tumor was in the risk sets at weeks 27 and 34; at week 27, the animal had no papilloma, while at week 34, it had five papillomas. Results of the analysis are shown in [Output 54.5.1](#).

Output 54.5.1. Cox Regression Analysis on the Survival of Rodents

After the number of papillomas is adjusted for, the dose effect of the tumor-promoting agent is not statistically significant.

Another way to handle time-dependent repeated measurements in the PHREG procedure is to use the counting process style of input. Multiple records are created for each subject, one record for each distinct pattern of the time-dependent measurements. Each record contains a T1 value and a T2 value representing the time interval (T1,T2] during which the values of the explanatory variables remain unchanged. Each record also contains the censoring status at T2.

One advantage of using the counting process formulation is that you can easily obtain various residuals and influence statistics that are not available when programming statements are used to compute the values of the time-dependent variables. On the other hand, creating multiple records for the counting process formulation requires extra effort in data manipulation.

Consider a counting process style of input data set named `Tumor1`. It contains multiple observations for each subject in the data set `Tumor`. In addition to variables `ID`, `Time`, `Dead`, and `Dose`, four new variables are generated:

- T1 (left endpoint of the risk interval)
- T2 (right endpoint of the risk interval)
- NPap (number of papillomas in the time interval (T1,T2])
- Status (censoring status at T2)

For example, five observations are generated for the rodent that died at week 47 and that had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. The values of T1, T2, NPap, and Status for these five observations are (0,27,0,0), (27,34,5,0), (34,37,6,0), (37,41,8,0), and (41,47,10,1). Note that the variables `ID`, `Time`, and `Dead` are not needed for the estimation of the regression parameters, but they are useful for plotting the residuals.

The following SAS statements create the data set Tumor1:

```

data Tumor1(keep=ID Time Dead Dose T1 T2 NPap Status);
  array pp{*} P1-P14;
  array qq{*} P2-P15;
  array tt{1:15} _temporary_
    (27 34 37 41 43 45 46 47 49 50 51 53 65 67 71);
  set Tumor;
  T1 = 0;
  T2 = 0;
  Status = 0;
  if ( Time = tt[1] ) then do;
    T2 = tt[1];
    NPap = p1;
    Status = Dead;
    output;
  end;
  else do _i_=1 to dim(pp);
    if ( tt[_i_] = Time ) then do;
      T2= Time;
      NPap = pp[_i_] ;
      Status = Dead;
      output;
    end;
    else if (tt[_i_] < Time ) then do;
      if (pp[_i_] ^= qq[_i_] ) then do;
        if qq[_i_] = . then T2= Time;
        else T2= tt[_i_] ;
        NPap= pp[_i_] ;
        Status= 0;
        output;
        T1 = T2;
      end;
    end;
  end;
  if ( Time >= tt[15] ) then do;
    T2 = Time;
    NPap = P15;
    Status = Dead;
    output;
  end;
run;

```

In the following SAS statements, the counting process MODEL specification is used. The DFBETA statistics are output to a SAS data set named Out1. Note that Out1 contains multiple observations for each subject, that is, one observation for each risk interval (T1,T2].

```
proc phreg data=Tumor1;
  model (T1,T2)*Status(0)=Dose NPap;
  output out=Out1 resmart=mart dfbeta=db1-db2/order=data;
  id ID Time Dead;
run;
```

The output from PROC PHREG (not shown) is identical to [Output 54.5.1](#) except for the “Summary of the Number of Event and Censored Values” table. The number of event observations remains unchanged between the two specifications of PROC PHREG, but the number of censored observations differs due to the splitting of each subject’s data into multiple observations for the counting process style of input.

Next, the MEANS procedure sums up the component statistics for each subject and outputs the results to a SAS data set named Out2.

```
proc means data=Out1 noprint;
  by ID Time Dead;
  var mart db1-db2;
  output out=Out2 sum=mart db_dose db_npap;
run;
```

Finally, DFBETA statistics are plotted against subject ID for easy identification of influential points.

```
symbol1 v=dot h=0.8 c=blue;
axis1 label = (angle=-90 rotate=90 'DFBETA for Dose')
  minor = none
  order = (-.04 to .04 by .01);
axis2 label = (angle=-90 rotate=90 'DFBETA for NPap')
  minor = none
  order = (-.030 to .020 by .005);
title 'Plot of DFBETA';
proc gplot data=Out2;
  plot db_dose * ID / frame hminor=0 vaxis=axis1 cframe=ligr;
  plot db_npap * ID / frame hminor=0 vaxis=axis2 cframe=ligr;
run;
```

The plots of the DFBETA statistics are shown in [Output 54.5.2](#) and [Output 54.5.3](#). Subject 30 appears to have a large influence on both the Dose and NPap coefficients. Subjects 31 and 35 have considerable influences on the DOSE coefficient, while subjects 22 and 44 have rather large influences on the NPap coefficient.

Output 54.5.2. Plot of DFBETA Statistic for DOSE versus Subject Number

Output 54.5.3. Plot of DFBETA Statistic for NPAP versus Subject Number

Example 54.6. Survivor Function Estimates for Specific Covariate Values

You may want to use your regression analysis results to generate predicted survival curves for subjects not in the study. This example illustrates how to use the `BASELINE` statement to obtain the survivor function for a new set of explanatory variable values. The various sets of explanatory variable values must be contained in a SAS data set.

In previous examples, `LogBUN` and `HGB` were identified as the most important prognostic factors for the myeloma data. Suppose you are interested in obtaining the survivor function estimates for the following two realizations of `LogBUN` and `HGB`, which are saved in a SAS data set called `Inrisks`.

```
data Inrisks;
  input LogBUN HGB;
  datalines;
1.00 10.0
1.80 12.0
;
```

In the `BASELINE` statement, you specify the name of the data set (`COVARIATE=Inrisk`) that contains the various sets of explanatory variable values and the name of the output SAS data set (`OUT=Pred1`) that contains the survivor function estimates. The option `SURVIVAL=S` puts the variable `S` containing the survivor function estimates in the output data set `Pred1`. Similarly, the options `LOWER=S_lower` and `UPPER=S_upper` put the variables `S_lower` and `S_upper` in `Pred1`; these variables contain, respectively, the lower and upper 95% confidence limits for the survival. The `NOPRINT` option in the `PROC PHREG` statement suppresses the displayed output (the analysis results are shown in [Example 54.1](#)). The `PRINT` procedure displays the observations in the data set `Pred1`.

```
proc phreg data=Myeloma noprint;
  model Time*VStatus(0)=LogBUN HGB;
  baseline covariates=Inrisks out=Pred1 survival=S
           lower=S_lower upper=S_upper;
run;
proc print data=Pred1;
run;
```

The first 32 observations of the data set `Pred1` are shown in [Output 54.6.1](#). They represent the survivor function for the realization `LogBUN=1.00` and `HGB=10.0`. The first observation has survival time 0 and survivor function estimate 1.0. Each of the remaining 31 observations represents each unique event time in the input data set `Myeloma`. These observations are presented in ascending order of the event times. Likewise, the next 32 observations of the data set `Pred1` (starting from the 33rd observation) represent the survivor function for the realization `LogBUN=1.80` and `HGB=12.0`.

Output 54.6.1. Survivor Function Estimates for `LogBUN=1.0` and `HGB=10.0`

Obs	Log BUN	HGB	Time	S	S_lower	S_upper

By default, the procedure also outputs the set of survivor function estimates for `LogBUN=1.3929` and `HGB=10.2015`, which are the sample means of `LogBUN` and `HGB` for the input data in `Myeloma`. (Note that in a stratified analysis, the sample means are calculated within each stratum.) The estimated survivor function estimates for these sample means are the last 32 observations in the data set `Pred1`. You can suppress this set of survival estimates by using the `NOMEAN` option in the `BASELINE` statement.

```

proc phreg data=Myeloma noprint;
  model Time*VStatus(0)=LogBUN HGB;
  baseline covariates=Inrisks out=Pred2 survival=S
           lower=S_lower upper=S_upper / nomean;
run;

```

The data set Pred2 consists of the first 64 observations of Pred1. If you are interested only in the survivor function estimates for the sample means of the explanatory variables, you can omit the COVARIATES= option in the BASELINE statement.

```

proc phreg data=Myeloma noprint;
  model Time*VStatus(0)=LogBUN HGB;
  baseline out=Pred3 survival=S lower=S_lower upper=S_upper;
run;

```

The data set Pred3 contains the last 32 observations of Pred1.

The following SAS statements are used to plot the survival curves in Pred1. For convenience, the variable Pattern is added to the data set Pred1 to identify the various patterns of explanatory variables.

```

data Pred1;
  set Pred1;
  if      LogBUN= 1.0 and HGB=10.0 then Pattern=1;
  else if LogBUN= 1.8 and HGB=12.0 then Pattern=2;
  else                                     Pattern=3;

legend1 label=none shape=symbol(3, .8)
  value=(f=swiss h=.8 'LogBUN=1.00 HGB=10.0'
        'LogBUN=1.80 HGB=12.0' 'LogBUN=1.39 HGB=10.2');
axis1 label=(h=1 f=swiss a=90) minor=(n=1);
axis2 label=(h=1 f=swiss 'Survival Time in Months') minor=(n=4);

proc gplot data=Pred1;
  plot S*Time=Pattern / legend=legend1 vaxis=axis1
           haxis=axis2 cframe=ligr;
  symbol1 interpol=stepLJ h=1 v=square c=blue;
  symbol2 interpol=stepLJ h=1 v=diamond c=yellow;
  symbol3 interpol=stepLJ h=1 v=circle c=red;
  note f=swiss h=1.5 j=c 'Myeloma Study';
  footnote h=.8 f=duplex
    'LogBUN=1.39 and HGB=10.2 correspond to the sample means';
run;

```

The survivor function estimates for these three patterns of explanatory variables are displayed in [Output 54.6.2](#). Note that these survivor functions are portrayed as right-continuous functions.

Output 54.6.2. Survival Curves for Specific Covariate Patterns

Example 54.7. Analysis of Residuals

Residuals are used to investigate the lack of fit of a model to a given subject. You can obtain martingale and deviance residuals for the Cox proportional hazards regression analysis by requesting that they be included in the OUTPUT data set. You can plot these statistics and look for outliers.

Consider the stepwise regression analysis performed in [Example 54.1](#). The final model included variables `LogBUN` and `HGB`. You can generate residual statistics for this analysis by refitting the model containing those variables and including an OUTPUT statement. The keywords `XBETA`, `RESMART`, and `RESDEV` identify new variables that contain the linear predictor scores $\mathbf{z}'_j \hat{\boldsymbol{\beta}}$, martingale residuals, and deviance residuals. These variables are `xb`, `mart`, and `dev`, respectively.

```
proc phreg data=Myeloma noprint;
  model Time*Vstatus(0)=LogBUN HGB;
  output out=Outp xbeta=xb resmart=mart resdev=dev;
run;
```

The following statements plot the residuals against the linear predictor scores:

```
proc gplot data=Outp;
  plot (mart dev)*xb / vref=0 cframe=ligr;
  symbol1 value=circle c=blue;
run;
```

The resulting plots are shown in [Output 54.7.1](#) and [Output 54.7.2](#). The martingale residuals are skewed because of the single event setting of the Cox model. The martingale residual plot shows an isolation point (with linear predictor score 1.09 and martingale residual -3.37), but this observation is no longer distinguishable in the deviance residual plot. In conclusion, there is no indication of a lack of fit of the model to individual observations.

Output 54.7.1. Martingale Residual Plot

Output 54.7.2. Deviance Residual Plot

Example 54.8. Analysis of Recurrent Events Data

Recurrent events data consists of times to a number of repeated events for each sample unit; for example, times of recurrent episodes of a disease in patients. Various ways for analyzing recurrent events data are described in the section “[Analysis of Multivariate Failure Time Data](#)” on page 3247. The bladder cancer data listed in Wei, Lin, and Weissfeld (1989) is used here to illustrate these methods.

The data consist of 86 patients with superficial bladder tumors, which were removed when the patients entered the study. Of these patients, 48 were randomized into the placebo group, and 38 were randomized into the thiotepa group. Many patients had multiple recurrences of tumors during the study, and new tumors were removed at each visit. The data set contains the first four recurrences of the tumor for each patient, and each recurrence time was measured from the patient’s entry time into the study.

The data consist of the following eight variables:

- Trt, treatment group (1=placebo and 2=thiotepa)
- Time, follow-up time
- Number, number of initial tumors
- Size, initial tumor size
- T1, T2, T3, and T4, times of the four potential recurrences of the bladder tumor. A patient with only two recurrences has missing values in T3 and T4.

In the data set **Bladder**, four observations are created for each patient, one for each of the four potential tumor recurrences. In addition to values of **Trt**, **Number**, and **Size** for the patient, each observation contains the following variables:

- **ID**, patient's identification (which is the sequence number of the subject)
- **Visit**, visit number (with value k for the k th potential tumor recurrence)
- **TStart**, time of the $(k-1)$ th recurrence for $\text{Visit}=k$, or the entry time 0 if $\text{VISIT}=1$, or the follow-up time if the $(k-1)$ th recurrence does not occur
- **TStop**, time of the k th recurrence if $\text{Visit}=k$ or follow-up time if the k th recurrence does not occur
- **Status**, event status of **TStop** (1=recurrence and 0=censored)

For instance, a patient with only one recurrence time at month 6, who was followed until month 10, will have values for **Visit**, **TStart**, **TStop**, and **Status** of (1,0,6,1), (2,6,10,0), (3,10,10,0), and (4,10,10,0). The last two observations are redundant for the intensity model and the proportional means model, but they are important for the analysis of the marginal Cox models. If the follow-up time is beyond the time of the fourth tumor recurrence, it is tempting to create a fifth observation with the time of the fourth tumor recurrence as the **TStart** value, the follow-up time as the **TStop** value, and a **Status** value of 0. However, Therneau and Grambsch (2000), Section 8.5) have warned against incorporating such observations into the analysis.

The following SAS statements create the data set **Bladder**:

```

data Bladder;
  keep ID TStart TStop Status Trt Number Size Visit;
  retain ID TStart 0;
  array tt T1-T4;
  infile datalines missover;
  input Trt Time Number Size T1-T4;
  ID + 1;
  TStart=0;
  do over tt;
    Visit=_i_;
    if tt = . then do;
      TStop=Time;
      Status=0;
    end;
    else do;
      TStop=tt;
      Status=1;
    end;
    output;
    TStart=TStop;
  end;
  if (TStart < Time) then delete;
  datalines;
1      0      1      1
1      1      1      3

```

First, consider fitting the intensity model (Andersen and Gill 1982) and the proportional means model (Lin et al. 2000). The counting process style of input is used in the PROC PHREG specification. For the proportional means model, inference is based on the robust sandwich covariance estimate, which is requested by the COVB(AGGREGATE) option in the PROC PHREG statement. The COVM option is specified for the analysis of the intensity model to use the model-based covariance estimate. Note that some of the observations in the data set `Bladder` have a degenerated interval of risk. The presence of these observations does not affect the results of the analysis since none of these observations are included in any of the risk sets. However, the procedure will run more efficiently without these observations; consequently, in the following SAS statements, the WHERE clause is used to eliminate these redundant observations.

```

title 'Intensity Model and Proportional Means Model';
proc phreg data=Bladder covm covs(aggregate);
  model (TStart, TStop) * Status(0) = Trt Number Size;
  id id;
  where TStart < TStop;
run;

```

Results of fitting the intensity model and the proportional means model are shown in [Output 54.8.1](#) and [Output 54.8.2](#), respectively. The robust sandwich standard error estimate for Trt is larger than its model-based counterpart, rendering the effect of thiotepa less significant in the proportional means model ($p=0.0747$) than in the intensity model ($p=0.0215$).

Output 54.8.1. Analysis of the Intensity Model

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates with Model-Based Variance Estimate						
Variable	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
Trt	1	-0.45979	0.19996	5.2873	0.0215	0.631
Number	1	0.17165	0.04733	13.1541	0.0003	1.187
Size	1	-0.04256	0.06903	0.3801	0.5375	0.958

Output 54.8.2. Analysis of the Proportional Means Model

Analysis of Maximum Likelihood Estimates with Sandwich Variance Estimate							
Variable	DF	Parameter Estimate	Standard Error	StdErr Ratio	Chi-Square	Pr > ChiSq	Hazard Ratio
Trt	1	-0.45979	0.25801	1.290	3.1757	0.0747	0.631
Number	1	0.17165	0.06131	1.296	7.8373	0.0051	1.187
Size	1	-0.04256	0.07555	1.094	0.3174	0.5732	0.958

Next, consider the conditional models of PWP (Prentice, Williams, and Peterson 1981). In the PWP models, the risk set for the $(k+1)$ th recurrence is restricted to those patients who have experienced the first k recurrences. For example, a patient who experienced only one recurrence is an event observation for the first recurrence; this patient is a censored observation for the second recurrence and should not be included in the risk set for the third or fourth recurrence. The following DATA step eliminates those observations that should not be in the risk sets, forming a new input data set (named `Bladder2`) for fitting the PWP models. The variable `Gaptime`, represented the gap times between successive recurrences, is also created.

```

data Bladder2(drop=LastStatus);
  retain LastStatus;
  set Bladder;
  by ID;
  if first.id then LastStatus=1;
  if (Status=0 and LastStatus=0) then delete;
  LastStatus=Status;
  Gaptime=Tstop-Tstart;
run;

```

The following statements fit the PWP total time model. Variables Trt1, Trt2, Trt3, and Trt4 are visit-specific variables for Trt; variables Number1, Number2, Number3, and Number4 are visit-specific variables for Number; and variables Size1, Size2, Size3, and Size4 are visit-specific variables for Size.

```

title 'PWP Total Time Model with Noncommon Effects';
proc phreg data=Bladder2;
  model (Tstart,Tstop) * Status(0) = Trt1-Trt4 Number1-Number4
                                     Size1-Size4;

  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);
  Trt4= Trt * (Visit=4);
  Number1= Number * (Visit=1);
  Number2= Number * (Visit=2);
  Number3= Number * (Visit=3);
  Number4= Number * (Visit=4);
  Size1= Size * (Visit=1);
  Size2= Size * (Visit=2);
  Size3= Size * (Visit=3);
  Size4= Size * (Visit=4);
  strata Visit;
run;

```

Results of the analysis of the PWP total time model are shown in [Output 54.8.3](#). Note that patients who were at risk for a second recurrence are those who had a first recurrence. There is no significant treatment effect on the total time in any of the four tumor recurrences.

Output 54.8.3. Analysis of the PWP Total Time Model with Noncommon Effects

The PHREG Procedure						
Summary of the Number of Event and Censored Values

Size4	1	0.0000732	0.34297	0.0000	0.9998	1.000

The following statements fit the PWP gap-time model.

```

title 'PWP Gap Time Model with Noncommon Effects';
proc phreg data=Bladder2;
  model Gaptime * Status(0) = Trt1-Trt4 Number1-Number4
                                Size1-Size4;

  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);
  Trt4= Trt * (Visit=4);
  Number1= Number * (Visit=1);
  Number2= Number * (Visit=2);
  Number3= Number * (Visit=3);
  Number4= Number * (Visit=4);
  Size1= Size * (Visit=1);
  Size2= Size * (Visit=2);
  Size3= Size * (Visit=3);
  Size4= Size * (Visit=4);
  strata Visit;
run;

```

Results of the analysis of the PWP gap-time model are shown in [Output 54.8.4](#). Note that the regression coefficients for the first tumor recurrence are the same as those of

the total time model, since the total time and the gap time are the same for the first recurrence. There is no significant treatment effect on the gap times for any of the four tumor recurrences.

Output 54.8.4. Analysis of the PWP Gap Time Model with Noncommon Effects

You can fit the PWP total time model with common effects with the following SAS statements. However, the analysis is not shown here.

```

title2 'PWP Total Time Model with Common Effects';
proc phreg data=Bladder2;
  model (tstart,tstop) * status(0) = Trt Number Size;
  strata Visit;
run;

```

You can fit the PWP gap time model with common effects with the following statements. Again, the analysis is not shown here.

```

title2 'PWP Gap Time Model with Common Effects';
proc phreg data=Bladder2;
  model Gaptime * Status(0) = Trt Number Vize;
  strata Visit;
run;

```

Recurrent events data are a special case of multiple events data in which the recurrence times are regarded as multivariate failure times and the marginal approach of WLW (Wei, Lin, and Weissfeld 1989) can be used. WLW fits a Cox model to each of the component times and makes statistical inference of the regression parameters based on a robust sandwich covariance matrix estimate. No specific correlation structure is imposed on the multivariate failure times. For the k th marginal model, let β_k denote the row vector of regression parameters, let $\hat{\beta}_k$ denote the maximum likelihood estimate of β_k , let \hat{A}_k denote the covariance matrix obtained by inverting the

observed information matrix, and let \mathbf{R}_k denote the matrix of score residuals. WLW showed that the joint distribution of $(\hat{\beta}_1, \dots, \hat{\beta}_4)'$ can be approximated by a multivariate normal distribution with mean vector $(\beta_1, \dots, \beta_4)'$ and robust covariance matrix

$$\begin{pmatrix} \mathbf{V}_{11} & \mathbf{V}_{12} & \mathbf{V}_{13} & \mathbf{V}_{14} \\ \mathbf{V}_{21} & \mathbf{V}_{22} & \mathbf{V}_{23} & \mathbf{V}_{24} \\ \mathbf{V}_{31} & \mathbf{V}_{32} & \mathbf{V}_{33} & \mathbf{V}_{34} \\ \mathbf{V}_{41} & \mathbf{V}_{42} & \mathbf{V}_{43} & \mathbf{V}_{44} \end{pmatrix}$$

with the submatrix \mathbf{V}_{ij} given by

$$\mathbf{V}_{ij} = \hat{\mathbf{A}}_i (\mathbf{R}'_i \mathbf{R}_j) \hat{\mathbf{A}}_j$$

In this example, there are four marginal proportional hazards models, one for each potential recurrence time. Instead of fitting one model at a time, you can fit all four marginal models in one analysis by using the STRATA statement and model-specific covariates. Using the Visit as the STRATA variable on the input data set **Bladder**, PROC PHREG simultaneously fits all four marginal models, one for each Visit value. The COVS(AGGREGATE) option is specified to compute the robust sandwich variance estimate by summing up the score residuals for each distinct pattern of ID value. The TEST statement TREATMENT is used to perform the global test of no treatment effect for each tumor recurrence, the AVERAGE option is specified to estimate the parameter for the common treatment effect, and the E option displays the optimal weights for the common treatment effect.

```
proc phreg data=Bladder covs(aggregate);
  model TStop*Status(0)=Trt1-Trt4 Number1-Number4 Size1-Size4;
  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);

  Size4= Size * (Visit=4);
  strata Visit;
  id ID;
  TREATMENT: test trt1,trt2,trt3,trt4/average e;
run;
```

Out of the 86 patients, 47 patients have only one tumor recurrence, 29 patients have two recurrences, 22 patients have three recurrences, and 14 patients have four recurrences (Output 54.8.5). Parameter estimates for the four marginal models are shown in Output 54.8.6. The 4 DF Wald test (Output 54.8.7) indicates a lack of evidence of a treatment effect in any of the four recurrences ($p=0.4105$). The optimal weights for estimating the parameter of the common treatment effect are 0.67684, 0.25723, -0.07547, and 0.14140 for Trt1, Trt2, Trt3, and Trt4, respectively, which gives a parameter estimate of -0.5489 with a standard error estimate of 0.2853. A more sensitive test for a treatment effect is the 1 DF test based on this common parameter; however, there is still insufficient evidence for such effect at the 0.05 level ($p=0.0543$).

Example 54.9. Analysis of Clustered Data

When experimental units are naturally or artificially clustered, failure times of experimental units within a cluster are correlated. Lee, Wei, and Amato (1992) estimate the regression parameters in the Cox model by the maximum partial likelihood estimates under an independent working assumption and use a robust sandwich covariance matrix estimate to account for the intracluster dependence. A subset of data from the Diabetic Retinopathy Study (DRS) is used to illustrate the methodology as in Lin (1994).

The data consist of 197 diabetic patients who have a high risk of experiencing blindness in both eyes as defined by DRS criteria. One eye of each patient is treated with laser photocoagulation. The hypothesis of interest is whether the laser treatment delays the occurrence of blindness. Since juvenile and adult diabetes have very different courses, it is also desirable to examine how the age of onset of diabetes may affect the time of blindness. Since there are no biological differences between the left eye and the right eye, it is natural to assume a common baseline hazard function for the failure times of the left and the right eyes.

Each patient is a cluster that contributes two observations to the input data set, one for each eye. The following variables are in the input data set Blind:

- ID, patient's identification
- Time, failure time
- Status, event indicator (0=censored and 1=uncensored)
- Treatment, treatment received (1=laser photocoagulation and 0=otherwise)
- DiabeticType, type of diabetes (0=juvenile onset with age of onset at 20 or under, and 1= adult onset with age of onset over 20)

```

```
run;
```

As a preliminary analysis, PROC FREQ is used to break down the numbers of blindness in the control and treated eyes.

```
proc freq data=Blind;
  table Treatment*Status;
run;
```

Output 54.9.1. Breakdown of Blindness in the Control and Treated Groups

The FREQ Procedure			
Table of Treatment by Status			
Treatment	Status		
Frequency	0	1	Total
Percent			
Row Pct			
Col Pct			
0	96	101	197
	24.37	25.63	50.00
	48.73	51.27	
	40.17	65.16	
1	143	54	197
	36.29	13.71	50.00
	72.59	27.41	
	59.83	34.84	
Total	239	155	394
	60.66	39.34	100.00

By the end of the study, 54 treated eyes and 101 untreated eyes have developed blindness (Output 54.9.1).

The analysis of Lee, Wei, and Amato (1992) can be carried out by the following PROC PHREG specification. The explanatory variables in this Cox model are Treatment, DiabeticType, and the Treatment \times DiabeticType interaction. The COVS(AGGREGATE) is specified to compute the robust sandwich covariance matrix estimate.

```
proc phreg data=Blind covs(aggregate);
  model Time*Status(0)=Treatment DiabeticType Interaction;
  Interaction= Treatment * DiabeticType;
  id ID;
run;
```

The robust standard error estimates are smaller than the model-based counterparts (Output 54.9.2), since the ratio of the robust standard error estimate relative to the model-based estimate is less than 1 for each variable. Laser photocoagulation appears

to be effective ($p=0.0217$) in delaying the occurrence of blindness. The effect is much more prominent for adult onset diabetes than for juvenile onset diabetes.

Output 54.9.2. Inference Based on the Robust Sandwich Covariance

The PHREG Procedure							
Analysis of Maximum Likelihood Estimates							
Variable	DF	Parameter Estimate	Standard Error	StdErr Ratio	Chi-Square	Pr > ChiSq	Hazard Ratio
Treatment	1	-0.42467	0.18497	0.850	5.2713	0.0217	0.654
DiabeticType	1	0.34084	0.19558	0.982	3.0371	0.0814	1.406
Interaction	1	-0.84566	0.30353	0.865	7.7622	0.0053	0.429

Example 54.10. Model Assessment Using Cumulative Sums of Martingale Residuals (Experimental)

The Mayo liver disease example of Lin, Wei, and Ying (1993) is reproduced here to illustrate the checking of the functional form of a covariate and the assessment of the proportional hazards assumption. The data consist of 418 patients with primary biliary cirrhosis (PBC), among which 161 had died as of the date of data listing. A subset of the variables are saved in the SAS data set Liver. The data set contains the following variables:

- Time, follow-up time in years
- Status, event indicator with value 1 for death time and value 0 for censored time
- Age, age in years from birth to study registration
- Albumin, serum albumin level in gm/dl
- Bilirubin, serum bilirubin level in mg/dl
- Edema, edema presence
- Prottime, prothrombin time in seconds

```

;
run;

```

Consider fitting a Cox model for the survival time of the PCB patients with covariates Bilirubin, log(Prottime), log(Albumin), Age and Edema. The log transform, which is often applied to blood chemistry measurements, is deliberately not employed for Bilirubin. It is of interest to assess the functional form of the variable Bilirubin in the Cox model.

```

ods html;
ods graphics on;

proc phreg data=Liver;
  model Time*Status(0)=Bilirubin logProttime logAlbumin Age Edema;
  logProttime=log(Prottime);
  logAlbumin=log(Albumin);
  assess var=(Bilirubin) / resample;
run;

ods graphics off;
ods html close;

```

The ASSESS statement creates a plot of the cumulative martingale residuals against the values of the covariate Bilirubin, which is specified in the VAR= option. The RESAMPLE option computes the p -value of a Kolmogorov-type supremum test based on a sample of 1,000 simulated residual patterns.

Parameter estimates of the model fit are shown in [Output 54.10.1](#). The plot in [Output 54.10.2](#) displays the observed cumulative martingale residual process for Bilirubin together with 20 simulated realizations from the null distribution. This graphical

display is requested by specifying the experimental ODS GRAPHICS statement and the experimental ASSESS statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the PHREG procedure, see the section “ODS Graphics” on page 3271. It is obvious that the observed process is atypical compared to the simulated realizations. Also, none of the 1,000 simulated realizations has an absolute maximum exceeding that of the observed cumulative martingale residual process. Both the graphical and numerical results indicate that a transform is deemed necessary for Bilirubin in the model.

Output 54.10.1. Cox Model with Bilirubin as a Covariate

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Variable	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
Bilirubin	1	0.11733	0.01298	81.7567	<.0001	1.124
logProtime	1	2.77581	0.71482	15.0794	0.0001	16.052
logAlbumin	1	-3.17195	0.62945	25.3939	<.0001	0.042
Age	1	0.03779	0.00805	22.0288	<.0001	1.039
Edema	1	0.84772	0.28125	9.0850	0.0026	2.334

Output 54.10.2. Cumulative Martingale Residuals vs Bilirubin (Experimental)

The cumulative martingale residual plots in [Output 54.10.3](#) provide guidance in suggesting a more appropriate functional form for a covariate. The four curves were created from simple forms of misspecification using 1,000 simulated times from an exponential model with 20% censoring. The true and fitted models are shown in [Table 54.3](#).

Output 54.10.3. Typical Cumulative Residual Plot Patterns

Table 54.3. Model Misspecifications

Plot	Data	Fitted Model
(a)	$\log(X)$	X
(b)	$\{X, X^2\}$	X
(c)	$\{X, X^2, X^3\}$	$\{X, X^2\}$
(d)	$I(X > 5)$	X

The curve of observed cumulative martingale residuals in [Output 54.10.2](#) most resembles the behavior of the curve in plot (a) of [Output 54.10.3](#), indicating that $\log(\text{Bilirubin})$ might be a more appropriate term in the model than Bilirubin .

Next, the analysis of the natural history of the PBC is repeated with $\log(\text{Bilirubin})$ replacing Bilirubin , and the functional form of $\log(\text{Bilirubin})$ is assessed. Also assessed is the proportional hazards assumption for the Cox model.

```
ods html;
ods graphics on;

proc phreg data=Liver;
  model Time*Status(0)=logBilirubin logProttime logAlbumin Age Edema;
```

```

logBilirubin=log(Bilirubin);
logProtime=log(Protime);
logAlbumin=log(Albumin);
assess var=(logBilirubin) ph / crpanel resample seed=19;
run;

ods graphics off;
ods html close;

```

The SEED= option specifies a integer seed for generating random numbers. The CRPANEL option in the ASSESS statement requests a panel of four plots. Each plot displays the observed cumulative martingale residual process along with two simulated realizations. The PH option checks the proportional hazards assumption of the model by plotting the observed standardized score process with 20 simulated realizations for each covariate in the model.

Output 54.10.4 displays the parameter estimates of the fitted model. The cumulative martingale residual plots in Output 54.10.5 and Output 54.10.6 show that the observed martingale residual process is more typical of the simulated realizations. The p -value for the Kolmogorov-type supremum test based on 1,000 simulations is 0.052, indicating that the log transform is a much improved functional form for Bilirubin.

Output 54.10.4. Model with log(Bilirubin) as a Covariate

The PHREG Procedure						
Analysis of Maximum Likelihood Estimates						
Variable	DF	Parameter Estimate	Standard Error	Chi-Square	Pr > ChiSq	Hazard Ratio
logBilirubin	1	0.87072	0.08263	111.0484	<.0001	2.389
logProtime	1	2.37789	0.76674	9.6181	0.0019	10.782
logAlbumin	1	-2.53264	0.64819	15.2664	<.0001	0.079
Age	1	0.03940	0.00765	26.5306	<.0001	1.040
Edema	1	0.85934	0.27114	10.0447	0.0015	2.362

Output 54.10.5. Panel Plot of Cumulative Martingale Residuals vs log(Bilirubin) (Experimental)

Output 54.10.6. Cumulative Martingale Residuals vs log(Bilirubin) (Experimental)

Output 54.10.7 and Output 54.10.8 display the results of proportional hazards assumption assessment for $\log(\text{Bilirubin})$ and $\log(\text{Prottime})$ respectively. The latter plot reveals nonproportional hazards for $\log(\text{Prottime})$.

Output 54.10.7. Standardized Score Process for $\log(\text{Bilirubin})$ (Experimental)

Output 54.10.8. Standardized Score Process for log(Protime) (Experimental)

Plots for log(Albumin), Age, and Edema are not shown here. The Kolmogorov-type supremum test results for all the covariates are shown in [Output 54.10.9](#). In addition to log(Protime), the proportional hazards assumption appears to be violated for Edema.

Output 54.10.9. Kolmogorov-type Supremum Tests for Proportional Hazards Assumption

Supremum Test for Proportionals Hazards Assumption				
Variable	Maximum Absolute Value	Replications	Seed	Pr > MaxAbsVal
logBilirubin	1.0880	1000	19	0.1480
logProtime	1.7243	1000	19	0.0010
logAlbumin	0.8443	1000	19	0.4390
Age	0.7387	1000	19	0.4780
Edema	1.4350	1000	19	0.0310

Chapter 55

The PLAN Procedure

Overview

The PLAN procedure constructs designs and randomizes plans for factorial experiments, especially nested and crossed experiments and randomized block designs. PROC PLAN can also be used for generating lists of permutations and combinations of numbers. The PLAN procedure can construct the following types of experimental designs:

- full factorials, with and without randomization
- certain balanced and partially balanced incomplete block designs
- generalized cyclic incomplete block designs
- Latin square designs

For other kinds of experimental designs, especially fractional factorial, response surface, and orthogonal array designs, refer to the FACTEX and OPTX procedures and the ADX Interface in SAS/QC software.

PROC PLAN generates designs by first generating a selection of the levels for the first factor. Then, for the second factor, PROC PLAN generates a selection of its levels for each level of the first factor. In general, for a given factor, the PLAN procedure generates a selection of its levels for all combinations of levels for the factors that precede it. The selection can be done in five different ways:

- randomized selection, for which the levels are returned in a random order
- ordered selection, for which the levels are returned in a standard order every time a selection is generated
- cyclic selection, for which the levels returned are computed by cyclically permuting the levels of the previous selection
- permuted selection, for which the levels are a permutation of the integers $1, \dots, n$
- combination selection, for which the m levels are selected as a combination of the integers $1, \dots, n$ taken m at a time

The randomized selection method can be used to generate randomized plans. Also, by appropriate use of cyclic selection, any of the designs in the very wide class of generalized cyclic block designs (Jarrett and Hall 1978) can be generated.

There is no limit to the depth to which the different factors can be nested, and any number of randomized plans can be generated.

You can also declare a list of factors to be selected simultaneously with the lowest (that is, the most nested) factor. The levels of the factors in this list can be seen as constituting the treatment to be applied to the cells of the design. For this reason, factors in this list are called *treatments*. With this list, you can generate and randomize plans in one run of PROC PLAN.

Getting Started

Three Replications with Four Factors

Suppose you want to determine if the order in which four drugs are given affects the response of a subject. If you have only three subjects to test, you can use the following statements to design the experiment.

```
proc plan seed=27371;
  factors Replicate=3 ordered Drug=4;
run;
```

These statements produce a design with three replicates of the four levels of the factor Drug arranged in random order. The three levels of Replicate are arranged in order, as shown in [Figure 55.1](#)

The PLAN Procedure			
Factor	Select	Levels	Order
Replicate	3	3	Ordered
Drug	4	4	Random
	Replicate	--Drug--	
	1	3 2 4 1	
	2	1 2 4 3	
	3	4 1 2 3	

Figure 55.1. Three Replications and Four Factors

You may also want to apply one of four different treatments to each cell of this plan (for example, applying different amounts of each drug). The following statements create the output shown in [Figure 55.2](#)

```
factors Replicate=3 ordered Drug=4;
  treatments Treatment=4;
run;
```

The PLAN Procedure			
Plot Factors			
Factor	Select	Levels	Order
Replicate	3	3	Ordered
Drug	4	4	Random
Treatment Factors			
Factor	Select	Levels	Order
Treatment	4	4	Random
Replicate	--Drug--	--Treatment--	
1	3 1 2 4	2 1 3 4	
2	4 3 2 1	4 1 2 3	
3	3 2 4 1	1 4 2 3	

Figure 55.2. Using the TREATMENTS Statement

Randomly Assigning Subjects to Treatments

You can use the PLAN procedure to design a completely randomized design. Suppose you have 12 experimental units, and want to assign one of two treatments to each unit. Use a DATA step to store the unrandomized design in a SAS data set, then call PROC PLAN to randomize it by specifying one RANDOM factor of 12 levels. The following statements produce [Figure 55.3](#) and [Figure 55.4](#):

```

title 'Completely Randomized Design';
/* The unrandomized design */
data a;
  do unit=1 to 12;
    if (unit <= 6) then treat=1;
    else          treat=2;
    output;
  end;
run;

/* Randomize the design */
proc plan seed=27371;
  factors unit=12;
  output data=a out=b;
run;

proc sort data=b;
  by unit;
proc print;
run;

```

Figure 55.3 shows that the 12 levels of the unit factor have been randomly reordered and then lists the new ordering.

Completely Randomized Design			
The PLAN Procedure			
Factor	Select	Levels	Order
unit	12	12	Random
-----unit-----			
8 5 1 4 6 2 12 7 3 9 10 11			

Figure 55.3. A Completely Randomized Design for Two Treatments

After the data is sorted by the unit variable, the randomized design is displayed in Figure 55.4.

Completely Randomized Design			
Obs	unit	treat	
1	1	1	
2	2	1	
3	3	2	
4	4	1	
5	5	1	
6	6	1	
7	7	2	
8	8	1	
9	9	2	
10	10	2	
11	11	2	
12	12	2	

Figure 55.4. A Completely Randomized Design for Two Treatments

You can also generate the plan by using a TREATMENTS statement instead of a DATA step. The following statements generate the same plan.

```
proc plan seed=27371;
  factors unit=12;
  treatments treat=12 cyclic (1 1 1 1 1 1 2 2 2 2 2 2);
  output out=b;
run;
```

Syntax

The following statements are available in PROC PLAN.

```
PROC PLAN < options > ;  
    FACTORS factor-selections < / NOPRINT > ;  
    OUTPUT OUT=SAS-data-set < factor-value-settings > ;  
    TREATMENTS factor-selections ;
```

To use PROC PLAN, you need to specify the PROC PLAN statement and at least one FACTORS statement before the first RUN statement. The TREATMENTS statement, OUTPUT statement, and additional FACTORS statements can appear either before the first RUN statement or after it. The rest of this section gives detailed syntax information for each of the statements, beginning with the PROC PLAN statement. The remaining statements are described in alphabetical order.

You can use PROC PLAN interactively by specifying multiple groups of statements, separated by RUN statements. For details, see the “[Using PROC PLAN Interactively](#)” section on page 3346.

PROC PLAN Statement

```
PROC PLAN < options > ;
```

The PROC PLAN statement starts the PLAN procedure and, optionally, specifies a random number seed or a default method for selecting levels of factors. By default, the procedure uses a random number seed generated from reading the time of day from the computer’s clock and randomly selects levels of factors. These defaults can be modified with the SEED= and ORDERED options, respectively. Unlike many SAS/STAT procedures, the PLAN procedure does not have a DATA= option in the PROC statement; in this procedure, both the input and output data sets are specified in the OUTPUT statement.

You can specify the following options in the PROC PLAN statement:

SEED=*number*

specifies an integer used to start the pseudo-random number generator for selecting factor levels randomly. If you don’t specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

ORDERED

selects the levels of the factor as the integers 1, 2, . . . , *m*, in order. For more detail, see the “[Selection-Types](#)” section on page 3340 and see the “[Specifying Factor Structures](#)” section on page 3348.

FACTORS Statement

FACTORS *factor-selections* < / **NOPRINT** > ;

The FACTORS statement specifies the factors of the plan and generates the plan. Taken together, the *factor-selections* specify the plan to be generated; more than one *factor-selection* request can be used in a FACTORS statement. The form of a *factor-selection* is

name=*m* < **OF** *n* > < *selection-type* >

where

<i>name</i>	is a valid SAS name. This gives the name of a factor in the design.
<i>m</i>	is a positive integer that gives the number of values to be selected. If <i>n</i> is specified, the value of <i>m</i> must be less than or equal to <i>n</i> .
<i>n</i>	is a positive integer that gives the number of values to be selected from.
<i>selection-type</i>	specifies one of five methods for selecting <i>m</i> values. Possible values are COMB, CYCLIC, ORDERED, PERM or RANDOM. The CYCLIC <i>selection-type</i> has additional optional specifications that enable you to specify an initial block of numbers to be cyclically permuted and an increment used to permute the numbers. By default, the <i>selection-type</i> is RANDOM, unless you use the ORDERED option in the PROC PLAN statement. In this case, the default <i>selection-type</i> is ORDERED. For details, see the following section, “ Selection-Types ”; for examples, see the “ Syntax Examples ” section.

The following option can appear in the FACTORS statement after the slash:

NOPRINT

suppresses the display of the plan. This is particularly useful when you require only an output data set. Note that this option temporarily disables the Output Delivery System (ODS); see [Chapter 14](#), “Using the Output Delivery System,” for more information.

Selection-Types

PROC PLAN interprets *selection-type* as follows:

RANDOM	selects the <i>m</i> levels of the factor randomly without replacement from the integers 1, 2, . . . , <i>n</i> . Or, if <i>n</i> is not specified, RANDOM selects levels by randomly ordering the integers 1, 2, . . . , <i>m</i> .
ORDERED	selects the levels of the factor as the integers 1, 2, . . . , <i>m</i> , in that order.
PERM	selects the <i>m</i> levels of the factor as a permutation of the integers 1, . . . , <i>m</i> according to an algorithm that cycles through all <i>m</i> ! permutations. The permutations are produced in a sorted standard order; see Example 55.6 on page 3358.

COMB selects the m levels of the factor as a combination of the integers $1, \dots, n$ taken m at a time, according to an algorithm that cycles through all $n!/(m!(n-m)!)$ combinations. The combinations are produced in a sorted standard order; see [Example 55.6](#) on page 3358.

CYCLIC $\langle(\textit{initial-block}) \rangle \langle \textit{increment} \rangle$

selects the levels of the factor by cyclically permuting the integers $1, 2, \dots, n$. Wrapping occurs at m if n is not specified, and at n if n is specified. Additional optional specifications are as follows:

With the *selection-type* CYCLIC, you can optionally specify an *initial-block* and an *increment*. The *initial-block* must be specified within parentheses, and it specifies the block of numbers to permute. The first permutation is the block you specify, the second is the block permuted by 1 (or by the *increment* you specify), and so on. By default, the *initial-block* is the integers $1, 2, \dots, m$. If you specify an *initial-block*, it must have m values. Values specified in the *initial-block* do not have to be given in increasing order.

The *increment* specifies the increment by which to permute the block of numbers. By default, the *increment* is 1.

Syntax Examples

This section gives some simple syntax examples. For more complex examples and details on how to generate various designs, see the “[Specifying Factor Structures](#)” section on page 3348. The examples in this section assume that you use the default random selection method and do not use the ORDERED option in the PROC PLAN statement.

The following specification generates a random permutation of the numbers 1, 2, 3, 4, and 5.

```
factors A=5;
```

The following specification generates a random permutation of 5 of the integers from 1 to 8, selected without replacement.

```
factors A=5 of 8;
```

Adding the ORDERED *selection-type* to the two previous specifications generates an ordered list of the integers 1 to 5. The following specification cyclically permutes the integers 1, 2, 3, and 4.

```
factors A=4 cyclic;
```

Since this simple request generates only one permutation of the numbers, the procedure generates an ordered list of the integers 1 to 4. The following specification cyclically permutes the integers 5 to 8.

```
factors A=4 of 8 cyclic (5 6 7 8);
```

In this case, since only one permutation is performed, the procedure generates an ordered list of the integers 5 to 8. The following specification produces an ordered list for A, with values 1 and 2.

```
factors A=2 ordered B=4 of 8 cyclic (5 6 7 8) 2;
```

The associated factor levels for B are 5, 6, 7, 8 for level 1 of A; and 7, 8, 1, 2 for level 2 of A.

Handling More than One Factor-Selection

For cases with more than one *factor-selection* in the same FACTORS statement, PROC PLAN constructs the design as follows:

1. PROC PLAN first generates levels for the first *factor-selection*. These levels are permutations of integers (1, 2, and so on) appropriate for the selection type chosen. If you do not specify a selection type, PROC PLAN uses the default (RANDOM); if you specify the ORDERED option in the PROC PLAN statement, the procedure uses ORDERED as the default selection type.
2. For every integer generated for the first *factor-selection*, levels are generated for the second *factor-selection*. These levels are generated according to the specifications following the second equal sign.
3. This process is repeated until levels for all *factor-selections* have been generated.

The following statements give an example of generating a design with two random factors:

```
proc plan;
  factors One=4 Two=3;
run;
```

The procedure first generates a random permutation of the integers 1 to 4 and then, for each of these, generates a random permutation of the integers 1 to 3. You can think of factor TWO as being nested within factor ONE, where the levels of factor ONE are to be randomly assigned to 4 units.

As another example, six random permutations of the numbers 1, 2, 3 can be generated by specifying

```
proc plan;
  factors a=6 ordered b=3;
run;
```

OUTPUT Statement

```
OUTPUT OUT=SAS-data-set < DATA=SAS-data-set >
      < factor-value-settings > ;
```

The OUTPUT statement applies only to the last plan generated. If you use PROC PLAN interactively, the OUTPUT statement for a given plan must be immediately preceded by the FACTORS statement (and the TREATMENTS statement, if appropriate) for the plan. See the “[Output Data Sets](#)” section on page 3346 for more information on how output data sets are constructed. You can specify the following options in the OUTPUT statement:

OUT=SAS-data-set

DATA=SAS-data-set

You can use the OUTPUT statement both to output the last plan generated and to use the last plan generated to randomize another SAS data set.

When you specify only the OUT= option in the OUTPUT statement, PROC PLAN saves the last plan generated to the specified data set. The output data set contains one variable for each factor in the plan and one observation for each cell in the plan. The value of a variable in a given observation is the level of the corresponding factor for that cell. The OUT= option is required.

When you specify both the DATA= and OUT= options in the OUTPUT statement, then PROC PLAN uses the last plan generated to randomize the input data set (DATA=), saving the results to the output data set (OUT=). The output data set has the same form as the input data set but has modified values for the variables that correspond to factors (see the “[Output Data Sets](#)” section on page 3346 for details). Values for variables not corresponding to factors are transferred without change.

factor-value-settings

specify the values input or output for the factors in the design. The form for *factor-value-settings* is different when only an OUT= data set is specified and when both OUT= and DATA= data sets are specified. Both forms are discussed in the following section.

Factor-Value-Settings with Only an OUT= Data Set

When you specify only an OUT= data set, the form for each *factor-value-setting* specification is one of the following:

```
factor-name < NVALS=list-of-n-numbers >
      < ORDERED | RANDOM >
```

or

```
factor-name < CVALS=list-of-n-strings >
      < ORDERED | RANDOM >
```

where

factor-name is a factor in the last FACTORS statement preceding the OUTPUT statement.

NVALS= lists n numeric values for the factor. By default, the procedure uses `NVALS=(1 2 3 ... n)`.

CVALS= lists n character strings for the factor. Each string can have up to 40 characters, and each string must be enclosed in quotes. **Warning:** When you use the `CVALS=` option, the variable created in the output data set has a length equal to the length of the longest string given as a value; shorter strings are padded with trailing blanks. For example, the values output for the first level of a two-level factor with the following two different specifications are not the same.

```
CVALS=('String 1' "String 2")
```

```
CVALS=('String 1' "A longer string")
```

The value output with the second specification is 'String 1' followed by seven blanks. In order to match two such values (for example, when merging two plans), you must use the `TRIM` function in the `DATA` step (refer to *SAS Language Reference: Dictionary*).

ORDERED | RANDOM specifies how values (those given with the `NVALS=` or `CVALS=` option, or the default values) are associated with the levels of a factor (the integers $1, 2, \dots, n$). The default association type is `ORDERED`, for which the first value specified is output for a factor level setting of 1, the second value specified is output for a level of 2, and so on. You can also specify an association type of `RANDOM`, for which the levels are associated with the values in a random order. Specifying `RANDOM` is useful for randomizing crossed experiments (see the “[Randomizing Designs](#)” section on page 3351).

The following statements give an example of using the `OUTPUT` statement with only an `OUT=` data set and with both the `NVALS=` and `CVALS=` specifications.

```
proc plan;
  factors a=6 ordered b=3;
  output out=design a nvals=(10 to 60 by 10)
             b cvals=('HSX' 'SB2' 'DNY');
run;
```

The `DESIGN` data set contains two variables, `a` and `b`. The values of the variable `a` are 10 when factor `a` equals 1, 20 when factor `a` equals 2, and so on. Values of the variable `b` are 'HSX' when factor `b` equals 1, 'SB2' when factor `b` equals 2, and 'DNY' when factor `b` equals 3.

Factor-Value-Settings with `OUT=` and `DATA=` Data Sets

If you specify an input data set with `DATA=`, then `PROC PLAN` assumes that each factor in the last plan generated corresponds to a variable in the input set. If the variable name is different from the name of the factor to which it corresponds, the two can be associated in the values specification by

input-variable-name = factor-name

Then, the NVALS= or CVALS= specification can be used. The values given by NVALS= or CVALS= specify the input values as well as the output values for the corresponding variable.

Since the procedure assumes that the collection of input factor values constitutes a plan position description (see the “Output Data Sets” section on page 3346), the values must correspond to integers less than or equal to m , the number of values selected for the associated factor. If any input values do not correspond, then the collection does not define a plan position, and the corresponding observation is output without changing the values of any of the factor variables.

The following statements demonstrate the use of factor-value settings. The input SAS data set **a** contains variables **Block** and **Plot**, which are renamed **Day** and **Hour**, respectively.

```
proc plan;
  factors Day=7 Hour=6;
  output data=a out=b
    Block = Day  cvals=('Mon' 'Tue' 'Wed' 'Thu'
                       'Fri' 'Sat' 'Sun'      )
    Plot  = Hour;
run;
```

For another example of using both a DATA= and OUT= data set, see the “Randomly Assigning Subjects to Treatments” section on page 3337.

TREATMENTS Statement

TREATMENTS *factor-selections* ;

The TREATMENTS statement specifies the *treatments* of the plan to generate, but it does not generate a plan. If you supply several FACTORS and TREATMENTS statements before the first RUN statement, the procedure uses only the last TREATMENTS specification and applies it to the plans generated by each of the FACTORS statements. The TREATMENTS statement has the same form as the FACTORS statement. The individual *factor-selections* also have the same form as in the FACTORS statement:

name=m < **OF** *n* > < *selection-type* >

The procedure generates each *treatment* simultaneously with the lowest (that is, the most nested) factor in the last FACTORS statement. The m value for each *treatment* must be at least as large as the m for the most-nested factor.

The following statements give an example of using both a FACTORS and a TREATMENTS statement. First the FACTORS statement sets up the rows and columns of a 3×3 square (factors **r** and **c**). Then, the TREATMENTS statement augments the square with two cyclic treatments. The resulting design is a 3×3 Graeco-Latin square, a type of design useful in main-effects factorial experiments.

```
proc plan;
  factors r=3 ordered c=3 ordered;
  treatments a=3 cyclic
            b=3 cyclic 2;
run;
```

The resulting Graeco-Latin square design is reproduced below. Notice how the values of *r* and *c* are ordered (1, 2, 3) as requested.

<i>r</i>	--c--	--a--	--b--
1	1 2 3	1 2 3	1 2 3
2	1 2 3	2 3 1	3 1 2
3	1 2 3	3 1 2	2 3 1

Details

Using PROC PLAN Interactively

After specifying a design with a **FACTORS** statement and running PROC PLAN with a **RUN** statement, you can generate additional plans and output data sets without reinvoking PROC PLAN.

In PROC PLAN, all statements can be used interactively. You can execute statements singly or in groups by following the single statement or group of statements with a **RUN** statement.

If you use PROC PLAN interactively, you can end the procedure with a **DATA** step, another PROC step, an **ENDSAS** statement, or a **QUIT** statement. The syntax of this statement is

```
quit;
```

When you use PROC PLAN interactively, additional **RUN** statements do not end the procedure but tell PROC PLAN to execute additional statements.

Output Data Sets

To understand how PROC PLAN creates output data sets, you need to look at how the procedure represents a plan. A plan is a list of values for all the factors, the values being chosen according to the factor-selection requests you specify. For example, consider the plan produced by the following statements:

```
proc plan seed=12345;
  factors a=3 b=2;
run;
```

The plan as displayed by PROC PLAN is shown in [Figure 55.5](#).

The PLAN Procedure			
Factor	Select	Levels	Order
a	3	3	Random
b	2	2	Random
	a	-b-	
	2	2 1	
	1	1 2	
	3	2 1	

Figure 55.5. A Simple Plan

The first cell of the plan has $a=2$ and $b=2$, the second $a=2$ and $b=1$, the third $a=1$ and $b=1$, and so on. If you output the plan to a data set with the OUTPUT statement, by default the output data set contains a numeric variable with that factor's name; the values of this numeric variable are the numbers of the successive levels selected for the factor in the plan. For example, the following statements produce [Figure 55.6](#).

```
proc plan seed=12345;
  factors a=3 b=2;
  output out=out;
  proc print data=out;
run;
```

Obs	a	b
1	2	2
2	2	1
3	1	1
4	1	2
5	3	2
6	3	1

Figure 55.6. Output Data Set from Simple Plan

Alternatively, you can specify the values that are output for a factor with the CVALS= or NVALS= option. Also, you can specify that the internal values be associated with the output values in a random order with the RANDOM option. See the “[OUTPUT Statement](#)” section on page 3343.

If you also specify an input data set (DATA=), each factor is associated with a variable in the DATA= data set. This occurs either implicitly by the factor and variable having the same name or explicitly as described in the specifications for the OUTPUT statement. In this case, the values of the variables corresponding to the factors are first read and then interpreted as describing the position of a cell in the plan. Then the respective values taken by the factors at that position are assigned to the variables

in the OUT= data set. For example, consider the data set defined by the following statements.

```
data in;
  input a b;
  datalines;
1 1
2 1
3 1
;
```

Suppose you specify this data set as an input data set for the OUTPUT statement.

```
proc plan seed=12345;
  factors a=3 b=2;
  output out=out data=in;
proc print data=out;
run;
```

PROC PLAN interprets the first observation as referring to the cell in the first row and column of the plan, since $a=1$ and $b=1$; likewise, the second observation is interpreted as the cell in the second row and first column, and the third observation as the cell in the third row and first column. In the output data set a and b have the values they have in the plan at these positions, as shown in [Figure 55.7](#).

Obs	a	b
1	2	2
2	1	1
3	3	2

Figure 55.7. Output Form of Input Data Set from Simple Plan

When the factors are random, this has the effect of randomizing the input data set in the same manner as the plan produced (see the “[Randomizing Designs](#)” section on page 3351 and the “[Randomly Assigning Subjects to Treatments](#)” section on page 3337).

Specifying Factor Structures

By appropriately combining features of the PLAN procedure, you can construct an extensive set of designs. The basic tools are the *factor-selections*, which are used in the FACTORS and TREATMENTS statements. [Table 55.1](#) summarizes how the procedure interprets various *factor-selections* (assuming that the ORDERED option is not specified in the PROC PLAN statement).

Table 55.1. Factor Selection Interpretation

Form of Request	Interpretation	Example	Results
<i>name=m</i>	produce a random permutation of the integers $1, 2, \dots, m$.	t=15	lists a random ordering of the numbers $1, 2, \dots, 15$.
<i>name=m</i> cyclic	cyclically permute the integers $1, 2, \dots, m$.	t=5 cyclic	selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,1; then 3,4,5,1,2; and so on.
<i>name=m</i> of <i>n</i>	choose a random sample of <i>m</i> integers (without replacement) from the set of integers $1, 2, \dots, n$.	t=5 of 15	lists a random selection of 5 numbers from 1 to 15. First, the procedure selects 5 numbers and then arranges them in random order.
<i>name=m</i> of <i>n</i> ordered	has the same effect as <i>name=m</i> ordered.	t=5 of 15 ordered	lists the integers 1 to 5 in increasing order (same as t=5 ordered).
<i>name=m</i> of <i>n</i> cyclic	permute <i>m</i> of the <i>n</i> integers.	t=5 of 30 cyclic	selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,6; then 3,4,5,6,7; and so on. The 30th iteration 30,1,2,3,4; the 31st iteration produces 1,2,3,4,5; and so on.
<i>name=m</i> perm	produce a list of all permutations of <i>m</i> integers.	t=5 perm	lists the integers 1,2,3,4,5 on the first iteration; on the second lists 1,2,3,5,4; and on the 119th iteration lists 5,4,3,1,2; and on the last (120th) lists 5,4,3,2,1.
<i>name=m</i> of <i>n</i> comb	choose combinations of <i>m</i> integers from <i>n</i> integers.	t=3 of 5 comb	lists all combinations of 5 choose 3 integers. The first iteration is 1,2,3; the second is 1,2,4; the third is 1,2,5; and so on until the last iteration 3,4,5.

Table 55.1. (continued)

Form of Request	Interpretation	Example	Results
<i>name=m</i> of <i>n</i> cyclic (<i>initial-block</i>)	permute <i>m</i> of the <i>n</i> integers, starting with the values specified in the <i>initial-block</i> .	t=4 of 30 cyclic (2 10 15 18)	selects the integers 2,10,15,18. On the next iteration, selects 3,11,16,19; then 4,12,17,20; and so on. The thirteenth iteration is 14,22,27,30; the fourteenth iteration is 15,23,28,1; and so on.
<i>name=m</i> of <i>n</i> cyclic (<i>initial-block</i>) <i>increment</i>	permute <i>m</i> of the <i>n</i> integers. Start with the values specified in the <i>initial-block</i> , then add the <i>increment</i> to each value.	t=4 of 30 cyclic (2 10 15 18) 2	selects the integers 2,10,15,18. On the next iteration, selects 4,12,17,20; then 6,14,19,22; and so on. The wrap occurs at the eighth iteration. The eighth iteration is 16,24,29,2; and so on.

In Table 55.1, in order for more than one iteration to appear in the plan, another *name=j* factor selection (with $j > 1$) must precede the example factor selection. For example, the following statements produce six of the iterations described in the last entry of Table 55.1.

```
proc plan;
  factors c=6 ordered t=4 of 30 cyclic (2 10 15 18) 2;
run;
```

The following statements create a randomized complete block design and output the design to a data set.

```
proc plan ordered;
  factors blocks=3 cell=5;
  treatments t=5 random;
  output out=rcdb;
run;
```

Table 55.2 lists other kinds of experiment designs that can be constructed by PROC PLAN, along with section and page references for them in this chapter.

Table 55.2. Experimental Design Examples

Design	Page Number
Completely randomized design	page 3337
Split-plot design	page 3352
Nested design	page 3353
Latin square design	page 3356
Generalized cyclic incomplete block design	page 3357

Randomizing Designs

In many situations, proper randomization is crucial for the validity of any conclusions to be drawn from an experiment. Randomization is used both to neutralize the effect of any unknown systematic biases that may be involved in the design as well as to provide a basis for the assumptions underlying the analysis.

You can use PROC PLAN to randomize an already-existing design: one produced by a previous call to PROC PLAN, perhaps, or a more specialized design taken from a standard reference such as Cochran and Cox (1957). The method is to specify the appropriate block structure in the FACTORS statement and then to specify the data set where the design is stored with the DATA= option in the OUTPUT statement. For an illustration of this method, see the “[Randomly Assigning Subjects to Treatments](#)” section on page 3337).

Two sorts of randomization are provided for, corresponding to the RANDOM factor selection and association types in the FACTORS and OUTPUT statements, respectively. Designs in which factors are completely nested (for example, block designs) should be randomized by specifying that the selection type of each factor is RANDOM in the FACTORS statement, which is the default (see [Example 55.3](#) on page 3354). On the other hand, if the factors are crossed (for example, row-and-column designs), they should be randomized by one random reassignment of their values for the whole design. To do this, specify that the association type of each factor is RANDOM in the OUTPUT statement (see [Example 55.4](#) on page 3356).

Displayed Output

The PLAN procedure displays

- the m value for each factor, which is the number of values to be selected
- the n value for each factor, which is the number of values to be selected from
- the selection type for each factor, as specified in the FACTORS statement
- the initial block and increment number for cyclic factors
- the factor value selections making up each plan

In addition, notes are written to the log giving the starting and ending values of the random number seed for each call to PROC PLAN.

ODS Table Names

PROC PLAN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 55.3. ODS Tables Produced by PROC PLAN

ODS Table Name	Description	Statement
FInfo	General factor information	FACTOR & no TREATMENT
PFInfo	Plot factor information	FACTOR & TREATMENT
Plan	Computed plan	default
TFInfo	Treatment factor information	FACTOR & TREATMENT

Examples

Example 55.1. A Split-Plot Design

This plan is appropriate for a split-plot design with main plots forming a randomized complete block design. In this example, there are three blocks, four main plots per block, and two subplots per main plot. First, three random permutations (one for each of the blocks) of the integers 1, 2, 3, and 4 are produced. The four integers correspond to the four levels of the main plot factor *a*; the permutation determines how the levels of *a* are assigned to the main plots within a block. For each of these twelve numbers (four numbers per block for three blocks), a random permutation of the integers 1 and 2 is produced. Each two-integer permutation determines the assignment of the two levels of the subplot factor *b* within a main plot. The following statements produce [Output 55.1.1](#):

```
title 'Split Plot Design';
proc plan seed=37277;
  factors block=3 ordered a=4 b=2;
run;
```

Output 55.1.1. A Split-Plot Design

Split Plot Design

	2	1 2
3	4	2 1
	2	2 1
	3	2 1
	1	2 1

Example 55.2. A Hierarchical Design

In this example, three plants are nested within four pots, which are nested within three houses. The FACTORS statement requests a random permutation of the numbers 1, 2, and 3 to choose **Houses** randomly. The second step requests a random permutation of the numbers 1, 2, 3, and 4 for each of those first three numbers to randomly assign **Pots** to **Houses**. Finally, the FACTORS statement requests a random permutation of 1, 2, and 3 for each of the twelve integers in the second set of permutations. This last step randomly assigns **Plants** to **Pots**. The following statements produce [Output 55.2.1](#):

```

title 'Hierarchical Design';
proc plan seed=17431;
  factors Houses=3 Pots=4 Plants=3 / noprint;
  output out=nested;
run;

proc print data=nested;
run;

```

Example 55.3. An Incomplete Block Design

Jarrett and Hall (1978) give an example of a generalized cyclic design with good efficiency characteristics. The design consists of two replicates of 52 treatments in 13 blocks of size 8. The following statements use the PLAN procedure to generate this design in an appropriately randomized form and store it in a SAS data set. Then, the TABULATE procedure is used to display the randomized plan. The following statements produce [Output 55.3.1](#) and [Output 55.3.2](#):

```

title 'Generalized Cyclic Block Design';
proc plan seed=33373;
  treatments trtmnts=8 of 52 cyclic (1 2 3 4 32 43 46 49) 4;
  factors blocks=13 plots=8;
  output out=c;
quit;

proc tabulate;
  class blocks plots;
  var trtmnts;

```

```
table blocks, plots*(trtmnts*f=8.) / rts=8;
run;
```

Output 55.3.1. A Generalized Cyclic Block Design

Example 55.4. A Latin Square Design

All of the preceding examples involve designs with completely nested block structures, for which PROC PLAN was especially designed. However, by appropriate coordination of its facilities, a much wider class of designs can be accommodated. A Latin square design is based on experimental units that have a row-and-column block structure. The following example uses the CYCLIC option for a treatment factor `trmts` to generate a simple 4×4 Latin square. Randomizing a Latin square design involves randomly permuting the row, column, and treatment values independently. In order to do this, use the RANDOM option in the OUTPUT statement of PROC PLAN. The example also uses *factor-value-settings* in the OUTPUT statement. The following statements produce [Output 55.4.1](#):

```

title 'Latin Square Design';
proc plan seed=37430;
  factors rows=4 ordered cols=4 ordered / noprint;
  treatments tmts=4 cyclic;
  output out=g
    rows cvals=('Day 1' 'Day 2' 'Day 3' 'Day 4') random
    cols cvals=('Lab 1' 'Lab 2' 'Lab 3' 'Lab 4') random
    tmts nvals=( 0      100    250    450 ) random;
quit;

proc tabulate;
  class rows cols;
  var tmts;
  table rows, cols*(tmts*f=6.) / rts=8;
run;

```

Output 55.4.1. A Randomized Latin Square Design

Latin Square Design				
	cols			
	Lab 1	Lab 2	Lab 3	Lab 4
	tmts	tmts	tmts	tmts
	Sum	Sum	Sum	Sum
rows				
Day 1	0	250	100	450
Day 2	250	450	0	100
Day 3	100	0	450	250
Day 4	450	100	250	0

Example 55.5. A Generalized Cyclic Incomplete Block Design

The following statements depict how to create an appropriately randomized generalized cyclic incomplete block design for v treatments (given by the value of t) in b blocks (given by the value of b) of size k (with values of p indexing the cells within a block) with initial block $(e_1 e_2 \cdots e_k)$ and increment number i .

```

factors b=b p=k ;
treatments t=k of v cyclic (e1 e2 ⋯ ek) i ;

```

For example, the specification

```
proc plan seed=37430;
  factors b=10 p=4;
  treatments t=4 of 30 cyclic (1 3 4 26) 2;
run;
```

generates the generalized cyclic incomplete block design given in Example 1 of Jarrett and Hall (1978), which is given by the rows and columns of the plan associated with the treatment factor *t* in [Output 55.5.1](#).

Output 55.5.1. A Generalized Cyclic Incomplete Block Design

The PLAN Procedure				
Plot Factors				
Factor	Select	Levels	Order	
b	10	10	Random	
p	4	4	Random	
Treatment Factors				
Factor	Select	Levels	Order	Initial Block / Increment
t	4	30	Cyclic	(1 3 4 26) / 2
	b	---p---	-----t-----	
	2	2 3 1 4	1 3 4 26	
	1	3 2 4 1	3 5 6 28	
	3	2 3 4 1	5 7 8 30	
	10	4 2 3 1	7 9 10 2	
	9	4 1 2 3	9 11 12 4	
	4	1 3 2 4	11 13 14 6	
	5	1 2 4 3	13 15 16 8	
	8	3 2 4 1	15 17 18 10	
	7	2 4 1 3	17 19 20 12	
	6	2 1 4 3	19 21 22 14	

Example 55.6. Permutations and Combinations

Occasionally, you may need to generate all possible permutations of n things, or all possible combinations of n things taken m at a time.

For example, suppose you are planning an experiment in cognitive psychology where you want to present four successive stimuli to each subject. You want to observe each permutation of the four stimuli. The following statements use PROC PLAN to create a data set containing all possible permutations of 4 numbers in random order.

```

title 'All Permutations of 1,2,3,4';
proc plan seed=60359;
  factors    Subject  = 24
            Order    = 4 ordered;
  treatments Stimulus = 4 perm;
  output out=Psych;
proc sort data=Psych out=Psych;
  by Subject Order;
proc tabulate formchar='          ' noseps;
  class Subject Order;
  var Stimulus;
  table Subject, Order*(Stimulus*f=8.)*sum=' ' / rts=9;
run;

```

The variable `Subject` is set at 24 levels because there are $4! = 24$ total permutations to be listed. If `Subject > 24`, the list repeats. [Output 55.6.1](#) and [Output 55.6.2](#) display the PROC PLAN output. Note that the variable `Subject` is listed in random order.

Output 55.6.1. List of Permutations

All Permutations of 1,2,3,4			
The PLAN Procedure			
Plot Factors			
Factor	Select	Levels	Order
Subject	24	24	Random
Order	4	4	Ordered
Treatment Factors			
Factor	Select	Levels	Order
Stimulus	4	4	Perm

Output 55.6.2. List of Permutations

All Permutations of 1,2,3,4		
The PLAN Procedure		
Subject	-Order-	-Stimulus-
4	1 2 3 4	1 2 3 4
15	1 2 3 4	1 2 4 3
24	1 2 3 4	1 3 2 4
1	1 2 3 4	1 3 4 2
5	1 2 3 4	1 4 2 3
17	1 2 3 4	1 4 3 2
19	1 2 3 4	2 1 3 4
14	1 2 3 4	2 1 4 3
6	1 2 3 4	2 3 1 4
23	1 2 3 4	2 3 4 1
8	1 2 3 4	2 4 1 3
2	1 2 3 4	2 4 3 1
13	1 2 3 4	3 1 2 4
16	1 2 3 4	3 1 4 2
12	1 2 3 4	3 2 1 4
18	1 2 3 4	3 2 4 1
21	1 2 3 4	3 4 1 2
9	1 2 3 4	3 4 2 1
22	1 2 3 4	4 1 2 3
10	1 2 3 4	4 1 3 2
7	1 2 3 4	4 2 1 3
11	1 2 3 4	4 2 3 1
3	1 2 3 4	4 3 1 2
20	1 2 3 4	4 3 2 1

The output data set `Psych` contains 96 observations of the 3 variables (`Subject`, `Order`, and `Stimulus`). Sorting the output data set by `Subject` and by `Order` within `Subject` results in all possible permutations of `Stimulus` in random order. PROC TABULATE displays these permutations in [Output 55.6.3](#).

Output 55.6.3. Randomized Permutations

All Permutations of 1,2,3,4				
	Order			
	1	2	3	4
	Stimulus	Stimulus	Stimulus	Stimulus
Subject				
1	1	3	4	2
2	2	4	3	1
3	4	3	1	2
4	1	2	3	4
5	1	4	2	3
6	2	3	1	4
7	4	2	1	3
8	2	4	1	3
9	3	4	2	1
10	4	1	3	2
11	4	2	3	1
12	3	2	1	4
13	3	1	2	4
14	2	1	4	3
15	1	2	4	3
16	3	1	4	2
17	1	4	3	2
18	3	2	4	1
19	2	1	3	4
20	4	3	2	1
21	3	4	1	2
22	4	1	2	3
23	2	3	4	1
24	1	3	2	4

As another example, suppose you have six alternative treatments, any four of which can occur together in a block (in no particular order). The following statements use PROC PLAN to create a data set containing all possible combinations of six numbers taken four at a time. In this case, you use ODS to create the data set.

```

title 'All Combinations of (6 Choose 4) Integers';
ods output Plan=Combinations;
proc plan;
  factors Block=15 ordered
         Treat= 4 of 6 comb;
run;
proc print data=Combinations noobs;
run;

```

The variable **Block** has 15 levels since there are a total of $6!/(4!2!) = 15$ combinations of four integers chosen from six integers. The data set formed by ODS from the displayed plan has one row for each block, with the four values of **Treat** corresponding to four different variables, as shown in [Output 55.6.4](#).

Output 55.6.4. List of Combinations

All Combinations of (6 Choose 4) Integers			
The PLAN Procedure			
Factor	Select	Levels	Order
Block	15	15	Ordered
Treat	4	6	Comb
Block	-Treat-		
1	1	2	3 4
2	1	2	3 5
3	1	2	3 6
4	1	2	4 5
5	1	2	4 6
6	1	2	5 6
7	1	3	4 5
8	1	3	4 6
9	1	3	5 6
10	1	4	5 6
11	2	3	4 5
12	2	3	4 6
13	2	3	5 6
14	2	4	5 6
15	3	4	5 6

Output 55.6.5. Combinations Data Set Created by ODS

All Combinations of (6 Choose 4) Integers				
Block	Treat1	Treat2	Treat3	Treat4
1	1	2	3	4
2	1	2	3	5
3	1	2	3	6
4	1	2	4	5
5	1	2	4	6
6	1	2	5	6

Chapter 56

The PLS Procedure

Overview

The PLS procedure fits models using any one of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in SAS/STAT procedures such as PROC GLM and PROC REG, has the single goal of minimizing sample response prediction error, seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors, under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components*, *latent vectors*, or *latent variables*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

Note that the name “partial least squares” also applies to a more general statistical method that is *not* implemented in this procedure. The partial least squares method was originally developed in the 1960s by the econometrician Herman Wold (1966) for modeling “paths” of causal relation between any number of “blocks” of variables. However, the PLS procedure fits only *predictive* partial least squares models, with one “block” of predictors and one “block” of responses. If you are interested in fitting more general path models, you should consider using the CALIS procedure.

Basic Features

The techniques implemented by the PLS procedure are

- principal components regression, which extracts factors to explain as much predictor sample variation as possible.
- reduced rank regression, which extracts factors to explain as much response variation as possible. This technique, also known as (maximum) redundancy analysis, differs from multivariate linear regression only when there are multiple responses.
- partial least squares regression, which balances the two objectives of explaining response variation and explaining predictor variation. Two different formulations for partial least squares are available: the original predictive method of Wold (1966) and the SIMPLS method of de Jong (1993).

The number of factors to extract depends on the data. Basing the model on more extracted factors improves the model fit to the observed data, but extracting too many factors can cause *over-fitting*, that is, tailoring the model too much to the current data, to the detriment of future predictions. The PLS procedure enables you to choose the number of extracted factors by *cross validation*, that is, fitting the model to part of the data, minimizing the prediction error for the unfitted part, and iterating with different portions of the data in the roles of fitted and unfitted. Various methods of cross validation are available, including one-at-a-time validation, and splitting the data into blocks. The PLS procedure also offers test set validation, where the model is fit to the entire primary input data set and the fit is evaluated over a distinct test data set.

You can use the general linear modeling approach of the GLM procedure to specify a model for your design, allowing for general polynomial effects as well as classification or ANOVA effects. You can save the model fit by the PLS procedure in a data set and apply it to new data by using the SCORE procedure.

Getting Started

Spectrometric Calibration

The example in this section illustrates basic features of the PLS procedure. The data are reported in Umetrics (1995); the original source is Lindberg, Persson, and Wold (1983). Suppose that you are researching pollution in the Baltic Sea, and you would like to use the spectra of samples of sea water to determine the amounts of three compounds present in samples from the Baltic Sea: lignin sulfonate (ls: pulp industry pollution), humic acids (ha: natural forest products), and optical whitener from detergent (dt). Spectrometric calibration is a type of problem in which partial least squares can be very effective. The predictors are the spectra emission intensities at different frequencies in sample spectrum, and the responses are the amounts of various chemicals in the sample.

For the purposes of calibrating the model, samples with known compositions are used. The calibration data consist of 16 samples of known concentrations of ls, ha, and dt, with spectra based on 27 frequencies (or, equivalently, wavelengths). The following statements create a SAS data set named **Sample** for these data.

```

;

Fitting a PLS Model

To isolate a few underlying spectral factors that provide a good predictive model, you can fit a PLS model to the 16 samples using the following SAS statements:

```
proc pls data=sample;
  model ls ha dt = v1-v27;
run;
```

By default, the PLS procedure extracts at most 15 factors. The procedure lists the amount of variation accounted for by each of these factors, both individual and cumulative; this listing is shown in [Figure 56.1](#).

The PLS Procedure					
Percent Variation Accounted for by Partial Least Squares Factors					
Number of Extracted Factors	Model Effects		Dependent Variables

Figure 56.1. PLS Variation Summary

Note that all of the variation in both the predictors and the responses is accounted for by only 15 factors; this is because there are only 16 sample observations. More importantly, almost all of the variation is accounted for with even fewer factors—one or two for the predictors and three to eight for the responses.

Selecting the Number of Factors by Cross Validation

A PLS model is not complete until you choose the number of factors. You can choose the number of factors by using cross validation, in which the data set is divided into two or more groups. You fit the model to all groups except one, then you check the capability of the model to predict responses for the group omitted. Repeating this for each group, you then can measure the overall capability of a given form of the model. The Predicted REsidual Sum of Squares (PRESS) statistic is based on the residuals generated by this process.

To select the number of extracted factors by cross validation, you specify the `CV=` option with an argument that says which cross validation method to use. For example, a common method is split-sample validation, in which the different groups are comprised of every n th observation beginning with the first, every n th observation beginning with the second, and so on. You can use the `CV=SPLIT` option to specify split-sample validation with $n = 7$ by default, as in the following SAS statements:

```
proc pls data=sample cv=split;
  model ls ha dt = v1-v27;
run;
```

The resulting output is shown in [Figure 56.2](#) and [Figure 56.3](#).

6	0.0106	99.9935	2.2808	97.7681

Figure 56.3. PLS Variation Summary for Split-Sample Validated Model

The absolute minimum PRESS is achieved with six extracted factors. Notice, however, that this is not much smaller than the PRESS for three factors. By using the CVTEST option, you can perform a statistical model comparison suggested by van der Voet (1994) to test whether this difference is significant, as shown in the following SAS statements:

```
proc pls data=sample cv=split cvtest(seed=12345);
  model ls ha dt = v1-v27;
run;
```

The model comparison test is based on a rerandomization of the data. By default, the seed for this randomization is based on the system clock, but it is specified here. The resulting output is shown in [Figure 56.4](#) and [Figure 56.5](#).

The PLS Procedure

	Current	Total	Current	Total
1	97.4607	97.4607	41.9155	41.9155
2	2.1830	99.6436	24.2435	66.1590
3	0.1781	99.8217	24.5339	90.6929

Figure 56.5. PLS Variation Summary for Tested Split-Sample Validated Model

The p -value of 0.1430 in comparing the cross-validated residuals from models with 6 and 3 factors indicates that the difference between the two models is insignificant;

therefore, the model with fewer factors is preferred. The variation summary shows that over 99% of the predictor variation and over 90% of the response variation are accounted for by the three factors.

Predicting New Observations

Now that you have chosen a three-factor PLS model for predicting pollutant concentrations based on sample spectra, suppose that you have two new samples. The following SAS statements create a data set containing the spectra for the new samples:

```
data newobs;
  input obsnam $ v1-v27 @@;
  datalines;
EM17  3933 4518 5637 6006 5721 5187 4641 4149 3789
      3579 3447 3381 3327 3234 3078 2832 2571 2274
      2040 1818 1629 1470 1350 1245 1134 1050  987
EM25  2904 2997 3255 3150 2922 2778 2700 2646 2571
      2487 2370 2250 2127 2052 1713 1419 1200  984
      795  648  525  426  351  291  240  204  162
;
```

You can apply the PLS model to these samples to estimate pollutant concentration. To do so, append the new samples to the original 16, and specify that the predicted values for all 18 be output to a data set, as shown in the following statements:

```
data all; set sample newobs;
proc pls data=all nfac=3;
  model ls ha dt = v1-v27;
  output out=pred p=p_ls p_ha p_dt;
proc print data=pred;
  where (obsnam in ('EM17','EM25'));
  var obsnam p_ls p_ha p_dt;
run;
```

The new observations are not used in calculating the PLS model, since they have no response values. Their predicted concentrations are shown in [Figure 56.6](#).

Obs	obsnam	p_ls	p_ha	p_dt
17	EM17	2.54261	0.31877	81.4174
18	EM25	-0.24716	1.37892	46.3212

Figure 56.6. Predicted Concentrations for New Observations

Syntax

The following statements are available in PROC PLS. Items within the brackets < > are optional.

```
PROC PLS < options > ;
  BY variables ;
  CLASS variables < / option > ;
  MODEL dependent-variables = effects < / options > ;
  OUTPUT OUT= SAS-data-set < options > ;
```

To analyze a data set, you must use the PROC PLS and MODEL statements. You can use the other statements as needed.

PROC PLS Statement

```
PROC PLS < options > ;
```

You use the PROC PLS statement to invoke the PLS procedure and, optionally, to indicate the analysis data and method. The following options are available.

CENSCALE

lists the centering and scaling information for each response and predictor.

CV=ONE

CV=SPLIT < (*n*) >

CV=BLOCK < (*n*) >

CV=RANDOM < (*cv-random-opts*) >

CV=TESTSET(SAS-data-set)

specifies the cross validation method to be used. By default, no cross validation is performed. The method CV=ONE requests one-at-a-time cross validation, CV=SPLIT requests that every *n*th observation be excluded, CV=BLOCK requests that *n* blocks of consecutive observations be excluded, CV=RANDOM requests that observations be excluded at random, and CV=TESTSET(SAS-data-set) specifies a test set of observations to be used for validation (formally, this is called “test set validation” rather than “cross validation”). You can, optionally, specify *n* for CV=SPLIT and CV=BLOCK; the default is *n* = 7. You can also specify the following optional *cv-random-options* in parentheses after the CV=RANDOM option:

NITER=*n* specifies the number of random subsets to exclude. The default value is 10.

NTEST=*n* specifies the number of observations in each random subset chosen for exclusion. The default value is one-tenth of the total number of observations.

SEED=*n* specifies an integer used to start the pseudo-random number generator for selecting the random test set. If you don’t specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

CVTEST < (*cvtest-options*) >

specifies that van der Voet's (1994) randomization-based model comparison test be performed to test models with different numbers of extracted factors against the model that minimizes the predicted residual sum of squares; see the “[Cross Validation](#)” section on page 3384 for more information. You can also specify the following *cv-test-options* in parentheses after the CVTEST option:

PVAL=*n* specifies the cut-off probability for declaring an insignificant difference. The default value is 0.10.

STAT=*test-statistic* specifies the test statistic for the model comparison. You can specify either T2, for Hotelling's T^2 statistic, or PRESS, for the predicted residual sum of squares. The default value is T2.

NSAMP=*n* specifies the number of randomizations to perform. The default value is 1000.

SEED=*n* specifies the seed value for randomization generation (the clock time is used by default).

DATA=SAS-*data-set*

names the SAS data set to be used by PROC PLS. The default is the most recently created data set.

DETAILS

lists the details of the fitted model for each successive factor. The details listed are different for different extraction methods: see the “[Displayed Output](#)” section on page 3387 for more information.

METHOD=PLS < (*PLS-options*) >**METHOD=SIMPLS****METHOD=PCR****METHOD=RRR**

specifies the general factor extraction method to be used. The value PLS requests partial least squares, SIMPLS requests the SIMPLS method of de Jong (1993), PCR requests principal components regression, and RRR requests reduced rank regression. The default is METHOD=PLS. You can also specify the following optional *PLS-options* in parentheses after METHOD=PLS:

ALGORITHM=NIPALS | SVD | EIG | RLGW names the specific algorithm used to compute extracted PLS factors. NIPALS requests the usual iterative NIPALS algorithm, SVD bases the extraction on the singular value decomposition of $X'Y$, EIG bases the extraction on the eigenvalue decomposition of $Y'XX'Y$, and RLGW is an iterative approach that is efficient when there are many predictors (Ränner et al. 1994). ALGORITHM=SVD is the most accurate but least efficient approach; the default is ALGORITHM=NIPALS.

MAXITER=*n* specifies the maximum number of iterations for the NIPALS and RLGW algorithms. The default value is 200.

EPSILON=*n* specifies the convergence criterion for the NIPALS and RLGW algorithms. The default value is 10^{-12} .

Experimental

MISSING=NONE

MISSING=AVG

MISSING=EM < (*EM-options*) >

specifies how observations with missing values are to be handled in computing the fit. The default is **MISSING=NONE**, for which observations with any missing variables (dependent or independent) are excluded from the analysis. **MISSING=AVG** specifies that the fit be computed by filling in missing values with the average of the nonmissing values for the corresponding variable. If you specify **MISSING=EM** then the procedure first computes the model with **MISSING=AVG**, then fills in missing values by their predicted values based on that model and computes the model again. You can also specify the following optional *EM-options* in parentheses after **MISSING=EM**:

MAXITER=*n* specifies the maximum number of iterations for the imputation/fit loop. The default value is 1. If you specify a large value of **MAXITER=** then the loop will iterate until it converges (as controlled by the **EPSILON=** option).

EPSILON=*n* specifies the convergence criterion for the imputation/fit loop. The default value for is 10^{-8} . This option is only effective if you specify a large value for the **MAXITER=** option.

NFAC=*n*

specifies the number of factors to extract. The default is $\min\{15, p, N\}$, where p is the number of predictors (the number of dependent variables for **METHOD=RRR**) and N is the number of runs (observations). This is probably more than you need for most applications. Extracting too many factors can lead to an over-fit model, one that matches the training data too well, sacrificing predictive ability. Thus, if you use the default **NFAC=** specification, you should also either use the **CV=** option to select the appropriate number of factors for the final model or consider the analysis to be preliminary and examine the results to determine the appropriate number of factors for a subsequent analysis.

NOCENTER

suppresses centering of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the “[Centering and Scaling](#)” section on page 3386 for more information.

NOCVSTDIZE

suppresses re-centering and re-scaling of the responses and predictors before each model is fit in the cross validation. See the “[Centering and Scaling](#)” section on page 3386 for more information.

NOPRINT

suppresses the normal display of results. This is useful when you want only the output statistics saved in a data set. Note that this option temporarily disables the Output Delivery System (ODS); see [Chapter 14, “Using the Output Delivery System,”](#) for more information.

NOSCALE

suppresses scaling of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the [“Centering and Scaling”](#) section on page 3386 for more information.

VARSCALE

specifies that continuous model variables should be centered and scaled prior to centering and scaling the model effects in which they are involved. The rescaling specified by the VARSCALE option may be more appropriate if the model involves cross products between model variables; however, the VARSCALE option still may not produce the model you expect. See the [“Centering and Scaling”](#) section on page 3386 for more information.

VARSS

lists, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PLS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The *variables* are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PLS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS *variables* < / *option* > ;

The CLASS statement names the classification variables to be used in the analysis. If the CLASS statement is used, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. In releases prior to Version 9, class levels were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option on the CLASS statement. In any case, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

Any variable in the model that is not listed in the CLASS statement is assumed to be continuous. Continuous variables must be numeric.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE

specifies that class levels should be determined using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.

MODEL Statement

MODEL *response-variables* = *predictor-effects* < / *options* >;

The MODEL statement names the responses and the predictors, which determine the Y and X matrices of the model, respectively. Usually you simply list the names of the predictor variables as the model effects, but you can also use the effects notation of PROC GLM to specify polynomial effects and interactions; see the “[Specification of Effects](#)” section on page 1784 in [Chapter 32, “The GLM Procedure,”](#) for further details. The MODEL statement is required. You can specify only one MODEL statement (in contrast to the REG procedure, for example, which allows several MODEL statements in the same PROC REG run).

You can specify the following options in the MODEL statement after a slash (/).

INTERCEPT

By default, the responses and predictors are centered; thus, no intercept is required in the model. You can specify the INTERCEPT option to override the default.

SOLUTION

lists the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

OUTPUT Statement

OUTPUT OUT= SAS-data-set keyword=names < . . . keyword=names >;

You use the OUTPUT statement to specify a data set to receive quantities that can be computed for every input observation, such as extracted factors and predicted values. The following *keywords* are available:

PREDICTED	predicted values for responses
YRESIDUAL	residuals for responses
XRESIDUAL	residuals for predictors
XSCORE	extracted factors (X-scores, latent vectors, latent variables, T)
YSCORE	extracted responses (Y-scores, U)
STDY	standardized (centered and scaled) responses
STDX	standardized (centered and scaled) predictors
H	approximate leverage
PRESS	approximate predicted residuals
TSQUARE	scaled sum of squares of score values
STDXSSE	sum of squares of residuals for standardized predictors
STDYSSE	sum of squares of residuals for standardized responses

Suppose that there are N_x predictors and N_y responses and that the model has N_f selected factors.

- The keywords XRESIDUAL and STDX define an output variable for each predictor, so N_x names are required after each one.
- The keywords PREDICTED, YRESIDUAL, STDY, and PRESS define an output variable for each response, so N_y names are required after each of these keywords.
- The keywords XSCORE and YSCORE specify an output variable for each selected model factor. For these keywords, you provide only one base name, and the variables corresponding to each successive factor are named by appending the factor number to the base name. For example, if $N_f = 3$ then a specification of XSCORE=T would produce the variables T1, T2, and T3.
- Finally, the keywords H, TSQUARE, STDXSSE, and STDYSSE each specify a single output variable, so only one name is required after each of these keywords.

Details

Regression Methods

All of the predictive methods implemented in PROC PLS work essentially by finding linear combinations of the predictors (factors) to use to predict the responses linearly. The methods differ only in how the factors are derived, as explained in the following sections.

Partial Least Squares

Partial least squares (PLS) works by extracting one factor at a time. Let $X = X_0$ be the centered and scaled matrix of predictors and $Y = Y_0$ the centered and scaled matrix of response values. The PLS method starts with a linear combination $\mathbf{t} = X_0\mathbf{w}$ of the predictors, where \mathbf{t} is called a *score* vector and \mathbf{w} is its associated *weight* vector. The PLS method predicts both X_0 and Y_0 by regression on \mathbf{t} :

$$\begin{aligned}\hat{X}_0 &= \mathbf{t}\mathbf{p}', \text{ where } \mathbf{p}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'X_0 \\ \hat{Y}_0 &= \mathbf{t}\mathbf{c}', \text{ where } \mathbf{c}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'Y_0\end{aligned}$$

The vectors \mathbf{p} and \mathbf{c} are called the X- and Y-*loadings*, respectively.

The specific linear combination $\mathbf{t} = X_0\mathbf{w}$ is the one that has maximum covariance $\mathbf{t}'\mathbf{u}$ with some response linear combination $\mathbf{u} = Y_0\mathbf{q}$. Another characterization is that the X- and Y-weights \mathbf{w} and \mathbf{q} are proportional to the first left and right singular vectors of the covariance matrix $X_0'Y_0$ or, equivalently, the first eigenvectors of $X_0'Y_0Y_0'X_0$ and $Y_0'X_0X_0'Y_0$, respectively.

This accounts for how the first PLS factor is extracted. The second factor is extracted in the same way by replacing X_0 and Y_0 with the X- and Y-residuals from the first factor

$$\begin{aligned}X_1 &= X_0 - \hat{X}_0 \\ Y_1 &= Y_0 - \hat{Y}_0\end{aligned}$$

These residuals are also called the *deflated* X and Y blocks. The process of extracting a score vector and deflating the data matrices is repeated for as many extracted factors as are desired.

SIMPLS

Note that each extracted PLS factor is defined in terms of different X-variables X_i . This leads to difficulties in comparing different scores, weights, and so forth. The SIMPLS method of de Jong (1993) overcomes these difficulties by computing each score $\mathbf{t}_i = X\mathbf{r}_i$ in terms of the original (centered and scaled) predictors X . The SIMPLS X-weight vectors \mathbf{r}_i are similar to the eigenvectors of $SS' = X'YY'X$,

but they satisfy a different orthogonality condition. The \mathbf{r}_1 vector is just the first eigenvector \mathbf{e}_1 (so that the first SIMPLS score is the same as the first PLS score), but whereas the second eigenvector maximizes

$$\mathbf{e}'_1 S S' \mathbf{e}_2 \text{ subject to } \mathbf{e}'_1 \mathbf{e}_2 = 0$$

the second SIMPLS weight \mathbf{r}_2 maximizes

$$\mathbf{r}'_1 S S' \mathbf{r}_2 \text{ subject to } \mathbf{r}'_1 X' X \mathbf{r}_2 = \mathbf{t}'_1 \mathbf{t}_2 = 0$$

The SIMPLS scores are identical to the PLS scores for one response but slightly different for more than one response; refer to de Jong (1993) for details. The X- and Y-loadings are defined as in PLS, but since the scores are all defined in terms of X , it is easy to compute the overall model coefficients B :

$$\begin{aligned} \hat{Y} &= \sum_i \mathbf{t}_i \mathbf{c}_i' \\ &= \sum_i X \mathbf{r}_i \mathbf{c}_i' \\ &= X B, \text{ where } B = R C' \end{aligned}$$

Principal Components Regression

Like the SIMPLS method, principal components regression (PCR) defines all the scores in terms of the original (centered and scaled) predictors X . However, unlike both the PLS and SIMPLS methods, the PCR method chooses the X-weights/X-scores without regard to the response data. The X-scores are chosen to explain as much variation in X as possible; equivalently, the X-weights for the PCR method are the eigenvectors of the predictor covariance matrix $X'X$. Again, the X- and Y-loadings are defined as in PLS; but, as in SIMPLS, it is easy to compute overall model coefficients for the original (centered and scaled) responses Y in terms of the original predictors X .

Reduced Rank Regression

As discussed in the preceding sections, partial least squares depends on selecting factors $\mathbf{t} = X\mathbf{w}$ of the predictors and $\mathbf{u} = Y\mathbf{q}$ of the responses that have maximum covariance, whereas principal components regression effectively ignores \mathbf{u} and selects \mathbf{t} to have maximum variance, subject to orthogonality constraints. In contrast, reduced rank regression selects \mathbf{u} to account for as much variation in the *predicted* responses as possible, effectively ignoring the predictors for the purposes of factor extraction. In reduced rank regression, the Y-weights \mathbf{q}_i are the eigenvectors of the covariance matrix $\hat{Y}'_{LS} \hat{Y}_{LS}$ of the responses predicted by ordinary least squares regression; the X-scores are the projections of the Y-scores $Y\mathbf{q}_i$ onto the X space.

Relationships Between Methods

When you develop a predictive model, it is important to consider not only the explanatory power of the model for current responses, but also how well sampled the predictive functions are, since this impacts how well the model can extrapolate to future observations. All of the techniques implemented in the PLS procedure work by extracting successive factors, or linear combinations of the predictors, that optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, principal components regression selects factors that explain as much predictor variation as possible, reduced rank regression selects factors that explain as much response variation as possible, and partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

To see the relationships between these methods, consider how each one extracts a single factor from the following artificial data set consisting of two predictors and one response:

```

data data;
  input x1 x2 y;
  datalines;
    3.37651  2.30716      0.75615
    0.74193 -0.88845      1.15285

Figure 56.9. Variation Explained by First Partial Least Squares Regression Factor

Notice that, while the first reduced rank regression factor explains *all* of the response variation, it accounts for only about 15% of the predictor variation. In contrast, the first principal components regression factor accounts for most of the predictor variation (93%) but only 9% of the response variation. The first partial least squares factor accounts for only slightly less predictor variation than principal components but about three times as much response variation.

Figure 56.10 illustrates how partial least squares balances the goals of explaining response and predictor variation in this case.

Figure 56.10. Depiction of First Factors for Three Different Regression Methods

The ellipse shows the general shape of the 11 observations in the predictor space, with the contours of increasing y overlaid. Also shown are the directions of the first factor for each of the three methods. Notice that, while the predictors vary most in the $x_1 = x_2$ direction, the response changes most in the orthogonal $x_1 = -x_2$ direction. This explains why the first principal component accounts for little variation in the response and why the first reduced rank regression accounts for little variation in the predictors. The direction of the first partial least squares factor represents a compromise between the other two directions.

Cross Validation

None of the regression methods implemented in the PLS procedure fit the observed data any better than ordinary least squares (OLS) regression; in fact, all of the methods approach OLS as more factors are extracted. The crucial point is that, when there are many predictors, OLS can *over-fit* the observed data; biased regression methods with fewer extracted factors can provide better predictability of *future* observations. However, as the preceding observations imply, the quality of the observed data fit cannot be used to choose the number of factors to extract; the number of extracted factors must be chosen on the basis of how well the model fits observations not involved in the modeling procedure itself.

One method of choosing the number of extracted factors is to fit the model to only part of the available data (the *training set*) and to measure how well models with different numbers of extracted factors fit the other part of the data (the *test set*). This is called *test set validation*. However, it is rare that you have enough data to make both parts large enough for pure test set validation to be useful. Alternatively, you can make several different divisions of the observed data into training set and test set. This is called *cross validation*, and there are several different types. In *one-at-a-time* cross validation, the first observation is held out as a single-element test set, with all

other observations as the training set; next, the second observation is held out, then the third, and so on. Another method is to hold out successive blocks of observations as test sets, for example, observations 1 through 7, then observations 8 through 14, and so on; this is known as *blocked* validation. A similar method is *split-sample* cross validation, in which successive groups of widely separated observations are held out as the test set, for example, observations {1, 11, 21, ...}, then observations {2, 12, 22, ...}, and so on. Finally, test sets can be selected from the observed data randomly; this is known as *random sample* cross validation.

Which validation you should use depends on your data. Test set validation is preferred when you have enough data to make a division into a sizable training set and test set that represent the predictive population well. You can specify that the number of extracted factors be selected by test set validation by using the `CV=TESTSET(data set)` option, where *data set* is the name of the data set containing the test set. If you do not have enough data for test set validation, you can use one of the cross validation techniques. The most common technique is one-at-a-time validation (which you can specify with the `CV=ONE` option or just the `CV` option), unless the observed data is serially correlated, in which case either blocked or split-sample validation may be more appropriate (`CV=BLOCK` or `CV=SPLIT`); you can specify the number of test sets in blocked or split-sample validation with a number in parentheses after the `CV=` option. Note that `CV=ONE` is the most computationally intensive of the cross validation methods, since it requires a recomputation of the PLS model for every input observation. Also, note that using random subset selection with `CV=RANDOM` may lead two different researchers to produce different PLS models on the same data (unless the same seed is used).

Whichever validation method you use, the number of factors chosen is usually the one that minimizes the predicted residual sum of squares (PRESS); this is the default choice if you specify any of the CV methods with PROC PLS. However, often models with fewer factors have PRESS statistics that are only marginally larger than the absolute minimum. To address this, van der Voet (1994) has proposed a statistical test for comparing the predicted residuals from different models; when you apply van der Voet's test, the number of factors chosen is the fewest with residuals that are insignificantly larger than the residuals of the model with minimum PRESS.

To see how van der Voet's test works, let $R_{i,jk}$ be the j th predicted residual for response k for the model with i extracted factors; the PRESS statistic is $\sum_{jk} R_{i,jk}^2$. Also, let i_{\min} be the number of factors for which PRESS is minimized. The critical value for van der Voet's test is based on the differences between squared predicted residuals

$$D_{i,jk} = R_{i,jk}^2 - R_{i_{\min},jk}^2$$

One alternative for the critical value is $C_i = \sum_{jk} D_{i,jk}$, which is just the difference between the PRESS statistics for i and i_{\min} factors; alternatively, van der Voet suggests Hotelling's T^2 statistic $C_i = \mathbf{d}'_{i,\cdot} S_i^{-1} \mathbf{d}_{i,\cdot}$, where $\mathbf{d}_{i,\cdot}$ is the sum of the vectors $\mathbf{d}_{i,j} = \{D_{i,j1}, \dots, D_{i,jN_y}\}'$ and S_i is the sum of squares and crossproducts matrix

$$S_i = \sum_j \mathbf{d}_{i,j} \mathbf{d}'_{i,j}$$

Virtually, the significance level for van der Voet's test is obtained by comparing C_i with the distribution of values that result from randomly exchanging $R_{i,jk}^2$ and $R_{i_{\min},jk}^2$. In practice, a Monte Carlo sample of such values is simulated and the significance level is approximated as the proportion of simulated critical values that are greater than C_i . If you apply van der Voet's test by specifying the CVTEST option, then, by default, the number of extracted factors chosen is the least number with an approximate significance level that is greater than 0.10.

Centering and Scaling

By default, the predictors and the responses are centered and scaled to have mean 0 and standard deviation 1. Centering the predictors and the responses ensures that the criterion for choosing successive factors is based on how much *variation* they explain, in either the predictors or the responses or both. (See the “Regression Methods” section on page 3380 for more details on how different methods explain variation.) Without centering, both the mean variable value and the variation around that mean are involved in selecting factors. Scaling serves to place all predictors and responses on an equal footing relative to their variation in the data. For example, if Time and Temp are two of the predictors, then scaling says that a change of $\text{std}(\text{Time})$ in Time is roughly equivalent to a change of $\text{std}(\text{Temp})$ in Temp.

Usually, both the predictors and responses should be centered and scaled. However, if their values already represent variation around a nominal or target value, then you can use the NOCENTER option in the PROC PLS statement to suppress centering. Likewise, if the predictors or responses are already all on comparable scales, then you can use the NOSCALE option to suppress scaling.

Note that, if the predictors involve crossproduct terms, then, by default, the variables are *not* standardized before standardizing the cross product. That is, if the i th values of two predictors are denoted x_i^1 and x_i^2 , then the default standardized i th value of the cross product is

$$\frac{x_i^1 x_i^2 - \text{mean}(x_j^1 x_j^2)}{\text{std}(x_j^1 x_j^2)}$$

If you want the cross product to be based instead on standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2}$$

where $m^k = \text{mean}(x_j^k)$ and $s^k = \text{std}(x_j^k)$ for $k = 1, 2$, then you should use the VARSCALE option in the PROC PLS statement. Standardizing the variables separately is usually a good idea, but unless the model also contains all cross products nested within each term, the resulting model may not be equivalent to a simple linear model in the same terms. To see this, note that a model involving the cross product of two standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2} = x_i^1 x_i^2 \frac{1}{s^1 s^2} - x_i^1 \frac{m^2}{s^1 s^2} - x_i^2 \frac{m^1}{s^1 s^2} + \frac{m^1 m^2}{s^1 s^2}$$

involves both the crossproduct term and the linear terms for the unstandardized variables.

When cross validation is performed for the number of effects, there is some disagreement among practitioners as to whether each cross validation training set should be retransformed. By default, PROC PLS does so, but you can suppress this behavior by specifying the NOCVSTDIZE option in the PROC PLS statement.

Missing Values

By default, PROC PLS handles missing values very simply. Observations with any missing independent variables (including all class variables) are excluded from the analysis, and no predictions are computed for such observations. Observations with no missing independent variables but any missing dependent variables are also excluded from the analysis, but predictions are computed.

However, the experimental MISSING= option on the PROC PLS statement provides more sophisticated ways of modeling in the presence of missing values. If you specify MISSING=AVG or MISSING=EM, then all observations in the input data set contribute to both the analysis and the OUTPUT OUT= data set. With MISSING=AVG, the fit is computed by filling in missing values with the average of the nonmissing values for the corresponding variable. With MISSING=EM, the procedure first computes the model with MISSING=AVG, then fills in missing values by their predicted values based on that model and computes the model again. Alternatively, you can specify MISSING=EM(MAXITER=*n*) with a large value of *n* in order to perform this imputation/fit loop until convergence.

Displayed Output

By default, PROC PLS displays just the amount of predictor and response variation accounted for by each factor.

If you perform a cross validation for the number of factors by specifying the CV option on the PROC PLS statement, then the procedure displays a summary of the cross validation for each number of factors, along with information about the optimal number of factors.

If you specify the DETAILS option on the PROC PLS statement, then details of the fitted model are displayed for each successive factor. These details include for each number of factors

- the predictor loadings
- the predictor weights
- the response weights
- the coded regression coefficients (for METHOD = SIMPLS, PCR, or RRR)

If you specify the CENSCALE option on the PROC PLS statement, then centering and scaling information for each response and predictor is displayed.

If you specify the VARSS option on the PROC PLS statement, the procedure displays, in addition to the average response and predictor sum of squares accounted for by

each successive factor, the amount of variation accounted for in each response and predictor.

If you specify the `SOLUTION` option on the `MODEL` statement, then PROC PLS displays the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

ODS Table Names

PROC PLS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 56.1. ODS Tables Produced in PROC PLS

ODS Table Name	Description	Statement	Option
CVResults	Results of cross validation	PROC	CV
CenScaleParms	Parameter estimates for centered and scaled data	MODEL	SOLUTION
CodedCoef	Coded coefficients	PROC	DETAILS
ParameterEstimates	Parameter estimates for raw data	MODEL	SOLUTION
PercentVariation	Variation accounted for by each factor	PROC	default
ResidualSummary	Residual summary from cross validation	PROC	CV
XEffectCenScale	Centering and scaling information for predictor effects	PROC	CENSCALE
XLoadings	Loadings for independents	PROC	DETAILS
XVariableCenScale	Centering and scaling information for predictor variables	PROC	CENSCALE and VARSCALE
XWeights	Weights for independents	PROC	DETAILS
YVariableCenScale	Centering and scaling information for responses	PROC	CENSCALE
YWeights	Weights for dependents	PROC	DETAILS

Examples

Example 56.1. Examining Model Details

The following example, from Umetrics (1995), demonstrates different ways to examine a PLS model. The data come from the field of drug discovery. New drugs are developed from chemicals that are biologically active. Testing a compound for biological activity is an expensive procedure, so it is useful to be able to predict biological activity from cheaper chemical measurements. In fact, computational chemistry makes it possible to calculate certain chemical measurements without even making the compound. These measurements include size, lipophilicity, and polarity at various sites on the molecule. The following statements create a data set named `penta`, which contains these data.

run;

```

You would like to study the relationship between these measurements and the activity of the compound, represented by the logarithm of the relative Bradykinin activating activity (\log_RAI). Notice that these data consist of many predictors relative to the

number of observations. Partial least squares is especially appropriate in this situation as a useful tool for finding a few underlying predictive factors that account for most of the variation in the response. Typically, the model is fit for part of the data (the “training” or “work” set), and the quality of the fit is judged by how well it predicts the other part of the data (the “test” or “prediction” set). For this example, the first 15 observations serve as the training set and the rest constitute the test set (refer to Ufkes et al. 1978, 1982).

When you fit a PLS model, you hope to find a few PLS factors that explain most of the variation in both predictors and responses. Factors that explain response variation provide good predictive models for new responses, and factors that explain predictor variation are well represented by the observed values of the predictors. The following statements fit a PLS model with two factors and save predicted values, residuals, and other information for each data point in a data set named `outpls`.

```
proc pls data=ptrain nfac=2;
  model log_RAI = S1-S5 L1-L5 P1-P5;
  output out=outpls predicted = yhat1
                    yresidual = yres1
                    xresidual = xres1-xres15
                    xscore    = xscr
                    yscore    = yscr;
run;
```

The PLS procedure displays a table, shown in [Output 56.1.1](#), showing how much predictor and response variation is explained by each PLS factor.

Output 56.1.1. Amount of Training Set Variation Explained

The PLS Procedure				
Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	16.9014	16.9014	89.6399	89.6399
2	12.7721	29.6735	7.8368	97.4767

From [Output 56.1.1](#), note that 97% of the response variation is already explained, but only 29% of the predictor variation is explained.

Partial least squares algorithms choose successive orthogonal factors that maximize the covariance between each X-score and the corresponding Y-score. For a good PLS model, the first few factors show a high correlation between the X- and Y-scores. The correlation usually decreases from one factor to the next. You can plot the X-scores versus the Y-scores for the first PLS factor using the following SAS statements.

```

%let ifac = 1;
data pltanno; set outpls;
  length text $ 2;
  retain function 'label' position '5' hsys '3' xsys '2' ysys '2'
    color 'blue' style 'swissb';
  text=%str(n); x=xscr&ifac; y=yscr&ifac;
axis1 label=(angle=270 rotate=90 "Y score &ifac")
  major=(number=5) minor=none;
axis2 label=("X-score &ifac") minor=none;
symbol1 v=none i=none;
proc gplot data=outpls;
  plot yscr&ifac*xscr&ifac=1
    / anno=pltanno vaxis=axis1 haxis=axis2 frame cframe=ligr;
run;

```

By changing the macro variable `ifac` to 2 instead of 1, you can use the same statements to plot the X-scores versus the Y-scores for the second PLS factor. The resulting plots are shown in [Output 56.1.2](#) and [Output 56.1.3](#). The numbers on the plot represent the observation number in the `penta` data set.

Output 56.1.2. First X- and Y-scores for Penta-Peptide Model 1

Output 56.1.3. Second X- and Y-scores for Penta-Peptide Model 1

For this example, the figures show high correlation between X- and Y-scores for the first factor but somewhat lower correlation for the second factor.

You can also plot the X-scores against each other to look for irregularities in the data. You should look for patterns or clearly grouped observations. If you see a curved pattern, for example, you may want to add a quadratic term. Two or more groupings of observations indicate that it might be better to analyze the groups separately, perhaps by including classification effects in the model. The following SAS statements produce a plot of the first and second X-scores:

```

data pltanno; set outpls;
  length text $ 2;
  retain function 'label' position '5' hsys '3' xsys '2' ysys '2'
        color 'blue' style 'swissb';
  text=%str(n); x=xscr1; y=xscr2;
axis1 label=(angle=270 rotate=90 "X score 2")
      major=(number=5) minor=none;
axis2 label=("X-score 1") minor=none;
symbol1 v=none i=none;
proc gplot data=outpls;
  plot xscr2*xscr1=1
      / anno=pltanno vaxis=axis1 haxis=axis2 frame cframe=ligr;
run;

```

The plot is shown in [Output 56.1.4](#).

Output 56.1.4. First and Second X-scores for Penta-Peptide Model 1

This plot appears to show most of the observations close together, with a few being more spread out with larger positive X-scores for factor 2. There are no clear grouping patterns, but observation 13 stands out; note that this observation is the most extreme on all three plots so far. This run may be overly influential in the PLS analysis; thus, you should check to make sure it is reliable.

Plots of the weights give the directions toward which each PLS factor projects. They show which predictors are most represented in each factor. Those predictors with small weights in absolute value are less important than those with large weights.

You can use the `DETAILS` option in the `PROC PLS` statement to display various model details, including the X-weights. You can then use the `ODS` statement to send the weights to an output data set, as follows:

```
ods output XWeights=xweights;
proc pls data=ptrain nfac=2 details;
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

Once the X-weights are in a data set, you can use the following statements to plot the weights for the first two PLS factors against one another:

```
proc transpose data=xweights(drop=NumberOfFactors InnerRegCoef)
  out =xweights;
data xweights; set xweights;
```

```

rename coll=w1 col2=w2;
data wt_anno; set xweights;
length text $ 2;
retain function 'label'
      position '5'
      hsys     '3'
      xsys     '2'
      ysys     '2'
      color    'blue'
      style    'swissb';
text=%str(_name_); x=w1; y=w2;
run;

axis1 label=(angle=270 rotate=90 "X weight 2")
      major=(number=5) minor=none;
axis2 label=("X-weight 1") minor=none;
symbol1 v=none i=none;
proc gplot data=xweights;
  plot w2*w1=1 / anno=wt_anno vaxis=axis1
        haxis=axis2 frame cframe=ligr;
run; quit;

```

The plot of the X-weights is shown in [Output 56.1.5](#).

Output 56.1.5. First and Second X-weights for Penta-Peptide Model 1

The weights plot shows a cluster of X-variables that are weighted at nearly zero for both factors. These variables add little to the model fit, and removing them may improve the model's predictive capability.

To explore further which predictors can be eliminated from the analysis, you can look at the regression coefficients for the standardized data. Predictors with small coefficients (in absolute value) make a small contribution to the response prediction. Another statistic summarizing the contribution a variable makes to the model is the *Variable Importance for Projection* (VIP) of Wold (1994). Whereas the regression coefficients represent the importance each predictor has in the prediction of just the response, the VIP represents the value of each predictor in fitting the PLS model for both predictors and response. If a predictor has a relatively small coefficient (in absolute value) *and* a small value of VIP, then it is a prime candidate for deletion. Wold in Umetrics (1995) considers a value less than 0.8 to be “small” for the VIP. The following statements produce coefficients and the VIP.

```

/*
/ Put coefficients, weights, and R**2's into data sets.
/-----*/
ods listing close;
ods output PercentVariation = pctvar
           XWeights          = xweights
           CenScaleParms     = solution;
proc pls data=ptrain nfac=2 details;
  model log_RAI = S1 L1 P1
              S2 L2 P2
              S3 L3 P3
              S4 L4 P4
              S5 L5 P5 / solution;

run;
ods listing;

/*
/ Just reformat the coefficients.
/-----*/
data solution; set solution;
  format log_RAI 8.5;
  if (RowName = 'Intercept') then delete;
  rename RowName = Predictor log_RAI = B;
run;

/*
/ Transpose weights and R**2's.
/-----*/
data xweights; set xweights; _name_='W' || trim(left(_n_));
data pctvar ; set pctvar ; _name_='R' || trim(left(_n_));
proc transpose data=xweights(drop=NumberOfFactors InnerRegCoef)
  out =xweights;
proc transpose data=pctvar(keep=_name_ CurrentYVariation)
  out =pctvar;
run;

/*
/ Sum the normalized squared weights times the
/ normalized R**2's. The VIP is defined as the square
/ root of this weighted average times the number of

```

```

/ predictors.
/-----*/
proc sql;
  create table vip as
    select *,
      w1 /sqrt(uss(w1)) as wnorm1,
      w2 /sqrt(uss(w2)) as wnorm2
    from xweights left join pctvar(drop=_name_) on 1;
data vip; set vip; keep _name_ vip;
  array wnorm{2};
  array r{2};
  VIP = 0;
  do i = 1 to 2;
    VIP = VIP + r{i}*(wnorm{i>**2)/sum(of r1-r2);
  end;
  VIP = sqrt(VIP * 15);
data vipbpls; merge solution vip(drop=_name_);
proc print data=vipbpls;
run;

```

The output appears in [Output 56.1.6](#).

Output 56.1.6. Estimated PLS Regression Coefficients and VIP (Model 1)

Obs	Predictor	B	VIP
1	S1	-0.13831	0.61108
2	L1	0.05720	0.31822
3	P1	-0.19064	0.75127
4	S2	0.12383	0.50482
5	L2	0.05909	0.27123
6	P2	0.09361	0.35927
7	S3	-0.28415	1.57775
8	L3	0.47131	2.43480
9	P3	0.26613	1.13222
10	S4	-0.09145	1.22255
11	L4	0.12265	1.17994
12	P4	-0.04878	0.88380
13	S5	0.03320	0.21288
14	L5	0.03320	0.21288
15	P5	-0.03320	0.21288

For this data set, the variables L1, L2, P2, S5, L5, and P5 have small absolute coefficients and small VIP. Looking back at the weights plot in [Output 56.1.5](#), you can see that these variables tend to be the ones near zero for both PLS factors. You should consider dropping these variables from the model.

Example 56.2. Examining Outliers

This example is a continuation of [Example 56.1](#) on page 3388.

A PLS model effectively models both the predictors and the responses. In order to check for outliers, you should, therefore, look at the Euclidean distance from each point to the PLS model in both the standardized predictors and the standardized responses. No point should be dramatically farther from the model than the rest. If there is a group of points that are all farther from the model than the rest, they may have something in common, in which case they should be analyzed separately. The following statements compute and plot these distances to the reduced model, dropping variables L1, L2, P2, P4, S5, L5, and P5:

```
proc pls data=ptrain nfac=2 noprint;
  model log_RAI = S1    P1
              S2
              S3 L3 P3
              S4 L4   ;
  output out=stdres stdxsse=stdxsse
         stdysse=stdysse;
data stdres; set stdres;
  xdist = sqrt(stdxsse);
  ydist = sqrt(stdysse);
run;

symbol1 i=needles v=dot c=blue;
proc gplot data=stdres;
  plot xdist*n=1 / cframe=ligr;
proc gplot data=stdres;
  plot ydist*n=1 / cframe=ligr;
run;
```

The plots are shown in [Output 56.2.1](#) and [Output 56.2.2](#).

Output 56.2.1. Distances from the X-variables to the Model (Training Set)

Output 56.2.2. Distances from the Y-variables to the Model (Training Set)

There appear to be no profound outliers in either the predictor space or the response space.

Example 56.3. Choosing a PLS Model by Test Set Validation

The following example demonstrates issues in spectrometric calibration. The data (Umetrics 1995) consist of spectrographic readings on 33 samples containing known concentrations of two amino acids, tyrosine and tryptophan. The spectra are measured at 30 frequencies across the overall range of frequencies. For example, [Output 56.3.1](#) shows the observed spectra for three samples, one with only tryptophan, one with only tyrosine, and one with a mixture of the two, all at a total concentration of 10^{-6} .

Output 56.3.1. Spectra for Three Samples of Tyrosine and Tryptophan

Of the 33 samples, 18 are used as a training set and 15 as a test set. The data originally appear in McAvoy et al. (1989).

These data were created in a lab, with the concentrations fixed in order to provide a wide range of applicability for the model. You want to use a linear function of the logarithms of the spectra to predict the logarithms of tyrosine and tryptophan concentration, as well as the logarithm of the total concentration. Actually, because of the possibility of zeros in both the responses and the predictors, slightly different transformations are used. The following statements create SAS data sets containing the training and test data, named `fttrain` and `fttest`, respectively:

```

data ftrain;
  input obsnam $ tot tyr f1-f30 @@;
  try = tot - tyr;
  if (tyr) then tyr_log = log10(tyr); else tyr_log = -8;
  if (try) then try_log = log10(try); else try_log = -8;
  tot_log = log10(tot);
  datalines;

The following statements fit a PLS model with 10 factors.

```

proc pls data=ftrain nfac=10;
  model tot_log tyr_log try_log = f1-f30;
run;

```

The table shown in [Output 56.3.2](#) indicates that only three or four factors are required to explain almost all of the variation in both the predictors and the responses.

Output 56.3.2. Amount of Training Set Variation Explained

The PLS Procedure				
Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	81.1654	81.1654	48.3385	48.3385
2	16.8113	97.9768	32.5465	80.8851
3	1.7639	99.7407	11.4438	92.3289
4	0.1951	99.9357	3.8363	96.1652
5	0.0276	99.9634	1.6880	97.8532
6	0.0132	99.9765	0.7247	98.5779
7	0.0052	99.9817	0.2926	98.8705
8	0.0053	99.9870	0.1252	98.9956
9	0.0049	99.9918	0.1067	99.1023
10	0.0034	99.9952	0.1684	99.2707

In order to choose the optimal number of PLS factors, you can explore how well models based on the training data with different numbers of factors fit the test data. To do so, use the `CV=TESTSET` option, with an argument pointing to the test data set `ftest`, as in the following statements:

```

proc pls data=ftrain nfac=10 cv=testset(ftest)
  cvtest(stat=press seed=12345);
  model tot_log tyr_log try_log = f1-f30;
run;

```

The results of the test set validation are shown in [Output 56.3.3](#). They indicate that, although five PLS factors give the minimum predicted residual sum of squares, the residuals for four factors are insignificantly different from those for five. Thus, the smaller model is preferred.

Output 56.3.3. Test Set Validation for the Number of PLS Factors

The PLS Procedure				
Test Set Validation for the Number of Extracted Factors				
Number of Extracted Factors	Root Mean PRESS	Prob > PRESS		
0	3.056797	<.0001		
1	2.630561	<.0001		
2	1.00706	0.0070		
3	0.664603	0.0020		
4	0.521578	0.3800

9	1.435085	0.1010		
10	1.720389	0.0320		
Minimum root mean PRESS			0.5000	
Minimizing number of factors			5	
Smallest number of factors with p > 0.1			4	
The PLS Procedure				
Percent Variation Accounted for by Partial Least Squares Factors				
Number of Extracted Factors	Model Effects		Dependent Variables	
	Current	Total	Current	Total
1	81.1654	81.1654	48.3385	48.3385
2	16.8113	97.9768	32.5465	80.8851
3	1.7639	99.7407	11.4438	92.3289
4	0.1951	99.9357	3.8363	96.1652

The factor loadings show how the PLS factors are constructed from the centered and scaled predictors. For spectral calibration, it is useful to plot the loadings against the frequency. In many cases, the physical meanings that can be attached to factor loadings help to validate the scientific interpretation of the PLS model. You can use the following statements to plot the loadings for the four PLS factors against frequency.

```
ods listing close;
ods output XLoadings=xloadings;
proc pls data=ftrain nfac=4 details method=pls;
    model tot_log tyr_log try_log = f1-f30;
run;
ods listing;
proc transpose data=xloadings(drop=NumberOfFactors)
    out =xloadings;
```

```

data xloadings; set xloadings;
  n = _n_;
  rename coll=Factor1 col2=Factor2
          col3=Factor3 col4=Factor4;
run;
goptions border;
axis1 label=("Loading" ) major=(number=5) minor=none;
axis2 label=("Frequency")          minor=none;
symbol1 v=none i=join c=red      l=1;
symbol2 v=none i=join c=green    l=1 /*l= 3*/;
symbol3 v=none i=join c=blue     l=1 /*l=34*/;
symbol4 v=none i=join c=yellow  l=1 /*l=46*/;
legend1 label=none cborder=black;
proc gplot data=xloadings;
  plot (Factor1 Factor2 Factor3 Factor4)*n
    / overlay legend=legend1 vaxis=axis1
      haxis=axis2 vref=0 lvref=2 frame cframe=ligr;
run; quit;

```

The resulting plot is shown in [Output 56.3.4](#).

Output 56.3.4. Predictor Loadings Across Frequencies

Notice that all four factors handle frequencies below and above about 7 or 8 differently. For example, the first factor is very nearly a simple contrast between the averages of the two sets of frequencies, and the second factor appears to be a weighted sum of only the frequencies in the first set.

Chapter 57

The POWER Procedure

Overview

Power and sample size analysis enables you to optimize the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The POWER procedure performs prospective power and sample size analyses for a variety of goals, such as the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here *prospective* indicates that the analysis pertains to planning for a future study. This is in contrast to *retrospective* power analysis for a past study, which is not supported by the procedure.

A variety of statistical analyses are covered:

- *t* tests for means
- equivalence tests for means
- confidence intervals for means
- tests of binomial proportions
- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves

For more complex linear models, see [Chapter 34, “The GLMPOWER Procedure.”](#)

Input for PROC POWER includes the components considered in study planning:

- design
- statistical model and test
- significance level (alpha)
- surmised effects and variability
- power
- sample size

You designate one of these components by a missing value in the input, in order to identify it as the result parameter. The procedure calculates this result value over one or more scenarios of input values for all other components. Power and sample size are the most common result values, but for some analyses the result can be something else. For example, you can solve for the sample size of a single group for a two-sample t test.

In addition to tabular results, PROC POWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol and panel) to analysis parameters, and legend appearance.

The POWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures.

The following sections of this chapter describe how to use PROC POWER and discuss the underlying statistical methodology. The “Getting Started” section on page 3412 introduces PROC POWER with simple examples of power computation for a one-sample t test and sample size determination for a two-sample t test. The “Syntax” section on page 3420 describes the syntax of the procedure. The “Details” section on page 3488 summarizes the methods employed by PROC POWER and provides details on several special topics. The “Examples” section on page 3536 illustrates the use of the POWER procedure with several applications.

For more discussion and examples on the main concepts in power and sample size analysis, refer to Castelloe (2000), Castelloe and O’Brien (2001), Muller and Benignus (1992), O’Brien and Muller (1993), and Lenth (2001).

Getting Started

Computing Power for a One-Sample t Test

Suppose you want to improve the accuracy of a machine used to print logos on sports jerseys. The machine has an inherently high variability, but its horizontal alignment can be adjusted. The operator agrees to pay for a costly adjustment if you can establish a non-zero mean horizontal displacement in either direction with high confidence. You have 150 jerseys at your disposal to measure, and you want to determine your chances of a significant result (power) using a one-sample t test with a 2-sided $\alpha = 0.05$.

You decide that 8 mm is the smallest displacement worth addressing. Hence, you will assume a true mean of 8 in the power computation. Experience indicates that the standard deviation is about 40.

Use the ONESAMPLEMEANS statement in the POWER procedure to compute the power. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Specify your conjectures for the mean and standard deviation

using the MEAN= and STDDEV= options and the sample size using the NTOTAL= option. The statements required to perform this analysis are as follows:

```
proc power;
  onesamplemeans
    mean      = 8
    ntotal    = 150
    stddev    = 40
    power     = .;
run;
```

Default values for the TEST=, DIST=, ALPHA=, NULL=, and SIDES= options specify a 2-sided *t* test for a mean of 0, assuming a normal distribution with a significance level of $\alpha = 0.05$.

Figure 57.1 shows the output.

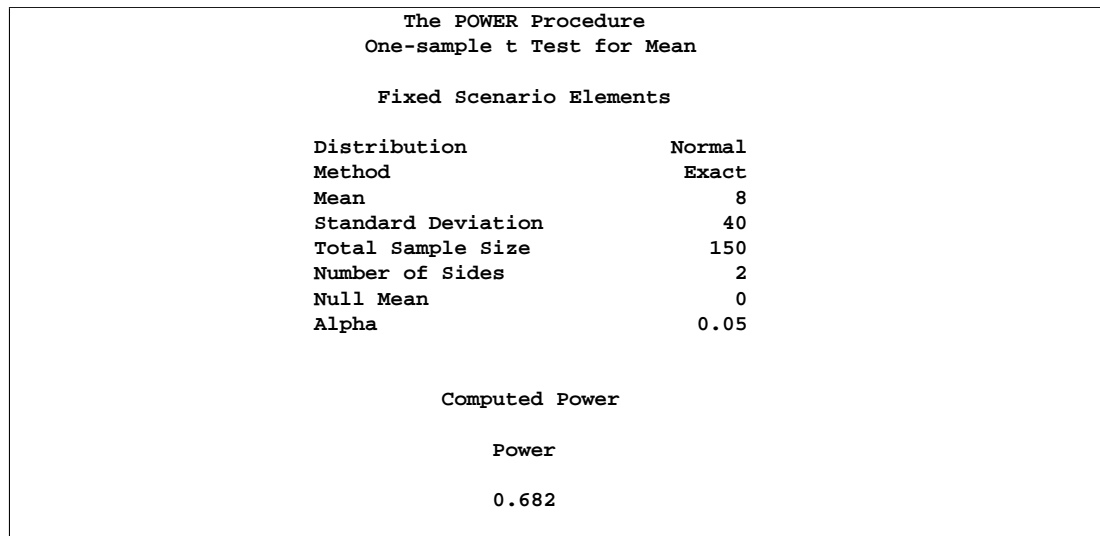

Figure 57.1. Sample Size Analysis for One-Sample *t* Test

The power is about 0.68. In other words, there is about a 2/3 chance that the *t* test will produce a significant result demonstrating the machine's average off-center displacement. This probability depends on the assumptions for the mean and standard deviation.

Now, suppose you want to account for some of your uncertainty in conjecturing the true mean and standard deviation by evaluating the power for four scenarios using reasonable low and high values, 5 and 10 for the mean, and 30 and 50 for the standard deviation. Also, you may be able to measure more than 150 jerseys, and you would like to know under what circumstances you could get by with fewer. You want to plot power for sample sizes between 100 and 200 to visualize how sensitive the power is to changes in sample size for these four scenarios of means and standard deviations. The following statements perform this analysis:

```

proc power;
  onesamplemeans
    mean    = 5 10
    ntotal  = 150
    stddev  = 30 50
    power   = .;
  plot x=n min=100 max=200;
run;

```

The new mean and standard deviation values are specified using the MEAN= and STDDEV= options in the ONESAMPLEMEANS statement. The PLOT statement with X=N produces a plot with sample size on the x-axis. (The result parameter, in this case the power, is always plotted on the other axis.) The MIN= and MAX= options in the PLOT statement determine the sample size range.

Figure 57.2 shows the output, and Figure 57.3 shows the plot.

The POWER Procedure			
One-sample t Test for Mean			
Fixed Scenario Elements			
Distribution	Normal		
Method	Exact		
Total Sample Size	150		
Number of Sides	2		
Null Mean	0		
Alpha	0.05		
Computed Power			
Index	Mean	Std Dev	Power
1	5	30	0.527
2	5	50	0.229
3	10	30	0.982
4	10	50	0.682

Figure 57.2. Sample Size Analysis for One-Sample t Test with Input Ranges

Figure 57.3. Plot of Power versus Sample Size for One-Sample t Test with Input Ranges

The power ranges from about 0.23 to 0.98 for a sample size of 150 depending on the mean and standard deviation. In Figure 57.3, the line style identifies the mean, and the plotting symbol identifies the standard deviation. The locations of plotting symbols indicate computed powers; the curves are linear interpolations of these points. The plot suggests sufficient power for a mean of 10 and standard deviation of 30 (for any of the sample sizes) but insufficient power for the other three scenarios.

Determining Required Sample Size for a Two-Sample t Test

In this example you want to compare two physical therapy treatments designed to increase muscle flexibility. You need to determine the number of patients required to achieve a power of at least 0.9 to detect a group mean difference in a two-sample t test. You will use $\alpha = 0.05$ (two-tailed).

The mean flexibility with the standard treatment (as measured on a scale of 1 to 20) is well known to be about 13 and is thought to be between 14 and 15 with the new treatment. You conjecture three alternative scenarios for the means,

1. $\mu_1 = 13, \mu_2 = 14$
2. $\mu_1 = 13, \mu_2 = 14.5$
3. $\mu_1 = 13, \mu_2 = 15$

You conjecture two scenarios for the common group standard deviation:

1. $\sigma = 1.2$
2. $\sigma = 1.7$

You also want to try three weighting schemes:

1. equal group sizes (balanced, or 1:1)
2. twice as many patients with the new treatment (1:2)
3. three times as many patients with the new treatment (1:3)

This makes $3 \times 2 \times 3 = 18$ scenarios in all.

Use the TWOSAMPLEMEANS statement in the POWER procedure to determine the sample sizes required to give 90% power for each of these 18 scenarios. Indicate total sample size as the result parameter by specifying the NTOTAL= option with a missing value (.). Specify your conjectures for the means using the GROUPMEANS= option. Using the “matched” notation (discussed in the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490), enclose the two group means for each scenario in parentheses. Use the STDDEV= option to specify scenarios for the common standard deviation. Specify the weighting schemes using the GROUPWEIGHTS= option. You could again use the matched notation. But for illustrative purposes, specify the scenarios for each group weight separately using the “crossed” notation, with scenarios for each group weight separated by a vertical bar (|). The statements that perform the analysis are as follows:

```
proc power;
  twosamplemeans
    groupmeans    = (13 14) (13 14.5) (13 15)
    stddev        = 1.2 1.7
    groupweights  = 1 | 1 2 3
    power         = 0.9
    ntotal        = .;
run;
```

Default values for the TEST=, DIST=, NULLDIFF=, ALPHA=, and SIDES= options specify a 2-sided t test of group mean difference equal to 0, assuming a normal distribution with a significance level of $\alpha = 0.05$. The results are shown in [Figure 57.4](#).

The POWER Procedure						
Two-sample <i>t</i> Test for Mean Difference

14	13	15.0	1.2	2	0.927	21
15	13	15.0	1.2	3	0.922	24
16	13	15.0	1.7	1	0.914	34
17	13	15.0	1.7	2	0.921	39
18	13	15.0	1.7	3	0.910	44

Figure 57.4. Sample Size Analysis for Two-Sample *t* Test Using Group Means

The interpretation is that in the best-case scenario (large mean difference of 2, small standard deviation of 1.2, and balanced design), a sample size of $N = 18$ ($n_1 = n_2 = 9$) patients is sufficient to achieve a power of at least 0.9. In the worst-case scenario (small mean difference of 1, large standard deviation of 1.7, and a 1:3 unbalanced design), a sample size of $N = 164$ ($n_1 = 41, n_2 = 123$) patients is necessary. The Nominal Power of 0.9 in the Fixed Scenario Elements table represents the input target power, and the Actual Power column in the Computed N Total table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting exactly.

Note the following characteristics of the analysis, and ways you can modify them if you wish.

- The total sample sizes are rounded up to multiples of the weight sums (2 for the 1:1 design, 3 for the 1:2 design, and 4 for the 1:3 design) to ensure that each group size is an integer. To request raw fractional sample size solutions, use the NFRACTIONAL option.
- Only the group weight that varies (the one for group 2) is displayed as an

output column, while the weight for group 1 appears in the Fixed Scenario Elements table. To display the group weights together in output columns, use the matched version of the value list rather than the crossed version.

- If you can only specify differences between group means (instead of their individual values), or if you want to display the mean differences instead of the individual means, use the MEANDIFF= option instead of the GROUPMEANS= option.

The following statements implement all of these modifications.

```
proc power;  
  twosamplemeans  
    nfractional  
    meandiff      = 1 to 2 by 0.5  
    stddev        = 1.2 1.7  
    groupweights  = (1 1) (1 2) (1 3)  
    power         = 0.9  
    ntotal        = .;  
run;
```

Figure 57.5 shows the new results.

17	2.0	1.7	1	2	36.195531	0.907	37
18	2.0	1.7	1	3	42.504535	0.903	43

Figure 57.5. Sample Size Analysis for Two-Sample *t* Test Using Mean Differences

Note that the Nominal Power of 0.9 applies to the raw computed sample size (Fractional N Total), and the Actual Power column applies to the rounded sample size (Ceiling N Total). Some of the adjusted sample sizes in [Figure 57.5](#) are lower than those in [Figure 57.4](#) because underlying group sample sizes are allowed to be fractional (for example, the first Ceiling N Total of 63 corresponding to equal group sizes of 31.5).

Syntax

The following statements are available in PROC POWER.

```

PROC POWER < options > ;
    MULTREG < options > ;
    ONECORR < options > ;
    ONESAMPLEFREQ < options > ;
    ONESAMPLEMEANS < options > ;
    ONEWAYANOVA < options > ;
    PAIREFREQ < options > ;
    PAIREDMEANS < options > ;
    TWOSAMPLEFREQ < options > ;
    TWOSAMPLEMEANS < options > ;
    TWOSAMPLESURVIVAL < options > ;

    PLOT < plot-options > < / graph-options > ;

```

The statements in the POWER procedure consist of the PROC POWER statement, a set of *analysis statements* (for requesting specific power and sample size analyses), and the PLOT statement (for producing graphs). The PROC POWER statement and at least one of the analysis statements are required. The analysis statements are MULTREG, ONECORR, ONESAMPLEFREQ, ONESAMPLEMEANS, ONEWAYANOVA, PAIREFREQ, PAIREDMEANS, TWOSAMPLEFREQ, TWOSAMPLEMEANS, and TWOSAMPLESURVIVAL.

You can use multiple analysis statements and multiple PLOT statements. Each analysis statement produces a separate sample size analysis. Each PLOT statement refers to the previous analysis statement and generates a separate graph (or set of graphs).

The name of an analysis statement describes the framework of the statistical analysis for which sample size calculations are desired. You use options in the analysis statements to identify the result parameter to compute, to specify the statistical test and computational options, and to provide one or more scenarios for the values of relevant analysis parameters.

[Table 57.1](#) summarizes the basic functions of each statement in PROC POWER. The syntax of each statement in [Table 57.1](#) is described in the following pages.

Table 57.1. Statements in the POWER Procedure

Statement	Description
PROC POWER	invokes the procedure
MULTREG	tests of one or more coefficients in multiple linear regression
ONECORR	Fisher's z test and t test of (partial) correlation
ONESAMPLEFREQ	tests of a single binomial proportion
ONESAMPLEMEANS	one-sample t test, confidence interval precision, or equivalence test

Table 57.1. (continued)

Statement	Description
ONEWAYANOVA	one-way ANOVA including single-degree-of-freedom contrasts
PAIREFREQ	McNemar's test for paired proportions
PAIREDMEANS	paired <i>t</i> test, confidence interval precision, or equivalence test
TWOSAMPLEFREQ	chi-square, likelihood ratio, and Fisher's exact tests for two independent proportions
TWOSAMPLEMEANS	two-sample <i>t</i> test, confidence interval precision, or equivalence test
TWOSAMPLESURVIVAL	log-rank, Gehan, and Tarone-Ware tests for comparing two survival curves
PLOT	displays plots for previous sample size analysis

See the “[Summary of Analyses](#)” section on page 3488 for a summary of the analyses available and the syntax required for them.

PROC POWER Statement

PROC POWER < *options* > ;

The PROC POWER statement invokes the POWER procedure. You can specify the following option.

PLOTONLY

specifies that only graphical results from the PLOT statement should be produced.

MULTREG Statement

MULTREG < *options* > ;

The MULTREG statement performs power and sample size analyses for Type III *F* tests of sets of predictors in multiple linear regression, assuming either fixed or normally distributed predictors.

Summary of Options

Table 57.2 summarizes categories of options available in the MULTREG statement.

Table 57.2. Summary of Options in the MULTREG Statement

Table 57.3 summarizes the valid result parameters in the MULTREG statement.

Table 57.3. Summary of Result Parameters in the MULTREG Statement

Analyses	Solve for	Syntax
TEST=TYPE3	Power	POWER = .
	Sample size	NTOTAL = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

MODEL=*keyword-list*

specifies the assumed distribution of the tested predictors. MODEL=FIXED indicates a fixed predictor distribution. MODEL=RANDOM (the default) indicates a joint multivariate normal distribution for the response and tested predictors. You may use the aliases CONDITIONAL for FIXED and UNCONDITIONAL for RANDOM. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*.

FIXED fixed predictors

RANDOM random (multivariate normal) predictors

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NFULLPREDICTORS=*number-list*

NFULLPRED=*number-list*

specifies the number of predictors in the full model, not counting the intercept. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NOINT

specifies a no-intercept model (for both full and reduced models). By default, the intercept is included in the model. If you wish to test the intercept, you can specify the NOINT option and simply consider the intercept to be one of the predictors being tested. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NREDUCEDPREDICTORS=*number-list*

NREDUCEDPRED=*number-list*

NREDPRED=*number-list*

specifies the number of predictors in the reduced model, not counting the intercept. This is the same as the difference between values of the NFULLPREDICTORS= and NTESTPREDICTORS= options. Note that supplying a value of 0 is the same as specifying an F test of a Pearson correlation. This option cannot be used at the same time as the NTESTPREDICTORS= option. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NTESTPREDICTORS=*number-list*

NTESTPRED=*number-list*

specifies the number of predictors being tested. This is the same as the difference between values of the NFULLPREDICTORS= and NREDUCEDPREDICTORS= options. Note that supplying identical values for the NTESTPREDICTORS= and NFULLPREDICTORS= options is the same as specifying an F test of a Pearson correlation. This option cannot be used at the same time as the NREDUCEDPREDICTORS= option. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). The minimum acceptable value for the sample size depends on the MODEL=, NOINT, NFULLPREDICTORS=, NTESTPREDICTORS=, and NREDUCEDPREDICTORS= options. It ranges from $p + 1$ to $p + 3$, where p is the value of the NFULLPREDICTORS option. See [Table 57.26](#) on page 3501 for further information on minimum NTOTAL values, and see the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- MODEL
- NFULLPREDICTORS
- NTESTPREDICTORS
- NREDUCEDPREDICTORS
- ALPHA
- PARTIALCORR
- RSQUAREFULL
- RSQUAREREDUCED
- RSQUAREDIFF
- NTOTAL
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the MULTREG statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the MULTREG statement.

PARTIALCORR=*number-list*

PCORR=*number-list*

specifies the partial correlation between the tested predictors and the response, adjusting for any other predictors in the model. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

RSQUAREDIFF=*number-list*

RSQDIFF=*number-list*

specifies the difference in R^2 between the full and reduced models. This is equivalent to the proportion of variation explained by the predictors you are testing. It is also equivalent to the squared semipartial correlation of the tested predictors with the response. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

RSQUAREFULL=*number-list*

RSQFULL=*number-list*

specifies the R^2 of the full model, where R^2 is the proportion of variation explained by the model. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

RSQUAREREDUCED=*number-list*

RSQREDUCED=*number-list*

RSQRED=*number-list*

specifies the R^2 of the reduced model, where R^2 is the proportion of variation explained by the model. If the reduced model is an empty or intercept-only model (in other words, if NREDUCEDPREDICTORS = 0 or NTESTPREDICTORS = NFULLPREDICTORS), then RSQUAREREDUCED = 0 is assumed. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST= TYPE3

specifies a Type III F test of a set of predictors adjusting for any other predictors in the model. This is the default test option.

Restrictions on Option Combinations

To specify the number of predictors, use any two of these three options:

- the number of predictors in the full model (NFULLPREDICTORS=)
- the number of predictors in the reduced model (NREDUCEDPREDICTORS=)
- the number of predictors being tested (NTESTPREDICTORS=)

To specify the effect, choose one of the following parameterizations:

- partial correlation (using the PARTIALCORR= option)
- R^2 for the full and reduced models (using any two of RSQUAREDIFF=, RSQUAREFULL=, and RSQUAREREDUCED=)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the MULTREG statement.

Type III F Test of a Set of Predictors

You can express effects in terms of partial correlation. Default values of the TEST=, MODEL=, and ALPHA= options specify a Type III F test with a significance level of 0.05, assuming normally distributed predictors.

```
proc power;
  multreg
    model = random
    nfullpredictors = 7
    ntestpredictors = 3
    partialcorr = 0.35
    ntotal = 100
    power = .;
run;
```

You can also express effects in terms of R^2 .

```

proc power;
  multreg
    model = fixed
    nfullpredictors = 7
    ntestpredictors = 3
    rsquarefull = 0.9
    rsquarediff = 0.1
    ntotal = .
    power = 0.9;
run;

```

ONECORR Statement

ONECORR < options > ;

The ONECORR statement performs power and sample size analyses for tests of simple and partial Pearson correlation between two variables. Both Fisher's z test and the t test are supported.

Summary of Options

Table 57.4 summarizes categories of options available in the ONECORR statement.

Table 57.4. Summary of Options in the ONECORR Statement

Task	Options
Define analysis	DIST= TEST=
Specify analysis information	ALPHA= MODEL= NPARTIALVARS= NULL= SIDES=
Specify effects	CORR=
Specify sample size	NTOTAL=
Specify power	POWER=
Control sample size rounding	NFRACTIONAL
Control ordering in output	OUTPUTORDER=

Table 57.5 summarizes the valid result parameters in the ONECORR statement.

Table 57.5. Summary of Result Parameters in the ONECORR Statement

Analyses	Solve for	Syntax
TEST=PEARSON	Power	POWER = .
	Sample size	NTOTAL = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CORR=*number-list*

specifies the correlation between two variables, possibly adjusting for other variables as determined by the NPARTIALVARS= option. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DIST=FISHERZ

DIST=T

specifies the underlying distribution assumed for the test statistic. FISHERZ corresponds to Fisher’s z normalizing transformation of the correlation coefficient. T corresponds to the t transformation of the correlation coefficient. Note that DIST=T is equivalent to analyses in the MULTREG statement with NTESTPREDICTORS=1. The default value is FISHERZ.

MODEL=*keyword-list*

specifies the assumed distribution of the first variable when DIST=T. The second variable is assumed to have a normal distribution. MODEL=FIXED indicates a fixed distribution. MODEL=RANDOM (the default) indicates a joint bivariate normal distribution with the second variable. You may use the aliases CONDITIONAL for FIXED and UNCONDITIONAL for RANDOM. This option can only be used for DIST=T. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*.

FIXED fixed variables

RANDOM random (bivariate normal) variables

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPARTIALVARS=*number-list*

NPVARS=*number-list*

specifies the number of variables adjusted for in the correlation between the two primary variables. The default value is 0, corresponding to a simple correlation. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). Values for the sample size must be at least $p + 3$ when DIST=T

and MODEL=CONDITIONAL, and at least $p + 4$ when either DIST=FISHER or when DIST=T and MODEL=UNCONDITIONAL, where p is the value of the NPARTIALVARS option. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLCORR=*number-list*

NULLC=*number-list*

specifies the null value of the correlation. The default value is 0. This option can only be used with the DIST=FISHERZ analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- MODEL
- SIDES
- NULL
- ALPHA
- NPARTIALVARS
- CORR
- NTOTAL
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONECORR statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONECORR statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST= PEARSON

specifies a test of the Pearson correlation coefficient between two variables, possibly adjusting for other variables. This is the default test option.

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONECORR statement.

Fisher's z test for Pearson Correlation

Default values of TEST=PEARSON, ALPHA=.05, SIDES=2, and NPARTIALVARS=0 are assumed.

```
proc power;
  onecorr dist=fisherz
  null = 0.15
  corr = 0.35
  ntotal = 180
  power = .
run;
```

t test for Pearson Correlation

Default values of TEST=PEARSON, MODEL=RANDOM, ALPHA=.05, and SIDES=2 are assumed.

```
proc power;
  onecorr dist=t
  npartialvars = 4
  corr = 0.45
  ntotal = .
  power = 0.85
run;
```

ONESAMPLEFREQ Statement

ONESAMPLEFREQ < options > ;

The ONESAMPLEFREQ statement performs power and sample size analyses for exact and approximate tests of a single binomial proportion.

Summary of Options

Table 57.6 summarizes categories of options available in the ONESAMPLEFREQ statement.

Table 57.6. Summary of Options in the ONESAMPLEFREQ Statement

Task	Options
Define analysis	TEST=
Specify analysis information	ALPHA= NULLPROPORTION= SIDES=
Specify effect	PROPORTION=
Specify sample size	NTOTAL=
Specify power	POWER=
Control sample size rounding	NFRACTIONAL
Choose computational method	METHOD=
Control ordering in output	OUTPUTORDER=

Table 57.7 summarizes the valid result parameters for different analyses in the ONESAMPLEFREQ statement.

Table 57.7. Summary of Result Parameters in the ONESAMPLEFREQ Statement

Analyses	Solve for	Syntax
TEST=ADJZ METHOD=EXACT	Power	POWER = .
TEST=ADJZ METHOD=NORMAL	Power	POWER = .
	Sample size	NTOTAL = .
TEST=EXACT	Power	POWER = .
TEST=Z METHOD=EXACT	Power	POWER = .
TEST=Z METHOD=NORMAL	Power	POWER = .
	Sample size	NTOTAL = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

METHOD=EXACT

METHOD=NORMAL

specifies the computational method. METHOD=EXACT (the default) computes exact results using the binomial distribution. METHOD=NORMAL computes approximate results using the normal approximation to the binomial distribution.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLPROPORTION=*number-list*

NULLP=*number-list*

specifies the null proportion. A value of 0.5 corresponds to the sign test. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLPROPORTION
- ALPHA
- PROPORTION
- NTOTAL
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONESAMPLEFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONESAMPLEFREQ statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

PROPORTION=*number-list*

P=*number-list*

specifies the binomial proportion, that is, the expected proportion of successes in the hypothetical binomial trial. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *keyword-list*. Valid keywords are

- | | |
|---|---|
| 1 | 1-sided with alternative hypothesis in same direction as effect |
| 2 | 2-sided |
| U | upper 1-sided with alternative greater than null value |
| L | lower 1-sided with alternative less than null value |

The default value is 2.

TEST= ADJZ

TEST= EXACT

TEST= Z

specifies the statistical analysis. TEST=ADJZ specifies a normal-approximate z test with continuity adjustment. TEST=EXACT (the default) specifies the exact binomial test. TEST=Z specifies a normal-approximate z test without any continuity adjustment, which is the same as the chi-square test when SIDES=2.

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONESAMPLEFREQ statement.

Exact Test of a Binomial Proportion

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
  onesamplefreq test=binomial
    nullproportion = 0.2
    proportion = 0.3
    ntotal = 100
    power = .;
run;
```

z Test

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
  onesamplefreq test=z
    nullproportion = 0.8
    proportion = 0.85
    sides = u
    ntotal = .
    power = .9;
run;
```

z Test with Continuity Adjustment

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
  onesamplefreq test=adjz
    nullproportion = 0.15
    proportion = 0.1
    sides = 1
    ntotal = .
    power = .9;
run;
```

ONESAMPLEMEANS Statement

ONESAMPLEMEANS < options > ;

The ONESAMPLEMEANS statement performs power and sample size analyses for *t* tests, equivalence tests, and confidence interval precision involving one sample.

Summary of Options

Table 57.8 summarizes categories of options available in the ONESAMPLEMEANS statement.

Table 57.8. Summary of Options in the ONESAMPLEMEANS Statement

Task	Options
Define analysis	CI= DIST= TEST=
Specify analysis information	ALPHA= LOWER= NULL= SIDES= UPPER=
Specify effects	HALFWIDTH= MEAN=
Specify variability	CV= STDDEV=
Specify sample size	NTOTAL=
Specify power and related probabilities	POWER= PROBTYPE= PROBWIDTH=
Control sample size rounding	NFRACTIONAL
Control ordering in output	OUTPUTORDER=

Table 57.9 summarizes the valid result parameters for different analyses in the ONESAMPLEMEANS statement.

Table 57.9. Summary of Result Parameters in the ONESAMPLEMEANS Statement

Analyses	Solve for	Syntax
TEST=T DIST=NORMAL	Power	POWER = .
	Sample size	NTOTAL = .
	Alpha	ALPHA = .
	Mean	MEAN = .
	Standard Deviation	STDDEV = .
TEST=T DIST=LOGNORMAL	Power	POWER = .
	Sample size	NTOTAL = .
TEST=EQUIV	Power	POWER = .
	Sample size	NTOTAL = .
CI=T	Prob(width)	PROBWIDTH = .
	Sample size	NTOTAL = .

Dictionary of Options**ALPHA=number-list**

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CI**CI= T**

specifies an analysis of precision of the confidence interval for the mean. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the **HALFWIDTH=** option. If neither the **CI=** option nor the **TEST=** option is used, the default is **TEST=T**.

CV=number-list

specifies the coefficient of variation, defined as the ratio of the standard deviation to the mean. You can use this option only with **DIST=LOGNORMAL**. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DIST=LOGNORMAL**DIST=NORMAL**

specifies the underlying distribution assumed for the test statistic. **NORMAL** corresponds to the normal distribution, and **LOGNORMAL** corresponds to the lognormal distribution. The default value is **NORMAL**.

HALFWIDTH=number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the **CI=T** analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

LOWER=number-list

specifies the lower equivalence bound for the mean. This option can only be used with the **TEST=EQUIV** analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

MEAN=number-list

specifies the mean, in the original scale. The mean is arithmetic if **DIST=NORMAL** and geometric if **DIST=LOGNORMAL**. This option can only be used with the **TEST=T** and **TEST=EQUIV** analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLMEAN= *number-list***NULLM=** *number-list*

specifies the null mean, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). The default value is 0 when DIST=NORMAL and 1 when DIST=LOGNORMAL. This option can only be used with the TEST=T analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLMEAN
- LOWER
- UPPER
- ALPHA
- MEAN
- HALFWIDTH
- STDDEV
- CV
- NTOTAL
- POWER
- PROBTTYPE
- PROBWIDTH

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONESAMPLEMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONESAMPLEMEANS statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option can only be used with the TEST=T and TEST=EQUIV analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

PROBTYPE=*keyword-list*

specifies the type of probability for the PROBWIDTH= option. A value of CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option, given that the true mean is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option. You may use the alias GIVENVALIDITY for CONDITIONAL. The PROBTYPE= option can only be used with the CI=T analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=*number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH= option. A missing value (PROBWIDTH=.) requests a solution for this probability. The type of probability is controlled with the PROBTYPE= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the CI=T analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation for the TEST= analyses are

- 1 1-sided with alternative hypothesis in same direction as effect
- 2 2-sided
- U upper 1-sided with alternative greater than null value
- L lower 1-sided with alternative less than null value

For confidence intervals, SIDES=U refers to an interval between the lower confidence limit and infinity, and SIDES=L refers to an interval between negative infinity and the upper confidence limit. For both of these cases and SIDES=1, the confidence interval computations are equivalent. The SIDES= option can only be used with the TEST=T and CI=T analyses. The default value is 2.

STDDEV=*number-list***STD=***number-list*

specifies the standard deviation. You can use this option only with DIST=NORMAL. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST**TEST=EQUIV****TEST=T**

specifies the statistical analysis. TEST=EQUIV specifies an equivalence test of the mean using a two one-sided tests (TOST) analysis (Schuirmann 1987). TEST or TEST=T (the default) specifies a *t* test on the mean. If neither the TEST= option nor the CI= option is used, the default is TEST=T.

UPPER=number-list

specifies the upper equivalence bound for the mean, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONESAMPLEMEANS statement.

One-sample t Test

Default values for the DIST=, SIDES=, NULLMEAN=, and ALPHA= options specify a 2-sided test for zero mean with a normal distribution and a significance level of 0.05.

```
proc power;
  onesamplemeans test=t
    mean = 7
    stddev = 3
    ntotal = 50
    power = .;
run;
```

One-sample t Test with Lognormal Data

Default values for the SIDES=, NULLMEAN=, and ALPHA= options specify a 2-sided test for unit mean with a significance level of 0.05.

```
proc power;
  onesamplemeans test=t dist=lognormal
    mean = 7
    cv = 0.8
    ntotal = .
    power = 0.9;
run;
```

Equivalence Test for Mean of Normal Data

Default values for the DIST= and ALPHA= options specify a normal distribution and a significance level of 0.05.

```
proc power;
  onesamplemeans test=equiv
    lower = 2
    upper = 7
    mean = 4
    stddev = 3
    ntotal = 100
    power = .;
run;
```

Equivalence Test for Mean of Lognormal Data

The default of ALPHA=0.05 specifies a significance level of 0.05.

```
proc power;
  onesamplemeans test=equiv dist=lognormal
    lower = 1
    upper = 5
    mean = 3
    cv = 0.6
    ntotal = .
    power = 0.85;
run;
```

Confidence Interval for Mean

By default CI=T analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean. The defaults of SIDES=2 and ALPHA=0.05 specify a 2-sided interval with a confidence level of 0.95.

```
proc power;
  onesamplemeans ci = t
    halfwidth = 14
    stddev = 8
    ntotal = 50
    probwidth = .;
run;
```

ONEWAYANOVA Statement

ONEWAYANOVA < options > ;

The ONEWAYANOVA statement performs power and sample size analyses for one-degree-of-freedom contrasts and the overall F test in one-way analysis of variance.

Summary of Options

Table 57.10 summarizes categories of options available in the ONEWAYANOVA statement.

Table 57.10. Summary of Options in the ONEWAYANOVA Statement

Task	Options
Define analysis	TEST=
Specify analysis information	ALPHA= CONTRAST= SIDES= NULLCONTRAST=
Specify effects	GROUPMEANS=
Specify variability	STDDEV=
Specify sample size and allocation	GROUPNS= GROUPWEIGHTS= NPERGROUP= NTOTAL=
Specify power	POWER=
Control sample size rounding	NFRACTIONAL
Control ordering in output	OUTPUTORDER=

Table 57.11 summarizes the valid result parameters for different analyses in the ONEWAYANOVA statement.

Table 57.11. Summary of Result Parameters in the ONEWAYANOVA Statement

Analyses	Solve for	Syntax
TEST=CONTRAST	Power	POWER = .
	Sample size	NTOTAL = .
		NPERGROUP = .
TEST=OVERALL	Power	POWER = .
	Sample size	NTOTAL = .
		NPERGROUP = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CONTRAST= (*values*) < (... *values*) >

specifies coefficients for single-degree-of-freedom hypothesis tests. You must provide a coefficient for every mean appearing in the GROUPMEANS= option. Specify

multiple contrasts either with additional sets of coefficients or with additional CONTRAST= options. For example, you can specify two different contrasts of five means using

```
CONTRAST = (1 -1 0 0 0) (1 0 -1 0 0)
```

GROUPMEANS=*grouped-number-list*

GMEANS=*grouped-number-list*

specifies the group means. This option is used to implicitly set the number of groups. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

GROUPNS= *grouped-number-list*

GNS= *grouped-number-list*

specifies the group sample sizes. The number of groups represented must be the same as with the GROUPMEANS= option. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

GROUPWEIGHTS= *grouped-number-list*

GWEIGHTS= *grouped-number-list*

specifies the sample size allocation weights for the groups. This option controls how the total sample size is divided between the groups. Each set of values across all groups represents relative allocation weights. Additionally, if the NFRACTIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). The number of groups represented must be the same as with the GROUPMEANS= option. Values must be integers unless the NFRACTIONAL option is used. The default value is 1 for each group, amounting to a balanced design. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the [“Sample Size Adjustment Options”](#) section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPERGROUP= *number-list*

NPERG= *number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NULLCONTRAST=*number-list*

NULLC=*number-list*

specifies the null value of the contrast. The default value is 0. This option can only be used with the TEST=CONTRAST analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- CONTRAST
- SIDES
- NULLCONTRAST
- ALPHA
- GROUPMEANS
- STDDEV
- GROUPWEIGHTS
- NTOTAL
- NPERGROUP
- GROUPNS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONEWAYANOVA statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONEWAYANOVA statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*. Valid keywords are

- | | |
|---|---|
| 1 | 1-sided with alternative hypothesis in same direction as effect |
| 2 | 2-sided |
| U | upper 1-sided with alternative greater than null value |

L lower 1-sided with alternative less than null value

This option can only be used with the TEST=CONTRAST analysis. The default value is 2.

STDDEV=*number-list*

STD=*number-list*

specifies the error standard deviation. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST= CONTRAST

TEST= OVERALL

specifies the statistical analysis. TEST=CONTRAST specifies a one-degree-of-freedom test of a contrast of means. The test is the usual F test for the 2-sided case and the usual t test for the 1-sided case. TEST=OVERALL specifies the overall F test of equality of all means. The default is TEST=CONTRAST if the CONTRAST= option is used, and TEST=OVERALL otherwise.

Restrictions on Option Combinations

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONEWAYANOVA statement.

One-Degree-of-Freedom Contrast

You can use the NPERGROUP= option in a balanced design. Default values for the SIDES=, NULLCONTRAST=, and ALPHA= options specify a 2-sided test for a contrast value of 0 with a significance level of 0.05.

```
proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design with the NTOTAL= and GROUPWEIGHTS= options.

```

proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupweights = (1 2 2)
    ntotal = .
    power = 0.9;
run;

```

Another way to specify the sample sizes is with the GROUPN= option.

```

proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupns = (20 40 40)
    power = .;
run;

```

Overall F Test

The default of ALPHA=0.05 specifies a significance level of 0.05.

```

proc power;
  onewayanova test=overall
    groupmeans = 3 | 7 | 8
    stddev = 4
    npergroup = 50
    power = .;
run;

```

PAIREDFREQ Statement

PAIREDFREQ < options > ;

The PAIREDFREQ statement performs power and sample size analyses for McNemar's test for paired proportions.

Summary of Options

Table 57.12 summarizes categories of options available in the PAIREDFREQ statement.

TEST=MCNEMAR METHOD=EXACT	Power	POWER = .
TEST=MCNEMAR METHOD=MIETTINEN	Power	POWER = .
	Sample size	NPAIRS = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DISCPROPORTIONS=*grouped-number-list*

DISCPS=*grouped-number-list*

specifies the two discordant proportions, p_{10} and p_{01} . See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

DISCPROPDIFF=*number-list*

DISCPDIFF=*number-list*

specifies the difference $p_{01} - p_{10}$ between discordant proportions. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DISCPRORATIO=number-list

DISCRATIO=number-list

specifies the ratio p_{01}/p_{10} of discordant proportions. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DIST=EXACT_COND

DIST=NORMAL

specifies the underlying distribution assumed for the test statistic. EXACT_COND corresponds to the exact conditional test, based on the exact binomial distribution of the two types of discordant pairs given the total number of discordant pairs. NORMAL corresponds to the conditional test based on the normal approximation to the binomial distribution of the two types of discordant pairs given the total number of discordant pairs. The default value is EXACT_COND.

METHOD=CONNOR

METHOD=EXACT

METHOD=MIETTINEN

specifies the computational method. METHOD=EXACT (the default) uses the exact binomial distributions of the total number of discordant pairs and the two types of discordant pairs. METHOD=CONNOR uses an approximation from Connor (1987), and METHOD=MIETTINEN uses an approximation from Miettinen (1968). The CONNOR and MIETTINEN methods are valid only for DIST=NORMAL.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option. This option cannot be used with METHOD=EXACT.

NPAIRS= number-list

specifies the total number of proportion pairs (concordant and discordant) or requests a solution for the number of pairs with a missing value (NPAIRS=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLDISCPRORATIO=number-list

NULLDISCRATIO=number-list

NULLRATIO=number-list

NULLR=number-list

specifies the null value of the ratio of discordant proportions. The default value is 1. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDISCPRORATIO
- ALPHA
- DISCPROPORTIONS
- DISCPROPDIFF
- TOTALPROPDISC
- REFPROPORTION
- DISCPROPRATIO
- NPAIRS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the PAIREFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the PAIREFREQ statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

REFPROPORTION=*number-list*

REFP=*number-list*

specifies the reference discordant proportion p_{10} . See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation are

- | | |
|---|---|
| 1 | 1-sided with alternative hypothesis in same direction as effect |
| 2 | 2-sided |
| U | upper 1-sided with alternative greater than null value |
| L | lower 1-sided with alternative less than null value |

The default value is 2.

TEST=MCNEMAR

specifies the McNemar test of paired proportions. This is the default test option.

TOTALPROPDISC=*number-list*

TOTALPDISC=*number-list*

PDISC=*number-list*

specifies the sum of the two discordant proportions, $p_{10} + p_{01}$. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Restrictions on Option Combinations

To specify the proportions, choose one of the following parameterizations:

- discordant proportions (using the DISCPROPORTIONS= option)
- difference and sum of discordant proportions (using the DISCPROPORTIONDIFF= and TOTALPROPDISC= options)
- ratio of discordant proportions and reference discordant proportion (using the DISCPROPRATIO= and REFPROPORTION= options)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the PAIREFREQ statement.

McNemar Exact Conditional Test

You can express effects in terms of the individual discordant proportions. Default values for the TEST=, SIDES=, ALPHA=, and NULLDISCPROPRATIO= options specify a 2-sided McNemar test for no effect with a significance level of 0.05.

```
proc power;
  pairedfreq dist=exact_cond
    discproportions = 0.15 | 0.45
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the difference and sum of discordant proportions.

```
proc power;
  pairedfreq dist=exact_cond
    discpropdiff = 0.3
    totalpropdisc = 0.6
    npairs = .
    power = 0.9;
run;
```

You can also express effects in terms of the ratio of discordant proportions and the denominator of the ratio.

```

proc power;
  pairedfreq dist=exact_cond
    discpropratio = 3
    refproportion = 0.15
    npairs = 80
    power = .;
run;

```

McNemar Normal Approximation Test

The default value for the METHOD= option specifies an exact sample size computation. Default values for the TEST=, SIDES=, ALPHA=, and NULLDISCPRATIO= options specify a 2-sided McNemar test for no effect with a significance level of 0.05.

```

proc power;
  pairedfreq dist=normal
    discproportions = 0.15 | 0.45
    npairs = .
    power = .9;
run;

```

PAIREDMEANS Statement

PAIREDMEANS < options > ;

The PAIREDMEANS statement performs power and sample size analyses for *t* tests, equivalence tests, and confidence interval precision involving paired samples.

Summary of Options

Table 57.14 summarizes categories of options available in the PAIREDMEANS statement.

Table 57.14. Summary of Options in the PAIREDMEANS Statement

CI=DIFF	Prob(width)	PROBWIDTH = .
	Sample size	NPAIRS = .

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CI

CI=DIFF

specifies an analysis of precision of the confidence interval for the mean difference. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the observed confidence interval will be at most the value specified by the

HALFWIDTH= option. If neither the CI= option nor the TEST= option is used, the default is TEST=DIFF.

CORR=*number-list*

specifies the correlation between members of a pair. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CV=*number-list*

specifies the coefficient of variation assumed to be common to both members of a pair. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with DIST=LOGNORMAL. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DIST=LOGNORMAL

DIST=NORMAL

specifies the underlying distribution assumed for the test statistic. NORMAL corresponds the normal distribution, and LOGNORMAL corresponds to the log-normal distribution. The default value (also the only acceptable value in each case) is NORMAL for TEST=DIFF, TEST=EQUIV_DIFF, and CI=DIFF; and LOGNORMAL for TEST=RATIO and TEST=EQUIV_RATIO.

HALFWIDTH=*number-list*

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the CI=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

LOWER=*number-list*

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

MEANDIFF=*number-list*

specifies the mean difference, defined as the mean of the difference between the second and first members of a pair, $\mu_2 - \mu_1$. This option can only be used with the TEST=DIFF and TEST=EQUIV_DIFF analyses. When TEST=EQUIV_DIFF, the mean difference is interpreted as the treatment mean minus the reference mean. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

MEANRATIO=*number-list*

specifies the geometric mean ratio, defined as γ_2/γ_1 . This option can only be used with the TEST=RATIO and TEST=EQUIV_RATIO analyses. When TEST=EQUIV_RATIO, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NFRACTIONAL
NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPAIRS= *number-list*

specifies the number of pairs or requests a solution for the number of pairs with a missing value (NPAIRS=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLDIFF= *number-list*

NULLD= *number-list*

specifies the null mean difference. The default value is 0. This option can only be used with the TEST=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLRATIO= *number-list*

NULLR= *number-list*

specifies the null mean ratio. The default value is 1. This option can only be used with the TEST=RATIO analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDIFF
- NULLRATIO
- LOWER
- UPPER
- ALPHA
- PAIREFREQ
- MEANDIFF
- MEANRATIO
- HALFWIDTH
- STDDEV
- PAIREDSTDDEVS
- CV
- PAIREDCVS
- CORR
- NPAIRS

- POWER
- PROBTYP
- PROBWIDTH

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the PAIREDMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the PAIREDMEANS statement.

PAIREDCVS=*grouped-number-list*

specifies the coefficient of variation for each member of a pair. Unlike the CV= option, the PAIREDCVS= option supports different values for each member of a pair. This option can only be used with DIST=LOGNORMAL. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

PAIREDMEANS=*grouped-number-list*

PMEANS=*grouped-number-list*

specifies the two paired means, in the original scale. The means are arithmetic if DIST=NORMAL and geometric if DIST=LOGNORMAL. This option cannot be used with the CI=DIFF analysis. When TEST=EQUIV_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

PAIREDSTDDEVS=*grouped-number-list*

PAIREDSTDS=*grouped-number-list*

PSTDDEVS=*grouped-number-list*

PSTDS=*grouped-number-list*

specifies the standard deviation of each member of a pair. Unlike the STDDEV= option, the PAIREDSTDDEVS= option supports different values for each member of a pair. This option can only be used with DIST=NORMAL. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the CI=DIFF analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

PROBTYP=*keyword-list*

specifies the type of probability for the PROBWIDTH= option. A value of CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option, given that the true mean difference is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option.

You may use the alias GIVENVALIDITY for CONDITIONAL. The PROBTYP= option can only be used with the CI=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=*number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH= option. A missing value (PROBWIDTH=.) requests a solution for this probability. The type of probability is controlled with the PROBTYP= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the CI=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation for the TEST= analyses are

- 1 1-sided with alternative hypothesis in same direction as effect
- 2 2-sided
- U upper 1-sided with alternative greater than null value
- L lower 1-sided with alternative less than null value

For confidence intervals, SIDES=U refers to an interval between the lower confidence limit and infinity, and SIDES=L refers to an interval between negative infinity and the upper confidence limit. For both of these cases and SIDES=1, the confidence interval computations are equivalent. The SIDES= option cannot be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. The default value is 2.

STDDEV=*number-list*

STD=*number-list*

specifies the standard deviation assumed to be common to both members of a pair. This option can only be used with DIST=NORMAL. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST**TEST=DIFF****TEST=EQUIV_DIFF****TEST=EQUIV_RATIO****TEST=RATIO**

specifies the statistical analysis. TEST or TEST=DIFF (the default) specifies a paired t test on the mean difference. TEST=EQUIV_DIFF specifies an additive equivalence test of the mean difference using a two one-sided tests (TOST) analysis (Schuirmann 1987). TEST=EQUIV_RATIO specifies a multiplicative equivalence test of the mean ratio using a TOST analysis. TEST=RATIO specifies a paired t test on the geometric mean ratio. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

To specify the means, choose one of the following parameterizations:

- individual means (using the PAIREDMEANS= option)
- mean difference (using the MEANDIFF= option)
- mean ratio (using the MEANRATIO= option)

To specify the coefficient of variation, choose one of the following parameterizations:

- common coefficient of variation (using the CV= option)
- individual coefficients of variation (using the PAIREDCVS= option)

To specify the standard deviation, choose one of the following parameterizations:

- common standard deviation (using the STDDEV= option)
- individual standard deviations (using the PAIREDSTDDEVS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the PAIREDMEANS statement.

Paired t Test

You can express effects in terms of the mean difference and variability in terms of a correlation and common standard deviation. Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
  pairedmeans test=diff
    meandiff = 7
    corr = 0.4
    stddev = 12
    npairs = 50
    power = .;
run;
```

You can also express effects in terms of individual means and variability in terms of correlation and individual standard deviations.

```
proc power;
  pairedmeans test=diff
    pairedmeans = 8 | 15
    corr = 0.4
    pairedstddevs = (7 12)
    npairs = .
    power = 0.9;
run;
```

Paired t Test of Mean Ratio with Lognormal Data

You can express variability in terms of correlation and a common coefficient of variation. Defaults for the DIST=, SIDES=, NULLRATIO= and ALPHA= options specify a 2-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```
proc power;
  pairedmeans test=ratio
    meanratio = 7
    corr = 0.3
    cv = 1.2
    npairs = 30
    power = .;
run;
```

You can also express variability in terms of correlation and individual coefficients of variation.

```

proc power;
  pairedmeans test=ratio
    meanratio = 7
    corr = 0.3
    pairedcvs = 0.8 | 0.9
    npairs = 30
    power = .;
run;

```

Additive Equivalence Test for Mean Difference with Normal Data

Default values for the DIST= and ALPHA= options specify a normal distribution and a significance level of 0.05.

```

proc power;
  pairedmeans test=equiv_diff
    lower = 2
    upper = 5
    meandiff = 4
    corr = 0.2
    stddev = 8
    npairs = .
    power = 0.9;
run;

```

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data

Default values for the DIST= and ALPHA= options specify a lognormal distribution and a significance level of 0.05.

```

proc power;
  pairedmeans test=equiv_ratio
    lower = 3
    upper = 7
    meanratio = 5
    corr = 0.2
    cv = 1.1
    npairs = 50
    power = .;
run;

```

Confidence Interval for Mean Difference

By default CI=DIFF analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean difference. The defaults of SIDES=2 and ALPHA=0.05 specify a 2-sided interval with a confidence level of 0.95.

```
proc power;
  pairedmeans ci = diff
    halfwidth = 4
    corr = 0.35
    stddev = 8
    npairs = 30
    probwidth = .;
run;
```

TWOSAMPLEFREQ Statement

TWOSAMPLEFREQ < options > ;

The TWOSAMPLEFREQ statement performs power and sample size analyses for tests of two independent proportions. Pearson’s chi-square, Fisher’s exact, and likelihood ratio chi-square tests are supported.

Summary of Options

Table 57.16 summarizes categories of options available in the TWOSAMPLEFREQ statement.

Table 57.16. Summary of Options in the TWOSAMPLEFREQ Statement

TEST=PCHI	Power	POWER = .
	Sample size	NTOTAL = . NPERGROUP = .

Dictionary of Options

ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

GROUPPROPORTIONS=*grouped-number-list*

GPROPORTIONS=*grouped-number-list*

GROUPPS=*grouped-number-list*

GPS=*grouped-number-list*

specifies the two independent proportions, p_1 and p_2 . See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPNS= *grouped-number-list*

GNS= *grouped-number-list*

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPWEIGHTS= *grouped-number-list*

GWEIGHTS= *grouped-number-list*

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the NFRAGMENTAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the NFRAGMENTAL option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

NFRACTIONAL**NFRAC**

enables fractional input and output for sample sizes. See the [“Sample Size Adjustment Options”](#) section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPERGROUP= *number-list***NPERG=** *number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NULLODDSRATIO= *number-list***NULLOR=** *number-list*

specifies the null odds ratio. The default value is 1. This option can only be used along with the ODDSRATIO= option in the TEST=PCHI analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NULLPROPORTIONDIFF= *number-list***NULLPDIF=** *number-list*

specifies the null proportion difference. The default value is 0. This option can only be used along with the GROUPPROPORTIONS= or PROPORTIONDIFF= option in the TEST=PCHI analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

NULLRELATIVERISK= *number-list***NULLRR=** *number-list*

specifies the null relative risk. The default value is 1. This option can only be used along with the RELATIVERISK= option in the TEST=PCHI analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

ODDSRATIO= *number-list***OR=** *number-list*

specifies the odds ratio $[p_2/(1 - p_2)] / [p_1/(1 - p_1)]$. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDIFF
- NULLODDSRATIO
- NULLRELATIVERISK
- ALPHA
- GROUPPROPORTIONS
- REFPROPORTION
- PROPORTIONDIFF
- ODDSRATIO
- RELATIVERISK
- GROUPWEIGHTS
- NTOTAL
- NPERGROUP
- GROUPNS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLEFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLEFREQ statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

PROPORTIONDIFF=*number-list*

PDIFF=*number-list*

specifies the proportion difference $p_2 - p_1$. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

REFPROPORTION=*number-list*

REFP=*number-list*

specifies the reference proportion p_1 . See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

RELATIVERISK=*number-list*

RR=*number-list*

specifies the relative risk p_2/p_1 . See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

SIDES=keyword-list

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation are

- 1 1-sided with alternative hypothesis in same direction as effect
- 2 2-sided
- U upper 1-sided with alternative greater than null value
- L lower 1-sided with alternative less than null value

The default value is 2.

TEST=FISHER**TEST=LRCHI****TEST=PCHI**

specifies the statistical analysis. TEST=FISHER specifies Fisher’s exact test. TEST=LRCHI specifies the likelihood ratio chi-square test. TEST=PCHI (the default) specifies Pearson’s chi-square test.

Restrictions on Option Combinations

To specify the proportions, choose one of the following parameterizations:

- individual proportions (using the GROUPPROPORTIONS= option)
- difference between proportions and reference proportion (using the PROPORTIONDIFF and REFPROPORTION= options)
- odds ratio and reference proportion (using the ODDSRATIO= and REFPROPORTION= options)
- relative risk and reference proportion (using the RELATIVERISK= and REFPROPORTION= options)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the TWOSAMPLEFREQ statement.

Pearson Chi-square Test for Two Proportions

You can use the `NPERGROUP=` option in a balanced design and express effects in terms of the individual proportions. Default values for the `SIDES=` and `ALPHA=` options specify a 2-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=pchi
    groupproportions = (.15 .25)
    nullproportiondiff = .03
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design using the `NTOTAL=` and `GROUPWEIGHTS=` options and express effects in terms of the odds ratio. The default value of the `NULLODDSRATIO=` option specifies a test of no effect.

```
proc power;
  twosamplefreq test=pchi
    oddsratio = 2.5
    refproportion = 0.3
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;
```

You can also specify sample sizes with the `GROUPNS=` option and express effects in terms of relative risks. The default value of the `NULLRELATIVERISK=` option specifies a test of no effect.

```
proc power;
  twosamplefreq test=pchi
    relativerisk = 1.5
    refproportion = 0.2
    groupns = 40 | 60
    power = .;
run;
```

You can also express effects in terms of the proportion difference. The default value of the `NULLPROPORTIONDIFF=` option specifies a test of no effect, and the default value of the `GROUPWEIGHTS=` option specifies a balanced design.

```
proc power;
  twosamplefreq test=pchi
    proportiondiff = 0.15
    refproportion = 0.4
    ntotal = 100
    power = .;
run;
```

Fisher's Exact Conditional Test for Two Proportions

Default values for the SIDES= and ALPHA= options specify a 2-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=fisher
    groupproportions = (.35 .15)
    npergroup = 50
    power = .;
run;
```

Likelihood Ratio Chi-square Test for Two Proportions

Default values for the SIDES= and ALPHA= options specify a 2-sided test with a significance level of 0.05.

```
proc power;
  twosamplefreq test=lrchi
    oddsratio = 2
    refproportion = 0.4
    npergroup = .
    power = 0.9;
run;
```

TWOSAMPLEMEANS Statement

TWOSAMPLEMEANS < options >;

The TWOSAMPLEMEANS statement performs power and sample size analyses for pooled and unpooled *t* tests, equivalence tests, and confidence interval precision involving two independent samples.

Summary of Options

Table 57.18 summarizes categories of options available in the TWOSAMPLEMEANS statement.

Table 57.18. Summary of Options in the TWOSAMPLEMEANS Statement

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test or requests a solution for alpha with a missing value (ALPHA=.). The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CI

CI=DIFF

specifies an analysis of precision of the confidence interval for the mean difference, assuming equal variances. Instead of power, the relevant probability for this analysis is the probability that the interval half-width is at most the value specified by the HALFWIDTH= option. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

CV=number-list

specifies the coefficient of variation assumed to be common to both groups. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with DIST=LOGNORMAL. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

DIST=LOGNORMAL

DIST=NORMAL

specifies the underlying distribution assumed for the test statistic. NORMAL corresponds the normal distribution, and LOGNORMAL corresponds to the log-normal distribution. The default value (also the only acceptable value in each case) is NORMAL for TEST=DIFF, TEST=DIFF_SATT, TEST=EQUIV_DIFF, and CI=DIFF; and LOGNORMAL for TEST=RATIO and TEST=EQUIV_RATIO.

GROUPMEANS=*grouped-number-list*

GMEANS=*grouped-number-list*

specifies the two group means or requests a solution for one group mean given the other. Means are in the original scale. They are arithmetic if DIST=NORMAL and geometric if DIST=LOGNORMAL. This option cannot be used with the CI=DIFF analysis. When TEST=EQUIV_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

GROUPNS= *grouped-number-list*

GNS= *grouped-number-list*

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

GROUPSTDDEVS=*grouped-number-list*

GSTDDEVS=*grouped-number-list*

GROUPSTDS=*grouped-number-list*

GSTDS=*grouped-number-list*

specifies the standard deviation of each group. Unlike the STDDEV= option, the GROUPSTDDEVS= option supports different values for each group. It is valid only for the Satterthwaite *t* test (TEST=DIFF_SATT DIST=NORMAL). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

GROUPWEIGHTS= *grouped-number-list*

GWEIGHTS= *grouped-number-list*

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the NFRACTIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the NFRACTIONAL option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *grouped-number-list*.

HALFWIDTH=*number-list*

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the CI=DIFF analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

LOWER=*number-list*

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). Values must be greater than 0 when DIST=LOGNORMAL. This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the [“Specifying](#)

Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

MEANDIFF=*number-list*

specifies the mean difference, defined as $\mu_2 - \mu_1$, or requests a solution for the mean difference with a missing value (MEANDIFF=.). This option can only be used with the TEST=DIFF, TEST=DIFF_SATT, and TEST=EQUIV_DIFF analyses. When TEST=EQUIV_DIFF, the mean difference is interpreted as the treatment mean minus the reference mean. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

MEANRATIO=*number-list*

specifies the geometric mean ratio, defined as γ_2/γ_1 . This option can only be used with the TEST=RATIO and TEST=EQUIV_RATIO analyses. When TEST=EQUIV_RATIO, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NFRACTIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPERGROUP= *number-list*

NPERG= *number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLDIFF=*number-list*

NULLD=*number-list*

specifies the null mean difference. The default value is 0. This option can only be used with the TEST=DIFF and TEST=DIFF_SATT analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NULLRATIO=*number-list*

NULLR=*number-list*

specifies the null mean ratio. The default value is 1. This option can only be used with the TEST=RATIO analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL**OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDIFF
- NULLRATIO
- LOWER
- UPPER
- ALPHA
- GROUPMEANS
- MEANDIFF
- MEANRATIO
- HALFWIDTH
- STDDEV
- GROUPSTDDEVS
- CV
- GROUPWEIGHTS
- NTOTAL
- NPERGROUP
- GROUPNS
- POWER
- PROBTYP
- PROBWIDTH

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLEMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLEMEANS statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the CI=DIFF analysis. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

PROBTYP= *keyword-list*

specifies the type of probability for the PROBWIDTH= option. A value of

CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option, given that the true mean difference is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option. You may use the alias GIVENVALIDITY for CONDITIONAL. The PROBTYP= option can only be used with the CI=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*.

CONDITIONAL width probability conditional on interval containing the mean

UNCONDITIONAL unconditional width probability

PROBWIDTH=*number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH= option. A missing value (PROBWIDTH=.) requests a solution for this probability. The type of probability is controlled with the PROBTYP= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the CI=DIFF analysis. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation for the TEST= analyses are

- 1 1-sided with alternative hypothesis in same direction as effect
- 2 2-sided
- U upper 1-sided with alternative greater than null value
- L lower 1-sided with alternative less than null value

For confidence intervals, SIDES=U refers to an interval between the lower confidence limit and infinity, and SIDES=L refers to an interval between negative infinity and the upper confidence limit. For both of these cases and SIDES=1, the confidence interval computations are equivalent. The SIDES= option cannot be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. The default value is 2.

STDDEV=*number-list*

specifies the standard deviation assumed to be common to both groups, or requests a solution for the common standard deviation with a missing value (STDDEV=.). This option can only be used with DIST=NORMAL. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

TEST**TEST=DIFF****TEST=DIFF_SATT****TEST=EQUIV_DIFF****TEST=EQUIV_RATIO****TEST=RATIO**

specifies the statistical analysis. TEST or TEST=DIFF (the default) specifies a pooled t test on the mean difference, assuming equal variances. TEST=DIFF_SATT specifies a Satterthwaite unpooled t test on the mean difference, assuming unequal variances. TEST=EQUIV_DIFF specifies an additive equivalence test of the mean difference using a two one-sided tests (TOST) analysis (Schuirmann 1987). TEST=EQUIV_RATIO specifies a multiplicative equivalence test of the mean ratio using a TOST analysis. TEST=RATIO specifies a pooled t test on the mean ratio, assuming equal coefficients of variation. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

To specify the means, choose one of the following parameterizations:

- individual group means (using the GROUPMEANS= option)
- mean difference (using the MEANDIFF= option)
- mean ratio (using the MEANRATIO= option)

To specify standard deviations in the Satterthwaite t test (TEST=DIFF_SATT), choose one of the following parameterizations:

- common standard deviation (using the STDDEV= option)
- individual group standard deviations (using the GROUPSTDDEVS= option)

To specify the sample sizes and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the TWOSAMPLEMEANS statement.

Two-sample t Test Assuming Equal Variances

You can use the NPERGROUP= option in a balanced design and express effects in terms of the mean difference. Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
  twosamplemeans test=diff
    meandiff = 7
    stddev = 12
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design using the NTOTAL= and GROUPWEIGHTS= options and express effects in terms of individual group means.

```
proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupweights = (2 3)
    ntotal = .
    power = 0.9;
run;
```

Another way to specify the sample sizes is with the GROUPNS= option.

```
proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupns = (25 40)
    power = .;
run;
```

Two-sample Satterthwaite t Test Assuming Unequal Variances

Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
  twosamplemeans test=diff_satt
    meandiff = 3
    groupstddevs = 5 | 8
    groupweights = (1 2)
    ntotal = 60
    power = .;
run;
```

Two-sample Pooled t Test of Mean Ratio with Lognormal Data

Default values for the DIST=, SIDES=, NULLRATIO=, and ALPHA= options specify a 2-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```
proc power;
  twosamplemeans test=ratio
    meanratio = 7
    cv = 0.8
    groupns = 50 | 70
    power = .;
run;
```

Additive Equivalence Test for Mean Difference with Normal Data

A default value of GROUPWEIGHTS=(1 1) specifies a balanced design. Default values for the DIST= and ALPHA= options specify a significance level of 0.05 and an assumption of normally distributed data.

```
proc power;
  twosamplemeans test=equiv_diff
    lower = 2
    upper = 5
    meandiff = 4
    stddev = 8
    ntotal = .
    power = 0.9;
run;
```

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data

Default values for the DIST= and ALPHA= options specify a significance level of 0.05 and an assumption of lognormally distributed data.

```

proc power;
  twosamplemeans test=equiv_ratio
    lower = 3
    upper = 7
    meanratio = 5
    cv = 0.75
    npergroup = 50
    power = .;
run;

```

Confidence Interval for Mean Difference

By default CI=DIFF analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean difference. The defaults of SIDES=2 and ALPHA=0.05 specify a 2-sided interval with a confidence level of 0.95.

```

proc power;
  twosamplemeans ci = diff
    halfwidth = 4
    stddev = 8
    groupns = (30 35)
    probwidth = .;
run;

```

TWOSAMPLESURVIVAL Statement

TWOSAMPLESURVIVAL < options > ;

The TWOSAMPLESURVIVAL statement performs power and sample size analyses for comparing two survival curves. The log-rank, Gehan, and Tarone-Ware rank tests are supported.

Summary of Options

Table 57.20 summarizes categories of options available in the TWOSAMPLESURVIVAL statement.

Table 57.20. Summary of Options in the TWOSAMPLESURVIVAL Statement

TEST=TARONEWARE	Power	POWER = .
	Sample size	NTOTAL = . NPERGROUP = .

Dictionary of Options

ACCRUALTIME=*number-list*

ACCTIME=*number-list*

ACCRUALT=*number-list*

ACCT=*number-list*

specifies the accrual time. Accrual is assumed to occur uniformly from time 0 to the time specified by the ACCRUALTIME= option. If the GROUPSURVIVAL= or REFSURVIVAL= options are used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

CURVE("label")=points

defines a survival curve.

For the CURVE= option,

<i>label</i>	identifies the curve in the output and with the GROUPLOSS=, GROUPSURVIVAL=, and REFSURVIVAL= options.
<i>points</i>	specifies one or more (time, survival) pairs on the curve, where the survival value denotes the probability of surviving until at least the specified time.

A single-point curve is interpreted as exponential, and a multipoint curve is interpreted as piecewise linear. Points can be expressed in either of two forms:

- a series of time:survival pairs separated by spaces. For example,

1:0.9 2:0.7 3:0.6

- a DOLIST of times enclosed in parentheses, followed by a colon (:), followed by a DOLIST of survival values enclosed in parentheses. For example,

(1 to 3 by 1):(0.9 0.7 0.6)

The DOLIST format is the same as in the DATA step language.

Points can also be expressed as combinations of the two forms, for example,

1:0.9 2:0.8 (3 to 6 by 1):(0.7 0.65 0.6 0.55)

The points have the following restrictions:

- the time values must be nonnegative and strictly increasing
- the survival values must be strictly decreasing
- the survival value at a time of 0 must be equal to 1
- if there is only one point, then the time must be greater than 0, and the survival value cannot be 0 or 1

FOLLOWUPTIME=*number-list*

FUTIME=*number-list*

FOLLOWUPT=*number-list*

FUT=*number-list*

specifies the follow-up time, the amount of time in the study past the accrual time. If the **GROUPSURVIVAL=** or **REFSURVIVAL=** options are used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

GROUPLOSS= *grouped-name-list*

GLOSS= *grouped-name-list*

specifies the exponential loss survival curve for each group, using labels specified with the **CURVE=** option. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-name-list*.

GROUPLOSSEXPHAZARDS= *grouped-number-list*

GLOSSEXPHAZARDS= *grouped-number-list*

GROUPLOSSEXPHS= *grouped-number-list*

GLOSSEXPHS= *grouped-number-list*

specifies the exponential hazards of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. If none of the **GROUPLOSSEXPHAZARDS=**, **GROUPLOSS=**, and **GROUPMEDLOSSTIMES=** options are used, the default of **GROUPLOSSEXPHAZARDS=(0 0)** indicates no loss to follow-up. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPMEDLOSSTIMES= *grouped-number-list*

GMEDLOSSTIMES= *grouped-number-list*

GROUPMEDLOSSTS= *grouped-number-list*

GMEDLOSSTS= *grouped-number-list*

specifies the median times of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPMEDSURVTIMES= *grouped-number-list*

GMEDSURVTIMES= *grouped-number-list*

GROUPMEDSURVTS= *grouped-number-list*

GMEDSURVTS= *grouped-number-list*

specifies the median survival times in each group. When the **GROUPMEDSURVTIMES=** option is used, the survival curve in each group is assumed to be exponential. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPNS= *grouped-number-list*

GNS= *grouped-number-list*

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPSURVEXPHAZARDS= *grouped-number-list*

GSURVEXPHAZARDS= *grouped-number-list*

GROUPSURVEXPHS= *grouped-number-list*

GEXPHS= *grouped-number-list*

specifies exponential hazard rates of the survival curve for each group. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

GROUPSURVIVAL= *grouped-name-list*

GSURVIVAL= *grouped-name-list*

GROUPSURV= *grouped-name-list*

GSURV= *grouped-name-list*

specifies the survival curve for each group, using labels specified with the CURVE= option. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-name-list*.

GROUPWEIGHTS= *grouped-number-list*

GWEIGHTS= *grouped-number-list*

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the NFRATIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the NFRATIONAL option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *grouped-number-list*.

HAZARDRATIO= *number-list*

HR= *number-list*

specifies the hazard ratio of the second group’s survival curve to the first group’s survival curve. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NFRATIONAL

NFRAC

enables fractional input and output for sample sizes. See the “[Sample Size Adjustment Options](#)” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRATIONAL option.

NPERGROUP= *number-list*

NPERG= *number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NSUBINTERVAL= *number-list*

NSUBINTERVALS= *number-list*

NSUB= *number-list*

NSUBS= *number-list*

specifies the number of subintervals per unit time to use in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. The default value is 12. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

NTOTAL= *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

OUTPUTORDER=INTERNAL

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- ACCRUALTIME
- FOLLOWUPTIME
- TOTALTIME
- NSUBINTERVAL
- ALPHA
- REFSURVIVAL
- GROUPSURVIVAL
- REFSURVEXPHAZARD
- HAZARDRATIO
- GROUPSURVEXPHAZARDS
- GROUPMEDSURVTIMES
- GROUPLOSSEXPHAZARDS
- GROUPLOSS
- GROUPMEDLOSSTIMES
- GROUPWEIGHTS

- NTOTAL
- NPERGROUP
- GROUPNS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLESURVIVAL statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLESURVIVAL statement.

POWER= *number-list*

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

REFSURVEXPHAZARD= *number-list*

REFSURVEXPH= *number-list*

specifies the exponential hazard rate of the survival curve for the first (reference) group. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *number-list*.

REFSURVIVAL= *name-list*

REFSURV= *name-list*

specifies the survival curve for the first (reference) group, using labels specified with the CURVE= option. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *name-list*.

SIDES=*keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation are

- | | |
|---|---|
| 1 | 1-sided with alternative hypothesis in same direction as effect |
| 2 | 2-sided |
| U | upper 1-sided with the alternative hypothesis favoring better survival in the second group |
| L | lower 1-sided with the alternative hypothesis favoring better survival in the first (reference) group |

The default value is 2.

TEST=GEHAN**TEST=LOGRANK****TEST=TARONEWARE**

specifies the statistical analysis. TEST=GEHAN specifies the Gehan rank test. TEST=LOGRANK (the default) specifies the log-rank test. TEST=TARONEWARE specifies the Tarone-ware rank test.

TOTALTIME=number-list**TOTALT=number-list**

specifies the total time, which is equal to the sum of accrual and follow-up times. If the GROUPSURVIVAL= or REFSURVIVAL= options are used, then the value of the total time must be less than or equal to the largest time in *each* multipoint (piecewise linear) survival curve. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Restrictions on Option Combinations

To specify the survival curves, choose one of the following parameterizations:

- arbitrary piecewise linear or exponential curves (using the CURVE= and GROUPSURVIVAL= options)
- curves with proportional hazards (using the CURVE=, REFSURVIVAL=, and HAZARDRATIO= options)
- exponential curves, using one of the following parameterizations:
 - median survival times (using the GROUPMEDSURVTIMES= option)
 - the hazard ratio and the hazard of the reference curve (using the HAZARDRATIO= and REFSURVEXPHAZARD= options)
 - the individual hazards (using the GROUPSURVEXPHAZARDS= option)

To specify the study time, use any two of the following three options:

- accrual time (using the ACCRUALTIME= option)
- follow-up time (using the FOLLOWUPTIME= option)
- total time, the sum of accrual and follow-up times (using the TOTALTIME= option)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

To specify the exponential loss curves, choose one of the following parameterizations:

- a point on the loss curve of each group (using the CURVE= and GROUPLOSS= options)
- median loss times (using the GROUPMEDLOSSTIMES= option)
- the individual loss hazards (using the GROUPLOSSEXPHAZARDS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the TWOSAMPLESURVIVAL statement.

Log-Rank Test for Two Survival Curves

You can use the NPERGROUP= option in a balanced design and specify piecewise linear or exponential survival curves using the CURVE= and GROUPSURVIVAL= options. Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSSEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```
proc power;
  twosamplesurvival test=logrank
    curve("Control") = (1 2 3):(0.8 0.7 0.6)
    curve("Treatment") = (5):(0.6)
    groupsurvival = "Control" | "Treatment"
    accrualtime = 2
    followuptime = 1
    npergroup = 50
    power = .;
run;
```

In the preceding example, the “Control” curve is piecewise linear (since it has more than one point), and the “Treatment” curve is exponential (since it has only one point).

You can also specify an unbalanced design using the NTOTAL= and GROUPWEIGHTS= options and specify piecewise linear or exponential survival curves with proportional hazards using the CURVE=, REFSURVIVAL=, and HAZARDRATIO= options.

```
proc power;
  twosamplesurvival test=logrank
    curve("Control") = (1 2 3):(0.8 0.7 0.6)
    refsurvival = "Control"
    hazardratio = 1.5
    accrualtime = 2
    followuptime = 1
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;
```

You can also specify sample sizes with the GROUPNS= option and specify exponential survival curves in terms of median survival times.

```

proc power;
  twosamplesurvival test=logrank
    groupmedsurvtimes = (16 22)
    accrualtime = 6
    totaltime = 18
    groupns = 40 | 60
    power = .;
run;

```

You can also specify exponential survival curves in terms of the hazard ratio and reference hazard. The default value of the GROUPWEIGHTS= option specifies a balanced design.

```

proc power;
  twosamplesurvival test=logrank
    hazardratio = 1.2
    refsurvexphazard = 0.7
    accrualtime = 2
    totaltime = 4
    ntotal = 100
    power = .;
run;

```

You can also specify exponential survival curves in terms of the individual hazards.

```

proc power;
  twosamplesurvival test=logrank
    groupsurvexphazards = 0.7 | 0.84
    accrualtime = 2
    totaltime = 4
    ntotal = .
    power = 0.9;
run;

```

Gehan Rank Test for Two Survival Curves

Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSSEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```

proc power;
  twosamplesurvival test=gehan
    groupmedsurvtimes = 5 | 7
    accrualtime = 3
    totaltime = 6
    npergroup = .
    power = 0.8;
run;

```

Tarone-Ware Rank Test for Two Survival Curves

Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSSEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```
proc power;
  twosamplesurvival test=taroneware
    groupmedsurvtimes = 5 | 7
    accrualtime = 3
    totaltime = 6
    npergroup = 100
    power = .;
run;
```

PLOT Statement

PLOT < *plot-options* > < / *graph-options* > ;

The PLOT statement produces a graph or set of graphs for the sample size analysis defined by the previous analysis statement. The *plot-options* define the plot characteristics, and the *graph-options* are SAS/GRAPH-style options.

Options

You can specify the following *plot-options* in the PLOT statement.

INTERPOL=JOIN

INTERPOL=NONE

specifies the type of curve to draw through the computed points. The INTERPOL=JOIN option connects computed points by straight lines. The INTERPOL=NONE option leaves computed points unconnected.

KEY= BYCURVE < (*bycurve-options*) >

KEY= BYFEATURE < (*byfeature-options*) >

KEY= ONCURVES

specifies the style of key (or “legend”) for the plot. The default is KEY=BYFEATURE, which specifies a key with a column of entries for each plot feature (line style, color, and/or symbol). Each entry shows the mapping between a value of the feature and the value(s) of the analysis parameter(s) linked to that feature. The KEY=BYCURVE option specifies a key with each row identifying a distinct curve in the plot. The KEY=ONCURVES option places a curve-specific label adjacent to each curve.

You can specify the following *byfeature-options* in parentheses after the KEY=BYCURVE option.

NUMBERS=OFF

NUMBERS=ON specifies how the key should identify curves. If **NUMBERS=OFF**, then the key includes symbol, color, and line style samples to identify the curves. If **NUMBERS=ON**, then the key includes numbers matching numeric labels placed adjacent to the curves. The default is **NUMBERS=ON**.

POS=BOTTOM

POS=INSET specifies the position of the key. The **POS=BOTTOM** option places the key below the x-axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

You can specify the following *byfeature-options* in parentheses after the **KEY=BYFEATURE** option.

POS=BOTTOM

POS=INSET specifies the position of the key. The **POS=BOTTOM** option places the key below the x-axis. The **POS=INSET** option places the key inside the plotting region and attempts to choose the least crowded corner. The default is **POS=BOTTOM**.

MARKERS=ANALYSIS

MARKERS=COMPUTED

MARKERS=NICE

MARKERS=NONE

specifies the locations for plotting symbols.

The **MARKERS=ANALYSIS** option places plotting symbols at locations corresponding to the values of the relevant input parameter from the analysis statement preceding the **PLOT** statement.

The **MARKERS=COMPUTED** option (the default) places plotting symbols at the locations of actual computed points from the sample size analysis.

The **MARKERS=NICE** option places plotting symbols at tick mark locations (corresponding to the argument axis).

The **MARKERS=NONE** option disables plotting symbols.

MAX=number

specifies the maximum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The default is the maximum value occurring for this parameter in the analysis statement preceding the **PLOT** statement.

MIN=number

specifies the minimum of the range of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). The

default is the minimum value occurring for this parameter in the analysis statement preceding the PLOT statement.

NPOINTS=*number*

NPTS=*number*

specifies the number of values for the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the NPOINTS= and STEP= options simultaneously. The default value for typical situations is 20.

STEP=*number*

specifies the increment between values of the parameter associated with the “argument” axis (the axis that is *not* representing the parameter being solved for). You cannot use the STEP= and NPOINTS= options simultaneously. By default, the NPOINTS= option is used instead of the STEP= option.

VARY (*feature* < **BY** *parameter-list* > ... *feature* < **BY** *parameter-list* >)

specifies how plot features should be linked to varying analysis parameters. Available plot *features* are COLOR, LINESYLE, PANEL, and SYMBOL. A “panel” refers to a separate plot with a heading identifying the subset of values represented in the plot.

The *parameter-list* is a list of one or more names separated by spaces. Each name must match the name of an analysis option used in the analysis statement preceding the PLOT statement. Also, the name must be the *primary* name for the analysis option, that is, the one listed first in the syntax description.

If you omit the < **BY** *parameter-list* > portion for a feature, then one or more multi-valued parameters from the analysis will be automatically selected for you.

X=EFFECT

X=N

X=POWER

specifies a plot with the requested type of parameter on the x-axis and the parameter being solved for on the y-axis. When X=EFFECT, the parameter assigned to the x-axis is the one most representative of “effect size.” When X=N, the parameter assigned to the x-axis is the sample size. When X=POWER, the parameter assigned to the x-axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the X= and Y= options simultaneously. The default is X=POWER, unless the result parameter is power or Prob(Width), in which case the default is X=N.

You can only use the X=N option when a scalar sample size parameter is used as input in the analysis. For example, X=N can be used with total sample size or sample size per group, or with two group sample sizes when one is being solved for.

Table 57.22 summarizes the parameters representing effect size in different analyses.

Table 57.22. Effect Size Parameters For Different Analyses

Analysis Statement and Options	Effect Size Parameters
MULTREG	Partial correlation or R^2 difference
ONECORR	Correlation
ONESAMPLEFREQ	Proportion
ONESAMPLEMEANS TEST=T, ONESAMPLEMEANS TEST=EQUIV	Mean
ONESAMPLEMEANS CI=T	CI half-width
ONEWAYANOVA	none
PAIREFREQ	Discordant proportion difference or ratio
PAIREDMEANS TEST=DIFF, PAIREDMEANS TEST=EQUIV_DIFF	Mean difference
PAIREDMEANS TEST=RATIO, PAIREDMEANS TEST=EQUIV_RATIO	Mean ratio
PAIREDMEANS CI=DIFF	CI half-width
TWOSAMPLEFREQ	Proportion difference, odds ratio, or relative risk
TWOSAMPLEMEANS TEST=DIFF, TWOSAMPLEMEANS TEST=DIFF_SATT, TWOSAMPLEMEANS TEST=EQUIV_DIFF	Mean difference
TWOSAMPLEMEANS TEST=RATIO, TWOSAMPLEMEANS TEST=EQUIV_RATIO	Mean ratio
TWOSAMPLEMEANS CI=DIFF	CI half-width
TWOSAMPLESURVIVAL	Hazard ratio if used, else none

XOPTS= (*x-options*)

specifies plot characteristics pertaining to the x-axis.

You can specify the following *x-options* in parentheses.

CROSSREF=NO

CROSSREF=YES specifies whether the reference lines defined by the REF= *x-option* should be crossed with a reference line on the y-axis that indicates the solution point on the curve.

REF=number-list specifies locations for reference lines extending from the x-axis across the entire plotting region. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

Y=EFFECT**Y=N****Y=POWER**

specifies a plot with the requested type of parameter on the y-axis and the parameter being solved for on the x-axis. When Y=EFFECT, the parameter assigned to the y-axis is the one most representative of “effect size.” When Y=N, the parameter assigned to the y-axis is the sample size. When Y=POWER, the parameter assigned to the y-axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the Y= and X= options simultaneously. By default, the X= option is used instead of the Y= option.

YOPTS= (*y-options*)

specifies plot characteristics pertaining to the y-axis.

You can specify the following *y-options* in parentheses.

CROSSREF=NO

CROSSREF=YES specifies whether the reference lines defined by the REF= *y-option* should be crossed with a reference line on the x-axis that indicates the solution point on the curve.

REF=*number-list* specifies locations for reference lines extending from the y-axis across the entire plotting region. See the “[Specifying Value Lists in Analysis Statements](#)” section on page 3490 for information on specifying the *number-list*.

You can specify the following *graph-options* in the PLOT statement after a slash (/).

DESCRIPTION='string'

specifies a descriptive string of up to 40 characters that appears in the “Description” field of the graphics catalog. The description does not appear on the plots. By default, PROC POWER assigns a description either of the form “Y versus X” (for a single-panel plot) or of the form “Y versus X (S),” where Y is the parameter on the y-axis, X is the parameter on the x-axis, and S is a description of the subset represented on the current panel of a multipanel plot.

NAME='string'

specifies a name of up to eight characters for the catalog entry for the plot. The default name is PLOT*n*, where *n* is the number of the plot statement within the current invocation of PROC POWER. If the name duplicates the name of an existing entry, SAS/GRAPH software adds a number to the duplicate name to create a unique entry; for example, PLOT11 and PLOT12 for the second and third panels of a multipanel plot generated in the first PLOT statement in an invocation of PROC POWER.

Details

Overview of Power Concepts

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis H_1 . You state a null hypothesis H_0 as the assertion that the effect does *not* exist and attempt to gather evidence to reject H_0 in favor of H_1 . Evidence is gathered in the form of sample data, and a statistical test is used to assess H_0 . If H_0 is rejected but there really is *no* effect, this is called a *Type 1 error*. The probability of a Type 1 error is usually designated “alpha” or α , and statistical tests are designed to ensure that α is suitably small (for example, less than 0.05).

If there really is an effect in the population but H_0 is *not* rejected in the statistical test, then a *Type 2 error* has been made. The probability of a Type 2 error is usually designated “beta” or β . The probability $1 - \beta$ of avoiding a Type 2 error, that is, correctly rejecting H_0 and achieving statistical significance, is called the *power*. (**Note:** Another more general definition of power is the probability of rejecting H_0 for any given set of circumstances, even those corresponding to H_0 being true. The POWER procedure uses this more general definition.)

An important goal in study planning is to ensure an acceptably high level of power. Sample size plays a prominent role in power computations because the focus is often on determining a sufficient sample size to achieve a certain power, or assessing the power for a range of different sample sizes.

Some of the analyses in the POWER procedure focus on *precision* rather than power. An analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. The *CI Half-Width* is the margin of error associated with the confidence interval, the distance between the point estimate and an endpoint. The *Prob(Width)* is the probability of obtaining a confidence interval with *at most* a target half-width.

Summary of Analyses

Table 57.23 gives a summary of the analyses supported in the POWER procedure. The name of the analysis statement reflects the type of data and design. The TEST=, CI=, and DIST= options specify the focus of the statistical hypothesis (in other words, the criterion on which the research question is based) and the test statistic to be used in data analysis.

Table 57.23. Summary of Analyses

Statement	Options	
Multiple linear regression: Type III F test	MULTREG	
Correlation: Fisher’s z test	ONECORR	DIST=FISHERZ
Correlation: t test	ONECORR	DIST=T

Table 57.23. (continued)

Statement	Options	
Binomial proportion: Exact test	ONESAMPLEFREQ	TEST=EXACT
Binomial proportion: z test	ONESAMPLEFREQ	TEST=Z
Binomial proportion: z test with continuity adjustment	ONESAMPLEFREQ	TEST=ADJZ
One-sample t test	ONESAMPLEMEANS	TEST=T
One-sample t test with log-normal data	ONESAMPLEMEANS	TEST=T DIST=LOGNORMAL
One-sample equivalence test for mean of normal data	ONESAMPLEMEANS	TEST=EQUIV
One-sample equivalence test for mean of lognormal data	ONESAMPLEMEANS	TEST=EQUIV DIST=LOGNORMAL
Confidence interval for a mean	ONESAMPLEMEANS	CI=T
One-way ANOVA: One-degree-of-freedom contrast	ONEWAYANOVA	TEST=CONTRAST
One-way ANOVA: Overall F test	ONEWAYANOVA	TEST=OVERALL
McNemar exact conditional test	PAIREDFREQ	
McNemar normal approximation test	PAIREDFREQ	DIST=NORMAL
Paired t test	PAIREDMEANS	TEST=DIFF
Paired t test of mean ratio with lognormal data	PAIREDMEANS	TEST=RATIO

Gehan rank test for comparing two survival curves	TWOSAMPLESURVIVATEST=GEHAN
Tarone-Ware rank test for comparing two survival curves	TWOSAMPLESURVIVATEST=TARONEWARE

Specifying Value Lists in Analysis Statements

To specify one or more scenarios for an analysis parameter (or set of parameters), you provide a list of values for the statement option that corresponds to the parameter(s). To identify the parameter you wish to solve for, you place missing values in the appropriate list.

There are five basic types of such lists: *keyword-lists*, *number-lists*, *grouped-number-lists*, *name-lists*, and *grouped-name-lists*. Some parameters, such as the direction of a test, have values represented by one or more keywords in a *keyword-list*. Scenarios for scalar-valued parameters, such as power, are represented by a *number-list*. Scenarios for groups of scalar-valued parameters, such as group sample sizes in a multigroup design, are represented by a *grouped-number-list*. Scenarios for named parameters, such as reference survival curves, are represented by a *name-list*. Scenarios for groups of named parameters, such as group survival curves, are represented by a *grouped-name-list*.

The following subsections explain these five basic types of lists.

Keyword-lists

A *keyword-list* is a list of one or more keywords separated by spaces. For example, you can specify both 2-sided and upper-tailed versions of a one-sample t test:

```
SIDES = 2 U
```

Number-lists

A *number-list* can be one of two things: a series of one or more numbers expressed in the form of one or more DOLISTs, or a missing value indicator (.).

The DOLIST format is the same as in the DATA step language. For example, for the one-sample t test you can specify four scenarios (30, 50, 70, and 100) for a total sample size in any of the following ways.

```
NTOTAL = 30 50 70 100
NTOTAL = 30 to 70 by 20 100
```

A missing value identifies a parameter as the result parameter; it is valid only with options representing parameters you can solve for in a given analysis. For example, you can request a solution for NTOTAL:

```
NTOTAL = .
```

Grouped-number-lists

A *grouped-number-list* specifies multiple scenarios for numeric values in two or more groups, possibly including missing value indicators to solve for a specific group. The list can assume one of two general forms, a “crossed” version and a “matched” version.

Crossed Grouped-number-lists

The crossed version of a grouped number list consists of a series of *number-lists* (see the “Number-lists” section on page 3491), one representing each group, each separated by a vertical bar (|). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the sizes (n_1, n_2) of two groups

```
(20, 30)(20, 40)(20, 50)
(25, 30)(25, 40)(25, 50)
```

as follows:

```
GROUPNS = 20 25 | 30 40 50
```

If the analysis can solve for a value in one group given the other groups, then one of the *number-lists* in a *crossed grouped-number-list* can be a missing value indicator (.). For example, in a two-sample t test you can posit three scenarios for the group 2 sample size while solving for the group 1 sample size:

```
GROUPNS = . | 30 40 50
```

Some analyses can involve more than two groups. For example, you can specify $2 \times 3 \times 1 = 6$ scenarios for the means of three groups in a one-way ANOVA as follows:

```
GROUPMEANS = 10 12 | 10 to 20 by 5 | 24
```

Matched Grouped-number-lists

The matched version of a grouped number list consists of a series of numeric lists each enclosed in parentheses. Each list consists of a value for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-number-list

```
GROUPNS = 20 25 | 30 40 50
```

alternatively in a matched format:

```
GROUPNS = (20 30) (20 40) (20 50) (25 30) (25 40) (25 50)
```

The matched version is particularly useful when you wish to include only a subset of all combinations of individual group values. For example, you may want to pair 20 only with 50, and 25 only with 30 and 40:

```
GROUPNS = (20 50) (25 30) (25 40)
```

If the analysis can solve for a value in one group given the other groups, then you can replace the value for that group with a missing value indicator (.). If used, the missing value indicator must occur in the same group in every scenario. For example, you can solve for the group 1 sample size (as in the “[Crossed Grouped-number-lists](#)” section on page 3491) using a matched format:

```
GROUPNS = (. 30) (. 40) (. 50)
```

Some analyses can involve more than two groups. For example, you can specify two scenarios for the means of three groups in a one-way ANOVA:

```
GROUPMEANS = (15 24 32) (12 25 36)
```

Name-lists

A *name-list* is a list of one or more names in single or double quotes separated by spaces. For example, you can specify two scenarios for the reference survival curve in a log-rank test:

```
REFSURVIVAL = "Curve A" "Curve B"
```

Grouped-name-lists

A *grouped-name-list* specifies multiple scenarios for names in two or more groups. The list can assume one of two general forms, a “crossed” version and a “matched” version.

Crossed Grouped-name-lists

The crossed version of a grouped name list consists of a series of *name-lists* (see the “Name-lists” section on page 3492), one representing each group, each separated by a vertical bar (|). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the survival curves (c_1, c_2) of two groups

```
(“Curve A”, “Curve C”)(“Curve A”, “Curve D”)(“Curve A”, “Curve E”)
(“Curve B”, “Curve C”)(“Curve B”, “Curve D”)(“Curve B”, “Curve E”)
```

as follows:

```
GROUPSURVIVAL = "Curve A" "Curve B" | "Curve C" "Curve D"
                "Curve E"
```

Matched Grouped-name-lists

The matched version of a grouped name list consists of a series of name lists each enclosed in parentheses. Each list consists of a name for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-name-list

```
GROUPSURVIVAL = "Curve A" "Curve B" | "Curve C" "Curve D"
                "Curve E"
```

alternatively in a matched format:

```
GROUPSURVIVAL = ("Curve A" "Curve C")
                 ("Curve A" "Curve D")
                 ("Curve A" "Curve E")
                 ("Curve B" "Curve C")
                 ("Curve B" "Curve D")
                 ("Curve B" "Curve E")
```

The matched version is particularly useful when you wish to include only a subset of all combinations of individual group values. For example, you may want to pair “Curve A” only with “Curve C”, and “Curve B” only with “Curve D” and “Curve E”:

```
GROUPSURVIVAL = ("Curve A" "Curve C")
                 ("Curve B" "Curve D")
                 ("Curve B" "Curve E")
```

Sample Size Adjustment Options

By default, PROC POWER rounds sample sizes conservatively (down in the input, up in the output) so that all total sizes (and individual group sample sizes, if a multigroup design) are integers. This is generally considered conservative because it selects the closest realistic design providing *at most* the power of the (possibly fractional) input or mathematically optimized design. In addition, in a multigroup design, all group sizes are adjusted to be multiples of the corresponding group weights. For example, if `GROUPWEIGHTS = (2 6)`, then all group 1 sample sizes become multiples of 2, and all group 2 sample sizes become multiples of 6 (and all total sample sizes become multiples of 8).

With the `NFRACTIONAL` option, sample size input is not rounded, and sample size output (whether total or group-wise) are reported in two versions, a raw “fractional” version and a “ceiling” version rounded up to the nearest integer.

Whenever an input sample size is adjusted, both the original (“nominal”) and adjusted (“actual”) sample sizes are reported. Whenever computed output sample sizes are adjusted, both the original input (“nominal”) power and the achieved (“actual”) power at the adjusted sample size are reported.

Error and Information Output

The Error column in the main output table explains reasons for missing results and flags numerical results that are bounds rather than exact answers. For example, consider the sample size analysis implemented by the following statements:

```
proc power;
  twosamplefreq test=pchi
    oddsratio= 1.0001
    refproportion=.4
    nulloddsratio=1
    power=.9
    ntotal=.;
run;
```

The POWER Procedure		
Pearson Chi-square Test for Two Proportions		
Fixed Scenario Elements		
Distribution		Asymptotic normal
Method		Normal approximation
Null Odds Ratio		1
Reference (Group 1) Proportion		0.4
Odds Ratio		1.0001
Nominal Power		0.9
Number of Sides		2
Alpha		0.05
Group 1 Weight		1
Group 2 Weight		1
Computed N Total		
Actual	N Total	Error
Power		
0.206	2.15E+09	Solution is a lower bound

Figure 57.6. Error Column

The output in [Figure 57.6](#) reveals that the sample size to achieve a power of 0.9 could not be computed, but that the sample size 2.15E+09 achieves a power of 0.206.

The Information column provides further details about Error entries, warnings about any boundary conditions detected, and notes about any adjustments to input. Note that the Information column is hidden by default in the main output. You can view it by using the ODS OUTPUT statement to save the output as a data set and the PRINT procedure. For example, the following SAS statements print both the Error and Info columns for a power computation in a two-sample t test.

```
proc power;
  twosamplemeans
    meandiff= 0 7
    stddev=2
    ntotal=2 5
    power=.;
  ods output output=Power;
proc print noobs data=Power;
  var MeanDiff NominalNTotal NTotal Power Error Info;
run;
```

The output is shown in [Figure 57.7](#).

Mean Diff	Nominal NTotal	NTotal	Power	Error	Info
0	2	2	.	Invalid input	N too small / No effect
0	5	4	0.050		Input N adjusted / No effect
7	2	2	.	Invalid input	N too small
7	5	4	0.477		Input N adjusted

Figure 57.7. Error and Information Columns

The mean difference of 0 specified with the MEANDIFF= option leads to a “No effect” message to appear in the Info column. The sample size of 2 specified with the NTOTAL= option leads to an “Invalid input” message in the Error column and an “NTotal too small” message in the Info column. The sample size of 5 leads to an “Input N adjusted” message in the Info column because it is rounded down to 4 to produce integer group sizes of 2 per group.

Displayed Output

If you use the PLOTONLY option in the PROC POWER statement, the procedure only displays graphical output. Otherwise, the displayed output of the POWER procedure includes the following:

- the “Fixed Scenario Elements” table, which shows all applicable single-valued analysis parameters, in the following order: distribution, method, parameters input explicitly, and parameters supplied with defaults
- an output table showing the following when applicable (in order): the index of the scenario, all multivalued input, ancillary results, the primary computed result, and error descriptions
- plots (if requested)

For each input parameter, the order of the input values is preserved in the output.

Ancillary results include the following:

- Actual Power, the achieved power, if it differs from the input (Nominal) power value
- Actual Prob(Width), the achieved precision probability, if it differs from the input (Nominal) probability value
- Actual Alpha, the achieved significance level, if it differs from the input (Nominal) alpha value
- fractional sample size, if the NFRAGMENTAL option is used in the analysis statement

If sample size is the result parameter and the NFRAGMENTAL option is used in the analysis statement, then both “Fractional” and “Ceiling” sample size results are

displayed. Fractional sample sizes correspond to the “Nominal” values of power or precision probability. Ceiling sample sizes are simply the fractional sample sizes rounded up to the nearest integer; they correspond to “Actual” values of power or precision probability.

ODS Table Names

PROC POWER assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 57.24](#). For more information on ODS, see [Chapter 14](#), “Using the Output Delivery System.”

Table 57.24. ODS Tables Produced in PROC POWER

ODS Table Name	Description	Statement
FixedElements	factoid with single-valued analysis parameters	default*
Output	all input and computed analysis parameters, error messages, and information messages for each scenario	default
PlotContent	data contained in plots, including analysis parameters and indices identifying plot features. (Note: this table is saved as a data set and not displayed in PROC POWER output.)	PLOT

*Depends on input.

The ODS path names are created as follows:

- Power.<analysis statement name>< *n* >.FixedElements
- Power.<analysis statement name>< *n* >.Output
- Power.<analysis statement name>< *n* >.PlotContent
- Power.<analysis statement name>< *n* >.Plot< *m* >

where

- The Plot< *m* > objects are the graphs.
- The < *n* > indexing the analysis statement name is only used if there is more than one instance.
- The < *n* > indexing the plots increases with every panel in every plot statement, resetting to 1 only at new analysis statements.

Computational Resources

Memory

In the TWOSAMPLESURVIVAL statement, the amount of required memory is roughly proportional to the product of the number of subintervals (specified by the NSUBINTERVAL= option) and the total time of the study (specified by the ACCRUALTIME=, FOLLOWUPTIME=, and TOTALTIME= options).

CPU Time

In the Satterthwaite t test analysis (TWOSAMPLEMEANS TEST=DIFF_SATT), the required CPU time grows as the mean difference decreases relative to the standard deviations. In the PAIREDFREQ statement, the required CPU time for the exact power computation (METHOD=EXACT) grows with the sample size.

Computational Methods and Formulas

This section describes the approaches used in PROC POWER to compute power for each analysis. The first subsection defines some common notation. The following subsections describe the various power analyses, including discussions of the data, statistical test, and power formula for each analysis. Unless otherwise indicated, computed values for parameters besides power (for example, sample size) are obtained by solving power formulas for the desired parameters.

Common Notation

Table 57.25 displays notation for some of the more common parameters across analyses. The Associated Syntax column shows examples of relevant analysis statement options, where applicable.

Table 57.25. Common Notation

Symbol	Description	Associated Syntax
α	significance level	ALPHA=
N	total sample size	NTOTAL=, NPAIRS=
n_i	sample size in i th group	NPERGROUP=, GROUPNS=
w_i	allocation weight for i th group (standardized to sum to 1)	GROUPWEIGHTS=
μ	(arithmetic) mean	MEAN=
μ_i	(arithmetic) mean in i th group	GROUPMEANS=, PAIREDMEANS=
μ_{diff}	(arithmetic) mean difference, $\mu_2 - \mu_1$ or $\mu_T - \mu_R$	MEANDIFF=
μ_0	null mean or mean difference (arithmetic)	NULL=, NULLDIFF=
γ	geometric mean	MEAN=
γ_i	geometric mean in i th group	GROUPMEANS=, PAIREDMEANS=
γ_0	null mean or mean ratio (geometric)	NULL=, NULLRATIO=

Table 57.25. (continued)

Symbol	Description	Associated Syntax
σ	standard deviation (or common standard deviation per group)	STDDEV=
σ_i	standard deviation in i th group	GROUPSTDDEVS=, PAIREDSTDDEVS=
σ_{diff}	standard deviation of differences	
CV	coefficient of variation, defined as the ratio of the standard deviation to the (arithmetic) mean	CV=, PAIREDCVS=
ρ	correlation	CORR=
μ_T, μ_R	treatment and reference (arithmetic) means for equivalence test	GROUPMEANS=, PAIREDMEANS=
γ_T, γ_R	treatment and reference geometric means for equivalence test	GROUPMEANS=, PAIREDMEANS=
θ_L	lower equivalence bound	LOWER=
θ_U	upper equivalence bound	UPPER=
$t(\nu, \delta)$	t distribution with d.f. ν and noncentrality δ	
$F(\nu_1, \nu_2, \lambda)$	F distribution with numerator d.f. ν_1 , denominator d.f. ν_2 , and noncentrality λ	
$t_{p;\nu}$	p th percentile of t distribution with d.f. ν	
$F_{p;\nu_1,\nu_2}$	p th percentile of F distribution with numerator d.f. ν_1 and denominator d.f. ν_2	
$\text{Bin}(N, p)$	binomial distribution with sample size N and proportion p	

A “lower 1-sided” test is associated with SIDES=L (or SIDES=1 with the effect smaller than the null value), and an “upper 1-sided” test is associated with SIDES=U (or SIDES=1 with the effect larger than the null value).

Owen (1965) defines a function, known as Owen’s Q , that is convenient for representing terms in power formulas for confidence intervals and equivalence tests:

$$Q_\nu(t, \delta; a, b) = \frac{\sqrt{2\pi}}{\Gamma(\frac{\nu}{2})2^{\frac{\nu-2}{2}}} \int_a^b \Phi\left(\frac{tx}{\sqrt{\nu}} - \delta\right) x^{\nu-1} \phi(x) dx$$

where $\phi(\cdot)$ and $\Phi(\cdot)$ are the density and cumulative distribution function of the standard normal distribution, respectively.

Analyses in the MULTREG Statement**Type III F Test in Multiple Regression (TEST=TYPE3)**

Maxwell (2000) discusses a number of different ways to represent effect sizes (and to compute exact power based on them) in multiple regression. PROC POWER supports two of these, multiple partial correlation and R^2 in full and reduced models.

Let p denote the total number of predictors in the full model (excluding the intercept) and Y the response variable. You are testing that the coefficients of $p_1 \geq 1$ predictors in a set X_1 are 0, controlling for all of the other predictors X_{-1} , which is comprised of $p - p_1 \geq 0$ variables.

The hypotheses can be expressed in two different ways. The first is in terms of $\rho_{YX_1|X_{-1}}$, the multiple partial correlation between the predictors in X_1 and the response Y adjusting for the predictors in X_{-1} :

$$\begin{aligned} H_0 &: \rho_{YX_1|X_{-1}}^2 = 0 \\ H_1 &: \rho_{YX_1|X_{-1}}^2 > 0 \end{aligned}$$

The second is in terms of the multiple correlations in full ($\rho_{Y|(X_1, X_{-1})}$) and reduced ($\rho_{Y|X_{-1}}$) nested models:

$$\begin{aligned} H_0 &: \rho_{Y|(X_1, X_{-1})}^2 - \rho_{Y|X_{-1}}^2 = 0 \\ H_1 &: \rho_{Y|(X_1, X_{-1})}^2 - \rho_{Y|X_{-1}}^2 > 0 \end{aligned}$$

Note that the squared values of $\rho_{Y|(X_1, X_{-1})}$ and $\rho_{Y|X_{-1}}$ are the population R^2 values for full and reduced models.

The test statistic can be written in terms of the sample multiple partial correlation $R_{YX_1|X_{-1}}$,

$$F = \begin{cases} (N - 1 - p) \frac{R_{YX_1|X_{-1}}^2}{1 - R_{YX_1|X_{-1}}^2}, & \text{intercept} \\ (N - p) \frac{R_{YX_1|X_{-1}}^2}{1 - R_{YX_1|X_{-1}}^2}, & \text{no intercept} \end{cases}$$

or the sample multiple correlations in full ($R_{Y|(X_1, X_{-1})}$) and reduced ($R_{Y|X_{-1}}$) models,

$$F = \begin{cases} (N - 1 - p) \frac{R_{Y|(X_1, X_{-1})}^2 - R_{Y|X_{-1}}^2}{1 - R_{Y|(X_1, X_{-1})}^2}, & \text{intercept} \\ (N - p) \frac{R_{Y|(X_1, X_{-1})}^2 - R_{Y|X_{-1}}^2}{1 - R_{Y|(X_1, X_{-1})}^2}, & \text{no intercept} \end{cases}$$

The test is the usual Type III F test in multiple regression:

$$\text{Reject } H_0 \text{ if } \begin{cases} F \geq F_{1-\alpha}(p_1, N-1-p), & \text{intercept} \\ F \geq F_{1-\alpha}(p_1, N-p), & \text{no intercept} \end{cases}$$

Although the test is invariant to whether the predictors are assumed to be random or fixed, the power is affected by this assumption. If the response and predictors are assumed to have a joint multivariate normal distribution, then the exact power is given by the following formula:

$$\begin{aligned} \text{power} &= \begin{cases} P \left[\left(\frac{N-1-p}{p_1} \right) \left(\frac{R_{Y|X_1, X_{-1}}^2}{1-R_{Y|X_1, X_{-1}}^2} \right) \geq F_{1-\alpha}(p_1, N-1-p) \right], & \text{intercept} \\ P \left[\left(\frac{N-p}{p_1} \right) \left(\frac{R_{Y|X_1, X_{-1}}^2}{1-R_{Y|X_1, X_{-1}}^2} \right) \geq F_{1-\alpha}(p_1, N-p) \right], & \text{no intercept} \end{cases} \\ &= \begin{cases} P \left[R_{Y|X_1, X_{-1}}^2 \geq \frac{F_{1-\alpha}(p_1, N-1-p)}{F_{1-\alpha}(p_1, N-1-p) + \frac{N-1-p}{p_1}} \right], & \text{intercept} \\ P \left[R_{Y|X_1, X_{-1}}^2 \geq \frac{F_{1-\alpha}(p_1, N-p)}{F_{1-\alpha}(p_1, N-p) + \frac{N-p}{p_1}} \right], & \text{no intercept} \end{cases} \end{aligned}$$

The distribution of $R_{Y|X_1, X_{-1}}^2$ (for any $\rho_{Y|X_1, X_{-1}}^2$) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995). Sample size tables are presented in Gatsonis and Sampson (1989).

If the predictors are assumed to have fixed values, then the exact power is given by the noncentral F distribution. The noncentrality parameter is

$$\lambda = N \frac{\rho_{Y X_1 | X_{-1}}^2}{1 - \rho_{Y X_1 | X_{-1}}^2}$$

or equivalently,

$$\lambda = N \frac{\rho_{Y|X_1, X_{-1}}^2 - \rho_{Y|X_{-1}}^2}{1 - \rho_{Y|X_1, X_{-1}}^2}$$

The power is

$$\text{power} = \begin{cases} P(F(p_1, N-1-p, \lambda) \geq F_{1-\alpha}(p_1, N-1-p)), & \text{intercept} \\ P(F(p_1, N-p, \lambda) \geq F_{1-\alpha}(p_1, N-p)), & \text{no intercept} \end{cases}$$

The minimum acceptable input value of N depends on several factors, as shown in [Table 57.26](#).

Table 57.26. Minimum Acceptable Sample Size Values in the MULTREG Statement

Predictor Type	Intercept in Model?	$p_1 = 1?$	Minimum N
Random	Yes	Yes	$p + 3$
Random	Yes	No	$p + 2$
Random	No	Yes	$p + 2$
Random	No	No	$p + 1$
Fixed	Yes	Yes or No	$p + 2$
Fixed	No	Yes or No	$p + 1$

Analyses in the ONECORR Statement**Fisher's z Test for Pearson Correlation (TEST=PEARSON DIST=FISHERZ)**

Fisher's z transformation (Fisher 1921) of the sample correlation $R_{Y|(X_1, X_{-1})}$ is defined as

$$z = \frac{1}{2} \log \left(\frac{1 + R_{Y|(X_1, X_{-1})}}{1 - R_{Y|(X_1, X_{-1})}} \right)$$

Fisher's z test assumes the approximate normal distribution $N(\mu, \sigma^2)$ for z , where

$$\mu = \frac{1}{2} \log \left(\frac{1 + \rho_{Y|(X_1, X_{-1})}}{1 - \rho_{Y|(X_1, X_{-1})}} \right) + \frac{\rho_{Y|(X_1, X_{-1})}}{2(N - 1 - p^*)}$$

and

$$\sigma^2 = \frac{1}{N - 3 - p^*}$$

where p^* is the number of variables partialled out (Anderson 1984, pp. 132–133) and $\rho_{Y|(X_1, X_{-1})}$ is the partial correlation between Y and X_1 adjusting for the set of zero or more variables X_{-1} .

The test statistic

$$z^* = (N - 3 - p^*)^{\frac{1}{2}} \left[z - \frac{1}{2} \log \left(\frac{1 + \rho_0}{1 - \rho_0} \right) - \frac{\rho_0}{2(N - 1 - p^*)} \right]$$

is assumed to have a normal distribution $N(\delta, \nu)$ where ρ_0 is the null partial correlation and δ and ν are derived from section 16.33 of Stuart and Ord (1994):

$$\begin{aligned} \delta = & (N - 3 - p^*)^{\frac{1}{2}} \left[\frac{1}{2} \log \left(\frac{1 + \rho_{Y|(X_1, X_{-1})}}{1 - \rho_{Y|(X_1, X_{-1})}} \right) + \right. \\ & \frac{\rho_{Y|(X_1, X_{-1})}}{2(N - 1 - p^*)} \left(1 + \frac{5 + \rho_{Y|(X_1, X_{-1})}^2}{4(N - 1 - p^*)} + \right. \\ & \left. \left. \frac{11 + 2\rho_{Y|(X_1, X_{-1})}^2 + 3\rho_{Y|(X_1, X_{-1})}^4}{8(N - 1 - p^*)^2} \right) \right] \end{aligned}$$

$$\nu = \frac{N-3-p^*}{N-1-p^*} \left[1 + \frac{4 - \rho_{Y|(X_1, X_{-1})}^2}{2(N-1-p^*)} + \frac{22 - 6\rho_{Y|(X_1, X_{-1})}^2 - 3\rho_{Y|(X_1, X_{-1})}^4}{6(N-1-p^*)^2} \right] - \frac{1}{2} \log \left(\frac{1 + \rho_0}{1 - \rho_0} \right) - \frac{\rho_0}{2(N-1-p^*)}$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi \left(\frac{\delta - z_{1-\alpha}}{\nu^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\ \Phi \left(\frac{-\delta - z_{1-\alpha}}{\nu^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\ \Phi \left(\frac{\delta - z_{1-\frac{\alpha}{2}}}{\nu^{\frac{1}{2}}} \right) + \Phi \left(\frac{-\delta - z_{1-\frac{\alpha}{2}}}{\nu^{\frac{1}{2}}} \right), & \text{2-sided} \end{cases}$$

Because the test is biased, the achieved significance level may differ from the nominal significance level. The actual alpha is computed in the same way as the power except with the correlation $\rho_{Y|(X_1, X_{-1})}$ replaced by the null correlation ρ_0 .

t Test for Pearson Correlation (TEST=PEARSON DIST=T)

The 2-sided case is identical to multiple regression with an intercept and $p_1 = 1$, which is discussed in the “Analyses in the MULTREG Statement” section on page 3500.

Let p^* denote the number of variables partialled out. For the 1-sided cases, the test statistic is

$$t = (N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{(1 - R_{YX_1|X_{-1}}^2)^{\frac{1}{2}}}$$

which is assumed to have a null distribution of $t(N - 2 - p^*)$.

If the X and Y variables are assumed to have a joint multivariate normal distribution, then the exact power is given by the following formula:

$$\text{power} = \begin{cases} P \left[(N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{(1 - R_{YX_1|X_{-1}}^2)^{\frac{1}{2}}} \geq t_{1-\alpha}(N - 2 - p^*) \right], & \text{upper 1-sided} \\ P \left[(N - 2 - p^*)^{\frac{1}{2}} \frac{R_{YX_1|X_{-1}}}{(1 - R_{YX_1|X_{-1}}^2)^{\frac{1}{2}}} \leq t_{\alpha}(N - 2 - p^*) \right], & \text{lower 1-sided} \end{cases}$$

$$= \begin{cases} P \left[R_{Y|(X_1, X_{-1})} \geq \frac{t_{1-\alpha}(N-2-p^*)}{\left(t_{1-\alpha}^2(N-2-p^*) + \frac{1}{N-2-p^*}\right)^{\frac{1}{2}}} \right], & \text{upper 1-sided} \\ P \left[R_{Y|(X_1, X_{-1})} \leq \frac{t_{\alpha}(N-2-p^*)}{\left(t_{\alpha}^2(N-2-p^*) + \frac{1}{N-2-p^*}\right)^{\frac{1}{2}}} \right], & \text{lower 1-sided} \end{cases}$$

The distribution of $R_{Y|(X_1, X_{-1})}$ (given the underlying true correlation $\rho_{Y|(X_1, X_{-1})}$) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995).

If the X variables are assumed to have fixed values, then the exact power is given by the noncentral t distribution $t(N-2-p^*, \delta)$, where the noncentrality is

$$\delta = N^{\frac{1}{2}} \frac{\rho_{YX_1|X_{-1}}}{\left(1 - \rho_{YX_1|X_{-1}}^2\right)^{\frac{1}{2}}}$$

The power is

$$\text{power} = \begin{cases} P(t(N-2-p^*, \delta) \geq t_{1-\alpha}(N-2-p^*)), & \text{upper 1-sided} \\ P(t(N-2-p^*, \delta) \leq t_{\alpha}(N-2-p^*)), & \text{lower 1-sided} \end{cases}$$

Analyses in the ONESAMPLEFREQ Statement

Exact Test of a Binomial Proportion (TEST=EXACT)

Let X be distributed as $\text{Bin}(N, p)$. The hypotheses for the test of the proportion p are as follows:

$$H_0 : p = p_0$$

$$H_1 : \begin{cases} p \neq p_0, & \text{2-sided} \\ p > p_0, & \text{upper 1-sided} \\ p < p_0, & \text{lower 1-sided} \end{cases}$$

The exact test assumes binomially distributed data and requires $N \geq 1$ and $0 < p_0 < 1$. The test statistic is

$$X = \text{number of successes} \sim \text{Bin}(N, p)$$

The significance probability α is split symmetrically for 2-sided tests, in the sense that each tail is filled with as much as possible up to $\alpha/2$.

Exact power computations are based on the binomial distribution and computing formulas such as the following from Johnson and Kotz (1970, equation 3.20):

$$P(X \geq C | N, p) = P\left(F_{\nu_1, \nu_2} \leq \frac{\nu_2 p}{\nu_1(1-p)}\right)$$

where $\nu_1 = 2C$ and $\nu_2 = 2(N - C + 1)$

Let C_L and C_U denote lower and upper critical values, respectively. Let α_a denote the achieved (actual) significance level, which for 2-sided tests is the sum of the favorable major tail (α_M) and the opposite minor tail (α_m).

For the upper 1-sided case,

$$\begin{aligned} C_U &= \min\{C : P(X \geq C|p_0) \leq \alpha\} \\ \text{Reject } H_0 &\text{ if } X \geq C_U \\ \alpha_a &= P(X \geq C_U|p_0) \\ \text{power} &= P(X \geq C_U|p) \end{aligned}$$

For the lower 1-sided case,

$$\begin{aligned} C_L &= \max\{C : P(X \leq C|p_0) \leq \alpha\} \\ \text{Reject } H_0 &\text{ if } X \leq C_L \\ \alpha_a &= P(X \leq C_L|p_0) \\ \text{power} &= P(X \leq C_L|p) \end{aligned}$$

For the 2-sided case,

$$\begin{aligned} C_L &= \max\{C : P(X \leq C|p_0) \leq \frac{\alpha}{2}\} \\ C_U &= \min\{C : P(X \geq C|p_0) \leq \frac{\alpha}{2}\} \\ \text{Reject } H_0 &\text{ if } X \leq C_L \text{ or } X \geq C_U \\ \alpha_a &= P(X \leq C_L \text{ or } X \geq C_U|p_0) \\ \text{power} &= P(X \leq C_L \text{ or } X \geq C_U|p) \end{aligned}$$

z Test for Binomial Proportion (TEST=Z)

For the normal approximation test, the test statistic is

$$Z(X) = \frac{X - Np_0}{[Np_0(1 - p_0)]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, the computations are the same as described in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 except for the definitions of the critical values.

For the upper 1-sided case,

$$C_U = \min\{C : Z(C) \geq z_{1-\alpha}\}$$

For the lower 1-sided case,

$$C_L = \max\{C : Z(C) \leq z_\alpha\}$$

For the 2-sided case,

$$\begin{aligned} C_L &= \max\{C : Z(C) \leq z_{\frac{\alpha}{2}}\} \\ C_U &= \min\{C : Z(C) \geq z_{1-\frac{\alpha}{2}}\} \end{aligned}$$

For the METHOD=NORMAL option, the test statistic $Z(X)$ is assumed to have the normal distribution

$$N\left(\frac{N^{\frac{1}{2}}(p-p_0)}{[p_0(1-p_0)]^{\frac{1}{2}}}, \frac{p(1-p)}{p_0(1-p_0)}\right)$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(\frac{z_{\alpha} + \sqrt{N} \frac{p-p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{\frac{p(1-p)}{p_0(1-p_0)}}}\right), & \text{upper 1-sided} \\ \Phi\left(\frac{z_{\alpha} - \sqrt{N} \frac{p-p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{\frac{p(1-p)}{p_0(1-p_0)}}}\right), & \text{lower 1-sided} \\ \Phi\left(\frac{z_{\frac{\alpha}{2}} + \sqrt{N} \frac{p-p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{\frac{p(1-p)}{p_0(1-p_0)}}}\right) + \Phi\left(\frac{z_{\frac{\alpha}{2}} - \sqrt{N} \frac{p-p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{\frac{p(1-p)}{p_0(1-p_0)}}}\right), & \text{2-sided} \end{cases}$$

The approximate sample size is computed in closed form for the 1-sided cases by inverting the power equation,

$$N = \left(\frac{z_{\text{power}} \sqrt{p(1-p)} + z_{1-\alpha} \sqrt{p_0(1-p_0)}}{p-p_0}\right)^2$$

and by numerical inversion for the 2-sided case.

z Test for Binomial Proportion with Continuity Adjustment (TEST=ADJZ)

For the normal approximation test with continuity adjustment, the test statistic is (Pagano and Gauvreau 1993 p. 295):

$$Z_c(X) = \frac{X - Np_0 + 0.5(1_{\{X < Np_0\}}) - 0.5(1_{\{X > Np_0\}})}{[Np_0(1-p_0)]^{\frac{1}{2}}}$$

For the METHOD=EXACT option, the computations are the same as described in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 except for the definitions of the critical values.

For the upper 1-sided case,

$$C_U = \min\{C : Z_c(C) \geq z_{1-\alpha}\}$$

For the lower 1-sided case,

$$C_L = \max\{C : Z_c(C) \leq z_\alpha\}$$

For the 2-sided case,

$$\begin{aligned} C_L &= \max\{C : Z_c(C) \leq z_{\frac{\alpha}{2}}\} \\ C_U &= \min\{C : Z_c(C) \geq z_{1-\frac{\alpha}{2}}\} \end{aligned}$$

For the METHOD=NORMAL option, the test statistic $Z_c(X)$ is assumed to have the normal distribution $N(\mu, \sigma^2)$ where μ and σ^2 are derived as follows.

For convenience of notation, define

$$k = \frac{1}{2\sqrt{Np_0(1-p_0)}}$$

Then

$$E[Z_c(X)] = 2kNp - 2kNp_0 + kP(X < Np_0) - kP(X > Np_0)$$

and

$$\begin{aligned} \text{Var}[Z_c(X)] &= \frac{p(1-p)}{p_0(1-p_0)} + k^2 [1 - P(X = Np_0)] \\ &\quad - k^2 [P(X < Np_0) - P(X > Np_0)]^2 \\ &\quad + 4k^2 [E(X1_{\{X < Np_0\}}) - E(X1_{\{X > Np_0\}})] \\ &\quad - 4k^2 Np [P(X < Np_0) - P(X > Np_0)] \end{aligned}$$

The probabilities $P(X = Np_0)$, $P(X < Np_0)$, and $P(X > Np_0)$ and the truncated expectations $E(X1_{\{X < Np_0\}})$ and $E(X1_{\{X > Np_0\}})$ are approximated by assuming the normal-approximate distribution of X , $N(Np, Np(1-p))$. Letting $\phi(\cdot)$ and $\Phi(\cdot)$ denote the standard normal PDF and CDF, respectively, and defining d as

$$d = \frac{Np_0 - Np}{[Np(1-p)]^{\frac{1}{2}}}$$

the terms are computed as follows:

$$\begin{aligned} P(X = Np_0) &= 0 \\ P(X < Np_0) &= \Phi(d) \end{aligned}$$

$$\begin{aligned}
 P(X > Np_0) &= 1 - \Phi(d) \\
 E(X1_{\{X < Np_0\}}) &= Np\Phi(d) - [Np(1-p)]^{\frac{1}{2}}\phi(d) \\
 E(X1_{\{X > Np_0\}}) &= Np[1 - \Phi(d)] + [Np(1-p)]^{\frac{1}{2}}\phi(d)
 \end{aligned}$$

The mean and variance of $Z_c(X)$ are thus approximated by

$$\mu = k [2Np - 2Np_0 + 2\Phi(d) - 1]$$

and

$$\sigma^2 = 4k^2 \left[Np(1-p) + \Phi(d)(1 - \Phi(d)) - 2(Np(1-p))^{\frac{1}{2}}\phi(d) \right]$$

The approximate power is computed as

$$\text{power} = \begin{cases} \Phi\left(\frac{z_{\alpha} + \mu}{\sigma}\right), & \text{upper 1-sided} \\ \Phi\left(\frac{z_{\alpha} - \mu}{\sigma}\right), & \text{lower 1-sided} \\ \Phi\left(\frac{z_{\frac{\alpha}{2}} + \mu}{\sigma}\right) + \Phi\left(\frac{z_{\frac{\alpha}{2}} - \mu}{\sigma}\right), & \text{2-sided} \end{cases}$$

Analyses in the ONESAMPLEMEANS Statement

One-sample t Test (TEST=T)

The hypotheses for the one-sample t test are

$$\begin{aligned}
 H_0 &: \mu = \mu_0 \\
 H_1 &: \begin{cases} \mu \neq \mu_0, & \text{2-sided} \\ \mu > \mu_0, & \text{upper 1-sided} \\ \mu < \mu_0, & \text{lower 1-sided} \end{cases}
 \end{aligned}$$

The test assumes normally distributed data and requires $N \geq 2$. The test statistics are

$$\begin{aligned}
 t &= N^{\frac{1}{2}} \left(\frac{\bar{x} - \mu_0}{s} \right) \sim t(N - 1, \delta) \\
 t^2 &\sim F(1, N - 1, \delta^2)
 \end{aligned}$$

where \bar{x} is the sample mean, s is the sample standard deviation, and

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu - \mu_0}{\sigma} \right)$$

The test is

$$\text{Reject } H_0 \text{ if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N-1), & \text{2-sided} \\ t \geq t_{1-\alpha}(N-1), & \text{upper 1-sided} \\ t \leq t_{\alpha}(N-1), & \text{lower 1-sided} \end{cases}$$

Exact power computations for t tests are discussed in O'Brien and Muller (1993, section 8.2), although not specifically for the one-sample case. The power is based on the noncentral t and F distributions:

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{2-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper 1-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower 1-sided} \end{cases}$$

Solutions for N , α , and δ are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of δ , are as follows:

$$\begin{aligned} \mu &= \delta \sigma N^{-\frac{1}{2}} + \mu_0 \\ \sigma &= \begin{cases} \delta^{-1} N^{\frac{1}{2}} (\mu - \mu_0), & |\delta| > 0 \\ \text{undefined}, & \text{otherwise} \end{cases} \end{aligned}$$

One-sample t Test with Lognormal Data (TEST=T DIST=LOGNORMAL)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “One-sample t Test (TEST=T)” section on page 3508 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of a null arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the one-sample t test with lognormal data are

$$\begin{aligned} H_0 &: \frac{\gamma}{\gamma_0} = 1 \\ H_1 &: \begin{cases} \frac{\gamma}{\gamma_0} \neq 1, & \text{2-sided} \\ \frac{\gamma}{\gamma_0} > 1, & \text{upper 1-sided} \\ \frac{\gamma}{\gamma_0} < 1, & \text{lower 1-sided} \end{cases} \end{aligned}$$

Let μ^* and σ^* be the (arithmetic) mean and standard deviation of the normal distribution of the log-transformed data. The hypotheses can be rewritten as follows:

$$H_0 : \mu^* = \log(\gamma_0)$$

$$H_1 : \begin{cases} \mu^* \neq \log(\gamma_0), & \text{2-sided} \\ \mu^* > \log(\gamma_0), & \text{upper 1-sided} \\ \mu^* < \log(\gamma_0), & \text{lower 1-sided} \end{cases}$$

where $\mu^* = \log(\gamma)$.

The test assumes lognormally distributed data and requires $N \geq 2$.

The power is

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{2-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper 1-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower 1-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu^* - \log(\gamma_0)}{\sigma^*} \right)$$

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

Equivalence Test for Mean of Normal Data (TEST=EQUIV DIST=NORMAL)

The hypotheses for the equivalence test are

$$H_0 : \mu < \theta_L \text{ or } \mu > \theta_U$$

$$H_1 : \theta_L \leq \mu \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 2$. Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a one-sample design:

$$\text{power} = Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\mu - \theta_U}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) -$$

$$Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\mu - \theta_L}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right)$$

where $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the "Common Notation" section on page 3498.

Equivalence Test for Mean of Lognormal Data (TEST=EQUIV DIST=LOGNORMAL)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “[Equivalence Test for Mean of Normal Data \(TEST=EQUIV DIST=NORMAL\)](#)” section on page 3510 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of an arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the equivalence test are

$$H_0 : \gamma \leq \theta_L \text{ or } \gamma \geq \theta_U$$

$$H_1 : \theta_L < \gamma < \theta_U$$

$$\text{where } 0 < \theta_L < \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 2$. Diletti, Hauschke, and Steinijs (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a one-sample design:

$$\begin{aligned} \text{power} = & Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\log(\gamma) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ & Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\log(\gamma) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) \end{aligned}$$

where

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

is the standard deviation of the log-transformed data, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the “[Common Notation](#)” section on page 3498.

Confidence Interval for Mean (CI=T)

This analysis of precision applies to the standard t -based confidence interval:

$$\begin{cases} \left[\bar{x} - t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}}, \bar{x} + t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}} \right], & \text{2-sided} \\ \left[\bar{x} - t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}}, \infty \right), & \text{upper 1-sided} \\ \left(-\infty, \bar{x} + t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}} \right], & \text{lower 1-sided} \end{cases}$$

where \bar{x} is the sample mean and s is the sample standard deviation. The “half-width” is defined as the distance from the point estimate \bar{x} to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-1)\frac{s}{\sqrt{N}}, & \text{2-sided} \\ t_{1-\alpha}(N-1)\frac{s}{\sqrt{N}}, & \text{1-sided} \end{cases}$$

A “valid” confidence interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma^2(t_{1-\frac{\alpha}{2}}^2(N-1))}\right), & \text{2-sided} \\ P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma^2(t_{1-\alpha}^2(N-1))}\right), & \text{1-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-1}\left((t_{1-\frac{\alpha}{2}}(N-1)), 0; 0, b_1\right) - Q_{N-1}(0, 0; 0, b_1) \right], & \text{2-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-1}\left((t_{1-\alpha}(N-1)), 0; 0, b_1\right), & \text{1-sided} \end{cases} \end{aligned}$$

where

$$\begin{aligned} b_1 &= \frac{h(N-1)^{\frac{1}{2}}}{\sigma(t_{1-\frac{\alpha}{2}}(N-1))N^{-\frac{1}{2}}} \\ c &= \text{number of sides} \end{aligned}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the “Common Notation” section on page 3498.

A “quality” confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the ONEWAYANOVA Statement**One-Degree-of-Freedom Contrast (TEST=CONTRAST)**

The hypotheses are

$$H_0 : c_1\mu_1 + \cdots + c_G\mu_G = c_0$$

$$H_1 : \begin{cases} c_1\mu_1 + \cdots + c_G\mu_G \neq c_0, & \text{2-sided} \\ c_1\mu_1 + \cdots + c_G\mu_G > c_0, & \text{upper 1-sided} \\ c_1\mu_1 + \cdots + c_G\mu_G < c_0, & \text{lower 1-sided} \end{cases}$$

where G is the number of groups, $\{c_1, \dots, c_G\}$ are the contrast coefficients, and c_0 is the null contrast value.

The test is the usual F test for a contrast in one-way ANOVA. It assumes normal data with common group variances and requires $N \geq G + 1$ and $n_i \geq 1$.

O'Brien and Muller (1993, section 8.2.3.2) give the exact power as

$$\text{power} = \begin{cases} P(F(1, N - G, \delta^2) \geq F_{1-\alpha}(1, N - G)), & \text{2-sided} \\ P(t(N - G, \delta) \geq t_{1-\alpha}(N - G)), & \text{upper 1-sided} \\ P(t(N - G, \delta) \leq t_{\alpha}(N - G)), & \text{lower 1-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\sum_{i=1}^G c_i \mu_i - c_0}{\sigma \left(\sum_{i=1}^G \frac{c_i^2}{w_i} \right)^{\frac{1}{2}}} \right)$$

Overall F Test (TEST=OVERALL)

The hypotheses are

$$H_0 : \mu_1 = \mu_2 = \cdots = \mu_G$$

$$H_1 : \mu_i \neq \mu_j \text{ for some } i, j$$

where G is the number of groups.

The test is the usual overall F test for equality of means in one-way ANOVA. It assumes normal data with common group variances and requires $N \geq G + 1$ and $n_i \geq 1$.

O'Brien and Muller (1993, section 8.2.3.1) give the exact power as

$$\text{power} = P(F(G - 1, N - G, \lambda) \geq F_{1-\alpha}(G - 1, N - G))$$

where the noncentrality is

$$\lambda = N \left(\frac{\sum_{i=1}^G w_i (\mu_i - \bar{\mu})^2}{\sigma^2} \right)$$

and

$$\bar{\mu} = \sum_{i=1}^G w_i \mu_i$$

Analyses in the PAIREDFREQ Statement

Overview of Conditional McNemar tests

Notation:

		Case		
		Failure	Success	
Control	Failure	n_{00}	n_{01}	$n_{0\cdot}$
	Success	n_{10}	n_{11}	$n_{1\cdot}$
		$n_{\cdot 0}$	$n_{\cdot 1}$	N

$$n_{00} = \#\{\text{control=failure, case=failure}\}$$

$$n_{01} = \#\{\text{control=failure, case=success}\}$$

$$n_{10} = \#\{\text{control=success, case=failure}\}$$

$$n_{11} = \#\{\text{control=success, case=success}\}$$

$$N = n_{00} + n_{01} + n_{10} + n_{11}$$

$$n_D = n_{01} + n_{10} \equiv \#\text{ discordant pairs}$$

$$\hat{\pi}_{ij} = \frac{n_{ij}}{N}$$

$$\pi_{ij} = \text{theoretical population value of } \hat{\pi}_{ij}$$

$$\pi_{1\cdot} = \pi_{10} + \pi_{11}$$

$$\pi_{\cdot 1} = \pi_{01} + \pi_{11}$$

$$OR = \text{“odds ratio”} = \frac{\pi_{01}}{\pi_{10}}$$

$$OR_0 = \text{null odds ratio}$$

All McNemar tests covered in PROC POWER are *conditional*, meaning that n_D is assumed fixed at its observed value.

For the usual $OR_0 = 0$, the hypotheses are

$$\begin{aligned}
 H_0 & : \pi_{\cdot 1} = \pi_{1\cdot} \\
 H_1 & : \begin{cases} \pi_{\cdot 1} \neq \pi_{1\cdot}, & \text{2-sided} \\ \pi_{\cdot 1} > \pi_{1\cdot}, & \text{upper 1-sided} \\ \pi_{\cdot 1} < \pi_{1\cdot}, & \text{lower 1-sided} \end{cases}
 \end{aligned}$$

The test statistic for both tests covered in PROC POWER (DIST=EXACT_COND and DIST=NORMAL) is the McNemar statistic Q_M , which has the following form when $OR_0 = 0$:

$$Q_{M_0} = \frac{(n_{01} - n_{10})^2}{n_{01} + n_{10}}$$

For the conditional McNemar tests, this is equivalent to the square of the $Z(X)$ statistic for the test of a single proportion (normal approximation to binomial), where the proportion is $\frac{\pi_{01}}{\pi_{01} + \pi_{10}}$, the null is 0.5, and “ N ” is n_D (see, e.g., Schork and Williams 1980):

$$\begin{aligned}
 Z(X) & = \frac{n_{01} - n_D(0.5)}{[n_D 0.5(1 - 0.5)]^{\frac{1}{2}}} \sim N \left(\frac{n_D^{\frac{1}{2}} \left(\frac{\pi_{01}}{\pi_{01} + \pi_{10}} - 0.5 \right)}{[0.5(1 - 0.5)]^{\frac{1}{2}}}, \frac{\frac{\pi_{01}}{\pi_{01} + \pi_{10}} \left(1 - \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \right)}{0.5(1 - 0.5)} \right) \\
 & = \frac{n_{01} - (n_{01} + n_{10})(0.5)}{[(n_{01} + n_{10})0.5(1 - 0.5)]^{\frac{1}{2}}} \\
 & = \frac{n_{01} - n_{10}}{[n_{01} + n_{10}]^{\frac{1}{2}}} \\
 & = \sqrt{Q_{M_0}}
 \end{aligned}$$

This can be generalized to a custom null for $\frac{\pi_{01}}{\pi_{01} + \pi_{10}}$, which is equivalent to specifying a custom odds ratio:

$$\left[\frac{\pi_{01}}{\pi_{01} + \pi_{10}} \right]_0 \equiv \left[\frac{1}{1 + \frac{1}{\frac{\pi_{01}}{\pi_{10}}}} \right]_0 \equiv \frac{1}{1 + \frac{1}{OR_0}}$$

So, a conditional McNemar test (asymptotic or exact) with a custom null is equivalent to the test of a single proportion $p_1 \equiv \frac{\pi_{01}}{\pi_{01} + \pi_{10}}$ with a null value $p_0 \equiv \frac{1}{1 + \frac{1}{OR_0}}$, with a sample size of n_D :

$$\begin{aligned}
 H_0 & : p_1 = p_0 \\
 H_1 & : \begin{cases} p_1 \neq p_0, & \text{2-sided} \\ p_1 > p_0, & \text{1-sided U} \\ p_1 < p_0, & \text{1-sided L} \end{cases}
 \end{aligned}$$

which is equivalent to

$$H_0 : OR = OR_0$$

$$H_1 : \begin{cases} OR \neq OR_0, & \text{2-sided} \\ OR > OR_0, & \text{1-sided U} \\ OR < OR_0, & \text{1-sided L} \end{cases}$$

The general form of the test statistic is thus

$$Q_M = \frac{(n_{01} - n_D p_0)^2}{n_D p_0 (1 - p_0)}$$

The two most common conditional McNemar tests assume either the exact conditional distribution of Q_M (covered by the DIST=EXACT_COND analysis) or a standard normal distribution for Q_M (covered by the DIST=NORMAL analysis).

McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)

For DIST=EXACT_COND, the power is calculated assuming that the test is conducted using the exact conditional distribution of Q_M (conditional on n_D). The power is calculated by first computing the conditional power for each possible n_D . The unconditional power is computed as a weighted average over all possible outcomes of n_D :

$$\text{power} = \sum_{n_D=0}^N P(n_D) P(\text{Reject } p_1 = p_0 | n_D)$$

where $n_D \sim \text{Bin}(\pi_{01} + \pi_{10}, N)$, and $P(\text{Reject } p_1 = p_0 | n_D)$ is calculated using the exact method in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504.

The achieved significance level, reported as Actual Alpha in the analysis, is computed in the same way except using the actual alpha of the one-sample test in place of its power:

$$\text{actual alpha} = \sum_{n_D=0}^N P(n_D) \alpha^*(p_1, p_0 | n_D)$$

where $\alpha^*(p_1, p_0 | n_D)$ is the actual alpha calculated using the exact method in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 with proportion p_1 , null p_0 , and sample size n_D .

McNemar Normal Approximation Test (TEST=MCNEMAR DIST=NORMAL)

For DIST=NORMAL, power is calculated assuming the test is conducted using the normal-approximate distribution of Q_M (conditional on n_D).

For the METHOD=EXACT option, the power is calculated in the same way as described in the “McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)” section on page 3516, except that $P(\text{Reject } p_1 = p_0 | n_D)$ is calculated using the exact method in the “z Test for Binomial Proportion (TEST=Z)” section on page 3505. The achieved significance level is calculated in the same way as described at the end of the “McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT_COND)” section on page 3516.

For the METHOD=MIETTINEN option, approximate sample size for the 1-sided cases is computed according to equation (5.6) in Miettinen (1968):

$$N = \frac{\left\{ z_{1-\alpha}(p_{10} + p_{01}) + z_{power} \left[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01}) \right]^{\frac{1}{2}} \right\}^2}{(p_{10} + p_{01})(p_{01} - p_{10})^2}$$

Approximate power for the 1-sided cases is computed by solving the sample size equation for power, and approximate power for the 2-sided case follows easily by summing the 1-sided powers each at $\alpha/2$:

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\ \Phi \left(\frac{-(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\alpha}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\ \Phi \left(\frac{(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_{01} - p_{10})[N(p_{10} + p_{01})]^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10} + p_{01})}{[(p_{10} + p_{01})^2 - \frac{1}{4}(p_{01} - p_{10})^2(3 + p_{10} + p_{01})]^{\frac{1}{2}}} \right), & \text{2-sided} \end{cases}$$

The 2-sided solution for N is obtained by numerically inverting the power equation.

In general, compared to METHOD=CONNOR, the METHOD=MIETTINEN approximation tends to be slightly more accurate but may be slightly anticonservative in the sense of underestimating sample size and overestimating power (Lachin 1992, p. 1250).

For the METHOD=CONNOR option, approximate sample size for the 1-sided cases is computed according to equation (3) in Connor (1987):

$$N = \frac{\left\{ z_{1-\alpha}(p_{10} + p_{01})^{\frac{1}{2}} + z_{power} [p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}} \right\}^2}{(p_{01} - p_{10})^2}$$

Approximate power for the 1-sided cases is computed by solving the sample size equation for power, and approximate power for the 2-sided case follows easily by summing the 1-sided powers each at $\alpha/2$:

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_{01}-p_{10})N^{\frac{1}{2}} - z_{1-\alpha}(p_{10}+p_{01})^{\frac{1}{2}}}{[p_{10}+p_{01}-(p_{01}-p_{10})^2]^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\ \Phi \left(\frac{-(p_{01}-p_{10})N^{\frac{1}{2}} - z_{1-\alpha}(p_{10}+p_{01})^{\frac{1}{2}}}{[p_{10}+p_{01}-(p_{01}-p_{10})^2]^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\ \Phi \left(\frac{(p_{01}-p_{10})N^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10}+p_{01})^{\frac{1}{2}}}{[p_{10}+p_{01}-(p_{01}-p_{10})^2]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_{01}-p_{10})N^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}}(p_{10}+p_{01})^{\frac{1}{2}}}{[p_{10}+p_{01}-(p_{01}-p_{10})^2]^{\frac{1}{2}}} \right), & \text{2-sided} \end{cases}$$

The 2-sided solution for N is obtained by numerically inverting the power equation.

In general, compared to METHOD=MIETTINEN, the METHOD=CONNOR approximation tends to be slightly less accurate but slightly conservative in the sense of overestimating sample size and underestimating power (Lachin 1992, p. 1250).

Analyses in the PAIREDMEANS Statement

Paired t Test (TEST=DIFF)

The hypotheses for the paired t test are

$$H_0 : \mu_{\text{diff}} = \mu_0$$

$$H_1 : \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{2-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper 1-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower 1-sided} \end{cases}$$

The test assumes normally distributed data and requires $N \geq 2$. The test statistics are

$$t = N^{\frac{1}{2}} \left(\frac{\bar{d} - \mu_0}{s_d} \right) \sim t(N-1, \delta)$$

$$t^2 \sim F(1, N-1, \delta^2)$$

where \bar{d} and s_d are the sample mean and standard deviation of the differences and

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma_{\text{diff}}} \right)$$

and

$$\sigma_{\text{diff}} = (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}}$$

The test is

$$\text{Reject } H_0 \quad \text{if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N-1), & \text{2-sided} \\ t \geq t_{1-\alpha}(N-1), & \text{upper 1-sided} \\ t \leq t_{\alpha}(N-1), & \text{lower 1-sided} \end{cases}$$

Exact power computations for t tests are given in O'Brien and Muller (1993, section 8.2.2):

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{2-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper 1-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower 1-sided} \end{cases}$$

Paired t Test for Mean Ratio with Lognormal Data (TEST=RATIO)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Paired t Test (TEST=DIFF)” section on page 3518 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the paired t test with lognormal pairs $\{Y_1, Y_2\}$ are

$$H_0 : \frac{\gamma_2}{\gamma_1} = \gamma_0$$

$$H_1 : \begin{cases} \frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{2-sided} \\ \frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper 1-sided} \\ \frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower 1-sided} \end{cases}$$

Let μ_1^* , μ_2^* , σ_1^* , σ_2^* , and ρ^* be the (arithmetic) means, standard deviations, and correlation of the bivariate normal distribution of the log-transformed data $\{\log Y_1, \log Y_2\}$. The hypotheses can be rewritten as follows:

$$H_0 : \mu_2^* - \mu_1^* = \log(\gamma_0)$$

$$H_1 : \begin{cases} \mu_2^* - \mu_1^* \neq \log(\gamma_0), & \text{2-sided} \\ \mu_2^* - \mu_1^* > \log(\gamma_0), & \text{upper 1-sided} \\ \mu_2^* - \mu_1^* < \log(\gamma_0), & \text{lower 1-sided} \end{cases}$$

where

$$\begin{aligned} \mu_1^* &= \log \gamma_1 \\ \mu_2^* &= \log \gamma_2 \\ \sigma_1^* &= [\log(\text{CV}_1^2 + 1)]^{\frac{1}{2}} \end{aligned}$$

$$\begin{aligned}\sigma_2^* &= [\log(\text{CV}_2^2 + 1)]^{\frac{1}{2}} \\ \rho^* &= \frac{\log\{\rho \text{CV}_1 \text{CV}_2 + 1\}}{\sigma_1^* \sigma_2^*}\end{aligned}$$

and CV_1 , CV_2 , and ρ are the coefficients of variation and the correlation of the original untransformed pairs $\{Y_1, Y_2\}$. The conversion from ρ to ρ^* is shown in Jones and Miller (1966).

The test assumes lognormally distributed data and requires $N \geq 2$. The power is

$$\text{power} = \begin{cases} P(F(1, N-1, \delta^2) \geq F_{1-\alpha}(1, N-1)), & \text{2-sided} \\ P(t(N-1, \delta) \geq t_{1-\alpha}(N-1)), & \text{upper 1-sided} \\ P(t(N-1, \delta) \leq t_{\alpha}(N-1)), & \text{lower 1-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left(\frac{\mu_1^* - \mu_2^* - \log(\gamma_0)}{\sigma^*} \right)$$

and

$$\sigma^* = (\sigma_1^{*2} + \sigma_2^{*2} - 2\rho^* \sigma_1^* \sigma_2^*)^{\frac{1}{2}}$$

Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)

The hypotheses for the equivalence test are

$$\begin{aligned}H_0 &: \mu_{\text{diff}} < \theta_L \quad \text{or} \quad \mu_{\text{diff}} > \theta_U \\ H_1 &: \theta_L \leq \mu_{\text{diff}} \leq \theta_U\end{aligned}$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 2$. Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a paired design:

$$\begin{aligned}\text{power} &= Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\mu_{\text{diff}} - \theta_U}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma_{\text{diff}} N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ &Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\mu_{\text{diff}} - \theta_L}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N-1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma_{\text{diff}} N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right)\end{aligned}$$

where

$$\sigma_{\text{diff}} = (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the "Common Notation" section on page 3498.

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data (TEST=EQUIV_RATIO)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)” section on page 3520 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

$$H_0 : \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U$$

$$H_1 : \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U$$

$$\text{where } 0 < \theta_L < \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 2$. Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a paired design:

$$\begin{aligned} \text{power} = & Q_{N-1} \left((-t_{1-\alpha}(N-1)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) - \\ & Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-1)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(t_{1-\alpha}(N-1))} \right) \end{aligned}$$

where σ^* is the standard deviation of the differences between the log-transformed pairs (in other words, the standard deviation of $\log(Y_T) - \log(Y_R)$, where Y_T and Y_R are observations from the treatment and reference, respectively), computed as

$$\begin{aligned} \sigma^* &= (\sigma_R^{*2} + \sigma_T^{*2} - 2\rho^* \sigma_R^* \sigma_T^*)^{\frac{1}{2}} \\ \sigma_R^* &= [\log(\text{CV}_R^2 + 1)]^{\frac{1}{2}} \\ \sigma_T^* &= [\log(\text{CV}_T^2 + 1)]^{\frac{1}{2}} \\ \rho^* &= \frac{\log\{\rho \text{CV}_R \text{CV}_T + 1\}}{\sigma_R^* \sigma_T^*} \end{aligned}$$

where CV_R , CV_T , and ρ are the coefficients of variation and the correlation of the original untransformed pairs $\{Y_T, Y_R\}$, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function. The conversion from ρ to ρ^* is shown in Jones and Miller (1966), and Owen's Q function is defined in the "Common Notation" section on page 3498.

Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard t -based confidence interval:

$$\begin{cases} \left[\bar{d} - t_{1-\frac{\alpha}{2}}(N-1)\frac{s_d}{\sqrt{N}}, \bar{d} + t_{1-\frac{\alpha}{2}}(N-1)\frac{s_d}{\sqrt{N}} \right], & \text{2-sided} \\ \left[\bar{d} - t_{1-\alpha}(N-1)\frac{s_d}{\sqrt{N}}, \infty \right), & \text{upper 1-sided} \\ \left(-\infty, \bar{d} + t_{1-\alpha}(N-1)\frac{s_d}{\sqrt{N}} \right], & \text{lower 1-sided} \end{cases}$$

where \bar{d} and s_d are the sample mean and standard deviation of the differences. The "half-width" is defined as the distance from the point estimate \bar{d} to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-1)\frac{s_d}{\sqrt{N}}, & \text{2-sided} \\ t_{1-\alpha}(N-1)\frac{s_d}{\sqrt{N}}, & \text{1-sided} \end{cases}$$

A "valid" confidence interval captures the true mean difference. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma_{\text{diff}}^2(t_{1-\frac{\alpha}{2}}^2(N-1))}\right), & \text{2-sided} \\ P\left(\chi^2(N-1) \leq \frac{h^2 N(N-1)}{\sigma_{\text{diff}}^2(t_{1-\alpha}^2(N-1))}\right), & \text{1-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-1}\left((t_{1-\frac{\alpha}{2}}(N-1)), 0; 0, b_1\right) - Q_{N-1}(0, 0; 0, b_1) \right], & \text{2-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-1}\left((t_{1-\alpha}(N-1)), 0; 0, b_1\right), & \text{1-sided} \end{cases} \end{aligned}$$

where

$$\begin{aligned} \sigma_{\text{diff}} &= (\sigma_1^2 + \sigma_2^2 - 2\rho\sigma_1\sigma_2)^{\frac{1}{2}} \\ b_1 &= \frac{h(N-1)^{\frac{1}{2}}}{\sigma_{\text{diff}}(t_{1-\frac{\alpha}{2}}(N-1))N^{-\frac{1}{2}}} \\ c &= \text{number of sides} \end{aligned}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the "Common Notation" section on page 3498.

A "quality" confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the TWOSAMPLEFREQ Statement**Overview of the 2×2 Table**

Notation:

		Group 2		
		Failure	Success	
Group 1	Failure	x_1	x_2	m
	Success	$n_1 - x_1$	$n_2 - x_2$	$N - m$
		n_1	n_2	N

$$x_1 = \text{\# successes in group 1}$$

$$x_2 = \text{\# successes in group 2}$$

$$m = x_1 + x_2 = \text{total \# successes}$$

$$\hat{p}_1 = \frac{x_1}{n_1}$$

$$\hat{p}_2 = \frac{x_2}{n_2}$$

$$\hat{p} = \frac{m}{N} = w_1\hat{p}_1 + w_2\hat{p}_2$$

The hypotheses are

$$H_0 : p_2 - p_1 = p_0$$

$$H_1 : \begin{cases} p_2 - p_1 \neq p_0, & \text{2-sided} \\ p_2 - p_1 > p_0, & \text{upper 1-sided} \\ p_2 - p_1 < p_0, & \text{lower 1-sided} \end{cases}$$

where p_0 is constrained to be 0 for all but the unconditional Pearson chi-square test.Internal calculations are performed in terms of p_1 , p_2 , and p_0 . An input set consisting of OR , p_1 , and OR_0 is transformed as follows:

$$p_2 = \frac{(OR)p_1}{1 - p_1 + (OR)p_1}$$

$$p_{10} = p_1$$

$$p_{20} = \frac{OR_0 p_{10}}{1 - p_{10} + (OR_0)p_{10}}$$

$$p_0 = p_{20} - p_{10}$$

An input set consisting of RR , p_1 , and RR_0 is transformed as follows:

$$\begin{aligned} p_2 &= (RR)p_1 \\ p_{10} &= p_1 \\ p_{20} &= (RR_0)p_{10} \\ p_0 &= p_{20} - p_{10} \end{aligned}$$

Note that the transformation of either OR_0 or RR_0 to p_0 is not unique. The chosen parameterization fixes the null value p_{10} at the input value of p_1 .

Pearson Chi-square Test for Two Proportions (TEST=PCHI)

The usual Pearson chi-square test is unconditional. The test statistic

$$z_P = \frac{\hat{p}_2 - \hat{p}_1 - p_0}{\left[\hat{p}(1 - \hat{p}) \left(\frac{1}{n_1} + \frac{1}{n_2} \right) \right]^{\frac{1}{2}}} = [Nw_1w_2]^{\frac{1}{2}} \frac{\hat{p}_2 - \hat{p}_1 - p_0}{\hat{p}(1 - \hat{p})}$$

is assumed to have a null distribution of $N(0, 1)$.

Sample size for the 1-sided cases is given by equation (4) in Fleiss, Tytun, and Ury (1980). One-sided power is computed as suggested by Diegert and Diegert (1981) by inverting the sample size formula. Power for the 2-sided case is computed by adding the lower-sided and upper-sided powers each with $\alpha/2$, and sample size for the 2-sided case is obtained by numerically inverting the power formula. A custom null value p_0 for the proportion difference $p_2 - p_1$ is also supported.

$$\text{power} = \begin{cases} \Phi \left(\frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha} [(w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2)]^{\frac{1}{2}}}{[w_2p_1(1 - p_1) + w_1p_2(1 - p_2)]^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\ \Phi \left(\frac{-(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha} [(w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2)]^{\frac{1}{2}}}{[w_2p_1(1 - p_1) + w_1p_2(1 - p_2)]^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\ \Phi \left(\frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}} [(w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2)]^{\frac{1}{2}}}{[w_2p_1(1 - p_1) + w_1p_2(1 - p_2)]^{\frac{1}{2}}} \right) + \\ \Phi \left(\frac{-(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\frac{\alpha}{2}} [(w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2)]^{\frac{1}{2}}}{[w_2p_1(1 - p_1) + w_1p_2(1 - p_2)]^{\frac{1}{2}}} \right), & \text{2-sided} \end{cases}$$

For the 1-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \frac{\left[z_{1-\alpha} \{ (w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2) \}^{\frac{1}{2}} + z_{\text{power}} \{ w_2p_1(1 - p_1) + w_1p_2(1 - p_2) \}^{\frac{1}{2}} \right]^2}{w_1w_2(p_2 - p_1 - p_0)^2}$$

For the 2-sided case, the solution for N is obtained by numerically inverting the power equation.

Likelihood Ratio chi-square Test for Two Proportions (TEST=LRCHI)

The usual likelihood ratio chi-square test is unconditional. The test statistic

$$z_{LR} = (-1_{\{p_2 < p_1\}}) \sqrt{2N \sum_{i=1}^2 \left[w_i \hat{p}_i \log \left(\frac{\hat{p}_i}{\hat{p}} \right) + w_i (1 - \hat{p}_i) \log \left(\frac{1 - \hat{p}_i}{1 - \hat{p}} \right) \right]}$$

is assumed to have a null distribution of $N(0, 1)$ and an alternative distribution of $N(\delta, 1)$ where

$$\delta = N^{\frac{1}{2}} (-1_{\{p_2 < p_1\}}) \sqrt{2 \sum_{i=1}^2 \left[w_i p_i \log \left(\frac{p_i}{w_1 p_1 + w_2 p_2} \right) + w_i (1 - p_i) \log \left(\frac{1 - p_i}{1 - (w_1 p_1 + w_2 p_2)} \right) \right]}$$

The approximate power is

$$\text{power} = \begin{cases} \Phi(\delta - z_{1-\alpha}), & \text{upper 1-sided} \\ \Phi(-\delta - z_{1-\alpha}), & \text{lower 1-sided} \\ \Phi\left(\delta - z_{1-\frac{\alpha}{2}}\right) + \Phi\left(-\delta - z_{1-\frac{\alpha}{2}}\right), & \text{2-sided} \end{cases}$$

For the 1-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \left(\frac{z_{\text{power}} + z_{1-\alpha}}{\delta} \right)^2$$

For the 2-sided case, the solution for N is obtained by numerically inverting the power equation.

Fisher's Exact Conditional Test for Two Proportions (Test=FISHER)

Fisher's exact test is conditional on the observed total number of successes m . Power and sample size computations for the METHOD=WALTERS option are based on a test with similar power properties, the continuity-adjusted arcsine test. The test statistic

$$z_A = (4Nw_1w_2)^{\frac{1}{2}} \left[\arcsin \left(\left[\hat{p}_2 + \frac{1}{2Nw_2} (1_{\{\hat{p}_2 < \hat{p}_1\}} - 1_{\{\hat{p}_2 > \hat{p}_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left(\left[\hat{p}_1 + \frac{1}{2Nw_1} (1_{\{\hat{p}_1 < \hat{p}_2\}} - 1_{\{\hat{p}_1 > \hat{p}_2\}}) \right]^{\frac{1}{2}} \right) \right]$$

is assumed to have a null distribution of $N(0, 1)$ and an alternative distribution of $N(\delta, 1)$ where

$$\delta = (4Nw_1w_2)^{\frac{1}{2}} \left[\arcsin \left(\left[p_2 + \frac{1}{2Nw_2} (1_{\{p_2 < p_1\}} - 1_{\{p_2 > p_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left(\left[p_1 + \frac{1}{2Nw_1} (1_{\{p_1 < p_2\}} - 1_{\{p_1 > p_2\}}) \right]^{\frac{1}{2}} \right) \right]$$

The approximate power for the 1-sided balanced case is given by Walters (1979) and is easily extended to the unbalanced and 2-sided cases:

$$\text{power} = \begin{cases} \Phi(\delta - z_{1-\alpha}), & \text{upper 1-sided} \\ \Phi(-\delta - z_{1-\alpha}), & \text{lower 1-sided} \\ \Phi\left(\delta - z_{1-\frac{\alpha}{2}}\right) + \Phi\left(-\delta - z_{1-\frac{\alpha}{2}}\right), & \text{2-sided} \end{cases}$$

Analyses in the TWOSAMPLEMEANS Statement

Two-sample t Test Assuming Equal Variances (TEST=DIFF)

The hypotheses for the two-sample t test are

$$H_0 : \mu_{\text{diff}} = \mu_0$$

$$H_1 : \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{2-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper 1-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower 1-sided} \end{cases}$$

The test assumes normally distributed data and common standard deviation per group, and it requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. The test statistics are

$$t = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}} \left(\frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{s_p} \right) \sim t(N - 2, \delta)$$

$$t^2 \sim F(1, N - 2, \delta^2)$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_p is the pooled standard deviation, and

$$\delta = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}} \left(\frac{\mu_{\text{diff}} - \mu_0}{\sigma} \right)$$

The test is

$$\text{Reject } H_0 \text{ if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N - 2), & \text{2-sided} \\ t \geq t_{1-\alpha}(N - 2), & \text{upper 1-sided} \\ t \leq t_{\alpha}(N - 2), & \text{lower 1-sided} \end{cases}$$

Exact power computations for t tests are given in O'Brien and Muller (1993, section 8.2.1):

$$\text{power} = \begin{cases} P(F(1, N - 2, \delta^2) \geq F_{1-\alpha}(1, N - 2)), & \text{2-sided} \\ P(t(N - 2, \delta) \geq t_{1-\alpha}(N - 2)), & \text{upper 1-sided} \\ P(t(N - 2, \delta) \leq t_{\alpha}(N - 2)), & \text{lower 1-sided} \end{cases}$$

Solutions for N , n_1 , n_2 , α , and δ are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of δ , are as follows:

$$\begin{aligned}\mu_{\text{diff}} &= \delta\sigma(Nw_1w_2)^{-\frac{1}{2}} + \mu_0 \\ \mu_1 &= \delta\sigma(Nw_1w_2)^{-\frac{1}{2}} + \mu_0 - \mu_2 \\ \mu_2 &= \delta\sigma(Nw_1w_2)^{-\frac{1}{2}} + \mu_0 - \mu_1 \\ \sigma &= \begin{cases} \delta^{-1}(Nw_1w_2)^{\frac{1}{2}}(\mu_{\text{diff}} - \mu_0), & |\delta| > 0 \\ \text{undefined}, & \text{otherwise} \end{cases} \\ w_1 &= \begin{cases} \frac{1}{2} \pm \frac{1}{2} \left[1 - \frac{4\delta^2\sigma^2}{N(\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2}N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\ \text{undefined}, & \text{otherwise} \end{cases} \\ w_2 &= \begin{cases} \frac{1}{2} \pm \frac{1}{2} \left[1 - \frac{4\delta^2\sigma^2}{N(\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2}N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\ \text{undefined}, & \text{otherwise} \end{cases}\end{aligned}$$

Finally, here is a derivation of the solution for w_1 :

Solve the δ equation for w_1 (which requires the quadratic formula). Then determine the range of δ given w_1 :

$$\begin{aligned}\min_{w_1}(\delta) &= \begin{cases} 0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0 \\ \frac{1}{2}N^{\frac{1}{2}} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0 \end{cases} \\ \max_{w_1}(\delta) &= \begin{cases} 0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0 \\ \frac{1}{2}N^{\frac{1}{2}} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0 \end{cases}\end{aligned}$$

This implies

$$|\delta| \leq \frac{1}{2}N^{\frac{1}{2}} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma}$$

Two-sample Satterthwaite t Test Assuming Unequal Variances (TEST=DIFF_SATT)

The hypotheses for the two-sample Satterthwaite t test are

$$\begin{aligned}H_0 &: \mu_{\text{diff}} = \mu_0 \\ H_1 &: \begin{cases} \mu_{\text{diff}} \neq \mu_0, & \text{2-sided} \\ \mu_{\text{diff}} > \mu_0, & \text{upper 1-sided} \\ \mu_{\text{diff}} < \mu_0, & \text{lower 1-sided} \end{cases}\end{aligned}$$

The test assumes normally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. The test statistics are

$$\begin{aligned}t &= \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\left[\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right]^{\frac{1}{2}}} = N^{\frac{1}{2}} \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\left[\frac{s_1^2}{w_1} + \frac{s_2^2}{w_2} \right]^{\frac{1}{2}}} \\ F &= t^2\end{aligned}$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_1 and s_2 are the sample standard deviations.

As DiSantostefano and Muller (1995, p. 585) state, the test is based on assuming that under H_0 , F is distributed as $F(1, \nu)$, where ν is given by Satterthwaite's approximation (Satterthwaite 1946),

$$\nu = \frac{\left[\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2} \right]^2}{\frac{\left[\frac{\sigma_1^2}{n_1} \right]^2}{n_1 - 1} + \frac{\left[\frac{\sigma_2^2}{n_2} \right]^2}{n_2 - 1}} = \frac{\left[\frac{\sigma_1^2}{w_1} + \frac{\sigma_2^2}{w_2} \right]^2}{\frac{\left[\frac{\sigma_1^2}{w_1} \right]^2}{Nw_1 - 1} + \frac{\left[\frac{\sigma_2^2}{w_2} \right]^2}{Nw_2 - 1}}$$

Since ν is unknown, in practice it must be replaced by an estimate

$$\hat{\nu} = \frac{\left[\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right]^2}{\frac{\left[\frac{s_1^2}{n_1} \right]^2}{n_1 - 1} + \frac{\left[\frac{s_2^2}{n_2} \right]^2}{n_2 - 1}} = \frac{\left[\frac{s_1^2}{w_1} + \frac{s_2^2}{w_2} \right]^2}{\frac{\left[\frac{s_1^2}{w_1} \right]^2}{Nw_1 - 1} + \frac{\left[\frac{s_2^2}{w_2} \right]^2}{Nw_2 - 1}}$$

So the test is

$$\text{Reject } H_0 \text{ if } \begin{cases} F \geq F_{1-\alpha}(1, \hat{\nu}), & \text{2-sided} \\ t \geq t_{1-\alpha}(\hat{\nu}), & \text{upper 1-sided} \\ t \leq t_{\alpha}(\hat{\nu}), & \text{lower 1-sided} \end{cases}$$

Exact solutions for power for the 2-sided and upper 1-sided cases are given in Moser, Stevens, and Watts (1989). The lower 1-sided case follows easily using symmetry. The equations are as follows:

$$\text{power} = \begin{cases} \int_0^{\infty} P(F(1, N-2, \lambda) > h(u) F_{1-\alpha}(1, v(u)) | u) f(u) du, & \text{2-sided} \\ \int_0^{\infty} P\left(t(N-2, \lambda^{\frac{1}{2}}) > [h(u)]^{\frac{1}{2}} t_{1-\alpha}(v(u)) | u\right) f(u) du, & \text{upper 1-sided} \\ \int_0^{\infty} P\left(t(N-2, \lambda^{\frac{1}{2}}) < [h(u)]^{\frac{1}{2}} t_{\alpha}(v(u)) | u\right) f(u) du, & \text{lower 1-sided} \end{cases}$$

where

$$h(u) = \frac{\left(\frac{1}{n_1} + \frac{u}{n_2} \right) (n_1 + n_2 - 2)}{\left[(n_1 - 1) + (n_2 - 1) \frac{u \sigma_1^2}{\sigma_2^2} \right] \left(\frac{1}{n_1} + \frac{\sigma_2^2}{\sigma_1^2 n_2} \right)}$$

$$v(u) = \frac{\left(\frac{1}{n_1} + \frac{u}{n_2} \right)^2}{\frac{1}{n_1^2(n_1 - 1)} + \frac{u^2}{n_2^2(n_2 - 1)}}$$

$$\lambda = \frac{(\mu_{\text{diff}} - \mu_0)^2}{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$$

$$f(u) = \frac{\Gamma\left(\frac{n_1+n_2-2}{2}\right)}{\Gamma\left(\frac{n_1-1}{2}\right)\Gamma\left(\frac{n_2-1}{2}\right)} \left[\frac{\sigma_1^2(n_2-1)}{\sigma_2^2(n_1-1)}\right]^{\frac{n_2-1}{2}} \cdot u^{\frac{n_2-3}{2}} \left[1 + \left(\frac{n_2-1}{n_1-1}\right) \frac{u\sigma_1^2}{\sigma_2^2}\right]^{-\left(\frac{n_1+n_2-2}{2}\right)}$$

The density $f(u)$ is obtained from the fact that

$$\frac{u\sigma_1^2}{\sigma_2^2} \sim F(n_2-1, n_1-1)$$

Two-sample Pooled t Test of Mean Ratio with Lognormal Data (TEST=RATIO)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Two-sample t Test Assuming Equal Variances (TEST=DIFF)” section on page 3526 then apply.

In contrast to the usual t test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. The test assumes equal coefficients of variation in the two groups.

The hypotheses for the two-sample t test with lognormal data are

$$H_0 : \frac{\gamma_2}{\gamma_1} = \gamma_0$$

$$H_1 : \begin{cases} \frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{2-sided} \\ \frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper 1-sided} \\ \frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower 1-sided} \end{cases}$$

Let μ_1^* , μ_2^* , and σ^* be the (arithmetic) means and common standard deviation of the corresponding normal distributions of the log-transformed data. The hypotheses can be rewritten as follows:

$$H_0 : \mu_2^* - \mu_1^* = \log(\gamma_0)$$

$$H_1 : \begin{cases} \mu_2^* - \mu_1^* \neq \log(\gamma_0), & \text{2-sided} \\ \mu_2^* - \mu_1^* > \log(\gamma_0), & \text{upper 1-sided} \\ \mu_2^* - \mu_1^* < \log(\gamma_0), & \text{lower 1-sided} \end{cases}$$

where

$$\mu_1^* = \log \gamma_1$$

$$\mu_2^* = \log \gamma_2$$

The test assumes lognormally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$.

The power is

$$\text{power} = \begin{cases} P(F(1, N-2, \delta^2) \geq F_{1-\alpha}(1, N-2)), & \text{2-sided} \\ P(t(N-2, \delta) \geq t_{1-\alpha}(N-2)), & \text{upper 1-sided} \\ P(t(N-2, \delta) \leq t_{\alpha}(N-2)), & \text{lower 1-sided} \end{cases}$$

where

$$\delta = N^{\frac{1}{2}}(w_1 w_2)^{\frac{1}{2}} \left(\frac{\mu_2^* - \mu_1^* - \log(\gamma_0)}{\sigma^*} \right)$$

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)

The hypotheses for the equivalence test are

$$H_0 : \mu_{\text{diff}} < \theta_L \quad \text{or} \quad \mu_{\text{diff}} > \theta_U$$

$$H_1 : \theta_L \leq \mu_{\text{diff}} \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. Phillips (1990) derives an expression for the exact power assuming a balanced design; the results are easily adapted to an unbalanced design:

$$\text{power} = Q_{N-2} \left((-t_{1-\alpha}(N-2)), \frac{\mu_{\text{diff}} - \theta_U}{\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; \right. \\ \left. 0, \frac{(N-2)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right) - \\ Q_{N-2} \left((t_{1-\alpha}(N-2)), \frac{\mu_{\text{diff}} - \theta_L}{\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; \right. \\ \left. 0, \frac{(N-2)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right)$$

where $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen's Q function, defined in the "Common Notation" section on page 3498.

**Multiplicative Equivalence Test for Mean Ratio with Lognormal Data
(TEST=EQUIV_RATIO)**

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)” section on page 3530 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

$$H_0 : \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U$$

$$H_1 : \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U$$

where $0 < \theta_L < \theta_U$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to an unbalanced two-sample design:

$$\begin{aligned} \text{power} = & Q_{N-2} \left((-t_{1-\alpha}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-2)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right) - \\ & Q_{N-2} \left((t_{1-\alpha}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}}; \right. \\ & \left. 0, \frac{(N-2)^{\frac{1}{2}}(\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{-\frac{1}{2}}(w_1 w_2)^{-\frac{1}{2}}(t_{1-\alpha}(N-2))} \right) \end{aligned}$$

where

$$\sigma^* = [\log(\text{CV}^2 + 1)]^{\frac{1}{2}}$$

is the (assumed common) standard deviation of the normal distribution of the log-transformed data, and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the “Common Notation” section on page 3498.

Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard t -based confidence interval:

$$\begin{aligned} & \left[(\bar{x}_2 - \bar{x}_1) - t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, \right. \\ & \quad \left. (\bar{x}_2 - \bar{x}_1) + t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}} \right], \quad \text{2-sided} \\ & \left[(\bar{x}_2 - \bar{x}_1) - t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, \infty \right), \quad \text{upper 1-sided} \\ & \left(-\infty, (\bar{x}_2 - \bar{x}_1) + t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}} \right], \quad \text{lower 1-sided} \end{aligned}$$

where \bar{x}_1 and \bar{x}_2 are the sample means and s_p is the pooled standard deviation. The “half-width” is defined as the distance from the point estimate $\bar{x}_2 - \bar{x}_1$ to a finite endpoint,

$$\text{half-width} = \begin{cases} t_{1-\frac{\alpha}{2}}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, & \text{2-sided} \\ t_{1-\alpha}(N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, & \text{1-sided} \end{cases}$$

A “valid” confidence interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width h , unconditional or conditional on validity, is given by Beal (1989):

$$\begin{aligned} \Pr(\text{half-width} \leq h) &= \begin{cases} P\left(\chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\frac{\alpha}{2}}^2(N-2))}\right), & \text{2-sided} \\ P\left(\chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\alpha}^2(N-2))}\right), & \text{1-sided} \end{cases} \\ \Pr(\text{half-width} \leq h \mid \text{validity}) &= \begin{cases} \left(\frac{1}{1-\alpha}\right) 2 \left[Q_{N-2}\left((t_{1-\frac{\alpha}{2}}(N-2)), 0; 0, b_2\right) - Q_{N-2}(0, 0; 0, b_2) \right], & \text{2-sided} \\ \left(\frac{1}{1-\alpha}\right) Q_{N-2}\left((t_{1-\alpha}(N-2)), 0; 0, b_2\right), & \text{1-sided} \end{cases} \end{aligned}$$

where

$$\begin{aligned} b_2 &= \frac{h(N-2)^{\frac{1}{2}}}{\sigma(t_{1-\frac{\alpha}{2}}(N-2))N^{-\frac{1}{2}}(w_1w_2)^{-\frac{1}{2}}} \\ c &= \text{number of sides} \end{aligned}$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the “[Common Notation](#)” section on page 3498.

A “quality” confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$\begin{aligned} \Pr(\text{quality}) &= \Pr(\text{half-width} \leq h \text{ and validity}) \\ &= \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha) \end{aligned}$$

Analyses in the TWOSAMPLESURVIVAL Statement**Rank Tests for Two Survival Curves (TEST=LOGRANK, TEST=GEHAN, TEST=TARONEWARE)**

The method is from Lakatos (1988) and Cantor (1997, pp. 83–92).

Define the following notation:

$X_j(i)$	=	i th input time point on survival curve for group j
$S_j(i)$	=	input survivor function value corresponding to $X_j(i)$
$h_j(t)$	=	hazard rate for group j at time t
$\Psi_j(t)$	=	loss hazard rate for group j at time t
λ_j	=	exponential hazard rate for group j
R	=	hazard ratio of group 2 to group 1 \equiv (assumed constant) value of $\frac{h_2(t)}{h_1(t)}$
m_j	=	median survival time for group j
b	=	number of subintervals per time unit
T	=	accrual time
τ	=	post-accrual follow-up time
L_j	=	exponential loss rate for group j
XL_j	=	input time point on loss curve for group j
SL_j	=	input survivor function value corresponding to XL_j
mL_j	=	median survival time for group j
r_i	=	rank for i th time point

Each survival curve can be specified in one of several ways.

- For exponential curves:
 - a single point $(X_j(1), S_j(1))$ on the curve
 - median survival time
 - hazard rate
 - hazard ratio (for curve 2, with respect to curve 1)
- For piecewise linear curves with proportional hazards:
 - a set of points $\{(X_1(1), S_1(1)), (X_1(2), S_1(2)), \dots\}$ (for curve 1)
 - hazard ratio (for curve 2, with respect to curve 1)
- For arbitrary piecewise linear curves:
 - a set of points $\{(X_j(1), S_j(1)), (X_j(2), S_j(2)), \dots\}$

A total of M evenly spaced time points $\{t_0 = 0, t_1, t_2, \dots, t_M = T + \tau\}$ are used in calculations, where

$$M = \text{floor}((T + \tau)b)$$

The hazard function is calculated for each survival curve at each time point. For an exponential curve, the (constant) hazard is given by one of the following, depending on the input parameterization:

$$h_j(t) = \begin{cases} \lambda_j \\ \lambda_1 R \\ \frac{-\log(\frac{1}{2})}{m_j} \\ \frac{-\log(S_j(1))}{X_j(1)} \\ \frac{-\log(S_1(1))}{X_1(1)} R \end{cases}$$

For a piecewise linear curve, define the following additional notation:

$$\begin{aligned} t_i^- &= \text{largest input time } X \text{ such that } X \leq t_i \\ t_i^+ &= \text{smallest input time } X \text{ such that } X > t_i \end{aligned}$$

The hazard is computed using linear interpolation as follows:

$$h_j(t_i) = \frac{S_j(t_i^-) - S_j(t_i^+)}{[S_j(t_i^+) - S_j(t_i^-)] [t_i - t_i^-] + S_j(t_i^-) [t_i^+ - t_i^-]}$$

With proportional hazards, the hazard rate of group 2's curve in terms of the hazard rate of group 1's curve is

$$h_2(t) = h_1(t)R$$

Hazard function values $\{\Psi_j(t_i)\}$ for the loss curves are computed in an analogous way from $\{L_j, XL_j, SL_j, mL_j\}$.

The expected number at risk $N_j(i)$ at time i in group j is calculated for each group and time points 0 through $M - 1$, as follows:

$$\begin{aligned} N_j(0) &= Nw_j \\ N_j(i+1) &= N_j(i) \left[1 - h_j(t_i) \left(\frac{1}{b}\right) - \Psi_j(t_i) \left(\frac{1}{b}\right) - \left(\frac{1}{b(T + \tau - t_i)}\right) 1_{\{t_i > \tau\}} \right] \end{aligned}$$

Define θ_i as the ratio of hazards and ϕ_i as the ratio of expected numbers at risk for time t_i :

$$\begin{aligned} \theta_i &= \frac{h_2(t_i)}{h_1(t_i)} \\ \phi_i &= \frac{N_2(i)}{N_1(i)} \end{aligned}$$

The expected number of deaths in each subinterval is calculated as follows:

$$D_i = [h_1(t_i)N_1(i) + h_2(t_i)N_2(i)] \left(\frac{1}{b}\right)$$

The rank values are calculated as follows according to which test statistic is used:

$$r_i = \begin{cases} 1, & \text{log-rank} \\ \frac{N_1(i) + N_2(i)}{\sqrt{N_1(i) + N_2(i)}}, & \text{Gehan} \\ \sqrt{N_1(i) + N_2(i)}, & \text{Tarone-Ware} \end{cases}$$

The distribution of the test statistic is approximated by $N(E, 1)$ where

$$E = \frac{\sum_{i=0}^{M-1} D_i r_i \left[\frac{\phi_i \theta_i}{1 + \phi_i \theta_i} - \frac{\phi_i}{1 + \phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i r_i^2 \frac{\phi_i}{(1 + \phi_i)^2}}}$$

Note that $N^{\frac{1}{2}}$ can be factored out of the mean E , and so it can be expressed equivalently as

$$E = N^{\frac{1}{2}} E^* = N^{\frac{1}{2}} \left[\frac{\sum_{i=0}^{M-1} D_i^* r_i^* \left[\frac{\phi_i \theta_i}{1 + \phi_i \theta_i} - \frac{\phi_i}{1 + \phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i^* r_i^{*2} \frac{\phi_i}{(1 + \phi_i)^2}}} \right]$$

where E^* is free of N and

$$\begin{aligned} D_i^* &= [h_1(t_i)N_1^*(i) + h_2(t_i)N_2^*(i)] \left(\frac{1}{b}\right) \\ r_i^* &= \begin{cases} 1, & \text{log-rank} \\ \frac{N_1^*(i) + N_2^*(i)}{\sqrt{N_1^*(i) + N_2^*(i)}}, & \text{Gehan} \\ \sqrt{N_1^*(i) + N_2^*(i)}, & \text{Tarone-Ware} \end{cases} \\ N_j^*(0) &= w_j \\ N_j^*(i + 1) &= N_j^*(i) \left[1 - h_j(t_i) \left(\frac{1}{b}\right) - \Psi_j(t_i) \left(\frac{1}{b}\right) - \left(\frac{1}{b(T + \tau - t_i)}\right) 1_{\{t_i > \tau\}} \right] \end{aligned}$$

The approximate power is

$$\text{power} = \begin{cases} \Phi \left(-N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{upper 1-sided} \\ \Phi \left(N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{lower 1-sided} \\ \Phi \left(-N^{\frac{1}{2}} E^* - z_{1-\frac{\alpha}{2}} \right) + \Phi \left(N^{\frac{1}{2}} E^* - z_{1-\frac{\alpha}{2}} \right), & \text{2-sided} \end{cases}$$

Note that the upper and lower 1-sided cases are expressed differently than in other analyses. This is because $E^* > 0$ corresponds to a higher survival curve in group

1 and thus, by the convention used in PROC power for 2-group analyses, the lower side.

For the 1-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

$$N = \left(\frac{z_{\text{power}} + z_{1-\alpha}}{E^*} \right)^2$$

For the 2-sided case, the solution for N is obtained by numerically inverting the power equation.

Examples

Example 57.1. One-Way ANOVA

This example deals with the same situation as in Example 34.1 on page 1951 of Chapter 34, “The GLMPOWER Procedure.”

Hocking (1985, p. 109) describes a study of the effectiveness of electrolytes in reducing lactic acid buildup for long-distance runners. You are planning a similar study in which you will allocate five different fluids to runners on a 10-mile course and measure lactic acid buildup immediately after the race. The fluids consist of water and two commercial electrolyte drinks, EZDure and LactoZap, each prepared at two concentrations, low (EZD1 and LZ1) and high (EZD2 and LZ2).

You conjecture that the standard deviation of lactic acid measurements given any particular fluid is about 3.75, and that the expected lactic acid values will correspond roughly to those in Table 57.27. You are least familiar with the LZ1 drink and hence decide to consider a range of reasonable values for that mean.

Table 57.27. Mean Lactic Acid Buildup by Fluid

Water	EZD1	EZD2	LZ1	LZ2
35.6	33.7	30.2	29 or 28	25.9

You are interested in four different comparisons, shown in Table 57.28 with appropriate contrast coefficients.

Table 57.28. Planned Comparisons

Comparison	Contrast Coefficients				
	Water	EZD1	EZD2	LZ1	LZ2
Water versus electrolytes	4	-1	-1	-1	-1
EZD versus LZ	0	1	1	-1	-1
EZD1 versus EZD2	0	1	-1	0	0
LZ1 versus LZ2	0	0	0	1	-1

For each of these contrasts you want to determine the sample size required to achieve a power of 0.9 for detecting an effect with magnitude in accord with Table 57.27. You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed for individual contrasts. You plan to test

each contrast at $\alpha = 0.025$. In the interests of reducing costs, you will provide twice as many runners with water as with any of the electrolytes; in other words, you will use a sample size weighting scheme of 2:1:1:1:1. Use the ONEWAYANOVA statement in the POWER procedure to compute the sample sizes. The statements required to perform this analysis are as follows:

```
proc power;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
    alpha = 0.025
    ntotal = .
    power = 0.9
    contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
              (0 1 -1 0 0) (0 0 0 1 -1);
run;
```

The NTOTAL= option with a missing value (.) indicates total sample size as the result parameter. The GROUPMEANS= option with values from [Table 57.27](#) specifies your conjectures for the means. With only one mean varying (the LZ1 mean), the “crossed” notation is simpler, showing scenarios for each group mean separated by a vertical bar (|). See the [“Specifying Value Lists in Analysis Statements”](#) section on page 3490 for more details on crossed and matched notations for grouped values. The contrasts in [Table 57.28](#) are specified with the CONTRAST option, using the “matched” notation with each contrast enclosed in parentheses. The STDDEV=, ALPHA=, and POWER= options specify the error standard deviation, significance level, and power. The GROUPWEIGHTS= option specifies the weighting schemes. Default values for the NULL= and SIDES= options specify a 2-sided t test of the contrast equal to 0. See [Output 57.1.1](#) for the output.

Output 57.1.1. Sample Sizes for One-Way ANOVA Contrasts

The POWER Procedure												
Single DF Contrast in One-Way ANOVA												
Fixed Scenario Elements												
Method											Exact	
Alpha											0.025	
Standard Deviation											3.75	
Group Weights	2	1	1	1	1							
Nominal Power											0.9	
Number of Sides											2	
Null Contrast Value											0	
Computed N Total												
Index	-----Contrast-----					-----Means-----					Actual Power	N Total
1	4	-1	-1	-1	-1	35.6	33.7	30.2	29	25.9	0.947	30
2	4	-1	-1	-1	-1	35.6	33.7	30.2	28	25.9	0.901	24
3	0	1	1	-1	-1	35.6	33.7	30.2	29	25.9	0.929	60
4	0	1	1	-1	-1	35.6	33.7	30.2	28	25.9	0.922	48
5	0	1	-1	0	0	35.6	33.7	30.2	29	25.9	0.901	174
6	0	1	-1	0	0	35.6	33.7	30.2	28	25.9	0.901	174
7	0	0	0	1	-1	35.6	33.7	30.2	29	25.9	0.902	222
8	0	0	0	1	-1	35.6	33.7	30.2	28	25.9	0.902	480

The sample sizes in [Output 57.1.1](#) range from 24 for the comparison of water versus electrolytes to 480 for the comparison of LZ1 versus LZ2, both assuming the smaller LZ1 mean. The sample size for the latter comparison is relatively large because the small mean difference of $28 - 25.9 = 2.1$ is hard to detect.

The Nominal Power of 0.9 in the Fixed Scenario Elements table in [Output 57.1.1](#) represents the input target power, and the Actual Power column in the Computed N Total table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting. Note that all of the sample sizes are rounded up to multiples of 6 to preserve integer group sizes (since the group weights add up to 6). You can use the `NFRACTIONAL` option in the `ONEWAYANOVA` statement to compute raw fractional sample sizes.

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the `PLOTONLY` option to the `PROC POWER` statement to disable the nongraphical results. Next, specify the `PLOT` statement with `X=POWER` to request a plot with power on the x-axis. (The result parameter, here sample size, is always plotted on the other axis.) Use the `MIN=` and `MAX=` options in the `PLOT` statement to specify the power range.

```
proc power plotonly;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
```

```

alpha = 0.025
ntotal = .
power = 0.9
contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
           (0 1 -1 0 0) (0 0 0 1 -1);
plot x=power min=.5 max=.95;
run;

```

See [Output 57.1.2](#) for the resulting plot.

Output 57.1.2. Plot of Sample Size versus Power for One-Way ANOVA Contrasts

In [Output 57.1.2](#), the line style identifies the contrast, and the plotting symbol identifies the group means scenario. The plot shows that the required sample size is highest for the (0 0 0 1 -1) contrast, corresponding to the test of LZ1 versus LZ2 that was previously found to require the most resources, in either cell means scenario.

Note that some of the plotted points in [Output 57.1.2](#) are unevenly spaced. This is because the plotted points are the *rounded* sample size results at their corresponding *actual* power levels. The range specified with the MIN= and MAX= values in the PLOT statement correspond to *nominal* power levels. In some cases, actual power is substantially higher than nominal power. To obtain plots with evenly spaced points (but with *fractional* sample sizes at the computed points), you can use the NFRAC_{TIONAL} option in the analysis statement preceding the PLOT statement.

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 24 to 480 that achieves 0.9 power for different comparisons). In the ONEWAYANOVA statement, identify power as the result

(POWER=.), and specify NTOTAL=24. The following statements produce the plot:

```
proc power plotonly;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
    alpha = 0.025
    ntotal = 24
    power = .
    contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
              (0 1 -1 0 0) (0 0 0 1 -1);
  plot x=n min=24 max=480;
run;
```

The X=N option in the PLOT statement requests a plot with sample size on the x-axis.

Note that the value specified with the NTOTAL=24 option is not used. It is overridden in the plot by the MIN= and MAX= options in the PLOT statement, and the PLOTONLY option in the PROC POWER statement disables nongraphical results. But the NTOTAL= option (along with a value) is still needed in the ONEWAYANOVA statement as a placeholder, to identify the desired parameterization for sample size.

See [Output 57.1.3](#) for the plot.

Output 57.1.3. Plot of Power versus Sample Size for One-Way ANOVA Contrasts

Although [Output 57.1.2](#) and [Output 57.1.3](#) surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. [Output 57.1.2](#) reveals the range of required sample sizes for powers of interest, and [Output 57.1.3](#) reveals the range of achieved powers for sample sizes of interest.

Example 57.2. The Sawtooth Power Function in Proportion Analyses

For many common statistical analyses, the power curve is monotonically increasing: the more samples you take, the more power you achieve. However, in statistical analyses of discrete data, such as tests of proportions, the power curve is often non-monotonic. A small increase in sample size can result in a *decrease* in power, a decrease that is sometimes substantial. The explanation is that the actual significance level (in other words, the achieved Type 1 error rate) for discrete tests strays below the target level and varies with sample size. The power loss from a decrease in the Type 1 error rate may outweigh the power gain from an increase in sample size. The example discussed in this section demonstrates this “sawtooth” phenomenon. For additional discussion on the topic, refer to Chernick and Liu (2002).

Suppose you have a new scheduling system for an airline, and you want to determine how many flights you must observe to have at least an 80% chance of establishing an improvement in the proportion of late arrivals on a specific travel route. You will use a 1-sided exact binomial proportion test with a null proportion of 30%, the frequency of late arrivals under the previous scheduling system, and a nominal significance level of $\alpha = 0.05$. Well-supported predictions estimate the new late arrival rate to be about 20%, and you will base your sample size determination on this assumption.

The POWER procedure does not currently compute exact sample size directly for the exact binomial test. But you can get an initial estimate by computing the approximate sample size required for a z test. Use the ONESAMPLEFREQ statement in the POWER procedure with TEST=Z and METHOD=NORMAL to compute the approximate sample size to achieve a power of 0.8 using the z test. The following statements perform the analysis:

```
proc power;
  onesamplefreq test=z method=normal
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal         = .
    power          = 0.8;
run;
```

The NTOTAL= option with a missing value (.) indicates sample size as the result parameter. The SIDES=1 option specifies a 1-sided test. The ALPHA=, NULLPROPORTION=, and POWER= options specify the significance level of 0.05, null value of 0.3, and target power of 0.8. The PROPORTION= option specifies your conjecture of 0.3 for the true proportion.

Output 57.2.1. Approximate Sample Size for z Test of a Proportion

The POWER Procedure		
Z Test for Binomial Proportion		
Fixed Scenario Elements		
Method	Normal approximation	
Number of Sides		1
Null Proportion		0.3
Alpha		0.05
Binomial Proportion		0.2
Nominal Power		0.8
Computed N Total		
	Actual	N
	Power	Total
	0.800	119

The results, shown in [Output 57.2.1](#), indicate that you need to observe about $N=119$ flights to have an 80% chance of rejecting the hypothesis of a late arrival proportion of 30% or higher, if the true proportion is 20%, using the z test. A similar analysis ([Output 57.2.2](#)) reveals an approximate sample size of $N=129$ for the z test with continuity correction, which performed using TEST=ADJZ:

```
proc power;
  onesamplefreq test=adjz method=normal
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal        = .
    power         = 0.8;
run;
```

Output 57.2.2. Approximate Sample Size for z Test with Continuity Correction

The POWER Procedure		
Z Test for Binomial Proportion with Continuity Adjustment		
Fixed Scenario Elements		
Method	Normal approximation	
Number of Sides		1
Null Proportion		0.3
Alpha		0.05
Binomial Proportion		0.2
Nominal Power		0.8
Computed N Total		
Actual	N	
Power	Total	
0.801	129	

Based on the approximate sample size results, you decide to explore the power of the exact binomial test for sample sizes between 110 and 140. The following statements produce the plot:

```
proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal         = 119
    power          = .;
  plot x=n min=110 max=140 step=1
    yopts=(ref=.8) xopts=(ref=119 129);
run;
```

The TEST=EXACT option in the ONESAMPLEFREQ statement specifies the exact binomial test, and the missing value (.) for the POWER= option indicates power as the result parameter. The PLOTONLY option in the PROC POWER statement disables nongraphical output. The PLOT statement with X=N requests a plot with sample size on the x-axis. The MIN= and MAX= options in the PLOT statement specify the sample size range. The YOPTS=(REF=) and XOPTS=(REF=) options add reference lines to highlight the approximate sample size results. The STEP=1 option produces a point at each integer sample size. The sample size value specified with the NTOTAL= option in the ONESAMPLEFREQ statement is overridden by the MIN= and MAX= options in the PLOT statement. [Output 57.2.3](#) shows the plot.

Output 57.2.3. Plot of Power versus Sample Size for Exact Binomial Test

Note the sawtooth pattern in [Output 57.2.3](#). Although the power surpasses the target level of 0.8 at $N=119$, it decreases to 0.79 with $N=120$ and further to 0.76 with $N=122$ before rising again to 0.81 with $N=123$. Not until $N=130$ does the power stay above the 0.8 target. Thus, a more conservative sample size recommendation of 130 might be appropriate, depending on the precise goals of the sample size determination.

In addition to considering alternative sample sizes, you may also want to assess the sensitivity of the power to inaccuracies in assumptions about the true proportion. The following statements produce a plot including true proportion values of 0.18 and 0.22. They are identical to the previous statements except for the additional true proportion values specified with the PROPORTION= option in the ONESAMPLEFREQ statement.

```
proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.18 0.2 0.22
    ntotal        = 119
    power         = .;
  plot x=n min=110 max=140 step=1
      yopts=(ref=.8) xopts=(ref=119 129);
run;
```

[Output 57.2.4](#) shows the plot.

Output 57.2.4. Plot for Assessing Sensitivity to True Proportion Value

The plot reveals a dramatic sensitivity to the true proportion value. For $N=119$, the power is about 0.92 if the true proportion is 0.22, and as low as 0.62 if the proportion is 0.18. Note also that the power jumps occur at the same sample sizes in all three curves; the curves are only shifted and stretched vertically. This is because spikes and valleys in power curves are invariant to the true proportion value; they are due to changes in the critical value of the test.

A closer look at some ancillary output from the analysis sheds light on this property of the sawtooth pattern. You can add an ODS OUTPUT statement to save the plot content corresponding to [Output 57.2.3](#) to a data set:

```

proc power plotonly;
  ods output plotcontent=PlotData;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.3
    proportion     = 0.2
    ntotal        = 119
    power         = .;
  plot x=n min=110 max=140 step=1
       yopts=(ref=.8) xopts=(ref=119 129);
run;

```

The PlotData data set contains parameter values for each point in the plot. The parameters including underlying characteristics of

the putative test. The following statements print the critical value and actual significance level along with sample size and power.

```
proc print data=PlotData;
  var NTotal LowerCritVal Alpha Power;
run;
```

Output 57.2.5 shows the plot data.

Output 57.2.5. Numerical Content of Plot

Obs	NTotal	Lower CritVal	Alpha	Power
1	110	24	0.0356	0.729
2	111	24	0.0313	0.713
3	112	25	0.0446	0.771
4	113	25	0.0395	0.756
5	114	25	0.0349	0.741
6	115	26	0.0490	0.795
7	116	26	0.0435	0.781
8	117	26	0.0386	0.767
9	118	26	0.0341	0.752
10	119	27	0.0478	0.804
11	120	27	0.0425	0.790
12	121	27	0.0377	0.776
13	122	27	0.0334	0.762
14	123	28	0.0465	0.812
15	124	28	0.0414	0.799
16	125	28	0.0368	0.786
17	126	28	0.0327	0.772
18	127	29	0.0453	0.820
19	128	29	0.0404	0.807
20	129	29	0.0359	0.794
21	130	30	0.0493	0.838
22	131	30	0.0441	0.827
23	132	30	0.0394	0.815
24	133	30	0.0351	0.803
25	134	31	0.0480	0.845
26	135	31	0.0429	0.834
27	136	31	0.0384	0.823
28	137	31	0.0342	0.811
29	138	32	0.0466	0.851
30	139	32	0.0418	0.841
31	140	32	0.0374	0.830

Note that whenever the critical value changes, the actual α jumps up to a value close to the nominal $\alpha=0.05$, and the power also jumps up. Then while the critical value stays constant, the actual α and power slowly decrease. The critical value is independent of the true proportion value. So, you can achieve a locally maximal power by choosing a sample size corresponding to a spike on the sawtooth curve, and this choice is locally optimal *regardless* of the unknown value of the true proportion. Locally optimal sample sizes in this case include 115, 119, 123, 127, 130, and 134.

As a point of interest, the power does not always jump sharply and decrease gradually. The shape of the sawtooth depends on the direction of the test and

the location of the null proportion relative to 0.5. For example, if the direction of the hypothesis in this example is reversed (by switching true and null proportion values) so that the rejection region is in the upper tail, then the power curve exhibits sharp decreases and gradual increases. The following statements are similar to those producing the plot in [Output 57.2.3](#) but with values of the PROPORTION= and NULLPROPORTION= options switched.

```
proc power plotonly;
  onesamplefreq test=exact
    sides          = 1
    alpha          = 0.05
    nullproportion = 0.2
    proportion     = 0.3
    ntotal        = 119
    power         = .;
  plot x=n min=110 max=140 step=1;
run;
```

The resulting plot is shown in [Output 57.2.6](#).

Output 57.2.6. Plot of Power versus Sample Size for Another 1-Sided Test

Finally, 2-sided tests can lead to even more irregular power curve shapes, since changes in lower and upper critical values affect the power in different ways. The following statements produce a plot of power versus sample size for the scenario of a 2-sided test with high alpha and a true proportion close to the null value.

```

proc power plotonly;
  onesamplefreq test=exact
    sides          = 2
    alpha          = 0.2
    nullproportion = 0.1
    proportion     = 0.09
    ntotal        = 10
    power         = .;
  plot x=n min=2 max=100 step=1;
run;

```

The resulting plot is shown in [Output 57.2.7](#).

Output 57.2.7. Plot of Power versus Sample Size for a 2-Sided Test

Due to the irregular shapes of power curves for proportion tests, the question “Which sample size should I use?” is often insufficient. A sample size solution produced directly in PROC POWER reveals the smallest possible sample size to achieve your target power. But as the Examples in this section demonstrate, it is helpful to consult graphs for answers to questions such as the following:

- Which sample size will guarantee that all higher sample sizes also achieve my target power?
- Given a candidate sample size, can I increase it slightly to achieve locally maximal power, or perhaps even decrease it and get higher power?

Example 57.3. Simple AB/BA Crossover Designs

Crossover trials are experiments in which each subject is given a sequence of different treatments. They are especially common in clinical trials for medical studies. The reduction in variability from taking multiple measurements on a subject allows for more precise treatment comparisons. The simplest such design is the AB/BA crossover, in which each subject receives each of two treatments in a randomized order.

Under certain simplifying assumptions, you can test the treatment difference in an AB/BA crossover trial using either a paired or two-sample t test (or equivalence test, depending on the hypothesis). This example will demonstrate when and how you can use the PAIREDMEANS statement in PROC POWER to perform power analyses for AB/BA crossover designs.

Senn (1993, Chapter 3) discusses a study comparing the effects of two bronchodilator medications in treatment of asthma, using an AB/BA crossover design. Suppose you want to plan a similar study comparing two new medications, “Xilodol” and “Brantium.” Half of the patients would be assigned to sequence AB, getting a dose of Xilodol in the first treatment period, a wash-out period of one week, and then a dose of Brantium in the second treatment period. The other half would be assigned to sequence BA, following the same schedule but with the drugs reversed. In each treatment period you would administer the drugs in the morning and then measure peak expiratory flow (PEF) at the end of the day, with higher PEF representing better lung function.

You conjecture that the mean and standard deviation of PEF are about $\mu_A = 310$ and $\sigma_A = 40$ for Xilodol and $\mu_B = 330$ and $\sigma_B = 55$ for Brantium, and that each pair of measurements on the same subject will have a correlation of about 0.3. You want to compute the power of both 1-sided and 2-sided tests of mean difference, with a significance level of $\alpha = 0.01$, for a sample size of 100 patients and also plot the power for a range of 50 to 200 patients. Note that the allocation ratio of patients to the two sequences is irrelevant in this analysis.

The choice of statistical test depends on which assumptions are reasonable. One possibility is a t test. A paired or two-sample t test is valid when there is no carry-over effect and no interactions between patients, treatments, and periods. See Senn (1993, Chapter 3) for more details. The choice between a paired or a two-sample test depends on what you assume about the period effect. If you assume no period effect, then a paired t test is the appropriate analysis for the design, with the first member of each pair being the Xilodol measurement (regardless of which sequence the patient belongs to). Otherwise the two-sample t test approach is called for, since this analysis adjusts for the period effect using an extra degree of freedom.

Suppose you assume no period effect. Then you can use the PAIREDMEANS statement in PROC POWER with the TEST=DIFF option to perform a sample size analysis for the paired t test. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Specify the conjectured means and standard deviations for each drug using the PAIREDMEANS= and PAIREDSTDDEVS= options and the correlation using the CORR= option. Specify both 1- and 2-sided

tests using the SIDES= option, the significance level using the ALPHA= option, and the sample size (in terms of number of pairs) using the NPAIRS= option. Generate a plot of power versus sample size by specifying the PLOT statement with X=N to request a plot with sample size on the x-axis. (The result parameter, here power, is always plotted on the other axis.) Use the MIN= and MAX= options in the PLOT statement to specify the sample size range (as numbers of pairs).

The following statements perform the sample size analysis.

```
proc power;
  pairedmeans test=diff
    pairedmeans = (330 310)
    pairedstddevs = (40 55)
    corr         = 0.3
    sides       = 1 2
    alpha       = 0.01
    npairs      = 100
    power       = .;
  plot x=n min=50 max=200;
run;
```

Default values for the NULLDIFF= and DIST= options specify a null mean difference of 0 and the assumption of normally distributed data. The output is shown in [Output 57.3.1](#) and [Output 57.3.2](#).

Output 57.3.1. Power for Paired t Analysis of Crossover Design

The POWER Procedure		
Paired t Test for Mean Difference		
Fixed Scenario Elements		
Distribution		Normal
Method		Exact
Alpha		0.01
Mean 1		330
Mean 2		310
Standard Deviation 1		40
Standard Deviation 2		55
Correlation		0.3
Number of Pairs		100
Null Difference		0
Computed Power		
Index	Sides	Power
1	1	0.865
2	2	0.801

Output 57.3.2. Plot of Power versus Sample Size for Paired t Analysis of Crossover Design

The Computed Power table in [Output 57.3.1](#) shows that the power with 100 patients is about 0.8 for the 2-sided test and 0.87 for the 1-sided test with the alternative of larger Brantium mean. In [Output 57.3.2](#), the line style identifies the number of sides of the test. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points. The plot demonstrates how much higher the power is for the 1-sided test than the 2-sided test for the range of sample sizes.

Suppose now that instead of detecting a difference between Xilodol and Brantium, you want to establish that they are similar, in particular, that the absolute mean PEF difference is at most 35. You might consider this goal if, for example, one of the drugs has fewer side effects and if a difference of no more than 35 is considered clinically small. Instead of a standard t test, you would conduct an *equivalence test* of the treatment mean difference for the two drugs. You would test the hypothesis that the true difference is less than -35 or more than 35 against the alternative that the mean difference is between -35 and 35, using an additive model and a two one-sided tests (“TOST”) analysis.

Assuming no period effect, you can use the PAIREDMEANS statement with the TEST=EQUIV_DIFF option to perform a sample size analysis for the paired equivalence test. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Use the LOWER= and UPPER= options to specify the equivalence bounds of -35 and 35. Use the PAIREDMEANS=, PAIREDSTDDEVS=, CORR=, and ALPHA= options in the same way as in the t test at the beginning of this example to specify the remaining parameters.

The following statements perform the sample size analysis.

```
proc power;
  pairedmeans test=equiv_add
    lower      = -35
    upper      = 35
  pairedmeans = (330 310)
  pairedstddevs = (40 55)
  corr        = 0.3
  alpha       = 0.01
  npairs      = 100
  power       = .;
run;
```

The default option DIST=NORMAL specifies an assumption of normally distributed data. The output is shown in [Output 57.3.3](#).

Output 57.3.3. Power for Paired Equivalence Test for Crossover Design

The POWER Procedure	
Equivalence Test for Paired Mean Difference	
Fixed Scenario Elements	
Distribution	Normal
Method	Exact
Lower Equivalence Bound	-35
Upper Equivalence Bound	35
Alpha	0.01
Reference Mean	330
Treatment Mean	310
Standard Deviation 1	40
Standard Deviation 2	55
Correlation	0.3
Number of Pairs	100
Computed Power	
Power	0.598

The power for the paired equivalence test with 100 patients is about 0.6.

Example 57.4. Noninferiority Test with Lognormal Data

The typical goal in noninferiority testing is to conclude that a new treatment or process or product is not appreciably worse than some standard. This is accomplished by convincingly rejecting a 1-sided null hypothesis that the new treatment is appreciably worse than the standard. When designing such studies, investigators must define precisely what constitutes “appreciably worse.”

You can use the POWER procedure for sample size analyses for a variety of noninferiority tests, by specifying custom, 1-sided null hypotheses for common tests. This example illustrates the strategy (often called Blackwelder’s scheme, Blackwelder 1982) by comparing the means of two independent lognormal samples. The logic applies to one-sample, two-sample, and paired-sample problems involving normally distributed measures and proportions.

Suppose you are designing a study hoping to show that a new (less expensive) manufacturing process does not produce appreciably more pollution than the current process. Quantifying “appreciably worse” as 10%, you seek to show that the mean pollutant level from the new process is less than 110% of that from the current process. In standard hypothesis testing notation, you seek to reject

$$H_0: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} \geq 1.10$$

in favor of

$$H_A: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} < 1.10$$

This is described graphically in Figure 57.8. Mean ratios below 100% are better levels for the new process; a ratio of 100% indicates absolute equivalence; ratios of 100–110% are “tolerably” worse; and ratios exceeding 110% are appreciably worse.

Figure 57.8. Hypotheses for the Pollutant Study

An appropriate test for this situation is the common two-group *t* test on log-transformed data. The hypotheses become

$$\begin{aligned} H_0 &: \log(\mu_{\text{new}}) - \log(\mu_{\text{current}}) \geq \log(1.10) \\ H_A &: \log(\mu_{\text{new}}) - \log(\mu_{\text{current}}) < \log(1.10) \end{aligned}$$

Measurements of the pollutant level will be taken using laboratory models of the two processes and will be treated as independent lognormal observations with a coefficient of variation (σ/μ) between 0.5 and 0.6 for both processes. You will end up with 300 measurements for the current process and 180 for the new one. It is important to

avoid a Type 1 error here, so you set the Type 1 error rate to 0.01. Your theoretical work suggests that the new process will actually reduce the pollutant by about 10% (to 90% of current), but you need to compute and graph the power of the study if the new levels are actually between 70% and 120% of current levels.

Implement the sample size analysis using the TWOSAMPLEMEANS statement in PROC POWER with the TEST=RATIO option. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Specify a series of scenarios for the mean ratio between 0.7 and 1.2 using the MEANRATIO= option. Use the NULLRATIO= option to specify the null mean ratio of 1.10. Specify SIDES=L to indicate a 1-sided test with the alternative hypothesis stating that the mean ratio is *lower* than the null value. Specify the significance level, scenarios for the coefficient of variation, and the group sample sizes using the ALPHA=, CV=, and GROUPNS= options. Generate a plot of power versus mean ratio by specifying the PLOT statement with X=EFFECT to request a plot with mean ratio on the x-axis. (The result parameter, here power, is always plotted on the other axis.) Use the STEP= option in the PLOT statement to specify an interval of 0.05 between computed points in the plot.

The following statements perform the desired analysis.

```
proc power;
  twosamplemeans test=ratio
    meanratio = 0.7 to 1.2 by 0.1
    nullratio = 1.10
    sides      = L
    alpha      = 0.01
    cv         = 0.5 0.6
    groupns    = (300 180)
    power      = .;
  plot x=effect step=0.05;
run;
```

Note the use of SIDES=L, which forces computations for cases that need a rejection region that is opposite to the one providing the most one-tailed power; in this case, it is the lower tail. Such cases will show power that is less than the prescribed Type 1 error rate. The default option DIST=LOGNORMAL specifies the assumption of lognormally distributed data. The default MIN= and MAX= options in the plot statement specify an x-axis range identical to the effect size range in the TWOSAMPLEMEANS statement (mean ratios between 0.7 and 1.2).

See the output in [Output 57.4.1](#) and [Output 57.4.2](#).

Output 57.4.1. Power for Noninferiority Test of Ratio

The POWER Procedure			
Two-sample t Test for Mean Ratio			
Fixed Scenario Elements			
Distribution			Lognormal
Method			Exact
Number of Sides			L
Null Geometric Mean Ratio			1.1
Alpha			0.01
Group 1 Sample Size			300
Group 2 Sample Size			180
Computed Power			
Index	Geo Mean Ratio	CV	Power
1	0.7	0.5	>.999
2	0.7	0.6	>.999
3	0.8	0.5	>.999
4	0.8	0.6	>.999
5	0.9	0.5	0.985
6	0.9	0.6	0.933
7	1.0	0.5	0.424
8	1.0	0.6	0.306
9	1.1	0.5	0.010
10	1.1	0.6	0.010
11	1.2	0.5	<.001
12	1.2	0.6	<.001

Output 57.4.2. Plot of Power versus Mean Ratio for Noninferiority Test

The Computed Power table in [Output 57.4.1](#) shows that power exceeds 0.90 if the true mean ratio is 90% or less, as surmised. But power is unacceptably low (0.31–0.42) if the processes happen to be truly equivalent. Note that the power is identical to the alpha level (0.01) if the true mean ratio is 1.10 and below 0.01 if the true mean ratio is appreciably worse (> 110%). In [Output 57.4.2](#), the line style identifies the coefficient of variation. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points.

Example 57.5. Multiple Regression and Correlation

You are working with a team of preventive cardiologists investigating whether elevated serum homocysteine levels are linked to atherosclerosis (plaque buildup in coronary arteries). The planned analysis is an ordinary least squares regression to assess the relationship between total homocysteine level (tHcy) and a plaque burden index (PBI), adjusting for six other variables: age, gender, plasma levels of folate, vitamins B₆ and B₁₂, and a serum cholesterol index. You will regress PBI on tHcy and the six other predictors (plus the intercept) and use a Type III *F* test to assess whether tHcy is a significant predictor after adjusting for the others. You wonder whether 100 subjects will provide adequate statistical power.

This is a correlational study at a single time. Subjects will be screened so that about half will have had a heart problem. All eight variables will be measured during one visit. Most clinicians are familiar with simple correlations between two variables, so you decide to pose the statistical problem in terms of estimating and testing the partial correlation between $X_1 = \text{tHcy}$ and $Y = \text{PBI}$, controlling for the six other predictor

variables ($R_{YX_1|X_{-1}}$). This greatly simplifies matters, especially the elicitation of the conjectured effect.

You use partial regression plots like that shown in [Figure 57.9](#) to teach the team that the partial correlation between PBI and tHcy is the correlation of two sets of residuals obtained from ordinary regression models, one from regressing PBI on the six covariates and the other from regressing tHcy on the same covariates. Thus each subject has “expected” tHcy and PBI values based on the six covariates. The cardiologists believe that subjects who are relatively higher than expected on tHcy will also be relatively higher than expected on PBI. The partial correlation quantifies that adjusted association just like a standard simple correlation does with the unadjusted linear association between two variables.

Figure 57.9. Partial Regression Plot

Based on previously published studies of various coronary risk factors and after viewing a set of scatterplots showing various correlations, the team surmises that the true partial correlation is likely to be at least 0.35.

You want to compute the statistical power for a sample size of $N = 100$, using $\alpha = 0.05$. You also want to plot power for sample sizes between 50 and 150. Use the MULTREG statement to compute the power and the PLOT statement to produce the graph. Since the predictors are observed rather than fixed in advanced, and a joint multivariate normal assumption seems tenable, use MODEL=RANDOM. The following statements perform the power analysis:

```

proc power;
  multreg
    model = random
    nfullpredictors = 7
    ntestpredictors = 1
    partialcorr = 0.35
    ntotal = 100
    power = .;
  plot x=n min=50 max=150;
run;

```

The `POWER=.` option identifies power as the parameter to compute. The `NFULLPREDICTORS=` option specifies 7 total predictors (not including the intercept), and the `NTESTPREDICTORS=` option indicates that 1 of those predictors is being tested. The `PARTIALCORR=` and `NTOTAL=` options specify the partial correlation and sample size, respectively. The default value for the `ALPHA=` option sets the significance level to 0.05. The `X=N` option in the plot statement requests a plot of sample size on the x-axis, and the `MIN=` and `MAX=` options specify the sample size range.

[Output 57.5.1](#) shows the output, and [Output 57.5.2](#) shows the plot.

Output 57.5.1. Power Analysis for Multiple Regression

The POWER Procedure	
Type III F Test in Multiple Regression	
Fixed Scenario Elements	
Method	Exact
Model	Random X
Number of Predictors in Full Model	7
Number of Test Predictors	1
Partial Correlation	0.35
Total Sample Size	100
Alpha	0.05
Computed Power	
Power	0.939

Output 57.5.2. Plot of Power versus Sample Size for Multiple Regression

For the sample size $N = 100$, the study is almost balanced with respect to Type 1 and Type 2 error rates, with $\alpha = 0.05$ and $\beta = 1 - 0.937 = 0.063$. The study thus seems well designed at this sample size.

Now suppose that in a follow-up meeting with the cardiologists, you discover that their specific intent is to demonstrate that the (partial) correlation between PBI and tHcy is greater than 0.2. You suggest changing the planned data analysis to a 1-sided Fisher's z test with a null correlation of 0.2. The following statements perform a power analysis for this test:

```
proc power;
  onecorr dist=fisherz
    npvars = 6
    corr = 0.35
    nullcorr = 0.2
    sides = 1
    ntotal = 100
    power = .;
run;
```

The DIST=FISHERZ option in the ONECORR statement specifies Fisher's z test. The NPVARS= option specifies that 6 additional variables are adjusted for in the partial correlation. The CORR= option specifies the conjectured correlation of 0.35, and the NULLCORR= option indicates the null value of 0.2. The SIDES= option specifies a 1-sided test.

Output 57.5.3 shows the output.

Output 57.5.3. Power Analysis for Fisher's z Test

The POWER Procedure		
Fisher's z Test for Pearson Correlation		
Fixed Scenario Elements		
Distribution	Fisher's z transformation of r	
Method	Normal approximation	
Number of Sides	1	
Null Correlation	0.2	
Number of Variables Partialled Out	6	
Correlation	0.35	
Total Sample Size	100	
Nominal Alpha	0.05	
Computed Power		
	Actual	
	Alpha	Power
	0.05	0.466

The power for Fisher's z test is less than 50%, the decrease being mostly due to the smaller effect size (relative to the null value). When asked for a recommendation for a new sample size goal, you compute the required sample size to achieve a power of 0.95 (to balance Type 1 and Type 2 errors) and 0.85 (a threshold deemed to be minimally acceptable to the team). The following statements perform the sample size determination:

```
proc power;
  onecorr dist=fisherz
  npvars = 6
  corr = 0.35
  nullcorr = 0.2
  sides = 1
  ntotal = .
  power = 0.85 0.95;
run;
```

The `NTOTAL=.` option identifies sample size as the parameter to compute, and the `POWER=` option specifies the target powers.

Output 57.5.4. Sample Size Determination for Fisher’s z Test

The POWER Procedure				
Fisher’s z Test for Pearson Correlation				
Fixed Scenario Elements				
Distribution			Fisher’s z transformation of r	
Method			Normal approximation	
Number of Sides				1
Null Correlation				0.2
Number of Variables Partialled Out				6
Correlation				0.35
Nominal Alpha				0.05
Computed N Total				
Index	Nominal Power	Actual Alpha	Actual Power	N Total
1	0.85	0.05	0.850	280
2	0.95	0.05	0.950	417

The results in [Output 57.5.4](#) reveal a required sample size of 417 to achieve a power of 0.95 and 280 to achieve a power of 0.85.

Example 57.6. Comparing Two Survival Curves

You are consulting for a clinical research group planning a trial to compare survival rates for proposed and standard cancer treatments. The planned data analysis is a log-rank test to nonparametrically compare the overall survival curves for the two treatments. Your goal is to determine an appropriate sample size to achieve a power of 0.8 for a 2-sided test with $\alpha = 0.05$ using a balanced design.

The survival curve for patients on the standard treatment is well-known to be approximately exponential with a median survival time of five years. The research group conjectures that the new proposed treatment will yield a (nonexponential) survival curve similar to the dashed line in [Output 57.6.1](#). Patients will be accrued uniformly over two years and then followed for an additional three years past the accrual period. Some loss to follow-up is expected, with roughly exponential rates that would result in about 50% loss with the standard treatment within 10 years. The loss to follow-up with the proposed treatment is more difficult to predict, but 50% loss would be expected to occur sometime between years 5 and 20.

Output 57.6.1. Survival Curves

Use the TWOSAMPLESURVIVAL statement with the TEST=LOGRANK option to compute the required sample size for the log-rank test. The following statements perform the analysis:

```
proc power;
  twosamplesurvival test=logrank
    curve("Standard") = 5 : 0.5
    curve("Proposed") = (1 to 5 by 1):(0.95 0.9 0.75 0.7 0.6)
    groupsurvival = "Standard" | "Proposed"
    accrualtime = 2
    followuptime = 3
    groupmedlosstimes = 10 | 20 5
    power = 0.8
    npergroup = .;
run;
```

The CURVE= option defines the two survival curves. The “Standard” curve has only one point, specifying an exponential form with a survival probability of 0.5 at year 5. The “Proposed” curve is a piecewise linear curve defined by the five points shown in Output 57.6.1. The GROUPSURVIVAL= option assigns the survival curves to the two groups, and the ACCRUALTIME= and FOLLOWUPTIME= options specify the accrual and follow-up times. The GROUPMEDLOSSTIMES= option specifies the years at which 50% loss is expected to occur. The POWER= option specifies the target power, and the NPERGROUP=. option identifies sample size per group as the parameter to compute. Default values for the SIDES= and ALPHA= options specify a 2-sided test with $\alpha = 0.05$.

Output 57.6.2 shows the results.

Output 57.6.2. Sample Size Determination for Log-Rank Test

The POWER Procedure			
Log-Rank Test for Two Survival Curves			
Fixed Scenario Elements			
Method	Lakatos normal approximation		
Accrual Time			2
Follow-up Time			3
Group 1 Survival Curve			Standard
Form of Survival Curve 1			Exponential
Group 2 Survival Curve			Proposed
Form of Survival Curve 2			Piecewise Linear
Group 1 Median Loss Time			10
Nominal Power			0.8
Number of Sides			2
Number of Time Sub-Intervals			12
Alpha			0.05
Computed N Per Group			
Index	Median Loss Time	Actual Power	N Per Group
1	20	0.800	228
2	5	0.801	234

The required sample size per group to achieve a power of 0.8 is 228 if the median loss time is 20 years for the proposed treatment. Only six more patients are required in each group if the median loss time is as short as five years.

Example 57.7. Confidence Interval Precision

An investment firm has hired you to help plan a study to estimate the success of a new investment strategy called “IntuiVest.” The study involves complex simulations of market conditions over time, and it tracks the balance of a hypothetical brokerage account starting with \$50,000. Each simulation is very expensive in terms of computing time. You are asked to determine an appropriate number of simulations to estimate the average change in the account balance at the end of three years. The goal is to have a 95% chance of obtaining a 90% confidence interval whose half-width is at most \$1,000. That is, the firm wants to have a 95% chance of being able to correctly claim at the end of the study that “Our research shows with 90% confidence that IntuiVest yields a profit of \$X +/- \$1,000 at the end of three years on an initial investment of \$50,000 (under simulated market conditions).”

The probability of achieving the desired precision (that is, a small interval width) can be calculated either unconditionally or conditionally given that the true mean is captured by the interval. You decide to use the conditional form, considering two of its advantages:

- The conditional probability is usually lower than the unconditional probability for the same sample size, meaning that the conditional form is generally conservative.
- The overall probability of achieving the desired precision *and* capturing the true mean is easily computed as the product of the half-width probability and the confidence level. In this case, the overall probability is $0.95 \times 0.9 = 0.855$.

Based on some initial simulations, you expect a standard deviation between \$25,000 and \$45,000 for the ending account balance. You will consider both of these values in the sample size analysis.

As mentioned in the “[Overview of Power Concepts](#)” section on page 3488, an analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. In this example, the target CI Half-Width is 1000, and the desired Prob(Width) is 0.95.

In addition to computing sample sizes for a half-width of \$1,000, you are asked to plot the required number of simulations for a range of half-widths between \$500 and \$2,000. Use the ONESAMPLEMEANS statement with the CI=T option to implement the sample size determination. The following statements perform the analysis:

```
proc power;
  onesamplemeans ci=t
    alpha = 0.1
    halfwidth = 1000
    stddev = 25000 45000
    probwidth = 0.95
    ntotal = .;
  plot x=effect min=500 max=2000;
run;
```

The NTOTAL=. option identifies sample size as the parameter to compute. The ALPHA=0.1 option specifies a confidence level of $1 - \alpha = 0.9$. The HALFWIDTH= option specifies the target half-width, and the STDDEV= option specifies the conjectured standard deviation values. The PROBWIDTH= option specifies the desired probability of achieving the target precision. The default value PROBTYP=CONDITIONAL specifies that this probability is conditional on the true mean being captured by the interval. The default of SIDES=2 indicates a 2-sided interval.

[Output 57.7.1](#) shows the output, and [Output 57.7.2](#) shows the plot.

Output 57.7.1. Sample Size Determination for Confidence Interval Precision

The POWER Procedure			
Confidence Interval for Mean			
Fixed Scenario Elements			
Distribution		Normal	
Method		Exact	
Alpha		0.1	
CI Half-Width		1000	
Nominal Prob(Width)		0.95	
Number of Sides		2	
Prob Type		Conditional	
Computed N Total			
Index	Std Dev	Actual Prob (Width)	N Total
1	25000	0.951	1788
2	45000	0.950	5652

Output 57.7.2. Plot of Sample Size vs. Confidence Interval Half-Width

The number of simulations required in order to have a 95% chance of obtaining a half-width of at most 1000 is between 1788 and 5652, depending on the standard deviation. The plot reveals that over 20,000 simulations would be required for a half-width of 500 assuming the higher standard deviation.

Example 57.8. Customizing Plots

The example in this section demonstrates various ways you can modify and enhance plots:

- assigning analysis parameters to axes
- fine-tuning a sample size axis
- adding reference lines
- linking plot features to analysis parameters
- choosing key (legend) styles
- modifying symbol locations

The example plots are all based on a sample size analysis for a two-sample t test of group mean difference. You start by computing the sample size required to achieve a power of 0.9 using a 2-sided test with $\alpha = 0.05$, assuming the first mean is 12, the second mean is either 15 or 18, and the standard deviation is either 7 or 9.

Use the TWOSAMPLEMEANS statement with the TEST=DIFF option to compute the required sample sizes. Indicate total sample size as the result parameter by supplying a missing value (.) with the NTOTAL= option. Use the GROUPMEANS=, STDDEV=, and POWER= option to specify values of the other parameters. The following statements perform the sample size computations.

```
proc power;  
  twosamplemeans test=diff  
    groupmeans   = 12 | 15 18  
    stddev       = 7 9  
    power        = 0.9  
    ntotal       = .;  
run;
```

Default values for the NULLDIFF=, SIDES=, GROUPWEIGHTS=, and DIST= options specify a null mean difference of 0, 2-sided test, balanced design, and assumption of normally distributed data.

Output 57.8.1 shows that the required sample size ranges from 60 to 382 depending on the unknown standard deviation and second mean.

Output 57.8.1. Computed Sample Sizes

The POWER Procedure				
Two-sample t Test for Mean Difference				
Fixed Scenario Elements				
Distribution			Normal	
Method			Exact	
Group 1 Mean			12	
Nominal Power			0.9	
Number of Sides			2	
Null Difference			0	
Alpha			0.05	
Group 1 Weight			1	
Group 2 Weight			1	
Computed N Total				
Index	Mean2	Std Dev	Actual Power	N Total
1	15	7	0.902	232
2	15	9	0.901	382
3	18	7	0.904	60
4	18	9	0.904	98

Assigning Analysis Parameters to Axes

Use the PLOT statement to produce plots for all power and sample size analyses in PROC POWER. For the sample size analysis described at the beginning of this example, suppose you want to plot the required sample size on the y-axis against a range of powers between 0.5 and 0.95 on the x-axis. The X= and Y= options specify which parameter to plot against the result, and which axis to assign to this parameter. You can use either the X= or Y= option, but not both. Use the X=POWER option in PLOT statement to request a plot with power on the x-axis. The result parameter, here total sample size, is always plotted on the other axis. Use the MIN= and MAX= options to specify the range of the axis indicated with either the X= or the Y= option. Here, specify MIN=0.5 and MAX=0.95 to specify the power range. The following statements produce the plot.

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
    stddev     = 7 9
    power      = 0.9
    ntotal     = .;
  plot x=power min=0.5 max=0.95;
run;
```

Note that the value (0.9) of the POWER= option in the TWOSAMPLEMEANS statement is only a placeholder when the PLOTONLY option is used and both the MIN= and MAX= options are used, because the values of the MIN= and MAX= options

override the value of 0.9. But the `POWER=` option itself is still required in the `TWOSAMPLEMEANS` statement, to provide a complete specification of the sample size analysis.

The resulting plot is shown in [Output 57.8.2](#).

Output 57.8.2. Plot of Sample Size versus Power

The line style identifies the group means scenario, and the plotting symbol identifies the standard deviation scenario. The locations of plotting symbols indicate computed sample sizes; the curves are linear interpolations of these points. By default, each curve consists of approximately 20 computed points (sometimes slightly more or less, depending on the analysis).

If you would rather plot power on the y-axis versus sample size on the x-axis, you have two general strategies to choose from. One strategy is to use the `Y=` option instead of the `X=` option in the `PLOT` statement:

```
plot y=power min=0.5 max=0.95;
```

Output 57.8.3. Plot of Power versus Sample Size using First Strategy

Note that the resulting plot ([Output 57.8.3](#)) is essentially a mirror image of [Output 57.8.2](#). The axis ranges are set such that each curve in [Output 57.8.3](#) contains similar values of Y instead of X. Each plotted point represents the computed value of the x-axis at the input value of the y-axis.

A second strategy for plotting power versus sample size (when originally solving for sample size) is to invert the analysis and base the plot on computed power for a given range of sample sizes. This strategy works well for monotonic power curves (as is the case for the t test and most other continuous analyses). It is advantageous in the sense of preserving the traditional role of the y-axis as the computed parameter. A common way to implement this strategy is

- Determine the range of sample sizes sufficient to cover at the desired power range for all curves (where each “curve” represents a scenario for standard deviation and second group mean).
- Use this range for the x-axis of a plot.

To determine the required sample sizes for target powers of 0.5 and 0.95, change the values in the POWER= option to reflect this range:

```

proc power;
  twosamplemeans test=diff
    groupmeans   = 12 | 15 18
    stddev       = 7 9
    power        = 0.5 0.95
    ntotal       = .;
run;

```

Output 57.8.4 reveals that a sample size range of 24 to 470 is approximately sufficient to cover the desired power range of 0.5 to 0.95 for all curves (“approximately” because the actual power at the rounded sample size of 24 is slightly higher than the nominal power of 0.5).

Output 57.8.4. Computed Sample Sizes

The POWER Procedure						
Two-sample t Test for Mean Difference						
Fixed Scenario Elements						
Distribution	Normal					
Method	Exact					
Group 1 Mean	12					
Number of Sides	2					
Null Difference	0					
Alpha	0.05					
Group 1 Weight	1					
Group 2 Weight	1					
Computed N Total						
Index	Mean2	Std Dev	Nominal Power	Actual Power	N Total	
1	15	7	0.50	0.502	86	
2	15	7	0.95	0.951	286	
3	15	9	0.50	0.505	142	
4	15	9	0.95	0.950	470	
5	18	7	0.50	0.519	24	
6	18	7	0.95	0.953	74	
7	18	9	0.50	0.516	38	
8	18	9	0.95	0.952	120	

To plot power on the y-axis for sample sizes between 20 and 500, use the X=N option in the PLOT statement with MIN=20 and MAX=500:

```

proc power plotonly;
  twosamplemeans test=diff
    groupmeans   = 12 | 15 18
    stddev       = 7 9
    power        = .
    ntotal       = 200;
  plot x=n min=20 max=500;
run;

```

Each curve in the resulting plot in [Output 57.8.5](#) covers at least a power range of 0.5 to 0.95.

Output 57.8.5. Plot of Power versus Sample Size Using Second Strategy

Finally, suppose you want to produce a plot of sample size versus effect size for a power of 0.9. In this case, the “effect size” is defined to be the mean difference. You need to reparameterize the analysis by using the MEANDIFF= option instead of the GROUPMEANS= option to produce a plot, since each plot axis must be represented by a scalar parameter. Use the X=EFFECT option in the PLOT statement to assign the mean difference to the x-axis. The following statements produce a plot of required sample size to detect mean differences between 3 and 6.

```
proc power plotonly;
  twosamplemeans test=diff
    meandiff      = 3 6
    stddev        = 7 9
    power         = 0.9
    ntotal       = .;
  plot x=effect min=3 max=6;
run;
```

The resulting plot [Output 57.8.6](#) shows how the required sample size decreases with increasing mean difference.

Output 57.8.6. Plot of Sample Size versus Mean Difference

Fine-Tuning a Sample Size Axis

Consider the following plot request for a sample size analysis similar to the one in [Output 57.8.1](#) but with only a single scenario, and with unbalanced sample size allocation of 2:1.

```
proc power plotonly;
  ods output plotcontent=PlotData;
  twosamplemeans test=diff
    groupmeans = 12 | 18
    stddev      = 7
    groupweights = 2 | 1
    power       = .
    ntotal      = 20;
  plot x=n min=20 max=50 npoints=20;
run;
```

The MIN=, MAX=, and NPOINTS= options in the PLOT statement request a plot with 20 points between 20 and 50. But the resulting plot ([Output 57.8.7](#)) appears to have only 11 points, and they range from 18 to 48.

Output 57.8.7. Plot with Overlapping Points

The reason that this plot has fewer points than usual is due to the rounding of sample sizes. If you do not use the `NFRACTIONAL` option in the analysis statement (here, the `TWOSAMPLEMEANS` statement), then the set of sample size points determined by the `MIN=`, `MAX=`, `NPOINTS=`, and `STEP=` options in the `PLOT` statement may be rounded to satisfy the allocation weights. In this case, they are rounded down to the nearest multiples of 3 (the sum of the weights), and many of the points overlap. To see the overlap, you can print the `NominalNTotal` (unadjusted) and `NTotal` (rounded) variables in the `PlotContent` ODS object (here saved to a data set called `PlotData`):

```
proc print data=PlotData;
    var NominalNTotal NTotal;
run;
```

The output is shown in [Output 57.8.8](#).

Output 57.8.8. Sample Sizes

Obs	Nominal NTotal	NTotal
1	18.0	18
2	19.6	18
3	21.2	21
4	22.7	21
5	24.3	24
6	25.9	24
7	27.5	27
8	29.1	27
9	30.6	30
10	32.2	30
11	33.8	33
12	35.4	33
13	36.9	36
14	38.5	36
15	40.1	39
16	41.7	39
17	43.3	42
18	44.8	42
19	46.4	45
20	48.0	48

Besides overlapping of sample size points, another peculiarity that might occur without the NFRATIONAL option is unequal spacing; for example, in the plot in [Output 57.8.9](#), created with the following statements.

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 18
    stddev      = 7
    groupweights = 2 | 1
    power       = .
    ntotal      = 20;
  plot x=n min=20 max=50 npoints=5;
run;
```

Output 57.8.9. Plot with Unequally Spaced Points

If you want to guarantee evenly spaced, nonoverlapping sample size points in your plots, you can either (1) use the `NFRACTIONAL` option in the analysis statement preceding the `PLOT` statement, or (2) use the `STEP=` option and provide values for the `MIN=`, `MAX=`, and `STEP=` options in the `PLOT` statement that are multiples of the sum of the allocation weights. Note that this sum is simply 1 for one-sample and paired designs and 2 for balanced two-sample designs. So, any integer step value works well for one-sample and paired designs, and any even step value works well for balanced two-sample designs. Both of these strategies will avoid rounding adjustments.

The following statements implement the first strategy to create the plot in [Output 57.8.10](#), using the `NFRACTIONAL` option in the `TWOSAMPLEMEANS` statement.

```
proc power plotonly;
  twosamplemeans test=diff
    nfractional
    groupmeans    = 12 | 18
    stddev        = 7
    groupweights  = 2 | 1
    power         = .
    ntotal        = 20;
  plot x=n min=20 max=50 npoints=20;
run;
```

Output 57.8.10. Plot with Fractional Sample Sizes

To implement the second strategy, use multiples of 3 for the STEP=, MIN=, and MAX= options in the PLOT statement (because the sum of the allocation weights is $2 + 1 = 3$). The following statements use STEP=3, MIN=18, and MAX=48 to create a plot that looks identical to [Output 57.8.7](#) but suffers no overlapping of points.

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans   = 12 | 18
    stddev       = 7
    groupweights = 2 | 1
    power        = .
    ntotal       = 20;
  plot x=n min=18 max=48 step=3;
run;
```

Adding Reference Lines

Suppose you want to add reference lines to highlight power=0.8 and power=0.9 on the plot in [Output 57.8.5](#). You can add simple reference lines using the YOPTS= option and REF= sub-option in the PLOT statement to produce [Output 57.8.11](#), using the following statements.

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans   = 12 | 15 18
```

```

stddev      = 7 9
power       = .
ntotal     = 100;
plot x=n min=20 max=500
      yopts=(ref=0.8 0.9);
run;

```

Output 57.8.11. Plot with Simple Reference Lines on Y-Axis

Or, you can specify `CROSSREF=YES` to add reference lines that intersect each curve and cross over to the other axis:

```

plot x=n min=20 max=500
      yopts=(ref=0.8 0.9 crossref=yes);

```

The resulting plot is shown in [Output 57.8.12](#).

Output 57.8.12. Plot with CROSSREF=YES Style Reference Lines from Y-Axis

You can also add reference lines for the x-axis by using the XOPTS= option instead of the YOPTS= option. For example, the following plot statement produces [Output 57.8.13](#), which has crossing reference lines highlighting the sample size of 100.

```
plot x=n min=20 max=500
     xopts=(ref=100 crossref=yes);
```

Output 57.8.13. Plot with CROSSREF=YES Style Reference Lines from X-Axis

Linking Plot Features to Analysis Parameters

You can use the VARY option in the PLOT statement to specify which of the following features you wish to associate with analysis parameters.

- line style
- plotting symbol
- color
- panel

You can specify mappings between each of these features and one or more analysis parameters, or you can simply choose a subset of these features to use (and rely on default settings to associate these features with multiple-valued analysis parameters).

Suppose you supplement the sample size analysis in [Output 57.8.5](#) to include three values of alpha, using the following statements.

```

proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    alpha         = 0.01 0.025 0.1
    power         = .
    ntotal        = 100;
  plot x=n min=20 max=500;
run;

```

The defaults for the VARY option in the PLOT statement specify line style varying by the ALPHA= parameter, plotting symbol varying by the GROUPMEANS= parameter, panel varying by the STDDEV= parameter, and color remaining constant. The resulting plot, consisting of two panels, is shown in [Output 57.8.14](#) and [Output 57.8.15](#).

Output 57.8.14. Plot with Default VARY Settings: Panel 1 of 2

Output 57.8.15. Plot with Default VARY Settings: Panel 2 of 2

Suppose you want to produce a plot with only one panel that varies color in addition to line style and plotting symbol. Include the `LINestyle`, `SYMBOL`, and `COLOR` keywords in the `VARY` option in the `PLOT` statement, as follows, to produce the plot in [Output 57.8.16](#).

```
plot x=n min=20 max=500
    vary (linestyle, symbol, color);
```

Output 57.8.16. Plot with Varying Color Instead of Panel

Finally, suppose you want to specify which features are used *and* which analysis parameters they are linked to. The following PLOT statement produces a two-panel plot (shown in [Output 57.8.17](#) and [Output 57.8.18](#)) in which line style varies by standard deviation, plotting symbol varies by both alpha and sides, and panel varies by means.

```
plot x=n min=20 max=500
      vary (linestyle by stddev,
            symbol by alpha sides,
            panel by groupmeans);
```

Output 57.8.17. Plot with Features Explicitly Linked to Parameters: Panel 1 of 2

Output 57.8.18. Plot with Features Explicitly Linked to Parameters: Panel 2 of 2

Choosing Key (Legend) Styles

The default style for the key (or “legend”) is one that displays the association between levels of features and levels of analysis parameters, located below the x-axis. For example, [Output 57.8.5](#) demonstrates this style of key.

You can reproduce [Output 57.8.5](#) with the same key but a different location, inside the plotting region, using the POS=INSET option within the KEY=BYFEATURE option in the PLOT statement. The following statements product the plot in [Output 57.8.19](#).

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
    stddev      = 7 9
    power       = .
    ntotal      = 200;
  plot x=n min=20 max=500
      key = byfeature(pos=inset);
run;
```

Output 57.8.19. Plot with a By-Feature Key Inside the Plotting Region

Alternatively, you can specify a key that identifies each individual curve separately by number using the KEY=BYCURVE option in the PLOT statement:

```
plot x=n min=20 max=500
  key = bycurve;
```

The resulting plot is shown in [Output 57.8.20](#).

Output 57.8.20. Plot with a Numbered By-Curve Key

Use the `NUMBERS=OFF` option within the `KEY=BYCURVE` option to specify a nonnumbered key that identifies curves with samples of line styles, symbols, and colors:

```
plot x=n min=20 max=500
     key = bycurve(numbers=off pos=inset);
```

The `POS=INSET` suboption places the key within the plotting region. The resulting plot is shown in [Output 57.8.21](#).

Output 57.8.21. Plot with a Nonnumbered By-Curve Key

Finally, you can attach labels directly to curves with the `KEY=ONCURVES` option. The following plot statement produces [Output 57.8.22](#).

```
plot x=n min=20 max=500
     key = oncurves;
```

Output 57.8.22. Plot with Directly Labeled Curves

Modifying Symbol Locations

The default locations for plotting symbols are the points computed directly from the power and sample size algorithms. For example, [Output 57.8.5](#) shows plotting symbols corresponding to computed points. The curves connecting these points are interpolated (as indicated by the INTERPOL= option in the PLOT statement).

You can modify the locations of plotting symbols using the MARKERS= option in the plot statement. The MARKERS=ANALYSIS option places plotting symbols at locations corresponding to the input specified in the analysis statement preceding the PLOT statement. You may prefer this as an alternative to using reference lines to highlight specific points. For example, you can reproduce [Output 57.8.5](#), but with the plotting symbols located at the sample sizes shown in [Output 57.8.1](#), using the following statements.

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans    = 12 | 15 18
    stddev        = 7 9
    power         = .
    ntotal        = 232 382 60 98;
  plot x=n min=20 max=500
      markers=analysis;
run;
```

The analysis statement here is the TWOSAMPLEMEANS statement. The MARKERS=ANALYSIS option in the PLOT statement causes the plotting

symbols to occur at sample sizes specified by the NTOTAL= option in the TWOSAMPLEMEANS statement: 232, 382, 60, and 98. The resulting plot is shown in [Output 57.8.23](#).

Output 57.8.23. Plot with MARKERS=ANALYSIS

You can also use the MARKERS=NICE option to align symbols with the tick marks on one of the axes (the x-axis when the X= option is used, or the y-axis when the Y= is used):

```
plot x=n min=20 max=500
     markers=nice;
```

The plot created by this PLOT statement is shown in [Output 57.8.24](#).

Output 57.8.24. Plot with MARKERS=NICE

Note that the plotting symbols are aligned with the tick marks on the x-axis because the X= option is specified.

Chapter 58

The PRINCOMP Procedure

Overview

The PRINCOMP procedure performs principal component analysis. As input you can use raw data, a correlation matrix, a covariance matrix, or a sums of squares and crossproducts (SSCP) matrix. You can create output data sets containing eigenvalues, eigenvectors, and standardized or unstandardized principal component scores.

Principal component analysis is a multivariate technique for examining relationships among several quantitative variables. The choice between using factor analysis and principal component analysis depends in part upon your research objectives. You should use the PRINCOMP procedure if you are interested in summarizing data and detecting linear relationships. Plots of principal components are especially valuable tools in exploratory data analysis. You can use principal components to reduce the number of variables in regression, clustering, and so on. See [Chapter 5, “Introduction to Multivariate Procedures,”](#) for a detailed comparison of the PRINCOMP and FACTOR procedures.

Experimental graphics are now available with the PRINCOMP procedure. For more information, see the [“ODS Graphics”](#) section on page 3613.

Principal component analysis was originated by Pearson (1901) and later developed by Hotelling (1933). The application of principal components is discussed by Rao (1964), Cooley and Lohnes (1971), and Gnanadesikan (1977). Excellent statistical treatments of principal components are found in Kshirsagar (1972), Morrison (1976), and Mardia, Kent, and Bibby (1979).

Given a data set with p numeric variables, you can compute p principal components. Each principal component is a linear combination of the original variables, with coefficients equal to the eigenvectors of the correlation or covariance matrix. The eigenvectors are customarily taken with unit length. The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

Principal components have a variety of useful properties (Rao 1964; Kshirsagar 1972):

- The eigenvectors are orthogonal, so the principal components represent jointly perpendicular directions through the space of the original variables.
- The principal component scores are jointly uncorrelated. Note that this property is quite distinct from the previous one.
- The first principal component has the largest variance of any unit-length linear combination of the observed variables. The j th principal component has the largest variance of any unit-length linear combination orthogonal to the first

$j - 1$ principal components. The last principal component has the smallest variance of any linear combination of the original variables.

- The scores on the first j principal components have the highest possible generalized variance of any set of unit-length linear combinations of the original variables.
- The first j principal components provide a least-squares solution to the model

$$\mathbf{Y} = \mathbf{XB} + \mathbf{E}$$

where \mathbf{Y} is an $n \times p$ matrix of the centered observed variables; \mathbf{X} is the $n \times j$ matrix of scores on the first j principal components; \mathbf{B} is the $j \times p$ matrix of eigenvectors; \mathbf{E} is an $n \times p$ matrix of residuals; and you want to minimize $\text{trace}(\mathbf{E}'\mathbf{E})$, the sum of all the squared elements in \mathbf{E} . In other words, the first j principal components are the best linear predictors of the original variables among all possible sets of j variables, although any nonsingular linear transformation of the first j principal components would provide equally good prediction. The same result is obtained if you want to minimize the determinant or the Euclidean (Schur, Frobenius) norm of $\mathbf{E}'\mathbf{E}$ rather than the trace.

- In geometric terms, the j -dimensional linear subspace spanned by the first j principal components provides the best possible fit to the data points as measured by the sum of squared perpendicular distances from each data point to the subspace. This is in contrast to the geometric interpretation of least squares regression, which minimizes the sum of squared vertical distances. For example, suppose you have two variables. Then, the first principal component minimizes the sum of squared perpendicular distances from the points to the first principal axis. This is in contrast to least squares, which would minimize the sum of squared vertical distances from the points to the fitted line.

Principal component analysis can also be used for exploring polynomial relationships and for multivariate outlier detection (Gnanadesikan 1977), and it is related to factor analysis, correspondence analysis, allometry, and biased regression techniques (Mardia, Kent, and Bibby 1979).

Getting Started

The following example uses the PRINCOMP procedure to analyze job performance. Police officers were rated by their supervisors in 14 categories as part of standard police departmental administrative procedure.

The following statements create the Jobratings data set:

```
options validvarname=any;

data Jobratings;
  input ('Communication Skills'n
        'Problem Solving'n
        'Learning Ability'n
```

```

'Judgment Under Pressure'n
'Observational Skills'n
'Willingness to Confront Problems'n
'Interest in People'n
'Interpersonal Sensitivity'n
'Desire for Self-Improvement'n
'Appearance'n
'Dependability'n
'Physical Ability'n
'Integrity'n
'Overall Rating'n) (1.);
datalines;
26838853879867
74758876857667
56757863775875
67869777988997
...
99899899899899
76656399567486
;
```

The data set `Jobratings` contains 14 variables. Each variable contains the job ratings using a scale measurement from 1 to 10 (1=fail to comply, 10=exceptional). The last variable `Overall Rating` contains a score as an overall index on how each officer performs.

The following statement requests a principal component analysis on the `Jobratings` data set and outputs the scores to the `Scores` data set (`OUT= Scores`). Note that variable `Overall Rating` is excluded from the analysis.

```
proc princomp data=Jobratings(drop='Overall Rating'n) out=scores;
run;
```

Figure 58.1 to Figure 58.3 display the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. The PROC PRINCOMP statement requests by default principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 13. In this example, it would also be reasonable to use the `COV` option, which would cause variables with a high variance (such as `Dependability`) to have more influence on the results than variables with a low variance (such as `Learning Ability`). If you used the `COV` option, scores would be computed from centered rather than standardized variables.

Figure 58.3. (Continued) Correlation Matrix from the PRINCOMP Procedure

Figure 58.4 displays the eigenvalues. The first principal component explains about 50% of the total variance, the second principal component explains about 13.6%, and the third principal component explains about 7.7%. Note that the eigenvalues sum to the total variance. The eigenvalues indicate that three to five components provide a good summary of the data, with three components accounting for about 71.7% of the total variance and five components explaining about 82.7%. Subsequent components contribute less than 5% each.

Figure 58.4. Eigenvalues from the PRINCOMP Procedure

Figure 58.5 and Figure 58.6 display the eigenvectors. From the eigenvectors matrix, you can represent the first principal component Prin1 as a linear combination of the original variables

$$\begin{aligned}
 \text{Prin1} = & 0.303548 \times (\text{Communication Skills}) \\
 & +0.278034 \times (\text{Problem Solving}) \\
 & +0.266521 \times (\text{Learning Ability}) \\
 & \cdot \\
 & \cdot \\
 & \cdot \\
 & +0.298246 \times (\text{Integrity})
 \end{aligned}$$

and, similarly, the second principal component Prin2 is

$$\begin{aligned}
 \text{Prin2} = & 0.052039 \times (\text{Communication Skills}) \\
 & +0.057046 \times (\text{Problem Solving}) \\
 & +0.288152 \times (\text{Learning Ability}) \\
 & \cdot \\
 & \cdot \\
 & \cdot \\
 & -0.301812 \times (\text{Integrity})
 \end{aligned}$$

where the variables are standardized.

Figure 58.6. (Continued) Eigenvectors from the PRINCOMP Procedure

The first component reflects overall performance since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on the variables **Observational Skills** and **Willingness to Confront Problems** but even higher negative loadings on the variables **Interest in People** and **Interpersonal Sensitivity**. This component seems to reflect the ability to take action, but it also reflects a lack of interpersonal skills. The third eigenvector has a very high positive loading on the variable **Physical Ability** and high negative loadings on the variables **Problem Solving** and **Learning Ability**. This component seems to reflect physical strength, but also shows poor learning and problem-solving skills.

In short, the three components represent:

First Component: overall performance

Second Component: smart, tough, and introverted

Third Component: superior strength and average intellect

Syntax

The following statements are available in PROC PRINCOMP.

```

PROC PRINCOMP < options > ;
  BY variables ;
  FREQ variable ;
  PARTIAL variables ;
  VAR variables ;
  WEIGHT variable ;

```

Usually only the VAR statement is used in addition to the PROC PRINCOMP statement. The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINCOMP statement. The remaining statements are described in alphabetical order.

PROC PRINCOMP Statement

```

PROC PRINCOMP < options > ;

```

The PROC PRINCOMP statement starts the PRINCOMP procedure and, optionally, identifies input and output data sets, specifies details of the analysis, or suppresses the display of output. You can specify the following options in the PROC PRINCOMP statement.

Task	Options
Specify data sets	DATA= OUT= OUTSTAT=
Specify details of analysis	COV N= NOINT PREFIX= SINGULAR= STD VARDEF=
Suppress the display of output	NOPRINT

The following list provides details on these options.

COVARIANCE

COV

computes the principal components from the covariance matrix. If you omit the COV option, the correlation matrix is analyzed. Use of the COV option causes variables with large variances to be more strongly associated with components with large eigenvalues and causes variables with small variances to be more strongly associated with

components with small eigenvalues. You should not specify the COV option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

DATA=SAS-data-set

specifies the SAS data set to be analyzed. The data set can be an ordinary SAS data set or a TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV data set (see [Appendix A, “Special SAS Data Sets,”](#)). Also, the PRINCOMP procedure can read the _TYPE_='COVB' matrix from a TYPE=EST data set. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

N=number

specifies the number of principal components to be computed. The default is the number of variables. The value of the N= option must be an integer greater than or equal to zero.

NOINT

omits the intercept from the model. In other words, the NOINT option requests that the covariance or correlation matrix not be corrected for the mean. When you use the PRINCOMP procedure with the NOINT option, the covariance matrix and, hence, the standard deviations are not corrected for the mean. If you are interested in the standard deviations corrected for the mean, you can get them by using a procedure such as the MEANS procedure.

If you use a TYPE=SSCP data set as input to the PRINCOMP procedure and list the variable Intercept in the VAR statement, the procedure acts as if you had also specified the NOINT option. If you use NOINT and also create an OUTSTAT= data set, the data set is TYPE=UCORR or TYPE=UCOV rather than TYPE=CORR or TYPE=COV.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14, “Using the Output Delivery System.”](#)

OUT=SAS-data-set

creates an output SAS data set that contains all the original data as well as the principal component scores. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for information on permanent SAS data sets).

OUTSTAT=SAS-data-set

creates an output SAS data set that contains means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors. If you specify the COV option, the data set is TYPE=COV or TYPE=UCOV, depending on the NOINT option, and it contains covariances; otherwise, the data set is TYPE=CORR or TYPE=UCORR, depending on the NOINT option, and it contains correlations. If you specify the PARTIAL statement, the OUTSTAT= data set contains *R*-squares as well. If you want to create a permanent SAS data set, you must specify a two-level

name (refer to *SAS Language Reference: Concepts* for information on permanent SAS data sets).

PREFIX=*name*

specifies a prefix for naming the principal components. By default, the names are Prin1, Prin2, . . . , Prin*n*. If you specify PREFIX=ABC, the components are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the current name length defined by the VALIDVARNAME= system option.

SINGULAR=*p***SING=***p*

specifies the singularity criterion, where $0 < p < 1$. If a variable in a PARTIAL statement has an R-square as large as $1 - p$ when predicted from the variables listed before it in the statement, the variable is assigned a standardized coefficient of 0. By default, SINGULAR=1E-8.

STANDARD**STD**

standardizes the principal component scores in the OUT= data set to unit variance. If you omit the STANDARD option, the scores have variance equal to the corresponding eigenvalue. Note that STANDARD has no effect on the eigenvalues themselves.

VARDEF=DF | N | WDF | WEIGHT | WGT

specifies the divisor used in calculating variances and standard deviations. By default, VARDEF=DF. The following table displays the values and associated divisors.

Value	Divisor	Formula	
DF	error degrees of freedom	$n - i$	(before partialling)
		$n - p - i$	(after partialling)
N	number of observations	n	
WEIGHT WGT	sum of weights	$\sum_{j=1}^n w_j$	
WDF	sum of weights minus one	$\left(\sum_{j=1}^n w_j \right) - i$	(before partialling)
		$\left(\sum_{j=1}^n w_j \right) - p - i$	(after partialling)

In the formulas for VARDEF=DF and VARDEF=WDF, p is the number of degrees of freedom of the variables in the PARTIAL statement, and i is 0 if the NOINT option is specified and 1 otherwise.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PRINCOMP to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PRINCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

The FREQ statement specifies a variable that provides frequencies for each observation in the DATA= data set. Specifically, if n is the value of the FREQ variable for a given observation, then that observation is used n times.

The analysis produced using a FREQ statement reflects the expanded number of observations. The total number of observations is considered equal to the sum of the FREQ variable. You could produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated n_j times in the new data set, where n_j is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

PARTIAL Statement

PARTIAL *variables* ;

If you want to analyze a partial correlation or covariance matrix, specify the names of the numeric variables to be partialled out in the PARTIAL statement. The PRINCOMP procedure computes the principal components of the residuals from the prediction of the VAR variables by the PARTIAL variables. If you request an OUT= or OUTSTAT= data set, the residual variables are named by prefixing the characters R_ to the VAR variables. Thus, the number of characters required to distinguish the VAR variables should be, at most, two characters fewer than the current name length defined by the VALIDVARNAME= system option.

VAR Statement

VAR *variables* ;

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables not specified in other statements are analyzed. If, however, the DATA= data set is TYPE=SSCP, the default set of variables used as VAR variables does not include Intercept so that the correlation or covariance matrix is constructed correctly. If you want to analyze Intercept as a separate variable, you should specify it in the VAR statement.

WEIGHT Statement

WEIGHT *variable* ;

If you want to use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances.

The observation is used in the analysis only if the value of the WEIGHT statement variable is nonmissing and is greater than zero.

Details

Missing Values

Observations with missing values for any variable in the VAR, PARTIAL, FREQ, or WEIGHT statement are omitted from the analysis and are given missing values for principal component scores in the OUT= data set. If a correlation, covariance, or SSCP matrix is read, it can contain missing values as long as every pair of variables has at least one nonmissing entry.

Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the principal component scores. The N= option determines the number of new variables. The names of the new variables are formed by concatenating the value given by the PREFIX= option (or Prin if PREFIX= is omitted) and the numbers 1, 2, 3, and so on. The new variables have mean 0 and variance equal to the corresponding eigenvalue, unless you specify the STANDARD option to standardize the scores to unit variance. Also, if you specify the COV option, the procedure computes the principal component scores from the corrected or the uncorrected (if the NOINT option is specified) variables rather than the standardized variables.

If you use a PARTIAL statement, the OUT= data set also contains the residuals from predicting the VAR variables from the PARTIAL variables. The names of the residual variables are formed by prefixing R_ to the names of the VAR variables.

An OUT= data set cannot be created if the DATA= data set is TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=EST, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV.

OUTSTAT= Data Set

The OUTSTAT= data set is similar to the TYPE=CORR data set produced by the CORR procedure. The following table relates the TYPE= value for the OUTSTAT= data set to the options specified in the PROC PRINCOMP statement.

Options	TYPE=
(default)	CORR
COV	COV
NOINT	UCORR
COV NOINT	UCOV

Notice that the default (neither the COV nor NOINT option) produces a TYPE=CORR data set.

The new data set contains the following variables:

- the BY variables, if any
- two new variables, _TYPE_ and _NAME_, both character variables
- the variables analyzed, that is, those in the VAR statement; or, if there is no VAR statement, all numeric variables not listed in any other statement; or, if there is a PARTIAL statement, the residual variables as described under the OUT= data set

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

TYPE

MEAN	mean of each variable. If you specify the PARTIAL statement, this observation is omitted.
STD	standard deviations. If you specify the COV option, this observation is omitted, so the SCORE procedure does not standardize the variables before computing scores. If you use the PARTIAL statement, the standard deviation of a variable is computed as its root mean squared error as predicted from the PARTIAL variables.
USTD	uncorrected standard deviations. When you specify the NOINT option in the PROC PRINCOMP statement, the OUTSTAT= data set contains standard deviations not corrected for the mean. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
N	number of observations on which the analysis is based. This value is the same for each variable. If you specify the PARTIAL statement and the value of the VARDEF= option is DF or unspecified, then the number of observations is decremented by the degrees of freedom for the PARTIAL variables.
SUMWGT	the sum of the weights of the observations. This value is the same for each variable. If you specify the PARTIAL statement and VARDEF=WDF , then the sum of the weights is decremented by the degrees of freedom for the PARTIAL variables. This observation is output only if the value is different from that in the observation with _TYPE_='N' .
CORR	correlations between each variable and the variable specified by the _NAME_ variable. The number of observations with _TYPE_='CORR' is equal to the number of variables being analyzed. If you specify the COV option, no _TYPE_='CORR' observations are produced. If you use the PARTIAL statement, the partial correlations, not the raw correlations, are output.
UCORR	uncorrected correlation matrix. When you specify the NOINT option without the COV option in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of correlations not corrected for the means. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.
COV	covariances between each variable and the variable specified by the _NAME_ variable. _TYPE_='COV' observations are produced only if you specify the COV option. If you use the PARTIAL statement, the partial covariances, not the raw covariances, are output.
UCOV	uncorrected covariance matrix. When you specify the NOINT and COV options in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of covariances not corrected for the means.
EIGENVAL	eigenvalues. If the N= option requested fewer than the maximum number of principal components, only the specified number of eigenvalues are produced, with missing values filling out the observation.

- SCORE** eigenvectors. The `_NAME_` variable contains the name of the corresponding principal component as constructed from the `PREFIX=` option. The number of observations with `_TYPE_='SCORE'` equals the number of principal components computed. The eigenvectors have unit length unless you specify the `STD` option, in which case the unit-length eigenvectors are divided by the square roots of the eigenvalues to produce scores with unit standard deviations.
- To obtain the principal component scores, if the `COV` option is not specified, these coefficients should be multiplied by the standardized data. With the `COV` option, these coefficients should be multiplied by the centered data. Means obtained from the observation with `_TYPE_='MEAN'` and standard deviations obtained from the observation with `_TYPE_='STD'` should be used for centering and standardizing the data.
- USCORE** scoring coefficients to be applied without subtracting the mean from the raw variables. `_TYPE_='USCORE'` observations are produced when you specify the `NOINT` option in the `PROC PRINCOMP` statement.
- To obtain the principal component scores, these coefficients should be multiplied by the data that are standardized by the uncorrected standard deviations obtained from the observation with `_TYPE_='USTD'`.
- RSQUARED** R-squares for each VAR variable as predicted by the `PARTIAL` variables
- B** regression coefficients for each VAR variable as predicted by the `PARTIAL` variables. This observation is produced only if you specify the `COV` option.
- STB** standardized regression coefficients for each VAR variable as predicted by the `PARTIAL` variables. If you specify the `COV` option, this observation is omitted.

The data set can be used with the `SCORE` procedure to compute principal component scores, or it can be used as input to the `FACTOR` procedure specifying `METHOD=SCORE` to rotate the components. If you use the `PARTIAL` statement, the scoring coefficients should be applied to the residuals, not the original variables.

Computational Resources

Let

- n = number of observations
- v = number of VAR variables
- p = number of `PARTIAL` variables
- c = number of components

- The minimum allocated memory required is

$$232v + 120p + 48c + \max(8cv, 8vp + 4(v + p)(v + p + 1))$$

bytes

- The time required to compute the correlation matrix is roughly proportional to

$$n(v + p)^2 + \frac{p}{2}(v + p)(v + p + 1)$$

- The time required to compute eigenvalues is roughly proportional to v^3 .
- The time required to compute eigenvectors is roughly proportional to cv^2 .

Displayed Output

The PRINCOMP procedure displays the following items if the DATA= data set is not TYPE=CORR, TYPE=COV, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV:

- Simple Statistics, including the Mean and Std (standard deviation) for each variable. If you specify the NOINT option, the uncorrected standard deviation (UStD) is displayed.
- the Correlation or, if you specify the COV option, the Covariance Matrix

The PRINCOMP procedure displays the following items if you use the PARTIAL statement.

- Regression Statistics, giving the R -square and RMSE (root mean square error) for each VAR variable as predicted by the PARTIAL variables (not shown)
- Standardized Regression Coefficients or, if you specify the COV option, Regression Coefficients for predicting the VAR variables from the PARTIAL variables (not shown)
- the Partial Correlation Matrix or, if you specify the COV option, the Partial Covariance Matrix (not shown)

The PRINCOMP procedure displays the following item if you specify the COV option:

- the Total Variance

The PRINCOMP procedure displays the following items unless you specify the NOPRINT option:

- Eigenvalues of the correlation or covariance matrix, as well as the Difference between successive eigenvalues, the Proportion of variance explained by each eigenvalue, and the Cumulative proportion of variance explained
- the Eigenvectors

ODS Table Names

PROC PRINCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 58.1. ODS Tables Produced in PROC PRINCOMP

ODS Table Name	Description	Statement / Option
Corr	Correlation Matrix	default unless COV is specified
Cov	Covariance Matrix	default if COV is specified
Eigenvalues	Eigenvalues	default
Eigenvectors	Eigenvectors	default
NObsNVar	Number of Observations, Variables and (Partial) Variables	default
ParCorr	Partial Correlation Matrix	PARTIAL statement
ParCov	Uncorrected Partial Covariance Matrix	PARTIAL statement COV
RegCoef	Regression Coefficients	PARTIAL statement COV
RSquareRMSE	Regression Statistics: R-Squares and RMSEs	PARTIAL statement
SimpleStatistics	Simple Statistics	default
StdRegCoef	Standardized Regression Coefficients	PARTIAL statement
TotalVariance	Total Variance	PROC PRINCOMP COV

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the PRINCOMP procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

You can specify the N= option in the PRINCOMP statement to control the number of principal components to be displayed.

ODS Graph Names

PROC PRINCOMP assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 58.2.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

Table 58.2. ODS Graphics Produced by PROC PRINCOMP

ODS Graph Name	Plot Description	Statement
EigenvaluePlot	Eigenvalues and Proportion Plot	default
PaintedPrinCompScoresPlot	Painted Component Scores Plot: 2nd versus 3rd, painted by 1st	default and <i>nvar*</i> \geq 3
PrinCompMatrixPlot	Component Scores Matrix Plot	default and <i>nvar</i> \geq 2
PrinCompPatternPlot	Component Pattern Plot	default
PrinCompScoresPlot12	Component Scores Plot: 1st versus 2nd	default and <i>nvar</i> \geq 2
PrinCompScoresPlot13	Component Scores Plot: 1st versus 3rd	default and <i>nvar</i> \geq 3

Examples

Example 58.1. Temperatures

This example analyzes mean daily temperatures in selected cities in January and July. Both the raw data and the principal components are plotted to illustrate how principal components are orthogonal rotations of the original variables.

The following statements create the Temperature data set:

```
data Temperature;
  title 'Mean Temperature in January and July for Selected Cities ';
  input City $1-15 January July;
  cards;
Mobile          51.2 81.6
Phoenix         51.2 91.2
Little Rock     39.5 81.4
Sacramento     45.1 75.2
Denver          29.9 73.0
Hartford       24.8 72.7
Wilmington     32.0 75.8
Washington DC  35.6 78.7
Jacksonville   54.6 81.0
Miami          67.2 82.3
Atlanta        42.4 78.0
Boise          29.0 74.5
Chicago        22.9 71.9
Peoria         23.8 75.1
Indianapolis   27.9 75.0
Des Moines     19.4 75.1
Wichita        31.3 80.7
Louisville     33.3 76.9

Charleston, WV 34.5 75.0
Milwaukee     19.4 69.9
Cheyenne      26.6 69.1
;

```

The following statements plot the temperature data set. For information on the %PLOTIT macro, see [Appendix B, “Using the %PLOTIT Macro.”](#)

```

title2 'Plot of Raw Data';
%plotit(data=Temperature,labelvar=City,
         plotvars=July January, color=black, colors=black);
run;

```

The results are displayed in [Output 58.1.1](#), which shows a scatter diagram of the 64 pairs of data points with July temperatures plotted against January temperatures.

Output 58.1.1. Plot of Raw Data

The following statement requests a principal component analysis on the Temperature data set and outputs the scores to the Prin data set (OUT=Prin):

```
proc princomp data=Temperature cov out=Prin;
var July January;
run;
```

[Output 58.1.2](#) displays the PROC PRINCOMP output. The standard deviation of January (11.712) is higher than the standard deviation of July (5.128). The COV option in the PROC PRINCOMP statement requests the principal components to be computed from the covariance matrix. The total variance is 163.474. The first principal component explains about 94% of the total variance, and the second principal component explains only about 6%. The eigenvalues sum to the total variance.

Note that January receives a higher loading on Prin1 because it has a higher standard deviation than July, and the PRINCOMP procedure calculates the scores using the centered variables rather than the standardized variables.

Output 58.1.2. Results of Principal Component Analysis

Mean Temperature in January and July for Selected Cities				
The PRINCOMP Procedure				
Observations		64		
Variables		2		
Simple Statistics				
	July	January		
Mean	75.60781250	32.09531250		
StD	5.12761910	11.71243309		
Covariance Matrix				
	July	January		
July	26.2924777	46.8282912		
January	46.8282912	137.1810888		
Total Variance	163.47356647			
Eigenvalues of the Covariance Matrix				
	Eigenvalue	Difference	Proportion	Cumulative
1	154.310607	145.147647	0.9439	0.9439
2	9.162960		0.0561	1.0000
Eigenvectors				
	Prin1	Prin2		
July	0.343532	0.939141		
January	0.939141	-.343532		

The following statement plots the Prin data set created from the previous PROC PRINCOMP statement:

```

title2 'Plot of Principal Components';
%plotit(data=Prin,labelvar=City,
        plotvars=Prin2 Prin1, color=black, colors=black);
run;

```

Output 58.1.3 displays a plot of the second principal component Prin2 against the first principal component Prin1. It is clear from this plot that the principal components are orthogonal rotations of the original variables and that the first principal component has a larger variance than the second principal component. In fact, Prin1 has a larger variance than either of the original variables July and January.

Output 58.1.3. Plot of Principal Components

Example 58.2. Crime Rates

The following data provide crime rates per 100,000 people in seven categories for each of the fifty states in 1977. Since there are seven numeric variables, it is impossible to plot all the variables simultaneously. Principal components can be used to summarize the data in two or three dimensions, and they help to visualize the data. The following statements produce [Output 58.2.1](#):

```

data Crime;
  title 'Crime Rates per 100,000 Population by State';
  input State $1-15 Murder Rape Robbery Assault
         Burglary Larceny Auto_Theft;
cards;

```

The eigenvalues indicate that two or three components provide a good summary of the data, two components accounting for 76% of the total variance and three components explaining 87%. Subsequent components contribute less than 5% each.

The first component is a measure of overall crime rate since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on variables `Auto_Theft` and `Larceny` and high negative loadings on variables `Murder` and `Assault`. There is also a small positive loading on `Burglary` and a small negative loading on `Rape`. This component seems to measure the preponderance of property crime over violent crime. The interpretation of the third component is not obvious.

A simple way to examine the principal components in more detail is to display the output data set sorted by each of the large components. The following statements produce [Output 58.2.2](#) through [Output 58.2.3](#):

```
proc sort data=Crime_Components;
  by Prin1;
run;

proc print;
  id State;
  var Prin1 Prin2 Murder Rape Robbery
      Assault Burglary Larceny Auto_Theft;
  title2 'States Listed in Order of Overall Crime Rate';
  title3 'As Determined by the First Principal Component';
run;

proc sort data=Crime_Components;
  by Prin2;
run;

proc print;
  id State;
  var Prin1 Prin2 Murder Rape Robbery
      Assault Burglary Larceny Auto_Theft;
  title2 'States Listed in Order of Property Vs. Violent Crime';
  title3 'As Determined by the Second Principal Component';
run;
```

Output 58.2.2. OUT= Data Set Sorted by First Principal Component

Rhode Island	-0.20156	2.14658	3.6	10.5	86.5	201.0	1489.5	2844.1	791.4
Massachusetts	0.97844	2.63105	3.1	20.8	169.1	231.6	1532.2	2311.3	1140.1

Another recommended procedure is to make scatter plots of the first few components. The sorted listings help to identify observations on the plots. The following statements produce [Output 58.2.4](#) through [Output 58.2.5](#):

```

title2 'Plot of the First Two Principal Components';

%plotit(data=Crime_Components,labelvar=State,
        plotvars=Prin2 Prin1, color=black, colors=black);

run;

title2 'Plot of the First and Third Principal Components';

%plotit(data=Crime_Components,labelvar=State,
        plotvars=Prin3 Prin1, color=black, colors=black);

run;

```

Output 58.2.4. Plot of the First Two Principal Components

Output 58.2.5. Plot of the First and Third Principal Components

It is possible to identify regional trends on the plot of the first two components. Nevada and California are at the extreme right, with high overall crime rates but an average ratio of property crime to violent crime. North and South Dakota are on the extreme left with low overall crime rates. Southeastern states tend to be in the bottom of the plot, with a higher-than-average ratio of violent crime to property crime. New England states tend to be in the upper part of the plot, with a greater-than-average ratio of property crime to violent crime.

The most striking feature of the plot of the first and third principal components is that Massachusetts and New York are outliers on the third component.

Example 58.3. Basketball Data

The data in this example are rankings of 35 college basketball teams. The rankings were made before the start of the 1985–86 season by 10 news services.

The purpose of the principal component analysis is to compute a single variable that best summarizes all 10 of the preseason rankings.

Note that the various news services rank different numbers of teams, varying from 20 through 30 (there is a missing rank in one of the variables, WashPost). And,

of course, each service does not rank the same teams, so there are missing values in these data. Each of the 35 teams is ranked by at least one news service.

The PRINCOMP procedure omits observations with missing values. To obtain principal component scores for all of the teams, it is necessary to replace the missing values. Since it is the best teams that are ranked, it is not appropriate to replace missing values with the mean of the nonmissing values. Instead, an ad hoc method is used that replaces missing values by the mean of the unassigned ranks. For example, if 20 teams are ranked by a news service, then ranks 21 through 35 are unassigned. The mean of ranks 21 through 35 is 28, so missing values for that variable are replaced by the value 28. To prevent the method of missing-value replacement from having an undue effect on the analysis, each observation is weighted according to the number of nonmissing values it has. See [Example 59.3 in Chapter 59, “The PRINQUAL Procedure,”](#) for an alternative analysis of these data.

Since the first principal component accounts for 78% of the variance, there is substantial agreement among the rankings. The eigenvector shows that all the news services are about equally weighted, so a simple average would work almost as well as the first principal component. The following statements produce [Output 58.3.1](#) through [Output 58.3.3](#):

```

/*-----*/
/*
/* Preseason 1985 College Basketball Rankings          */
/* (rankings of 35 teams by 10 news services)          */
/*
/* Note: (a) news services rank varying numbers of teams; */
/*       (b) not all teams are ranked by all news services; */
/*       (c) each team is ranked by at least one service; */
/*       (d) rank 20 is missing for UPI.                */
/*

Example 58.4. PRINCOMP Graphics (Experimental)

This example illustrates the experimental ODS graphics in PROC PRINCOMP, using the example in the the “Getting Started” section on page 3596.

The following statements request plots in PROC PRINCOMP.

```
ods html;
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n) n=5;
  run;

ods graphics off;
ods html close;
```

These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see [Chapter 15, “Statistical Graphics Using ODS.”](#) For specific information about the graphics available in the PRINCOMP procedure, see the “[ODS Graphics](#)” section on page 3613.

The N= 5 option in the PROC PRINCOMP statement sets the number of principal components to 5.

[Output 58.4.1](#) shows the eigenvalue plots. Each point in the plot on the left shows an eigenvalue; each point in the plot on the right shows the (cumulative) proportion of variance explained by each component.

Output 58.4.1. Eigenvalue Scatter Plot (Experimental)

[Output 58.4.2](#) shows a scatter matrix plot between the first five components. The histogram of each component is displayed in the diagonal element of the matrix.

Output 58.4.2. Component Scores Matrix Plot (Experimental)

Output 58.4.3 shows a component pattern profile. The Y-axis shows the correlation between a component and a variable. There is one profile for each component. Line patterns are used to differentiate correlations between components.

The nearly horizontal profile from the first component indicates that the first component is mostly correlated evenly across all variables. The second component is positively correlated with the variables **Observational Skills** and **Willingness to Confront Problems** and is negatively correlated with the variables **Interest in People** and **Interpersonal Sensitivity**.

Output 58.4.3. Component Pattern Plot (Experimental)

Output 58.4.4 shows a scatter plot of the first and second components. Observation numbers are used as the plotting symbol.

Output 58.4.4. Component Scores Plot: 1st versus 2nd (Experimental)

Output 58.4.5 shows a scatter plot of the first and third components.

Output 58.4.5. Component Scores Plot: 1st versus 3rd (Experimental)

Output 58.4.6 shows a scatter plot of the second and third components, displaying density with color. Color interpolation is based on the first component, going from blue (or light gray) (minimum density), magenta (or dark gray) (median density), and to red (or black) (maximum density).

Output 58.4.6. Painted Components Scores Plot: 2nd versus 3rd, Painted by 1st (Experimental)

Chapter 59

The PRINQUAL Procedure

Overview

The PRINQUAL procedure obtains linear and nonlinear transformations of variables by using the method of alternating least squares to optimize properties of the transformed variables' covariance or correlation matrix. Nonoptimal transformations for logarithm, rank, exponentiation, inverse sine, and logit are also available with PROC PRINQUAL. Experimental graphics are now available with the PRINQUAL procedure. For more information, see the “[ODS Graphics](#)” section on page 3677.

The PRINQUAL (principal components of qualitative data) procedure is a data transformation procedure that is based on the work of Kruskal and Shepard (1974); Young, Takane, and de Leeuw (1978); Young (1981); and Winsberg and Ramsay (1983). You can use PROC PRINQUAL to

- generalize ordinary principal component analysis to a method capable of analyzing data that are not quantitative
- perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972)
- preprocess data, transforming variables prior to their use in other data analyses
- summarize mixed quantitative and qualitative data and detect nonlinear relationships
- reduce the number of variables for subsequent use in regression analyses, cluster analyses, and other analyses

The PRINQUAL procedure provides three methods of transforming a set of qualitative and quantitative variables to optimize the transformed variables' covariance or correlation matrix. These methods are

- maximum total variance (MTV)
- minimum generalized variance (MGV)
- maximum average correlation (MAC)

All three methods attempt to find transformations that decrease the rank of the covariance matrix computed from the transformed variables. Transforming the variables to maximize the variance accounted for by a few linear combinations (using the MTV method) locates the observations in a space with dimensionality that approximates the stated number of linear combinations as much as possible, given the transformation constraints. Transforming the variables to minimize their generalized variance or

maximize the sum of correlations also reduces the dimensionality. The transformed qualitative (nominal and ordinal) variables can be thought of as quantified by the analysis, with the quantification done in the context set by the algorithm. The data are quantified so that the proportion of variance accounted for by a stated number of principal components is locally maximal, the generalized variance of the variables is locally minimal, or the average of the correlations is locally maximal.

The data can contain variables with nominal, ordinal, interval, and ratio scales of measurement (Siegel 1956). Any mix is allowed with all methods. PROC PRINQUAL can

- transform nominal variables by scoring the categories to optimize the covariance matrix (Fisher 1938)
- transform ordinal variables monotonically by scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and the covariance matrix is optimized. You can untie ties optimally or leave them tied (Kruskal 1964). You can also transform ordinal variables to ranks.
- transform interval and ratio scale of measurement variables linearly, or transform them nonlinearly with spline transformations (de Boor 1978; van Rijckevorsel 1982) or monotone spline transformations (Winsberg and Ramsay 1983). In addition, nonoptimal transformations for logarithm, exponential, power, logit, and inverse trigonometric sine are available.
- for all transformations, estimate missing data without constraint, with category constraints (missing values within the same group get the same value), and with order constraints (missing value estimates in adjacent groups can be tied to preserve a specified ordering). Refer to Gifi (1990) and Young (1981).

The PROC PRINQUAL iterations produce a set of transformed variables. Each variable's new scoring satisfies a set of constraints based on the original scoring of the variable and the specified transformation type. First, all variables are required to satisfy transformation standardization constraints; that is, all variables have a fixed mean and variance. The other constraints include linear constraints, weak order constraints, category constraints, and smoothness constraints. The new set of scores is selected from the sets of possible scorings that do not violate the constraints so that the method criterion is locally optimized.

The displayed output from PROC PRINQUAL is a listing of the iteration history. However, the primary output from PROC PRINQUAL is an output data set. By default, the procedure creates an output data set that contains variables with `_TYPE_='SCORE'`. These observations contain original variables, transformed variables, components, or data approximations. If you specify the `CORRELATIONS` option in the PROC PRINQUAL statement, the data set also contains observations with `_TYPE_='CORR'`; these observations contain correlations or component structure information.

The Three Methods of Variable Transformation

The three methods of variable transformation provided by PROC PRINQUAL are discussed in the following sections.

The Maximum Total Variance (MTV) Method

The MTV method (Young, Takane, and de Leeuw 1978) is based on the principal component model, and it attempts to maximize the sum of the first r eigenvalues of the covariance matrix. This method transforms variables to be (in a least-squares sense) as similar to linear combinations of r principal component score variables as possible, where r can be much smaller than the number of variables. This maximizes the total variance of the first r components (the trace of the covariance matrix of the first r principal components). Refer to Kuhfeld, Sarle, and Young (1985).

On each iteration, the MTV algorithm alternates classical principal component analysis (Hotelling 1933) with optimal scaling (Young 1981). When all variables are ordinal preference ratings, this corresponds to Carroll's (1972) MDPREF analysis. You can request the dummy variable initialization method suggested by Tenenhaus and Vachette (1977), who independently proposed the same iterative algorithm for nominal and interval scale-of-measurement variables.

The Minimum Generalized Variance (MGV) Method

The MGV method (Sarle 1984) uses an iterated multiple regression algorithm in an attempt to minimize the determinant of the covariance matrix of the transformed variables. This method transforms each variable to be (in a least-squares sense) as similar to linear combinations of the remaining variables as possible. This locally minimizes the generalized variance of the transformed variables, the determinant of the covariance matrix, the volume of the parallelepiped defined by the transformed variables, and the sphericity (the extent to which a quadratic form in the optimized covariance matrix defines a sphere). Refer to Kuhfeld, Sarle, and Young (1985).

On each iteration for each variable, the MGV algorithm alternates multiple regression with optimal scaling. The multiple regression involves predicting the selected variable from all other variables. You can request a dummy variable initialization using a modification of the Tenenhaus and Vachette (1977) method that is appropriate with a regression algorithm. This method can be viewed as a way of investigating the nature of the linear and nonlinear dependencies in, and the rank of, a data matrix containing variables that can be nonlinearly transformed. This method tries to create a less-than-full-rank data matrix. The matrix contains the transformation of each variable that is most similar to what the other transformed variables predict.

The Maximum Average Correlation (MAC) Method

The MAC method (de Leeuw 1985) uses an iterated constrained multiple regression algorithm in an attempt to maximize the average of the elements of the correlation matrix. This method transforms each variable to be (in a least-squares sense) as similar to the average of the remaining variables as possible.

On each iteration for each variable, the MAC algorithm alternates computing an equally weighted average of the other variables with optimal scaling. The MAC

method is similar to the MGCV method in that each variable is scaled to be as similar to a linear combination of the other variables as possible, given the constraints on the transformation. However, optimal weights are not computed. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. Do not use this method with negatively correlated variables when some optimal transformations are constrained to be increasing because the signs of the correlations are not taken into account. The MAC method is useful as an initialization method for the MTV and MGCV methods.

Getting Started

In the following example, PROC PRINQUAL uses the MTV method. Suppose that the problem is to linearize a curve through three-dimensional space. Let

$$\begin{aligned} X_1 &= X^3 \\ X_2 &= X_1 - X^5 \\ X_3 &= X_2 - X^6 \end{aligned}$$

where $X = -1.00, -0.98, -0.96, \dots, 1.00$.

These three variables define a curve in three-dimensional space. The GPLLOT procedure is used to display two-dimensional views of this curve. These data are completely described by three linear components, but they define a single curve, which could be described as a single nonlinear component.

PROC PRINQUAL is used to attempt to straighten the curve into a one-dimensional line with a continuous transformation of each variable. The N=1 option in the PROC PRINQUAL statement requests one principal component. The TRANSFORM statement requests a cubic spline transformation with nine knots. *Splines* are curves, which are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree n with function values and first $n - 1$ derivatives that agree at the points where they join. The abscissa values of the join points are called *knots*. The term “spline” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. Refer to Smith (1979) for an excellent introduction to splines. For another example of using splines, see [Example 75.1 in Chapter 75, “The TRANSREG Procedure.”](#)

One component accounts for 71 percent of the variance of the untransformed data, and after 45 iterations, over 98 percent of the variance of the transformed data is accounted for by one component (see [Figure 59.2](#)). Note that the algorithm would

not have converged with 50 iterations and the default convergence criterion, so more iterations may be needed for this problem.

PROC PRINQUAL creates an output data set (which is not displayed) that contains both the original and transformed variables. The original variables have the names X1, X2, and X3. Transformed variables are named TX1, TX2, and TX3. All observations in the output data set have `_TYPE_='SCORE'`, since the CORRELATIONS option is not specified in the PROC PRINQUAL statement. The GPLOT procedure uses this output data set and displays the nonlinear transformations of all three variables and the nearly one-dimensional scatter plot (see [Figure 59.3](#) and [Figure 59.4](#)).

PROC PRINQUAL tries to project each variable on the first principal component. Notice that the curve in this example is closer to a circle than to a function from some views (see the plot of X3 vs. X2 in [Figure 59.1](#)) and that the first component does not run approximately from one end point of the curve to the other (see [Figure 59.4](#)). Since the curve has these characteristics, PROC PRINQUAL linearizes the scatter plot by collapsing the scatter around the principal axis, not by straightening the curve into a single line. PROC PRINQUAL would straighten simpler curves.

The following statements produce [Figure 59.1](#) through [Figure 59.4](#):

```

* Generate a Three-Dimensional Curve;
data X;
  do X = -1 to 1 by 0.02;
    X1 =      X ** 3;
    X2 = X1 - X ** 5;
    X3 = X2 - X ** 6;
    output;
  end;
  drop X;
run;

goptions goutmode=replace nodisplay;
%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
* Depending on your goptions, these plot options may work better:
* %let opts = haxis=axis2 vaxis=axis1 frame;

proc gplot data=X;
  title;
  axis1 minor=none label=(angle=90 rotate=0)
        order=(-1 to 1);
  axis2 minor=none order=(-1 to 1);
  plot X1*X2 / &opts name='prqin1';
  plot X3*X2 / &opts name='prqin2' vreverse;
  plot X1*X3 / &opts name='prqin3';
  symbol1 color=blue;
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:prqin1 2:prqin2 3:prqin3;
run; quit;

```

```

* Try to Straighten the Curve;
proc prinqual data=X n=1 maxiter=50 covariance converge=0.007;
  title 'Iteratively Derive Variable Transformations';
  transform spline(X1-X3 / nknots=9);
run;

* Plot the Transformations;
goptions nodisplay;
proc gplot;
  title;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
  plot TX1*X1 / &opts name='prqin4';
  plot TX2*X2 / &opts name='prqin5';
  plot TX3*X3 / &opts name='prqin6';
  symbol1 color=blue;
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:prqin4 2:prqin6 3:prqin5;
run; quit;

* Plot the Straightened Scatter Plot;
goptions nodisplay;
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0)
    order=(-1 to 1);
  axis2 minor=none order=(-1 to 1);
  plot TX1*TX2 / &opts name='prqin7';
  plot TX3*TX2 / &opts name='prqin8' vreverse;
  plot TX1*TX3 / &opts name='prqin9';
  symbol1 color=blue;
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:prqin7 2:prqin8 3:prqin9;
run; quit;

```

Figure 59.2. PROC PRINQUAL MTV Iteration History

Figure 59.3. Variable Transformation Plots

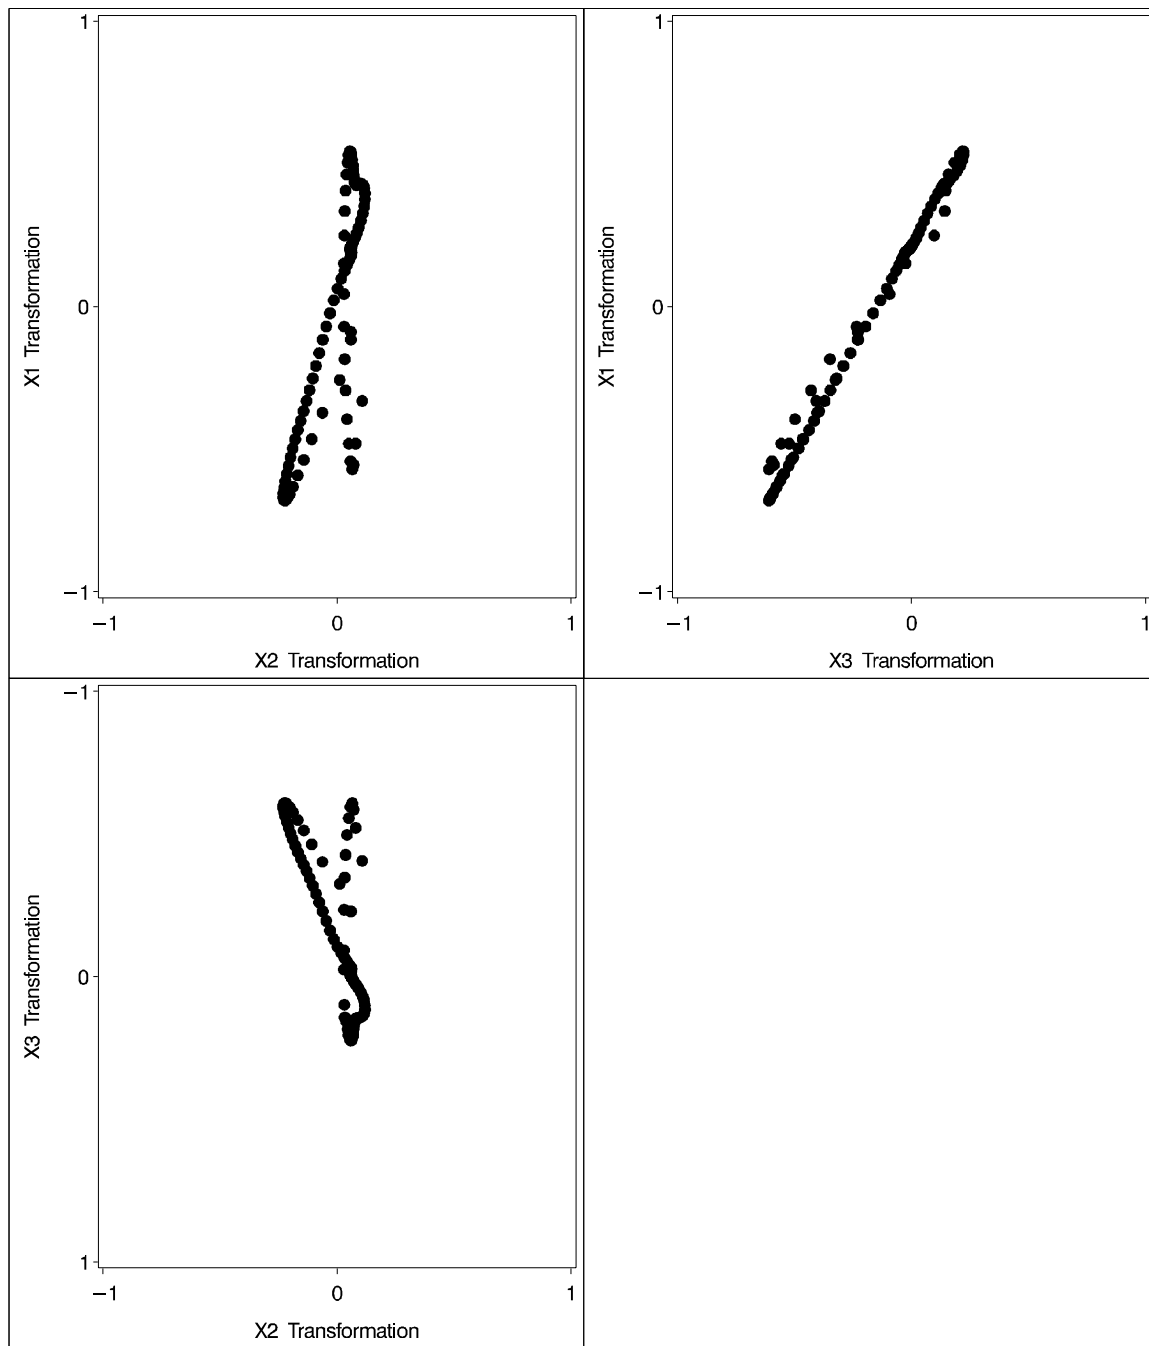

Figure 59.4. Plots of the Nearly One-Dimensional Curve

Syntax

The following statements are available in PROC PRINQUAL.

```
PROC PRINQUAL < options > ;  
  TRANSFORM transform(variables < / t-options >)  
    < ... transform(variables < / t-options > ) > ;  
  BY variables ;  
  FREQ variable ;  
  ID variables ;  
  WEIGHT variable ;
```

To use PROC PRINQUAL, you need the PROC PRINQUAL and TRANSFORM statements. You can abbreviate all *options* and *t-options* to their first three letters. This is a special feature of PROC PRINQUAL and is not generally true of other SAS/STAT procedures.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINQUAL statement. The remaining statements are described in alphabetical order.

PROC PRINQUAL Statement

```
PROC PRINQUAL < options > ;
```

The PROC PRINQUAL statement starts the PRINQUAL procedure. Optionally, this statement identifies an input data set, creates an output data set, specifies the algorithm and other computational details, and controls displayed output. The following table summarizes options available in the PROC PRINQUAL statement.

Task	Option
Identify input data set	
specifies input SAS data set	DATA=
Specify details for output data set	
outputs approximations to transformed variables	APPROXIMATIONS
specifies prefix for approximation variables	APREFIX=
outputs correlations and component structure matrix	CORRELATIONS
specifies a multidimensional preference analysis	MDPREF
specifies output data set	OUT=
specifies prefix for principal component scores variables	PREFIX=
replaces raw data with transformed data	REPLACE
outputs principal component scores	SCORES
standardizes principal component scores	STANDARD
specifies transformation standardization	TSTANDARD=
specifies prefix for transformed variables	TPREFIX=
Control iterative algorithm	
analyzes covariances	COVARIANCE
initializes using dummy variables	DUMMY
specifies iterative algorithm	METHOD=
specifies number of principal components	N=
suppresses numerical error checking	NOCHECK
specifies number of MGW models before refreshing	REFRESH=
restarts iterations	REITERATE
specifies singularity criterion	SINGULAR=
specifies input observation type	TYPE=
Control the number of iterations	
specifies minimum criterion change	CCONVERGE=
specifies number of first iteration to be displayed	CHANGE=
specifies minimum data change	CONVERGE=
specifies number of MAC initialization iterations	INITITER=
specifies maximum number of iterations	MAXITER=
Specify details for handling missing values	
includes monotone special missing values	MONOTONE=
excludes observations with missing values	NOMISS
unties special missing values	UNTIE=
Suppress displayed output	
suppresses displayed output	NOPRINT

The following list describes these options in alphabetical order.

APREFIX=*name*

APR=*name*

specifies a prefix for naming the approximation variables. By default, APREFIX=A. Specifying the APREFIX= option also implies the APPROXIMATIONS option.

APPROXIMATIONS**APPROX****APP**

includes principal component approximations to the transformed variables (Eckart and Young 1936) in the output data set. Variable names are constructed from the value of the APREFIX= option and the input variable names. If you specify the APREFIX= option, then approximations are automatically included. If you specify the APPROXIMATIONS option and not the APREFIX= option, then the APPROXIMATIONS option uses the default, APREFIX=A, to construct the variable names.

CCONVERGE=*n***CCO=*n***

specifies the minimum change in the criterion being optimized that is required to continue iterating. By default, CCONVERGE=0.0. The CCONVERGE= option is ignored for METHOD=MAC. For the MGCV method, specify CCONVERGE=-2 to ensure data convergence.

CHANGE=*n***CHA=*n***

specifies the number of the first iteration to be displayed in the iteration history table. The default is CHANGE=1. When you specify a larger value for *n*, the first *n* - 1 iterations are not displayed, thus speeding up the analysis. The CHANGE= option is most useful with the MGCV method, which is much slower than the other methods.

CONVERGE=*n***CON=*n***

specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations, that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values. For more information, see the section [“Optimal Transformations”](#) on page 3662.

COVARIANCE**COV**

computes the principal components from the covariance matrix. The variables are always centered to mean zero. If you do not specify the COVARIANCE option, the variables are also standardized to variance one, which means the analysis is based on the correlation matrix.

CORRELATIONS**COR**

includes correlations and the component structure matrix in the output data set. By default, this information is not included.

DATA=SAS-*data-set*

specifies the SAS data set to be analyzed. The data set must be an ordinary SAS data set; it cannot be a TYPE=CORR or TYPE=COV data set. If you omit the DATA= option, the PRINQUAL procedure uses the most recently created SAS data set.

DUMMY**DUM**

expands variables specified for OPSCORE optimal transformations to dummy variables for the initialization (Tenenhaus and Vachette 1977). By default, the initial values of OPSCORE variables are the actual data values. The dummy variable nominal initialization requires considerable time and memory, so it might not be possible to use the DUMMY option with large data sets. No separate report of the initialization is produced. Initialization results are incorporated into the first iteration displayed in the iteration history table. For details, see the section “[Optimal Transformations](#)” on page 3662.

INITITER=*n***INI=*n***

specifies the number of MAC iterations required to initialize the data before starting MTV or MGV iterations. By default, INITITER=0. The INITITER= option is ignored if METHOD=MAC.

MAXITER=*n***MAX=*n***

specifies the maximum number of iterations. By default, MAXITER=30.

MDPREF**MDP**

specifies a multidimensional preference analysis by implying the STANDARD, SCORES, and CORRELATIONS options. This option also suppresses warnings when there are more variables than observations.

METHOD=MAC | MGV | MTV**MET=MAC | MGV | MTV**

specifies the optimization method. By default, METHOD=MTV. Values of the METHOD= option are MTV for maximum total variance, MGV for minimum generalized variance, or MAC for maximum average correlation. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. See the section “[The Three Methods of Variable Transformation](#)” on page 3643.

MONOTONE=*two-letters***MON=*two-letters***

specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The *two-letters* value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of ._, .A through .C, and .G through .Z. For details, see the “[Missing Values](#)” section on page 3667, and “[Optimal Scaling](#)” in Chapter 75, “[The TRANSREG Procedure](#).”

N=*n*

specifies the number of principal components to be computed. By default, N=2.

NOCHECK**NOC**

turns off computationally intensive numerical error checking for the MGCV method. If you do not specify the NOCHECK option, the procedure computes R^2 from the squared length of the predicted values vector and compares this value to the R^2 computed from the error sum of squares that is a by-product of the sweep algorithm (Goodnight 1978). If the two values of R^2 differ by more than the square root of the value of the SINGULAR= option, a warning is displayed, the value of the REFRESH= option is halved, and the model is refit after refreshing. Specifying the NOCHECK option slightly speeds up the algorithm. Note that other less computationally intensive error checking is always performed.

NOMISS**NOM**

excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS option, PROC PRINQUAL simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error.

Casewise deletion of observations with missing values occurs when you specify the NOMISS option, when there are missing values in IDENTITY variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as *supplementary* or passive observations. See the “[Passive Observations](#)” section on page 3674 and the “[Missing Values](#)” section on page 3667 for more information on excluded observations and missing data.

NOPRINT**NO**

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14, “Using the Output Delivery System.”](#)

OUT=SAS-data-set

specifies an output SAS data set that contains results of the analysis. If you omit the OUT= option, PROC PRINQUAL still creates an output data set and names it using the DATA*n* convention. If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to the discussion in *SAS Language Reference: Concepts*.) You can use the REPLACE, APPROXIMATIONS, SCORES, and CORRELATIONS options to control what information is included in the output data set. For details, see the “[Output Data Set](#)” section on page 3669.

PREFIX=name**PRE=name**

specifies a prefix for naming the principal components. By default, PREFIX=Prin. As a result, the principal component default names are Prin1, Prin2, . . . , Prin*n*.

REFRESH=*n***REF=*n***

specifies the number of variables to scale in the MGCV method before computing a new inverse. By default, REFRESH=5. PROC PRINQUAL uses the REFRESH= option in the sweep algorithm of the MGCV method. Large values for the REFRESH= option make the method run faster but with increased error. Small values make the method run more slowly and with more numerical accuracy.

REITERATE**REI**

enables the PRINQUAL procedure to use previous transformations as starting points. The REITERATE option affects only variables that are iteratively transformed (specified as LINEAR, SPLINE, MSPLINE, SSPLINE, UNTIE, OPScore, and MONOTONE). For iterative transformations, the REITERATE option requests a search in the input data set for a variable that consists of the value of the TPREFIX= option followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the “REITERATE Option Usage” section on page 3673.

REPLACE**REP**

replaces the original data with the transformed data in the output data set. The names of the transformed variables in the output data set correspond to the names of the original variables in the input data set. If you do not specify the REPLACE option, both original variables and transformed variables (with names constructed from the TPREFIX= option and the original variable names) are included in the output data set.

SCORES**SCO**

includes principal component scores in the output data set. By default, scores are not included.

SINGULAR=*n***SIN=*n***

specifies the largest value within rounding error of zero. By default, SINGULAR=1E-8. The PRINQUAL procedure uses the value of the SINGULAR= option for checking $(1 - R^2)$ when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on.

STANDARD**STD**

standardizes the principal component scores in the output data set to mean zero and variance one instead of the default mean zero and variance equal to the corresponding eigenvalue. See the SCORES option.

TPREFIX=*name*

TPR=*name*

specifies a prefix for naming the transformed variables. By default, TPREFIX=T. The TPREFIX= option is ignored if you specify the REPLACE option.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | NOM | ORI | Z

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When the TSTANDARD= option is specified in the PROC statement, it specifies the default standardization for all variables. When you specify TSTANDARD= as a *t-option*, it overrides the default standardization just for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal *t-option* in the TRANSFORM statement. For example, if a variable X with no missing values is specified as LOG, then, by default, the final transformation of X is simply LOG(X), not LOG(X) standardized to the mean of X and variance of X.

TYPE='*text*'|*name*

TYP='*text*'|*name*

specifies the valid value for the _TYPE_ variable in the input data set. If PROC PRINQUAL finds an input _TYPE_ variable, it uses only observations with a _TYPE_ value that matches the TYPE= value. This enables a PROC PRINQUAL OUT= data set containing correlations to be used as input to PROC PRINQUAL without requiring a WHERE statement to exclude the correlations. If a _TYPE_ variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= option, only observations with _TYPE_ = 'SCORE' are used.

PROC PRINQUAL displays a note when it reads observations with blank values of `_TYPE_`, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank `_TYPE_` values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their `_TYPE_` value is blank.

UNTIE=*two-letters*

UNT=*two-letters*

specifies the first and last special missing value in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The *two-letters* value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the “Missing Values” section on page 3667. Also, see “Optimal Scaling” in Chapter 75, “The TRANSREG Procedure.”

BY Statement

BY *variables* ;

You can specify a BY statement with PROC PRINQUAL to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement options NOTSORTED or DESCENDING in the BY statement for the PRINQUAL procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

FREQ Statement

FREQ *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, list the variable’s name in a FREQ statement. PROC PRINQUAL then treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Noninteger values of the

FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID *variables* ;

The ID statement includes additional character or numeric variables in the output data set. The variables must be contained in the input data set.

TRANSFORM Statement

TRANSFORM *transform(variables < / t-options >)*
 < ... *transform(variables < / t-options >)* > ;

The TRANSFORM statement lists the variables to be analyzed (*variables*) and specifies the transformation (*transform*) to apply to each variable listed. You must specify a transformation for each variable list in the TRANSFORM statement. The variables are variables in the data set. The *t-options* are transformation options that provide details for the transformation; these depend on the *transform* chosen. The *t-options* are listed after a slash in the parentheses that enclose the variables.

For example, the following statements find a quadratic polynomial transformation of all variables in the data set:

```
proc prinqual;
  transform spline(_all_ / degree=2);
run;
```

Or, if N1 through N10 are nominal variables and M1 through M10 are ordinal variables, you can use the following statements.

```
proc prinqual;
  transform opscore(N1-N10) monotone(M1-M10);
run;
```

The following sections describe the transformations available (specified with *transform*) and the options available for some of the transformations (specified with *t-options*).

Families of Transformations

There are three types of transformation families: nonoptimal, optimal, and other. Each family is summarized as follows.

Nonoptimal transformations preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.

Optimal transformations	replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).
Other transformations	are the IDENTITY and SSPLINE transformations. These do not fit into either of the preceding categories.

The following table summarizes the transformations in each family.

Family	Members of Family
Nonoptimal transformations	
inverse trigonometric sine	ARSIN
exponential	EXP
logarithm	LOG
logit	LOGIT
raises variables to specified power	POWER
transforms to ranks	RANK
Optimal transformations	
linear	LINEAR
monotonic, ties preserved	MONOTONE
monotonic B-spline	MSPLINE
optimal scoring	OPSCORE
B-spline	SPLINE
monotonic, ties not preserved	UNTIE
Other transformations	
identity, no transformation	IDENTITY
iterative smoothing spline	SSPLINE

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. For example,

```
transform log(X Y);
```

computes the LOG transformation of X and Y. A more complex example is

```
transform spline(Y / nknots=2) log(X1 X2 X3);
```

The preceding statement uses the SPLINE transformation of the variable Y and the LOG transformation of the variables X1, X2, and X3. In addition, it uses the NKNOTS= option with the SPLINE transformation and specifies two knots.

The rest of this section provides syntax details for members of the three families of transformations. The *t-options* are discussed in the section “[Transformation Options \(t-options\)](#)” on page 3663.

Nonoptimal Transformations

Nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation and missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

ARS

finds an inverse trigonometric sine transformation. Variables following ARSIN must be numeric, in the interval $(-1.0 \leq X \leq 1.0)$, and they are typically continuous.

EXP

exponentiates variables (the variable X is transformed to a^X). To specify the value of a , use the `PARAMETER= t-option`. By default, a is the mathematical constant $e = 2.718\dots$. Variables following EXP must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (the variable X is transformed to $\log_a(X)$). To specify the base of the logarithm, use the `PARAMETER= t-option`. The default is a natural logarithm with base $e = 2.718\dots$. Variables following LOG must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of X is $\log(X/(1-X))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables following LOGIT must be numeric, in the interval $(0.0 < X < 1.0)$, and they are typically continuous.

POWER

POW

raises variables to a specified power (the variable X is transformed to X^a). You must specify the power parameter a by specifying the `PARAMETER= t-option` following the variables:

```
power(variable / parameter=number)
```

You can use POWER for squaring variables (`PARAMETER=2`), reciprocal transformations (`PARAMETER=-1`), square roots (`PARAMETER=0.5`), and so on. Variables following POWER must be numeric, and they are typically continuous.

RANK

RAN

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables following RANK must be numeric.

Optimal Transformations

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the “Missing Values” section on page 3667).

The following list provides syntax and details for optimal transformations.

LINEAR

LIN

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables following LINEAR must be numeric.

MONOTONE

MON

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least-squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables following MONOTONE must be numeric, and they are typically discrete.

MSPLINE

MSP

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with MSPLINE. By default, PROC PRINQUAL uses a quadratic spline. Variables following MSPLINE must be numeric, and they are typically continuous.

OPSCORE

OPS

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. Fisher’s (1938) optimal scoring method is used. Variables following OPSCORE can be either character or numeric; numeric variables should be discrete.

SPLINE

SPL

finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC PRINQUAL uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY *t-options* with SPLINE. Variables following SPLINE must be numeric, and they are typically continuous.

UNTIE

UNT

finds a monotonic transformation of each variable without the restriction that ties are preserved. The PRINQUAL procedure uses the Kruskal (1964) primary least-squares monotonic transformation method. This transformation weakly preserves order but not category membership (it may untie some previously tied values). Variables following UNTIE must be numeric, and they are typically discrete.

Other Transformations

IDENTITY

IDE

specifies variables that are not changed by the iterations. The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT, ADDITIVE, TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables following IDENTITY must be numeric.

SSPLINE

SSP

finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= *t-option* or the PARAMETER= *t-option*. The default smoothing parameter is SM=0. Variables following SSPLINE must be numeric, and they are typically continuous.

Transformation Options (*t-options*)

If you use a nonoptimal, optimal or other transformation, you can use *t-options*, which specify additional details of the transformation. The *t-options* are specified within the parentheses that enclose variables and are listed after a slash. For example,

```
proc prinqual;
  transform spline(X Y / nknots=3);
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the variables X and Y and use a *t-option* to specify the number of knots (NKNOTS=). The following is a more complex example.

```
proc prinqual;
  transform spline(Y / nknots=3) spline(X1 X2 / nknots=6);
run;
```

These statements use the SPLINE transformation for all three variables and use *t-options* as well; the NKNOTS= option specifies the number of knots for the spline.

The following sections discuss the *t-options* available for nonoptimal, optimal, and other transformations.

The following table summarizes the *t-options*.

Table 59.1. t-options Available in the TRANSFORM Statement

Task	Option
Nonoptimal transformation t-options	
uses original mean and variance	ORIGINAL
Parameter t-options	
specifies miscellaneous parameters	PARAMETER=
specifies smoothing parameter	SM=
Spline t-options	
specifies the degree of the spline	DEGREE=
spaces the knots evenly	EVENLY
specifies the interior knots or break points	KNOTS=
creates n knots	NKNOTS=
Other t-options	
renames variables	NAME=
reflects the variable around the mean	REFLECT
specifies transformation standardization	TSTANDARD=

Nonoptimal Transformation t-options

ORIGINAL

ORI

matches the variable's final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL *t-option* is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=*number*

PAR=*number*

specifies the transformation parameter. The PARAMETER= *t-option* is available for the EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (You can specify a SAS/GRAPH-style smoothing parameter with the SM= *t-option*.) The default for the PARAMETER= *t-option* for the LOG and EXP transformations is $e = 2.718 \dots$. The default parameter for SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= *t-option*; there is no default.

SM=*n*

specifies a SAS/GRAPH-style smoothing parameter in the range 0 to 100. You can specify the SM= *t-option* only with the SSPLINE transformation. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline t-options

The following *t-options* are available with the SPLINE and MSPLINE optimal transformations.

DEGREE=*n*

DEG=*n*

specifies the degree of the B-spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY

EVE

is used with the NKNOTS= *t-option* to space the knots evenly. The differences between adjacent knots are constant. If you specify NKNOTS=*k*, *k* knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k + 1))$$

for $i = 1, \dots, k$. For example, if you specify

```
spline(x / knots=2 evenly)
```

and the variable X has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY *t-option*, the NKNOTS= *t-option* places knots at percentiles, so the knots are not evenly spaced.

KNOTS=*number-list* | *n* TO *m* BY *p*

KNO=*number-list* | *n* TO *m* BY *p*

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the *n*th (from DEGREE=*n*) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the (*n* - 1)th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= *t-option* with the NKNOTS= *t-option*. You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613 in Chapter 75, “The TRANSREG Procedure.”).

NKNOTS=*n*

NKN=*n*

creates *n* knots, the first at the $100/(n + 1)$ percentile, the second at the $200/(n + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the twenty-fifth percentile, the median, and the seventy-fifth percentile. By default, NKNOTS=0. The NKNOTS= *t-option* must be ≥ 0 .

You cannot use the `NKNOTS=` *t-option* with the `KNOTS=` *t-option*. You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613 in Chapter 75, “The TRANSREG Procedure,”).

Other t-options

The following *t-options* are available for all transformations.

NAME=(*variable-list*)

NAM=(*variable-list*)

renames variables as they are used in the TRANSFORM statement. This option allows a variable to be used more than once. For example, if the variable `X` is a character variable, then the following step stores both the original character variable `X` and a numeric variable `XC` that contains category numbers in the output data set.

```
proc prinqual data=A n=1 out=B;
  transform linear(Y) opscore(X / name=(XC));
  id X;
run;
```

REFLECT

REF

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations.

TSTANDARD=CENTER | NOMISS | ORIGINAL | Z

TST=CEN | **NOM** | **ORI** | **Z**

specifies the standardization of the transformed variables in the `OUT=` data set. By default, `TSTANDARD=ORIGINAL`. When the `TSTANDARD=` option is specified in the PROC PRINQUAL statement, it specifies the default standardization for all variables. When you specify `TSTANDARD=` as a *t-option*, it overrides the default standardization just for selected variables.

WEIGHT Statement

WEIGHT *variable* ;

When you use a `WEIGHT` statement, a weighted residual sum of squares is minimized. The `WEIGHT` statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the `WEIGHT` statement variable is greater than 0.

Details

Missing Values

PROC PRINQUAL can estimate missing values, subject to optional constraints, so that the covariance matrix is optimized. The procedure provides several approaches for handling missing data. When you specify the NOMISS option in the PROC PRINQUAL statement, observations with missing values are excluded from the analysis. Otherwise, missing data are estimated, using variable means as initial estimates. Missing values for OPSCORE character variables are treated the same as any other category during the initialization. See the section “Missing Values” on page 4599 in Chapter 75, “The TRANSREG Procedure,” for more information on missing data estimation.

Controlling the Number of Iterations

Several options in the PROC PRINQUAL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER= option.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE= option.
- The criterion change is less than the value of the CCONVERGE= option.

With the MTV method, the change in the proportion of variance criterion can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Because the MTV algorithm is convergent, a negative criterion change is the result of very small amounts of rounding error. The MGW method displays the average squared multiple correlation (which is not the criterion being optimized), so the criterion change can become negative well before convergence. The MAC method criterion (average correlation) is never computed, so the CCONVERGE= option is ignored for METHOD=MAC. You can specify a negative value for either convergence option if you want to define convergence only in terms of the other convergence option.

With the MGW method, iterations minimize the generalized variance (determinant), but the generalized variance is not reported for two reasons. First, in most data sets, the generalized variance is almost always near zero (or will be after one or two iterations), which is its minimum. This does not mean that iteration is complete; it simply means that at least one multiple correlation is at or near one. The algorithm continues minimizing the determinant in $(m - 1)$, $(m - 2)$ dimensions, and so on. Because the generalized variance is almost always near zero, it does not provide a good indication of how the iterations are progressing. The mean R^2 provides a better indication of convergence. The second reason for not reporting the generalized variance is that almost no additional time is required to compute R^2 values for each step. This is because the error sum of squares is a by-product of the algorithm at each step.

Computing the determinant at the end of each iteration adds more computations to an already computationally intensive algorithm.

You can increase the number of iterations to ensure convergence by increasing the value of the MAXITER= option and decreasing the value of the CONVERGE= option. Because the average absolute change in standardized variable scores seldom decreases below $1E-11$, you typically do not specify a value for the CONVERGE= option less than $1E-8$ or $1E-10$. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the CONVERGE= and MAXITER= options to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, specify the REITERATE option, or try CONVERGE= $1E-8$ and MAXITER=50, or CONVERGE= $1E-10$ and MAXITER=200.

Performing a Principal Component Analysis of Transformed Data

PROC PRINQUAL produces an iteration history table that displays (for each iteration) the iteration number, the maximum and average absolute change in standardized variable scores computed over the iteratively transformed variables, the criterion being optimized, and the criterion change. In order to examine the results of the analysis in more detail, you can analyze the information in the output data set using other SAS procedures.

Specifically, use the PRINCOMP procedure to perform a components analysis on the transformed data. PROC PRINCOMP accepts the raw data from PROC PRINQUAL but issues a warning because the PROC PRINQUAL output data set has `_NAME_` and `_TYPE_` variables, but it is not a TYPE=CORR data set. You can ignore this warning.

If the output data set contains both scores and correlations, you must subset it for analysis with PROC PRINCOMP. Otherwise, the correlation observations are treated as ordinary observations and the PROC PRINCOMP results are incorrect. For example, consider the following statements:

```
proc prinqual data=a out=b correlations replace;
    transform spline(var1-var50 / nknots=3);
run;

proc princomp data=b;
    where _TYPE_='SCORE';
run;
```

Also note that the proportion of variance accounted for, as reported by PROC PRINCOMP, can exceed the proportion of variance accounted for in the last PROC PRINQUAL iteration. This is because PROC PRINQUAL reports the variance accounted for by the components analysis that generated the current scaling of the data, not a components analysis of the current scaling of the data.

Using the MAC Method

You can use the MAC algorithm alone by specifying `METHOD=MAC`, or you can use it as an initialization algorithm for `METHOD=MTV` and `METHOD=MGV` analyses by specifying the iteration option `INITITER=.` If any variables are negatively correlated, do not use the MAC algorithm with monotonic transformations (`MONOTONE`, `UNTIE`, and `MSPLINE`) because the signs of the correlations among the variables are not used when computing variable approximations. If an approximation is negatively correlated with the original variable, monotone constraints would make the optimally scaled variable a constant, which is not allowed (see the section “[Avoiding Constant Transformations](#)” on page 3672). When used with other transformations, the MAC algorithm can reverse the scoring of the variables. So, for example, if variable X is designated `LOG(X)` with `METHOD=MAC` and `TSTANDARD=ORIGINAL`, the final transformation (for example, `TX`) may not be `LOG(X)`. If `TX` is not `LOG(X)`, it has the same mean as `LOG(X)` and the same variance as `LOG(X)`, and it is perfectly negatively correlated with `LOG(X)`. `PROC PRINQUAL` displays a note for every variable that is reversed in this manner.

You can use the `METHOD=MAC` algorithm to reverse the scorings of some rating variables before a factor analysis. The correlations among bipolar ratings such as ‘like - dislike’, ‘hot - cold’, and ‘fragile - monumental’ are typically both positive and negative. If some items are reversed to say ‘dislike - like’, ‘cold - hot’, and ‘monumental - fragile’, some of the negative signs can be eliminated, and the factor pattern matrix would be cleaner. You can use `PROC PRINQUAL` with `METHOD=MAC` and `LINEAR` transformations to reverse some items, maximizing the average of the intercorrelations.

Output Data Set

The `PRINQUAL` procedure produces an output data set by default. By specifying the `OUT=`, `APPROXIMATIONS`, `SCORES`, `REPLACE`, and `CORRELATIONS` options in the `PROC PRINQUAL` statement, you can name this data set and control, to some extent, the contents of it.

Structure and Content

The output data set can have 16 different forms, depending on the specified combinations of the `REPLACE`, `SCORES`, `APPROXIMATIONS`, and `CORRELATIONS` options. You can specify any combination of these options. To illustrate, assume that the data matrix consists of N observations and m variables, and n components are computed. Then, define the following:

- D** the $N \times m$ matrix of original data with variable names that correspond to the names of the variables in the input data set. However, when you use the `OPSCORE` transformation on character variables, those variables are replaced by numeric variables that contain category numbers
- T** the $N \times m$ matrix of transformed data with variable names constructed from the value of the `TPREFIX=` option (if you do not specify the `REPLACE` option) and the names of the variables in the input data set

- S** the $N \times n$ matrix of component scores with variable names constructed from the value of the PREFIX= option and integers
- A** the $N \times m$ matrix of data approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set
- R_{TD}** the $m \times m$ matrix of correlations between the transformed variables and the original variables with variable names that correspond to the names of the variables in the input data set. When missing values exist, casewise deletion is used to compute the correlations.
- R_{TT}** the $m \times m$ matrix of correlations among the transformed variables with the variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set
- R_{TS}** the $m \times n$ matrix of correlations between the transformed variables and the principal component scores (component structure matrix) with variable names constructed from the value of the PREFIX= option and integers
- R_{TA}** the $m \times m$ matrix of correlations between the transformed variables and the variable approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set

To create a data set WORK.A that contains all information, specify the following options in the PROC PRINQUAL statement

```
proc prinqual scores approximations correlations out=a;
```

and also use a TRANSFORM statement appropriate for your data. Then the WORK.A data set contains

```

D      T      S      A
RTD  RTT  RTS  RTA
```

To eliminate the bottom partitions that contain the correlations and component structure, do not specify the CORRELATIONS option. For example, use the following PROC PRINQUAL statement with an appropriate TRANSFORM statement.

```
proc prinqual scores approximations out=a;
```

Then the WORK.A data set contains

```
D T S A
```

If you use the following PROC PRINQUAL statement (with an appropriate TRANSFORM statement)

```
proc prinqual out=a;
```

this creates a data set WORK.A of the form

```
D T
```

To output transformed data and component scores only, specify the following options in the PROC PRINQUAL statement:

```
proc prinqual replace scores out=a;
```

Then the WORK.A data set contains

```
T S
```

TYPE and _NAME_ Variables

In addition to the preceding information, the output data set contains two character variables, the variable `_TYPE_` (length 8) and the variable `_NAME_` (length 32).

The `_TYPE_` variable has the value 'SCORE' if the observation contains variables, transformed variables, components, or data approximations; the `_TYPE_` variable has the value 'CORR' if the observation contains correlations or component structure.

By default, the `_NAME_` variable has values 'ROW1', 'ROW2', and so on, for the observations with `_TYPE_='SCORE'`. If you use an ID statement, the variable `_NAME_` contains the formatted ID variable for SCORES observations. The values of the variable `_NAME_` for observations with `_TYPE_='CORR'` are the names of the transformed variables.

Certain procedures, such as PROC PRINCOMP, which can use the PROC PRINQUAL output data set, issue a warning that the PROC PRINQUAL data set contains `_NAME_` and `_TYPE_` variables but is not a TYPE=CORR data set. You can ignore this warning.

Variable Names

The TPREFIX=, APREFIX=, and PREFIX= options specify prefixes for the transformed and approximation variable names and for principal component score variables, respectively. PROC PRINQUAL constructs transformed and approximation variable names from a prefix and the first characters of the original variable name. The number of characters in the prefix plus the number of characters in the original variable name (including the final digits, if any) required to uniquely designate the new variables should not exceed 32. For example, if the APREFIX= parameter that you specify is one character, PROC PRINQUAL adds the first 31 characters of the original variable name; if your prefix is four characters, only the first 28 characters of the original variable name are added.

Effect of the TSTANDARD= and COVARIANCE Options

The values in the output data set are affected by the TSTANDARD= and COVARIANCE options. If you specify TSTANDARD=NOMISS, the NOMISS standardization is performed on the transformed data after the iterations have been completed, but before the output data set is created. The new means and variances are used in creating the output data set. Then, if you do not specify the COVARIANCE option, the data are transformed to mean zero and variance one. The principal component scores and data approximations are computed from the resulting matrix. The data are then linearly transformed to have the mean and variance specified by the TSTANDARD= option. The data approximations are transformed so that the means within each pair of a transformed variable and its approximation are the same. The ratio of the variance of a variable approximation to the variance of the corresponding transformed variable equals the proportion of the variance of the variable that is accounted for by the components model.

If you specify the COVARIANCE option and do not specify TSTANDARD=Z, you can input the transformed data to PROC PRINCOMP, again specifying the COVARIANCE option, to perform a components analysis of the results of PROC PRINQUAL. Similarly, if you do not specify the COVARIANCE option with PROC PRINQUAL and you input the transformed data to PROC PRINCOMP without the COVARIANCE option, you receive the same report. However, some combinations of PROC PRINQUAL options, such as COVARIANCE and TSTANDARD=Z, while valid, produce approximations and scores that cannot be reproduced by PROC PRINCOMP.

The component scores in the output data set are computed from the correlations among the transformed variables, or from the covariances if you specified the COVARIANCE option. The component scores are computed after the TSTANDARD=NOMISS transformation, if specified. The means of the component scores in the output data set are always zero. The variances equal the corresponding eigenvalues, unless you specify the STANDARD option; then the variances are set to one.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by -1 and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by -1 did not help, the procedure tries using a random target. If the transformation is still constant, the previous non-constant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for *name*.”

Constant Variables

Constant and almost constant variables are zeroed and ignored.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered when determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable on the ID statement (ID x;).

REITERATE Option Usage

You can use the REITERATE option to perform additional iterations when PROC PRINQUAL stops before the data have adequately converged. For example, suppose that you execute the following code:

```
proc prinqual data=A cor out=B;
  transform mspline(X1-X5);
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations.

```
proc prinqual data=B reiterate cor out=B;
  transform mspline(X1-X5);
run;
```

Note that a WHERE statement is not necessary to exclude the correlation observations. They are automatically excluded because their `_TYPE_` variable value is not 'SCORE'.

You can also use the REITERATE option to specify starting values other than the original values for the transformations. Providing alternate starting points may avoid local optima. Here are two examples.

```
proc prinqual data=A out=B;
  transform rank(X1-X5);
run;

proc prinqual data=B reiterate out=C;
  /* Use ranks as the starting point. */
  transform monotone(X1-X5);
run;

data B;
  set A;
```

```

    array TXS[5] TX1-TX5;
    do j = 1 to 5;
        TXS[j] = normal(0);
    end;
run;

proc prinqual data=B reiterate out=C;
    /* Use a random starting point. */
    transform monotone(X1-X5);
run;

```

Note that divergence with the REITERATE option, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE option, the iteration does not terminate when the criterion change is negative during the first ten iterations.

Passive Observations

Observations may be excluded from the analysis for several reasons, including zero weight, zero frequency, missing values in variables designated IDENTITY, or missing values with the NOMISS option specified. These observations are passive in that they do not contribute to determining transformations, R^2 , total variance, and so on. However, some information can be computed for them, such as approximations, principal component scores, and transformed values. Passive observations in the output data set have a blank value for the variable `_TYPE_`.

Missing value estimates for passive observations may converge slowly with METHOD=MTV. In the following example, the missing value estimates should be 2, 5, and 8. Since the nonpassive observations do not change, the procedure converges in one iteration but the missing value estimates do not converge. The extra iterations produced by specifying CONVERGE=-1 and CCONVERGE=-1, as shown in the second PROC PRINQUAL step, generate the expected results.

Computational Resources

This section provides information on the computational resources required to run PROC PRINQUAL.

Let

N = number of observations
 m = number of variables
 n = number of principal components
 k = maximum spline degree
 p = maximum number of knots

- For the MTV algorithm, more than

$$56m + 8Nm + 8(6N + (p + k + 2)(p + k + 11))$$

bytes of array space are required.

- For the MGV and MAC algorithms, more than $56m$ plus the maximum of the data matrix size and the optimal scaling work space bytes of array space are required. The data matrix size is $8Nm$ bytes. The optimal scaling work space requires less than $8(6N + (p + k + 2)(p + k + 11))$ bytes.
- For the MTV and MGV algorithms, more than $56m + 4m(m + 1)$ bytes of array space are required.
- PROC PRINQUAL tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas are underestimates of the amount of memory needed to handle most problems. These formulas give an absolute minimum amount of memory required. If a utility data set is used, and if memory could be used with perfect efficiency, then roughly the amount of memory stated previously would be needed. In reality, most problems require at least two or three times the minimum.

- PROC PRINQUAL sorts the data once. The sort time is roughly proportional to $mN^{3/2}$.
- For the MTV algorithm, the time required to compute the variable approximations is roughly proportional to $2Nm^2 + 5m^3 + nm^2$.
- For the MGV algorithm, one regression analysis per iteration is required to compute model parameter estimates. The time required for accumulating the crossproduct matrix is roughly proportional to Nm^2 . The time required to compute the regression coefficients is roughly proportional to m^3 . For each variable for each iteration, the swept crossproduct matrix is updated with time roughly proportional to $m(N+m)$. The swept crossproduct matrix is updated for each variable with time roughly proportional to m^2 , until computations are refreshed, requiring all sweeps to be performed again.
- The only computationally intensive part of the MAC algorithm is the optimal scaling, since variable approximations are simple averages.
- Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to Nk^2 .

Displayed Output

The main output from the PRINQUAL procedure is the output data set. However, the procedure does produce displayed output in the form of an iteration history table that includes the following:

- Iteration Number
- the criterion being optimized
- criterion change
- Maximum and Average Absolute Change in standardized variable scores computed over variables that can be iteratively transformed
- notes
- final convergence status

ODS Table Names

PROC PRINQUAL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 59.2. ODS Tables Produced in PROC PRINQUAL

ODS Table Name	Description	Statement	Option
ConvergenceStatus	Convergence Status		default
Footnotes	Iteration History Footnotes		default
MAC	MAC Iteration History	PROC	METHOD=MAC
MGV	MGV Iteration History	PROC	METHOD=MGV
MTV	MTV Iteration History	PROC	METHOD=MTV

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the PRINQUAL procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release. To request a graph you must specify the ODS GRAPHICS statement in addition to the following option. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

The following table shows the available plot *option*.

Option	Plot Description
MDPREF	Multidimensional preference analysis

ODS Graph Names

PROC PRINQUAL assigns a name to the graph it creates using ODS. You can use this name to reference the graph when using ODS. The name is listed in Table 59.3.

To request a graph you must specify the ODS GRAPHICS statement in addition to the option indicated in Table 59.3. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

Table 59.3. ODS Graphics Produced by PROC PRINQUAL

ODS Graph Name	Plot Description	Statement	Option
PrinqualPlot	Multidimensional preference analysis	PROC	MDPREF

Examples

Example 59.1. Multidimensional Preference Analysis of Cars Data

This example uses PROC PRINQUAL to perform a nonmetric multidimensional preference (MDPREF) analysis (Carroll 1972). MDPREF analysis is a principal component analysis of a data matrix with columns that correspond to people and rows that correspond to objects. The data are ratings or rankings of each person’s preference for each object. The data are the transpose of the usual multivariate data matrix. (In

other words, the columns are people instead of the more typical matrix where rows represent people.) The final result of an MDPREF analysis is a biplot (Gabriel 1981) of the resulting preference space. A biplot displays the judges and objects in a single plot by projecting them onto the plane in the transformed variable space that accounts for the most variance.

The data are ratings by 25 judges of their preference for each of 17 automobiles. The ratings are made on a 0 to 9 scale, with 0 meaning very weak preference and 9 meaning very strong preference for the automobile. These judgments were made in 1980 about that year's products. There are two additional variables that indicate the manufacturer and model of the automobile.

This example uses PROC PRINQUAL, PROC FACTOR, and the %PLOTIT macro. PROC FACTOR is used before PROC PRINQUAL to perform a principal component analysis of the raw judgments. PROC FACTOR is also used immediately after PROC PRINQUAL since PROC PRINQUAL is a scoring procedure that optimally scores the data but does not report the principal component analysis.

The %PLOTIT macro produces the biplot. For information on the %PLOTIT macro, see [Appendix B, "Using the %PLOTIT Macro."](#)

The scree plot, in the standard principal component analysis reported by PROC FACTOR, shows that two principal components should be retained for further use. (See the scree plot in [Output 59.1.1](#)—there is a clear separation between the first two components and the remaining components.) There are nine eigenvalues that are precisely zero because there are nine fewer observations than variables in the data matrix. PROC PRINQUAL is then used to monotonically transform the raw judgments to maximize the proportion of variance accounted for by the first two principal components. The following statements create the data set and perform a principal component analysis of the original data. These statements produce [Output 59.1.1](#).

Output 59.1.1. (continued)

To fit the nonmetric MDPREF model, you can use the PRINQUAL procedure. The MONOTONE option is specified in the TRANSFORM statement to request a non-metric MDPREF analysis; alternatively, you can instead specify the IDENTITY option for a metric analysis. Several options are used in the PROC PRINQUAL statement. The option DATA=CarPref specifies the input data set, OUT=Results creates an output data set, and N=2 and the default METHOD=MTV transform the data to better fit a two-component model. The REPLACE option replaces the original data with the monotonically transformed data in the OUT= data set. The MDPREF option standardizes the component scores to variance one so that the geometry of the biplot is correct, and it creates two variables in the OUT= data set named Prin1 and Prin2. These variables contain the standardized principal component scores and structure matrix, which are used to make the biplot. If the variables in data matrix \mathbf{X} are standardized to mean zero and variance one, and n is the number of rows in \mathbf{X} , then $\mathbf{X} = \mathbf{V}\mathbf{\Lambda}^{1/2}\mathbf{W}'$ is the principal component model, where $\mathbf{X}'\mathbf{X}/(n-1) = \mathbf{W}\mathbf{\Lambda}\mathbf{W}'$. The \mathbf{W} and $\mathbf{\Lambda}$ contain the eigenvectors and eigenvalues of the correlation matrix of \mathbf{X} . The first two columns of \mathbf{V} , the standardized component scores, and $\mathbf{W}\mathbf{\Lambda}^{1/2}$, which is the structure matrix, are output. The advantage of creating a biplot based on principal components is that coordinates do not depend on the sample size. The following statements transform the data and produce [Output 59.1.2](#).

30	0.00027	0.00454	0.82995	0.00000	Not Converged

WARNING: Failed to converge, however criterion change is less than 0.0001.

The iteration history displayed by PROC PRINQUAL indicates that the proportion of variance is increased from an initial 0.66946 to 0.82995. The proportion of variance accounted for by PROC PRINQUAL on the first iteration equals the cumulative proportion of variance shown by PROC FACTOR for the first two principal components. In this example, PROC PRINQUAL's initial iteration performs a standard principal component analysis of the raw data. The columns labeled Average Change, Maximum Change, and Variance Change contain values that always decrease, indicating that PROC PRINQUAL is improving the transformations at a monotonically decreasing rate over the iterations. This does not always happen, and when it does not, it suggests that the analysis may be converging to a degenerate solution. See [Example 59.3](#) on page 3688 for a discussion of a degenerate solution. The algorithm does not converge in 30 iterations. However, the criterion change is small, indicating that more iterations are unlikely to have much effect on the results.

The second PROC FACTOR analysis is performed on the transformed data. The WHERE statement is used to retain only the monotonically transformed judgments. The scree plot shows that the first two eigenvalues are now much larger than the remaining smaller eigenvalues. The second eigenvalue has increased markedly at the expense of the next several eigenvalues. Two principal components seem to be necessary and sufficient to adequately describe these judges' preferences for these automobiles. The cumulative proportion of variance displayed by PROC FACTOR for the first two principal components is 0.83. The following statements perform the analysis and produce [Output 59.1.3](#):

Output 59.1.3. (continued)

The remainder of the example constructs the MDPREF biplot. A biplot is a plot that displays the relation between the row points and the columns of a data matrix. The rows of \mathbf{V} , the standardized component scores, and $\mathbf{W}\Lambda^{1/2}$, which is the structure matrix, contain enough information to reproduce \mathbf{X} . The (i, j) element of \mathbf{X} is the product of row i of \mathbf{V} and row j of $\mathbf{W}\Lambda^{1/2}$. If all but the first two columns of \mathbf{V} and $\mathbf{W}\Lambda^{1/2}$ are discarded, the (i, j) element of \mathbf{X} is approximated by the product of row i of \mathbf{V} and row j of $\mathbf{W}\Lambda^{1/2}$.

Since the MDPREF analysis is based on a principal component model, the dimensions of the MDPREF biplot are the first two principal components. The first principal component is the longest dimension through the MDPREF biplot. The first principal component is overall preference, which is the most salient dimension in the preference judgments. One end points in the direction that is on the average preferred most by the judges, and the other end points in the least preferred direction. The second principal component is orthogonal to the first principal component, and it is the orthogonal direction that is the second most salient. The interpretation of the second dimension varies from example to example.

With an MDPREF biplot, it is geometrically appropriate to represent each automobile (object) by a point and each judge by a vector. The automobile points have coordinates that are the scores of the automobile on the first two principal components. The judge vectors emanate from the origin of the space and go through a point with coordinates that are the coefficients of the judge (variable) on the first two principal components.

The absolute length of a vector is arbitrary. However, the relative lengths of the vectors indicate fit, with the squared lengths being proportional to the communalities in the PROC FACTOR output. The direction of the vector indicates the direction that is most preferred by the individual judge, with preference increasing as the vector moves from the origin. Let \mathbf{v}' be row i of \mathbf{V} , \mathbf{u}' be row j of $\mathbf{U} = \mathbf{W}\Lambda^{1/2}$, $\|\mathbf{v}\|$ be the length of \mathbf{v} , $\|\mathbf{u}\|$ be the length of \mathbf{u} , and θ be the angle between \mathbf{v} and \mathbf{u} . The predicted degree of preference that an individual judge has for an automobile is $\mathbf{u}'\mathbf{v} = \|\mathbf{u}\| \|\mathbf{v}\| \cos \theta$. Each car point can be orthogonally projected onto the vector. The projection of car i on vector j is $\mathbf{u}((\mathbf{u}'\mathbf{v})/(\mathbf{u}'\mathbf{u}))$ and the length of this projection is $\|\mathbf{v}\| \cos \theta$. The automobile that projects farthest along a vector in the direction it points is that judge's most preferred automobile, since the length of this projection, $\|\mathbf{v}\| \cos \theta$, differs from the predicted preference, $\|\mathbf{u}\| \|\mathbf{v}\| \cos \theta$, only by $\|\mathbf{u}\|$, which is constant within each judge.

To interpret the biplot, look for directions through the plot that show a continuous change in some attribute of the automobiles, or look for regions in the plot that contain clusters of automobile points and determine what attributes the automobiles have in common. Those points that are tightly clustered in a region of the plot represent automobiles that have the same preference patterns across the judges. Those vectors that point in roughly the same direction represent judges who tend to have similar preference patterns.

The following statement constructs the biplot and produces [Output 59.1.4](#):

```
title3 'Biplot of Automobiles and Judges';
%plotit(data=results, datatype=mdpref 2);
```

The DATATYPE=MDPREF 2 option indicates that the coordinates come from an MDPREF analysis, so the macro represents the scores as points and the structure as vectors, with the vectors stretched by a factor of two to make a better graphical display.

Output 59.1.4. Preference Ratings for Automobiles Manufactured in 1980

In the biplot, American automobiles are located on the left of the space, while European and Japanese automobiles are located on the right. At the top of the space are expensive American automobiles (Cadillac Eldorado, Lincoln Continental) while at the bottom are inexpensive ones (Pinto, Chevette). The first principal component differentiates American from imported automobiles, and the second arranges automobiles by price and other associated characteristics.

The two expensive American automobiles form a cluster, the sporty automobile (Firebird) is by itself, the Volvo DL is by itself, and the remaining imported autos

form a cluster, as do the remaining American autos. It seems there are 5 prototypical automobiles in this set of 17, in terms of preference patterns among the 25 judges.

Most of the judges prefer the imported automobiles, especially the Volvo. There is also a fairly large minority that prefer the expensive cars, whether or not they are American (those with vectors that point towards one o'clock), or simply prefer expensive American automobiles (vectors that point towards eleven o'clock). There are two people who prefer anything except expensive American cars (five o'clock vectors), and one who prefers inexpensive American cars (seven o'clock vector).

Several vectors point toward the upper-right corner of the plot, toward a region with no cars. This is the region between the European and Japanese cars on the right and the luxury cars on the top. This suggests that there is a market for luxury Japanese and European cars.

Example 59.2. Multidimensional Preference Analysis of Cars Data, ODS Graphics (Experimental)

The following graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics see [Chapter 15, "Statistical Graphics Using ODS."](#) For specific information about the graphics available in the PRINQUAL procedure, see the "ODS Graphics" section on page 3677.

Output 59.2.1. Multidimensional Preference Analysis (Experimental)

Example 59.3. Principal Components of Basketball Rankings

The data in this example are 1985–1986 preseason rankings of 35 college basketball teams by 10 different news services. The services do not all rank the same teams or the same number of teams, so there are missing values in these data. Each of the 35 teams in the data set is ranked by at least one news service. One way of summarizing these data is with a principal component analysis, since the rankings should all be related to a single underlying variable, the first principal component.

You can use PROC PRINQUAL to estimate the missing ranks and compute scores for all observations. You can formulate a PROC PRINQUAL analysis that assumes that the observed ranks are ordinal variables and replaces the ranks with new numbers that are monotonic with the ranks and better fit the one principal component model.

The missing rank estimates need to be constrained since a news service would have positioned the unranked teams below the teams it ranked. PROC PRINQUAL should impose order constraints within the nonmissing values and between the missing and nonmissing values, but not within the missing values. PROC PRINQUAL has sophisticated missing data handling facilities; however, these facilities cannot directly handle this problem. The solution requires reformulating the problem.

By performing some preliminary data manipulations, specifying the N=1 option in the PROC PRINQUAL statement, and specifying the UNTIE transformation in the TRANSFORM statement, you can make the missing value estimates conform to the requirements. The PROC MEANS step finds the largest rank for each variable. The next DATA step replaces missing values with a value that is one larger than the largest observed rank. The N=1 option (in the PRINQUAL procedure) specifies that the variables should be transformed to make them as one-dimensional as possible. The UNTIE transformation in the TRANSFORM statement monotonically transforms the ranks, untying any ties in an optimal way. Because the only ties are for the values that replace the missing values, and because these values are larger than the observed values, the rescaling of the data satisfies the preceding requirements.

The following statements create the data set and perform the transformations discussed previously. These statements produce [Output 59.3.1](#).

30	0.00073	0.00805	0.94980	0.00000	Not Converged

WARNING: Failed to converge, however criterion change is less than 0.0001.

An alternative approach is to use the pairwise deletion option of the CORR procedure to compute the correlation matrix and then use PROC PRINCOMP or PROC FACTOR to perform the principal component analysis. This approach has several disadvantages. The correlation matrix may not be positive semidefinite (psd), an assumption required for principal component analysis. PROC PRINQUAL always produces a psd correlation matrix. Even with pairwise deletion, PROC CORR removes the six observations with only a single nonmissing value from this data set. Finally, it is still not possible to calculate scores on the principal components for those teams that have missing values.

It is possible to compute the composite ranking using PROC PRINCOMP and some preliminary data manipulations, similar to those discussed previously.

Chapter 58, “The PRINCOMP Procedure,” contains an example where the average

of the unused ranks in each poll is substituted for the missing values, and each observation is weighted by the number of nonmissing values. This method has much to recommend it. It is much faster and simpler than using PROC PRINQUAL. It is also much less prone to degeneracies and capitalization on chance. However, PROC PRINCOMP does not allow the nonmissing ranks to be monotonically transformed and the missing values untied to optimize fit.

PROC PRINQUAL monotonically transforms the observed ranks and estimates the missing ranks (within the constraints given previously) to account for almost 95 percent of the variance of the transformed data by just one dimension. PROC FACTOR is then used to report details of the principal component analysis of the transformed data. As shown by the Factor Pattern values in [Output 59.3.2](#), nine of the ten news services have a correlation of 0.95 or larger with the scores on the first principal component after the data are optimally transformed. The scores are sorted and the composite ranking is displayed following the PROC FACTOR output. More confidence can be placed in the stability of the scores for the teams that are ranked by the majority of the news services than in scores for teams that are seldom ranked.

The monotonic transformations are plotted for each of the ten news services. These plots are the values of the raw ranks (with the missing ranks replaced by the maximum rank plus one) versus the rescored (transformed) ranks. The transformations are the step functions that maximize the fit of the data to the principal component model. Smoother transformations could be found by using MSPLINE transformations, but MSPLINE transformations would not correctly handle the missing data problem.

The following statements perform the final analysis and produce [Output 59.3.2](#):

Output 59.3.3. Monotonic Transformation for Each News Service

Output 59.3.3. (continued)

Output 59.3.3. (continued)

The ordinary PROC PRINQUAL missing data handling facilities do not work for these data because they do not constrain the missing data estimates properly. If you code the missing ranks as missing and specify linear transformations, then you can compute least-squares estimates of the missing values without transforming the observed values. The first principal component then accounts for 92 percent of the variance after 20 iterations. However, Virginia Tech is ranked number 11 by its score even though it appeared in only one poll (InsideSports ranked it number 13, anchoring it firmly in the middle). Specifying monotone transformations is also inappropriate since they too allow unranked teams to move in between ranked teams.

With these data, the combination of monotone transformations and the freedom to score the missing ranks without constraint leads to degenerate transformations. PROC PRINQUAL tries to merge the 35 points into two points, producing a perfect fit in one dimension. There is evidence for this after 20 iterations when the Average Change, Maximum Change, and Variance Change values are all increasing, instead of the more stable decreasing change rate seen in the analysis shown. The change rates all stop increasing after 41 iterations, and it is clear by 70 or 80 iterations that one component will account for 100 percent of the transformed variables variance after sufficient iteration. While this may seem desirable (after all, it is a perfect fit), you should, in fact, be on guard when this happens. Whenever convergence is slow, the rates of change increase, or the final data perfectly fit the model, the solution is probably degenerating due to too few constraints on the scorings.

PROC PRINQUAL can account for 100 percent of the variance by scoring Montana and UCLA with one positive value on all variables and scoring all the other teams with one negative value on all variables. This inappropriate analysis suggests that all ranked teams are equally good except for two teams that are less good. Both of these two teams are ranked by only one news service, and their only nonmissing rank is last in the poll. This accounts for the degeneracy.

Chapter 60

The PROBIT Procedure

Overview

The PROBIT procedure calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

Probit analysis developed from the need to analyze qualitative (dichotomous or polytomous) dependent variables within the regression framework. Many response variables are binary by nature (yes/no), while others are measured ordinally rather than continuously (degree of severity). Collett (1991) and Agresti (1990), for example, have shown ordinary least squares (OLS) regression to be inadequate when the dependent variable is discrete. Probit or logit analyses are more appropriate in this case.

The PROBIT procedure computes maximum likelihood estimates of the parameters β and C of the probit equation using a modified Newton-Raphson algorithm. When the response Y is binary, with values 0 and 1, the probit equation is

$$p = \Pr(Y = 0) = C + (1 - C)F(\mathbf{x}'\beta)$$

where

- β is a vector of parameter estimates
- F is a cumulative distribution function (the normal, logistic, or extreme value)
- \mathbf{x} is a vector of explanatory variables
- p is the probability of a response
- C is the natural (threshold) response rate

Notice that PROC PROBIT, by default, models the probability of the *lower* response levels. The choice of the distribution function F (normal for the probit model, logistic for the logit model, and extreme value or Gompertz for the gompit model) determines the type of analysis. For most problems, there is relatively little difference between the normal and logistic specifications of the model. Both distributions are symmetric about the value zero. The extreme value (or Gompertz) distribution, however, is not symmetric, approaching 0 on the left more slowly than it approaches 1 on the right. You can use the extreme value distribution where such asymmetry is appropriate.

For ordinal response models, the response, Y , of an individual or an experimental unit may be restricted to one of a (usually small) number, $k + 1$ ($k \geq 1$), of ordinal values, denoted for convenience by $1, \dots, k, k + 1$. For example, the severity of coronary disease can be classified into three response categories as 1=no disease, 2=angina

pectoris, and 3=myocardial infarction. The PROBIT procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$\Pr(Y \leq 1 \mid \mathbf{x}) = F(\mathbf{x}'\boldsymbol{\beta})$$

$$\Pr(Y \leq i \mid \mathbf{x}) = F(\alpha_i + \mathbf{x}'\boldsymbol{\beta}), \quad 2 \leq i \leq k$$

where $\alpha_2, \dots, \alpha_k$ are $k - 1$ intercept parameters. By default, the covariate vector \mathbf{x} contains an overall intercept term.

You can set or estimate the natural (threshold) response rate C . Estimation of C can begin either from an initial value that you specify or from the rate observed in a control group. By default, the natural response rate is fixed at zero.

An observation in the data set analyzed by the PROBIT procedure may contain the response and explanatory values for one subject. Alternatively, it may provide the number of observed events from a number of subjects at a particular setting of the explanatory variables. In this case, PROC PROBIT models the probability of an event.

Getting Started

The following example illustrates how you can use the PROBIT procedure to compute the threshold response rate and regression parameter estimates for quantal response data.

Estimating the Natural Response Threshold Parameter

Suppose you want to test the effect of a drug at 12 dosage levels. You randomly divide 180 subjects into 12 groups of 15—one group for each dosage level. You then conduct the experiment and, for each subject, record the presence or absence of a positive response to the drug. You summarize the data by counting the number of subjects responding positively in each dose group. Your data set is as follows:

```
data study;
  input Dose Respond;
  Number = 15;
  datalines;
0      3
1.1    4
1.3    4
2.0    3
2.2    5
2.8    4
3.7    5
3.9    9
4.4    8
```

```

4.8 11
5.9 12
6.8 13
;
run;

```

The variable `dose` represents the amount of drug administered. The first group, receiving a dose level of 0, is the control group. The variable `number` represents the number of subjects in each group. All groups are equal in size; hence, `number` has the value 15 for all observations. The variable `respond` represents the number of subjects responding to the associated drug dosage.

You can model the probability of positive response as a function of dosage using the following statements:

```

proc probit data=study log10 optc;
  model respond/number=dose;
  output out = new p = p_hat;
  predpplot var = dose cfit = blue cframe=ligr inborder;
  inset;
  ippplot var = dose cfit = blue cframe=ligr inborder;
  inset;
run;

```

The `DATA=` option specifies that PROC PROBIT analyze the SAS data set `study`. The `LOG10` option replaces the first continuous independent variable (`dose`) by its common logarithm. The `OPTC` option estimates the natural response rate. When you use the `LOG10` option with the `OPTC` option, any observations with a dose value less than or equal to zero are used in the estimation as a control group.

The `OUTPUT` statement creates a new data set, `new`, that contains all the variables in the original data set, and a new variable, `p_hat`, that represents the predicted probabilities.

The `MODEL` statement specifies a proportional response using the variables `respond` and `number` in *events/trials* syntax. The variable `dose` is the stimulus or explanatory variable. The results from this analysis are displayed in the following figures.

Probit Procedure	
Model Information	
Data Set	WORK.STUDY
Events Variable	Respond
Trials Variable	Number
Number of Observations	12
Number of Events	81
Number of Trials	180
Number of Events In Control Group	3
Number of Trials In Control Group	15
Name of Distribution	Normal
Log Likelihood	-104.3945783

Algorithm converged.

Figure 60.1. Model Fitting Information for the PROBIT Procedure

Figure 60.1 displays background information about the model fit. Included are the name of the input data set, the response variables used, and the number of observations, events, and trials. The last line in Figure 60.1 shows the final value of the log-likelihood function.

Figure 60.2 displays the table of parameter estimates for the model. The parameter C , which is the natural response threshold or the proportion of individuals responding at zero dose, is estimated to be 0.2409. Since both the intercept and the slope coefficient have significant p -values (0.0020, 0.0010), you can write the model for

$$\text{Pr}(\text{response}) = C + (1 - C)F(\mathbf{x}'\beta)$$

as

$$\text{Pr}(\text{response}) = 0.2409 + 0.7591(\Phi(-4.1439 + 6.2308 \times \log_{10}(\text{dose})))$$

where Φ is the normal cumulative distribution function.

Probit Procedure							
Analysis of Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-4.1438	1.3415	-6.7731	-1.5146	9.54	0.0020
Log10(Dose)	1	6.2308	1.8996	2.5076	9.9539	10.76	0.0010
C	1	0.2409	0.0523	0.1385	0.3433		

Figure 60.2. Model Parameter Estimates for the PROBIT Procedure

Finally, PROC PROBIT specifies the resulting tolerance distribution by providing the mean MU and scale parameter SIGMA as well as the covariance matrix of the distribution parameters.

Probit Procedure			
Probit Model in Terms of Tolerance Distribution			
	MU	SIGMA	
	0.66506312	0.16049411	
Estimated Covariance Matrix for Tolerance Parameters			
	MU	SIGMA	_C_
MU	0.001158	-0.000493	0.000954
SIGMA	-0.000493	0.002394	-0.000999
C	0.000954	-0.000999	0.002731

Figure 60.3. Tolerance Distribution Estimates for the PROBIT Procedure

Figure 60.4. Plot of Observed and Fitted Probabilities versus Dose Level

The PREDPLOT statement creates the plot in [Figure 60.4](#), showing the relationship between dosage level, observed response proportions, and estimated probability values. The dashed lines represent pointwise confidence bands for the fitted probabilities, and a reference line is plotted at the estimated threshold value of .24.

Figure 60.5. Inverse Predicted Probability Plot with Fiducial Limits

The IPPPLOT statement creates the plot in [Figure 60.5](#), showing the inverse relationship between dosage level and observed response proportions/estimated probability values. The dashed lines represent pointwise fiducial limits for the predicted values of the dose variable, and a reference line is also plotted at the estimated threshold value of .24.

The INSET statement after each of these plot statements draws a box within the plot. In the inset box, summary information about the model fitting is printed.

Syntax

The following statements are available in PROC PROBIT.

```

PROC PROBIT < options > ;
  MODEL response=independents < / options > ;

  BY variables ;
  CLASS variables ;
  OUTPUT < OUT=SAS-data-set > < options > ;
  WEIGHT variable ;

  CDFPLOT < VAR = variable > < options > ;
  INSET < keyword-list > < / options > ;
  IPPPLOT < VAR = variable > < options > ;
  LPREDPLOT < VAR = variable > < options > ;
  PREDPLOT < VAR = variable > < options > ;

```

A MODEL statement is required. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last one is used. Main effects and higher-order terms can be specified in the MODEL statement, similar to the GLM procedure. If a CLASS statement is used, it must precede the MODEL statement.

The CDFPLOT, INSET, IPPLOT, LPREDPLOT, and PREDPLOT statements are used to produce graphical output. You can use any appropriate combination of the graphical statements after the MODEL statement.

PROC PROBIT Statement

PROC PROBIT < options > ;

The PROC PROBIT statement starts the procedure. You can specify the following options in the PROC PROBIT statement.

COVOUT

writes the parameter estimate covariance matrix to the OUTEST= data set.

C=rate

OPTC

controls how the natural response is handled. Specify the OPTC option to request that the natural response rate C be estimated. Specify the C=rate option to set the natural response rate or to provide the initial estimate of the natural response rate. The natural response rate value must be a number between 0 and 1.

- If you specify neither the OPTC nor the C= option, a natural response rate of zero is assumed.
- If you specify both the OPTC and the C= option, the C= option should be a reasonable initial estimate of the natural response rate. For example, you could use the ratio of the number of responses to the number of subjects in a control group.
- If you specify the C= option but not the OPTC option, the natural response rate is set to the specified value and not estimated.
- If you specify the OPTC option but not the C= option, PROC PROBIT's action depends on the response variable, as follows:
 - If you specify either the LN or LOG10 option and some subjects have the first independent variable (dose) values less than or equal to zero, these subjects are treated as a control group. The initial estimate of C is then the ratio of the number of responses to the number of subjects in this group.
 - If you do not specify the LN or LOG10 option or if there is no control group, then one of the following occurs:
 - If all responses are greater than zero, the initial estimate of the natural response rate is the minimal response rate (the ratio of the number of responses to the number of subjects in a dose group) across all dose levels.

- If one or more of the responses is zero (making the response rate zero in that dose group), the initial estimate of the natural rate is the reciprocal of twice the largest number of subjects in any dose group in the experiment.

DATA=SAS-data-set

specifies the SAS data set to be used by PROC PROBIT. By default, the procedure uses the most recently created SAS data set.

GOUT=graphics-catalog

specifies a graphics catalog in which to save graphics output.

HPROB= p

specifies a minimum probability level for the Pearson chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to $(k - 1) \times m - q$, where k is the number of levels for the response variable, m is the number of different sets of independent variable values, and q is the number of parameters fit in the model. Note that the HPROB= option can also appear in the MODEL statement.

INEST= SAS-data-set

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “[INEST= SAS-data-set](#)” on page 3757 for a detailed description of the contents of the INEST= data set.

INVERSECL

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. If the algorithm fails to converge (this can happen when C is nonzero), missing values are reported for the confidence limits. See the section “[Inverse Confidence Limits](#)” on page 3761 for details. Note that the INVERSECL option can also appear in the MODEL statement.

LACKFIT

performs two goodness-of-fit tests (a Pearson chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

Note: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the “[Lack of Fit Tests](#)” section on page 3759 for a description of the tests. Note that the LACKFIT option can also appear in the MODEL statement.

**LOG
LN**

analyzes the data by replacing the first continuous independent variable by its natural logarithm. This variable is usually the level of some treatment such as dosage. In addition to the usual output given by the INVERSECL option, the estimated dose values and 95% fiducial limits for dose are also displayed. If you specify the OPTC option, any observations with a dose value less than or equal to zero are used in the estimation as a control group. If you do not specify the OPTC option with the LOG or LN option, then any observations with the first continuous independent variable values less than or equal to zero are ignored.

LOG10

specifies an analysis like that of the LN or LOG option except that the common logarithm (log to the base 10) of the dose value is used rather than the natural logarithm.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

NOPRINT

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see [Chapter 14, “Using the Output Delivery System.”](#)

OPTC

controls how the natural response is handled. See the description of the [C= option](#) on page 3711 for details.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the classification variables specified in the CLASS statement, including the levels of the response variable. Response level ordering is important since PROC PROBIT always models the probability of response levels at the beginning of the ordering. See the section “[Response Level Ordering](#)” on page 3754 for further details. This ordering also determines which parameters in the model correspond to each level in the data. The following table shows how PROC PROBIT interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	formatted value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For the values FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter on the SORT procedure in the *SAS Procedures Guide*.

OUTEST= SAS-data-set

specifies a SAS data set to contain the parameter estimates and, if the COVOUT option is specified, their estimated covariances. If you omit this option, the output data set is not created. The contents of the data set are described in the section “OUTEST= SAS-data-set” on page 3762.

XDATA= SAS-data-set

specifies an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement. If there are covariates specified in a MODEL statement, you specify fixed values for the effects in the MODEL statement by the XDATA= data set when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. These specified values for the effects in the MODEL statement are also used for generating plots. See the section “XDATA= SAS-data-set” on page 3763 for a detailed description of the contents of the XDATA= data set.

BY Statement

BY variables ;

You can specify a BY statement with PROC PROBIT to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order on each of the BY variables, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PROBIT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CDFPLOT Statement

CDFPLOT *<var = variable>* *<options >*;

The CDFPLOT statement plots the predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). You can only use this statement after a multinomial model statement.

VAR= *(variable)*

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted cumulative distribution function is defined as

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}})$$

where $j = 1, \dots, k$ are the indexes of the k levels of the multinomial response variable, F is the CDF of the distribution used to model the cumulative probabilities, $\hat{\mathbf{b}}$ is the vector of estimated parameters, \mathbf{x} is the covariate vector, \hat{a}_j are estimated ordinal intercepts with $\hat{a}_1 = 0$, and C is the threshold parameter, either known or estimated from the model. Let x_1 be the covariate corresponding to the dose variable and \mathbf{x}_{-1} be the vector of the rest of the covariates. Let the corresponding estimated parameters be \hat{b}_1 and $\hat{\mathbf{b}}_{-1}$. Then

$$\hat{F}_j(\mathbf{x}) = C + (1 - C)F(\hat{a}_j + x_1\hat{b}_1 + \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})$$

To plot \hat{F}_j as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

specify the levels of the multinomial response variable for which the cdf curves are requested, and add features to the plot. There are $k - 1$ curves for a k -level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= option in the CDFPLOT statement. See the LEVEL= option for how to specify the levels.

An attached box on the right side of the plot is used to label these curves with the names of their levels. You can specify the color of this box using the CLABBOX= option.

You can use options in the CDFPLOT statement to

- superimpose specification limits
- specify the levels for which the cdf curves are requested
- specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all *options* by function. The “[Dictionary of Options](#)” on page 3718 describes each option in detail.

CDF Options

Table 60.1. Options for CDFPLOT

LEVEL= <i>character-list</i>	specifies the names of the levels for which the cdf curves are requested
NOTHRESH	suppresses the threshold line
THRESHLABPOS= <i>value</i>	specifies the position for the label of the threshold line

General Options

Table 60.2. Color Options

CAXIS= <i>color</i>	specifies color for axis
CFIT= <i>color</i>	specifies color for fitted curves
CFRAME= <i>color</i>	specifies color for frame
CGRID= <i>color</i>	specifies color for grid lines
CHREF= <i>color</i>	specifies color for HREF= lines
CLABBOX= <i>color</i>	specifies color for label box
CTEXT= <i>color</i>	specifies color for text
CVREF= <i>color</i>	specifies color for VREF= lines

Table 60.3. Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	specifies an ANNOTATE data set
INBORDER	requests a border around plot
LFIT= <i>linetype</i>	specifies line style for fitted curves
LGRID= <i>linetype</i>	specifies line style for grid lines
NOFRAME	suppresses the frame around plotting areas
NOGRID	suppresses grid lines
NOFIT	suppresses cdf curves
NOHLABEL	suppresses horizontal labels
NOHTICK	suppresses horizontal ticks
NOVTICK	suppresses vertical ticks
TURNVLABELS	vertically strings out characters in vertical labels
WFIT= <i>n</i>	specifies thickness for fitted curves
WGRID= <i>n</i>	specifies thickness for grids
WREFL= <i>n</i>	specifies thickness for reference lines

Table 60.4. Axis Options

HAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	specifies offset for horizontal axis
HLOWER= <i>value</i>	specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for vertical axis
VAXISLABEL= <i>'label'</i>	specifies label for vertical axis
VOFFSET= <i>value</i>	specifies offset for vertical axis
VLOWER= <i>value</i>	specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	specifies thickness for axis

Table 60.5. Graphics Catalog Options

DESCRIPTION= <i>'string'</i>	specifies description for graphics catalog member
NAME= <i>'string'</i>	specifies name for plot in graphics catalog

Table 60.6. Options for Text Enhancement

FONT= <i>font</i>	specifies software font for text
HEIGHT= <i>value</i>	specifies height of text used outside framed areas
INFONT= <i>font</i>	specifies software font for text inside framed areas
INHEIGHT= <i>value</i>	specifies height of text inside framed areas

Table 60.7. Options for Reference Lines

HREF<(INTERSECT)> =value-list	requests horizontal reference line
HREFLABELS= (‘label1’,...,‘labeln’)	specifies labels for HREF= lines
HREFLABPOS= <i>n</i>	specifies vertical position of labels for HREF= lines
LHREF= <i>linetype</i>	specifies line style for HREF= lines
LVREF= <i>linetype</i>	specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	requests vertical reference line
VREFLABELS= (‘label1’,...,‘labeln’)	specifies labels for VREF= lines
VREFLABPOS= <i>n</i>	specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the CDFPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the cdf plot. The ANNOTATE= data set you specify in the CDFPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted cdf curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CLABBOX=*color*

specifies the color for the area enclosed by the label box for cdf curves. This area is not shaded by default.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*'string'*

DES=*'string'*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2<by value3>*

specifies tick mark values for the horizontal axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

```

haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10

```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF <(INTERSECT)>=*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS='*label1*', . . . , '*labeln*'**HREFLABEL=**'*label1*', . . . , '*labeln*'**HREFLAB=**'*label1*', . . . , '*labeln*'

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	top
2	staggered from top
3	bottom
4	staggered from bottom
5	alternating from top
6	alternating from bottom

INBORDER

requests a border around cdf plots.

LEVEL= (*character-list*)**ORDINAL=** (*character-list*)

specifies the names of the levels for which cdf curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no cdf curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1).

LGRID=*linetype*

specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype***LH=***linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype***LV=***linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOFIT

suppresses the fitted cdf curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the vertical axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL='*string*'

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS='*label1*',...,'*labeln*'**VREFLABEL=**'*label1*',...,'*labeln*'**VREFLAB=**'*label1*',...,'*labeln*'

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

CLASS Statement

CLASS *variables* ;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric. If a single response variable is specified in the MODEL statement, it must also be specified in a CLASS statement.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary*.

If the CLASS statement is used, it must appear before any of the MODEL statements.

INSET Statement

INSET <*keyword-list*> <*options*>;

The box or table of summary information produced on plots made with the [CDFPLOT](#), [IPPPLOT](#), [LPREDPLOT](#), and [PREDPPLOT](#) statement is called an *inset*. You can use the INSET statement to customize both the information that is printed in the inset box and the appearance of the inset box. To supply the information that is displayed in the inset box, you specify *keywords* corresponding to the information you want shown. For example, the following statements produce a predicted probability plot with the number of trials, the number of events, the name of the distribution, and the estimated optimum natural threshold in the inset.

```
proc probit data=epidemic;
  model r/n = dose;
  predpplot ;
  inset nobs ntrials nevents dist optc;
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the *keyword* for that entry followed by the equal sign (=) and the label in quotes. For example, the following INSET statement produces an inset containing the number of observations and the name of the distribution, labeled “Sample Size” and “Distribution” in the inset.

```
inset nobobs='Sample Size' dist='Distribution';
```

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

The *options* control the appearance of the box.

If you specify more than one INSET statement, only the first one is used.

Keywords Used in the INSET Statement

The following tables list keywords available in the INSET statement to display summary statistics, distribution parameters, and distribution fitting information.

Table 60.8. Summary Statistics

NOBS	number of observations
NTRIALS	number of trials
NEVENTS	number of events
C	the user inputted threshold
OPTC	the estimated natural threshold
NRESPLEV	number of levels of the response variable

Table 60.9. General Information

CONFIDENCE	confidence coefficient for all confidence intervals or for the Weibayes fit
DIST	name of the distribution

Options Used in the INSET Statement

The following tables list the options available in the INSET statement.

Table 60.10. General Appearance Options

FONT= <i>font</i>	specifies software font for text
HEIGHT= <i>value</i>	specifies height of text
HEADER= <i>'quoted string'</i>	specifies text for header or box title
NOFRAME	omits frame around box
POS= <i>value</i> <DATA PERCENT>	determines the position of the inset. The <i>value</i> can be a compass point (N, NE, E, SE, S, SW, W, NW) or a pair of coordinates (x, y) enclosed in parentheses. The coordinates can be specified in axis percent units or axis data units.
REFPOINT= <i>name</i>	specifies the reference point for an inset that is positioned by a pair of coordinates with the POS= option. You use the REFPOINT= option in conjunction with the POS= coordinates. The REFPOINT= option specifies which corner of the inset frame you have specified with coordinates (x, y) and it can take the value of BR (bottom right), BL (bottom left), TR (top right), or TL (top left). The default is REFPOINT=BL. If the inset position is specified as a compass point, then the REFPOINT= option is ignored.

Table 60.11. Color and Pattern Options

CFILL= <i>color</i>	specifies color for filling box
CFILLH= <i>color</i>	specifies color for filling box header
CFRAME= <i>color</i>	specifies color for frame
CHEADER= <i>color</i>	specifies color for text in header
CTEXT= <i>color</i>	specifies color for text

IPPLOT Statement

IPPLOT <*var = variable*> <*options*>;

The IPPLOT statement plots the inverse of the predicted probability against a single continuous variable (dose variable) in the MODEL statement for the binomial model. You can only use this statement after a binomial model statement. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. Refer to the section “[Inverse Confidence Limits](#)” on page 3761 for more details.

VAR= (*variable*)

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

For the binomial model, the response variable is a probability. An estimate of the

dose level \hat{x}_1 needed for a response of p is given by

$$\hat{x}_1 = (F^{-1}(p) - \mathbf{x}'_{-1}\hat{\mathbf{b}}_{-1})/\hat{b}_1$$

where F is the cumulative distribution function used to model the probability, \mathbf{x}_{-1} is the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ is the vector of the estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 is the estimated parameter for the dose variable of interest.

To plot \hat{x}_1 as a function of p , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

You can use options in the IPPLOT statement to

- superimpose specification limits
- suppress or add the observed data points on the plot
- suppress or add the fiducial limits on the plot
- specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all *options* by function. The “[Dictionary of Options](#)” on page 3728 describes each option in detail.

IPP Options

Table 60.12. Plot Layout Options for IPPLOT

NOCONF	suppresses fiducial limits
NODATA	suppresses observed data points on the plot
NOTHRESH	suppresses the threshold line
THRESLABPOS= <i>value</i>	specifies the position for the label of the threshold line

General Options

Table 60.13. Color Options

CAXIS= <i>color</i>	specifies color for axis
CFIT= <i>color</i>	specifies color for fitted curves
CFRAME= <i>color</i>	specifies color for frame
CGRID= <i>color</i>	specifies color for grid lines
CHREF= <i>color</i>	specifies color for HREF= lines
CTEXT= <i>color</i>	specifies color for text
CVREF= <i>color</i>	specifies color for VREF= lines

Table 60.14. Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	specifies an ANNOTATE data set
INBORDER	requests a border around plot
LFIT= <i>linetype</i>	specifies line style for fitted curves and confidence limits
LGRID= <i>linetype</i>	specifies line style for grid lines
NOFRAME	suppresses the frame around plotting areas
NOGRID	suppresses grid lines
NOFIT	suppresses fitted curves
NOHLABEL	suppresses horizontal labels
NOHTICK	suppresses horizontal ticks
NOVTICK	suppresses vertical ticks
TURNVLABELS	vertically strings out characters in vertical labels
WFIT= <i>n</i>	specifies thickness for fitted curves
WGRID= <i>n</i>	specifies thickness for grids
WREFL= <i>n</i>	specifies thickness for reference lines

Table 60.15. Axis Options

HAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	specifies offset for horizontal axis
HLOWER= <i>value</i>	specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for vertical axis
VAXISLABEL= <i>'label'</i>	specifies label for vertical axis
VOFFSET= <i>value</i>	specifies offset for vertical axis
VLOWER= <i>value</i>	specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	specifies thickness for axis

Table 60.16. Options for Reference Lines

HREF<(INTERSECT)> =value-list	requests horizontal reference line
HREFLABELS= (‘label1’,...,‘labeln’)	specifies labels for HREF= lines
HREFLABPOS= <i>n</i>	specifies vertical position of labels for HREF= lines
LHREF= <i>linetype</i>	specifies line style for HREF= lines
LVREF= <i>linetype</i>	specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	requests vertical reference line
VREFLABELS= (‘label1’,...,‘labeln’)	specifies labels for VREF= lines
VREFLABPOS= <i>n</i>	specifies horizontal position of labels for VREF= lines

Table 60.17. Graphics Catalog Options

DESCRIPTION= <i>‘string’</i>	specifies description for graphics catalog member
NAME= <i>‘string’</i>	specifies name for plot in graphics catalog

Table 60.18. Options for Text Enhancement

FONT= <i>font</i>	specifies software font for text
HEIGHT= <i>value</i>	specifies height of text used outside framed areas
INFONT= <i>font</i>	specifies software font for text inside framed areas
INHEIGHT= <i>value</i>	specifies height of text inside framed areas

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the IPPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the ipp plot. The ANNOTATE= data set you specify in the IPPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted ipp curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color*

CV=*color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=*'string'*

DES=*'string'*

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2<by value3>*

specifies tick mark values for the horizontal axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

```

haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10

```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS='*label1*',...,'*labeln*'**HREFLABEL=**'*label1*',...,'*labeln*'**HREFLAB=**'*label1*',...,'*labeln*'

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	top
2	staggered from top
3	bottom
4	staggered from bottom
5	alternating from top
6	alternating from bottom

INBORDER

requests a border around ipp plots.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=linetypespecifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.**LHREF=linetype****LH=linetype**

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=linetype**LV=linetype**

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses fiducial limits from the plot.

NODATA

suppresses observed data points from the plot.

NOFIT

suppresses the fitted ipp curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*specifies the vertical position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	top
2	bottom

VAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the vertical axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL='*string*'

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS='*label1*',...,'*labeln*'**VREFLABEL=**'*label1*',...,'*labeln*'**VREFLAB=**'*label1*',...,'*labeln*'

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

LPREDPLOT Statement

LPREDPLOT <*var = variable*> <*options*>;

The LPREDPLOT statement plots the linear predictor $\mathbf{x}'\mathbf{b}$ against a single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are only available for the binomial model.

VAR= (*variable*)

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement for which the linear predictor plot is plotted. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

Let x_1 be the covariate of the dose variable, \mathbf{x}_{-1} be the vector of the rest of the covariates, $\hat{\mathbf{b}}_{-1}$ be the vector of estimated parameters corresponding to \mathbf{x}_{-1} , and \hat{b}_1 be the estimated parameter for the dose variable of interest.

To plot $\hat{\mathbf{x}}'\mathbf{b}$ as a function of x_1 , \mathbf{x}_{-1} must be specified. You can use the XDATA= option to provide the values of \mathbf{x}_{-1} (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

For the multinomial model, you can use the LEVEL= option to specify the levels for which the linear predictor lines are plotted. The lines are labeled by the names of their levels in the middle.

You can use options in the LPREDPLOT statement to

- superimpose specification limits

- suppress or add the observed data points on the plot for the binomial model
- suppress or add the confidence limits for the binomial model
- specify the levels for which the linear predictor lines are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all *options* by function. The “[Dictionary of Options](#)” on page 3736 describes each option in detail.

LPRED Options

Table 60.19. Plot Layout Options for LPREDPLOT

LEVEL= <i>character-list</i>	specifies the names of the levels for which the linear predictor lines are requested (only for the multinomial model)
NOCONF	suppresses fiducial limits (only for the binomial model)
NODATA	suppresses observed data points on the plot (only for the binomial model)
NOTHRESH	suppresses the threshold line
THRESHLABPOS= <i>value</i>	specifies the position for the label of the threshold line

General Options

Table 60.20. Color Options

CAXIS= <i>color</i>	specifies color for axis
CFIT= <i>color</i>	specifies color for fitted curves
CFRAME= <i>color</i>	specifies color for frame
CGRID= <i>color</i>	specifies color for grid lines
CHREF= <i>color</i>	specifies color for HREF= lines
CTEXT= <i>color</i>	specifies color for text
CVREF= <i>color</i>	specifies color for VREF= lines

Table 60.21. Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	specifies an ANNOTATE data set
INBORDER	requests a border around plot
LFIT= <i>linetype</i>	specifies line style for fitted curves and confidence limits
LGRID= <i>linetype</i>	specifies line style for grid lines
NOFRAME	suppresses the frame around plotting areas
NOGRID	suppresses grid lines
NOFIT	suppresses fitted curves
NOHLABEL	suppresses horizontal labels
NOHTICK	suppresses horizontal ticks
NOVTICK	suppresses vertical ticks
TURNVLABELS	vertically strings out characters in vertical labels
WFIT= <i>n</i>	specifies thickness for fitted curves
WGRID= <i>n</i>	specifies thickness for grids
WREFL= <i>n</i>	specifies thickness for reference lines

Table 60.22. Axis Options

HAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for horizontal axis
HOFFSET= <i>value</i>	specifies offset for horizontal axis
HLOWER= <i>value</i>	specifies lower limit on horizontal axis scale
HUPPER= <i>value</i>	specifies upper limit on horizontal axis scale
NHTICK= <i>n</i>	specifies number of ticks for horizontal axis
NVTICK= <i>n</i>	specifies number of ticks for vertical axis
VAXIS= <i>value1 to value2</i> < <i>by value3</i> >	specifies tick mark values for vertical axis
VAXISLABEL= <i>'label'</i>	specifies label for vertical axis
VOFFSET= <i>value</i>	specifies offset for vertical axis
VLOWER= <i>value</i>	specifies lower limit on vertical axis scale
VUPPER= <i>value</i>	specifies upper limit on vertical axis scale
WAXIS= <i>n</i>	specifies thickness for axis

Table 60.23. Graphics Catalog Options

DESCRIPTION= <i>'string'</i>	specifies description for graphics catalog member
NAME= <i>'string'</i>	specifies name for plot in graphics catalog

Table 60.24. Options for Text Enhancement

FONT= <i>font</i>	specifies software font for text
HEIGHT= <i>value</i>	specifies height of text used outside framed areas
INFONT= <i>font</i>	specifies software font for text inside framed areas
INHEIGHT= <i>value</i>	specifies height of text inside framed areas

Table 60.25. Options for Reference Lines

HREF<(INTERSECT)> =value-list	requests horizontal reference line
HREFLABELS= (‘label1’, . . . , ‘labeln’)	specifies labels for HREF= lines
HREFLABPOS= <i>n</i>	specifies vertical position of labels for HREF= lines
LHREF= <i>linetype</i>	specifies line style for HREF= lines
LVREF= <i>linetype</i>	specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	requests vertical reference line
VREFLABELS= (‘label1’, . . . , ‘labeln’)	specifies labels for VREF= lines
VREFLABPOS= <i>n</i>	specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the LPREDPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the lpred plot. The ANNOTATE= data set you specify in the LPREDPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted lpred lines. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color***CV=***color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='*string*'**DES=**'*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the horizontal axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

```

haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10

```

HEIGHT=*value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies offset for horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =*value-list*

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=*'label1', . . . , 'labeln'*

HREFLABEL=*'label1', . . . , 'labeln'*

HREFLAB=*'label1', . . . , 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	top
2	staggered from top
3	bottom
4	staggered from bottom
5	alternating from top
6	alternating from bottom

INBORDER

requests a border around lpred plots.

LEVEL= (*character-list*)

ORDINAL= (*character-list*)

specifies the names of the levels for which linear predictor lines are requested. Names should be quoted and separated by space. If there is no correct name provided, no lpred line is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='*string*'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses confidence limits from the plot. This only works for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This only works for the binomial model. Data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted lpred lines.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the vertical axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL='*string*'

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS='*label1*',...,'*labeln*'**VREFLABEL=**'*label1*',...,'*labeln*'**VREFLAB=**'*label1*',...,'*labeln*'

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VUPPER=*number*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *number* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted lines. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

MODEL Statement

```
<label:>    MODEL response=effects < / options > ;
```

```
<label:>    MODEL events/trials=effects < / options > ;
```

The MODEL statement names the variables used as the response and the independent variables. Additionally, you can specify the distribution used to model the response, as well as other options. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last is used. Main effects and interaction terms can be specified in the MODEL statement, similar to the GLM procedure.

The optional *label* is used to label output from the matching MODEL statement.

The *response* can be a single variable with a value that is used to indicate the level of the observed response. Such a response variable must be listed in the CLASS statement. For example, the response might be a variable called **Symptoms** that takes on the values ‘None,’ ‘Mild,’ or ‘Severe.’ Note that, for dichotomous response variables, the probability of the lower sorted value is modeled by default (see the “**Details**” section beginning on page 3754). Because the model fit by the PROBIT procedure requires ordered response levels, you may need to use either the ORDER=DATA option in the PROC PROBIT statement or a numeric coding of the response to get the desired ordering of levels.

Alternatively, the response can be specified as a pair of variable names separated by a slash (/). The value of the first variable, *events*, is the number of positive responses (or events). The value of the second variable, *trials*, is the number of trials. Both variables must be numeric and non-negative, and the ratio of the first variable value to the second variable value must be between 0 and 1, inclusive. For example, the variables might be **hits**, a variable containing the number of hits for a baseball player, and **AtBats**, a variable containing the number of times at bat. A model for hitting proportion (batting average) as a function of age could be specified as

```
model hits/AtBats=age;
```

The *effects* following the equal sign are the covariates in the model. Higher-order effects, such as interactions and nested terms, are allowed in the list, similar to the GLM procedure. Variable names and combinations of variable names representing

higher-order terms are allowed to appear in this list. Class variables can be used as effects, and indicator variables are generated for the class levels. If you do not specify any covariates following the equal sign, an intercept-only model is fit.

The following options are available in the MODEL statement.

AGGREGATE

AGGREGATE= *(variable-list)*

specifies the subpopulations on which the Pearson chi-square test statistic and the log-likelihood ratio chi-square test statistic (deviance) are calculated if the LACKFIT option is specified. See the section “[Rescaling the Covariance Matrix](#)” on page 3760 for details of Pearson’s chi-square and deviance calculations.

Observations with common values in the given list of variables are regarded as coming from the same subpopulation. Variables in the list can be any variables in the input data set. Specifying the AGGREGATE option is equivalent to specifying the AGGREGATE= option with a variable list that includes all independent variables in the MODEL statement. The PROBIT procedure sorts the input data set according to the variables specified in this list. Information for the sorted data set is reported in the “Response-Covariate Profile” table.

The deviance and Pearson goodness-of-fit statistics are calculated if the LACKFIT option is specified in the MODEL statement. The calculated results are reported in the “Goodness-of-Fit” table. If the Pearson chi-square test is significant with the test level specified by the HPROB= option, the fiducial limits, if required with the INVERSECL option in the MODEL statement, are modified (see the section “[Inverse Confidence Limits](#)” on page 3761 for details). Also, the covariance matrix is re-scaled by the dispersion parameter when the SCALE= option is specified.

ALPHA=*value*

sets the significance level for the confidence intervals for regression parameters, fiducial limits for the predicted values, and confidence intervals for the predicted probabilities. The value must be between 0 and 1. The default value is ALPHA=0.05.

CONVERGE=*value*

specifies the convergence criterion. Convergence is declared when the maximum change in the parameter estimates between Newton-Raphson steps is less than the value specified. The change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change.

By default, CONVERGE=1.0E-8.

CORRB

displays the estimated correlation matrix of the parameter estimates.

COVB

displays the estimated covariance matrix of the parameter estimates.

DISTRIBUTION=*distribution-type*

DIST=*distribution-type*

D=*distribution-type*

specifies the cumulative distribution function used to model the response probabili-

ties. The distributions are described in the “[Details](#)” section beginning on page 3754. Valid values for *distribution-type* are

NORMAL the normal distribution for the probit model

LOGISTIC the logistic distribution for the logit model

EXTREMEVALUE | EXTREME | GOMPERTZ the extreme value, or Gompertz distribution for the gompit model

By default, DISTRIBUTION=NORMAL.

HPROB=*p*

specifies a minimum probability level for the Pearson chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the *t* distribution with degrees of freedom equal to $(k - 1) \times m - q$, where *k* is the number of levels for the response variable, *m* is the number of different sets of independent variable values, and *q* is the number of parameters fit in the model. If you specify the HPROB= option in both the PROC PROBIT and MODEL statements, the MODEL statement option takes precedence.

INITIAL=*values*

sets initial values for the parameters in the model other than the intercept. The values must be given in the order in which the variables are listed in the MODEL statement. If some of the independent variables listed in the MODEL statement are classification variables, then there must be as many values given for that variable as there are classification levels minus 1. The INITIAL option can be specified as follows.

Type of List	Specification
list separated by blanks	initial=3 4 5
list separated by commas	initial=3,4,5

By default, all parameters have initial estimates of zero.

Note: The INITIAL= option is overwritten by the INEST= option in the PROC PROBIT statement.

INTERCEPT=*value*

initializes the intercept parameter to *value*. By default, INTERCEPT=0.

INVERSECL

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. If the algorithm fails to converge (this can happen when *C* is nonzero), missing values are reported for the confidence limits. See the section “[Inverse Confidence Limits](#)” on page 3761 for details.

ITPRINT

displays the iteration history, the final evaluation of the gradient, and the second derivative matrix (Hessian).

LACKFIT

performs two goodness-of-fit tests (a Pearson chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option to this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

Note: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section “[Lack of Fit Tests](#)” on page 3759 for a description of the tests. Note that the LACKFIT option can also appear in the PROC PROBIT statement. See the section “[PROC PROBIT Statement](#)” on page 3711 for details.

MAXITER=*value***MAXIT=***value*

specifies the maximum number of iterations to be performed in estimating the parameters. By default, MAXITER=50.

NOINT

fits a model with no intercept parameter. If the INTERCEPT= option is also specified, the intercept is fixed at the specified value; otherwise, it is set to zero. This is most useful when the response is binary. When the response has k levels, then $k - 1$ intercept parameters are fit. The NOINT option sets the intercept parameter corresponding to the lowest response level equal to zero. A Lagrange multiplier, or score, test for the restricted model is computed when the NOINT option is specified.

SCALE= *scale*

enables you to specify the method for estimating the dispersion parameter. To correct for overdispersion or underdispersion, the covariance matrix is multiplied by the estimate of the dispersion parameter. Valid values for *scale* are as follows:

D DEVIANCE	specifies that the dispersion parameter be estimated by the deviance divided by its degrees of freedom.
P PEARSON	specifies that the dispersion parameter be estimated by the Pearson chi-square statistic divided by its degrees of freedom. This is set as the default.

You can use the AGGREGATE= option to define the subpopulations for calculating the Pearson chi-square statistic and the deviance.

The “Goodness-of-Fit ” table includes the Pearson chi-square statistic, the deviance, their degrees of freedom, the ratio of each statistic divided by its degrees of freedom, and the corresponding p -value.

SINGULAR=value

specifies the singularity criterion for determining linear dependencies in the set of independent variables. The sum of squares and cross-products matrix of the independent variables is formed and swept. If the relative size of a pivot becomes less than the value specified, then the variable corresponding to the pivot is considered to be linearly dependent on the previous set of variables considered. By default, SINGULAR=1E-12.

OUTPUT Statement

OUTPUT <OUT=SAS-data-set> <keyword=name...keyword=name>;

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the fitted probabilities, the estimate of $\mathbf{x}'\beta$, and the estimate of its standard error. Estimates of the probabilities, $\mathbf{x}'\beta$, and the standard errors are computed for observations with missing response values as long as the values of all the explanatory variables are nonmissing. This enables you to compute these statistics for additional settings of the explanatory variables that are of interest but for which responses are not observed.

You can specify multiple OUTPUT statements. Each OUTPUT statement creates a new data set and applies only to the preceding MODEL statement. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for more information on permanent SAS data sets).

Details on the specifications in the OUTPUT statement are as follows:

keyword=name specifies the statistics to include in the output data set and assigns names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

PROB | P cumulative probability estimates

$$p = C + (1 - C)F(a_j + \mathbf{x}'\beta)$$

STD standard error estimates of $a_j + \mathbf{x}'\mathbf{b}$

XBETA estimates of $a_j + \mathbf{x}'\beta$

OUT=SAS-data-set names the output data set. By default, the new data set is named using the DATA n convention.

When the *single variable response* syntax is used, the `_LEVEL_` variable is added to the output data set, and there are $k - 1$ output observations for each input observation, where k is the number of response levels. There is no observation output corresponding to the highest response level. For each of the $k - 1$ observations, the `PROB` variable contains the fitted probability of obtaining a response level up to the level indicated by the `_LEVEL_` variable, the `XBETA` variable contains $a_j + \mathbf{x}'\mathbf{b}$, where j references the levels ($a_1 = 0$), and the `STD` variable contains the standard error estimate of the `XBETA` variable. See the “Details” section, which follows, for the formulas for the parameterizations.

PREDPLOT Statement

PREDPLOT *<var = variable>* *<options>*;

The `PREDPLOT` statement plots the predicted probability against a single continuous variable (dose variable) in the `MODEL` statement for both the binomial model and the multinomial model. Confidence limits are only available for the binomial model. An attached box on the right side of the plot is used to label predicted probability curves with the names of their levels for the multinomial model. You can specify the color of this box using the `CLABBOX=` option.

VAR= *(variable)*

specifies a single continuous variable (dose variable) in the independent variable list of the `MODEL` statement. If a `VAR=` variable is not specified, the first single continuous variable in the independent variable list of the `MODEL` statement is used. If such a variable does not exist in the independent variable list of the `MODEL` statement, an error is reported.

The predicted probability is

$$\hat{p} = C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}})$$

for the binomial model and

$$\begin{aligned}\hat{p}_1 &= C + (1 - C)F(\mathbf{x}'\hat{\mathbf{b}}) \\ \hat{p}_j &= (1 - C)(F(\hat{a}_j + \mathbf{x}'\hat{\mathbf{b}}) - F(\hat{a}_{j-1} + \mathbf{x}'\hat{\mathbf{b}})) \quad j = 2, \dots, k - 1 \\ \hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + \mathbf{x}'\hat{\mathbf{b}}))\end{aligned}$$

for the multinomial model with k response levels, where F is the cumulative distribution function used to model the probability, \mathbf{x}' is the vector of the covariates, \hat{a}_j are the estimated ordinal intercepts with $\hat{a}_1 = 0$, C is the threshold parameter, either known or estimated from the model, and $\hat{\mathbf{b}}'$ is the vector of estimated parameters.

To plot \hat{p} (or \hat{p}_j) as a function of a continuous variable x_1 , the remaining covariates \mathbf{x}_{-1} must be specified. You can use the `XDATA=` option to provide the values of \mathbf{x}_{-1} (see the `XDATA=` option in the `PROC PROBIT` statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

enable you to plot the observed data and add features to the plot.

You can use options in the PREDPLOT statement to

- superimpose specification limits
- suppress or add observed data points for the binomial model
- suppress or add confidence limits for the binomial model
- specify the levels for which predicted probability curves are requested for the multinomial model
- specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all *options* by function. The “[Dictionary of Options](#)” on page 3749 describes each option in detail.

PREDPLOT Options

Table 60.26. Plot Layout Options for PREDPLOT

LEVEL= <i>character-list</i>	specifies the names of the levels for which the predicted probability curves are requested (only for the multinomial model)
NOCONF	suppresses confidence limits
NODATA	suppresses observed data points on the plot
NOTHRESH	suppresses the threshold line
THRESLABPOS= <i>value</i>	specifies the position for the label of the threshold line

General Options

Table 60.27. Color Options

CAXIS= <i>color</i>	specifies color for the axes
CFIT= <i>color</i>	specifies color for fitted curves
CFRAME= <i>color</i>	specifies color for frame
CGRID= <i>color</i>	specifies color for grid lines
CHREF= <i>color</i>	specifies color for HREF= lines
CLABBOX= <i>color</i>	specifies color for label box
CTEXT= <i>color</i>	specifies color for text
CVREF= <i>color</i>	specifies color for VREF= lines

Table 60.28. Options to Enhance Plots Produced on Graphics Devices

ANNOTATE= <i>SAS-data-set</i>	specifies an ANNOTATE data set
INBORDER	requests a border around plot
LFIT= <i>linetype</i>	specifies line style for fitted curves and confidence limits
LGRID= <i>linetype</i>	specifies line style for grid lines
NOFRAME	suppresses the frame around plotting areas
NOGRID	suppresses grid lines
NOFIT	suppresses fitted curves
NOHLABEL	suppresses horizontal labels
NOHTICK	suppresses horizontal ticks
NOVTICK	suppresses vertical ticks
TURNVLABELS	vertically strings out characters in vertical labels
WFIT= <i>n</i>	specifies thickness for fitted curves
WGRID= <i>n</i>	specifies thickness for grids
WREFL= <i>n</i>	specifies thickness for reference lines

HREF<(INTERSECT)> =value-list	requests horizontal reference line
HREFLABELS= (‘label1’, . . . , ‘labeln’)	specifies labels for HREF= lines
HREFLABPOS= <i>n</i>	specifies vertical position of labels for HREF= lines
LHREF= <i>linetype</i>	specifies line style for HREF= lines
LVREF= <i>linetype</i>	specifies line style for VREF= lines
VREF<(INTERSECT)> =value-list	requests vertical reference line
VREFLABELS= (‘label1’, . . . , ‘labeln’)	specifies labels for VREF= lines
VREFLABPOS= <i>n</i>	specifies horizontal position of labels for VREF= lines

Dictionary of Options

The following entries provide detailed descriptions of the *options* in the PREDPLOT statement.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the predicted probability plot. The ANNOTATE= data set you specify in the PREDPLOT statement is used for all plots created by the statement.

CAXIS=*color*

CAXES=*color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=*color*

specifies the color for the fitted predicted probability curves. The default is the first color in the device color list.

CFRAME=*color*

CFR=*color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=*color*

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=*color*

CH=*color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=*color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=*color***CV=***color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='*string*'**DES=**'*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=*font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the horizontal axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. If *value3* is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

```
haxis = 0 to 10
haxis = 2 to 10 by 2
haxis = 0 to 200 by 10
```

HEIGHT=*value*

specifies the height of text used outside framed areas.

HLOWER=*value*

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies *value* as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=*value*

specifies the offset for the horizontal axis. The default value is 1.

HUPPER=*value*

specifies *value* as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =value-list

requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS='label1',...,'labeln'

HREFLABEL='label1',...,'labeln'

HREFLAB='label1',...,'labeln'

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=*n*

specifies the vertical position of labels for HREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	top
2	staggered from top
3	bottom
4	staggered from bottom
5	alternating from top
6	alternating from bottom

INBORDER

requests a border around predicted probability plots.

LEVEL= (character-list)

ORDINAL= (character-list)

specifies the names of the levels for which predicted probability curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no fitted probability curve is plotted.

LFIT=*linetype*

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1) and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

LGRID=*linetype*

specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

LHREF=*linetype*

LH=*linetype*

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=*linetype*

LV=*linetype*

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME='string'

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses confidence limits from the plot. This only works for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This only works for the binomial model. The data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted predicted probability curves.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=*n*

specifies the horizontal position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VAXIS=*value1 to value2*<*by value3*>

specifies tick mark values for the vertical axis. *value1*, *value2*, and *value3* must be numeric, and *value1* must be less than *value2*. The lower tick mark is *value1*. Tick marks are drawn at increments of *value3*. The last tick mark is the greatest value that does not exceed *value2*. This method of specification of tick marks is not valid for logarithmic axes. If *value3* is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

```
vaxis = 0 to 10
vaxis = 0 to 2 by .1
```

VAXISLABEL='*string*'

specifies a label for the vertical axis.

VLOWER=*value*

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies *value* as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=*value-list*

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS='*label1*',...,'*labeln*'

VREFLABEL='*label1*',...,'*labeln*'

VREFLAB='*label1*',...,'*labeln*'

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=*n*

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for *n* and the corresponding label placements.

<i>n</i>	label placement
1	left
2	right

VUPPER=*value*

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies *value* as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

WAXIS=*n*

specifies line thickness for axes and frame. The default value is 1.

WFIT=*n*

specifies line thickness for fitted curves. The default value is 1.

WGRID=*n*

specifies line thickness for grids. The default value is 1.

WREFL=*n*

specifies line thickness for reference lines. The default value is 1.

WEIGHT Statement

WEIGHT *variable* ;

A WEIGHT statement can be used with PROC PROBIT to weight each observation by the value of the variable specified. The contribution of each observation to the likelihood function is multiplied by the value of the weight variable. Observations with zero, negative, or missing weights are not used in model estimation.

Details

Missing Values

PROC PROBIT does not use any observations having missing values for any of the independent variables, the response variables, or the weight variable. If only the response variables are missing, statistics requested in the OUTPUT statement are computed.

Response Level Ordering

For binary response data, PROC PROBIT fits the following model by default,

$$\Phi^{-1} \left(\frac{p - C}{1 - C} \right) = \mathbf{x}'\boldsymbol{\beta}$$

where p is the probability of the response level identified as the first level in the “Weighted Frequency Counts for the Ordered Response Categories” table in the output and Φ is the normal cumulative distribution function. By default, the covariate vector \mathbf{x} contains an intercept term. This is sometimes called Abbot’s formula.

Because of the symmetry of the normal (and logistic) distribution, the effect of reversing the order of the two response values is to change the signs of $\boldsymbol{\beta}$ in the preceding equation.

By default, response levels appear in ascending, sorted order (that is, the lowest level appears first and then the next lowest, and so on). There are a number of ways that you can control the sort order of the response categories and, therefore, which level is assigned the first ordered level. One of the most common sets of response levels is $\{0,1\}$, with 1 representing the event with the probability that is to be modeled.

Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and EXPOSURE is the explanatory variable. By default, PROC PROBIT assigns the first ordered level to response level 0, causing the probability of the nonevent to be modeled. There are several ways to change this.

Besides recoding the variable Y, you can

- assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, Y=0 could be assigned formatted value 'nonevent' and Y=1 could be assigned formatted value 'event.' Since ORDER=FORMATTED by default, Y=1 becomes the first ordered level. See [Example 60.3](#) for an illustration of this method.

```
proc format;
  value disease 1='event' 0='nonevent';
run;
proc probit;
  model y=exposure;
  format y disease.;
run;
```

- arrange the input data set so that Y=1 appears first and use the ORDER=DATA option in the PROC PROBIT statement. Since ORDER=DATA sorts levels in order of their appearance in the data set, Y=1 becomes the first ordered level. Note that this option causes class variables to be sorted by their order of appearance in the data set, also.

Computational Method

The log-likelihood function is maximized by means of a ridge-stabilized Newton-Raphson algorithm. Initial regression parameter estimates are set to zero. The INITIAL= and INTERCEPT= options in the MODEL statement can be used to give nonzero initial estimates.

The log-likelihood function, L , is computed as

$$L = \sum_i w_i \ln(p_i)$$

where the sum is over the observations in the data set, w_i is the weight for the i th observation, and p_i is the modeled probability of the observed response. In the case of the events/trials syntax in the MODEL statement, each observation contributes two terms corresponding to the probability of the event and the probability of its complement:

$$L = \sum_i w_i [r_i \ln(p_i) + (n_i - r_i) \ln(1 - p_i)]$$

where r_i is the number of events and n_i is the number of trials for observation i . This log-likelihood function differs from the log-likelihood function for a binomial

or multinomial distribution by additive terms consisting of the log of binomial or multinomial coefficients. These terms are parameter-independent and do not affect the model estimation or the standard errors and tests.

The estimated covariance matrix, V , of the parameter estimates is computed as the negative inverse of the information matrix of second derivatives of L with respect to the parameters evaluated at the final parameter estimates. Thus, the estimated covariance matrix is derived from the observed information matrix rather than the expected information matrix (these are generally not the same). The standard error estimates for the parameter estimates are taken as the square roots of the corresponding diagonal elements of V .

If convergence of the maximum likelihood estimates is attained, a Type III chi-square test statistic is computed for each effect, testing whether there is any contribution from any of the levels of the effect. This statistic is computed as a quadratic form in the appropriate parameter estimates using the corresponding submatrix of the asymptotic covariance matrix estimate. Refer to Chapter 32, “The GLM Procedure,” and Chapter 11, “The Four Types of Estimable Functions,” for more information about Type III estimable functions.

The asymptotic covariance matrix is computed as the inverse of the observed information matrix. Note that if the NOINT option is specified and class variables are used, the first class variable contains a contribution from an intercept term. The results are displayed in an ODS table named **Type3Analysis**.

Chi-square tests for individual parameters are Wald tests based on the observed information matrix and the parameter estimates. If an effect has a single degree of freedom in the parameter estimates table, the chi-square test for this parameter is equivalent to the Type III test for this effect.

In releases previous to Version 8.2, a multiple degree of freedom statistic was computed for each effect to test for contribution from any level of the effect. In general, the Type III test statistic in a main effect only model (no interaction terms) will be equal to the previously computed effect statistic, unless there are collinearities among the effects. If there are collinearities, the Type III statistic will adjust for them, and the value of the Type III statistic and the number of degrees of freedom might not be equal to those of the previous effect statistic.

The theory behind these tests assumes large samples. If the samples are not large, it may be better to base the tests on log-likelihood ratios. These changes in log likelihood can be obtained by fitting the model twice, once with all the parameters of interest and once leaving out the parameters to be tested. Refer to Cox and Oakes (1984) for a discussion of the merits of some possible test methods.

If some of the independent variables are perfectly correlated with the response pattern, then the theoretical parameter estimates may be infinite. Although fitted probabilities of 0 and 1 are not especially pathological, infinite parameter estimates are required to yield these probabilities. Due to the finite precision of computer arithmetic, the actual parameter estimates are not infinite. Indeed, since the tails of the distributions allowed in the PROBIT procedure become small rapidly, an argument to the cumulative distribution function of around 20 becomes effectively infinite. In the

case of such parameter estimates, the standard error estimates and the corresponding chi-square tests are not trustworthy.

Distributions

The distributions, $F(x)$, allowed in the PROBIT procedure are specified with the DISTRIBUTION= option in the model statement. The cumulative distribution functions for the available distributions are

$$\int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right) dz \text{ (normal)}$$

$$\frac{1}{1 + e^{-x}} \text{ (logistic)}$$

$$1 - e^{-e^x} \text{ (extreme value or Gompertz)}$$

The variances of these three distributions are not all equal to 1, and their means are not all equal to zero. Their means and variances are shown in the following table, where γ is the Euler constant.

Distribution	Mean	Variance
Normal	0	1
Logistic	0	$\pi^2/3$
extreme value or Gompertz	$-\gamma$	$\pi^2/6$

When comparing parameter estimates using different distributions, you need to take into account the different scalings and, for the extreme value (or Gompertz) distribution, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from the logistic model should be about $\pi/\sqrt{3}$ larger than the estimates from the probit model.

INEST= SAS-data-set

The INEST= data set names a SAS data set that specifies initial estimates for all the parameters in the model.

The INEST= data set must contain the intercept variables (named Intercept for binary response model and Intercept, Intercept2, Intercept3, and so forth, for multinomial response models) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value 'PARMS' are used as starting values. Combining the INEST= data

set and the option MAXIT= in the MODEL statement, partial scoring can be done, such as predicting on a validation data set by using the model built from a training data set.

You can specify starting values for the iterative algorithm in the INEST= data set. This data set overwrites the INITIAL= option in the MODEL statement, which is a little difficult to use for models with multilevel interaction effects. The INEST= data set has the same structure as the “OUTEST= SAS-data-set” on page 3762, but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

Model Specification

For a two-level response, the probability that the lesser response occurs is modeled by the probit equation as

$$p = C + (1 - C)F(\mathbf{x}'\mathbf{b})$$

The probability of the other (complementary) event is $1 - p$.

For a multilevel response with outcomes labeled l_i for $i = 1, 2, \dots, k$, the probability, p_j , of observing level l_j is as follows.

$$\begin{aligned} p_1 &= C + (1 - C)F(\mathbf{x}'\mathbf{b}) \\ p_2 &= (1 - C) (F(a_2 + \mathbf{x}'\mathbf{b}) - F(\mathbf{x}'\mathbf{b})) \\ &\vdots \\ p_j &= (1 - C) (F(a_j + \mathbf{x}'\mathbf{b}) - F(a_{j-1} + \mathbf{x}'\mathbf{b})) \\ &\vdots \\ p_k &= (1 - C)(1 - F(a_{k-1} + \mathbf{x}'\mathbf{b})) \end{aligned}$$

Thus, for a k -level response, there are $k - 2$ additional parameters, a_2, a_3, \dots, a_{k-1} , estimated. These parameters are denoted by Intercept j , $j = 2, 3, \dots, k - 1$ in the output.

An intercept parameter is always added to the set of independent variables as the first term in the model unless the NOINT option is specified in the MODEL statement. If a classification variable taking on k levels is used as one of the independent variables, a set of k indicator variables is generated to model the effect of this variable. Because of the presence of the intercept term, there are at most $k - 1$ degrees of freedom for this effect in the model.

Lack of Fit Tests

Two goodness-of-fit tests can be requested from the PROBIT procedure: a Pearson chi-square test and a log-likelihood ratio chi-square test.

To compute the test statistics, you can use the AGGREGATE or AGGREGATE= option grouping the observations into subpopulations. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes that each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the *events/trials* syntax.

If the Pearson goodness-of-fit chi-square test is requested and the p -value for the test is too small, variances and covariances are adjusted by a heterogeneity factor (the goodness-of-fit chi-square divided by its degrees of freedom) and a critical value from the t distribution is used to compute the fiducial limits. The Pearson chi-square test statistic is computed as

$$\chi_P^2 = \sum_{i=1}^m \sum_{j=1}^k \frac{(r_{ij} - n_i \hat{p}_{ij})^2}{n_i \hat{p}_{ij}}$$

where the sum on i is over grouping, the sum on j is over levels of response, the r_{ij} is the frequency of response level j for the i th grouping, n_i is the total frequency for the i th grouping, and \hat{p}_{ij} is the fitted probability for the j th level at the i th grouping.

The likelihood ratio chi-square test statistic is computed as

$$\chi_D^2 = 2 \sum_{i=1}^m \sum_{j=1}^k r_{ij} \ln \left(\frac{r_{ij}}{n_i \hat{p}_{ij}} \right)$$

This quantity is sometimes called the deviance. If the modeled probabilities fit the data, these statistics should be approximately distributed as chi-square with degrees of freedom equal to $(k-1) \times m - q$, where k is the number of levels of the multinomial or binomial response, m is the number of sets of independent variable values (covariate patterns), and q is the number of parameters fit in the model.

In order for the Pearson statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the groupings. When this is not true, the data are sparse, and the p -values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

Rescaling the Covariance Matrix

One way of correcting overdispersion is to multiply the covariance matrix by a dispersion parameter. You can supply the value of the dispersion parameter directly, or you can estimate the dispersion parameter based on either the Pearson chi-square statistic or the deviance for the fitted model.

The Pearson chi-square statistic χ_P^2 and the deviance χ_D^2 are defined in the section “Lack of Fit Tests” on page 3759. If the SCALE= option is specified in the MODEL statement, the dispersion parameter is estimated by

$$\hat{\sigma}^2 = \begin{cases} \chi_P^2 / (m(k-1) - q) & \text{SCALE=PEARSON} \\ \chi_D^2 / (m(k-1) - q) & \text{SCALE=DEVIANC} \\ (\text{constant})^2 & \text{SCALE=constant} \end{cases}$$

In order for the Pearson statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the subpopulations. When this is not true, the data are sparse, and the p -values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

You can use the AGGREGATE (or AGGREGATE=) option to define the subpopulation profiles. If you do not specify this option, each observation is regarded as coming from a separate subpopulation. For *events/trials* syntax, each observation represents n Bernoulli trials, where n is the value of the *trials* variable; for *single-trial* syntax, each observation represents a single trial. Without the AGGREGATE (or AGGREGATE=) option, the Pearson chi-square statistic and the deviance are calculated only for *events/trials* syntax.

Note that the parameter estimates are not changed by this method. However, their standard errors are adjusted for overdispersion, affecting their significance tests.

Tolerance Distribution

For a single independent variable, such as a dosage level, the models for the probabilities can be justified on the basis of a population with mean μ and scale parameter σ of tolerances for the subjects. Then, given a dose x , the probability, P , of observing a response in a particular subject is the probability that the subject's tolerance is less than the dose or

$$P = F\left(\frac{x - \mu}{\sigma}\right)$$

Thus, in this case, the intercept parameter, \mathbf{b}_0 , and the regression parameter, \mathbf{b}_1 , are related to μ and σ by

$$\mathbf{b}_1 = \frac{1}{\sigma}$$

$$\mathbf{b}_0 = -\frac{\mu}{\sigma}$$

Note: The parameter σ is not equal to the standard deviation of the population of tolerances for the logistic and extreme value distributions.

Inverse Confidence Limits

In bioassay problems, estimates of the values of the independent variables that yield a desired response are often needed. For instance, the value yielding a 50% response rate (called the ED50 or LD50) is often used. The INVERSECL option requests that confidence limits be computed for the value of the independent variable that yields a specified response. These limits are computed only for the first continuous variable effect in the model. The other variables are set either at their mean values if they are continuous or at the reference (last) level if they are discrete variables. For a discussion of inverse confidence limits, refer to Hubert, Bohidar, and Peace (1988).

For the PROBIT procedure, the response variable is a probability. An estimate of the first continuous variable value needed to achieve a response of p is given by

$$\hat{x}_1 = \frac{1}{b_1} (F^{-1}(p) - \mathbf{x}^* \mathbf{b}^*)$$

where F is the cumulative distribution function used to model the probability, \mathbf{x}^* is the vector of independent variables excluding the first one, which can be specified by the XDATA= option described in the section “XDATA= SAS-data-set” on page 3763, \mathbf{b}^* is the vector of parameter estimates excluding the first one, and b_1 is the estimated regression coefficient for the independent variable of interest. Note that, for both binary and ordinal models, the INVERSECL option provides estimates of the value of x_1 yielding $\Pr(\text{first response level}) = p$, for various values of p .

This estimator is given as a ratio of random variables, for example, $r = a/b$. Confidence limits for this ratio can be computed using Fieller’s theorem. A brief description of this theorem follows. Refer to Finney (1971) for a more complete description of Fieller’s theorem.

If the random variables a and b are thought to be distributed as jointly normal, then for any fixed value r the following probability statement holds if z is an $\alpha/2$ quantile from the standard normal distribution and \mathbf{V} is the variance-covariance matrix of a and b .

$$\Pr((a - rb)^2 > z^2(V_{aa} - 2rV_{ab} + r^2V_{bb})) = \alpha$$

Usually the inequality can be solved for r to yield a confidence interval. The PROBIT procedure uses a value of 1.96 for z , corresponding to an α value of 0.05, unless the goodness-of-fit p -value is less than the specified value of the HPROB= option. When this happens, the covariance matrix is scaled by the heterogeneity factor, and a t distribution quantile is used for z .

It is possible for the roots of the equation for r to be imaginary or for the confidence interval to be all points outside of an interval. In these cases, the limits are set to missing by the PROBIT procedure.

Although the normal and logistic distribution give comparable fitted values of p if the empirically observed proportions are not too extreme, they can give appreciably different values when extrapolated into the tails. Correspondingly, the estimates of the confidence limits and dose values can be different for the two distributions even when they agree quite well in the body of the data. Extrapolation outside of the range of the actual data are often sensitive to model assumptions, and caution is advised if extrapolation is necessary.

OUTEST= *SAS-data-set*

The OUTEST= data set contains parameter estimates and the log likelihood for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different modeling using the PROBIT procedure. If you specify the COVOUT option, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates.

The OUTEST= data set contains each variable used as a dependent or independent variable in any MODEL statement. One observation consists of parameter values for the model with the dependent variable having the value -1 . If you specify the COVOUT option, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

MODEL	a character variable containing the label of the MODEL statement, if present, or blank otherwise
NAME	a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
TYPE	a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
DIST	a character variable containing the name of the distribution modeled
LNLIKE	a numeric variable containing the last computed value of the log likelihood
C	a numeric variable containing the estimated threshold parameter
INTERCEPT	a numeric variable containing the intercept parameter estimates and covariances

Any BY variables specified are also added to the OUTEST= data set.

XDATA= SAS-data-set

The XDATA= data set is used for specifying values for the effects in the MODEL statement when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. It is also used for plots specified by the CDFPLOT, IPPLOT, LPREDPLOT, and PREDPLOT statement.

The XDATA= data names a SAS data set that contains user input values for all the independent variables in the MODEL statement and the variables in the CLASS statement. The XDATA= data set has the same structure as the DATA= data set but is not required to have all the variables or observations that appear in the DATA= data set.

The XDATA= data set must contain all the independent variables in the MODEL statement and variables in the CLASS statement. Even though variables in the CLASS statement may not be used in the MODEL statement, valid values are required for these variables in the XDATA= data set. Missing values are not allowed. For independent variables in the MODEL statement, although the dose variable's value is not used in the computing of predicted values and/or fiducial limits for the dose variable, missing values are not allowed in the XDATA= data set for any of the independent variables. Missing values are allowed for the dependent variables and other variables if they are included in the XDATA= data set and not listed in the CLASS statement.

If BY processing is used, the XDATA= data set should also include the BY variables, and there must be at least one valid observation for each BY group. If there is more than one valid observation in one BY group, the last one read is used for that BY group.

If there is no XDATA= data set in the PROC PROBIT statement, by default, the PROBIT procedure will use overall mean for effects containing continuous variable (or variables) and the highest level of a single classification variable as reference level. The rules are summarized as follows:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

Displayed Output

If you request the iteration history (ITPRINT), PROC PROBIT displays

- the current value of the log likelihood
- the ridging parameter for the modified Newton-Raphson optimization process
- the current estimate of the parameters
- the current estimate of the parameter C for a natural (threshold) model
- the values of the gradient and the Hessian on the last iteration

If you include CLASS variables, PROC PROBIT displays

- the numbers of levels for each CLASS variable
- the (ordered) values of the levels
- the number of observations used

After the model is fit, PROC PROBIT displays

- the name of the input data set
- the name of the dependent variables
- the number of observations used
- the number of events and the number of trials
- the final value of the log-likelihood function
- the parameter estimates
- the standard error estimates of the parameter estimates
- approximate chi-square test statistics for the test

If you specify the COVB or CORRB options, PROC PROBIT displays

- the estimated covariance matrix for the parameter estimates
- the estimated correlation matrix for the parameter estimates

If you specify the LACKFIT option, PROC PROBIT displays

- a count of the number of levels of the response and the number of distinct sets of independent variables
- a goodness-of-fit test based on the Pearson chi-square
- a goodness-of-fit test based on the likelihood-ratio chi-square

If you specify only one independent variable, the normal distribution is used to model the probabilities, and the response is binary, PROC PROBIT displays

- the mean MU of the stimulus tolerance
- the scale parameter SIGMA of the stimulus tolerance
- the covariance matrix for MU, SIGMA, and the natural response parameter C

If you specify the INVERSECL options, PROC PROBIT also displays

- the estimated dose along with the 95% fiducial limits for probability levels 0.01 to 0.10, 0.15 to 0.85 by 0.05, and 0.90 to 0.99

ODS Table Names

PROC PROBIT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 60.33. ODS Tables Produced in PROC PROBIT

ODS Table Name	Description	Statement	Option
ClassLevels	Class variable levels	CLASS	default
ConvergenceStatus	Convergence status	MODEL	default
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB
CovTolerance	Covariance matrix for location and scale	MODEL	default*
GoodnessOfFit	Goodness of fit tests	MODEL	LACKFIT
IterHistory	Iteration history	MODEL	ITPRINT
LagrangeStatistics	Lagrange statistics	MODEL	NOINT
LastGrad	Last evaluation of the gradient	MODEL	ITPRINT
LastHess	Last evaluation of the Hessian	MODEL	ITPRINT
LogProbitAnalysis	Probit analysis for log dose	MODEL	INVERSECL
ModelInfo	Model information	MODEL	default
MuSigma	Location and scale	MODEL	default*
NObs	Observations Summary	PROC	default
ParameterEstimates	Parameter estimates	MODEL	default
ParmInfo	Parameter indices	MODEL	default
ProbitAnalysis	Probit analysis for linear dose	MODEL	INVERSECL
ResponseLevels	Response-covariate profile	MODEL	LACKFIT
ResponseProfiles	Counts for ordinal data	MODEL	default
Type3Analysis	Type 3 tests	MODEL	default*

* Depends on data.

Examples

Example 60.1. Dosage Levels

In this example, `Dose` is a variable representing the level of a stimulus, `N` represents the number of subjects tested at each level of the stimulus, and `Response` is the number of subjects responding to that level of the stimulus. Both probit and logit response models are fit to the data. The `LOG10` option in the `PROC PROBIT` statement requests that the log base 10 of `Dose` is used as the independent variable. Specifically, for a given level of `Dose`, the probability p of a positive response is modeled as

$$p = \Pr(\text{Response}) = F(b_0 + b_1 \times \log_{10}(\text{Dose}))$$

The probabilities are estimated first using the normal distribution function (the default) and then using the logistic distribution function. Note that, in this model specification, the natural rate is assumed to be zero.

The `LACKFIT` option specifies lack-of-fit tests and the `INVERSECL` option specifies inverse confidence limits.

In the `DATA` step that reads the data, a number of observations are generated that have a missing value for the response. Although the `PROBIT` procedure does not use the observations with the missing values to fit the model, it does give predicted values for all nonmissing sets of independent variables. These data points fill in the plot of fitted and observed values in the logistic model displayed in [Output 60.1.2](#). The plot, requested with the `PREDPLOT` statement, displays the estimated logistic cumulative distribution function and the observed response rates. The `VAR= DOSE` option specifies the horizontal axis variable in the plot.

The following statements produce [Output 60.1.1](#):

```

Both the ED50 and the LD50 are similar to those for the normal model.

The statement PREDPLOT creates the plot of observed and fitted probabilities in [Output 60.1.2](#). The dashed line represent pointwise confidence bands for the probabilities.

Output 60.1.2. Plot of Observed and Fitted Probabilities

Example 60.2. Multilevel Response

In this example, two preparations, a standard preparation and a test preparation, are each given at several dose levels to groups of insects. The symptoms are recorded for each insect within each group, and two multilevel probit models are fit. Because the natural sort order of the three levels is not the same as the response order, the ORDER=DATA option is specified in the PROC PROBIT statement to get the desired order.

The following statements produce [Output 60.2.1](#):

```

data multi;
  input Prep $ Dose Symptoms $ N;
  LDose=log10(Dose);
  if Prep='test' then PrepDose=LDose;
  else PrepDose=0;
  datalines;
stand    10    None    33
stand    10    Mild    7

run;

```

The first model allows for nonparallelism between the dose response curves for the two preparations by inclusion of an interaction between Prep and LDose. The interaction term is labeled PrepDose in the “Analysis of Parameter Estimates” table. The results of this first model indicate that the parameter for the interaction term is not significant, having a Wald chi-square of 0.73. Also, since the first model is a generalization of the second, a likelihood ratio test statistic for this same parameter can be obtained by multiplying the difference in log likelihoods between the two models by 2. The value obtained, $2 \times (-345.94 - (-346.31))$, is 0.73. This is in close agreement with the Wald chi-square from the first model. The lack-of-fit test statistics for the two models do not indicate a problem with either fit.

Prep test	0	0.0000	0.0000	0.0000	0.0000	.	.
LDose	1	-2.3721	0.2949	-2.9502	-1.7940	64.68	<.0001

The negative coefficient associated with LDose indicates that the probability of having no symptoms (Symptoms='None') or no or mild symptoms (Symptoms='None' or Symptoms='Mild') decreases as LDose increases; that is, the probability of a severe symptom increases with LDose. This association is apparent for both treatment groups.

The negative coefficient associated with the standard treatment group (Prep = stand) indicates that the standard treatment is associated with more severe symptoms across all LDose values.

The following statements use the PREDPLOT statement to create the plot shown in [Output 60.2.2](#) of the probabilities of the response taking on individual levels as a function of LDose. Since there are two covariates, LDose and Prep, the value of the CLASS variable Prep is fixed at the highest level, test. Although not shown here, the CDFPLOT statement creates similar plots of the cumulative response probabilities, instead of individual response level probabilities.

```

  title 'Predicted Probabilities for Standard Preparation';
run;

```

Output 60.2.3. Plot of Predicted Probabilities for the Standard Preparation Group

Example 60.3. Logistic Regression

In this example, a series of people are questioned as to whether or not they would subscribe to a new newspaper. For each person, the variables `sex` (Female, Male), `age`, and `subs` (1=yes,0=no) are recorded. The PROBIT procedure is used to fit a logistic regression model to the probability of a positive response (subscribing) as a function of the variables `sex` and `age`. Specifically, the probability of subscribing is modeled as

$$p = \Pr(\text{subs} = 1) = F(b_0 + b_1 \times \text{sex} + b_2 \times \text{age})$$

where F is the cumulative logistic distribution function.

By default, the PROBIT procedure models the probability of the lower response level for binary data. One way to model $\Pr(\text{subs} = 1)$ is to format the response variable so that the formatted value corresponding to `subs=1` is the lower level. The following statements format the values of `subs` as 1 = 'accept' and 0 = 'reject', so that PROBIT models $\Pr(\text{accept}) = \Pr(\text{subs} = 1)$.

The following statements produce [Output 60.3.1](#):

```
data news;
  input sex $ age subs;

Analysis of Parameter Estimates

Parameter      DF Estimate      Standard      95% Confidence      Chi-
                DF Estimate      Error          Limits              Square Pr > ChiSq
Intercept      1 -5.7620      2.7635 -11.1783 -0.3458      4.35      0.0371
sex Female     1 -2.4224      0.9559 -4.2959 -0.5489      6.42      0.0113
sex Male       0  0.0000      0.0000  0.0000  0.0000      .         .
age            1  0.1649      0.0652  0.0371  0.2927      6.40      0.0114

```

From [Output 60.3.1](#), there appears to be an effect due to both the variables `sex` and `age`. The positive coefficient for `age` indicates that older people are more likely to subscribe than younger people. The negative coefficient for `sex` indicates that females are less likely to subscribe than males.

Example 60.4. An Epidemiology Study

The data, which is from an epidemiology study, consists of five variables: the number, *r*, of individuals surviving after an epidemic, out of *n* treated, for combinations of medicine dosage (*dose*), treatment (*treat* = A, B), and sex (*sex* = 0(Female), 1(Male)).

To see if the two treatments have different effects on male and female individual survival rate, the interaction term between the two variables *treat* and *sex* is included in the model.

The following invocation of PROC PROBIT fits the binary probit model to the grouped data:

```

data epidemic;
  input treat$ dose n r sex;
  label dose = Dose;
  datalines;
A 2.17 142 142 0
A .57 132 47 1

        cfill = white
        ctext = blue;

    lpredplot
        font = swiss
        vref(intersect) = 1.
        vreflab = 'unit probit'
        vreflabpos = 2
        cfit=blue
        cframe=ligr
        ;
    inset /
        cfill = white
        ctext = blue;

run;

```

The results of this analysis are shown in the following tables and figures.

Beginning with SAS Release 8.2, the PROBIT procedure does not support multiple MODEL statements. Only the last one is used if there is more than one MODEL statement in one invocation of the PROBIT procedure.

Output 60.4.1. Class Level Information

Epidemiology Study		
Probit Procedure		
Class Level Information		
Name	Levels	Values
treat	2	A B
sex	2	0 1

Output 60.4.1 displays the table of level information for *all* classification variables in the CLASS statement.

Output 60.4.2. Parameter Information

Epidemiology Study			
Probit Procedure			
Parameter Information			
Parameter	Effect	treat	sex
Intercept	Intercept		
dose	dose		
treatA	treat	A	
treatB	treat	B	
sex0	sex		0
sex1	sex		1
treatAsex0	treat*sex	A	0
treatAsex1	treat*sex	A	1
treatBsex0	treat*sex	B	0
treatBsex1	treat*sex	B	1

Output 60.4.2 displays the table of parameter information for the effects in the MODEL statement. The name of a parameter is generated from combining the variable names and level names in the effect. The maximum length of a parameter name is 32. The name of the effects are specified in the MODEL statement. The length of names of effects can be specified by the NAMELEN= option in the PROC PROBIT statement, with the default length 20.

Output 60.4.3. Model Information

Epidemiology Study	
Probit Procedure	
Model Information	
Data Set	WORK.EPIDEMIC
Events Variable	r
Trials Variable	n
Number of Observations	10
Number of Events	1011
Number of Trials	1204
Name of Distribution	Normal
Log Likelihood	-387.2467391

Algorithm converged.

Output 60.4.3 displays background information about the model fit. Included are the name of the input data set, the response variables used, and the number of observations, events, and trials. The table also includes the status of the convergence of the model fitting algorithm and the final value of log-likelihood function.

Output 60.4.4. Goodness-of-Fit Tests and Response-Covariate Profile

Epidemiology Study			
Probit Procedure			
Goodness-of-Fit Tests			
Statistic	Value	DF	Pr > ChiSq
Pearson Chi-Square	4.9317	4	0.2944
L.R. Chi-Square	5.7079	4	0.2220
Response-Covariate Profile			
Response Levels		2	
Number of Covariate Values		10	

Output 60.4.4 displays the table of goodness-of-fit tests requested with the LACKFIT option in the PROC PROBIT statement. Two goodness-of-fit statistics, the Pearson chi-square statistic and the likelihood ratio chi-square statistic, are computed. The grouping method for computing these statistics can be specified by the AGGREGATE= option. The details can be found in the AGGREGATE= option and an example can be found in the second part of this example. By default, the PROBIT procedure uses the covariates in the MODEL statement to do grouping. Observations with the same values of the covariates in the MODEL statement are grouped into cells and the two statistics are computed according to these cells. The total number of cells, and the number of levels for the response variable are reported next in the “Response-Covariate Profile.”

In this example, neither the Pearson chi-square nor the log-likelihood ratio chi-square tests are significant at the 0.1 level, which is the default test level used by the PROBIT procedure. That means that the model, which includes the interaction of *treat* and *sex*, is suitable for this epidemiology data set. (Further investigation shows that models without the interaction of *treat* and *sex* are not acceptable by either test.)

Output 60.4.5. Type III Tests

Epidemiology Study			
Probit Procedure			
Type III Analysis of Effects			
Effect	DF	Wald	Pr > ChiSq
		Chi-Square	
dose	1	42.1691	<.0001
treat	1	16.1421	<.0001
sex	1	1.7710	0.1833
treat*sex	1	13.9343	0.0002

Output 60.4.5 displays the Type III test results for all effects specified in the MODEL statement, which include the degrees of freedom for the effect, the Wald Chi-Square test statistic, and the *p*-value.

Output 60.4.6. Analysis of Parameter Estimates

Output 60.4.6 displays the table of parameter estimates for the model. The PROBIT procedure displays information for all the parameters of an effect. Degenerate parameters are indicated by 0 degree of freedom. Confidence intervals are computed for all parameters with non-zero degrees of freedom, including the natural threshold C if the OPTC option is specified in the PROC PROBIT statement. The confidence level can be specified by the ALPHA= option in the MODEL statement. The default confidence level is 95%.

From this table, you can see the following results:

- **dose** has significant positive effect on the survival rate.
- Individuals under treatment A have a lower survival rate.
- Male individuals have a higher survival rate.
- Female individuals under treatment A have a higher survival rate.

Output 60.4.9 displays the computed values and fiducial limits for the first single continuous variable `dose` in the `MODEL` statement, given the probability levels, without the effect of the natural threshold, and when the option `INSERSECL` in the `MODEL` statement is specified. If there is no single continuous variable in the `MODEL` specification but the `INVERSECL` option is specified, an error is reported. If the `XDATA=` option is used to input a data set for the independent variables in the `MODEL` statement, the `PROBIT` procedure uses these values for the independent variables other than the single continuous variable. Missing values are not permitted in the `XDATA=` data set for the independent variables, although the value for the single continuous variable is not used in the computing of the fiducial limits. A suitable valid value should be given. In the data set `xval` created by the SAS statements on page 3784, `Dose = 2`.

See the section “XDATA= SAS-data-set” on page 3763 for the default values for those effects other than the single continuous variable, for which the fiducial limits are computed.

In this example, there are two classification variables, `treat` and `sex`. Fiducial limits for the `dose` variable are computed for the highest level of the classification variables, `treat = B` and `sex = 1`, which is the default specification. Since these are the default values, you would get the same values and fiducial limits if you did not specify the XDATA= option in this example. The confidence level for the fiducial limits can be specified by the ALPHA= option in the MODEL statement. The default level is 95%.

If a LOG10 or LOG option is used in the PROC PROBIT statement, the values and the fiducial limits are computed for both the single continuous variable and its logarithm.

Output 60.4.10. Outest Data Set for Epidemiology Study

Output 60.4.10 displays the OUTEST= data set. All parameters for an effect are included.

The following three outputs, Output 60.4.11, Output 60.4.12, and Output 60.4.13, are generated from the three plot statements. The first plot, specified with the PREDPLOT statement, is the plot of the predicted probability against the single continuous variable Dose, which is specified by the VAR= option in the PREDPLOT statement. This single continuous variable must be in the MODEL statement. If the VAR= option is not used, the first single continuous variable in the MODEL statement is used. In this example, you would get the same plot if the VAR = dose was not used in the PREDPLOT statement. You can specify values of other independent

variables in the MODEL statement using an XDATA= data set, or by using the default values.

The second plot, specified with the IPPPLOT statement, is the inverse of the predicted probability plot with the fiducial limits. It should be pointed out that the fiducial limits are *not* just the inverse of the confidence limits in the predicted probability plot; see the section “[Inverse Confidence Limits](#)” on page 3761 for the computation of these limits. The third plot, specified with the LPREDPLOT statement, is the plot of the linear predictor $\mathbf{x}'\beta$ against the first single continuous variable (or the single continuous variable specified by the VAR= option) with the Wald confidence intervals.

After each plot statement, an optional INSET statement is used to draw a box within the plot (inset box). In the inset box, information about the model fitting can be specified. See “[INSET Statement](#)” on page 3723 for more detail.

Output 60.4.11. Predicted Probability Plot

Output 60.4.12. Inverse Predicted Probability Plot

Output 60.4.13. Linear Predictor Plot

Combining INEST= data set and the MAXIT= option in the MODEL statement, the PROBIT procedure can do prediction, if the parameterizations for the models used for the training data and the validation data are exactly the same.

After the first invocation of PROC PROBIT, you have the estimated parameters and their covariance matrix in the data set OUTEST = Out1, and the fitted probabilities for the training data set epidemic in the data set OUTPUT = Out2. See [Output 60.4.10](#) on page 3791 for the data set Out1 and [Output 60.4.14](#) on page 3795 for the data set Out2.

The validation data are collected in data set `validate`. The second invocation of PROC PROBIT simply passes the estimated parameters from the training data set `epidemic` to the validation data set `validate` for prediction. The predicted probabilities are stored in the data set `OUTPUT = Out3` (see [Output 60.4.15](#) on page 3795). The third invocation of PROC PROBIT passes the estimated parameters as initial values for a new fit of the validation data set using the same model. Predicted probabilities are stored in the data set `OUTPUT = Out4` (see [Output 60.4.16](#) on page 3795). Goodness-of-Fit tests are computed based on the cells grouped by the `AGGREGATE=` group variable. Results are shown in [Output 60.4.17](#) on page 3796.

Chapter 61

The REG Procedure

Overview

The REG procedure is one of many regression procedures in the SAS System. It is a general-purpose procedure for regression, while other SAS regression procedures provide more specialized applications. Other SAS/STAT procedures that perform at least one type of regression analysis are the CATMOD, GENMOD, GLM, LOGISTIC, MIXED, NLIN, ORTHOREG, PROBIT, RSREG, and TRANSREG procedures. SAS/ETS procedures are specialized for applications in time-series or simultaneous systems. These other SAS/STAT regression procedures are summarized in [Chapter 2, “Introduction to Regression Procedures,”](#) which also contains an overview of regression techniques and defines many of the statistics computed by PROC REG and other regression procedures.

PROC REG provides the following capabilities:

- multiple MODEL statements
- nine model-selection methods
- interactive changes both in the model and the data used to fit the model
- linear equality restrictions on parameters
- tests of linear hypotheses and multivariate hypotheses
- collinearity diagnostics
- predicted values, residuals, studentized residuals, confidence limits, and influence statistics
- correlation or crossproduct input
- requested statistics available for output through output data sets
- experimental ODS graphics are now available. For more information, see the [“ODS Graphics”](#) section on page 3922. These plots are available in addition to the line-printer and the traditional high resolution plots currently available in PROC REG.
- plots
 - plot model fit summary statistics and diagnostic statistics
 - produce normal quantile-quantile (Q-Q) and probability-probability (P-P) plots for statistics such as residuals
 - specify special shorthand options to plot ridge traces, confidence intervals, and prediction intervals
 - display the fitted model equation, summary statistics, and reference lines on the plot

- control the graphics appearance with PLOT statement options and with global graphics statements including the TITLE, FOOTNOTE, NOTE, SYMBOL, and LEGEND statements
- “paint” or highlight line-printer scatter plots
- produce partial regression leverage line-printer plots

Nine model-selection methods are available in PROC REG. In the simplest method, PROC REG fits the complete model that you specify. The other eight methods involve various ways of including or excluding variables from the model. You specify these methods with the **SELECTION=** option in the MODEL statement.

The methods are identified in the following list and are explained in detail in the “[Model-Selection Methods](#)” section on page 3873.

NONE	no model selection. This is the default. The complete model specified in the MODEL statement is fit to the data.
FORWARD	forward selection. This method starts with no variables in the model and adds variables.
BACKWARD	backward elimination. This method starts with all variables in the model and deletes variables.
STEPWISE	stepwise regression. This is similar to the FORWARD method except that variables already in the model do not necessarily stay there.
MAXR	forward selection to fit the best one-variable model, the best two-variable model, and so on. Variables are switched so that R^2 is maximized.
MINR	similar to the MAXR method, except that variables are switched so that the increase in R^2 from adding a variable to the model is minimized.
RSQUARE	finds a specified number of models with the highest R^2 in a range of model sizes.
ADJRSQ	finds a specified number of models with the highest adjusted R^2 in a range of model sizes.
CP	finds a specified number of models with the lowest C_p in a range of model sizes.

Getting Started

Simple Linear Regression

Suppose that a response variable Y can be predicted by a linear function of a regressor variable X . You can estimate β_0 , the intercept, and β_1 , the slope, in

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$. Fitting this model with the REG procedure requires only the following MODEL statement, where y is the outcome variable and x is the regressor variable.

```
proc reg;
  model y=x;
run;
```

For example, you might use regression analysis to find out how well you can predict a child's weight if you know that child's height. The following data are from a study of nineteen children. Height and weight are measured for each child.

```
title 'Simple Linear Regression';
data class;
  input Name $ Height Weight Age @@;
  datalines;
Alfred 69.0 112.5 14 Alice 56.5 84.0 13 Barbara 65.3 98.0 13

William 66.5 112.0 15
;
```

The equation of interest is

$$\text{Weight} = \beta_0 + \beta_1 \text{Height} + \epsilon$$

The variable **Weight** is the response or dependent variable in this equation, and β_0 and β_1 are the unknown parameters to be estimated. The variable **Height** is the regressor or independent variable, and ϵ is the unknown error. The following commands invoke the REG procedure and fit this model to the data.

```
proc reg;
  model Weight = Height;
run;
```

Figure 61.1 includes some information concerning model fit.

Simple Linear Regression					
The REG Procedure					
Model: MODEL1					
Dependent Variable: Weight					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	7193.24912	7193.24912	57.08	<.0001
Error	17	2142.48772	126.02869		
Corrected Total	18	9335.73684			
	Root MSE	11.22625	R-Square	0.7705	
	Dependent Mean	100.02632	Adj R-Sq	0.7570	
	Coeff Var	11.22330			

Figure 61.1. ANOVA Table

The F statistic for the overall model is highly significant ($F=57.076$, $p<0.0001$), indicating that the model explains a significant portion of the variation in the data.

The degrees of freedom can be used in checking accuracy of the data and model. The model degrees of freedom are one less than the number of parameters to be estimated. This model estimates two parameters, β_0 and β_1 ; thus, the degrees of freedom should be $2 - 1 = 1$. The corrected total degrees of freedom are always one less than the total number of observations in the data set, in this case $19 - 1 = 18$.

Several simple statistics follow the ANOVA table. The Root MSE is an estimate of the standard deviation of the error term. The coefficient of variation, or Coeff Var, is a unitless expression of the variation in the data. The R-Square and Adj R-Square are two statistics used in assessing the fit of the model; values close to 1 indicate a better fit. The R-Square of 0.77 indicates that Height accounts for 77% of the variation in Weight.

The “Parameter Estimates” table shown in [Figure 61.2](#) contains the estimates of β_0 and β_1 . The table also contains the t statistics and the corresponding p -values for testing whether each parameter is significantly different from zero. The p -values ($t = -4.43$, $p = 0.0004$ and $t = 7.55$, $p < 0.0001$) indicate that the intercept and Height parameter estimates, respectively, are highly significant.

Simple Linear Regression					
The REG Procedure					
Model: MODEL1					
Dependent Variable: Weight					
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-143.02692	32.27459	-4.43	0.0004
Height	1	3.89903	0.51609	7.55	<.0001

Figure 61.2. Parameter Estimates

From the parameter estimates, the fitted model is

$$\text{Weight} = -143.0 + 3.9 \times \text{Height}$$

The REG procedure can be used interactively. After you specify a model with the MODEL statement and submit the PROC REG statements, you can submit further statements without reinvoking the procedure. The following command can now be issued to request a plot of the residual versus the predicted values, as shown in [Figure 61.3](#).

```
plot r.*p.; run;
```

Figure 61.3. Plot of Residual vs. Predicted Values

A trend in the residuals would indicate nonconstant variance in the data. [Figure 61.3](#) may indicate a slight trend in the residuals; they appear to increase slightly as the predicted values increase. A fan-shaped trend may indicate the need for a variance-stabilizing transformation. A curved trend (such as a semi-circle) may indicate the need for a quadratic term in the model. Since these residuals have no apparent trend, the analysis is considered to be acceptable.

Polynomial Regression

Consider a response variable Y that can be predicted by a polynomial function of a regressor variable X . You can estimate β_0 , the intercept, β_1 , the slope due to X , and β_2 , the slope due to X^2 , in

$$Y_i = \beta_0 + \beta_1 X_i + \beta_2 X_i^2 + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$.

Consider the following example on population growth trends. The population of the United States from 1790 to 2000 is fit to linear and quadratic functions of time. Note that the quadratic term, `YearSq`, is created in the `DATA` step; this is done since polynomial effects such as `Year*Year` cannot be specified in the `MODEL` statement in `PROC REG`. The data are as follows:

```
data USPopulation;
  input Population @@;
  retain Year 1780;
  Year=Year+10;
  YearSq=Year*Year;
  Population=Population/1000;
  datalines;
3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
62947 75994 91972 105710 122775 131669 151325 179323 203211
226542 248710 281422
;
```

The following statements begin the analysis. (Influence diagnostics and autocorrelation information for the full model are shown in [Figure 61.43](#) on page 3900 and [Figure 61.57](#) on page 3916.)

```
symbol1 c=blue;
proc reg data=USPopulation;
  var YearSq;
  model Population=Year / r cli clm;
  plot r.*p. / cframe=ligr;
run;
```

The `DATA` option ensures that the procedure uses the intended data set. Any variable that you might add to the model but that is not included in the first `MODEL` statement must appear in the `VAR` statement. In the `MODEL` statement, three options are

specified: R requests a residual analysis to be performed, CLI requests 95% confidence limits for an individual value, and CLM requests these limits for the expected value of the dependent variable. You can request specific $100(1 - \alpha)\%$ limits with the ALPHA= option in the PROC REG or MODEL statement. A plot of the residuals against the predicted values is requested by the PLOT statement.

The ANOVA table is displayed in Figure 61.4.

The REG Procedure					
Model: MODEL1					
Dependent Variable: Population					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	1	146869	146869	228.92	<.0001
Error	20	12832	641.58160		
Corrected Total	21	159700			
	Root MSE	25.32946	R-Square	0.9197	
	Dependent Mean	94.64800	Adj R-Sq	0.9156	
	Coeff Var	26.76175			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	-2345.85498	161.39279	-14.54	<.0001
Year	1	1.28786	0.08512	15.13	<.0001

Figure 61.4. ANOVA Table and Parameter Estimates

The Model F statistic is significant ($F=228.92$, $p<0.0001$), indicating that the model accounts for a significant portion of variation in the data. The R-Square indicates that the model accounts for 92% of the variation in population growth. The fitted equation for this model is

$$\text{Population} = -2345.85 + 1.29 \times \text{Year}$$

Figure 61.5 shows the confidence limits for both individual and expected values resulting from the CLM and CLI options.

Predicted Residual SS (PRESS)				16662			

Figure 61.6. Residual Analysis

The residual, its standard error, and the studentized residuals are displayed for each observation. The studentized residual is the residual divided by its standard error. The magnitude of each studentized residual is shown in a plot. Studentized residuals follow a t distribution and can be used to identify outlying or extreme observations. Asterisks (*) extending beyond the dashed lines indicate that the residual is more than three standard errors from zero. Many observations having absolute studentized residuals greater than 2 may indicate an inadequate model. The wave pattern seen in this plot is also an indication that the model is inadequate; a quadratic term may be needed or autocorrelation may be present in the data. Cook's D is a measure of the change in the predicted values upon deletion of that observation from the data set; hence, it measures the influence of the observation on the estimated regression coefficients. A fairly close agreement between the PRESS statistic (see Table 61.6 on page 3897) and the Sum of Squared Residuals indicates that the MSE is a reasonable measure of the predictive accuracy of the fitted model (Neter, Wasserman, and Kutner, 1990).

A plot of the residuals versus predicted values is shown in Figure 61.7.

Figure 61.7. Plot of Residual vs. Predicted Values

The wave pattern of the studentized residual plot is seen here again. The semi-circle shape indicates an inadequate model; perhaps additional terms (such as the quadratic) are needed, or perhaps the data need to be transformed before analysis. If a model fits well, the plot of residuals against predicted values should exhibit no apparent trends.

Using the interactive feature of PROC REG, the following commands add the variable YearSq to the independent variables and refit the model.

```
add YearSq;
print;
plot / cframe=ligr;
run;
```

The ADD statement requests that YearSq be added to the model, and the PRINT command displays the ANOVA table for the new model. The PLOT statement with no variables recreates the most recent plot requested, in this case a plot of residual versus predicted values.

Figure 61.8 displays the ANOVA table and estimates for the new model.

The REG Procedure					
Model: MODEL1.1

Intercept	1	21631	639.50181	33.82	<.0001
Year	1	-24.04581	0.67547	-35.60	<.0001
YearSq	1	0.00668	0.00017820	37.51	<.0001

Figure 61.8. ANOVA Table and Parameter Estimates

The overall F statistic is still significant ($F=8864.19$, $p<0.0001$). The R-square has increased from 0.9197 to 0.9989, indicating that the model now accounts for 99.9% of the variation in Population. All effects are significant with $p<0.0001$ for each effect in the model.

The fitted equation is now

$$\text{Population} = 21631 - 24.046 \times \text{Year} + 0.0067 \times \text{Yearsq}$$

The confidence limits and residual analysis for the second model are displayed in [Figure 61.9](#).

Sum of Residuals -4.4596E-11
Sum of Squared Residuals 170.97193
Predicted Residual SS (PRESS) 237.71229

Figure 61.9. Confidence Limits and Residual Analysis

The plot of the studentized residuals shows that the wave structure is gone. The PRESS statistic is much closer to the Sum of Squared Residuals now, and both statistics have been dramatically reduced. Most of the Cook's D statistics have also been reduced.

**Figure 61.10.** Plot of Residual vs. Predicted Values

The plot of residuals versus predicted values seen in [Figure 61.10](#) has improved since a major trend is no longer visible.

To create a plot of the observed values, predicted values, and confidence limits against Year all on the same plot and to exert some control over the look of the resulting plot, you can submit the following statements.

```
symbol1 v=dot      c=yellow h=.3;
symbol2 v=square  c=red;
symbol3 f=simplex c=blue  h=2 v='--';
symbol4 f=simplex c=blue  h=2 v='--';
plot (Population predicted. u95. l95.)*Year
      / overlay cframe=ligr;
run;
```

Figure 61.11. Plot of Population vs Year with Confidence Limits

The SYMBOL statements requests that the actual data be displayed as dots, the predicted values as squares, and the upper and lower 95% confidence limits for an individual value (sometimes called a *prediction interval*) as dashes. PROC REG provides the short-hand commands CONF and PRED to request confidence and prediction intervals for simple regression models; see the “PLOT Statement” section on page 3839 for details.

To complete an analysis of these data, you may want to examine influence statistics and, since the data are essentially time series data, examine the Durbin-Watson statistic. You might also want to examine other residual plots, such as the residuals vs. regressors.

Using PROC REG Interactively

PROC REG can be used interactively. After you specify a model with a MODEL statement and run REG with a RUN statement, a variety of statements can be executed without reinvoking REG.

The “Interactive Analysis” section on page 3869 describes which statements can be used interactively. These interactive statements can be executed singly or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement can be repeated. This is an important difference from the GLM procedure, which allows only one MODEL statement.

If you use REG interactively, you can end the REG procedure with a DATA step, another PROC step, an ENDSAS statement, or with a QUIT statement. The syntax

of the QUIT statement is

```
quit;
```

When you are using REG interactively, additional RUN statements do not end REG but tell the procedure to execute additional statements.

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

When using REG interactively, you can fit a model, perform diagnostics, then refit the model, and perform diagnostics on the refitted model. Most of the interactive statements implicitly refit the model; for example, if you use the ADD statement to add a variable to the model, the regression equation is automatically recomputed. The two exceptions to this automatic recomputing are the PAINT and REWEIGHT statements. These two statements do not cause the model to be refitted. To do so, you can follow these statements either with a REFIT statement, which causes the model to be explicitly recomputed, or with another interactive statement that causes the model to be implicitly recomputed.

Syntax

The following statements are available in PROC REG.

```
PROC REG < options > ;
  < label: > MODEL dependents=<regressors> < / options > ;
  BY variables ;
  FREQ variable ;
  ID variables ;
  VAR variables ;
  WEIGHT variable ;
  ADD variables ;
  DELETE variables ;
  < label: > MTEST <equation, ... ,equation> < / options > ;
  OUTPUT < OUT=SAS-data-set > keyword=names
    < ... keyword=names > ;
  PAINT <condition | ALLOBS>
    < / options > | < STATUS | UNDO > ;
  PLOT <yvariable*xvariable> <=symbol>
    < ...yvariable*xvariable> <=symbol> < / options > ;
  PRINT < options > < ANOVA > < MODELDATA > ;
  REFIT;
  RESTRICT equation, ... ,equation ;
  REWEIGHT <condition | ALLOBS>
    < / options > | < STATUS | UNDO > ;
  < label: > TEST equation,<, ... ,equation> < / option > ;
```

Although there are numerous statements and options available in PROC REG, many analyses use only a few of them. Often you can find the features you need by looking at an example or by scanning this section.

In the preceding list, brackets denote optional specifications, and vertical bars denote a choice of one of the specifications separated by the vertical bars. In all cases, *label* is optional.

The PROC REG statement is required. To fit a model to the data, you must specify the MODEL statement. If you want to use only the options available in the PROC REG statement, you do not need a MODEL statement, but you must use a VAR statement. (See the example in the “OUTSSCP= Data Sets” section on page 3868.) Several MODEL statements can be used. In addition, several MTEST, OUTPUT, PAINT, PLOT, PRINT, RESTRICT, and TEST statements can follow each MODEL statement. The ADD, DELETE, and REWEIGHT statements are used interactively to change the regression model and the data used in fitting the model. The ADD, DELETE, MTEST, OUTPUT, PLOT, PRINT, RESTRICT, and TEST statements implicitly refit the model; changes made to the model are reflected in the results from these statements. The REFIT statement is used to refit the model explicitly and is most helpful when it follows PAINT and REWEIGHT statements, which do not refit the model. The BY, FREQ, ID, VAR, and WEIGHT statements are optionally specified once for the entire PROC step, and they must appear before the first RUN statement.

When TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used as input data sets to PROC REG, statements and options that require the original data are not available. Specifically, the OUTPUT, PAINT, PLOT, and REWEIGHT statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, DWPROB, INFLUENCE, and PARTIAL are disabled.

You can specify the following statements with the REG procedure in addition to the PROC REG statement:

ADD	adds independent variables to the regression model.
BY	specifies variables to define subgroups for the analysis.
DELETE	deletes independent variables from the regression model.
FREQ	specifies a frequency variable.
ID	names a variable to identify observations in the tables.
MODEL	specifies the dependent and independent variables in the regression model, requests a model selection method, displays predicted values, and provides details on the estimates (according to which options are selected).
MTEST	performs multivariate tests across multiple dependent variables.
OUTPUT	creates an output data set and names the variables to contain predicted values, residuals, and other diagnostic statistics.
PAINT	paints points in scatter plots.
PLOT	generates scatter plots.

PRINT	displays information about the model and can reset options.
REFIT	refits the model.
RESTRICT	places linear equality restrictions on the parameter estimates.
REWEIGHT	excludes specific observations from analysis or changes the weights of observations used.
TEST	performs an F test on linear functions of the parameters.
VAR	lists variables for which crossproducts are to be computed, variables that can be interactively added to the model, or variables to be used in scatter plots.
WEIGHT	declares a variable to weight observations.

PROC REG Statement

PROC REG < options > ;

The PROC REG statement is required. If you want to fit a model to the data, you must also use a MODEL statement. If you want to use only the PROC REG options, you do not need a MODEL statement, but you must use a VAR statement. If you do not use a MODEL statement, then the COVOUT and OUTEST= options are not available.

Table 61.1 lists the options you can use with the PROC REG statement. Note that any option specified in the PROC REG statement applies to all MODEL statements.

Table 61.1. PROC REG Statement Options

Option	Description
Data Set Options	
DATA=	names a data set to use for the regression
OUTEST=	outputs a data set that contains parameter estimates and other model fit summary statistics
OUTSSCP=	outputs a data set that contains sums of squares and crossproducts
COVOUT	outputs the covariance matrix for parameter estimates to the OUTEST= data set
EDF	outputs the number of regressors, the error degrees of freedom, and the model R^2 to the OUTEST= data set
OUTSTB	outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTSEB	outputs standard errors of the parameter estimates to the OUTEST= data set
OUTVIF	outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PCOMIT=	performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
PRESS	outputs the PRESS statistic to the OUTEST= data set
RIDGE=	performs ridge regression analysis and outputs estimates to the OUTEST= data set
RSQUARE	same effect as the EDF option

Table 61.1. (continued)

Option	Description
TABLEOUT	outputs standard errors, confidence limits, and associated test statistics of the parameter estimates to the OUTEST= data set
High Resolution Graphics Options	
ANNOTATE=	specifies an annotation data set
GOUT=	specifies the graphics catalog in which graphics output is saved
Display Options	
CORR	displays correlation matrix for variables listed in MODEL and VAR statements
SIMPLE	displays simple statistics for each variable listed in MODEL and VAR statements
USSCP	displays uncorrected sums of squares and crossproducts matrix
ALL	displays all statistics (CORR, SIMPLE, and USSCP)
NOPRINT	suppresses output
LINEPRINTER	creates plots requested as line printer plot
Other Options	
ALPHA=	sets significance value for confidence and prediction intervals and tests
SINGULAR=	sets criterion for checking for singularity

Following are explanations of the options that you can specify in the PROC REG statement (in alphabetical order). Note that any option specified in the PROC REG statement applies to all MODEL statements.

ALL

requests the display of many tables. Using the ALL option in the PROC REG statement is equivalent to specifying ALL in every MODEL statement. The ALL option also implies the [CORR](#), [SIMPLE](#), and [USSCP](#) options.

ALPHA=number

sets the significance level used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the PROC REG option TABLEOUT; the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL., LCLM., UCL., and UCLM.; and the PLOT statement options CONF and PRED.

ANNOTATE=SAS-data-set**ANNO= SAS-data-set**

specifies an input data set containing annotate variables, as described in *SAS/GRAPH Software: Reference*. You can use this data set to add features to plots. Features provided in this data set are applied to all plots produced in the current run of PROC REG. To add features to individual plots, use the ANNOTATE= option in the PLOT statement. This option cannot be used if the [LINEPRINTER](#) option is specified.

CORR

displays the correlation matrix for all variables listed in the MODEL or VAR statement.

COVOUT

outputs the covariance matrices for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is also specified. See the “OUTEST= Data Set” section on page 3863.

DATA=SAS-data-set

names the SAS data set to be used by PROC REG. The data set can be an ordinary SAS data set or a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set. If one of these special TYPE= data sets is used, the OUTPUT, PAINTE, PLOT, and REWEIGHT statements and some options in the MODEL and PRINT statements are not available. See [Appendix A, “Special SAS Data Sets,”](#) for more information on TYPE= data sets. If the DATA= option is not specified, PROC REG uses the most recently created SAS data set.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R^2 to the OUTEST= data set.

GOUT=graphics-catalog

specifies the graphics catalog in which graphics output is saved. The default *graphics-catalog* is WORK.GSEG. The GOUT= option cannot be used if the [LINEPRINTER](#) option is specified.

LINEPRINTER | LP

creates plots requested as line printer plots. If you do not specify this option, requested plots are created on a high resolution graphics device. This option is required if plots are requested and you do not have SAS/GRAPH software.

NOPRINT

suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see [Chapter 14, “Using the Output Delivery System,”](#) for more information.

OUTEST=SAS-data-set

requests that parameter estimates and optional model fit summary statistics be output to this data set. See the “OUTEST= Data Set” section on page 3863 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section “SAS Files” in *SAS Language Reference: Concepts* for more information on permanent SAS data sets).

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable `_TYPE_` identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable `_TYPE_`. The standard errors for ridge regression estimates and IPC estimates are limited in their

usefulness because these estimates are biased. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

OUTSSCP=SAS-data-set

requests that the sums of squares and crossproducts matrix be output to this TYPE=SSCP data set. See the “[OUTSSCP= Data Sets](#)” section on page 3868 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section “SAS Files” in *SAS Language Reference: Concepts* for more information on permanent SAS data sets).

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable _TYPE_.

PCOMIT=list

requests an incomplete principal components (IPC) analysis for each value m in the list. The procedure computes parameter estimates using all but the last m principal components. Each value of m produces a set of IPC estimates, which are output to the OUTEST= data set. The values of m are saved by the variable _PCOMIT_, and the value of the variable _TYPE_ is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable _PRESS_. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

RIDGE=list

requests a ridge regression analysis and specifies the values of the ridge constant k (see the “[Computations for Ridge Regression and IPC Analysis](#)” section on page 3916). Each value of k produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable _RIDGE_, and the value of the variable _TYPE_ is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. [Example 61.10](#) on page 3956 illustrates this option.

If ODS graphics are in effect (see the “[ODS Graphics](#)” section on page 3922), then ridge regression plots are automatically produced. These plots consist of panels containing ridge traces for the regressors, with at most eight ridge traces per panel.

If you specify the RIDGE= option, RESTRICT statements are ignored.

RSQUARE

has the same effect as the EDF option.

SIMPLE

displays the sum, mean, variance, standard deviation, and uncorrected sum of squares for each variable used in PROC REG.

SINGULAR=*n*

tunes the mechanism used to check for singularities. The default value is machine dependent but is approximately $1E-7$ on most machines. This option is rarely needed. Singularity checking is described in the “Computational Methods” section on page 3917.

TABLEOUT

outputs the standard errors and $100(1 - \alpha)\%$ confidence limits for the parameter estimates, the *t* statistics for testing if the estimates are zero, and the associated *p*-values to the OUTEST= data set. The _TYPE_ variable values STDERR, LnB, UnB, T, and PVALUE, where $n = 100(1 - \alpha)$, identify these rows in the OUTEST= data set. The α -level can be set with the ALPHA= option in the PROC REG or MODEL statement. The OUTEST= option must be specified in the PROC REG statement for this option to take effect.

USSCP

displays the uncorrected sums-of-squares and crossproducts matrix for all variables used in the procedure.

ADD Statement

ADD *variables* ;

The ADD statement adds independent variables to the regression model. Only variables used in the VAR statement or used in MODEL statements before the first RUN statement can be added to the model. You can use the ADD statement interactively to add variables to the model or to include a variable that was previously deleted with a DELETE statement. Each use of the ADD statement modifies the MODEL label. See the “Interactive Analysis” section on page 3869 for an example.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC REG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in the order of the BY variables. The *variables* are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives.

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the REG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure. A BY statement that appears after the first RUN statement is ignored.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Contents*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

DELETE Statement

DELETE *variables* ;

The DELETE statement deletes independent The DELETE statement performs the opposite function of the ADD statement and is used in a similar manner. Each use of the DELETE statement modifies the MODEL label. For an example of how the ADD statement is used (and how the DELETE statement can be used), see the “[Interactive Analysis](#)” section on page 3869.

FREQ Statement

FREQ *variable* ;

When a FREQ statement appears, each observation in the input data set is assumed to represent n observations, where n is the value of the FREQ variable. The analysis produced using a FREQ statement is the same as an analysis produced using a data set that contains n observations in place of each observation in the input data set. When the procedure determines degrees of freedom for significance tests, the total number of observations is considered to be equal to the sum of the values of the FREQ variable.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

The FREQ statement must appear before the first RUN statement, or it is ignored.

ID Statement

ID *variables* ;

When one of the MODEL statement options CLI, CLM, P, R, or INFLUENCE is requested, the variables listed in the ID statement are displayed beside each observation. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

Although there are no restrictions on the length of ID variables, PROC REG may truncate ID values to 16 characters for display purposes.

MODEL Statement

< label: > **MODEL** *dependents*=*< regressors >* *< / options >* ;

After the keyword MODEL, the dependent (response) variables are specified, followed by an equal sign and the regressor variables. Variables specified in the MODEL statement must be numeric variables in the data set being analyzed. For example, if you want to specify a quadratic term for variable *X1* in the model, you cannot use *X1*X1* in the MODEL statement but must create a new variable (for example, *X1SQUARE=X1*X1*) in a DATA step and use this new variable in the MODEL statement. The label in the MODEL statement is optional.

Table 61.2 lists the options available in the MODEL statement. Equations for the statistics available are given in the “[Model Fit and Diagnostic Statistics](#)” section on page 3896.

Table 61.2. MODEL Statement Options

Option	Description
Model Selection and Details of Selection	
SELECTION=	specifies model selection method
BEST=	specifies maximum number of subset models displayed or output to the OUTEST= data set
DETAILS	produces summary statistics at each step
DETAILS=	specifies the display details for forward, backward, and stepwise methods
GROUPNAMES=	provides names for groups of variables
INCLUDE=	includes first <i>n</i> variables in the model
MAXSTEP=	specifies maximum number of steps that may be performed
NOINT	fits a model without the intercept term
PCOMIT=	performs incomplete principal component analysis and outputs estimates to the OUTEST= data set
SLE=	sets criterion for entry into model
RIDGE=	performs ridge regression analysis and outputs estimates to the OUTEST= data set
SLS=	sets criterion for staying in model
START=	specifies number of variables in model to begin the comparing and switching process
STOP=	stops selection criterion

Table 61.2. (continued)

Option	Description
Fit Statistics	
ADJRSQ	computes adjusted R^2
AIC	computes Akaike's information criterion
B	computes parameter estimates for each model
BIC	computes Sawa's Bayesian information criterion
CP	computes Mallows' C_p statistic
GMSEP	computes estimated MSE of prediction assuming multivariate normality
JP	computes J_p , the final prediction error
MSE	computes MSE for each model
PC	computes Amemiya's prediction criterion
RMSE	displays root MSE for each model
SBC	computes the SBC statistic
SP	computes S_p statistic for each model
SSE	computes error sum of squares for each model
Data Set Options	
EDF	outputs the number of regressors, the error degrees of freedom, and the model R^2 to the OUTEST= data set
OUTSEB	outputs standard errors of the parameter estimates to the OUTEST= data set
OUTSTB	outputs standardized parameter estimates to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
OUTVIF	outputs the variance inflation factors to the OUTEST= data set. Use only with the RIDGE= or PCOMIT= option.
PRESS	outputs the PRESS statistic to the OUTEST= data set
RSQUARE	has same effect as the EDF option
Regression Calculations	
I	displays inverse of sums of squares and crossproducts
XPX	displays sums-of-squares and crossproducts matrix
Details on Estimates	
ACOV	displays asymptotic covariance matrix of estimates assuming heteroscedasticity
COLLIN	produces collinearity analysis
COLLINOINT	produces collinearity analysis with intercept adjusted out
CORRB	displays correlation matrix of estimates
COVB	displays covariance matrix of estimates
PARTIALR2	displays squared semi-partial correlation coefficients using Type I sums of squares
PCORR1	displays squared partial correlation coefficients using Type I sums of squares
PCORR2	displays squared partial correlation coefficients using Type II sums of squares
SCORR1	displays squared semi-partial correlation coefficients using Type I sums of squares

Table 61.2. (continued)

Option	Description
SCORR2	displays squared semi-partial correlation coefficients using Type II sums of squares
SEQB	displays a sequence of parameter estimates during selection process
SPEC	tests that first and second moments of model are correctly specified
SS1	displays the sequential sums of squares
SS2	displays the partial sums of squares
STB	displays standardized parameter estimates
TOL	displays tolerance values for parameter estimates
VIF	computes variance-inflation factors
Predicted and Residual Values	
CLB	computes $100(1 - \alpha)\%$ confidence limits for the parameter estimates
CLI	computes $100(1 - \alpha)\%$ confidence limits for an individual predicted value
CLM	computes $100(1 - \alpha)\%$ confidence limits for the expected value of the dependent variable
DW	computes a Durbin-Watson statistic
DWPROB	computes a Durbin-Watson statistic and p-value
INFLUENCE	computes influence statistics
P	computes predicted values
PARTIAL	displays partial regression plots for each regressor
R	produces analysis of residuals
Display Options and Other Options	
ALL	requests the following options: ACOV, CLB, CLI, CLM, CORRB, COVB, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, XPX
ALPHA=	sets significance value for confidence and prediction intervals and tests
NOPRINT	suppresses display of results
SIGMA=	specifies the true standard deviation of error term for computing CP and BIC
SINGULAR=	sets criterion for checking for singularity

You can specify the following options in the MODEL statement after a slash (/).

ACOV

displays the estimated asymptotic covariance matrix of the estimates under the hypothesis of heteroscedasticity. See the section “[Testing for Heteroscedasticity](#)” on page 3910 for more information.

ADJRSQ

computes R^2 adjusted for degrees of freedom for each model selected (Darlington 1968; Judge et al. 1980).

AIC

outputs Akaike's information criterion for each model selected (Akaike 1969; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the AIC statistic is also added to the SubsetSelSummary table.

ALL

requests all these options: ACOV, CLB, CLI, CLM, CORRB, COVB, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, and XPX.

ALPHA=number

sets the significance level used for the construction of confidence intervals for the current MODEL statement. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL., LCLM., UCL., and UCLM.; and the PLOT statement options CONF and PRED. Specifying this option in the MODEL statement takes precedence over the ALPHA= option in the PROC REG statement.

B

is used with the RSQUARE, ADJRSQ, and CP model-selection methods to compute estimated regression coefficients for each model selected.

BEST=n

is used with the RSQUARE, ADJRSQ, and CP model-selection methods. If SELECTION=CP or SELECTION=ADJRSQ is specified, the BEST= option specifies the maximum number of subset models to be displayed or output to the OUTEST= data set. For SELECTION=RSQUARE, the BEST= option requests the maximum number of subset models for each size.

If the BEST= option is used without the B option (displaying estimated regression coefficients), the variables in each MODEL are listed in order of inclusion instead of the order in which they appear in the MODEL statement.

If the BEST= option is omitted and the number of regressors is less than 11, all possible subsets are evaluated. If the BEST= option is omitted and the number of regressors is greater than 10, the number of subsets selected is, at most, equal to the number of regressors. A small value of the BEST= option greatly reduces the CPU time required for large problems.

BIC

outputs Sawa's Bayesian information criterion for each model selected (Sawa 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the BIC statistic is also added to the SubsetSelSummary table.

CLB

requests the $100(1 - \alpha)\%$ upper- and lower-confidence limits for the parameter estimates. By default, the 95% limits are computed; the `ALPHA=` option in the PROC REG or MODEL statement can be used to change the α -level.

CLI

requests the $100(1 - \alpha)\%$ upper- and lower-confidence limits for an individual predicted value. By default, the 95% limits are computed; the `ALPHA=` option in the PROC REG or MODEL statement can be used to change the α -level. The confidence limits reflect variation in the error, as well as variation in the parameter estimates. See the “[Predicted and Residual Values](#)” section on page 3879 and [Chapter 2](#), “[Introduction to Regression Procedures](#),” for more information.

CLM

displays the $100(1 - \alpha)\%$ upper- and lower-confidence limits for the expected value of the dependent variable (mean) for each observation. By default, the 95% limits are computed; the `ALPHA=` in the PROC REG or MODEL statement can be used to change the α -level. This is not a prediction interval (see the `CLI` option) because it takes into account only the variation in the parameter estimates, not the variation in the error term. See the section “[Predicted and Residual Values](#)” on page 3879 and [Chapter 2](#) for more information.

COLLIN

requests a detailed analysis of collinearity among the regressors. This includes eigenvalues, condition indices, and decomposition of the variances of the estimates with respect to each eigenvalue. See the “[Collinearity Diagnostics](#)” section on page 3895.

COLLINOINT

requests the same analysis as the `COLLIN` option with the intercept variable adjusted out rather than included in the diagnostics. See the “[Collinearity Diagnostics](#)” section on page 3895.

CORRB

displays the correlation matrix of the estimates. This is the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix scaled to unit diagonals.

COVB

displays the estimated covariance matrix of the estimates. This matrix is $(\mathbf{X}'\mathbf{X})^{-1}s^2$, where s^2 is the estimated mean squared error.

CP

outputs Mallows' C_p statistic for each model selected (Mallows 1973; Hocking 1976). See the “[Criteria Used in Model-Selection Methods](#)” section on page 3876 for a discussion of the use of C_p . to the `OUTEST=` data set. If `SELECTION=ADJRSQ`, `SELECTION=RSQUARE`, or `SELECTION=CP` is specified, then the CP statistic is also added to the `SubsetSelSummary` table.

DETAILS**DETAILS=***name*

specifies the level of detail produced when the `BACKWARD`, `FORWARD` or `STEPWISE` methods are used, where *name* can be `ALL`, `STEPS` or `SUMMARY`. The

DETAILS or DETAILS=ALL option produces entry and removal statistics for each variable in the model building process, ANOVA and parameter estimates at each step, and a selection summary table. The option DETAILS=STEPS provides the step information and summary table. The option DETAILS=SUMMARY produces only the summary table. The default if the DETAILS option is omitted is DETAILS=STEPS.

DW

calculates a Durbin-Watson statistic to test whether or not the errors have first-order autocorrelation. (This test is appropriate only for time series data.) The sample autocorrelation of the residuals is also produced. See the section [“Autocorrelation in Time Series Data”](#) on page 3915.

DWPROB

calculates a Durbin-Watson statistic and a p-value to test whether or not the errors have first-order autocorrelation. Note that it is not necessary to specify the DW option if the DWPROB option is specified. (This test is appropriate only for time series data.) The sample autocorrelation of the residuals is also produced. See the section [“Autocorrelation in Time Series Data”](#) on page 3915.

EDF

outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model R^2 to the OUTEST= data set.

GMSEP

outputs the estimated mean square error of prediction assuming that both independent and dependent variables are multivariate normal (Stein 1960; Darlington 1968). Note that Hocking’s formula (1976, eq. 4.20) contains a misprint: “ $n - 1$ ” should read “ $n - 2$.”) to the OUTEST= data set. If SELECTION=ADJRSQL, SELECTION=RSQUARE, or SELECTION=CP is specified, then the GMSEP statistic is also added to the SubsetSelSummary table.

GROUPNAMES=*'name1' 'name2' ...*

provides names for variable groups. This option is available only in the BACKWARD, FORWARD, and STEPWISE methods. The group name can be up to 32 characters. Subsets of independent variables listed in the MODEL statement can be designated as variable groups. This is done by enclosing the appropriate variables in braces. Variables in the same group are entered into or removed from the regression model at the same time. However, if the tolerance of any variable (see the [TOL option](#) on page 3832) in a group is less than the setting of the [SINGULAR=](#) option, then the variable is not entered into the model with the rest of its group. If the GROUPNAMES= option is not used, then the names GROUP1, GROUP2, ..., GROUP n are assigned to groups encountered in the MODEL statement. Variables not enclosed by braces are used as groups of a single variable.

For example,

```
model y={x1 x2} x3 / selection=stepwise
      groupnames='x1 x2' 'x3';
```

As another example,

```
model y={ht wgt age} bodyfat / selection=forward
      groupnames='htwgtage' 'bodyfat';
```

I

displays the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix. The inverse of the crossproducts matrix is bordered by the parameter estimates and SSE matrices.

INCLUDE=*n*

forces the first *n* independent variables listed in the MODEL statement to be included in all models. The selection methods are performed on the other variables in the MODEL statement. The INCLUDE= option is not available with SELECTION=NONE.

INFLUENCE

requests a detailed analysis of the influence of each observation on the estimates and the predicted values. See the “[Influence Diagnostics](#)” section on page 3898 for details.

JP

outputs J_p , the estimated mean square error of prediction for each model selected assuming that the values of the regressors are fixed and that the model is correct to the OUTEST= data set. The J_p statistic is also called the final prediction error (FPE) by Akaike (Nicholson 1948; Lord 1950; Mallows 1967; Darlington 1968; Rothman 1968; Akaike 1969; Hocking 1976; Judge et al. 1980). If SELECTION=ADJRSQL, SELECTION=RSQUARE, or SELECTION=CP is specified, then the J_p statistic is also added to the SubsetSelSummary table.

MSE

computes the mean square error for each model selected (Darlington 1968).

MAXSTEP=*n*

specifies the maximum number of steps that are done when SELECTION=FORWARD, SELECTION=BACKWARD or SELECTION=STEPWISE is used. The default value is the number of independent variables in the model for the forward and backward methods and three times this number for the stepwise method.

NOINT

suppresses the intercept term that is otherwise included in the model.

NOPRINT

suppresses the normal display of regression results. Note that this option temporarily disables the Output Delivery System (ODS); see [Chapter 14](#), “[Using the Output Delivery System](#),” for more information.

OUTSEB

outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable `_TYPE_` identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable `_TYPE_`. The standard errors for ridge regression estimates and incomplete principal components (IPC) estimates are limited in their usefulness because these estimates are biased. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

OUTSTB

outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable `_TYPE_` identify ridge regression estimates and IPC estimates, respectively.

OUTVIF

outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable `_TYPE_`.

P

calculates predicted values from the input data and the estimated model. The display includes the observation number, the ID variable (if one is specified), the actual and predicted values, and the residual. If the CLI, CLM, or R option is specified, the P option is unnecessary. See the section “[Predicted and Residual Values](#)” on page 3879 for more information.

PARTIAL

requests partial regression leverage plots for each regressor. If ODS Graphics are in effect (see the “[ODS Graphics](#)” section on page 3922), then these partial plots are produced in panels with up to six plots per panel. See the “[Influence Diagnostics](#)” section on page 3898 for more information.

PARTIALR2 < (< TESTS > < SEQTESTS >) >

See the [SCORR1](#) option.

PC

outputs Amemiya’s prediction criterion for each model selected (Amemiya 1976; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the PC statistic is also added to the SubsetSelSummary table.

PCOMIT=list

requests an IPC analysis for each value m in the list. The procedure computes parameter estimates using all but the last m principal components. Each value of m produces a set of IPC estimates, which is output to the OUTEST= data set. The values of m are saved by the variable `_PCOMIT_`, and the value of the variable `_TYPE_` is set

to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored. The PCOMIT= option is ignored if you use the SELECTION= option in the MODEL statement.

PCORR1

displays the squared partial correlation coefficients using Type I Sum of Squares (SS). This is calculated as $SS/(SS+SSE)$, where SSE is the error Sum of Squares.

PCORR2

displays the squared partial correlation coefficients using Type II sums of squares. These are calculated the same way as with the PCORR1 option, except that Type II SS are used instead of Type I SS.

PRESS

outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable `_PRESS_`. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

R

requests an analysis of the residuals. The results include everything requested by the [P option](#) plus the standard errors of the mean predicted and residual values, the studentized residual, and Cook's D statistic to measure the influence of each observation on the parameter estimates. See the section "[Predicted and Residual Values](#)" on page 3879 for more information.

RIDGE=*list*

requests a ridge regression analysis and specifies the values of the ridge constant k (see the "[Computations for Ridge Regression and IPC Analysis](#)" section on page 3916). Each value of k produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable `_RIDGE_`, and the value of the variable `_TYPE_` is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. [Example 61.10](#) on page 3956 illustrates this option.

If you specify the RIDGE= option, RESTRICT statements are ignored. The RIDGE= option is ignored if you use the SELECTION= option in the MODEL statement.

RMSE

displays the root mean square error for each model selected.

RSQUARE

has the same effect as the [EDF](#) option.

SBC

outputs the SBC statistic for each model selected (Schwarz 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SBC statistic is also added to the SubsetSelSummary table.

SCORR1 < (< **TESTS** > < **SEQTESTS** >) >

displays the squared semi-partial correlation coefficients using Type I sums of squares. This is calculated as SS/SST , where SST is the corrected total SS . If the **NOINT** option is used, the uncorrected total SS is used in the denominator. The optional arguments **TESTS** and **SEQTESTS** request F-tests, p-values, and cumulative R-Square values as variables are sequentially added to a model. The F-test values are computed as the Type I sum of squares for the variable in question divided by a mean square error. If you specify the **TESTS** option, the denominator MSE is the residual mean square for the full model specified in the **MODEL** statement. If you specify the **SEQTESTS** option, the denominator MSE is the residual mean square for the model containing all the independent variables that have been added to the model up to and including the variable in question. The **TESTS** and **SEQTESTS** options are not supported if you specify model selection methods, or the **RIDGE** or **PCOMIT** options. Note that the **PARTIALR2** option is a synonym for the **SCORR1** option.

SCORR2 < (**TESTS**) >

displays the squared semi-partial correlation coefficients using Type II sums of squares. These are calculated the same way as with the **SCORR1** option, except that Type II SS are used instead of Type I SS . The optional **TEST** argument requests F-tests and p-values as variables are sequentially added to a model. The F-test values are computed as the Type II sum of squares for the variable in question divided by the residual mean square for the full model specified in the **MODEL** statement. The **TESTS** option is not supported if you specify model selection methods, or the **RIDGE** or **PCOMIT** options.

SELECTION=*name*

specifies the method used to select the model, where *name* can be **FORWARD** (or **F**), **BACKWARD** (or **B**), **STEPWISE**, **MAXR**, **MINR**, **RSQUARE**, **ADJRSQ**, **CP**, or **NONE** (use the full model). The default method is **NONE**. See the “[Model-Selection Methods](#)” section on page 3873 for a description of each method.

SEQB

produces a sequence of parameter estimates as each variable is entered into the model. This is displayed as a matrix where each row is a set of parameter estimates.

SIGMA=*n*

specifies the true standard deviation of the error term to be used in computing the **CP** and **BIC** statistics. If the **SIGMA=** option is not specified, an estimate from the full model is used. This option is available in the **RSQUARE**, **ADJRSQ**, and **CP** model-selection methods only.

SINGULAR=*n*

tunes the mechanism used to check for singularities. Specifying this option in the **MODEL** statement takes precedence over the **SINGULAR=** option in the **PROC REG** statement. The default value is machine dependent but is approximately $1E-7$ on most machines. This option is rarely needed. Singularity checking is described in the “[Computational Methods](#)” section on page 3917.

SLENTRY=*value***SLE=***value*

specifies the significance level for entry into the model used in the FORWARD and STEPWISE methods. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

SLSTAY=*value***SLS=***value*

specifies the significance level for staying in the model for the BACKWARD and STEPWISE methods. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

SP

outputs the S_p statistic for each model selected (Hocking 1976) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the SP statistic is also added to the SubsetSelSummary table.

SPEC

performs a test that the first and second moments of the model are correctly specified. See the section [“Testing for Heteroscedasticity”](#) on page 3910 for more information.

SS1

displays the sequential sums of squares (Type I SS) along with the parameter estimates for each term in the model. See [Chapter 11, “The Four Types of Estimable Functions,”](#) for more information on the different types of sums of squares.

SS2

displays the partial sums of squares (Type II SS) along with the parameter estimates for each term in the model. See the [SS1](#) option also.

SSE

computes the error sum of squares for each model selected.

START=*s*

is used to begin the comparing-and-switching process in the MAXR, MINR, and STEPWISE methods for a model containing the first *s* independent variables in the MODEL statement, where *s* is the START value. For these methods, the default is START=0.

For the RSQUARE, ADJRSQ, and CP methods, START=*s* specifies the smallest number of regressors to be reported in a subset model. For these methods, the default is START=1.

The START= option cannot be used with model-selection methods other than the six described here.

STB

produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.

STOP=*s*

causes PROC REG to stop when it has found the “best” *s*-variable model, where *s* is the STOP value. For the RSQUARE, ADJRSQ, and CP methods, STOP=*s* specifies the largest number of regressors to be reported in a subset model. For the MAXR and MINR methods, STOP=*s* specifies the largest number of regressors to be included in the model.

The default setting for the STOP= option is the number of variables in the MODEL statement. This option can be used only with the MAXR, MINR, RSQUARE, ADJRSQ and CP methods.

TOL

produces tolerance values for the estimates. Tolerance for a variable is defined as $1 - R^2$, where R^2 is obtained from the regression of the variable on all other regressors in the model. See the section “[Collinearity Diagnostics](#)” on page 3895 for more detail.

VIF

produces variance inflation factors with the parameter estimates. Variance inflation is the reciprocal of tolerance. See the section “[Collinearity Diagnostics](#)” on page 3895 for more detail.

XPX

displays the $X'X$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $X'Y$ and $Y'Y$ matrices.

MTEST Statement

```
< label: > MTEST < equation < , ... , equation > > < / options > ;
```

where each *equation* is a linear function composed of coefficients and variable names. The *label* is optional.

The MTEST statement is used to test hypotheses in multivariate regression models where there are several dependent variables fit to the same regressors. If no equations or options are specified, the MTEST statement tests the hypothesis that all estimated parameters except the intercept are zero.

The hypotheses that can be tested with the MTEST statement are of the form

$$(\mathbf{L}\beta - \mathbf{c}\mathbf{j})\mathbf{M} = 0$$

where \mathbf{L} is a linear function on the regressor side, β is a matrix of parameters, \mathbf{c} is a column vector of constants, \mathbf{j} is a row vector of ones, and \mathbf{M} is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\beta\mathbf{M} = 0$$

See the section “[Multivariate Tests](#)” on page 3910 for more details.

Each linear function extends across either the regressor variables or the dependent variables. If the equation is across the dependent variables, then the constant term, if

specified, must be zero. The equations for the regressor variables form the **L** matrix and **c** vector in the preceding formula; the equations for dependent variables form the **M** matrix. If no equations for the dependent variables are given, PROC REG uses an identity matrix for **M**, testing the same hypothesis across all dependent variables. If no equations for the regressor variables are given, PROC REG forms a linear function corresponding to a test that all the nonintercept parameters are zero.

As an example, consider the following statements:

```
model y1 y2 y3=x1 x2 x3;
mtest x1,x2;
mtest y1-y2, y2 -y3, x1;
mtest y1-y2;
```

The first MTEST statement tests the hypothesis that the *X*1 and *X*2 parameters are zero for *Y*1, *Y*2 and *Y*3. In addition, the second MTEST statement tests the hypothesis that the *X*1 parameter is the same for all three dependent variables. For the same model, the third MTEST statement tests the hypothesis that all parameters except the intercept are the same for dependent variables *Y*1 and *Y*2.

You can specify the following options in the MTEST statement.

CANPRINT

displays the canonical correlations for the hypothesis combinations and the dependent variable combinations. If you specify

```
mtest / canprint;
```

the canonical correlations between the regressors and the dependent variables are displayed.

DETAILS

displays the **M** matrix and various intermediate calculations.

PRINT

displays the **H** and **E** matrices.

OUTPUT Statement

```
OUTPUT < OUT=SAS-data-set > keyword=names
      < ... keyword=names > ;
```

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated after fitting the model. The OUTPUT statement refers to the most recent MODEL statement. At least one *keyword=names* specification is required.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you want to create a permanent SAS data set, you must specify

a two-level name (for example, *libref.data-set-name*). For more information on permanent SAS data sets, refer to the section “SAS Files” in *SAS Language Reference: Concepts*.

The OUTPUT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. See the “Input Data Sets” section on page 3860 for more details.

The statistics created in the OUTPUT statement are described in this section. More details are contained in the “Predicted and Residual Values” section on page 3879 and the “Influence Diagnostics” section on page 3898. Also see Chapter 2, “Introduction to Regression Procedures,” for definitions of the statistics available from the REG procedure.

You can specify the following options in the OUTPUT statement.

OUT=SAS data set

gives the name of the new data set. By default, the procedure uses the DATA*n* convention to name the new data set.

keyword=names

specifies the statistics to include in the output data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable or variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains that statistic for the first dependent variable listed in the MODEL statement; the second variable contains the statistic for the second dependent variable in the MODEL statement, and so on. The list of variables following the equal sign can be shorter than the list of dependent variables in the MODEL statement. In this case, the procedure creates the new names in order of the dependent variables in the MODEL statement.

For example, the SAS statements

```
proc reg data=a;
  model y z=x1 x2;
  output out=b
    p=yhat zhat
    r=yresid zresid;
run;
```

create an output data set named b. In addition to the variables in the input data set, b contains the following variables:

- *yhat*, with values that are predicted values of the dependent variable *y*
- *zhat*, with values that are predicted values of the dependent variable *z*
- *yresid*, with values that are the residual values of *y*
- *zresid*, with values that are the residual values of *z*

You can specify the following keywords in the OUTPUT statement. See the “[Model Fit and Diagnostic Statistics](#)” section on page 3896 for computational formulas.

Table 61.3. Keywords for OUTPUT Statement

Keyword	Description
COOKD= <i>names</i>	Cook’s D influence statistic
COVRATIO= <i>names</i>	standard influence of observation on covariance of betas, as discussed in the “ Influence Diagnostics ” section on page 3898
DFFITS= <i>names</i>	standard influence of observation on predicted value
H= <i>names</i>	leverage, $x_i(\mathbf{X}'\mathbf{X})^{-1}x_i'$
LCL= <i>names</i>	lower bound of a $100(1 - \alpha)\%$ confidence interval for an individual prediction. This includes the variance of the error, as well as the variance of the parameter estimates.
LCLM= <i>names</i>	lower bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the dependent variable
PREDICTED P= <i>names</i>	predicted values
PRESS= <i>names</i>	i th residual divided by $(1 - h)$, where h is the leverage, and where the model has been refit without the i th observation
RESIDUAL R= <i>names</i>	residuals, calculated as ACTUAL minus PREDICTED
RSTUDENT= <i>names</i>	a studentized residual with the current observation deleted
STDI= <i>names</i>	standard error of the individual predicted value
STDP= <i>names</i>	standard error of the mean predicted value
STDR= <i>names</i>	standard error of the residual
STUDENT= <i>names</i>	studentized residuals, which are the residuals divided by their standard errors
UCL= <i>names</i>	upper bound of a $100(1 - \alpha)\%$ confidence interval for an individual prediction
UCLM= <i>names</i>	upper bound of a $100(1 - \alpha)\%$ confidence interval for the expected value (mean) of the dependent variable

PAINT Statement

PAINT < *condition* | **ALLOBS** > < / *options* > ;

PAINT < **STATUS** | **UNDO** > ;

The PAINT statement selects observations to be *painted* or highlighted in a scatter plot on line printer output; the PAINT statement is ignored if the LINEPRINTER option is not specified in the PROC REG statement.

All observations that satisfy *condition* are painted using some specific symbol. The PAINT statement does not generate a scatter plot and must be followed by a PLOT statement, which does generate a scatter plot. Several PAINT statements can be used before a PLOT statement, and all prior PAINT statement requests are applied to all later PLOT statements.

The PAIN statement lists the observation numbers of the observations selected, the total number of observations selected, and the plotting symbol used to paint the points.

On a plot, paint symbols take precedence over all other symbols. If any position contains more than one painted point, the paint symbol for the observation plotted last is used.

The PAIN statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. Also, the PAIN statement cannot be used for models with more than one dependent variable. Note that the syntax for the PAIN statement is the same as the syntax for the REWEIGHT statement.

For detailed examples of painting scatter plots, see the section “[Painting Scatter Plots](#)” on page 3889.

Specifying Condition

Condition is used to select observations to be painted. The syntax of *condition* is

variable compare value

or

variable compare value logical variable compare value

where

variable is one of the following:

- a variable name in the input data set
- OBS., which is the observation number
- *keyword.*, where *keyword* is a keyword for a statistic requested in the OUTPUT statement

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^ =. The operators LT, LE, GT, GE, EQ, and NE can be used instead of the preceding symbols. Refer to the “Expressions” section in *SAS Language Reference: Concepts* for more information on comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be painted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the statements

```
paint name='henry';
```

and

```
paint name='Henry';
```

are not the same.

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Examples of the *variable compare value* form are

```
paint name='Henry';
paint residual.>=20;
paint obs.=99;
```

Examples of the *variable compare value logical variable compare value* form are

```
paint name='Henry' | name='Mary';
paint residual.>=20 or residual.<=10;
paint obs.>=11 and residual.<=20;
```

Using ALLOBS

Instead of specifying *condition*, the ALLOBS option can be used to select all observations. This is most useful when you want to unpaint all observations. For example,

```
paint allobs / reset;
```

resets the symbols for all observations.

Options in the PAINT Statement

The following options can be used when either a condition is specified, the ALLOBS option is specified, or when nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous PAINT statement, *not* to the observations selected by reapplying the condition from the previous PAINT statement. For example, in the statements

```
paint r.>0 / symbol='a';
reweight r.>0;
refit;
paint / symbol='b';
```

the second PAINT statement paints only those observations selected in the first PAINT statement. No additional observations are painted even if, after refitting the model, there are new observations that meet the condition in the first PAINT statement.

Note: Options are not available when either the UNDO or STATUS option is used.

You can specify the following options after a slash (/).

NOLIST

suppresses the display of the selected observation numbers. If the NOLIST option is not specified, a list of observations selected is written to the log. The list includes the observation numbers and painting symbol used to paint the points. The total number of observations selected to be painted is also shown.

RESET

changes the painting symbol to the current default symbol, effectively unpainting the observations selected. If you set the default symbol by using the SYMBOL= option in the PLOT statement, the RESET option in the PAINT statement changes the painting symbol to the symbol you specified. Otherwise, the default symbol of '1' is used.

SYMBOL = 'character'

specifies a painting symbol. If the SYMBOL= option is omitted, the painting symbol is either the one used in the most recent PAINT statement or, if there are no previous PAINT statements, the symbol '@'. For example,

```
paint / symbol='#';
```

changes the painting symbol for the observations selected by the most recent PAINT statement to '#'. As another example,

```
paint temp lt 22 / symbol='c';
```

changes the painting symbol to 'c' for all observations with TEMP<22. In general, the numbers 1, 2, . . . , 9 and the asterisk are not recommended as painting symbols. These symbols are used as default symbols in the PLOT statement, where they represent the number of replicates at a point. If SYMBOL="" is used, no painting is done in the current plot. If SYMBOL=' ' is used, observations are painted with a blank and are no longer seen on the plot.

STATUS and UNDO

Instead of specifying *condition* or the ALLOBS option, you can use the STATUS or UNDO option as follows:

STATUS

lists (on the log) the observation number and plotting symbol of all currently painted observations.

UNDO

undoes changes made by the most recent PAINT statement. Observations may be, but are not necessarily, unpainted. For example,

```
paint obs. <=10 / symbol='a';
...other interactive statements
paint obs.=1 / symbol='b';
...other interactive statements
paint undo;
```

The last PAINT statement changes the plotting symbol used for observation 1 back to 'a'. If the statement

```
paint / reset;
```

is used instead, observation 1 is unpainted.

PLOT Statement

```
PLOT < yvariable*xvariable >< =symbol >
      < ... yvariable*xvariable > < =symbol > < / options >;
```

The PLOT statement in PROC REG displays scatter plots with *yvariable* on the vertical axis and *xvariable* on the horizontal axis. Line printer plots are generated if the LINEPRINTER option is specified in the PROC REG statement; otherwise, the traditional high-resolution graphics plots are created. Points in line printer plots can be marked with *symbols*, while global graphics statements such as GOPTIONS and SYMBOL are used to enhance the high-resolution graphics plots. Note that the plots you request using the PLOT statement are independent of the experimental ODS graphics (see the “[ODS Graphics](#)” section on page 3922) that are now available in PROC REG.

As with most other interactive statements, the PLOT statement implicitly refits the model. For example, if a PLOT statement is preceded by a REWEIGHT statement, the model is recomputed, and the plot reflects the new model.

If there are multiple MODEL statements preceding a PLOT statement, then the PLOT statement refers to the latest MODEL statement.

The PLOT statement cannot be used when TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used as input to PROC REG.

You can specify several PLOT statements for each MODEL statement, and you can specify more than one plot in each PLOT statement. For detailed examples of using the PLOT statement and its options, see the section “[Producing Scatter Plots](#)” on page 3882.

Specifying Yvariables, Xvariables, and Symbol

More than one *yvariable*xvariable* pair can be specified to request multiple plots. The *yvariables* and *xvariables* can be

- any variables specified in the VAR or MODEL statement before the first RUN statement
- *keyword.*, where *keyword* is a regression diagnostic statistic available in the OUTPUT statement (see [Table 61.4](#) on page 3842). For example,

```
plot predicted.*residual.;
```

generates one plot of the predicted values by the residuals for each dependent variable in the MODEL statement. These statistics can also be plotted against any of the variables in the VAR or MODEL statements.

- the keyword OBS. (the observation number), which can be plotted against any of the preceding variables
- the keyword NPP. or NQQ., which can be used with any of the preceding variables to construct normal P-P or Q-Q plots, respectively (see the section “Construction of Q-Q and P-P Plots” on page 3917 and Example 61.8 on page 3953 for more information)
- keywords for model fit summary statistics available in the OUTEST= data set with _TYPE_= PARMS (see Table 61.4 on page 3842). A SELECTION= method (other than NONE) must be requested in the MODEL statement for these variables to be plotted. If one member of a *yvariable***xvariable* pair is from the OUTEST= data set, the other member must also be from the OUTEST= data set.

The OUTPUT statement and the OUTEST= option are not required when their keywords are specified in the PLOT statement.

The *yvariable* and *xvariable* specifications can be replaced by a set of variables and statistics enclosed in parentheses. When this occurs, all possible combinations of *yvariable* and *xvariable* are generated. For example, the following two statements are equivalent.

```
plot (y1 y2)*(x1 x2);
plot y1*x1 y1*x2 y2*x1 y2*x2;
```

The statement

```
plot;
```

is equivalent to respecifying the most recent PLOT statement without any options. However, the line printer options COLLECT, HPLOTS=, SYMBOL=, and VPLOTS=, described in the “Line Printer Plots” section on page 3848, apply across PLOT statements and remain in effect if they have been previously specified.

Options used for the traditional high-resolution graphics plots are described in the following section; see for more information.

Traditional High-Resolution Graphics Plots

The display of high-resolution graphics plots is described in the following paragraphs, the options are summarized in Table 61.4 and described in the section “Dictionary of PLOT Statement Options” on page 3844, and the “Examples” section on page 3924 contains several examples of the graphics output.

Several line printer statements and options are not supported for high-resolution graphics. In particular the PAINT statement is disabled, as are the PLOT statement options CLEAR, COLLECT, HPLOTS=, NOCOLLECT, SYMBOL=, and

VPLOTS=. To display more than one plot per page or to collect plots from multiple PLOT statements, use the PROC GREPLAY statement (refer to *SAS/GRAPH Software: Reference*). Also note that high-resolution graphics options are not recognized for line printer plots.

The fitted model equation and a label are displayed in the top margin of the plot; this display can be suppressed with the NOMODEL option. If the label is requested but cannot fit on one line, it is not displayed. The equation and label are displayed on one line when possible; if more lines are required, the label is displayed in the first line with the model equation in successive lines. If displaying the entire equation causes the plot to be unacceptably small, the equation is truncated. [Table 61.5](#) on page 3843 lists options to control the display of the equation. The “[Examples](#)” section on page 3924 illustrates the display of the model equation.

Four statistics are displayed by default in the right margin: the number of observations, R^2 , the adjusted R^2 , and the root mean square error. (See [Output 61.4.1](#) on page 3949.) The display of these statistics can be suppressed with the NOSTAT option. You can specify other options to request the display of various statistics in the right margin; see [Table 61.5](#) on page 3843.

A default reference line at zero is displayed if residuals are plotted; see [Output 61.7.1](#) on page 3952. If the dependent variable is plotted against the independent variable in a simple linear regression model, the fitted regression line is displayed by default. (See [Output 61.4.1](#) on page 3949.) Default reference lines can be suppressed with the NOLINE option; the lines are not displayed if the OVERLAY option is specified.

Specialized plots are requested with special options. For each coefficient, the RIDGEPLOT option plots the ridge estimates against the ridge values k ; see the description of the RIDGEPLOT option in the section “[Dictionary of PLOT Statement Options](#)” beginning on page 3844 and [Example 61.10](#) on page 3956 for more details. The CONF option plots $100(1 - \alpha)\%$ confidence intervals for the mean while the PRED option plots $100(1 - \alpha)\%$ prediction intervals; see the description of these options in the section “[Dictionary of PLOT Statement Options](#)” beginning on page 3844 and in [Example 61.9](#) on page 3955 for more details.

If a SELECTION= method is requested, the fitted model equation and the statistics displayed in the margin correspond to the selected model. For the ADJRSQ and CP methods, the selected model is treated as a submodel of the full model. If a CP.*NP. plot is requested, the CHOCKING= and CMALLOWS= options display model selection reference lines; see the descriptions of these options in the section “[Dictionary of PLOT Statement Options](#)” beginning on page 3844 and [Example 61.5](#) on page 3949 for more details.

PLOT Statement *variable* **Keywords**

The following table lists the keywords available as PLOT statement *xvariables* and *yvariables*. All keywords have a trailing dot; for example, “*COOKD.*” requests Cook’s D statistic. Neither the OUTPUT statement nor the OUTEST= option needs to be specified.

Table 61.4. Keywords for PLOT Statement *xvariables* and *yvariables*

Keyword	Description
Diagnostic Statistics	
COOKD.	Cook's D influence statistics
COVRATIO.	standard influence of observation on covariance of betas
DFFITS.	standard influence of observation on predicted value
H.	leverage
LCL.	lower bound of $100(1 - \alpha)\%$ confidence interval for individual prediction
LCLM.	lower bound of $100(1 - \alpha)\%$ confidence interval for the mean of the dependent variable
PREDICTED. PRED. P.	predicted values
PRESS.	residuals from refitting the model with current observation deleted
RESIDUAL. R.	residuals
RSTUDENT.	studentized residuals with the current observation deleted
STDI.	standard error of the individual predicted value
STDP.	standard error of the mean predicted value
STDR.	standard error of the residual
STUDENT.	residuals divided by their standard errors
UCL.	upper bound of $100(1 - \alpha)\%$ confidence interval for individual prediction
UCLM.	upper bound of $100(1 - \alpha)\%$ confidence interval for the mean of the dependent variables
Other Keywords Used with Diagnostic Statistics	
NPP.	normal probability-probability plot
NQQ.	normal quantile-quantile plot
OBS.	observation number (cannot plot against OUTEST= statistics)
Model Fit Summary Statistics	
ADJRSQ.	adjusted R-square
AIC.	Akaike's information criterion
BIC.	Sawa's Bayesian information criterion
CP.	Mallows' C_p statistic
EDF.	error degrees of freedom
GMSEP.	estimated MSE of prediction, assuming multivariate normality
IN.	number of regressors in the model not including the intercept
JP.	final prediction error
MSE.	mean squared error
NP.	number of parameters in the model (including the intercept)
PC.	Amemiya's prediction criterion
RMSE.	root MSE
RSQ.	R-square
SBC.	SBC statistic
SP.	SP statistic
SSE.	error sum of squares

Summary of PLOT Statement Graphics Options

The following table lists the PLOT statement *options* by function. These *options* are available unless the LINEPRINTER option is specified in the PROC REG statement. For complete descriptions, see the section “[Dictionary of PLOT Statement Options](#)” beginning on page 3844.

Table 61.5. High-Resolution Graphics Options

Option	Description
General Graphics Options	
ANNOTATE= <i>SAS-data-set</i>	specifies the annotate data set
CHOCKING= <i>color</i>	requests a reference line for C_p model selection criteria
CMALLOWS= <i>color</i>	requests a reference line for the C_p model selection criterion
CONF	requests plots of $100(1 - \alpha)\%$ confidence intervals for the mean
DESCRIPTION= <i>'string'</i>	specifies a description for graphics catalog member
NAME= <i>'string'</i>	names the plot in graphics catalog
OVERLAY	overlays plots from the same model
PRED	requests plots of $100(1 - \alpha)\%$ prediction intervals for individual responses
RIDGEPLOT	requests the ridge trace for ridge regression
Axis and Legend Options	
LEGEND= <i>LEGENDn</i>	specifies LEGEND statement to be used
HAXIS= <i>values</i>	specifies tick mark values for horizontal axis
VAXIS= <i>values</i>	specifies tick mark values for vertical axis
Reference Line Options	
HREF= <i>values</i>	specifies reference lines perpendicular to horizontal axis
LHREF= <i>linetype</i>	specifies line style for HREF= lines
LLINE= <i>linetype</i>	specifies line style for lines displayed by default
LVREF= <i>linetype</i>	specifies line style for VREF= lines
NOLINE	suppresses display of any default reference line
VREF= <i>values</i>	specifies reference lines perpendicular to vertical axis
Color Options	
CAXIS= <i>color</i>	specifies color for axis line and tick marks
CFRAME= <i>color</i>	specifies color for frame
CHREF= <i>color</i>	specifies color for HREF= lines
CLINE= <i>color</i>	specifies color for lines displayed by default
CTEXT= <i>color</i>	specifies color for text
CVREF= <i>color</i>	specifies color for VREF= lines
Options for Displaying the Fitted Model Equation	
MODELFONT= <i>font</i>	specifies font of model equation and model label
MODELHT= <i>value</i>	specifies text height of model equation and model label
MODELLAB= <i>'label'</i>	specifies model label
NOMODEL	suppresses display of the fitted model and the label
Options for Displaying Statistics in the Plot Margin	
AIC	displays Akaike's information criterion

Table 61.5. (continued)

Option	Description
BIC	displays Sawa's Bayesian information criterion
CP	displays Mallows' C_p statistic
EDF	displays the error degrees of freedom
GMSEP	displays the estimated MSE of prediction assuming multivariate normality
IN	displays the number of regressors in the model not including the intercept
JP	displays the J_p statistic
MSE	displays the mean squared error
NOSTAT	suppresses display of the default statistics: the number of observations, R-square, adjusted R-square, and the root mean square error
NP	displays the number of parameters in the model including the intercept, if any
PC	displays the PC statistic
SBC	displays the SBC statistic
SP	displays the S(p) statistic
SSE	displays the error sum of squares
STATFONT= <i>font</i>	specifies font of text displayed in the margin
STATHT= <i>value</i>	specifies height of text displayed in the margin

Dictionary of PLOT Statement Options

The following entries describe the PLOT statement *options* in detail. Note that these *options* are available unless you specify the LINEPRINTER option in the PROC REG statement.

AIC

displays Akaike's information criterion in the plot margin.

ANNOTATE=*SAS-data-set*

ANNO=*SAS-data-set*

specifies an input data set that contains appropriate variables for annotation. This applies only to displays created with the current PLOT statement. Refer to *SAS/GRAPH Software: Reference* for more information.

BIC

displays Sawa's Bayesian information criterion in the plot margin.

CAXIS=*color*

CAXES=*color*

CA=*color*

specifies the color for the axes, frame, and tick marks.

CFRAME=*color*

CFR=*color*

specifies the color for filling the area enclosed by the axes and the frame.

CHOCKING=*color*

requests reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{full}$, where p_{full} is the number of parameters in the full model (excluding the intercept) and p is the number of parameters in the subset model (including the intercept). The *color* must be specified; the $C_p = p$ line is solid and the $C_p = 2p - p_{full}$ line is dashed. Only PLOT statements of the form PLOT CP.*NP. produce these lines.

For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{full}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. You can request the single reference line $C_p = p$ with the CMALLOWS= option. If, for example, you specify both CHOCKING=RED and CMALLOWS=BLUE, then the $C_p = 2p - p_{full}$ line is red and the $C_p = p$ line is blue (see [Example 61.5](#) on page 3949).

CHREF=*color***CH=***color*

specifies the color for lines requested with the HREF= option.

CLINE=*color***CL=***color*

specifies the color for lines displayed by default. See the [NOLINE](#) option later in this section for details.

CMALLOWS=*color*

requests a $C_p = p$ reference line, where p is the number of parameters (including the intercept) in the subset model. The *color* must be specified; the line is solid. Only PLOT statements of the form PLOT CP.*NP. produce this line.

Mallows (1973) suggests that all subset models with C_p small and near p be considered for further study. See the [CHOCKING=](#) option for related model selection criteria.

CONF

is a keyword used as a shorthand option to request plots that include $(100 - \alpha)\%$ confidence intervals for the mean response (see [Example 61.9](#) on page 3955). The ALPHA= option in the PROC REG or MODEL statement selects the significance level α , which is 0.05 by default. The CONF option is valid for simple regression models only, and is ignored for plots where confidence intervals are inappropriate. The CONF option replaces the CONF95 option; however, the CONF95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the CONF option is specified.

CP

displays Mallows' C_p statistic in the plot margin.

CTEXT=*color***CT=***color*

specifies the color for text including tick mark labels, axis labels, the fitted model label and equation, the statistics displayed in the margin, and legends. (See [Example 61.6](#) on page 3950.)

CVREF=*color***CV=***color*

specifies the color for lines requested with the VREF= option.

DESCRIPTION='*string*'**DESC=**'*string*'

specifies a descriptive string, up to 40 characters, that appears in the description field of the PROC GREPLAY master menu.

EDF

displays the error degrees of freedom in the plot margin.

GMSEP

displays the estimated mean square error of prediction in the plot margin. Note that the estimate is calculated under the assumption that both independent and dependent variables have a multivariate normal distribution.

HAXIS=*values***HA=***values*

specifies tick mark values for the horizontal axis.

HREF=*values*

specifies where reference lines perpendicular to the horizontal axis are to appear.

IN

displays the number of regressors in the model (not including the intercept) in the plot margin.

JPdisplays the J_p statistic in the plot margin.**LEGEND=**LEGEND*n*specifies the LEGEND*n* statement to be used. The LEGEND*n* statement is a global graphics statement; refer to *SAS/GRAPH Software: Reference* for more information.**LHREF=***linetype***LH=***linetype*specifies the line style for lines requested with the HREF= option. The default *linetype* is 2. Note that LHREF=1 requests a solid line. Refer to *SAS/GRAPH Software: Reference* for a table of available line types.**LLINE=***linetype***LL=***linetype*specifies the line style for reference lines displayed by default; see the NOLINE option for details. The default *linetype* is 2. Note that LLINE=1 requests a solid line.**LVREF=***linetype***LV=***linetype*specifies the line style for lines requested with the VREF= option. The default *linetype* is 2. Note that LVREF=1 requests a solid line.**MODELFONT=***font*

specifies the font used for displaying the fitted model label and the fitted model equa-

tion. Refer to *SAS/GRAPH Software: Reference* for tables of software fonts.

MODELHT=*height*

specifies the text height for the fitted model label and the fitted model equation.

MODELLAB='*label*'

specifies the label to be displayed with the fitted model equation. By default, no label is displayed. If the label does not fit on one line, it is not displayed. See the explanation in the section “[Traditional High-Resolution Graphics Plots](#)” beginning on page 3840 for more information.

MSE

displays the mean squared error in the plot margin.

NAME='*string*'

specifies a descriptive string, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default *string* is REG.

NOLINE

suppresses the display of default reference lines. A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple regression model, then the fitted regression line is displayed by default. Default reference lines are not displayed if the OVERLAY option is specified.

NOMODEL

suppresses the display of the fitted model equation.

NOSTAT

suppresses the display of statistics in the plot margin. By default, the number of observations, R-square, adjusted R-square, and the root MSE are displayed.

NP

displays the number of regressors in the model including the intercept, if any, in the plot margin.

OVERLAY

overlays all plots specified in the PLOT statement from the same model on one set of axes. The variables for the first plot label the axes. The procedure automatically scales the axes to fit all of the variables unless the HAXIS= or VAXIS= option is used. Default reference lines are not displayed. A default legend is produced; the LEGEND= option can be used to customize the legend. See [Example 61.11](#) on page 3958.

PC

displays the PC statistic in the plot margin.

PRED

is a keyword used as a shorthand option to request plots that include $(100 - \alpha)\%$ prediction intervals for individual responses (see [Example 61.9](#) on page 3955). The ALPHA= option in the PROC REG or MODEL statement selects the significance level α , which is 0.05 by default. The PRED option is valid for simple regression models only, and is ignored for plots where prediction intervals are inappropriate.

The PRED option replaces the PRED95 option; however, the PRED95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the PRED option is specified.

RIDGEPLOT

creates overlaid plots of ridge estimates against ridge values for each coefficient. The points corresponding to the estimates of each coefficient in the plot are connected by lines. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the PROC REG statement, and the RIDGE= list must be specified in either the PROC REG or the MODEL statement. See [Example 61.10](#) on page 3956.

SBC

displays the SBC statistic in the plot margin.

SP

displays the S_p statistic in the plot margin.

SSE

displays the error sum of squares in the plot margin.

STATFONT=font

specifies the font used for displaying the statistics that appear in the plot margin. Refer to *SAS/GRAPH Software: Reference* for tables of software fonts.

STATHT=height

specifies the text height of the statistics that appear in the plot margin.

USEALL

specifies that predicted values at data points with missing dependent variable(s) are included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

VAXIS=values**VA=values**

specifies tick mark values for the vertical axis.

VREF=values

specifies where reference lines perpendicular to the vertical axis are to appear.

Line Printer Plots

Line printer plots are requested with the LINEPRINTER option in the PROC REG statement. Points in line printer plots can be marked with *symbols*, which can be specified as a single character enclosed in quotes or the name of any variable in the input data set.

If a character variable is used for the symbol, the first (left-most) nonblank character in the formatted value of the variable is used as the plotting symbol. If a character in quotes is specified, that character becomes the plotting symbol. If a character is used as the plotting symbol, and if there are different plotting symbols needed at the same point, the symbol '?' is used at that point.

If an unformatted numeric variable is used for the symbol, the symbols '1', '2', . . . , '9' are used for variable values 1, 2, . . . , 9. For noninteger values, only the integer

portion is used as the plotting symbol. For values of 10 or greater, the symbol '*' is used. For negative values, a '?' is used. If a numeric variable is used, and if there is more than one plotting symbol needed at the same point, the sum of the variable values is used at that point. If the sum exceeds 9, the symbol '*' is used.

If a symbol is not specified, the number of replicates at the point is displayed. The symbol '*' is used if there are ten or more replicates.

If the LINEPRINTER option is used, you can specify the following options in the PLOT statement after a slash (/):

CLEAR

clears any collected scatter plots before plotting begins but does not turn off the COLLECT option. Use this option when you want to begin a new collection with the plots in the current PLOT statement. For more information on collecting plots, see the [COLLECT](#) and [NOCOLLECT](#) options in this section.

COLLECT

specifies that plots begin to be collected from one PLOT statement to the next and that subsequent plots show an overlay of all collected plots. This option enables you to overlay plots before and after changes to the model or to the data used to fit the model. Plots collected before changes are unaffected by the changes and can be overlaid on later plots. You can request more than one plot with this option, and you do not need to request the same number of plots in subsequent PLOT statements. If you specify an unequal number of plots, plots in corresponding positions are overlaid. For example, the statements

```
plot residual.*predicted. y*x / collect;
run;
```

produce two plots. If these statements are then followed by

```
plot residual.*x;
run;
```

two plots are again produced. The first plot shows residual against X values overlaid on residual against predicted values. The second plot is the same as that produced by the first PLOT statement.

Axes are scaled for the first plot or plots collected. The axes are not rescaled as more plots are collected.

Once specified, the COLLECT option remains in effect until the [NOCOLLECT](#) option is specified.

HLOTS=*number*

sets the number of scatter plots that can be displayed across the page. The procedure begins with one plot per page. The value of the HLOTS= option remains in effect until you change it in a later PLOT statement. See the [VLOTS=](#) option for an example.

NOCOLLECT

specifies that the collection of scatter plots ends after adding the plots in the current PLOT statement. PROC REG starts with the NOCOLLECT option in effect. After you specify the NOCOLLECT option, any following PLOT statement produces a new plot that contains only the plots requested by that PLOT statement.

For more information, see the [COLLECT](#) option.

OVERLAY

allows requested scatter plots to be superimposed. The axes are scaled so that points on all plots are shown. If the HPLOTS= or VPLOTS= option is set to more than one, the overlaid plot occupies the first position on the page. The OVERLAY option is similar to the COLLECT option in that both options produce superimposed plots. However, OVERLAY superimposes only the plots in the associated PLOT statement; COLLECT superimposes plots across PLOT statements. The OVERLAY option can be used when the COLLECT option is in effect.

SYMBOL='character'

changes the default plotting symbol used for all scatter plots produced in the current and in subsequent PLOT statements. Both SYMBOL=" and SYMBOL=' ' are allowed.

If the SYMBOL= option has not been specified, the default symbol is '1' for positions with one observation, '2' for positions with two observations, and so on. For positions with more than 9 observations, '*' is used. The SYMBOL= option (or a plotting symbol) is needed to avoid any confusion caused by this default convention. Specifying a particular symbol is especially important when either the OVERLAY or COLLECT option is being used.

If you specify the SYMBOL= option and use a number for *character*, that number is used for all points in the plot. For example, the statement

```
plot y*x / symbol='1';
```

produces a plot with the symbol '1' used for all points.

If you specify a plotting symbol and the SYMBOL= option, the plotting symbol overrides the SYMBOL= option. For example, in the statements

```
plot y*x y*v='.' / symbol='*';
```

the symbol used for the plot of Y against X is '*', and a '.' is used for the plot of Y against V.

If a paint symbol is defined with a PAINT statement, the paint symbol takes precedence over both the SYMBOL= option and the default plotting symbol for the PLOT statement.

VPLOTS=number

sets the number of scatter plots that can be displayed down the page. The procedure begins with one plot per page. The value of the VPLOTS= option remains in effect until you change it in a later PLOT statement.

For example, to specify a total of six plots per page, with two rows of three plots, use the HPLOTS= and VPLOTS= options as follows:

```
plot y1*x1 y1*x2 y1*x3 y2*x1 y2*x2 y2*x3 /
      hplots=3 vplots=2;
run;
```

PRINT Statement

PRINT < options > < ANOVA > < MODELDATA > ;

The PRINT statement enables you to interactively display the results of MODEL statement options, produce an ANOVA table, display the data for variables used in the current model, or redisplay the options specified in a MODEL or a previous PRINT statement. In addition, like most other interactive statements in PROC REG, the PRINT statement implicitly refits the model; thus, effects of REWEIGHT statements are seen in the resulting tables. If the experimental ODS graphics are in effect (see the “[ODS Graphics](#)” section on page 3922), the PRINT statement also requests the display of the ODS graphics associated with the current model.

The following specifications can appear in the PRINT statement:

options interactively displays the results of MODEL statement options, where *options* is one or more of the following: ACOV, ALL, CLI, CLM, COLLIN, COLLINOINT, CORRB, COVB, DW, I, INFLUENCE, P, PARTIAL, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, or XPX. See the “[MODEL Statement](#)” section on page 3821 for a description of these options.

ANOVA produces the ANOVA table associated with the current model. This is either the model specified in the last MODEL statement or the model that incorporates changes made by ADD, DELETE or REWEIGHT statements after the last MODEL statement.

MODELDATA displays the data for variables used in the current model.

Use the statement

```
print;
```

to reprint options in the most recently specified PRINT or MODEL statement.

Options that require original data values, such as R or INFLUENCE, cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set to PROC REG. See the “[Input Data Sets](#)” section on page 3860 for more detail.

REFIT Statement

REFIT;

The REFIT statement causes the current model and corresponding statistics to be recomputed immediately. No output is generated by this statement. The REFIT statement is needed after one or more REWEIGHT statements to cause them to take effect before subsequent PAIN or REWEIGHT statements. This is sometimes necessary when you are using statistical conditions in REWEIGHT statements. For example, with these statements

```
paint student.>2;
plot student.*p.;
reweight student.>2;
refit;
paint student.>2;
plot student.*p.;
```

the second PAIN statement paints any additional observations that meet the condition after deleting observations and refitting the model. The REFIT statement is used because the REWEIGHT statement does not cause the model to be recomputed. In this particular example, the same effect could be achieved by replacing the REFIT statement with a PLOT statement.

Most interactive statements can be used to implicitly refit the model; any plots or statistics produced by these statements reflect changes made to the model and changes made to the data used to compute the model. The two exceptions are the PAIN and REWEIGHT statements, which do not cause the model to be recomputed.

RESTRICT Statement

RESTRICT *equation* < , ... , *equation* > ;

A RESTRICT statement is used to place restrictions on the parameter estimates in the MODEL preceding it. More than one RESTRICT statement can follow each MODEL statement. Each RESTRICT statement replaces any previous RESTRICT statement. To lift all restrictions on a model, submit a new MODEL statement. If there are several restrictions, separate them with commas. The statement

```
restrict equation1=equation2=equation3;
```

is equivalent to imposing the two restrictions

```
restrict equation1=equation2;
restrict equation2=equation3;
```

Each restriction is written as a linear equation and can be written as

equation

or

$$\text{equation} = \text{equation}$$

The form of each *equation* is

$$c_1 \times \text{variable}_1 \pm c_2 \times \text{variable}_2 \pm \cdots \pm c_n \times \text{variable}_n$$

where the c_j 's are constants and the *variable_j*'s are any regressor variables.

When no equal sign appears, the linear combination is set equal to zero. Each variable name mentioned must be a variable in the MODEL statement to which the RESTRICT statement refers. The keyword INTERCEPT can also be used as a variable name, and it refers to the intercept parameter in the regression model.

Note that the parameters associated with the variables are restricted, not the variables themselves. Restrictions should be consistent and not redundant.

Examples of valid RESTRICT statements include the following:

```
restrict x1;
restrict a+b=1;
restrict a=b=c;
restrict a=b, b=c;
restrict 2*f=g+h, intercept+f=0;
restrict f=g=h=intercept;
```

The third and fourth statements in this list produce identical restrictions. You cannot specify

```
restrict f-g=0,
        f-intercept=0,
        g-intercept=1;
```

because the three restrictions are not consistent. If these restrictions are included in a RESTRICT statement, one of the restrict parameters is set to zero and has zero degrees of freedom, indicating that PROC REG is unable to apply a restriction.

The restrictions usually operate even if the model is not of full rank. Check to ensure that $DF = -1$ for each restriction. In addition, the Model DF should decrease by 1 for each restriction.

The parameter estimates are those that minimize the quadratic criterion (SSE) subject to the restrictions. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as zero.

The method used for restricting the parameter estimates is to introduce a Lagrangian parameter for each restriction (Pringle and Raynor 1971). The estimates of these parameters are displayed with test statistics. Note that the t statistic reported for

the Lagrangian parameters does not follow a Student's t distribution, but its square follows a beta distribution (LaMotte 1994). The p -value for these parameters is computed using the beta distribution.

The Lagrangian parameter γ measures the sensitivity of the SSE to the restriction constant. If the restriction constant is changed by a small amount ϵ , the SSE is changed by $2\gamma\epsilon$. The t ratio tests the significance of the restrictions. If γ is zero, the restricted estimates are the same as the unrestricted estimates, and a change in the restriction constant in either direction increases the SSE.

RESTRICT statements are ignored if the PCOMIT= or RIDGE= option is specified in the PROC REG statement.

REWEIGHT Statement

REWEIGHT < *condition* | **ALLOBS** > < / *options* > ;

REWEIGHT < **STATUS** | **UNDO** > ;

The REWEIGHT statement interactively changes the weights of observations that are used in computing the regression equation. The REWEIGHT statement can change observation weights, or set them to zero, which causes selected observations to be excluded from the analysis. When a REWEIGHT statement sets observation weights to zero, the observations are not deleted from the data set. More than one REWEIGHT statement can be used. The requests from all REWEIGHT statements are applied to the subsequent statements. Each use of the REWEIGHT statement modifies the MODEL label.

The model and corresponding statistics are not recomputed after a REWEIGHT statement. For example, with the following statements

```
reweight r.>0;
reweight r.>0;
```

the second REWEIGHT statement does not exclude any additional observations since the model is not recomputed after the first REWEIGHT statement. Use either a [REFIT](#) statement to explicitly refit the model, or implicitly refit the model by following the REWEIGHT statement with any other interactive statement except a PAINT statement or another REWEIGHT statement.

The REWEIGHT statement cannot be used if a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to PROC REG. Note that the syntax used in the REWEIGHT statement is the same as the syntax in the PAINT statement.

The syntax of the REWEIGHT statement is described in the following sections. For detailed examples of using this statement see the section “[Reweighting Observations in an Analysis](#)” on page 3903.

Specifying Condition

Condition is used to find observations to be reweighted. The syntax of *condition* is

variable compare value

or

variable compare value logical variable compare value

where

variable is one of the following:

- a variable name in the input data set
- OBS, which is the observation number
- *keyword .*, where *keyword* is a keyword for a statistic requested in the OUTPUT statement. The keyword specification is applied to all dependent variables in the model.

compare is an operator that compares *variable* to *value*. *Compare* can be any one of the following: <, <=, >, >=, =, ^=. The operators LT, LE, GT, GE, EQ, and NE can be used instead of the preceding symbols. Refer to the “Expressions” chapter in *SAS Language Reference: Concepts* for more information on comparison operators.

value gives an unformatted value of *variable*. Observations are selected to be reweighted if they satisfy the condition created by *variable compare value*. *Value* can be a number or a character string. If *value* is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, *value* is case-sensitive. In other words, the following two statements are not the same:

```
reweight name='steve';
reweight name='Steve';
```

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Examples of the *variable compare value* form are

```
reweight obs. le 10;
reweight temp=55;
reweight type='new';
```

Examples of the *variable compare value logical variable compare value* form are

```
reweight obs.<=10 and residual.<2;
reweight student.<-2 or student.>2;
reweight name='Mary' | name='Susan';
```

Using ALLOBS

Instead of specifying *condition*, you can use the ALLOBS option to select all observations. This is most useful when you want to restore the original weights of all observations. For example,

```
reweight allobs / reset;
```

resets weights for all observations and uses all observations in the subsequent analysis. Note that

```
reweight allobs;
```

specifies that all observations be excluded from analysis. Consequently, using ALLOBS is useful only if you also use one of the options discussed in the following section.

Options in the REWEIGHT Statement

The following options can be used when either a condition, ALLOBS, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous REWEIGHT statement, not to the observations selected by reapplying the condition from the previous REWEIGHT statement. For example, with the statements

```
reweight r.>0 / weight=0.1;
refit;
reweight;
```

the second REWEIGHT statement excludes from the analysis only those observations selected in the first REWEIGHT statement. No additional observations are excluded even if there are new observations that meet the condition in the first REWEIGHT statement.

Note: Options are not available when either the UNDO or STATUS option is used.

NOLIST

suppresses the display of the selected observation numbers. If you omit the NOLIST option, a list of observations selected is written to the log.

RESET

resets the observation weights to their original values as defined by the WEIGHT statement or to WEIGHT=1 if no WEIGHT statement is specified. For example,

```
reweight / reset;
```

resets observation weights to the original weights in the data set. If previous REWEIGHT statements have been submitted, this REWEIGHT statement applies

only to the observations selected by the previous REWEIGHT statement. Note that, although the RESET option does reset observation weights to their original values, it does not cause the model and corresponding statistics to be recomputed.

WEIGHT=value

changes observation weights to the specified nonnegative real number. If you omit the WEIGHT= option, the observation weights are set to zero, and observations are excluded from the analysis. For example,

```
reweight name='Alan';
...other interactive statements
reweight / weight=0.5;
```

The first REWEIGHT statement changes weights to zero for all observations with name='Alan', effectively deleting these observations. The subsequent analysis does not include these observations. The second REWEIGHT statement applies only to those observations selected by the previous REWEIGHT statement, and it changes the weights to 0.5 for all the observations with NAME='Alan'. Thus, the next analysis includes all original observations; however, those observations with NAME='Alan' have their weights set to 0.5.

STATUS and UNDO

If you omit *condition* and the ALLOBS options, you can specify one of the following options.

STATUS

writes to the log the observation's number and the weight of all reweighted observations. If an observation's weight has been set to zero, it is reported as deleted. However, the observation is not deleted from the data set, only from the analysis.

UNDO

undoes the changes made by the most recent REWEIGHT statement. Weights may be, but are not necessarily, reset. For example, in these statements

```
reweight student.>2 / weight=0.1;
reweight;
reweight undo;
```

the first REWEIGHT statement sets the weights of observations that satisfy the condition to 0.1. The second REWEIGHT statement sets the weights of the same observations to zero. The third REWEIGHT statement undoes the second, changing the weights back to 0.1.

TEST Statement

`< label: > TEST equation < , ... , equation > < / options > ;`

The TEST statement tests hypotheses about the parameters estimated in the preceding MODEL statement. It has the same syntax as the RESTRICT statement except that it allows an option. Each equation specifies a linear hypothesis to be tested. The rows of the hypothesis are separated by commas.

Variable names must correspond to regressors, and each variable name represents the coefficient of the corresponding variable in the model. An optional label is useful to identify each test with a name. The keyword INTERCEPT can be used instead of a variable name to refer to the model's intercept.

The REG procedure performs an F test for the joint hypotheses specified in a single TEST statement. More than one TEST statement can accompany a MODEL statement. The numerator is the usual quadratic form of the estimates; the denominator is the mean squared error. If hypotheses can be represented by

$$\mathbf{L}\beta = \mathbf{c}$$

then the numerator of the F test is

$$\mathbf{Q} = (\mathbf{Lb} - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb} - \mathbf{c})$$

divided by degrees of freedom, where \mathbf{b} is the estimate of β . For example,

```
model y=a1 a2 b1 b2;
  aplus: test a1+a2=1;
  b1:    test b1=0, b2=0;
  b2:    test b1, b2;
```

The last two statements are equivalent; since no constant is specified, zero is assumed.

Note that, when the ACOV option is specified in the MODEL statement, tests are recomputed using the heteroscedasticity consistent covariance matrix (see the section “Testing for Heteroscedasticity” on page 3910).

One option can be specified in the TEST statement after a slash (/):

PRINT

displays intermediate calculations. This includes $\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}'$ bordered by $\mathbf{Lb} - \mathbf{c}$, and $(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}$ bordered by $(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{Lb} - \mathbf{c})$.

VAR Statement

VAR *variables* ;

The VAR statement is used to include numeric variables in the crossproducts matrix that are not specified in the first MODEL statement.

Variables not listed in MODEL statements before the first RUN statement must be listed in the VAR statement if you want the ability to add them interactively to the model with an ADD statement, to include them in a new MODEL statement, or to plot them in a scatter plot with the PLOT statement.

In addition, if you want to use options in the PROC REG statement and do not want to fit a model to the data (with a MODEL statement), you must use a VAR statement.

WEIGHT Statement

WEIGHT *variable* ;

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted least-squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation's weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the WEIGHT statement can be found in [Chapter 32, "The GLM Procedure."](#)

Observation weights can be changed interactively with the REWEIGHT statement; see the section "[REWEIGHT Statement](#)" beginning on page 3854.

Details

Missing Values

PROC REG constructs only one crossproducts matrix for the variables in all regressions. If any variable needed for any regression is missing, the observation is excluded from all estimates. If you include variables with missing values in the VAR statement, the corresponding observations are excluded from all analyses, even if you never include the variables in a model. PROC REG assumes that you may want to include these variables after the first RUN statement and deletes observations with missing values.

Input Data Sets

PROC REG does not compute new regressors. For example, if you want a quadratic term in your model, you should create a new variable when you prepare the input data. For example, the statement

```
model y=x1 x1*x1;
```

is not valid. Note that this MODEL statement is valid in the GLM procedure.

The input data set for most applications of PROC REG contains standard rectangular data, but special TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets can also be used. TYPE=CORR and TYPE=COV data sets created by the CORR procedure contain means and standard deviations. In addition, TYPE=CORR data sets contain correlations and TYPE=COV data sets contain covariances. TYPE=SSCP data sets created in previous runs of PROC REG that used the OUTSSCP= option contain the sums of squares and crossproducts of the variables. See [Appendix A, “Special SAS Data Sets,”](#) and the “SAS Files” section in *SAS Language Reference: Concepts* for more information on special SAS data sets.

These summary files save CPU time. It takes nk^2 operations (where n =number of observations and k =number of variables) to calculate crossproducts; the regressions are of the order k^3 . When n is in the thousands and k is less than 10, you can save 99 percent of the CPU time by reusing the SSCP matrix rather than recomputing it.

When you want to use a special SAS data set as input, PROC REG must determine the TYPE for the data set. PROC CORR and PROC REG automatically set the type for their output data sets. However, if you create the data set by some other means (such as a DATA step) you must specify its type with the TYPE= data set option. If the TYPE for the data set is not specified when the data set is created, you can specify TYPE= as a data set option in the DATA= option in the PROC REG statement. For example,

```
proc reg data=a(type=corr);
```

When TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used with PROC REG, statements and options that require the original data values have no effect. The OUTPUT, PAIN, PLOT, and REWEIGHT statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, INFLUENCE, and PARTIAL are disabled since the original observations needed to calculate predicted and residual values are not present.

Example Using TYPE=CORR Data Set

This example uses PROC CORR to produce an input data set for PROC REG. The fitness data for this analysis can be found in [Example 61.1](#) on page 3924.

```
proc corr data=fitness outp=r noprint;
  var Oxygen RunTime Age Weight RunPulse MaxPulse RestPulse;
```

```

proc print data=r;
proc reg data=r;
    model Oxygen=RunTime Age Weight;
run;

```

Since the OUTP= data set from PROC CORR is automatically set to TYPE=CORR, the TYPE= data set option is not required in this example. The data set containing the correlation matrix is displayed by the PRINT procedure as shown in [Figure 61.12](#). [Figure 61.13](#) shows results from the regression using the TYPE=CORR data as an input data set.

Figure 61.13. Regression on TYPE=CORR Data Set

Example Using TYPE=SSCP Data Set

The following example uses the saved crossproducts matrix:

```
proc reg data=fitness outsscp=sscp noprint;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse;
proc print data=sscp;
proc reg data=sscp;
  model Oxygen=RunTime Age Weight;
run;
```

First, all variables are used to fit the data and create the SSCP data set. [Figure 61.14](#) shows the PROC PRINT display of the SSCP data set. The SSCP data set is then used as the input data set for PROC REG, and a reduced model is fit to the data. [Figure 61.15](#) also shows the PROC REG results for the reduced model. (For the PROC REG results for the full model, see [Figure 61.27](#) on page 3877.)

In the preceding example, the TYPE= data set option is not required since PROC REG sets the OUTSSCP= data set to TYPE=SSCP.

Figure 61.15. Regression on TYPE=SSCP Data Set

Output Data Sets

OUTEST= Data Set

The OUTEST= specification produces a TYPE=EST output SAS data set containing estimates and optional statistics from the regression models. For each BY group on each dependent variable occurring in each MODEL statement, PROC REG outputs an observation to the OUTEST= data set. The variables output to the data set are as follows:

- the BY variables, if any
- `_MODEL_`, a character variable containing the label of the corresponding MODEL statement, or `MODEL n` if no label is specified, where n is 1 for the first MODEL statement, 2 for the second model statement, and so on
- `_TYPE_`, a character variable with the value 'PARMS' for every observation
- `_DEPVAR_`, the name of the dependent variable
- `_RMSE_`, the root mean squared error or the estimate of the standard deviation of the error term
- `Intercept`, the estimated intercept, unless the NOINT option is specified
- all the variables listed in any MODEL or VAR statement. Values of these variables are the estimated regression coefficients for the model. A variable

that does not appear in the model corresponding to a given observation has a missing value in that observation. The dependent variable in each model is given a value of -1 .

If you specify the COVOUT option, the covariance matrix of the estimates is output after the estimates; the `_TYPE_` variable is set to the value 'COV' and the names of the rows are identified by the 8-byte character variable, `_NAME_`.

If you specify the TABLEOUT option, the following statistics listed by `_TYPE_` are added after the estimates:

- STDERR, the standard error of the estimate
- T, the t statistic for testing if the estimate is zero
- PVALUE, the associated p -value
- LnB, the $100(1 - \alpha)$ lower confidence for the estimate, where n is the nearest integer to $100(1 - \alpha)$ and α defaults to 0.05 or is set using the ALPHA= option in the PROC REG or MODEL statement
- UnB, the $100(1 - \alpha)$ upper confidence for the estimate

Specifying the option ADJRSQ, AIC, BIC, CP, EDF, GMSEP, JP, MSE, PC, RSQUARE, SBC, SP, or SSE in the PROC REG or MODEL statement automatically outputs these statistics and the model R^2 for each model selected, regardless of the model selection method. Additional variables, in order of occurrence, are as follows.

- `_IN_`, the number of regressors in the model not including the intercept
- `_P_`, the number of parameters in the model including the intercept, if any
- `_EDF_`, the error degrees of freedom
- `_SSE_`, the error sum of squares, if the SSE option is specified
- `_MSE_`, the mean squared error, if the MSE option is specified
- `_RSQ_`, the R^2 statistic
- `_ADJRSQ_`, the adjusted R^2 , if the ADJRSQ option is specified
- `_CP_`, the C_p statistic, if the CP option is specified
- `_SP_`, the S_p statistic, if the SP option is specified
- `_JP_`, the J_p statistic, if the JP option is specified
- `_PC_`, the PC statistic, if the PC option is specified
- `_GMSEP_`, the GMSEP statistic, if the GMSEP option is specified
- `_AIC_`, the AIC statistic, if the AIC option is specified
- `_BIC_`, the BIC statistic, if the BIC option is specified
- `_SBC_`, the SBC statistic, if the SBC option is specified

The following is an example with a display of the OUTEST= data set. This example uses the population data given in the section “Polynomial Regression” beginning on page 3804. Figure 61.16 on page 3865 through Figure 61.18 on page 3866 show the regression equations and the resulting OUTEST= data set.

```
proc reg data=USPopulation outest=est;
  m1: model Population=Year;
  m2: model Population=Year YearSq;
proc print data=est;
run;
```

Figure 61.18. OUTEST= Data Set

The following modification of the previous example uses the TABLEOUT and ALPHA= options to obtain additional information in the OUTEST= data set:

```
proc reg data=USPopulation outest=est tableout alpha=0.1;
  m1: model Population=Year/noprint;
  m2: model Population=Year YearSq/noprint;
proc print data=est;
run;
```

Notice that the TABLEOUT option causes standard errors, t statistics, p -values, and confidence limits for the estimates to be added to the OUTEST= data set. Also note that the ALPHA= option is used to set the confidence level at 90%. The OUTEST= data set follows.

Obs	MODEL	TYPE	DEPVAR	RMSE	Intercept	Year	Population	YearSq

Figure 61.19. The OUTEST= Data Set When TABLEOUT is Specified

A slightly different OUTEST= data set is created when you use the RSQUARE selection method. This example requests only the “best” model for each subset size but asks for a variety of model selection statistics, as well as the estimated regression coefficients. An OUTEST= data set is created and displayed. See [Figure 61.20](#) and [Figure 61.21](#) for results.

```
proc reg data=fitness outest=est;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=rsquare mse jp gmsep cp aic bic sbc b best=1;
proc print data=est;
run;
```

Figure 61.21. PROC PRINT Output for Physical Fitness Data: OUTEST= Data Set

OUTSSCP= Data Sets

The OUTSSCP= option produces a TYPE=SSCP output SAS data set containing sums of squares and crossproducts. A special row (observation) and column (variable) of the matrix called Intercept contain the number of observations and sums.

Observations are identified by the character variable `_NAME_`. The data set contains all variables used in MODEL statements. You can specify additional variables that you want included in the crossproducts matrix with a VAR statement.

The SSCP data set is used when a large number of observations are explored in many different runs. The SSCP data set can be saved and used for subsequent runs, which are much less expensive since PROC REG never reads the original data again. If you run PROC REG once to create only a SSCP data set, you should list all the variables that you may need in a VAR statement or include all the variables that you may need in a MODEL statement.

The following example uses the fitness data from [Example 61.1](#) on page 3924 to produce an output data set with the `OUTSSCP=` option. The resulting output is shown in [Figure 61.22](#).

```
proc reg data=fitness outsscp=sscp;
    var Oxygen RunTime Age Weight RestPulse RunPulse MaxPulse;
proc print data=sscp;
run;
```

Since a model is not fit to the data and since the only request is to create the SSCP data set, a MODEL statement is not required in this example. However, since the MODEL statement is not used, the VAR statement is required.

Figure 61.22. SSCP Data Set Created with `OUTSSCP=` Option: REG Procedure

Interactive Analysis

PROC REG enables you to change interactively both the model and the data used to compute the model, and to produce and highlight scatter plots. See the section [“Using PROC REG Interactively”](#) on page 3812 for an overview of interactive analysis using PROC REG. The following statements can be used interactively (without reinvoking PROC REG): ADD, DELETE, MODEL, MTEST, OUTPUT, PAINT, PLOT, PRINT, REFIT, RESTRICT, REWEIGHT, and TEST. All interactive features are disabled if there is a BY statement.

The ADD, DELETE and REWEIGHT statements can be used to modify the current MODEL. Every use of an ADD, DELETE or REWEIGHT statement causes the model label to be modified by attaching an additional number to it. This number

is the cumulative total of the number of ADD, DELETE or REWEIGHT statements following the current MODEL statement.

A more detailed explanation of changing the data used to compute the model is given in the section “[Reweighting Observations in an Analysis](#)” on page 3903. Extra features for line printer scatter plots are discussed in the section “[Line Printer Scatter Plot Features](#)” on page 3882.

The following example illustrates the usefulness of the interactive features. First, the full regression model is fit to the class data (see the “[Getting Started](#)” section on page 3800), and [Figure 61.23](#) is produced.

```
proc reg data=Class;
  model Weight=Age Height;
run;
```

The REG Procedure					
Model: MODEL1					
Dependent Variable: Weight

Figure 61.24. Interactive Analysis: Reduced Model

Note that the MODEL label has been changed from MODEL1 to MODEL1.1, as the original MODEL has been changed by the delete statement.

The following statements generate a scatter plot of the residuals against the predicted values from the full model. [Figure 61.25](#) is produced, and the scatter plot shows a possible outlier.

```
add age;
plot r.*p. / cframe=ligr;
run;
```

Figure 61.25. Interactive Analysis: Scatter Plot

The following statements delete the observation with the largest residual, refit the regression model, and produce a scatter plot of residuals against predicted values for the refitted model. [Figure 61.26](#) shows the new scatter plot.

```
reweight r.>20;
plot / cframe=ligr;
run;
```

Figure 61.26. Interactive Analysis: Scatter Plot for Refitted Model

Model-Selection Methods

The nine methods of model selection implemented in PROC REG are specified with the SELECTION= option in the MODEL statement. Each method is discussed in this section.

Full Model Fitted (NONE)

This method is the default and provides no model selection capability. The complete model specified in the MODEL statement is used to fit the model. For many regression analyses, this may be the only method you need.

Forward Selection (FORWARD)

The forward-selection technique begins with no variables in the model. For each of the independent variables, the FORWARD method calculates F statistics that reflect the variable's contribution to the model if it is included. The p -values for these F statistics are compared to the SLENTY= value that is specified in the MODEL statement (or to 0.50 if the SLENTY= option is omitted). If no F statistic has a significance level greater than the SLENTY= value, the FORWARD selection stops. Otherwise, the FORWARD method adds the variable that has the largest F statistic to the model. The FORWARD method then calculates F statistics again for the variables still remaining outside the model, and the evaluation process is repeated. Thus, variables are added one by one to the model until no remaining variable produces a significant F statistic. Once a variable is in the model, it stays.

Backward Elimination (BACKWARD)

The backward elimination technique begins by calculating F statistics for a model, including all of the independent variables. Then the variables are deleted from the model one by one until all the variables remaining in the model produce F statistics significant at the SLSTAY= level specified in the MODEL statement (or at the 0.10 level if the SLSTAY= option is omitted). At each step, the variable showing the smallest contribution to the model is deleted.

Stepwise (STEPWISE)

The stepwise method is a modification of the forward-selection technique and differs in that variables already in the model do not necessarily stay there. As in the forward-selection method, variables are added one by one to the model, and the F statistic for a variable to be added must be significant at the SLENTY= level. After a variable is added, however, the stepwise method looks at all the variables already included in the model and deletes any variable that does not produce an F statistic significant at the SLSTAY= level. Only after this check is made and the necessary deletions accomplished can another variable be added to the model. The stepwise process ends when none of the variables outside the model has an F statistic significant at the SLENTY= level and every variable in the model is significant at the SLSTAY= level, or when the variable to be added to the model is the one just deleted from it.

Maximum R^2 Improvement (MAXR)

The maximum R^2 improvement technique does not settle on a single model. Instead, it tries to find the “best” one-variable model, the “best” two-variable model, and so forth, although it is not guaranteed to find the model with the largest R^2 for each size.

The MAXR method begins by finding the one-variable model producing the highest R^2 . Then another variable, the one that yields the greatest increase in R^2 , is added. Once the two-variable model is obtained, each of the variables in the model is compared to each variable not in the model. For each comparison, the MAXR method determines if removing one variable and replacing it with the other variable increases R^2 . After comparing all possible switches, the MAXR method makes the switch that produces the largest increase in R^2 . Comparisons begin again, and the process continues until the MAXR method finds that no switch could increase R^2 . Thus, the two-variable model achieved is considered the “best” two-variable model the technique can find. Another variable is then added to the model, and the comparing-and-switching process is repeated to find the “best” three-variable model, and so forth.

The difference between the STEPWISE method and the MAXR method is that all switches are evaluated before any switch is made in the MAXR method. In the STEPWISE method, the “worst” variable may be removed without considering what adding the “best” remaining variable might accomplish. The MAXR method may require much more computer time than the STEPWISE method.

Minimum R^2 (MINR) Improvement

The MINR method closely resembles the MAXR method, but the switch chosen is the one that produces the smallest increase in R^2 . For a given number of variables in the model, the MAXR and MINR methods usually produce the same “best” model, but the MINR method considers more models of each size.

R^2 Selection (RSQUARE)

The RSQUARE method finds subsets of independent variables that best predict a dependent variable by linear regression in the given sample. You can specify the largest and smallest number of independent variables to appear in a subset and the number of subsets of each size to be selected. The RSQUARE method can efficiently perform all possible subset regressions and display the models in decreasing order of R^2 magnitude within each subset size. Other statistics are available for comparing subsets of different sizes. These statistics, as well as estimated regression coefficients, can be displayed or output to a SAS data set.

The subset models selected by the RSQUARE method are optimal in terms of R^2 for the given sample, but they are not necessarily optimal for the population from which the sample is drawn or for any other sample for which you may want to make predictions. If a subset model is selected on the basis of a large R^2 value or any other criterion commonly used for model selection, then all regression statistics computed for that model under the assumption that the model is given a priori, including all statistics computed by PROC REG, are biased.

While the RSQUARE method is a useful tool for exploratory model building, no statistical method can be relied on to identify the “true” model. Effective model building requires substantive theory to suggest relevant predictors and plausible functional forms for the model.

The RSQUARE method differs from the other selection methods in that RSQUARE always identifies the model with the largest R^2 for each number of variables considered. The other selection methods are not guaranteed to find the model with the largest R^2 . The RSQUARE method requires much more computer time than the other selection methods, so a different selection method such as the STEPWISE method is a good choice when there are many independent variables to consider.

Adjusted R^2 Selection (ADJRSQ)

This method is similar to the RSQUARE method, except that the adjusted R^2 statistic is used as the criterion for selecting models, and the method finds the models with the highest adjusted R^2 within the range of sizes.

Mallows' C_p Selection (CP)

This method is similar to the ADJRSQ method, except that Mallows' C_p statistic is used as the criterion for model selection. Models are listed in ascending order of C_p .

Additional Information on Model-Selection Methods

If the RSQUARE or STEPWISE procedure (as documented in *SAS User's Guide: Statistics, Version 5 Edition*) is requested, PROC REG with the appropriate model-selection method is actually used.

Reviews of model-selection methods by Hocking (1976) and Judge et al. (1980) describe these and other variable-selection methods.

Criteria Used in Model-Selection Methods

When many significance tests are performed, each at a level of, for example, 5 percent, the overall probability of rejecting at least one true null hypothesis is much larger than 5 percent. If you want to guard against including any variables that do not contribute to the predictive power of the model in the population, you should specify a very small SLE= significance level for the FORWARD and STEPWISE methods and a very small SLS= significance level for the BACKWARD and STEPWISE methods.

In most applications, many of the variables considered have some predictive power, however small. If you want to choose the model that provides the best prediction using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size, so you should use a moderate significance level, perhaps in the range of 10 percent to 25 percent.

In addition to R^2 , the C_p statistic is displayed for each model generated in the model-selection methods. The C_p statistic is proposed by Mallows (1973) as a criterion for selecting a model. It is a measure of total squared error defined as

$$C_p = \frac{SSE_p}{s^2} - (N - 2p)$$

where s^2 is the MSE for the full model, and SSE_p is the sum-of-squares error for a model with p parameters including the intercept, if any. If C_p is plotted against p , Mallows recommends the model where C_p first approaches p . When the right model is chosen, the parameter estimates are unbiased, and this is reflected in C_p near p . For further discussion, refer to Daniel and Wood (1980).

The Adjusted R^2 statistic is an alternative to R^2 that is adjusted for the number of parameters in the model. The adjusted R^2 statistic is calculated as

$$\text{ADJRSQ} = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where n is the number of observations used in fitting the model, and i is an indicator variable that is 1 if the model includes an intercept, and 0 otherwise.

Limitations in Model-Selection Methods

The use of model-selection methods can be time-consuming in some cases because there is no built-in limit on the number of independent variables, and the calculations for a large number of independent variables can be lengthy. The recommended limit on the number of independent variables for the MINR method is $20 + i$, where i is the value of the INCLUDE= option.

For the RSQUARE, ADJRSQ, or CP methods, with a large value of the BEST= option, adding one more variable to the list from which regressors are selected may significantly increase the CPU time. Also, the time required for the analysis is highly dependent on the data and on the values of the BEST=, START=, and STOP= options.

Parameter Estimates and Associated Statistics

The following example uses the fitness data from [Example 61.1](#) on page 3924. [Figure 61.28](#) shows the parameter estimates and the tables from the SS1, SS2, STB, CLB, COVB, and CORRB options:

```
proc reg data=fitness;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
    / ss1 ss2 stb clb covb corrb;
run;
```

The procedure first displays an Analysis of Variance table ([Figure 61.27](#)). The F statistic for the overall model is significant, indicating that the model explains a significant portion of the variation in the data.

The REG Procedure						
Model: MODEL1						
Dependent Variable: Oxygen						
Analysis of Variance						
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F	
Model	6	722.54361	120.42393	22.43	<.0001	
Error	24	128.83794	5.36825

Root MSE		2.31695	R-Square	0.8487		
Dependent Mean		47.37581	Adj R-Sq	0.8108		
Coeff Var		4.89057				

Figure 61.27. ANOVA Table

The procedure next displays Parameter Estimates and some associated statistics ([Figure 61.28](#)). First, the estimates are shown, followed by their Standard Errors. The next two columns of the table contain the t statistics and the corresponding probabilities for testing the null hypothesis that the parameter is not significantly different

from zero. These probabilities are usually referred to as p -values. For example, the Intercept term in the model is estimated to be 102.9 and is significantly different from zero. The next two columns of the table are the result of requesting the SS1 and SS2 options, and they show sequential and partial Sums of Squares (SS) associated with each variable. The Standardized Estimates (produced by the STB option) are the parameter estimates that result when all variables are standardized to a mean of 0 and a variance of 1. These estimates are computed by multiplying the original estimates by the standard deviation of the regressor (independent) variable and then dividing by the standard deviation of the dependent variable. The CLB option adds the upper and lower 95% confidence limits for the parameter estimates; the α level can be changed by specifying the ALPHA= option in the PROC REG or MODEL statement.

Figure 61.29. SS1, SS2, STB, CLB, COVB, and CORRB Options: Covariances and Correlations

For further discussion of the parameters and statistics, see the “Displayed Output” section on page 3918, and Chapter 2, “Introduction to Regression Procedures.”

Predicted and Residual Values

The display of the predicted values and residuals is controlled by the P, R, CLM, and CLI options in the MODEL statement. The P option causes PROC REG to display the observation number, the ID value (if an ID statement is used), the actual value, the predicted value, and the residual. The R, CLI, and CLM options also produce the items under the P option. Thus, P is unnecessary if you use one of the other options.

The R option requests more detail, especially about the residuals. The standard errors of the mean predicted value and the residual are displayed. The studentized residual, which is the residual divided by its standard error, is both displayed and plotted. A measure of influence, Cook’s *D*, is displayed. Cook’s *D* measures the change to the estimates that results from deleting each observation (Cook 1977, 1979). This statistic is very similar to DFFITS.

The CLM option requests that PROC REG display the $100(1 - \alpha)\%$ lower and upper confidence limits for the mean predicted values. This accounts for the variation due to estimating the parameters only. If you want a $100(1 - \alpha)\%$ confidence interval for observed values, then you can use the CLI option, which adds in the variability of the error term. The α level can be specified with the ALPHA= option in the PROC REG or MODEL statement.

You can use these statistics in PLOT and PAINT statements. This is useful in performing a variety of regression diagnostics. For definitions of the statistics produced

by these options, see Chapter 2, “Introduction to Regression Procedures.”

The following example uses the US population data found on the section “Polynomial Regression” beginning on page 3804.

```
data USPop2;
  input Year @@;
  YearSq=Year*Year;
  datalines;
2010 2020 2030
;
data USPop2;
  set USPopulation USPop2;

proc reg data=USPop2;
  id Year;
  model Population=Year YearSq / r cli clm;
run;
```

Figure 61.31. Regression Using the R, CLI, and CLM Options

After producing the usual Analysis of Variance and Parameter Estimates tables

(Figure 61.30), the procedure displays the results of requesting the options for predicted and residual values (Figure 61.31). For each observation, the requested information is shown. Note that the ID variable is used to identify each observation. Also note that, for observations with missing dependent variables, the predicted value, standard error of the predicted value, and confidence intervals for the predicted value are still available.

The plot of studentized residuals and Cook's D statistics are displayed as a result of requesting the R option. In the plot of studentized residuals, a large number of observations with absolute values greater than two indicates an inadequate model. A version of the studentized residual plot can be created on a high-resolution graphics device; see Example 61.7 on page 3952 for a similar example.

Line Printer Scatter Plot Features

This section discusses the special options available with line printer scatter plots. Detailed examples of high resolution graphics plots and options are given in Example 61.6 on page 3950.

Producing Scatter Plots

The interactive PLOT statement available in PROC REG enables you to look at scatter plots of data and diagnostic statistics. These plots can help you to evaluate the model and detect outliers in your data. Several options enable you to place multiple plots on a single page, superimpose plots, and collect plots to be overlaid by later plots. The PAINTE statement can be used to highlight points on a plot. See the section “Painting Scatter Plots” on page 3889 for more information on painting.

The Class data set introduced in is used in the following examples.

You can superimpose several plots with the OVERLAY option. With the following statements, a plot of Weight against Height is overlaid with plots of the predicted values and the 95% prediction intervals. The model on which the statistics are based is the full model including Height and Age. These statements produce Figure 61.32:

```
proc reg data=Class lineprinter;
  model Weight=Height Age / noprint;
  plot (ucl. lcl. p.)*Height='-' Weight*Height
      / overlay symbol='o';
run;
```

Figure 61.32. Scatter Plot Showing Data, Predicted Values, and Confidence Limits

In this plot, the data values are marked with the symbol 'o' and the predicted values and prediction interval limits are labeled with the symbol '-'. The plot is scaled to accommodate the points from all plots. This is an important difference from the COLLECT option, which does not rescale plots after the first plot or plots are collected. You could separate the overlaid plots by using the following statements:

```
plot;
run;
```

This places each of the four plots on a separate page, while the statements

```
plot / overlay;  
run;
```

repeat the previous overlaid plot. In general, the statement

```
plot;
```

is equivalent to respecifying the most recent PLOT statement without any options. However, the COLLECT, HPLOTS=, SYMBOL=, and VPLOTS= options apply across PLOT statements and remain in effect.

The next example shows how you can overlay plots of statistics before and after a change in the model. For the full model involving Height and Age, the ordinary residuals and the studentized residuals are plotted against the predicted values. The COLLECT option causes these plots to be collected or retained for re-display later. The option HPLOTS=2 allows the two plots to appear side by side on one page. The symbol 'f' is used on these plots to identify them as resulting from the full model. These statements produce [Figure 61.33](#):

```
plot r.*p. student.*p. / collect hplots=2 symbol='f';  
run;
```

Figure 61.33. Collecting Residual Plots for the Full Model

Note that these plots are not overlaid. The COLLECT option does not overlay the plots in one PLOT statement but retains them so that they can be overlaid by later plots. When the COLLECT option appears in a PLOT statement, the plots in that statement become the first plots in the collection.

Next, the model is reduced by deleting the *Age* variable. The PLOT statement requests the same plots as before but labels the points with the symbol 'r' denoting the reduced model. The following statements produce [Figure 61.34](#):

```
delete Age;
plot r.*p. student.*p. / symbol='r';
run;
```

The previous example overlays the residual plots for two different models. You may prefer to see them side by side on the same page. This can also be done with the COLLECT option by using a blank plot. Continuing from the last example, the COLLECT, HPLOTS=2, and SYMBOL='r' options are still in effect. In the following PLOT statement, the CLEAR option deletes the collected plots and allows the specified plot to begin a new collection. The plot created is the residual plot for the reduced model. These statements produce [Figure 61.35](#):

```
plot r.*p. / clear;
run;
```

Figure 61.35. Residual Plot for Reduced Model Only

The next statements add the variable AGE to the model and place the residual plot for the full model next to the plot for the reduced model. Notice that a blank plot is created in the first plot request by placing nothing between the quotes. Since the COLLECT option is in effect, this plot is superimposed on the residual plot for the reduced model. The residual plot for the full model is created by the second request. The result is the desired side-by-side plots. The NOCOLLECT option turns off the collection process after the specified plots are added and displayed. Any PLOT statements that follow show only the newly specified plots. These statements produce [Figure 61.36](#):

```
add Age;  
plot r.*p.=' r.*p.='f' / nocollect;  
run;
```

Figure 61.36. Side-by-Side Residual Plots for the Full and Reduced Models

Frequently, when the COLLECT option is in effect, you want the current and following PLOT statements to show only the specified plots. To do this, use both the CLEAR and NOCOLLECT options in the current PLOT statement.

Painting Scatter Plots

Painting scatter plots is a useful interactive tool that enables you to mark points of interest in scatter plots. Painting can be used to identify extreme points in scatter plots or to reveal the relationship between two scatter plots. The CLASS data (from the “Simple Linear Regression” section on page 3800) is used to illustrate some of these applications. First, a scatter plot of the studentized residuals against the predicted values is generated. This plot is shown in Figure 61.37.

```

proc reg data=Class lineprinter;
  model Weight=Age Height / noprint;
  plot student.*p.;
run;

```

Figure 61.37. Plotting Studentized Residuals Against Predicted Values

Then, the following statements identify the observation 'Henry' in the scatter plot and produce [Figure 61.38](#):

```

paint Name='Henry' / symbol = 'H';
plot;
run;

```

Figure 61.40. Painting Observations on More than One Plot

Models of Less Than Full Rank

If the model is not full rank, there are an infinite number of least-squares solutions for the estimates. PROC REG chooses a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This solution corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of \mathbf{X} multiplied by the true parameters:

$$E(\mathbf{b}) = (\mathbf{X}'\mathbf{X})^{-}(\mathbf{X}'\mathbf{X})\beta$$

Degrees of freedom for the zeroed estimates are reported as zero. The hypotheses that are not testable have t tests reported as missing. The message that the model is not full rank includes a display of the relations that exist in the matrix.

The next example uses the fitness data from [Example 61.1](#) on page 3924. The variable `Dif=RunPulse-RestPulse` is created. When this variable is included in the model along with `RunPulse` and `RestPulse`, there is a linear dependency (or exact collinearity) between the independent variables. [Figure 61.41](#) shows how this problem is diagnosed.

```
data fit2;
  set fitness; Dif=RunPulse-RestPulse;
proc reg data=fit2;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse Dif;
run;
```

The REG Procedure					
Model: MODEL1					
Dependent Variable: Oxygen					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	6	722.54361	120.42393	22.43	<.0001
Error	24	128.83794	5.36825		
Corrected Total	30	851.38154			
		Root MSE	2.31695	R-Square	0.8487
		Dependent Mean	47.37581	Adj R-Sq	0.8108
		Coeff Var	4.89057		
NOTE: Model is not full rank. Least-squares solutions for the parameters are not unique. Some statistics will be misleading. A reported DF of 0 or B means that the estimate is biased.					
NOTE: The following parameters have been set to 0, since the variables are a linear combination of other variables as shown.					
Dif = RunPulse - RestPulse

Dif	0	0	.	.	.

Figure 61.41. Model That Is Not Full Rank: REG Procedure

PROC REG produces a message informing you that the model is less than full rank. Parameters with DF=0 are not estimated, and parameters with DF=B are biased. In addition, the form of the linear dependency among the regressors is displayed.

Collinearity Diagnostics

When a regressor is nearly a linear combination of other regressors in the model, the affected estimates are unstable and have high standard errors. This problem is called *collinearity* or *multicollinearity*. It is a good idea to find out which variables are nearly collinear with which other variables. The approach in PROC REG follows that of Belsley, Kuh, and Welsch (1980). PROC REG provides several methods for detecting collinearity with the COLLIN, COLLINOINT, TOL, and VIF options.

The COLLIN option in the MODEL statement requests that a collinearity analysis be performed. First, $\mathbf{X}'\mathbf{X}$ is scaled to have 1s on the diagonal. If you specify the COLLINOINT option, the intercept variable is adjusted out first. Then the eigenvalues and eigenvectors are extracted. The analysis in PROC REG is reported with eigenvalues of $\mathbf{X}'\mathbf{X}$ rather than singular values of \mathbf{X} . The eigenvalues of $\mathbf{X}'\mathbf{X}$ are the squares of the singular values of \mathbf{X} .

The condition indices are the square roots of the ratio of the largest eigenvalue to each individual eigenvalue. The largest condition index is the condition number of the scaled \mathbf{X} matrix. Belsley, Kuh, and Welsch (1980) suggest that, when this number is around 10, weak dependencies may be starting to affect the regression estimates. When this number is larger than 100, the estimates may have a fair amount of numerical error (although the statistical standard error almost always is much greater than the numerical error).

For each variable, PROC REG produces the proportion of the variance of the estimate accounted for by each principal component. A collinearity problem occurs when a component associated with a high condition index contributes strongly (variance proportion greater than about 0.5) to the variance of two or more variables.

The VIF option in the MODEL statement provides the Variance Inflation Factors (VIF). These factors measure the inflation in the variances of the parameter estimates due to collinearities that exist among the regressor (independent) variables. There are no formal criteria for deciding if a VIF is large enough to affect the predicted values.

The TOL option requests the tolerance values for the parameter estimates. The tolerance is defined as $1/VIF$.

For a complete discussion of the preceding methods, refer to Belsley, Kuh, and Welsch (1980). For a more detailed explanation of using the methods with PROC REG, refer to Freund and Littell (1986).

This example uses the COLLIN option on the fitness data found in [Example 61.1](#) on page 3924. The following statements produce [Figure 61.42](#).

```
proc reg data=fitness;
    model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
        / tol vif collin;
run;

Model Fit and Diagnostic Statistics

This section gathers the formulas for the statistics available in the MODEL, PLOT, and OUTPUT statements. The model to be fit is $Y = X\beta + \epsilon$, and the parameter estimate is denoted by $b = (X'X)^{-1}X'Y$. The subscript i denotes values for the i th observation, the parenthetical subscript (i) means that the statistic is computed using all observations except the i th observation, and the subscript jj indicates the j th diagonal matrix entry. The ALPHA= option in the PROC REG or MODEL statement is used to set the α value for the t statistics.

Table 61.6 contains the summary statistics for assessing the fit of the model.

Table 61.6. Formulas and Definitions for Model Fit Summary Statistics

MODEL Option or Statistic	Definition or Formula
n	the number of observations
p	the number of parameters including the intercept
i	1 if there is an intercept, 0 otherwise
$\hat{\sigma}^2$	the estimate of pure error variance from the SIGMA= option or from fitting the full model
SST ₀	the uncorrected total sum of squares for the dependent variable
SST ₁	the total sum of squares corrected for the mean for the dependent variable
SSE	the error sum of squares
MSE	$\frac{SSE}{n - p}$
R^2	$1 - \frac{SSE}{SST_i}$
ADJRSQ	$1 - \frac{(n - i)(1 - R^2)}{n - p}$
AIC	$n \ln \left(\frac{SSE}{n} \right) + 2p$
BIC	$n \ln \left(\frac{SSE}{n} \right) + 2(p + 2)q - 2q^2$ where $q = \frac{n\hat{\sigma}^2}{SSE}$
CP (C_p)	$\frac{SSE}{\hat{\sigma}^2} + 2p - n$
GMSEP	$\frac{MSE(n + 1)(n - 2)}{n(n - p - 1)} = \frac{1}{n} S_p(n + 1)(n - 2)$
JP (J_p)	$\frac{n + p}{n} MSE$
PC	$\frac{n + p}{n - p} (1 - R^2) = J_p \left(\frac{n}{SST_i} \right)$
PRESS	the sum of squares of $predr_i$ (see Table 61.7)
RMSE	\sqrt{MSE}
SBC	$n \ln \left(\frac{SSE}{n} \right) + p \ln(n)$
SP (S_p)	$\frac{MSE}{n - p - 1}$

Table 61.7 contains the diagnostic statistics and their formulas; these formulas and further information can be found in Chapter 2, “Introduction to Regression Procedures,” and in the “Influence Diagnostics” section on page 3898. Each statistic is computed for each observation.

Table 61.7. Formulas and Definitions for Diagnostic Statistics

MODEL Option or Statistic	Formula
PRED (\hat{Y}_i)	$\mathbf{X}_i \mathbf{b}$
RES (r_i)	$\mathbf{Y}_i - \hat{Y}_i$
H (h_i)	$x_i(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_i'$
STDP	$\sqrt{h_i\hat{\sigma}^2}$
STDI	$\sqrt{(1+h_i)\hat{\sigma}^2}$
STDR	$\sqrt{(1-h_i)\hat{\sigma}^2}$
LCL	$\hat{Y}_i - t_{\frac{\alpha}{2}}\text{STDI}$
LCLM	$\hat{Y}_i - t_{\frac{\alpha}{2}}\text{STDP}$
UCL	$\hat{Y}_i + t_{\frac{\alpha}{2}}\text{STDI}$
UCLM	$\hat{Y}_i + t_{\frac{\alpha}{2}}\text{STDP}$
STUDENT	$\frac{r_i}{\text{STDR}_i}$
RSTUDENT	$\frac{r_i}{\hat{\sigma}_{(i)}\sqrt{1-h_i}}$
COOKD	$\frac{1}{p}\text{STUDENT}^2\left(\frac{\text{STDP}}{\text{STDR}^2}\right)$
COVRATIO	$\frac{\det(\hat{\sigma}_{(i)}^2(\mathbf{X}'_{(i)}\mathbf{x}_{(i)})^{-1})}{\det(\hat{\sigma}^2(\mathbf{X}'\mathbf{X})^{-1})}$
DFFITS	$\frac{(\hat{Y}_i - \hat{Y}_{(i)})}{(\hat{\sigma}_{(i)}\sqrt{h_i})}$
DFBETAS _j	$\frac{\mathbf{b}_j - \mathbf{b}_{(i)j}}{\hat{\sigma}_{(i)}\sqrt{(\mathbf{X}'\mathbf{X})_{jj}}}$
PRESS($predr_i$)	$\frac{r_i}{1-h_i}$

Influence Diagnostics

This section discusses the INFLUENCE option, which produces several influence statistics, and the PARTIAL option, which produces partial regression leverage plots.

The INFLUENCE Option

The INFLUENCE option (in the MODEL statement) requests the statistics proposed by Belsley, Kuh, and Welsch (1980) to measure the influence of each observation on the estimates. Influential observations are those that, according to various criteria, appear to have a large influence on the parameter estimates.

Let $\mathbf{b}(i)$ be the parameter estimates after deleting the i th observation; let $s(i)^2$ be the variance estimate after deleting the i th observation; let $\mathbf{X}(i)$ be the \mathbf{X} matrix without the i th observation; let $\hat{y}(i)$ be the i th value predicted without using the i th

observation; let $r_i = y_i - \hat{y}_i$ be the i th residual; and let h_i be the i th diagonal of the projection matrix for the predictor space, also called the *hat matrix*:

$$h_i = \mathbf{x}_i(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_i'$$

Belsley, Kuh, and Welsch propose a cutoff of $2p/n$, where n is the number of observations used to fit the model and p is the number of parameters in the model. Observations with h_i values above this cutoff should be investigated.

For each observation, PROC REG first displays the residual, the studentized residual (RSTUDENT), and the h_i . The studentized residual RSTUDENT differs slightly from STUDENT since the error variance is estimated by $s_{(i)}^2$ without the i th observation, not by s^2 . For example,

$$\text{RSTUDENT} = \frac{r_i}{s_{(i)}\sqrt{(1-h_i)}}$$

Observations with RSTUDENT larger than 2 in absolute value may need some attention.

The COVRATIO statistic measures the change in the determinant of the covariance matrix of the estimates by deleting the i th observation:

$$\text{COVRATIO} = \frac{\det(s_{(i)}^2(\mathbf{X}'_{(i)}\mathbf{X}_{(i)})^{-1})}{\det(s^2(\mathbf{X}'\mathbf{X})^{-1})}$$

Belsley, Kuh, and Welsch suggest that observations with

$$|\text{COVRATIO} - 1| \geq \frac{3p}{n}$$

where p is the number of parameters in the model and n is the number of observations used to fit the model, are worth investigation.

The DFFITS statistic is a scaled measure of the change in the predicted value for the i th observation and is calculated by deleting the i th observation. A large value indicates that the observation is very influential in its neighborhood of the \mathbf{X} space.

$$\text{DFFITS} = \frac{\hat{y}_i - \hat{y}_{(i)}}{s_{(i)}\sqrt{h_{(i)}}}$$

Large values of DFFITS indicate influential observations. A general cutoff to consider is 2; a size-adjusted cutoff recommended by Belsley, Kuh, and Welsch is $2\sqrt{p/n}$, where n and p are as defined previously.

The DFFITS statistic is very similar to Cook's D , defined in the section [“Predicted and Residual Values”](#) on page 3879.

The DFBETAS statistics are the scaled measures of the change in each parameter estimate and are calculated by deleting the i th observation:

$$\text{DFBETAS}_j = \frac{b_j - b_{(i)j}}{s_{(i)} \sqrt{(\mathbf{X}'\mathbf{X})_{jj}^{-1}}}$$

where $(\mathbf{X}'\mathbf{X})_{jj}$ is the (j, j) th element of $(\mathbf{X}'\mathbf{X})^{-1}$.

In general, large values of DFBETAS indicate observations that are influential in estimating a given parameter. Belsley, Kuh, and Welsch recommend 2 as a general cutoff value to indicate influential observations and $2/\sqrt{n}$ as a size-adjusted cutoff.

Figure 61.43 shows the tables produced by the INFLUENCE option for the population example (the section “Polynomial Regression” beginning on page 3804). See Figure 61.30 for the fitted regression equation.

```
proc reg data=USPopulation;
  model Population=Year YearSq / influence;
run;
```

Figure 61.43. Regression Using the INFLUENCE Option

In Figure 61.43, observations 16, 17, and 19 exceed the cutoff value of 2 for RSTUDENT. None of the observations exceeds the general cutoff of 2 for DFFITS or

the DFBETAS, but observations 16, 17, and 19 exceed at least one of the size-adjusted cutoffs for these statistics. Observations 1 and 19 exceed the cutoff for the hat diagonals, and observations 1, 2, 16, 17, and 18 exceed the cutoffs for COVRATIO. Taken together, these statistics indicate that you should look first at observations 16, 17, and 19 and then perhaps investigate the other observations that exceeded a cutoff.

The PARTIAL Option

The PARTIAL option in the MODEL statement produces partial regression leverage plots. If the experimental ODS graphics are not in effect, this option requires the use of the LINEPRINTER option in the PROC REG statement. One plot is created for each regressor in the current full model. For example, plots are produced for regressors included by using ADD statements; plots are not produced for interim models in the various model-selection methods but only for the full model. If you use a model-selection method and the final model contains only a subset of the original regressors, the PARTIAL option still produces plots for all regressors in the full model. If the experimental ODS graphics are in effect, these plots are produced as high-resolution graphics, in panels with a maximum of six partial regression leverage plots per panel. Multiple panels are displayed for models with more than six regressors.

For a given regressor, the partial regression leverage plot is the plot of the dependent variable and the regressor after they have been made orthogonal to the other regressors in the model. These can be obtained by plotting the residuals for the dependent variable against the residuals for the selected regressor, where the residuals for the dependent variable are calculated with the selected regressor omitted, and the residuals for the selected regressor are calculated from a model where the selected regressor is regressed on the remaining regressors. A line fit to the points has a slope equal to the parameter estimate in the full model.

When the experimental ODS graphics are not in effect, points in the plot are marked by the number of replicates appearing at one position. The symbol '*' is used if there are ten or more replicates. If an ID statement is specified, the left-most nonblank character in the value of the ID variable is used as the plotting symbol.

The following statements use the fitness data in [Example 61.1](#) on page 3924 with the PARTIAL option and the ODS GRAPHICS statement to produce the partial regression leverage plots. The plots are shown in [Figure 61.44](#). For general information about ODS graphics, see [Chapter 15](#), “Statistical Graphics Using ODS.” For specific information about the graphics available in the REG procedure, see the “[ODS Graphics](#)” section on page 3922.

```
ods html;
ods graphics on;

proc reg data=fitness;
    model Oxygen=RunTime Weight Age / partial;
run;

ods graphics off;
ods html close;
```

Figure 61.44. Partial Regression Leverage Plots (Experimental)

The following statements create a similar panel of partial regression plots using the OUTPUT dataset and the GPLOT procedure. Four plots (created by regressing Oxygen and one of the variables on the remaining variables) are displayed in [Figure 61.45](#). Notice that the Int variable is explicitly added to be used as the intercept term.

```

data fitness2;
  set fitness;
  Int=1;
proc reg data=fitness2 noprint;
  model Oxygen Int = RunTime Weight Age / noint;
  output out=temp r=ry rx;
  symbol1 c=blue;
proc gplot data=temp;
  plot ry*rx / cframe=ligr;
  label ry='Oxygen'
        rx='Intercept';
run;

```

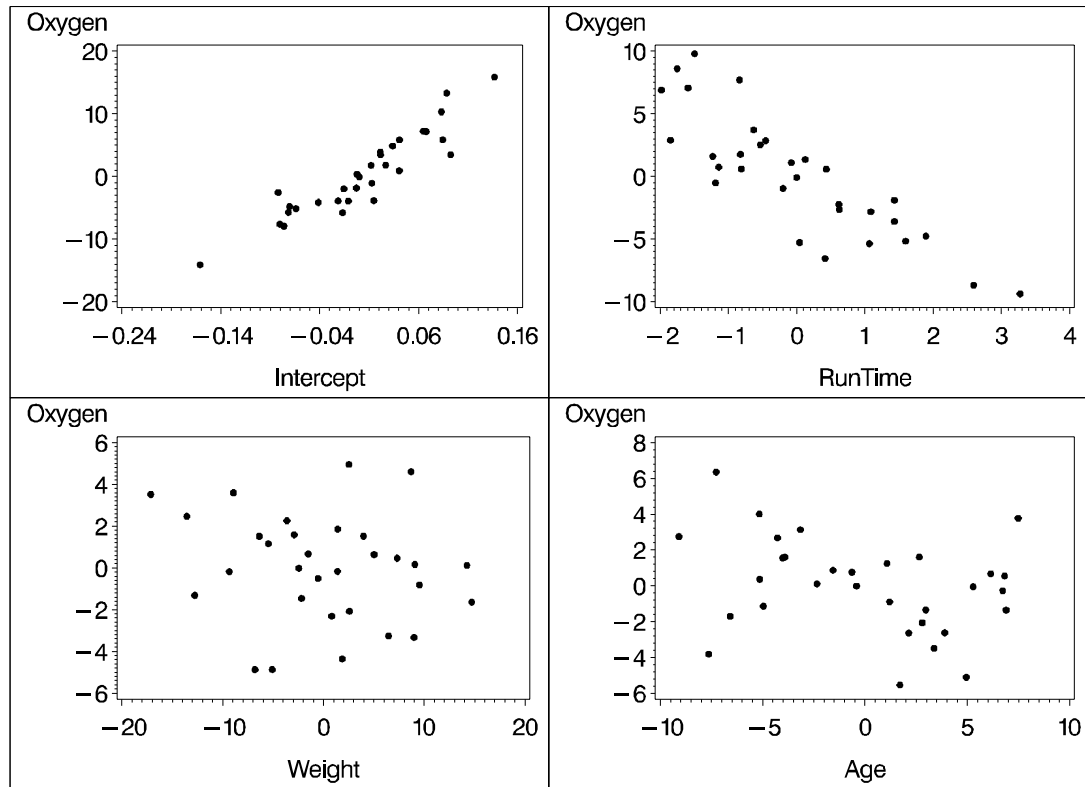

Figure 61.45. Partial Regression Leverage Plots

Reweighting Observations in an Analysis

Reweighting observations is an interactive feature of PROC REG that enables you to change the weights of observations used in computing the regression equation. Observations can also be deleted from the analysis (not from the data set) by changing their weights to zero. The *Class* data (in the “Getting Started” section on page 3800) are used to illustrate some of the features of the REWEIGHT statement. First, the full model is fit, and the residuals are displayed in Figure 61.46.

```
proc reg data=Class;
    model Weight=Age Height / p;
    id Name;
run;
```

Figure 61.46. Full Model for CLASS Data, Residuals Shown

Upon examining the data and residuals, you realize that observation 17 (Ronald) was mistakenly included in the analysis. Also, you would like to examine the effect of reweighting to 0.5 those observations with residuals that have absolute values greater than or equal to 17.

```
reweight obs.=17;
reweight r. le -17 or r. ge 17 / weight=0.5;
print p;
run;
```

At this point, a message (on the log) appears that tells you which observations have been reweighted and what the new weights are. [Figure 61.47](#) is produced.

NOTE: The above statistics use observation weights or frequencies.

Figure 61.47. Model with Reweighted Observations

The first REWEIGHT statement excludes observation 17, and the second REWEIGHT statement reweights observations 12 and 16 to 0.5. An important feature to note from this example is that the model is not refit until after the PRINT statement. REWEIGHT statements do not cause the model to be refit. This is so that multiple REWEIGHT statements can be applied to a subsequent model.

In this example, since the intent is to reweight observations with large residuals, the observation that was mistakenly included in the analysis should be deleted; then, the model should be fit for those remaining observations, and the observations with large residuals should be reweighted. To accomplish this, use the REFIT statement. Note that the model label has been changed from MODEL1 to MODEL1.2 as two REWEIGHT statements have been used. These statements produce Figure 61.48:

```
reweight allobs / weight=1.0;
reweight obs.=17;
refit;
reweight r. le -17 or r. ge 17 / weight=.5;
print;
run;
```

NOTE: The above statistics use observation weights or frequencies.

Figure 61.48. Observations Excluded from Analysis, Model Refitted and Observations Reweighted

Notice that this results in a slightly different model than the previous set of statements: only observation 16 is reweighted to 0.5. Also note that the model label is now MODEL1.5 since five REWEIGHT statements have been used for this model.

Another important feature of the REWEIGHT statement is the ability to nullify the effect of a previous or all REWEIGHT statements. First, assume that you have several REWEIGHT statements in effect and you want to restore the original weights of all the observations. The following REWEIGHT statement accomplishes this and produces [Figure 61.49](#):

```
reweight allobs / reset;
print;
run;
```

Figure 61.51. REWEIGHT Statement with RESET option

Note that observations that meet the condition of the second REWEIGHT statement (residuals with an absolute value greater than or equal to 17) now have weights reset to their original value of 1. Observations 1, 3, 9, 10, and 17 have weights of 0.75, but observations 12 and 16 (which meet the condition of the second REWEIGHT statement) have their weights reset to 1.

Notice how the last three examples show three ways to change weights back to a previous value. In the first example, ALLOBS and the RESET option are used to change weights for all observations back to their original values. In the second example, the UNDO option is used to negate the effect of a previous REWEIGHT statement, thus changing weights for observations selected in the previous REWEIGHT statement to the weights specified in still another REWEIGHT statement. In the third example, the RESET option is used to change weights for observations selected in a previous REWEIGHT statement back to their original values. Finally, note that the label MODEL1.12 indicates that twelve REWEIGHT statements have been applied to the original model.

Testing for Heteroscedasticity

The regression model is specified as $y_i = \mathbf{x}_i\beta + \epsilon_i$, where the ϵ_i 's are identically and independently distributed: $E(\epsilon) = 0$ and $E(\epsilon'\epsilon) = \sigma^2\mathbf{I}$. If the ϵ_i 's are not independent or their variances are not constant, the parameter estimates are unbiased, but the estimate of the covariance matrix is inconsistent. In the case of heteroscedasticity, the ACOV option provides a consistent estimate of the covariance matrix. If the regression data are from a simple random sample, the ACOV option produces the covariance matrix. This matrix is

$$(\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\text{diag}(e_i^2)\mathbf{X})(\mathbf{X}'\mathbf{X})^{-1}$$

where

$$e_i = y_i - \mathbf{x}_i\mathbf{b}$$

The SPEC option performs a model specification test. The null hypothesis for this test maintains that the errors are homoscedastic, independent of the regressors and that several technical assumptions about the model specification are valid. For details, see theorem 2 and assumptions 1–7 of White (1980). When the model is correctly specified and the errors are independent of the regressors, the rejection of this null hypothesis is evidence of heteroscedasticity. In implementing this test, an estimator of the average covariance matrix (White 1980, p. 822) is constructed and inverted. The nonsingularity of this matrix is one of the assumptions in the null hypothesis about the model specification. When PROC REG determines this matrix to be numerically singular, a generalized inverse is used and a note to this effect is written to the log. In such cases, care should be taken in interpreting the results of this test.

When you specify the SPEC option, tests listed in the TEST statement are performed with both the usual covariance matrix and the heteroscedasticity consistent covariance matrix. Tests performed with the consistent covariance matrix are asymptotic. For more information, refer to White (1980).

Both the ACOV and SPEC options can be specified in a MODEL or PRINT statement.

Multivariate Tests

The MTEST statement described in the “[MTEST Statement](#)” section on page 3832 can test hypotheses involving several dependent variables in the form

$$(\mathbf{L}\beta - \mathbf{c}\mathbf{j})\mathbf{M} = 0$$

where \mathbf{L} is a linear function on the regressor side, β is a matrix of parameters, \mathbf{c} is a column vector of constants, \mathbf{j} is a row vector of ones, and \mathbf{M} is a linear function on the dependent side. The special case where the constants are zero is

$$\mathbf{L}\beta\mathbf{M} = 0$$

To test this hypothesis, PROC REG constructs two matrices called **H** and **E** that correspond to the numerator and denominator of a univariate F test:

$$\begin{aligned} \mathbf{H} &= \mathbf{M}'(\mathbf{LB} - \mathbf{c}\mathbf{j})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{LB} - \mathbf{c}\mathbf{j})\mathbf{M} \\ \mathbf{E} &= \mathbf{M}'(\mathbf{Y}'\mathbf{Y} - \mathbf{B}'(\mathbf{X}'\mathbf{X})\mathbf{B})\mathbf{M} \end{aligned}$$

These matrices are displayed for each MTEST statement if the PRINT option is specified.

Four test statistics based on the eigenvalues of $\mathbf{E}^{-1}\mathbf{H}$ or $(\mathbf{E} + \mathbf{H})^{-1}\mathbf{H}$ are formed. These are Wilks' Lambda, Pillai's Trace, the Hotelling-Lawley Trace, and Roy's maximum root. These test statistics are discussed in Chapter 2, "Introduction to Regression Procedures."

The following statements perform a multivariate analysis of variance and produce Figure 61.52 through Figure 61.56:

Figure 61.56. Multivariate Analysis of Variance: Second Test (continued)

The four multivariate test statistics are all highly significant, giving strong evidence that the coefficients of drug1 and drug2 are not zero for both dependent variables.

Autocorrelation in Time Series Data

When regression is performed on time series data, the errors may not be independent. Often errors are autocorrelated; that is, each error is correlated with the error immediately before it. Autocorrelation is also a symptom of systematic lack of fit. The DW option provides the Durbin-Watson d statistic to test that the autocorrelation is zero:

$$d = \frac{\sum_{i=2}^n (e_i - e_{i-1})^2}{\sum_{i=1}^n e_i^2}$$

The value of d is close to 2 if the errors are uncorrelated. The distribution of d is reported by Durbin and Watson (1951). Tables of the distribution are found in most econometrics textbooks, such as Johnston (1972) and Pindyck and Rubinfeld (1981).

The sample autocorrelation estimate is displayed after the Durbin-Watson statistic. The sample is computed as

$$r = \frac{\sum_{i=2}^n e_i e_{i-1}}{\sum_{i=1}^n e_i^2}$$

This autocorrelation of the residuals may not be a very good estimate of the autocorrelation of the true errors, especially if there are few observations and the independent variables have certain patterns. If there are missing observations in the regression, these measures are computed as though the missing observations did not exist.

Positive autocorrelation of the errors generally tends to make the estimate of the error variance too small, so confidence intervals are too narrow and true null hypotheses are rejected with a higher probability than the stated significance level. Negative

autocorrelation of the errors generally tends to make the estimate of the error variance too large, so confidence intervals are too wide and the power of significance tests is reduced. With either positive or negative autocorrelation, least-squares parameter estimates are usually not as efficient as generalized least-squares parameter estimates. For more details, refer to Judge et al. (1985, Chapter 8) and the *SAS/ETS User's Guide*.

The following SAS statements request the DW option for the US population data (see Figure 61.57):

```
proc reg data=USPopulation;
  model Population=Year YearSq / dw;
run;
```

The REG Procedure

Dependent Variable: Population	
Durbin-Watson D	1.191
Number of Observations	22
1st Order Autocorrelation	0.323

Figure 61.57. Regression Using DW Option

Computations for Ridge Regression and IPC Analysis

In ridge regression analysis, the crossproduct matrix for the independent variables is centered (the NOINT option is ignored if it is specified) and scaled to one on the diagonal elements. The ridge constant k (specified with the RIDGE= option) is then added to each diagonal element of the crossproduct matrix. The ridge regression estimates are the least-squares estimates obtained by using the new crossproduct matrix.

Let \mathbf{X} be an $n \times p$ matrix of the independent variables after centering the data, and let \mathbf{Y} be an $n \times 1$ vector corresponding to the dependent variable. Let \mathbf{D} be a $p \times p$ diagonal matrix with diagonal elements as in $\mathbf{X}'\mathbf{X}$. The ridge regression estimate corresponding to the ridge constant k can be computed as

$$\mathbf{D}^{-\frac{1}{2}}(\mathbf{Z}'\mathbf{Z} + k\mathbf{I}_p)^{-1}\mathbf{Z}'\mathbf{Y}$$

where $\mathbf{Z} = \mathbf{X}\mathbf{D}^{-\frac{1}{2}}$ and \mathbf{I}_p is a $p \times p$ identity matrix.

For IPC analysis, the smallest m eigenvalues of $\mathbf{Z}'\mathbf{Z}$ (where m is specified with the PCOMIT= option) are omitted to form the estimates.

For information about ridge regression and IPC standardized parameter estimates, parameter estimate standard errors, and variance inflation factors, refer to Rawlings (1988), Neter, Wasserman, and Kutner (1990), and Marquardt and Snee (1975). Unlike Rawlings (1988), the REG procedure uses the mean squared errors of the submodels instead of the full model MSE to compute the standard errors of the parameter estimates.

Construction of Q-Q and P-P Plots

If a normal probability-probability or quantile-quantile plot for the variable x is requested, the n nonmissing values of x are first ordered from smallest to largest:

$$x_{(1)} \leq x_{(2)} \leq \cdots \leq x_{(n)}$$

If a Q-Q plot is requested (with a PLOT statement of the form PLOT *yvariable**NQQ.), the i^{th} ordered value $x_{(i)}$ is represented by a point with y -coordinate $x_{(i)}$ and x -coordinate $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi(\cdot)$ is the standard normal distribution.

If a P-P plot is requested (with a PLOT statement of the form PLOT *yvariable**NPP.), the i^{th} ordered value $x_{(i)}$ is represented by a point with y -coordinate $\frac{i}{n}$ and x -coordinate $\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right)$, where μ is the mean of the nonmissing x -values and σ is the standard deviation. If an x -value has multiplicity k (that is, $x_{(i)} = \cdots = x_{(i+k-1)}$), then only the point $\left(\Phi\left(\frac{x_{(i)}-\mu}{\sigma}\right), \frac{i+k-1}{n}\right)$ is displayed.

Computational Methods

The REG procedure first composes a crossproducts matrix. The matrix can be calculated from input data, reformed from an input correlation matrix, or read in from an SSCP data set. For each model, the procedure selects the appropriate crossproducts from the main matrix. The normal equations formed from the crossproducts are solved using a sweep algorithm (Goodnight 1979). The method is accurate for data that are reasonably scaled and not too collinear.

The mechanism that PROC REG uses to check for singularity involves the diagonal (pivot) elements of $\mathbf{X}'\mathbf{X}$ as it is being swept. If a pivot is less than SINGULAR*CSS, then a singularity is declared and the pivot is not swept (where CSS is the corrected sum of squares for the regressor and SINGULAR is machine dependent but is approximately $1\text{E}-7$ on most machines or reset in the PROC statement).

The sweep algorithm is also used in many places in the model-selection methods. The RSQUARE method uses the leaps and bounds algorithm by Furnival and Wilson (1974).

Computer Resources in Regression Analysis

The REG procedure is efficient for ordinary regression; however, requests for optional features can greatly increase the amount of time required.

The major computational expense in the regression analysis is the collection of the crossproducts matrix. For p variables and n observations, the time required is proportional to np^2 . For each model run, PROC REG needs time roughly proportional to k^3 , where k is the number of regressors in the model. Add an additional nk^2 for one of the R, CLM, or CLI options and another nk^2 for the INFLUENCE option.

Most of the memory that PROC REG needs to solve large problems is used for crossproducts matrices. PROC REG requires $4p^2$ bytes for the main crossproducts matrix plus $4k^2$ bytes for the largest model. If several output data sets are requested, memory is also needed for buffers.

See the “[Input Data Sets](#)” section on page 3860 for information on how to use TYPE=SSCP data sets to reduce computing time.

Displayed Output

Many of the more specialized tables are described in detail in previous sections. Most of the formulas for the statistics are in [Chapter 2, “Introduction to Regression Procedures,”](#) while other formulas can be found in the section “[Model Fit and Diagnostic Statistics](#)” on page 3896 and the “[Influence Diagnostics](#)” section on page 3898.

The analysis-of-variance table includes

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the NOINT option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>F, the probability of getting a greater F statistic than that observed if the hypothesis is true. This is the significance probability.

Other statistics displayed include the following:

- Root MSE is an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean is the sample mean of the dependent variable.
- C.V. is the coefficient of variation, computed as 100 times Root MSE divided by Dep Mean. This expresses the variation in unitless values.
- R-Square is a measure between 0 and 1 that indicates the portion of the (corrected) total variation that is attributed to the fit rather than left to residual error. It is calculated as $SS(\text{Model})$ divided by $SS(\text{Total})$. It is also called the *coefficient of determination*. It is the square of the multiple correlation; in other words, the square of the correlation between the dependent variable and the predicted values.

- Adj R-Sq, the adjusted R^2 , is a version of R^2 that has been adjusted for degrees of freedom. It is calculated as

$$\bar{R}^2 = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where i is equal to 1 if there is an intercept and 0 otherwise; n is the number of observations used to fit the model; and p is the number of parameters in the model.

The parameter estimates and associated statistics are then displayed, and they include the following:

- the Variable used as the regressor, including the name Intercept to represent the estimate of the intercept parameter
- the degrees of freedom (DF) for the variable. There is one degree of freedom unless the model is not full rank.
- the Parameter Estimate
- the Standard Error, the estimate of the standard deviation of the parameter estimate
- T for H0: Parameter=0, the t test that the parameter is zero. This is computed as the Parameter Estimate divided by the Standard Error.
- the Prob > |T|, the probability that a t statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability.

If model-selection methods other than NONE, RSQUARE, ADJR SQ, or CP are used, the analysis-of-variance table and the parameter estimates with associated statistics are produced at each step. Also displayed are

- C(p), which is Mallows' C_p statistic
- bounds on the condition number of the correlation matrix for the variables in the model (Berk 1977)

After statistics for the final model are produced, the following is displayed when the method chosen is FORWARD, BACKWARD, or STEPWISE:

- a Summary table listing Step number, Variable Entered or Removed, Partial and Model R-Square, and C(p) and F statistics

The RSQUARE method displays its results beginning with the model containing the fewest independent variables and producing the largest R^2 . Results for other models with the same number of variables are then shown in order of decreasing R^2 , and so

on, for models with larger numbers of variables. The ADJRSQ and CP methods group models of all sizes together and display results beginning with the model having the optimal value of adjusted R^2 and C_p , respectively.

For each model considered, the RSQUARE, ADJRSQ, and CP methods display the following:

- Number in Model or IN, the number of independent variables used in each model
- R-Square or RSQ, the squared multiple correlation coefficient

If the B option is specified, the RSQUARE, ADJRSQ, and CP methods produce the following:

- Parameter Estimates, the estimated regression coefficients

If the B option is not specified, the RSQUARE, ADJRSQ, and CP methods display the following:

- Variables in Model, the names of the independent variables included in the model

ODS Table Names

PROC REG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 61.8. ODS Tables Produced in PROC REG

ODS Table Name	Description	Statement	Option
ACovEst	Consistent covariance of estimates matrix	MODEL	ALL, ACOV
ACovTestANOVA	Test ANOVA using ACOV estimates	TEST	ACOV (MODEL statement)
ANOVA	Model ANOVA table	MODEL	default
CanCorr	Canonical correlations for hypothesis combinations	MTEST	CANPRINT
CollinDiag	Collinearity Diagnostics table	MODEL	COLLIN
CollinDiagNoInt	Collinearity Diagnostics for no intercept model	MODEL	COLLINOINT
ConditionBounds	Bounds on condition number	MODEL	(SELECTION=BACKWARD FORWARD STEPWISE MAXR MINR) and DETAILS

ODS Graphics (Experimental)

This section describes the use of ODS for creating statistical graphs with the REG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see [Chapter 15, “Statistical Graphics Using ODS.”](#)

When the experimental ODS graphics are in effect, the REG procedure produces a variety of plots. For models with multiple dependent variables, separate plots are produced for each dependent variable. For jobs with more than one MODEL statement, plots are produced for each model statement.

The plots available are as follows:

- With a single regressor, a scatterplot of the input data overlaid with the fitted regression line, confidence band, and prediction limits.
- A summary panel of fit diagnostics:
 - Residuals versus the predicted values
 - Studentized residuals versus the predicted values
 - Studentized residuals versus the leverage
 - Normal quantile plot of the residuals
 - Dependent variable values versus the predicted values
 - Cook's D versus observation number
 - Histogram of the residuals

- A “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland, 1993).

If the PLOTS(UNPACKPANELS) option is specified in the PROC REG statement, then the eight plots in the fit diagnostics panel are displayed individually.

- Panels of the residuals versus the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used in the case that there are more than six regressors (including the intercept) in the model.
- If the PARTIAL option is specified in a MODEL statement, panels of the partial regression plots for each regressor (see the “[The PARTIAL Option](#)” section on page 3901). Note that each panel contains at most six partial plots, and multiple panels are used in the case that there are more than six regressors in the model.
- If the RIDGE= option is specified in the model statement, panels of ridge traces versus the specified ridge parameters for each regressor in the model. At most eight ridge traces are included on a panel and multiple panels are used for models with more than eight regressors.

PLOTS (*general-plot-options*)

specifies characteristics of the graphics produced when you use the experimental ODS GRAPHICS statement. You can specify the following *general-plot-options* in parentheses after the PLOTS option:

UNPACK | UNPACKPANELS specifies that plots in the fit diagnostics panel should be displayed separately.

MAXPOINTS=*number* | NONE specifies that plots with elements that require processing more than *number* points are suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

ODS Graph Names

PROC REG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 61.9](#).

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see [Chapter 15, “Statistical Graphics Using ODS.”](#)

Table 61.9. ODS Graphics Produced by PROC REG

ODS Graph Name	Plot Description	PLOTS Option
ActualByPredicted	Dependent variable versus predicted values	UNPACKPANELS
CooksD	Cook's D statistic versus observation number	UNPACKPANELS
DiagnosticsPanel	Panel of fit diagnostics	
Fit	Regression line, confidence band, and prediction limits overlaid on scatterplot of data	
PartialPlotPanel <i>i</i>	Panel <i>i</i> of partial regression plots	
QQPlot	Normal quantile plot residuals	UNPACKPANELS
ResidualByPredicted	Residuals versus predicted values	UNPACKPANELS
ResidualHistogram	Histogram of fit residuals	UNPACKPANELS
ResidualPanel <i>i</i>	Panel <i>i</i> of residuals versus regressors	
RFPlot	Side-by-side plots of quantiles of centered fit and residuals	UNPACKPANELS
RidgePanel <i>i</i>	Panel <i>i</i> of ridge traces	
RStudentByLeverage	Studentized residuals versus leverage	UNPACKPANELS
RStudentByPredicted	Studentized residuals versus predicted values	UNPACKPANELS

Examples

Example 61.1. Aerobic Fitness Prediction

Aerobic fitness (measured by the ability to consume oxygen) is fit to some simple exercise tests. The goal is to develop an equation to predict fitness based on the exercise tests rather than on expensive and cumbersome oxygen consumption measurements. Three model-selection methods are used: forward selection, backward selection, and MAXR selection. The following statements produce [Output 61.1.1](#) through [Output 61.1.5](#). (Collinearity diagnostics for the full model are shown in [Figure 61.42](#) on page 3896.)

```

*-----Data on Physical Fitness-----*
| These measurements were made on men involved in a physical |
| fitness course at N.C.State Univ. The variables are Age    |

MaxPulse	0.30322	0.13650	26.49142	4.93	0.0360

Bounds on condition number: 8.7438, 137.13

The above model is the best 6-variable model found.

No further improvement in R-Square is possible.

Note that for all three of these methods, RestPulse contributes least to the model. In the case of forward selection, it is not added to the model. In the case of backward selection, it is the first variable to be removed from the model. In the case of MAXR selection, RestPulse is included only for the full model.

For the STEPWISE, BACKWARDS and FORWARD selection methods, you can control the amount of detail displayed by using the DETAILS option. For example, the following statements display only the selection summary table for the FORWARD selection method.

```
proc reg data=fitness;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=forward details=summary;
run;
```

Output 61.1.4. Forward Selection Summary

The REG Procedure							
Model: MODEL1							
Dependent Variable: Oxygen							
Summary of Forward Selection							
Step	Variable Entered	Number Vars In	Partial R-Square	Model R-Square	C(p)	F Value	Pr > F
1	RunTime	1	0.7434	0.7434	13.6988	84.01	<.0001

6	0.8487	7.0000	Age Weight RunTime RunPulse RestPulse MaxPulse

The models in [Output 61.1.5](#) are arranged first by the number of variables in the model and second by the magnitude of R^2 for the model. Before making a final decision about which model to use, you would want to perform collinearity diagnostics. Note that, since many different models have been fit and the choice of a final model is based on R^2 , the statistics are biased and the p -values for the parameter estimates are not valid.

Example 61.2. Predicting Weight by Height and Age

In this example, the weights of school children are modeled as a function of their heights and ages. Modeling is performed separately for boys and girls. The example shows the use of a BY statement with PROC REG, multiple MODEL statements, and the OUTEST= and OUTSSCP= options, which create data sets. Since the BY statement is used, interactive processing is not possible in this example; no statements can appear after the first RUN statement. The following statements produce [Output 61.2.1](#) through [Output 61.2.4](#):

```

*-----Data on Age, Weight, and Height of Children-----*

```

For both females and males, the overall F statistics for both models are significant, indicating that the model explains a significant portion of the variation in the data. For females, the full model is

$$\text{weight} = -150.57 + 3.60 \times \text{height} + 1.91 \times \text{age}$$

and, for males, the full model is

$$\text{weight} = -113.71 + 2.68 \times \text{height} + 3.08 \times \text{age}$$

Output 61.2.3. SSCP Matrix

----- Data on age, weight, and height of children -----							
SSCP type data set

3	f	SSCP	weight	10975.5	669469.85	1123360.75	182444.95
4	f	SSCP	age	1824.9	110818.32	182444.95	30363.81
5	f	N		111.0	111.00	111.00	111.00
6	m	SSCP	Intercept	126.0	7825.00	13034.50	2072.10
7	m	SSCP	height	7825.0	488243.60	817919.60	129432.57
8	m	SSCP	weight	13034.5	817919.60	1398238.75	217717.45
9	m	SSCP	age	2072.1	129432.57	217717.45	34515.95
10	m	N		126.0	126.00	126.00	126.00

The OUTSSCP= data set is shown in [Output 61.2.3](#). Note how the BY groups are separated. Observations with _TYPE_='N' contain the number of observations in the associated BY group. Observations with _TYPE_='SSCP' contain the rows of the uncorrected sums of squares and crossproducts matrix. The observations with _NAME_='Intercept' contain crossproducts for the intercept.

Output 61.2.4. OUTEST Data Set

----- Data on age, weight, and height of children -----													
EST type data set													
Obs	sex	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	height	weight	age	_IN_	_P_	_EDF_	_RSQ_
1	f	eq1	PARMS	weight	12.3461	-153.129	4.16361	-1	.	1	2	109	0.56416
2	f	eq2	PARMS	weight	12.0527	-150.597	3.60378	-1	1.90703	2	3	108	0.58845
3	m	eq1	PARMS	weight	12.2850	-125.698	3.68977	-1	.	1	2	124	0.62451
4	m	eq2	PARMS	weight	11.7098	-113.713	2.68075	-1	3.08167	2	3	123	0.66161

The OUTEST= data set is displayed in [Output 61.2.4](#); again, the BY groups are separated. The _MODEL_ column contains the labels for models from the MODEL statements. If no labels are specified, the defaults MODEL1 and MODEL2 would appear as values for _MODEL_. Note that _TYPE_='PARMS' for all observations, indicating that all observations contain parameter estimates. The _DEPVAR_ column displays the dependent variable, and the _RMSE_ column gives the Root Mean Square Error for the associated model. The Intercept column gives the estimate for the intercept for the associated model, and variables with the same name

as variables in the original data set (height, age) give parameter estimates for those variables. The dependent variable, weight, is shown with a value of -1 . The `_IN_` column contains the number of regressors in the model not including the intercept; `_P_` contains the number of parameters in the model; `_EDF_` contains the error degrees of freedom; and `_RSQ_` contains the R^2 statistic. Finally, note that the `_IN_`, `_P_`, `_EDF_` and `_RSQ_` columns appear in the `OUTEST=` data set since the `RSQUARE` option is specified in the `PROC REG` statement.

Example 61.3. Regression with Quantitative and Qualitative Variables

At times it is desirable to have independent variables in the model that are qualitative rather than quantitative. This is easily handled in a regression framework. Regression uses qualitative variables to distinguish between populations. There are two main advantages of fitting both populations in one model. You gain the ability to test for different slopes or intercepts in the populations, and more degrees of freedom are available for the analysis.

Regression with qualitative variables is different from analysis of variance and analysis of covariance. Analysis of variance uses qualitative independent variables only. Analysis of covariance uses quantitative variables in addition to the qualitative variables in order to account for correlation in the data and reduce MSE; however, the quantitative variables are not of primary interest and merely improve the precision of the analysis.

Consider the case where Y_i is the dependent variable, $X1_i$ is a quantitative variable, $X2_i$ is a qualitative variable taking on values 0 or 1, and $X1_iX2_i$ is the interaction. The variable $X2_i$ is called a dummy, binary, or indicator variable. With values 0 or 1, it distinguishes between two populations. The model is of the form

$$Y_i = \beta_0 + \beta_1 X1_i + \beta_2 X2_i + \beta_3 X1_i X2_i + \epsilon_i$$

for the observations $i = 1, 2, \dots, n$. The parameters to be estimated are β_0 , β_1 , β_2 , and β_3 . The number of dummy variables used is one less than the number of qualitative levels. This yields a nonsingular $X'X$ matrix. See Chapter 10 of Neter, Wasserman, and Kutner (1990) for more details.

An example from Neter, Wasserman, and Kutner (1990) follows. An economist is investigating the relationship between the size of an insurance firm and the speed at which they implement new insurance innovations. He believes that the type of firm may affect this relationship and suspects that there may be some interaction between the size and type of firm. The dummy variable in the model allows the two firms to have different intercepts. The interaction term allows the firms to have different slopes as well.

In this study, Y_i is the number of months from the time the first firm implemented the innovation to the time it was implemented by the i th firm. The variable $X1_i$ is the size of the firm, measured in total assets of the firm. The variable $X2_i$ denotes the firm type and is 0 if the firm is a mutual fund company and 1 if the firm is a stock

company. The dummy variable allows each firm type to have a different intercept and slope.

The previous model can be broken down into a model for each firm type by plugging in the values for $X2_i$. If $X2_i = 0$, the model is

$$Y_i = \beta_0 + \beta_1 X1_i + \epsilon_i$$

This is the model for a mutual company. If $X2_i = 1$, the model for a stock firm is

$$Y_i = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)X1_i + \epsilon_i$$

This model has intercept $\beta_0 + \beta_2$ and slope $\beta_1 + \beta_3$.

The data* follow. Note that the interaction term is created in the DATA step since polynomial effects such as `size*type` are not allowed in the MODEL statement in the REG procedure.

```

title 'Regression With Quantitative and Qualitative Variables';
data insurance;
  input time size type @@;
  sizetype=size*type;
  datalines;

21 224 1    20 166 1    13 305 1    30 124 1    14 246 1
;
run;

```

The following statements begin the analysis:

```

proc reg data=insurance;
  model time = size type sizetype;
run;

```

The ANOVA table is displayed in [Output 61.3.1](#).

*From Neter, J. et al., *Applied Linear Statistical Models*, Third Edition, Copyright (c) 1990, Richard D. Irwin. Reprinted with permission of The McGraw-Hill Companies.

Output 61.3.1. ANOVA Table and Parameter Estimates

Regression With Quantitative and Qualitative Variables					
The REG Procedure					
Model: MODEL1					
Dependent Variable: time					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	3	1504.41904	501.47301	45.49	<.0001
Error	16	176.38096	11.02381		
Corrected Total	19	1680.80000			
Root MSE		3.32021	R-Square	0.8951	
Dependent Mean		19.40000	Adj R-Sq	0.8754	
Coeff Var		17.11450			
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	33.83837	2.44065	13.86	<.0001
size	1	-0.10153	0.01305	-7.78	<.0001
type	1	8.13125	3.65405	2.23	0.0408
sizetype	1	-0.00041714	0.01833	-0.02	0.9821

The overall F statistic is significant ($F=45.490$, $p<0.0001$). The interaction term is not significant ($t=-0.023$, $p=0.9821$). Hence, this term should be removed and the model re-fitted, as shown in the following statements.

```

delete sizetype;
print;
run;

```

The DELETE statement removes the interaction term (sizetype) from the model. The new ANOVA table is shown in [Output 61.3.2](#).

Output 61.3.2. ANOVA Table and Parameter Estimates

Regression With Quantitative and Qualitative Variables					
The REG Procedure					
Model: MODEL1.1					
Dependent Variable: time					
Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	2	1504.41333	752.20667	72.50	<.0001
Error	17	176.38667	10.37569		
Corrected Total	19	1680.80000			
		Root MSE	3.22113	R-Square	0.8951
		Dependent Mean	19.40000	Adj R-Sq	0.8827
		Coeff Var	16.60377		
Parameter Estimates					
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t
Intercept	1	33.87407	1.81386	18.68	<.0001
size	1	-0.10174	0.00889	-11.44	<.0001
type	1	8.05547	1.45911	5.52	<.0001

The overall F statistic is still significant ($F=72.497$, $p<0.0001$). The intercept and the coefficients associated with `size` and `type` are significantly different from zero ($t=18.675$, $p<0.0001$; $t=-11.443$, $p<0.0001$; $t=5.521$, $p<0.0001$, respectively). Notice that the R^2 did not change with the omission of the interaction term.

The fitted model is

$$\text{time} = 33.87 - 0.102 \times \text{size} + 8.055 \times \text{type}$$

The fitted model for a mutual fund company ($X2_i = 0$) is

$$\text{time} = 33.87 - 0.102 \times \text{size}$$

and the fitted model for a stock company ($X2_i = 1$) is

$$\text{time} = (33.87 + 8.055) - 0.102 \times \text{size}$$

So the two models have different intercepts but the same slope.

Now plot the residual versus predicted values using the firm type as the plot symbol (PLOT=TYPE); this can be useful in determining if the firm types have different residual patterns. PROC REG does not support the `plot y*x=type` syntax for high-resolution graphics, so use PROC GPLOT to create [Output 61.3.3](#). First, the

OUTPUT statement saves the residuals and predicted values from the new model in the OUT= data set.

```

output out=out r=r p=p;
run;
symbol1 v='0' c=blue f=swissb;
symbol2 v='1' c=yellow f=swissb;
axis1 label=(angle=90);
proc gplot data=out;
  plot r*p=type / nolegend vaxis=axis1 cframe=ligr;
  plot p*size=type / nolegend vaxis=axis1 cframe=ligr;
run;

```

Output 61.3.3. Plot of Residual vs. Predicted Values

The residuals show no major trend. Neither firm type by itself shows a trend either. This indicates that the model is satisfactory.

A plot of the predicted values versus `size` appears in [Output 61.3.4](#), where the firm type is again used as the plotting symbol.

Output 61.3.4. Plot of Predicted vs. Size

The different intercepts are very evident in this plot.

Example 61.4. Displaying Plots for Simple Linear Regression

This example introduces the basic PROC REG graphics syntax used to produce a standard plot of data from the aerobic fitness data set (Example 61.1 on page 3924). A simple linear regression of Oxygen on RunTime is performed, and a plot of Oxygen*RunTime is requested. The fitted model, the regression line, and the four default statistics are also displayed in Output 61.4.1.

```

data fitness;
  set fitness;
  label Age      = 'age(years)'
        Weight   = 'weight(kg)'
        Oxygen   = 'oxygen uptake(ml/kg/min)'
        RunTime  = '1.5 mile time(min)'
        RestPulse = 'rest pulse'
        RunPulse = 'running pulse'
        MaxPulse = 'maximum running pulse';
proc reg data=fitness;
  model Oxygen=RunTime;
  plot Oxygen*RunTime / cframe=ligr;
run;

```

Output 61.4.1. Simple Linear Regression**Example 61.5. Creating a C_p Plot**

The C_p statistics for model selection are plotted against the number of parameters in the model, and the CHOCKING= and CMALLOWS= options draw useful reference lines. Note the four default statistics in the plot margin, the default model equation, and the default legend in [Output 61.5.1](#).

```

title 'Cp Plot with Reference Lines';
symbol1 c=green;
proc reg data=fitness;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=rsquare noprint;
  plot cp.*np.
    / chocking=red cmallows=blue
      vaxis=0 to 15 by 5 cframe=ligr;
run;

```

Output 61.5.1. C_p Plot

Using the criteria suggested by Hocking (1976) (see the section “[Dictionary of PLOT Statement Options](#)” beginning on page 3844), [Output 61.5.1](#) indicates that a 6-variable model is a reasonable choice for doing parameter estimation, while a 5-variable model may be suitable for doing prediction.

Example 61.6. Controlling Plot Appearance with Graphic Options

This example uses model fit summary statistics from the OUTEST= data set to create a plot for a model selection analysis. Global graphics statements and PLOT statement options are used to control the appearance of the plot.

```
goptions ctitle=black   htitle=3.5pct ftitle=swiss
         ctext =magenta htext =3.0pct ftext =swiss
         cback =ligr    border;
symbol1 v=circle c=red h=1 w=2;
title1 'Selection=Rsquare';
title2 'plot Rsquare versus the number of parameters P in '
       'each model';

proc reg data=fitness;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
    / selection=rsquare noprint;
  plot rsq.*np.
    / aic bic edf gmsep jp np pc sbc sp
    haxis=2 to 7 by 1
```

```

caxis=red cframe=white ctext=blue
modellab='Full Model' modelht=2.4
statht=2.4;

run;

```

In the GOPTIONS statement,

- BORDER frames the entire display
- CBACK= specifies the background color
- CTEXT= selects the default color for the border and all text, including titles, footnotes, and notes
- CTITLE= specifies the title, footnote, note, and border color
- HTEXT= specifies the height for all text in the display
- HTITLE= specifies the height for the first title line
- FTEXT= selects the default font for all text, including titles, footnotes, notes, the model label and equation, the statistics, the axis labels, the tick values, and the legend
- FTITLE= specifies the first title font

For more information on the GOPTIONS statement and other global graphics statements, refer to *SAS/GRAPH Software: Reference*.

Output 61.6.1. Controlling Plot Appearance and Plotting OUTEST= Statistics

In [Output 61.6.1](#), note the following:

- The PLOT statement option CTEXT= affects all text not controlled by the CTITLE= option in the GOPTIONS statement. Hence, the GOPTIONS statement option CTEXT=MAGENTA has no effect. Therefore, the color of the title is black and all other text is blue.
- The area enclosed by the axes and the frame has a white background, while the background outside the plot area is gray.
- The MODELHT= option allows the entire model equation to fit on one line.
- The STATHT= option allows the statistics in the margin to fit in one column.
- The displayed statistics and the fitted model equation refer to the selected model. See the “[Traditional High-Resolution Graphics Plots](#)” section beginning on page 3840 for more information.

Example 61.7. Plotting Model Diagnostic Statistics

This example illustrates how you can display diagnostics for checking the adequacy of a regression model. The following statements plot the studentized deleted residuals against the observation number for the full model. Vertical reference lines at $\pm t_{inv}(.95, n - p - 1) = \pm 1.714$ are added to identify possible outlying Oxygen values. A vertical reference line is displayed at zero by default when the RSTUDENT option is specified. The graph is shown in [Output 61.7.1](#). Observations 15 and 17 are indicated as possible outliers.

```

title 'Check for Outlying Observations';
symbol v=dot h=1 c=green;

proc reg data=fitness;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse;
  plot rstudent.*obs.
      / vref= -1.714 1.714 cvref=blue lvref=1
      href= 0 to 30 by 5 chref=red cframe=ligr;
run;

```

Output 61.7.1. Plotting Model Diagnostic Statistics

Example 61.8. Creating PP and QQ Plots

The following program creates probability-probability plots and quantile-quantile plots of the residuals ([Output 61.8.1](#) and [Output 61.8.2](#), respectively). An annotation data set is created to produce the (0,0)–(1,1) reference line for the PP-plot. Note that the NOSTAT option for the PP-plot suppresses the statistics that would be displayed in the margin.

```

data annotel;
  length function color $8;
  retain ysys xsys '2' color 'black';
  function='move';
  x=0;
  y=0;
  output;
  function='draw';
  x=1;
  y=1;
  output;
run;

symbol1 c=blue;
proc reg data=fitness;
  title 'PP Plot';
  model Oxygen=RunTime / noprint;
  plot npp.*r.
    / annotate=annotel nostat cframe=ligr
      modellab="'Best' Two-Parameter Model:";
run;
  title 'QQ Plot';
  plot r.*nqq.
    / noline mse cframe=ligr
      modellab="'Best' Two-Parameter Model:";
run;

```

Output 61.8.1. Normal Probability-Probability Plot for the Residuals

Output 61.8.2. Normal Quantile-Quantile Plot for the Residuals

Example 61.9. Displaying Confidence and Prediction Intervals

This example illustrates how you can use shorthand commands to plot the dependent variable, the predicted value, and the 95% confidence or prediction intervals against a regressor. The following statements use the PRED option to create a plot with prediction intervals; the CONF option works similarly. Results are displayed in [Output 61.9.1](#). Note that the statistics displayed by default in the margin are suppressed while three other statistics are exhibited.

```

legend1 position=(bottom left inside)
        across=1 cborder=red offset=(0,0)
        shape=symbol(3,1) label=none
        value=(height=.8);
title 'Prediction Intervals';
symbol1 c=yellow v=- h=1;
symbol2 c=red;
symbol3 c=blue;
symbol4 c=blue;

proc reg data=fitness;
    model Oxygen=RunTime / noprint;
    plot Oxygen*RunTime / pred nostat mse aic bic
        caxis=red ctext=blue cframe=ligr
        legend=legend1 modellab='          ';
run;

```

Output 61.9.1. Prediction Intervals

Plots can be produced with both confidence and prediction intervals using the following statement.

```
plot Oxygen*RunTime / conf pred;
```

Example 61.10. Displaying the Ridge Trace for Acetylene Data

This example and [Example 61.11](#) use the acetylene data in Marquardt and Snee (1975) to illustrate the RIDGEPLOT and OUTVIF options.

```
data acetyl;
  input x1-x4 @@;
  x1x2 = x1 * x2;
  x1x1 = x1 * x1;
  label x1 = 'reactor temperature(celsius)'
        x2 = 'h2 to n-heptone ratio'
        x3 = 'contact time(sec)'
        x4 = 'conversion percentage'
        x1x2 = 'temperature-ratio interaction'
        x1x1 = 'squared temperature';
  datalines;

      vref=0 lvref=1 cvref=blue cframe=ligr;
run;

```

The results produced by the RIDGEPLOT option are shown in [Output 61.10.1](#). The OUTVIF option outputs the variance inflation factors to the OUTEST= data set, which is used in [Example 61.11](#).

Output 61.10.1. Using the RIDEGPLOT Option for Ridge Regression

If you specify the experimental ODS GRAPHICS statement (see the “[ODS Graphics](#)” section on page 3922), a plot of ridge traces is produced, without the need to specify the RIDGEPLOT option in the PLOT statement. For general information about

ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” The following statements provide an example:

```
ods html;
ods graphics on;

proc reg data=acetyl outest=b ridge=0 to 0.02 by .002;
  model x4=x1 x2 x3 x1x2 x1x1/noprint;
run;

ods graphics off;
ods html close;
```

Output 61.10.2. Ridge Traces Produced with ODS Graphics (Experimental)

Example 61.11. Plotting Variance Inflation Factors

This example uses the REG procedure to create plots from a data set. The variance inflation factors (output by the OUTVIF option in the previous example) are plotted against the ridge regression control values k . The following statements create [Output 61.11.1](#):

```

data b (keep=_RIDGE_ x1-x3 x1x2 x1x1);
  set b;
  if _TYPE_='RIDGEVIF';
  label x1='variance inflation factor';
run;

legend3 position=(top right inside) across=3
  cborder=black cframe=white
  label=(color=blue position=(top center)
    'independent variables')
  value=('X1' 'X2' 'X3' 'X1X2' 'X1X1');
symbol1 c=blue /*v=circle */;
symbol2 c=yellow /*v=x */;
symbol3 c=cyan /*v=triangle*/;
symbol4 c=green /*v=square */;
symbol5 c=orange /*v=diamond */;
title 'Variance Inflation Factors of Acetylene Data';

proc reg data=b;
  var _RIDGE_ x3 x1x2 x1x1;
  model x1=x2 / noprint;
  plot (x1 x2 x3 x1x2 x1x1)*_RIDGE_
    / nomodel nostat legend=legend3 overlay
    vaxis = 0 to 75 by 25 cframe=ligr
    haxis = 0 to .02 by .002;
  footnote "Note: the VIF at k=0 is 7682 for X1, "
    "6643 for X1X1, 345 for X1X2, and 320 for X2";
run;

```

The GPLOT procedure can create the same plot with the following statements. The resulting display is not shown in this report.

```

axis1 label=(a=90 r=0 'variance inflation factor')
  order=(0 to 75 by 25) minor=none;
proc gplot data=b;
  plot (x1 x2 x3 x1x2 x1x1)*_RIDGE_
    / legend=legend3 overlay frame
    vaxis = axis1
    haxis = 0 to .02 by .002 hminor=0;
  footnote "Note: the VIF at k=0 is 7682 for X1, "
    "6643 for X1X1, 345 for X1X2, and 320 for X2";
run;

```

Output 61.11.1. Using PROC REG to Plot the VIFs

Example 61.12. ODS Graphics

This example highlights the use of ODS for creating statistical graphs with the REG procedure. The USPopulation example is revisited, showing how these graphics can be used to enrich the analysis. Note that the ODS graphics available with PROC REG can be obtained in addition to the graphics you can request with the PLOT statement.

To request the ODS plots you need to specify the experimental ODS GRAPHICS statement. For general information about ODS graphics, see [Chapter 15, “Statistical Graphics Using ODS.”](#) For specific information about the graphics available in the REG procedure, see the [“ODS Graphics”](#) section on page 3922.

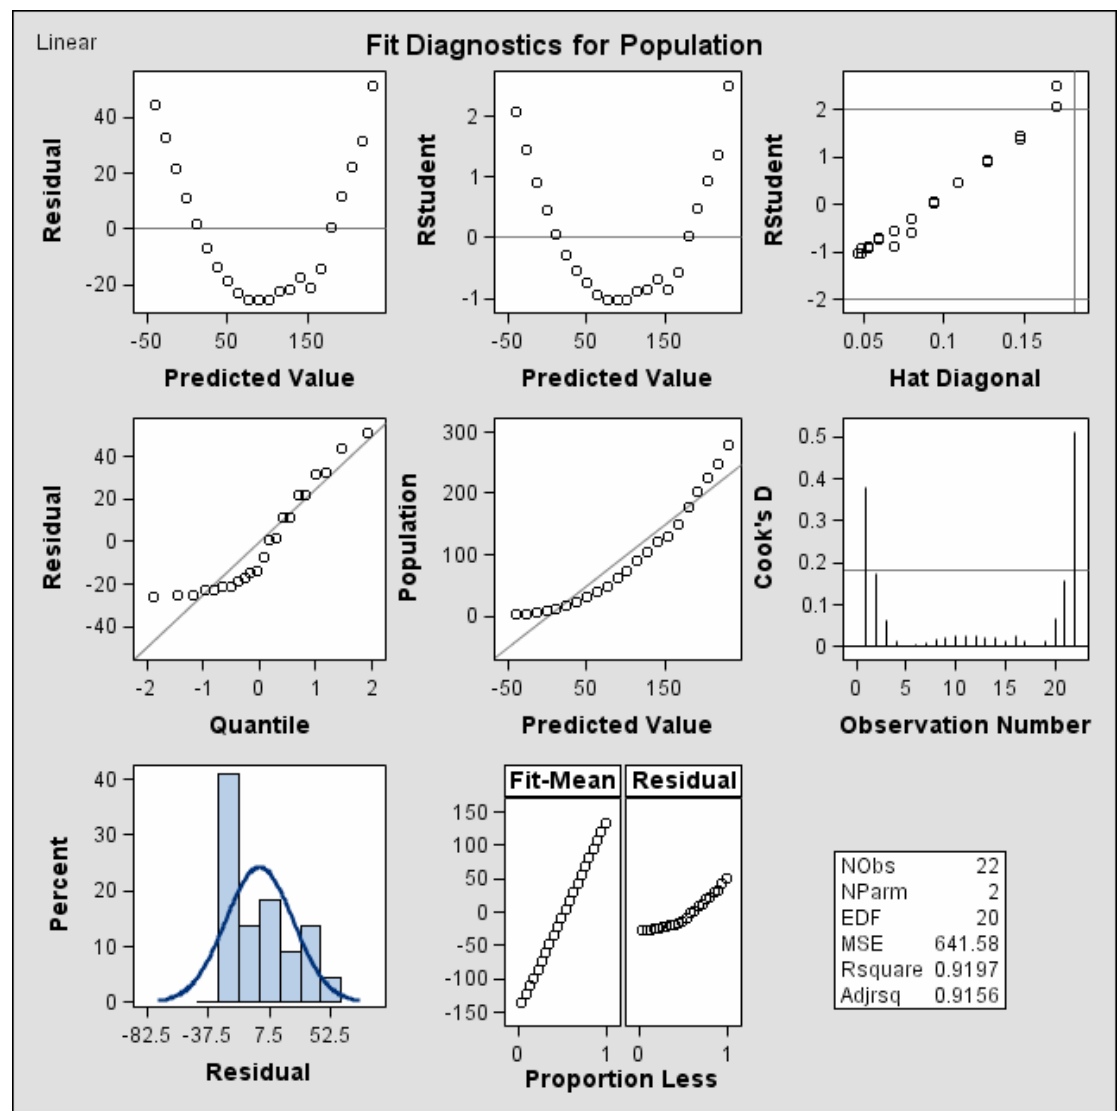

The following statements produce the default plots:

```
ods html;
ods graphics on;

proc reg data=USPopulation;
  Linear: model Population=Year;
  Quadratic: model Population=Year YearSq;
run;quit;

ods graphics off;
ods html close;
```

Output 61.12.1. Fit Diagnostics For the Model Linear in Year (Experimental)

When the experimental ODS graphics are in effect, the fit diagnostic panel [Output 61.12.1](#) is produced by default. These diagnostic plots suggest that while the linear model captures the increasing trend in the data, the model could be significantly improved by adding a term which is quadratic in the variable year:

- The plots of residual and studentized residual versus predicted value show a clear quadratic pattern.
- The plot of studentized residual versus leverage seems to indicate that there are two outlying data points. However, the plot of Cook's D distance versus observation number reveals that these two points are just the data points for the endpoint years 1790 and 2000. These points show up as apparent outliers be-

cause the departure of the linear model from the underlying quadratic behavior in the data shows up most strongly at these endpoints.

- The normal quantile plot of the residuals and the residual histogram are not consistent with the assumption of gaussian errors. This occurs as the residuals themselves still contain the quadratic behavior that is not captured by the linear model.
- The plot of the dependent variable versus the predicted value exhibits a quadratic form around the 45 degree line which represents a perfect fit.
- The “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals shows that the spread in the residuals is no greater than the spread in the centered fit. For inappropriate models, the spread of the residuals in such a plot is often greater than the spread of the centered fit. In this case, the RF plot shows that the linear model does indeed capture the increasing trend in the data, and hence accounts for much of the variation in the response.

Output 61.12.2. Residual By Year For the Model Linear in Year (Experimental)

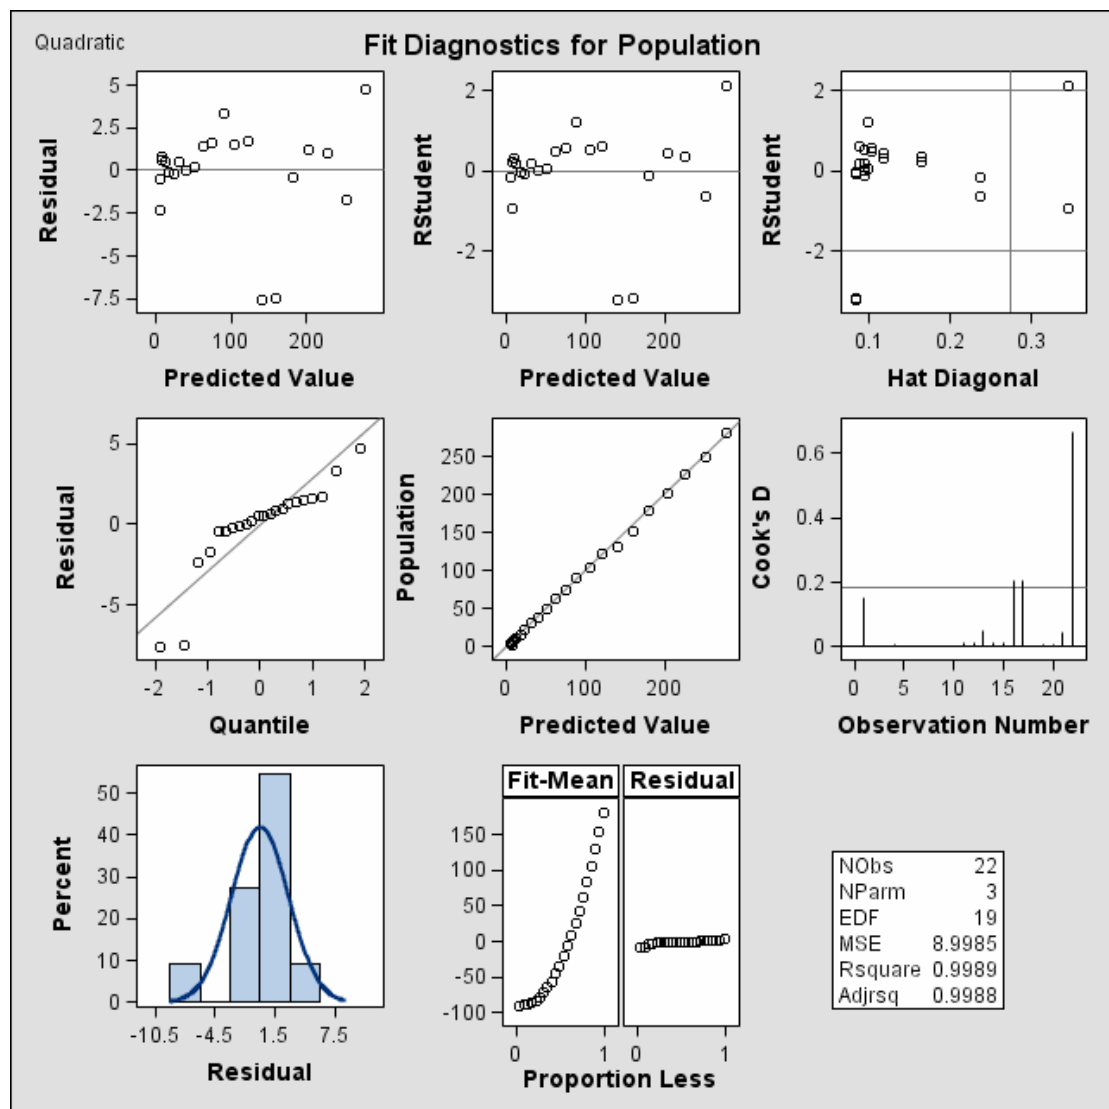

The plot of residual versus the regressor shown in [Output 61.12.2](#) also indicates the need for a quadratic term in the model. There is a strong quadratic trend still remain-

ing in the residuals. Note for models with multiple regressors the plots of residual versus each of the regressors are displayed in panels with up to six plots per panel.

Output 61.12.3. Fit Plot with Confidence Band and Prediction Limits
(Experimental)

Output 61.12.3 shows as scatterplot of the data overlaid with the regression line, and 95% confidence band and prediction limits. Note that this plot also indicates that the model fails to capture the quadratic nature of the data. This plot is produced for models containing a single regressor. You can use the ALPHA= option in the model statement to change the significance level of the confidence band and prediction limits.

Output 61.12.4. Fit Diagnostics For the Model Linear in Year (Experimental)

By contrast, [Output 61.12.4](#) shows the fit diagnostics panel for the model that includes a quadratic term for year. These diagnostics indicate that this model is significantly more successful than the corresponding linear model:

- The plots of residuals and studentized residuals versus predicted values exhibit no obvious patterns.
- The points on the plot of the dependent variable versus the predicted values lie along a 45 degree line, indicating that the model successfully predicts the behavior of the dependent variable.
- The plot of studentized residual versus leverage shows that the years 1790 and 2000 are leverage points with 2000 showing up as an outlier. This is confirmed by the plot of Cook's D distance versus observation number. This suggests that

while the quadratic model fits the current data well, the model may not be quite so successful over a wider range of data. You might want to investigate whether the population trend over the last couple of decades is growing slightly faster than quadratically.

If you want to obtain the plots in the Diagnostics Panel as individual plots, you can do so by specifying the PLOTS(UNPACKPANELS) option in the PROC REG statement. The following statements provide an example:

```
ods html;
ods graphics on;

proc reg data=USPopulation plots(unpackpanels);
  Quadratic:model Population=Year YearSq;
run;quit;

ods graphics off;
ods html close;
```

Output 61.12.5. Residual Histogram (Experimental)

The residual histogram is shown in [Output 61.12.5](#).

Chapter 62

The ROBUSTREG Procedure

Overview

The main purpose of robust regression is to detect outliers and provide resistant (stable) results in the presence of outliers. In order to achieve this stability, robust regression limits the influence of outliers. Historically, three classes of problems have been addressed with robust regression techniques:

- problems with outliers in the y -direction (response direction)
- problems with multivariate outliers in the x -space (i.e., outliers in the covariate space, which are also referred to as leverage points)
- problems with outliers in both the y -direction and the x -space

Many methods have been developed in response to these problems. However, in statistical applications of outlier detection and robust regression, the methods most commonly used today are Huber M estimation, high breakdown value estimation, and combinations of these two methods. The new ROBUSTREG procedure in this version provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

1. M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in analyzing data for which it can be assumed that the contamination is mainly in the response direction.
2. Least Trimmed Squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. The performance of this method was improved by the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000).
3. S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.
4. MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

Experimental graphics are now available with the ROBUSTREG procedure. For more information, see the section “[ODS Graphics](#)” on page 4013.

Getting Started

The following examples demonstrate how you can use the ROBUSTREG procedure to fit a linear regression model and conduct outlier and leverage point diagnostics.

M Estimation

This example shows how you can use the ROBUSTREG procedure to do M estimation, which is a commonly used method for outlier detection and robust regression when contamination is mainly in the response direction.

```
data stack;
  input x1 x2 x3 y;
  datalines;
80 27 89 42
80 27 88 37
75 25 90 37
62 24 87 28
62 22 87 18
62 23 87 18
62 24 93 19
62 24 93 20
58 23 87 15
58 18 80 14
58 18 89 14
58 17 88 13
58 18 82 11
58 19 93 12
50 18 89 8
50 18 86 7
50 19 72 8
50 19 79 8
50 20 80 9
56 20 82 15
70 20 91 15
;
```

The data set `stack` is the well-known `stackloss` data set presented by Brownlee (1965). The data describe the operation of a plant for the oxidation of ammonia to nitric acid and consist of 21 four-dimensional observations. The explanatory variables for the response `stackloss` (`y`) are the rate of operation (`x1`), the cooling water inlet temperature (`x2`), and the acid concentration (`x3`).

The following ROBUSTREG statements analyze the data:

```
proc robustreg data=stack;
  model y = x1 x2 x3 / diagnostics leverage;
  id x1;
  test x3;
run;
```

By default, the procedure does M estimation with the bisquare weight function, and it uses the median method for estimating the scale parameter. The MODEL statement specifies the covariate effects. The DIAGNOSTICS option requests a table for outlier diagnostics, and the LEVERAGE option adds leverage point diagnostic results to this table for continuous covariate effects. The ID statement specifies that variable x1 is used to identify each observation in this table. If the ID statement is omitted, the observation number is used to identify the observations. The TEST statement requests a test of significance for the covariate effects specified. The results of this analysis are displayed in the following figures.

The ROBUSTREG Procedure						
Model Information						
Data Set	WORK.STACK					
Dependent Variable	y					
Number of Covariates	3					
Number of Observations	21					
Method	M Estimation					
Summary Statistics						
Variable	Q1	Median	Q3	Mean	Standard Deviation	MAD
x1	53.0000	58.0000	62.0000	60.4286	9.1683	5.9304
x2	18.0000	20.0000	24.0000	21.0952	3.1608	2.9652
x3	82.0000	87.0000	89.5000	86.2857	5.3586	4.4478
y	10.0000	15.0000	19.5000	17.5238	10.1716	5.9304

Figure 62.1. Model Fitting Information and Summary Statistics

Figure 62.1 displays the model fitting information and summary statistics for the response variable and the continuous covariates. The columns labeled Q1, Median, and Q3 provide the lower quantile, median, and upper quantile. The column labeled MAD provides a robust estimate of the univariate scale, which is computed as the corrected median absolute deviation (MAD). The columns labeled Mean and Standard Deviation provide the usual mean and standard deviation. Large difference between the standard deviation and the MAD for a variable indicates some big jumps for this variable. In the stackloss data, the stackloss (response variable y) has the biggest difference between the standard deviation and the dispersion.

The ROBUSTREG Procedure							
Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-42.2854	9.5045	-60.9138	-23.6569	19.79	<.0001
x1	1	0.9276	0.1077	0.7164	1.1387	74.11	<.0001
x2	1	0.6507	0.2940	0.0744	1.2270	4.90	0.0269
x3	1	-0.1123	0.1249	-0.3571	0.1324	0.81	0.3683
Scale	1	2.2819					

Figure 62.2. Model Parameter Estimates

Figure 62.2 displays the table of robust parameter estimates, standard errors, and confidence limits. The row labeled Scale provides a point estimate of the scale parameter in the linear regression model, which is obtained by the median method. See the section “M Estimation” on page 3993 for more information about scale estimation methods. For the stackloss data, M estimation yields the fitted linear model:

$$\hat{y} = -42.2845 + 0.9276x_1 + 0.6507x_2 - 0.1123x_3$$

The ROBUSTREG Procedure						
Diagnostics						
Obs	x1	Mahalanobis Distance	Robust MCD Distance	Leverage	Standardized Robust Residual	Outlier
1	80.000000	2.2536	5.5284	*	1.0995	
2	80.000000	2.3247	5.6374	*	-1.1409	
3	75.000000	1.5937	4.1972	*	1.5604	
4	62.000000	1.2719	1.5887		3.0381	*
21	70.000000	2.1768	3.6573	*	-4.5733	*

Diagnostics Summary			
Observation Type	Proportion	Cutoff	
Outlier	0.0952	3.0000	
Leverage	0.1905	3.0575	

Figure 62.3. Diagnostics

Figure 62.3 displays outlier and leverage point diagnostics. Standardized robust residuals are computed based on the estimated parameters. Both the Mahalanobis distance and the robust MCD distance are displayed. Outliers and leverage points, identified with asterisks, are defined by the standardized robust residuals and robust MCD distances which exceed the corresponding cutoff values displayed in the diagnostics profile. Observations 4 and 21 are outliers because their standardized robust residuals exceed the cutoff value in absolute value. The procedure detects 4 observations with high leverage, which is contributed mainly by x1, especially for the first three observations. This can be verified by the definition of the robust MCD distance in the section “Robust Multivariate Location and Scale Estimates” on page 4009. Leverage points (points with high leverage) with smaller standardized robust residuals than the cutoff value in absolute value are called good leverage points; otherwise, called bad leverage points. Observations 21 is a bad leverage point.

Two particularly useful plots for revealing outliers and leverage points are a scatter plot of the standardized robust residuals against the robust distances (RDPLLOT) and a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT).

For the stackloss data, the following statements produce the RDPLLOT in Figure 62.4 and the DDPLOT in Figure 62.5. The histogram and the normal quantile-quantile plots for the standardized robust residuals are also created with the

RESHISTOGRAM and RESQQPLOT options in the PROC statement. See Figure 62.6 and Figure 62.7.

Figure 62.4. RDPlot for Stackloss Data (Experimental)

Figure 62.5. DDPlot for Stackloss Data (Experimental)

Figure 62.6. Histogram (Experimental)

Figure 62.7. Q-Q PLOT (Experimental)

```
ods html;
ods graphics on;

proc robustreg data=stack
  plots=(rdplot ddplot reshistogram resqqplot);
  model y = x1 x2 x3;
run;

ods graphics off;
ods html close;
```

These plots are helpful in identifying outliers, good, and bad high leverage points.

These graphical displays are requested by specifying the experimental ODS GRAPHICS statement and the experimental PLOT | PLOTS= option in the PROC statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the ROBUSTREG procedure, see the section “ODS Graphics” on page 4013.

The ROBUSTREG Procedure	
Goodness-of-Fit	
Statistic	Value
R-Square	0.6659
AICR	29.5231
BICR	36.3361
Deviance	125.7905

Figure 62.8. Goodness-of-Fit

Figure 62.8 displays robust versions of goodness-of-fit statistics for the model. You can use the robust information criteria, AICR and BICR, for model selection and comparison. For both AICR and BICR, the lower the value the more describable the model.

The ROBUSTREG Procedure					
Robust Linear Tests					
Test					
Test	Test Statistic	Lambda	DF	Chi- Square	Pr > ChiSq
Rho	0.9378	0.7977	1	1.18	0.2782
Rn2	0.8092		1	0.81	0.3683

Figure 62.9. Test of Significance

Figure 62.9 displays the test results requested by the TEST statement. The ROBUSTREG procedure conducts two robust linear tests, the ρ -test and the R_n^2 -test. See the section “Linear Tests” on page 3998 for information on how the procedure computes test statistics and the correction factor *lambda*. You can conclude that the effect x3 is not significant.

For the bisquare weight function, the default constant c is 4.685 such that the asymptotic efficiency of the M estimates is 95% with the Gaussian distribution. See the section “M Estimation” on page 3993 for details. The smaller the constant c , the lower the asymptotic efficiency but the sharper the M estimate as an outlier detector. For the stackloss data set, you could consider using a sharper outlier detector.

In the following invocation of the ROBUSTREG procedure, a smaller constant, e.g. $c = 3.5$, is used.

```
proc robustreg method=m(wf=bisquare(c=3.5)) data=stack;
  model y = x1 x2 x3 / diagnostics leverage;
  id    x1;
  test  x3;
run;
```

The ROBUSTREG Procedure							
Parameter Estimates							
Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	-37.1076	5.4731	-47.8346	-26.3805	45.97	<.0001
x1	1	0.8191	0.0620	0.6975	0.9407	174.28	<.0001
x2	1	0.5173	0.1693	0.1855	0.8492	9.33	0.0022
x3	1	-0.0728	0.0719	-0.2138	0.0681	1.03	0.3111
Scale	1	1.4265					

Figure 62.10. Model Parameter Estimates

Figure 62.10 displays the table of robust parameter estimates, standard errors, and confidence limits with the constant $c = 3.5$. The refitted linear model is:

$$\hat{y} = -37.1076 + 0.8191x_1 + 0.5173x_2 - 0.0728x_3$$

The ROBUSTREG Procedure						
Diagnostics						
Obs	x1	Mahalanobis Distance	Robust MCD Distance	Leverage	Standardized Robust Residual	Outlier
1	80.000000	2.2536	5.5284	*	4.2719	*
2	80.000000	2.3247	5.6374	*	0.7158	
3	75.000000	1.5937	4.1972	*	4.4142	*
4	62.000000	1.2719	1.5887		5.7792	*
21	70.000000	2.1768	3.6573	*	-6.2727	*

Diagnostics Summary		
Observation Type	Proportion	Cutoff
Outlier	0.1905	3.0000
Leverage	0.1905	3.0575

Figure 62.11. Diagnostics

Figure 62.11 displays outlier and leverage point diagnostics with the constant $c = 3.5$. Besides observations 4 and 21, observations 1 and 3 are also detected as outliers.

LTS Estimation

If the data are contaminated in the x -space, M estimation does not do well. The following example shows how you can use LTS estimation to deal with this situation.

```

data hbk;
  input index$ x1 x2 x3 y @@;
  datalines;

```

The data set `hbk` is an artificial data set generated by Hawkins, Bradu, and Kass (1984). Both ordinary least squares (OLS) estimation and M estimation (not shown

here) suggest that observations 11 to 14 are serious outliers. However, these four observations were generated from the underlying model, whereas observations 1 to 10 were contaminated. The reason that OLS estimation and M estimation do not pick up the contaminated observations is that they cannot distinguish good leverage points (observations 11 to 14) from bad leverage points (observations 1 to 10). In such cases, the LTS method identifies the true outliers.

The following statements invoke the ROBUSTREG procedure with the LTS estimation method.

```
proc robustreg data=hbk fwls method=lts;
  model y = x1 x2 x3 / diagnostics leverage;
  id index;
run;
```

The ROBUSTREG Procedure						
Model Information						
Data Set	WORK.HBK					
Dependent Variable	y					
Number of Covariates	3					
Number of Observations	75					
Method	LTS Estimation					
Summary Statistics						
Variable	Q1	Median	Q3	Mean	Standard Deviation	MAD
x1	0.8000	1.8000	3.1000	3.2067	3.6526	1.9274
x2	1.0000	2.2000	3.3000	5.5973	8.2391	1.6309
x3	0.9000	2.1000	3.0000	7.2307	11.7403	1.7791
y	-0.5000	0.1000	0.7000	1.2787	3.4928	0.8896

Figure 62.12. Model Fitting Information and Summary Statistics

Figure 62.12 displays the model fitting information and summary statistics for the response variable and independent covariates.

The ROBUSTREG Procedure	
LTS Profile	
Total Number of Observations	75
Number of Squares Minimized	57
Number of Coefficients	4
Highest Possible Breakdown Value	0.2533

Figure 62.13. LTS Profile

Figure 62.13 displays information about the LTS fit, which includes the breakdown value of the LTS estimate. Roughly speaking, the breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. In this example the LTS estimate minimizes the sum of 57

smallest squares of residuals. It can still pick up the right model if the remaining 18 observations are contaminated. This corresponds to the breakdown value around 0.25, which is set as the default.

The ROBUSTREG Procedure		
LTS Parameter Estimates		
Parameter	DF	Estimate
Intercept	1	-0.3431
x1	1	0.0901
x2	1	0.0703
x3	1	-0.0731
Scale (sLTS)	0	0.7451
Scale (Wscale)	0	0.5749

Figure 62.14. LTS Parameter Estimates

Figure 62.14 displays parameter estimates for covariates and scale. Two robust estimates of the scale parameter are displayed. See the section “Final Weighted Scale Estimator” on page 4002 for how these estimates are computed. The weighted scale estimate (Wscale) is a more efficient estimate of the scale parameter.

Figure 62.16. Final Weighted LS Estimates

Figure 62.16 displays the final weighted least squares estimates. These estimates are least squares estimates computed after deleting the detected outliers.

Syntax

```

PROC ROBUSTREG < options > ;
  BY variables ;
  CLASS variables ;
  ID variables ;
  MODEL response = < effects > < / options > ;
  OUTPUT < OUT= SAS-data-set > < options > ;
  PERFORMANCE < options > ;
  TEST 'label' effects ;
  WEIGHT variable ;

```

The PROC ROBUSTREG statement invokes the procedure. The METHOD= option in the PROC ROBUSTREG statement selects one of the four estimation methods, M, LTS, S, and MM. By default, Huber M estimation is used. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure. The CLASS statement specifies which explanatory variables are treated as categorical. These variables are allowed in the MODEL statement only for M estimation, and not for other estimation methods. The ID statement names variables to identify observations in the outlier diagnostics tables. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. The OUTPUT statement creates an output data set containing final weights, predicted values, and residuals. The TEST statement requests robust linear tests for the model parameters. The PERFORMANCE statement tunes the performance of the procedure by using single or multiple processors available on the hardware. In one invocation of PROC ROBUSTREG, multiple OUTPUT and TEST statements are allowed.

PROC ROBUSTREG Statement

PROC ROBUSTREG < options > ;

The PROC ROBUSTREG statement invokes the procedure. You can specify the following options in the PROC ROBUSTREG statement.

COVOUT

saves the estimated covariance matrix in the OUTEST= data set for M estimation and MM estimation.

DATA=SAS-data-set

specifies the input SAS data set used by PROC ROBUSTREG. By default, the most recently created SAS data set is used.

FWLS

requests that final weighted least squares estimators be computed.

INEST= SAS-data-set

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “[INEST= Data Set](#)” on page 4011 for a detailed description of the contents of the INEST= data set.

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the MODEL statement.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the classification variables (specified in the CLASS statement). This ordering determines which parameters in the model correspond to each level in the data. The following table explains how PROC ROBUSTREG interprets values of the ORDER= option.

Table 62.1. Options for Order

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	formatted value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, refer to the chapter titled “The SORT Procedure” in the *SAS Procedures Guide*.

OUTEST=SAS-data-set

specifies an output SAS data set containing the parameter estimates, and, if the COVOUT option is specified, the estimated covariance matrix. See the section “[OUTEST= Data Set](#)” on page 4011 for a detailed description of the contents of the OUTEST= data set.

SEED=number

specifies the seed for the random number generator used to randomly select the subgroups and subsets for LTS and S estimation. By default or you specify zero, the ROBUSTREG procedure generates a seed between one and one billion.

METHOD= method type < (options) >

specifies the estimation method and *options* specify some additional options for the estimation method. PROC ROBUSTREG provides four estimation methods: M estimation, LTS estimation, S estimation, and MM estimation. The default method is M estimation.

Since the LTS and S methods use subsampling algorithms, it is not suitable to apply these methods to an analysis with continuous independent variables which have only a few nonzero values or a few nonzero values within one BY group.

Options with METHOD=M

With METHOD=M, you can specify the following additional *options*:

ASYMPCOV=H1 | H2 | H3

specifies the type of asymptotic covariance computed for the M estimate. The three types are described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 3997. By default, ASYMPCOV= H1.

CONVERGENCE=criterion <(EPS=value)>

specifies a convergence criterion for the M estimate.

Table 62.2. Options to Specify Convergence Criteria

Type	Option
residual	CONVERGENCE= RESID
weight	CONVERGENCE= WEIGHT
coefficient	CONVERGENCE= COEF

By default, CONVERGENCE = COEF. You can specify the precision of the convergence can be specified with the EPS= option. By default, EPS=1.E–8.

MAXITER=n

sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

SCALE=scale type | value

specifies the scale parameter or a method for estimating the scale parameter.

Table 62.3. Options to Specify Scale

Scale	Option	Default d
Median estimate	SCALE=MED	
Tukey estimate	SCALE=TUKEY<(D=d)>	2.5
Huber estimate	SCALE=HUBER<(D=d)>	2.5
Fixed constant	SCALE= <i>value</i>	

By default, SCALE = MED.

WF | WEIGHTFUNCTION=*function type*

specifies the weight function used for the M estimate. The ROBUSTREG procedure provides ten weight functions, which are listed in the following table. You can specify the parameters in these functions with the A=, B=, and C= options. These functions are described in the section “M Estimation” on page 3993. The default weight function is bisquare.

Table 62.4. Options to Specify Weight Functions

Weight Function	Option	Default a, b, c
andrews	WF = ANDREWS<(C=c)>	1.339
bisquare	WF = BISQUARE<(C=c)>	4.685
cauchy	WF = CAUCHY<(C=c)>	2.385
fair	WF = FAIR<(C=c)>	1.4
hampel	WF = HAMPEL<(<A=a> <B=b> <C=c>)>	2, 4, 8
huber	WF = HUBER<(C=c)>	1.345
logistic	WF = LOGISTIC<(C=c)>	1.205
median	WF = MEDIAN<(C=c)>	0.01
talworth	WF = TALWORTH<(C=c)>	2.795
welsch	WF = WELSCH<(C=c)>	2.985

Options with METHOD=LTS

With METHOD=LTS, you can specify the following additional *options*:

CSTEP=*n*

specifies the number of C-steps for the LTS estimate. See the section “LTS Estimate” on page 4000 for how the default value is determined.

IADJUST=ALL | NONE

requests (IADJUST=ALL) or suppresses (IADJUST=NONE) the intercept adjustment for all estimates in the LTS-algorithm. By default, the intercept adjustment is used for data sets with less than 10000 observations. See the section “Algorithm” on page 4001 for details.

H=*n*

specifies the quantile for the LTS estimate. See the section “LTS Estimate” on page 4000 for how the default value is determined.

NBEST=*n*

specifies the number of best solutions kept for each subgroup during the computation of the LTS estimate. The default number is 10, which is the maximum number allowed.

NREP=*n*

specifies the number of repeats of least squares fit in subgroups during the computation of the LTS estimate. See the section “[LTS Estimate](#)” on page 4000 for how the default number is determined.

SUBANALYSIS

requests a display of the subgrouping information and parameter estimates within subgroups. This option may generate the following ODS tables:

Table 62.5. ODS Tables Available with SUBANALYSIS

ODS Table Name	Description
BestEstimates	Best final estimates for LTS
BestSubEstimates	Best estimates for each subgroup
CStep	C-Step information for LTS
Groups	Grouping information for LTS

Some of these tables are data dependent.

SUBGROUPSIZE=*n*

specifies the data set size of the subgroups in the computation of the LTS estimate. The default number is 300.

Options with METHOD=S

With METHOD=S, you can specify the following additional *options*:

ASYMPCOV=H1 | H2 | H3 | H4

specifies the type of asymptotic covariance computed for the S estimate. The four types are described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 4005. By default, ASYMPCOV= H4.

CHIF= TUKEY | YOHAI

specifies the χ function for the S estimate. PROC ROBUSTREG provides two χ functions, Tukey’s BISQUARE function and Yohai’s OPTIMAL function, which you can request with CHIF=TUKEY and CHIF=YOHA1, respectively. The default is Tukey’s bisquare function.

EFF=*value*

specifies the efficiency for the S estimate. The parameter k_0 in the χ function is determined by this efficiency. The default efficiency is determined such that the consistent S estimate has the breakdown value of 25%.

MAXITER=*n*

sets the maximum number of iterations for computing the scale parameter of the S estimate. By default, MAXITER=1000.

NREP=*n*

specifies the number of repeats of subsampling in the computation of the S estimate. See the section “Algorithm” on page 4004 for how the default number of repeats is determined.

NOREFINE

suppresses the refinement for the S estimate. See the section “Algorithm” on page 4004 for details.

SUBSETSIZE=*n*

specifies the size of the subset for the S estimate. See the section “Algorithm” on page 4004 for how its default value is determined.

TOLERANCE=*value*

specifies the tolerance for the S estimate of the scale. The default value is .001.

Options with METHOD=MM

With METHOD=MM, you can specify the following additional *options*:

ASYMPCOV=*H1* | *H2* | *H3* | *H4*

specifies the type of asymptotic covariance computed for the MM estimate. The four types are described in the “Details” section. By default, ASYMPCOV= H4.

BIATEST<(ALPHA= *number*)>

requests the bias test for the final MM estimate. See the section “Bias Test” on page 4008 for details about this test.

CHIF= TUKEY | YOHAI

selects the χ function for the MM estimate. PROC ROBUSTREG provides two χ functions: Tukey’s BISQUARE function and Yohai’s OPTIMAL function, which you can request with CHIF=TUKEY and CHIF=YOHAII, respectively. The default is Tukey’s bisquare function. This χ function is also used by the initial S estimate if you specify the INITEST=S option.

CONVERGENCE=*criterion* <(EPS=*number*)>

specifies a convergence criterion for the MM estimate.

Table 62.6. Options to Specify Convergence Criteria

Type	Option
residual	CONVERGENCE= RESID
weight	CONVERGENCE= WEIGHT
coefficient	CONVERGENCE= COEF

By default, CONVERGENCE = COEF. You can specify the precision of the convergence with the EPS= option. By default, EPS=1.E–8.

EFF=*value*

specifies the efficiency for the MM estimate. The parameter k_1 in the χ function is determined by this efficiency. The default efficiency is set to 85%, which corresponds to $k_1 = 3.440$ for CHIF=DUKE or $k_1 = 0.868$ for CHIF=YOHA1.

INITH=*n*

specifies the integer h for the initial LTS estimator used by the MM estimator. See the section “Algorithm” on page 4007 for how to specify h and how the default is determined.

INITEST= LTS | S

specifies the initial estimator for the MM estimator. By default, the LTS estimator is used as the initial estimator for the MM estimator.

K0=*number*

specifies the parameter k_0 in the χ function for the MM estimate. For CHIF=DUKE, the default is $k_0 = 2.9366$. For CHIF=YOHA1, the default is $k_0 = 0.7405$. These default values correspond to the 25% breakdown value of the MM estimator.

MAXITER=*n*

sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC ROBUSTREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the ROBUSTREG procedure. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the *SAS Procedures Guide*.

CLASS Statement

CLASS *variables* ;

Explanatory variables that are classification variables rather than quantitative numeric variables must be listed in the CLASS statement. For each explanatory variable listed in the CLASS statement, indicator variables are generated for the levels assumed by the CLASS variable. If the CLASS statement is used, it must appear before the MODEL statement.

ID Statement

ID *variables* ;

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed besides the observation number. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

MODEL Statement

<label:> **MODEL** *response* = *<effects>* *</options >* ;

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure. Class variables are not allowed in the MODEL statement when you specify MM estimation or LTS estimation using the METHOD= option in the PROC statement.

The optional *label* is used to label output from the matching MODEL statement.

Options

You can specify the following options for the model fit.

ALPHA=*value*

specifies the significance level for the confidence intervals for regression parameters. The value must be between 0 and 1. By default, ALPHA = 0.05.

CORRB

produces the estimated correlation matrix of the parameter estimates.

COVB

produces the estimated covariance matrix of the parameter estimates.

CUTOFF=*value*

specifies the multiplier of the cutoff value for outlier detection. By default, CUTOFF = 3.

DIAGNOSTICS*<(ALL)>*

requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. To request that all observations be displayed, specify the ALL option.

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the PROC statement.

LEVERAGE<(CUTOFF=*value* | CUTOFFALPHA=*value* | QUANTILE=*n*)>

requests an analysis of leverage points for the continuous covariates. The results are added to the diagnostics table, which you can request with the DIAGNOSTICS option in the MODEL statement. You can specify the cutoff value for leverage point detection with the CUTOFF= option. The default cutoff value is $\sqrt{\chi_{p;1-\alpha}^2}$, where α can be specified with the CUTOFFALPHA= option. By default, $\alpha = .025$. You can use the QUANTILE= option to specify the quantile to be minimized for the MCD algorithm used for the leverage point analysis. By default, $\text{QUANTILE} = [(3n + p + 1)/4]$, where n is the number of observations and p is the number of independent variables. The LEVERAGE option is ignored if the model includes class variables as covariates.

Since the MCD algorithm uses subsampling, it is not suitable to apply the leverage point analysis to continuous variables which have only a few nonzero values or a few nonzero values within one BY group.

NOGOODFIT

suppresses the computation of goodness-of-fit statistics.

NOINT

specifies no-intercept regression.

SINGULAR=*value*

specifies the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least-squares estimates. Roughly, the test requires that a pivot be at least this value times the original diagonal value. By default, $\text{SINGULAR} = 1.E-12$.

OUTPUT Statement

```
OUTPUT <OUT=SAS-data-set> keyword=name <...keyword=name>
      ;
```

The OUTPUT statement creates an output SAS data set containing statistics calculated after fitting the model. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables created with *keyword* options in the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for more information on permanent SAS data sets).

The following specifications can appear in the OUTPUT statement:

OUT=SAS-data-set specifies the new data set. By default, the procedure uses the **DATA***n* convention to name the new data set.

keyword=name specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

LEVERAGE specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the PROC statement. See the section “[Leverage Point and Outlier Detection](#)” on page 4010 for how to define LEVERAGE.

OUTLIER specifies a variable to indicate outliers. See the section “[Leverage Point and Outlier Detection](#)” on page 4010 for how to define OUTLIER.

PREDICTED | P specifies a variable to contain the estimated response.

RESIDUAL | R specifies a variable to contain the residuals

$$y_i - \mathbf{x}_i^T \mathbf{b}$$

SRESIDUAL | SR specifies a variable to contain the standardized residuals

$$\frac{y_i - \mathbf{x}_i^T \mathbf{b}}{\hat{\sigma}}$$

STDP specifies a variable to contain the estimates of the standard errors of the estimated response.

WEIGHT specifies a variable to contain the computed final weights.

PERFORMANCE Statement

You use the PERFORMANCE statement to specify options that tune the performance of PROC ROBUSTREG. By default these options are chosen to maximize performance. See Chen (2002) for some empirical results.

PERFORMANCE < options > ;

The following option is available:

CPUCOUNT=*n*

specifies the number of threads to use in the computation of LTS or S estimation (initial LTS or S estimation for MM estimation). By default this will be equal to the number of processors on the hardware.

TEST Statement

<label:> **TEST** *effects* ;

With M estimation and MM estimation, the TEST statement provides a means for obtaining a test for the canonical linear hypothesis concerning the model parameters:

$$\theta_j = 0, \quad j = q + 1, \dots, p$$

where p is the total number of parameters in the model, and q is the number of parameters for testing of significance.

PROC ROBUSTREG provides two kinds of robust tests: the ρ -test and the R_n^2 -test. They are described in the “Details” section. No test is available for LTS and S estimation.

The optional *label* is used to label output from the corresponding TEST statement.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement specifies a weight variable in the input data set.

If you want to use fixed weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model.

Details

This section describes the statistical and computational aspects of the ROBUSTREG procedure. The following notation is used throughout this section.

Let $X = (x_{ij})$ denote an $n \times p$ matrix, $y = (y_1, \dots, y_n)^T$ a given n -vector of responses, and $\theta = (\theta_1, \dots, \theta_p)^T$ an unknown p -vector of parameters or coefficients whose components are to be estimated. The matrix X is called the design matrix. Consider the usual linear model

$$y = X\theta + e$$

where $e = (e_1, \dots, e_n)^T$ is an n -vector of unknown errors. It is assumed that (for a given X) the components e_i of e are independent and identically distributed according to a distribution $L(\cdot/\sigma)$, where σ is a scale parameter (usually unknown). The vector of residuals for a given value of $\hat{\theta}$ is denoted by $r = (r_1, \dots, r_n)^T$ and the i th row of the matrix X is denoted by x_i^T .

M Estimation

M estimation in the context of regression was first introduced by Huber (1973) as a result of making the least squares approach robust. Although M estimators are not robust with respect to leverage points, they are popular in applications where leverage points are not an issue.

Instead of minimizing a sum of squares of the residuals, a Huber-type M estimator $\hat{\theta}_M$ of θ minimizes a sum of less rapidly increasing functions of the residuals:

$$Q(\theta) = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

where $r = y - X\theta$. For the ordinary least squares estimation, ρ is the quadratic function.

If σ is known, by taking derivatives with respect to θ , $\hat{\theta}_M$ is also a solution of the system of p equations:

$$\sum_{i=1}^n \psi\left(\frac{r_i}{\sigma}\right) x_{ij} = 0, \quad j = 1, \dots, p$$

where $\psi = \rho'$. If ρ is convex, $\hat{\theta}_M$ is the unique solution.

The ROBUSTREG procedure solves this system by using iteratively reweighted least squares (IRLS). The weight function $w(x)$ is defined as

$$w(x) = \frac{\psi(x)}{x}$$

The ROBUSTREG procedure provides ten kinds of weight functions (corresponding to ten ρ -functions) through the WEIGHTFUNCTION= option in the MODEL statement. See the section “Weight Functions” on page 3995 for a complete discussion. You can specify the scale parameter σ with the SCALE= option in the PROC statement.

If σ is unknown, both θ and σ are estimated by minimizing the function

$$Q(\theta, \sigma) = \sum_{i=1}^n \left[\rho\left(\frac{r_i}{\sigma}\right) + a \right] \sigma, \quad a > 0$$

The algorithm proceeds by alternately improving $\hat{\theta}$ in a location step and $\hat{\sigma}$ in a scale step.

For the scale step, three methods are available to estimate σ , which you can select with the SCALE= option.

1. (SCALE=HUBER<(D=d)>) Compute $\hat{\sigma}$ by the iteration

$$(\hat{\sigma}^{(m+1)})^2 = \frac{1}{nh} \sum_{i=1}^n \chi_d\left(\frac{r_i}{\hat{\sigma}^{(m)}}\right) (\hat{\sigma}^{(m)})^2$$

where

$$\chi_d(x) = \begin{cases} x^2/2 & \text{if } |x| < d \\ d^2/2 & \text{otherwise} \end{cases}$$

is the Huber function and $h = \frac{n-p}{n}(d^2 + (1-d^2)\Phi(d) - .5 - d\sqrt{2\pi}e^{-\frac{1}{2}d^2})$ is the Huber constant (refer to Huber 1981, p. 179). You can specify d with the D= option. By default, $d = 2.5$.

2. (SCALE=TUKEY<(D=d)>) Compute $\hat{\sigma}$ by solving the supplementary equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi_d\left(\frac{r_i}{\sigma}\right) = \beta$$

where

$$\chi_d(x) = \begin{cases} \frac{3x^2}{d^2} - \frac{3x^4}{d^4} + \frac{x^6}{d^6} & \text{if } |x| < d \\ 1 & \text{otherwise} \end{cases}$$

Here $\psi = \frac{1}{6}\chi_1'$ is Tukey's biweight function, and $\beta = \int \chi_d(s)d\Phi(s)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (refer to Hampel et. al. 1986, p. 149). You can specify d with the D= option. By default, $d = 2.5$.

3. (SCALE=MED) Compute $\hat{\sigma}$ by the iteration

$$\hat{\sigma}^{(m+1)} = \text{median}\{|y_i - x_i^T \hat{\theta}^{(m)}|/\beta_0, i = 1, \dots, n\}$$

where $\beta_0 = \Phi^{-1}(.75)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (refer to Hampel et. al. 1986, p. 312).

Note that SCALE = MED is the default.

Algorithm

The basic algorithm for computing M estimates for regression is iteratively reweighted least squares (IRLS). As the name suggests, a weighted least squares fit is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. Initial weights are based on residuals from an initial fit. The ROBUSTREG procedure uses the unweighted least squares fit as a default initial fit. The iteration terminates when a convergence criterion is satisfied. The maximum number of iterations is set to 1000. You can specify the weight function and the convergence criteria.

Weight Functions

You can specify the weight function for M estimation with the WEIGHTFUNCTION= option. The ROBUSTREG procedure provides ten weight functions. By default, the procedure uses the bisquare weight function. In most cases, M estimates are more sensitive to the parameters of these weight functions than to the type of the weight function. The median weight function is not stable and is seldom recommended in data analysis; it is included in the procedure for completeness. You can specify the parameters for these weight functions. Except for the hampel and median weight functions, default values for these parameters are defined such that the corresponding M estimates have 95% asymptotic efficiency in the location model with the Gaussian distribution (see Holland and Welsch (1977)).

The following list shows the weight functions available.

andrews
$$W(x, c) = \begin{cases} \frac{\sin(\frac{x}{c})}{\frac{x}{c}} & \text{if } |x| \leq \pi c \\ 0 & \text{otherwise} \end{cases}$$

bisquare
$$W(x, c) = \begin{cases} (1 - (\frac{x}{c})^2)^2 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$

cauchy
$$W(x, c) = \frac{1}{1 + (\frac{|x|}{c})^2}$$

fair
$$W(x, c) = \frac{1}{(1 + \frac{|x|}{c})}$$

hampel
$$W(x, a, b, c) = \begin{cases} 1 & |x| < a \\ \frac{a}{|x|} & a < |x| \leq b \\ \frac{a}{|x|} \frac{c-|x|}{c-b} & b < |x| \leq c \\ 0 & \text{otherwise} \end{cases}$$

huber
$$W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ \frac{c}{|x|} & \text{otherwise} \end{cases}$$

logistic
$$W(x, c) = \frac{\tanh(\frac{x}{c})}{\frac{x}{c}}$$

median
$$W(x, c) = \begin{cases} \frac{1}{c} & \text{if } x = 0 \\ \frac{1}{|x|} & \text{otherwise} \end{cases}$$

talworth
$$W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$

welsch $W(x, c) = \exp(-\frac{1}{2}(\frac{x}{c})^2)$

See Table 62.4 on page 3985 for the default values of the constants in these weight functions.

Convergence Criteria

The following convergence criteria are available in PROC ROBUSTREG:

1. Relative change in the scaled residuals (CONVERGENCE= RESID)
2. Relative change in the coefficients (CONVERGENCE= COEF)
3. Relative change in weights (CONVERGENCE= W)

You can specify the criteria with the CONVERGENCE= option in the PROC statement. The default is CONVERGENCE= COEF.

You can specify the precision of the convergence criterion with the EPS= sub-option.

In addition to these convergence criteria, a convergence criterion based on scale-independent measure of the gradient is always checked. See Coleman, et. al. (1980). A warning is issued if this criterion is not satisfied.

Asymptotic Covariance and Confidence Intervals

The following three estimators of the asymptotic covariance of the robust estimator are available in PROC ROBUSTREG:

$$H1: K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} (X^T X)^{-1}$$

$$H2: K \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]} W^{-1}$$

$$H3: K^{-1} \frac{1}{(n-p)} \sum (\psi(r_i))^2 W^{-1} (X^T X) W^{-1}$$

where $K = 1 + \frac{p \text{ var}(\psi')}{n (E\psi')^2}$ is a correction factor and $W_{jk} = \sum \psi'(r_i) x_{ij} x_{ik}$. Refer to Huber (1981, p. 173) for more details.

You can specify the asymptotic covariance estimate with the option ASYMPCOV= option. The ROBUSTREG procedure uses H1 as the default because of its simplicity and stability. Confidence intervals are computed from the diagonal elements of the estimated asymptotic covariance matrix.

R^2 and Deviance

The robust version of R^2 is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right) - \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 -scale:

$$D = 2(\hat{s})^2 \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)$$

where $\rho' = \psi$, $\hat{\theta}$ is the M estimator of θ , $\hat{\mu}$ is the M estimator of location, and \hat{s} is the M estimator of the scale parameter in the full model.

Linear Tests

Two tests are available in PROC ROBUSTREG for the canonical linear hypothesis

$$\mathcal{H}_0 : \theta_j = 0, \quad j = q + 1, \dots, p$$

The first test is a robust version of the F test, which is referred to as the ρ -test. Denote the M estimators in the full and reduced model as $\hat{\theta}_0 \in \Omega_0$ and $\hat{\theta}_1 \in \Omega_1$, respectively. Let

$$\begin{aligned} Q_0 &= Q(\hat{\theta}_0) = \min\{Q(\theta) | \theta \in \Omega_0\} \\ Q_1 &= Q(\hat{\theta}_1) = \min\{Q(\theta) | \theta \in \Omega_1\} \end{aligned}$$

with

$$Q = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

The robust F test is based on the test statistic

$$S_n^2 = \frac{2}{p - q} [Q_1 - Q_0]$$

Asymptotically $S_n^2 \sim \lambda \chi_{p-q}^2$ under \mathcal{H}_0 , where the standardization factor is $\lambda = \int \psi^2(s) d\Phi(s) / \int \psi'(s) d\Phi(s)$ and Φ is the cumulative distribution function of the standard normal distribution. Large values of S_n^2 are significant. This test is a special case of the general τ -test of Hampel et. al. (1986, Section 7.2).

The second test is a robust version of the Wald test, which is referred to as R_n^2 -test. The test uses a test statistic

$$R_n^2 = n(\hat{\theta}_{q+1}, \dots, \hat{\theta}_p) H_{22}^{-1}(\hat{\theta}_{q+1}, \dots, \hat{\theta}_p)^T$$

where $\frac{1}{n} H_{22}$ is the $(p - q) \times (p - q)$ lower right block of the asymptotic covariance matrix of the M estimate $\hat{\theta}_M$ of θ in a p -parameter linear model.

Under \mathcal{H}_0 , the statistic R_n^2 has an asymptotic χ^2 distribution with $p - q$ degrees of freedom. Large absolute values of R_n^2 are significant. Refer to Hampel et. al. (1986, Chapter 7).

Model Selection

When M estimation is used, two criteria are available in PROC ROBUSTREG for model selection. The first criterion is a counterpart of the Akaike (1974) AIC criterion for robust regression, and it is defined as

$$AICR = 2 \sum_{i=1}^n \rho(r_{i:p}) + \alpha p$$

where $r_{i:p} = (y_i - x_i^T \hat{\theta}) / \hat{\sigma}$, $\hat{\sigma}$ is a robust estimate of σ and $\hat{\theta}$ is the M estimator with p -dimensional design matrix.

As with AIC, α is the weight of the penalty for dimensions. The ROBUSTREG procedure uses $\alpha = 2E\psi^2/E\psi'$ (Ronchetti (1985)) and estimates it using the final robust residuals.

The second criterion is a robust version of the Schwarz information criteria(BIC), and it is defined as

$$BICR = 2 \sum_{i=1}^n \rho(r_{i:p}) + p \log(n)$$

High Breakdown Value Estimation

The *breakdown value* of an estimator is defined as the smallest fraction of contamination that can cause the estimator to take on values arbitrarily far from its value on the uncontaminated data. The breakdown value of an estimator can be used as a measure of the robustness of the estimator. Rousseeuw and Leroy (1987) and others introduced the following high breakdown value estimators for linear regression.

LTS Estimate

The least trimmed squares (LTS) estimate proposed by Rousseeuw (1984) is defined as the p -vector

$$\hat{\theta}_{LTS} = \arg \min_{\theta} Q_{LTS}(\theta)$$

where

$$Q_{LTS}(\theta) = \sum_{i=1}^h r_{(i)}^2$$

$r_{(1)}^2 \leq r_{(2)}^2 \leq \dots \leq r_{(n)}^2$ are the ordered squared residuals $r_i^2 = (y_i - x_i^T \theta)^2$, $i = 1, \dots, n$, and h is defined in the range $\frac{n}{2} + 1 \leq h \leq \frac{3n+p+1}{4}$.

You can specify the parameter h with the H= option in the PROC statement. By default, $h = \lfloor \frac{3n+p+1}{4} \rfloor$. The breakdown value is $\frac{n-h}{n}$ for the LTS estimate.

The least median of squares (LMS) estimate is defined as the p -vector

$$\hat{\theta}_{LMS} = \arg \min_{\theta} Q_{LMS}(\theta)$$

where

$$Q_{LMS}(\theta) = r_{(h)}^2$$

$r_{(1)}^2 \leq r_{(2)}^2 \leq \dots \leq r_{(n)}^2$ are the ordered squared residuals $r_i^2 = (y_i - x_i^T \theta)^2$, $i = 1, \dots, n$, and h is defined in the range $\frac{n}{2} + 1 \leq h \leq \frac{3n+p+1}{4}$.

The breakdown value for the LMS estimate is also $\frac{n-h}{n}$. However the LTS estimate has several advantages over the LMS estimate. Its objective function is smoother, making the LTS estimate less “jumpy” (i.e. sensitive to local effects) than the LMS estimate. Its statistical efficiency is better, because the LTS estimate is asymptotically normal whereas the LMS estimate has a lower convergence rate (Rousseeuw and Leroy (1987)). Another important advantage is that, using the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000), the LTS estimate takes less computing time and is more accurate.

The ROBUSTREG procedure computes LTS estimates using the FAST-LTS algorithm. The estimates are often used to detect outliers in the data, which are then downweighted in the resulting weighted LS regression.

Algorithm

Least trimmed squares (LTS) regression is based on the subset of h observations (out of a total of n observations) whose least squares fit possesses the smallest sum of squared residuals. The coverage h may be set between $\frac{n}{2}$ and n . The LTS method was proposed by Rousseeuw (1984, p. 876) as a highly robust regression estimator with breakdown value $\frac{n-h}{n}$. The ROBUSTREG procedure uses the FAST-LTS algorithm given by Rousseeuw and Van Driessen (1998). The intercept adjustment technique is also used in this implementation. However, because this adjustment is expensive to compute, it is optional. You can use the IADJUST option in the PROC statement to request or suppress the intercept adjustment. By default, PROC ROBUSTREG does intercept adjustment for data sets with less than 10000 observations. The algorithm is described briefly as follows. Refer to Rousseeuw and Van Driessen (2000) for details.

1. The default h is $\lceil \frac{3n+p+1}{4} \rceil$, where p is the number of independent variables. You can specify any integer h with $\lceil \frac{n}{2} \rceil + 1 \leq h \leq \lceil \frac{3n+p+1}{4} \rceil$ with the H= option in the MODEL statement. The breakdown value for LTS, $\frac{n-h}{n}$, is reported. The default h is a good compromise between breakdown value and statistical efficiency.
2. If $p = 1$ (single regressor) the procedure uses the exact algorithm of Rousseeuw and Leroy (1987, p. 172-172).
3. If $p \geq 2$, the procedure uses the following algorithm. If $n < 2ssubs$, where $ssubs$ is the size of the subgroups (you can specify $ssubs$ using the SUBGROUPSIZE= option in the PROC statement, by default, $ssubs = 300$), draw a random p -subset and compute the regression coefficients using these p points (if the regression is degenerate, draw another p -subset). Compute the absolute residuals for all observations in the data set and select the first h points with smallest absolute residuals. From this selected h -subset, carry out $nsteps$ C-steps (Concentration step, see Rousseeuw and Van Driessen (2000) for details. You can specify $nsteps$ with the CSTEP= option in the PROC statement, by default, $nsteps = 2$). Redraw p -subsets and repeat the preceding computing procedure $nrep$ times and find the $nbsol$ (at most) solutions with the lowest sums of h squared residuals. $nrep$ can be specified with the NREP= option in the PROC statement. By default, $NREP = \min\{500, \binom{n}{p}\}$. For small n and p , all $\binom{n}{p}$ subsets are used and the NREP= option is ignored (Rousseeuw and Hubert (1996)). $nbsol$ can be specified with the NBEST= option in the PROC statement. By default, $NBEST = 10$. For each of these $nbsol$ best solutions, take C-steps until convergence and find the best final solution.
4. If $n \geq 5ssubs$, construct 5 disjoint random subgroups with size $ssubs$. If $2ssubs < n < 5ssubs$, the data are split into at most four subgroups with $ssubs$ or more observations in each subgroup, so that each observation belongs to a subgroup and such that the subgroups have roughly the same size. Let $nsubs$ denote the number of subgroups. Inside each subgroup, repeat the procedure in Step 3 $\lceil \frac{nrep}{nsubs} \rceil$ times and keep the $nbsol$ best solutions. Pool the subgroups, yielding the merged set of size n_{merged} . In the merged set, for each of the $nsubs \times nbsol$ best solutions, carry out $nsteps$ C-steps using n_{merged} and $h_{merged} = \lceil n_{merged} \frac{h}{n} \rceil$ and keep the $nbsol$ best solutions. In the full data set, for

each of these $nbsol$ best solutions, take C-steps using n and h until convergence and find the best final solution.

R^2

The robust version of R^2 for the LTS estimate is defined as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(X, y)}{s_{LTS}^2(\mathbf{1}, y)}$$

for models with the intercept term and as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(X, y)}{s_{LTS}^2(\mathbf{0}, y)}$$

for models without the intercept term, where

$$s_{LTS}(X, y) = d_{h,n} \sqrt{\frac{1}{h} \sum_{i=1}^h r_{(i)}^2}$$

s_{LTS} is a preliminary estimate of the parameter σ in the distribution function $L(\cdot/\sigma)$.

Here $d_{h,n}$ is chosen to make s_{LTS} consistent assuming a Gaussian model. Specifically,

$$d_{h,n} = 1 / \sqrt{1 - \frac{2n}{hc_{h,n}} \phi(1/c_{h,n})}$$

$$c_{h,n} = 1 / \Phi^{-1}\left(\frac{h+n}{2n}\right)$$

with Φ and ϕ being the distribution function and the density function of the standard normal distribution, respectively.

Final Weighted Scale Estimator

The ROBUSTREG procedure displays two scale estimators, s_{LTS} and Wscale. The estimate Wscale is a more efficient scale estimate based on the preliminary estimate s_{LTS} , and it is defined as

$$\text{Wscale} = \sqrt{\frac{\sum_i w_i r_i^2}{\sum_i w_i - p}}$$

where

$$w_i = \begin{cases} 0 & \text{if } |r_i|/s_{LTS} > k \\ 1 & \text{otherwise} \end{cases}$$

You can specify k with the CUTOFF= option in the MODEL statement. By default, $k = 3$.

S Estimate

The S estimate proposed by Rousseeuw and Yohai (1984) is defined as the p -vector

$$\hat{\theta}_S = \arg \min_{\theta} S(\theta)$$

where the dispersion $S(\theta)$ is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi\left(\frac{y_i - x_i^T \theta}{S}\right) = \beta.$$

Here β is set to $\int \chi(s) d\Phi(s)$ such that $\hat{\theta}_S$ and $S(\hat{\theta}_S)$ are asymptotically consistent estimates of θ and σ for the Gaussian regression model. The breakdown value of the S estimate is

$$\frac{\beta}{\sup_s \chi(s)}$$

The ROBUSTREG procedure provides two choices for χ : the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6, & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

The constant k_0 controls the breakdown value and efficiency of the S estimate. By specifying the efficiency using the EFF= option, you can determine the corresponding k_0 . The default k_0 is 2.9366 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 75.9%.

The Yohai function, which you can specify with the option CHIF=YOHA, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1\left(\frac{s}{k_0}\right)^2 + b_2\left(\frac{s}{k_0}\right)^4 + b_3\left(\frac{s}{k_0}\right)^6 + b_4\left(\frac{s}{k_0}\right)^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. By specifying the efficiency using the EFF= option, you can determine the corresponding k_0 . By default, k_0 is set to 0.7405 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 72.7%.

Algorithm

The ROBUSTREG procedure implements the algorithm by Marazzi (1993) for the S estimate, which is a refined version of the algorithm proposed by Ruppert (1992). The refined algorithm is briefly described as follows.

Initialize iter = 1.

1. Draw a random q -subset of the total n observations and compute the regression coefficients using these q observations (if the regression is degenerate, draw another q -subset), where $q \geq p$ can be specified with the SUBSIZE= option. By default, $q = p$.
2. Compute the residuals: $r_i = y_i - \sum_{j=1}^p x_{ij}\theta_j$ for $i = 1, \dots, n$. If iter = 1, set $s^* = 2\text{median}\{|r_i|, i = 1, \dots, n\}$; if $s^* = 0$, set $s^* = \min\{|r_i|, i = 1, \dots, n\}$; while $\sum_{i=1}^n \chi(r_i/s^*) > (n-p)\beta$, set $s^* = 1.5s^*$; go to Step 3. If iter > 1 and $\sum_{i=1}^n \chi(r_i/s^*) \leq (n-p)\beta$, go to the Step 3; else go to Step 5.
3. Solve for s the equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi(r_i/s) = \beta$$

using an iterative algorithm.

4. If iter > 1 and $s > s^*$, go to Step 5. Otherwise, set $s^* = s$ and $\theta^* = \theta$. If $s^* < TOLS$, return s^* and θ^* ; else go to Step 5.
5. If iter < NREP, set iter = iter + 1 and return to Step 1; else return s^* and θ^* .

The ROBUSTREG procedure does the following refinement step by default. You can request this refinement not be done using the NOREFINE option in the PROC statement.

6. Let $\psi = \chi'$. Using the values s^* and θ^* from the previous steps, compute M estimates θ_M and σ_M of θ and σ with the setup for M estimation in the section “M Estimation” on page 3993. If $\sigma_M > s^*$, give a warning and return s^* and θ^* ; otherwise, return σ_M and θ_M .

You can specify *TOLS* with the TOLERANCE= option; by default, *TOLS* = .001. Alternately You can specify *NREP* with the NREP= option. You can also use the options NREP= NREP0 or NREP= NREP1 to determine *NREP* according to the following table. NREP= NREP0 is set as the default.

Table 62.7. Default NREP

P	NREP0	NREP1
1	150	500
2	300	1000
3	400	1500
4	500	2000
5	600	2500
6	700	3000
7	850	3000
8	1250	3000
9	1500	3000
>9	1500	3000

 R^2 and Deviance

The robust version of R^2 for the S estimate is defined as

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{(n-1)S_\mu^2}$$

for the model with the intercept term and

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{nS_0^2}$$

for the model without the intercept term, where S_p is the S estimate of the scale in the full model, S_μ is the S estimate of the scale in the regression model with only the intercept term, and S_0 is the S estimate of the scale without any regressor. The deviance D is defined as the optimal value of the objective function on the σ^2 -scale:

$$D = S_p^2$$

Asymptotic Covariance and Confidence Intervals

Since the S estimate satisfies the first-order necessary conditions as the M estimate, it has the same asymptotic covariance as that of the M estimate. All three estimators of the asymptotic covariance for the M estimate in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 3997 can be used for the S estimate. Besides, the weighted covariance estimator H4 described in the section “[Asymptotic Covariance and Confidence Intervals](#)” on page 4008 is also available and is set as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

MM Estimation

MM estimation is a combination of high breakdown value estimation and efficient estimation, which was introduced by Yohai (1987). It has three steps:

1. Compute an initial (consistent) high breakdown value estimate $\hat{\theta}'$. The ROBUSTREG procedure provides two kinds of estimates as the initial estimate, the LTS estimate and the S estimate. By default, the LTS estimate because of its speed, efficiency, and high breakdown value. The breakdown value of the final MM estimate is decided by the breakdown value of the initial LTS estimate and the constant k_0 in the χ function. To use the S estimate as the initial estimate, you specify the INITEST=S option in the PROC statement. In this case, the breakdown value of the final MM estimate is decided only by the constant k_0 . Instead of computing the LTS estimate or the S estimate as initial estimates, you can also specify the initial estimate explicitly using the INEST= option in the PROC statement. See the section “[INEST= Data Set](#)” on page 4011 for details.
2. Find $\hat{\sigma}'$ such that

$$\frac{1}{n-p} \sum_{i=1}^n \chi\left(\frac{y_i - x_i^T \hat{\theta}'}{\hat{\sigma}'}\right) = \beta$$

where $\beta = \int \chi(s) d\Phi(s)$.

The ROBUSTREG procedure provides two choices for χ : the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6, & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

where k_0 can be specified with the K0= option. The default $k_0 = 2.9366$ such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

The Yohai function, which you can specify with the option CHIF=YOHAJ, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1\left(\frac{s}{k_0}\right)^2 + b_2\left(\frac{s}{k_0}\right)^4 + b_3\left(\frac{s}{k_0}\right)^6 + b_4\left(\frac{s}{k_0}\right)^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where $b_0 = 1.792$, $b_1 = -0.972$, $b_2 = 0.432$, $b_3 = -0.052$, and $b_4 = 0.002$. You can specify k_0 with the K0= option. The default k_0 is .7405 such that the asymptotically consistent scale estimate $\hat{\sigma}'$ has the breakdown value of 25%.

3. Find a local minimum $\hat{\theta}_{MM}$ of

$$Q_{MM} = \sum_{i=1}^n \rho\left(\frac{y_i - x_i^T \theta}{\hat{\sigma}'}\right)$$

such that $Q_{MM}(\hat{\theta}_{MM}) \leq Q_{MM}(\hat{\theta}')$. The algorithm for M estimation is used here.

The ROBUSTREG procedure provides two choices for χ : the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} 3\left(\frac{s}{k_1}\right)^2 - 3\left(\frac{s}{k_1}\right)^4 + \left(\frac{s}{k_1}\right)^6, & \text{if } |s| \leq k_1 \\ 1 & \text{otherwise} \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 3.440 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

The Yohai function, which you can specify with the option CHIF=Yohai, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_1 \\ k_1^2 [b_0 + b_1\left(\frac{s}{k_1}\right)^2 + b_2\left(\frac{s}{k_1}\right)^4 + b_3\left(\frac{s}{k_1}\right)^6 + b_4\left(\frac{s}{k_1}\right)^8] & \text{if } 2k_1 < |s| \leq 3k_1 \\ 3.25k_1^2 & \text{if } |s| > 3k_1 \end{cases}$$

where k_1 can be specified with the K1= option. The default k_1 is 0.868 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Algorithm

The initial LTS estimate is computed using the algorithm described in the section “LTS Estimate” on page 4000. You can control the quantile of the LTS estimate with the option INITH= h , where h is an integer between $\lfloor \frac{n}{2} \rfloor + 1$ and $\lfloor \frac{3n+p+1}{4} \rfloor$. By default, $h = \lfloor \frac{3n+p+1}{4} \rfloor$, which corresponds to a breakdown value of around 25%.

The initial S estimate is computed using the algorithm described in the section “S Estimate” on page 4003. You can control the breakdown value and efficiency of this initial S estimate by the constant k_0 which can be specified with the K0 option.

The scale parameter σ is solved by an iterative algorithm

$$(\sigma^{(m+1)})^2 = \frac{1}{(n-p)\beta} \sum_{i=1}^n \chi_{k_0}\left(\frac{r_i}{\sigma^{(m)}}\right) (\sigma^{(m)})^2$$

where $\beta = \int \chi_{k_0}(s) d\Phi(s)$.

Once the scale parameter is computed, the iteratively reweighted least squares (IRLS) algorithm with fixed scale parameter is used to compute the final MM estimator.

Convergence Criteria

In the iterative algorithm for the scale parameter, the relative change of the scale parameter controls the convergence.

In the iteratively reweighted least squares algorithm, the same convergence criteria for the M estimate used before are used here.

Bias Test

Although the final MM estimate inherits the high-breakdown-value property, its bias due to the distortion of the outliers can be high. Yohai, Stahel, and Zamar (1991) introduced a bias test. The ROBUSTREG procedure implements this test when you specify the BIASTEST option in the PROC statement. This test bases on the initial scale estimate $\hat{\sigma}'$ and the final scale estimate $\hat{\sigma}'_1$, which is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi\left(\frac{y_i - x_i^T \hat{\theta}_{MM}}{\hat{\sigma}'_1}\right) = \beta$$

Let $\psi_{k_0}(\cdot) = \chi'_{k_0}(\cdot)$ and $\psi_{k_1}(\cdot) = \chi'_{k_1}(\cdot)$, where $'$ denotes the derivative with respect to the argument. Compute

$$\begin{aligned} \tilde{r}_i &= (y_i - x_i^T \hat{\theta}') / \hat{\sigma}' \quad \text{for } i = 1, \dots, n \\ v_0 &= \frac{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)}{(\hat{\sigma}'_1/n) \sum \psi_{k_0}(\tilde{r}_i) \tilde{r}_i} \\ p_i^{(0)} &= \frac{\psi_{k_0}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n \\ p_i^{(1)} &= \frac{\psi_{k_1}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_1}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n \\ d^2 &= \frac{1}{n} \sum (p_i^{(1)} - p_i^{(0)})^2 \\ T &= \frac{2n(\hat{\sigma}'_1 - \hat{\sigma}')}{v_0 d^2 (\hat{\sigma}')^2} \end{aligned}$$

Standard asymptotic theory shows that T approximately follows a χ^2 -distribution with p degrees of freedom. If T exceeds the α quantile χ^2_α of the χ^2 -distribution with p degrees of freedom, then the ROBUSTREG procedure gives a warning and recommends to use other methods. Otherwise the final MM estimate and the initial scale estimate are reported. You can specify α with the ALPHA= option following the BIASTEST option. By default, ALPHA= 0.99.

Asymptotic Covariance and Confidence Intervals

Since the MM estimate is computed as a M estimate with a fixed scale in the last step, the asymptotic covariance for the M estimate can be used here for the asymptotic covariance of the MM estimate. Besides the three estimators H1, H2, and H3 as

described in the section “Asymptotic Covariance and Confidence Intervals” on page 3997, a weighted covariance estimator H4 is available:

$$\text{H4: } K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} W^{-1}$$

where $K = 1 + \frac{p}{n} \frac{\text{var}(\psi')}{(E\psi')^2}$ is the correction factor and $W_{jk} = \frac{1}{\bar{w}} \sum w_i x_{ij} x_{ik}$, $\bar{w} = \frac{1}{n} \sum w_i$.

You can specify these estimators with the option `ASYMPCOV= [H1 | H2 | H3 | H4]`. The `ROBUSTREG` procedure uses H4 as default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

***R*² and Deviance**

The robust version of R^2 for the MM estimate is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right) - \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the σ^2 -scale:

$$D = 2(\hat{s})^2 \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)$$

where $\rho' = \psi$, $\hat{\theta}$ is the MM estimator of θ , $\hat{\mu}$ is the MM estimator of location, and \hat{s} is the MM estimator of the scale parameter in the full model.

Linear Tests

For MM estimation, the same ρ -test and R_n^2 -test used for M estimation can be used. See the section “[Linear Tests](#)” on page 3998 for details.

Model Selection

For MM estimation, the same two model selection methods used for M estimation can be used. See the section “[Model Selection](#)” on page 3999 for details.

Robust Multivariate Location and Scale Estimates

The `ROBUSTREG` procedure uses the robust multivariate location and scale estimates for leverage points detection. The procedure provides the minimum covariance determinant (MCD) method, which was introduced by Rousseeuw (1984).

Algorithm

PROC ROBUSTREG implements the algorithm given by Rousseeuw and Van Driessen (1999) for MCD, which is similar to the algorithm for LTS.

Robust Distance

The Mahalanobis Distance is defined as

$$MD(x_i) = [(x_i - \bar{x})^T \bar{C}(X)^{-1} (x_i - \bar{x})]^{1/2}$$

where $\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$ and $\bar{C} = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^T (x_i - \bar{x})$. Here $x_i = (x_{i1}, \dots, x_{i(p-1)})^T$ do not include the constant variable. The relation between the Mahalanobis distance $MD(x_i)$ and the hat matrix $H = (h_{ij}) = X(X^T X)^{-1} X^T$ is

$$h_{ii} = \frac{1}{n-1} MD_i^2 + \frac{1}{n}$$

The Robust Distance is defined as

$$RD(x_i) = [(x_i - T(X))^T C(X)^{-1} (x_i - T(X))]^{1/2}$$

where $T(X)$ and $C(X)$ are the robust multivariate location and scale obtained by MCD.

These distances are used to detect leverage points.

Leverage Point and Outlier Detection

Let $C(p) = \sqrt{\chi_{p;1-\alpha}^2}$ be the cutoff value. The variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } RD(x_i) \leq C(p) \\ 1 & \text{otherwise} \end{cases}$$

You can specify a cutoff value with the LEVERAGE option in the MODEL statement.

Residuals $r_i, i = 1, \dots, n$ based on robust regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \leq k\sigma \\ 1 & \text{otherwise} \end{cases}$$

You can specify the multiplier k of the cutoff value by using the CUTOFF= option in the MODEL statement.

An ODS table called DIAGNOSTICS contains these two variables.

INEST= Data Set

When you use the M or MM estimation, you can use the INEST= data set to specify initial estimates for all the parameters in the model. The INEST= option is ignored if you specify LTS or S estimation using the METHOD=LTS or METHOD=S option or if you specify the INITEST= option after the METHOD=MM option in the PROC statement. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in one BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value "PARMS" are used as starting values.

You can specify starting values for the iteratively reweighted least squares algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different modeling using the ROBUSTREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. Note that, if the ROBUSTREG procedure does not converge, the parameter estimates are set to missing in the OUTEST data set.

The OUTEST= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value -1 . If the COVOUT option is specified, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

<code>_MODEL_</code>	a character variable containing the label of the MODEL statement, if present. Otherwise, the variable's value is blank
<code>_NAME_</code>	a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
<code>_TYPE_</code>	a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
<code>_METHOD_</code>	a character variable of containing the type of estimation method, either M estimation, or LTS estimation, or S estimation, or MM estimation

<code>_STATUS_</code>	a character variable containing the status of model fitting, either Converged, or Warning, or Failed
<code>INTERCEPT</code>	a numeric variable containing the intercept parameter estimates and covariances
<code>_SCALE_</code>	a numeric variable containing the scale parameter estimates

Any BY variables specified are also added to the OUTEST= data set.

Computational Resources

The algorithms for the various different estimation methods need different amount of memory for working space. Let p be the number of parameters estimated and n be the number of observations used in the model estimation.

For M estimation, the minimum working space (in bytes) needed is

$$3n + 2p^2 + 30p$$

If sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is reread for computing the iteratively reweighted least squares estimates and the execution time of the procedure increases substantially. For each reweighted least squares, $O(np^2 + p^3)$ multiplications and additions are required for computing the cross product matrix and its inverse. The $O(v)$ notation means that, for large values of the argument, v , $O(v)$ is approximately a constant times v .

Since the iteratively reweighted least squares algorithm converges very quickly (normally within less than 20 iterations), the computation of M estimates is fast.

LTS estimation is more expensive in computation. The minimum working space (in bytes) needed is

$$np + 12n + 4p^2 + 60p$$

The memory is mainly used to store the current data used by LTS for modeling. The LTS algorithm uses subsampling and spends much of its computing time on resampling and computing estimates for subsamples. Since it resamples if singularity is detected, it may take more time if the data set has serious singularities.

The MCD algorithm for high leverage point diagnostics is similar to the LTS algorithm.

ODS Table Names

The ROBUSTREG procedures assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

Table 62.8. ODS Tables Produced in PROC ROBUSTREG

ODS Table Name	Description	Statement	Option
BestEstimates	Best final estimates for LTS	PROC	SUBANALYSIS
BestSubEstimates	Best estimates for each subgroup	PROC	SUBANALYSIS*
BiasTest	Bias test for MM estimation	PROC	BIATEST
ClassLevels	Class variable levels	CLASS	default*
CorrB	Parameter estimate correlation matrix	MODEL	CORRB
CovB	Parameter estimate covariance matrix	MODEL	COVB

ODS Graphics (Experimental)

Graphical displays are important in robust regression and outlier detection. Two plots are particularly useful for revealing outliers and leverage points. The first is a scatter plot of the standardized robust residuals against the robust distances (RDPLOT). The second is a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT). See [Figure 62.4](#) on page 3975 and [Figure 62.5](#) on page 3975 for examples. In addition to these two plots, a histogram and a quantile-quantile plot of the standardized robust residuals are also helpful. See [Figure 62.6](#) on page 3976 and [Figure 62.7](#) on page 3976 for examples.

This section describes the use of ODS for creating these four plots with the ROBUSTREG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these plots you must specify the ODS GRAPHICS statement in addition to the PLOT= (or PLOTS=) option, which is described as follows. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

You can specify the PLOT= or PLOTS= option in the PROC statement to request one or more plots:

PLOT=*keyword*

PLOTS=(*keyword-list*)

requests plots for robust regression. You can specify one or more of the following *keywords*:

Table 62.9. Options for Plots

Keyword	Plot
DDPLOT	Robust distance - Mahalanobis distance
RDPLOT	Standardized robust residual - Robust distance
RESHISTOGRAM	Histogram of standardized robust residuals
RESQQPLOT	Q-Q plot of standardized robust residuals
ALL	All plots

With the RDPLOT and DDPLOT options, you can label the points on the plots by specifying the LABEL= suboption immediately after the keyword:

PLOT=DDPLOT<(LABEL=*label method*)>

PLOT=RDPLOT<(LABEL=*label method*)>

You can specify one of the following *label methods*:

Table 62.10. Label Methods

Value of LABEL=	Label Method
ALL	label all points
OUTLIER	label outliers
LEVERAGE	label leverage points
NONE	no labels

By default, the ROBUSTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

The histogram is superimposed with a normal density curve and a kernel density curve.

ODS Graph Names

PROC ROBUSTREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 62.11 on page 4015.

To request these graphs you must specify the ODS GRAPHICS statement in addition to the PLOT= (or PLOTS=) option described in [Table 62.9](#) on page 4014. For more information on the ODS GRAPHICS statement, see [Chapter 15](#), “Statistical Graphics Using ODS.”

Table 62.11. ODS Graphics Produced by PROC ROBUSTREG

ODS Graph Name	Plot Description	Statement	PLOTS= Option
DDPlot	Robust distance - Mahalanobis distance	PROC	DDPLOT
RDPlot	Standardized robust residual - Robust distance	PROC	RDPLOT
ResidualHistogram	Histogram of standardized robust residuals	PROC	RESHISTOGRAM
ResidualQQPlot	Q-Q plot of standardized robust residuals	PROC	RESQQPLOT

Examples

Example 62.1. Comparison of Robust Estimates

This example illustrates differences in the performance of robust estimates available in the ROBUSTREG procedure.

The following statements generate 1000 random observations. The first 900 observations are from a linear model and the last 100 observations are significantly biased in the y -direction. In other words, ten percent of the observations are contaminated with outliers.

```

data a (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 900 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    output;
  end;
run;

proc reg data=a;
  model y = x1 x2;
run;

proc robustreg data=a method=m ;
  model y = x1 x2;
run;

proc robustreg data=a method=mm;
  model y = x1 x2;
run;

```

```

The tables of parameter estimates generated by the ROBUSTREG procedure using M estimation and MM estimation are shown in [Output 62.1.2](#) and [Output 62.1.3](#). For comparison, the ordinary least squares (OLS) estimates produced by the REG procedure are shown in [Output 62.1.1](#). Both the M estimate and the MM estimate correctly estimate the regression coefficients for the underlying model (10, 5, and 3), but the OLS estimate does not.

The next statements demonstrate that if the percentage of contamination is increased to 40%, the M estimates and MM estimates with default options fail to pick up the underlying model. However, by tuning the constant c for the M estimate and the constants INITH and K0 for the MM estimate, you can increase the breakdown values of these estimates and capture the right model. [Output 62.1.4](#) and [Output 62.1.5](#) display these estimates.

```

data b (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 600 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    output;
  end;
run;

proc robustreg data=b method=m(wf=bisquare(c=2));
  model y = x1 x2;
run;

proc robustreg data=b method=mm(inith=502 k0=1.8);
  model y = x1 x2;
run;

Output 62.1.6 displays the S estimates and Output 62.1.7 displays the MM estimates with initial LTS estimates.

Example 62.2. Robust ANOVA

The classical analysis of variance (ANOVA) technique based on least squares assumes that the underlying experimental errors are normally distributed. However, data often contain outliers due to recording or other errors. In other cases, extreme responses occur when control variables in the experiments is set to extremes. It is important to distinguish these extreme points and determine whether they are outliers or important extreme cases. You can use the ROBUSTREG procedure for robust analysis of variance based on M estimation. Typically, there are no high leverage points in a well-designed experiment, so M estimation is appropriate.

The following example shows how to use the ROBUSTREG procedure for robust ANOVA.

An experiment was carried out to study the effects of two successive treatments (T1, T2) on the recovery time of mice with certain diseases. Sixteen mice were randomly assigned into four groups for the four different combinations of the treatments. The recovery times (time) were recorded (in hours).

```
data recover;
  input id T1 $ T2 $ time;
  datalines;
1 0 0 20.2
2 0 0 23.9
3 0 0 21.9
4 0 0 42.4
5 1 0 27.2
6 1 0 34.0
7 1 0 27.4
8 1 0 28.5
9 0 1 25.9
10 0 1 34.5
```

```

11 0 1 25.1
12 0 1 34.2
13 1 1 35.0
14 1 1 33.9
15 1 1 38.3
16 1 1 39.9
;

```

The following statements invoke the GLM procedure for a standard ANOVA.

```

proc glm data=recover;
  class T1 T2;
  model time = T1 T2 T1*T2;
run;

```

Output 62.2.1. Overall ANOVA

The GLM Procedure					
Dependent Variable: time					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	3	209.9118750	69.9706250	1.86	0.1905
Error	12	451.9225000	37.6602083		
Corrected Total	15	661.8343750			
	R-Square	Coeff Var	Root MSE	time Mean	
	0.317167	19.94488	6.136791	30.76875	

Output 62.2.2. Model ANOVA

The GLM Procedure					
Dependent Variable: time					
Source	DF	Type I SS	Mean Square	F Value	Pr > F
T1	1	81.4506250	81.4506250	2.16	0.1671
T2	1	106.6056250	106.6056250	2.83	0.1183
T1*T2	1	21.8556250	21.8556250	0.58	0.4609
Source	DF	Type III SS	Mean Square	F Value	Pr > F
T1	1	81.4506250	81.4506250	2.16	0.1671
T2	1	106.6056250	106.6056250	2.83	0.1183
T1*T2	1	21.8556250	21.8556250	0.58	0.4609

Output 62.2.1 indicates that the overall model effect is not significant at the 10% level and Output 62.2.2 indicates that neither treatment is significant at the 10% level.

The following statements invoke the ROBUSTREG procedure with the same model.

```
proc robustreg data=recover;
  class T1 T2;
  model time = T1 T2 T1*T2 / diagnostics;
  T1_T2: test T1*T2;
  output out=robout r=resid sr=stdres;
run;
```

Output 62.2.3 shows some basic information about the model and the response variable time.

Output 62.2.3. Model Fitting Information and Summary Statistics

Example 62.3. Growth Study of De Long and Summers

Robust regression and outlier detection techniques have considerable applications to econometrics. The following example from Zaman, Rousseeuw, and Orhan (2001) shows how these techniques substantially improve the ordinary least squares (OLS) results for the growth study of De Long and Summers.

De Long and Summers (1991) studied the national growth of 61 countries from 1960 to 1985 using OLS.

The regression equation they used is:

$$GDP = \beta_0 + \beta_1 LFG + \beta_2 GAP + \beta_3 EQP + \beta_4 NEQ + \epsilon,$$

where the response variable is the growth in gross domestic product per worker (*GDP*) and the regressors are labor force growth (*LFG*), relative GDP gap (*GAP*), equipment investment (*EQP*), and non-equipment investment (*NEQ*).

The following statements invoke the REG procedure for the OLS analysis:

```
proc reg data=growth;
  model GDP = LFG GAP EQP NEQ ;
run;
```

Output 62.3.1. OLS Estimates

The REG Procedure						
Model: MODEL1						
Dependent Variable: GDP						
Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t

Output 62.3.3 displays the M estimates. Besides *GAP* and *EQP*, the robust analysis also indicates that *NEQ* is significant. This new finding is explained by Output 62.3.4, which shows that Zambia, the sixtieth country in the data, is an outlier. Output 62.3.4 also identifies leverage points based the robust MCD distances; however, there are no serious high leverage points in this data set. Output 62.3.5 displays robust versions of goodness-of-fit statistics for the model.

The following statements invoke the ROBUSTREG procedure with LTS estimation, which was used by Zaman, Rousseeuw, and Orhan (2001). The results are consistent with those of M estimation.

```
proc robustreg method=lts(h=33) fwls data=growth;
  model GDP = LFG GAP EQP NEQ / diagnostics leverage ;
  output out=robout r=resid sr=stdres;
run;
```

Chapter 63

The RSREG Procedure

Overview

The RSREG procedure uses the method of least squares to fit quadratic response surface regression models. Response surface models are a kind of general linear model in which attention focuses on characteristics of the fit response function and in particular, where optimum estimated response values occur.

In addition to fitting a quadratic function, you can use the RSREG procedure to

- test for lack of fit
- test for the significance of individual factors
- analyze the canonical structure of the estimated response surface
- compute the ridge of optimum response
- predict new values of the response

Comparison to Other SAS Software

Other SAS/STAT procedures can be used to fit the response surface, but the RSREG procedure is more specialized. The following statements model a three-factor response surface in PROC RSREG:

```
proc rsreg;  
  model y=x1 x2 x3;  
run;
```

These statements are more compact than the statements for other regression procedures in SAS/STAT software. For example, the equivalent statements for the GLM procedure are

```
proc glm;  
  model y=x1 x1*x1  
        x2 x1*x2 x2*x2  
        x3 x1*x3 x2*x3 x3*x3;  
run;
```

Additionally, PROC RSREG includes specialized methodology for analyzing the fitted response surface, such as canonical analysis and optimum response ridges.

Note that the ADX Interface in SAS/QC software provides an *interactive* environment for constructing and analyzing many different kinds of experiments, including response surface experiments. The ADX Interface is the preferred interactive SAS

System tool for analyzing experiments, since it includes facilities for checking underlying assumptions and graphically optimizing the response surface. The RSREG procedure is appropriate for analyzing experiments in a batch environment.

Terminology

Variables are referred to according to the following conventions:

factor variables	independent variables used in constructing the quadratic response surface. To estimate the necessary parameters, each variable must have at least three distinct values in the data. Independent variables must be numeric.
response variables	the dependent variables to which the quadratic response surface is fit. Dependent variables must be numeric.
covariates	additional independent variables for use in the regression but not in the formation of the quadratic response surface. Covariates must be numeric.
WEIGHT variable	a variable for weighting the observations in the regression. The WEIGHT variable must be numeric.
ID variables	variables not in the above lists that are transferred to an output data set containing statistics for each observation in the input data set. This data set is created using the OUT= option in the PROC RSREG statement. ID variables can be either character or numeric.
BY variables	variables for grouping observations. Separate analyses are obtained for each BY group. BY variables can be either character or numeric.

Getting Started

A Response Surface with a Simple Optimum

This example uses the three-factor quadratic model discussed in John (1971). Schneider and Stockett (1963) performed an experiment aimed at reducing the unpleasant odor of a chemical produced with several factors. The objective is to minimize the unpleasant odor of a chemical. The following statements read the data.

```

title 'Response Surface with a Simple Optimum';
data smell;
  input Odor T R H @@;
  label
    T = "Temperature"
    R = "Gas-Liquid Ratio"
    H = "Packing Height";
  datalines;
66 40 .3 4      39 120 .3 4      43 40 .7 4      49 120 .7 4

```

```

58 40 .5 2      17 120 .5 2      -5 40 .5 6      -40 120 .5 6
65 80 .3 2      7 80 .7 2      43 80 .3 6      -22 80 .7 6
-31 80 .5 4     -35 80 .5 4     -26 80 .5 4
;

```

The INPUT statement names the variables contained in the SAS data set `smell`; the variable `Odor` is the response, while the variables `T`, `R`, and `H` are the independent factors.

The following statements invoke PROC RSREG on the data set `smell`. Figure 63.1 through Figure 63.3 display the results of the analysis, including a lack-of-fit test requested with the LACKFIT option.

```

proc rsreg data=smell;
  model Odor = T R H / lackfit;
run;

```

Figure 63.1. Summary Statistics and Analysis of Variance

Figure 63.1 displays the coding coefficients for the transformation of the independent variables to lie between -1 and 1 , simple statistics for the response variable,

hypothesis tests for linear, quadratic, and crossproduct terms, and the lack-of-fit test. The hypothesis tests can be used to gain a rough idea of importance of the effects; here the crossproduct terms are not significant. However, the lack-of-fit for the model is significant, so more complicated modeling or further experimentation with additional variables should be performed before firm statements are made concerning the underlying process.

Response Surface with a Simple Optimum						
The RSREG Procedure						
Parameter	DF	Estimate	Standard Error	t Value	Pr > t	Parameter Estimate from Coded Data

R	4	11045	2761.150641	5.46	0.0454	Gas-Liquid Ratio
H	4	3813.016026	953.254006	1.89	0.2510	Packing Height

Figure 63.2. Parameter Estimates and Hypothesis Tests

Parameter estimates and the factor ANOVA are shown in [Figure 63.2](#). Looking at the parameter estimates, you can see that the crossproduct terms are not significantly different from zero, as noted previously. The “Estimate” column contains estimates based on the raw data, and the “Parameter Estimate from Coded Data” column contains those based on the coded data. The factor ANOVA table displays tests for all four parameters corresponding to each factor—the parameters corresponding to the linear effect, the quadratic effect, and the effects of the cross products with each of the other two factors. The only factor with a significant over-all effect is R, indicating that the level of noise left unexplained by the model is still too high to estimate the effects of T and H accurately. This may be due to the lack of fit.

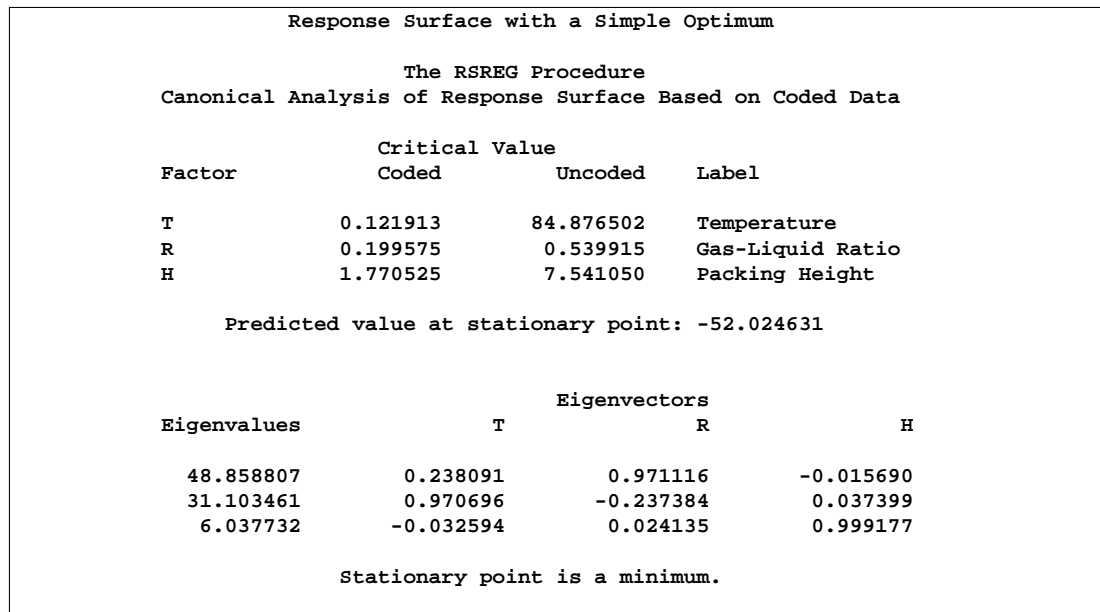

Figure 63.3. Canonical Analysis and Eigenvectors

Figure 63.3 contains the canonical analysis and eigenvectors. The canonical analysis indicates that the directions of principle orientation for the predicted response surface are along the axes associated with the three factors, confirming the small interaction effect in the Regression ANOVA. The largest eigenvalue (48.8588) corresponds to the eigenvector $\{0.238091, 0.971116, -0.015690\}$, the largest component of which (0.971116) is associated with R; similarly, the second largest eigenvalue (31.1035) is associated with T. The third eigenvalue (6.0377), associated with H, is quite a bit smaller than the other two, indicating that the response surface is relatively insensitive to changes in this factor. The coded form of the canonical analysis indicates that the estimated response surface is at a minimum when T and R are both near the middle of their respective ranges and H is relatively high; in uncoded, terms, the model predicts that the unpleasant odor will be minimized when $T = 84.876502$, $R = 0.539915$, and $H = 7.541050$.

To plot the response surface with respect to two of the factor variables, first fix H, the least significant factor variable, at its estimated optimum value and generate a grid of points for T and R. To ensure that the grid data do not affect parameter estimates, the response variable (Odor) is set to missing. (See the “Missing Values” section on page 4048.) The following statements produce and graph the necessary data. Initial data steps creates a grid over T and R, with H set to a constant value, and combine this grid with the original data. Then, PROC RSREG is used to create predictions for the combined data. Finally, PROC G3D is used to create a surface plot of the predictions.

```

data grid;
  do;
    Odor = . ;
    H    = 7.541;
    do T = 20 to 140 by 5;
      do R = .1 to .9 by .05;
        output;
      end;
    end;
  end;
end;
data grid;
  set smell grid;
run;

proc rsreg data=grid out=predict noprint;
  model Odor = T R H / predict;
run;

data plot;
  set predict;
  if H = 7.541;
proc g3d data=plot;
  plot T*R=Odor / rotate=38 tilt=75 xticknum=3 yticknum=3
  zmax=300 zmin=-60 ctop=red cbottom=blue caxis=black;
run;

```

The first DATA step creates grid points for T and R at H=7.541 and sets Odor to missing, and the second DATA step concatenates these grid points with the original data. Predicted values are created in the SAS data set `predict` by invoking the RSREG procedure with the PREDICT option in the MODEL statement. The analysis is not displayed due to the NOPRINT option. The third DATA step subsets the predicted values over just the grid points (excluding the predictions at the original points). PROC G3D is then used to create the three-dimensional plot shown in [Figure 63.4](#).

Figure 63.4. The Response Surface Obtained from the PREDICT Option

Syntax

The following statements are available in PROC RSREG.

```

PROC RSREG < options > ;
  MODEL responses= independents < / options > ;
  RIDGE < options > ;
  WEIGHT variable ;
  ID variables ;
  BY variables ;

```

The PROC RSREG and MODEL statements are required. The BY, ID, MODEL, RIDGE, and WEIGHT statements are described after the PROC RSREG statement, and they can appear in any order.

PROC RSREG Statement

```

PROC RSREG < options > ;

```

The PROC RSREG statement invokes the procedure. You can specify the following options in the PROC RSREG statement.

DATA=SAS-data-set

specifies the input SAS data set that contains the data to be analyzed. By default, PROC RSREG uses the most recently created SAS data set.

NOPRINT

suppresses the normal display of results when only the output data set is required. For more information, see the description of the NOPRINT option in the “MODEL Statement” and “RIDGE Statement” sections. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

OUT=SAS-data-set

creates an output SAS data set that contains statistics for each observation in the input data set. In particular, this data set contains the BY variables, the ID variables, the WEIGHT variable, the variables in the MODEL statement, and the output options requested in the MODEL statement. You must specify output options in the MODEL statement; otherwise, the output data set is created but contains no observations. To create a permanent SAS data set, you must specify a two-level name (refer to the discussion in *SAS Language Reference: Concepts* for more information on permanent SAS data sets). For details on the data set created by PROC RSREG, see the “Output Data Sets” section on page 4051.

BY Statement

BY variables ;

You can specify a BY statement with PROC RSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the RSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

ID Statement

ID *variables* ;

The ID statement names variables that are to be transferred to the data set created by the OUT= option in the PROC RSREG statement.

MODEL Statement

MODEL *responses=independents* < / *options* > ;

The MODEL statement lists response (dependent) variables followed by an equal sign and then lists independent variables, some of which may be covariates. The output options to the MODEL statement specify which statistics are output to the data set created using the OUT= option in the PROC RSREG statement. If none of the options are selected, the data set is created but contains no observations. The option keywords become values of the special variable _TYPE_ in the output data set. Any of the following options can be specified.

Task	Options
Analyze Original Data	NOCODE
Fit Model to First BY Group Only	BYOUT
Declare Covariates	COVAR=
Request Additional Statistics	PRESS
Request Additional Tests	LACKFIT
Suppress Displayed Output	NOANOVA NOOPTIMAL NOPRINT
Output Statistics	ACTUAL PREDICT RESIDUAL L95 U95 L95M U95M D

ACTUAL

specifies that the observed response values from the input data set be written to the output data set.

BYOUT

uses only the first BY group to estimate the model. Subsequent BY groups have scoring statistics computed in the output data set only. The BYOUT option is used only when a BY statement is specified.

COVAR=*n*

declares that the first n variables on the right-hand side of the model are simple linear regressors (covariates) and not factors in the quadratic response surface. By default, PROC RSREG forms quadratic and crossproduct effects for all regressor variables in the MODEL statement. See the “[Handling Covariates](#)” section on page 4050 for more details and [Example 63.2](#) on page 4059 for an example using covariates.

D

specifies that Cook’s D influence statistic be written to the output data set. See [Chapter 2, “Introduction to Regression Procedures,”](#) for details and formulas.

LACKFIT

performs a lack-of-fit test. Refer to Draper and Smith (1981) for a discussion of lack-of-fit tests.

L95

specifies that the lower bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates. See [Chapter 2](#) for details and formulas.

L95M

specifies that the lower bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates. See [Chapter 2](#) for details and formulas.

NOANOVA**NOAOV**

suppresses the display of the analysis of variance and parameter estimates from the model fit.

NOCODE

performs the canonical and ridge analyses with the parameter estimates derived from fitting the response to the original values of the factors variables, rather than their coded values (see the “[Coding the Factor Variables](#)” section on page 4047 for more details.) Use this option if the data are already stored in a coded form.

NOOPTIMAL**NOOPT**

suppresses the display of the canonical analysis for the quadratic response surface.

NOPRINT

suppresses the display of both the analysis of variance and the canonical analysis.

PREDICT

specifies that the values predicted by the model be written to the output data set.

PRESS

computes and displays the predicted residual sum of squares (PRESS) statistic for each dependent variable in the model. The PRESS statistic is added to the summary information at the beginning of the analysis of variance, so if the NOANOVA or

NOPRINT option is specified, PRESS has no effect. See [Chapter 2](#) for details and formulas.

RESIDUAL

specifies that the residuals, calculated as ACTUAL – PREDICTED, be written to the output data set.

U95

specifies that the upper bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates. See [Chapter 2](#) for details and formulas.

U95M

specifies that the upper bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates. See [Chapter 2](#) for details and formulas.

RIDGE Statement

RIDGE < options > ;

A RIDGE statement computes the ridge of optimum response. The ridge starts at a given point \mathbf{x}_0 , and the point on the ridge at radius r from \mathbf{x}_0 is the collection of factor settings that optimizes the predicted response at this radius. You can think of the ridge as climbing or falling as fast as possible on the surface of predicted response. Thus, the ridge analysis can be used as a tool to help interpret an existing response surface or to indicate the direction in which further experimentation should be performed.

The default starting point, \mathbf{x}_0 , has each coordinate equal to the point midway between the highest and lowest values of the factor in the design. The default radii at which the ridge is computed are 0, 0.1, . . . , 0.9, 1. If, as usual, the ridge analysis is based on the response surface fit to coded values for the factor variables (see the “[Coding the Factor Variables](#)” section on page 4047 for details), then this results in a ridge that starts at the point with a coded zero value for each coordinate and extends toward, but not beyond, the edge of the range of experimentation. Alternatively, both the center point for the ridge and the radii at which it is to be computed can be specified.

You can specify the following options in the RIDGE statement:

CENTER=*uncoded-factor-values*

gives the coordinates of the point \mathbf{x}_0 from which to begin the ridge. The coordinates should be given in the original (uncoded) factor variable values and should be separated by commas. There must be as many coordinates specified as there are factors in the model, and the order of the coordinates must be the same as that used in the MODEL statement. This starting point should be well inside the range of experimentation. The default sets each coordinate equal to the value midway between the highest and lowest values for the associated factor.

MAXIMUM**MAX**

computes the ridge of maximum response. Both the MIN and MAX options can be specified; at least one must be specified.

MINIMUM**MIN**

computes the ridge of minimum response. Both the MIN and MAX options can be specified; at least one must be specified.

NOPRINT

suppresses the display of the ridge analysis when only an output data set is required.

OUTR=SAS-data-set

creates an output SAS data set containing the computed optimum ridge. For details, see the “[Output Data Sets](#)” section on page 4051.

RADIUS=coded-radii

gives the distances from the ridge starting point at which to compute the optimum. The values in the list represent distances between coded points. The list can take any of the following forms or can be composed of mixtures of them:

m_1, m_2, \dots, m_n several values

m TO n a sequence where m equals the starting value, n equals the ending value, and the increment equals 1

m TO n BY i a sequence where m equals the starting value, n equals the ending value, and i equals the increment

Mixtures of the preceding forms should be separated by commas. The default list runs from 0 to 1 by increments of 0.1. The following are examples of valid lists.

```
radius=0 to 5 by .5;
radius=0, .2, .25, .3, .5 to 1.0 by .1;
```

WEIGHT Statement

WEIGHT *variable* ;

When a WEIGHT statement is used, a weighted residual sum of squares

$$\sum_i w_i (y_i - \hat{y}_i)^2$$

is minimized, where w_i is the value of the variable specified in the WEIGHT statement, y_i is the observed value of the response variable, and \hat{y}_i is the predicted value of the response variable.

The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than zero. The WEIGHT statement has no effect on degrees of freedom or number of observations. If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least-squares estimates are best linear unbiased estimators (BLUE).

Details

Introduction to Response Surface Experiments

Many industrial experiments are conducted to discover which values of given factor variables optimize a response. If each factor is measured at three or more values, a quadratic response surface can be estimated by least-squares regression. The predicted optimal value can be found from the estimated surface if the surface is shaped like a simple hill or a valley. If the estimated surface is more complicated, or if the predicted optimum is far from the region of experimentation, then the shape of the surface can be analyzed to indicate the directions in which new experiments should be performed.

Suppose that a response variable y is measured at combinations of values of two factor variables, x_1 and x_2 . The quadratic response-surface model for this variable is written as

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_1^2 + \beta_4x_2^2 + \beta_5x_1x_2 + \epsilon$$

The steps in the analysis for such data are

1. model fitting and analysis of variance to estimate parameters
2. canonical analysis to investigate the shape of the predicted response surface
3. ridge analysis to search for the region of optimum response

Model Fitting and Analysis of Variance

The first task in analyzing the response surface is to estimate the parameters of the model by least-squares regression and to obtain information about the fit in the form of an analysis of variance. The estimated surface is typically curved: a “hill” whose peak occurs at the unique estimated point of maximum response, a “valley,” or a “saddle-surface” with no unique minimum or maximum. Use the results of this phase of the analysis to answer the following questions:

- What is the contribution of each type of effect—linear, quadratic, and crossproduct—to the statistical fit? The ANOVA table with sources labeled “Regression” addresses this question.
- What part of the residual error is due to lack of fit? Does the quadratic response model adequately represent the true response surface? If you specify the LACKFIT option in the MODEL statement, then the ANOVA table with sources labeled “Residual” addresses this question.
- What is the contribution of each factor variable to the statistical fit? Can the response be predicted as well if the variable is removed? The ANOVA table with sources labeled “Factor” addresses this question.
- What are the predicted responses for a grid of factor values? (See the section “Plotting the Surface” on page 4048 and the “Searching for Multiple Response Conditions” section on page 4048.)

Lack-of-Fit Test

The test for lack-of-fit compares the variation around the model with “pure” variation within replicated observations. This measures the adequacy of the quadratic response surface model. In particular, if there are n_i replicated observations Y_{i1}, \dots, Y_{in_i} of the response all at the same values \mathbf{x}_i of the factors, then we can predict the true response at \mathbf{x}_i either by using the predicted value \hat{Y}_i based on the model or by using the mean \bar{Y}_i of the replicated values. The test for lack-of-fit decomposes the residual error into a component due to the variation of the replications around their mean value (the “pure” error), and a component due to the variation of the mean values around the model prediction (the “bias” error):

$$\sum_i \sum_{j=1}^{n_i} (Y_{ij} - \hat{Y}_i)^2 = \sum_i \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2 + \sum_i n_i (\bar{Y}_i - \hat{Y}_i)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the LACKFIT option in the MODEL statement. Note that, since all other tests use total error rather than pure error, you may want to hand-calculate the tests with respect to pure error if the lack-of-fit is significant. On the other hand, significant lack-of-fit indicates the quadratic model is inadequate, so if this is a problem you can also try to refine the model, possibly using PROC GLM for general polynomial modeling; refer to Chapter 32, “The GLM Procedure,” for more information. Example 63.1 on page 4055 illustrates the use of the LACKFIT option.

Canonical Analysis

The second task in analyzing the response surface is to examine the overall shape of the curve and determine whether the estimated stationary point is a maximum, a minimum, or a saddle point. The canonical analysis can be used to answer the following questions:

- Is the surface shaped like a hill, a valley, a saddle surface, or a flat surface?
- If there is a unique optimum combination of factor values, where is it?
- To which factor or factors are the predicted responses most sensitive?

The eigenvalues and eigenvectors in the matrix of second-order parameters characterize the shape of the response surface. The eigenvectors point in the directions of principle orientation for the surface, and the signs and magnitudes of the associated eigenvalues give the shape of the surface in these directions. Positive eigenvalues indicate directions of upward curvature, and negative eigenvalues indicate directions of downward curvature. The larger an eigenvalue is in absolute value, the more pronounced is the curvature of the response surface in the associated direction. Often, all of the coefficients of an eigenvector except for one are relatively small, indicating that the vector points roughly along the axis associated with the factor corresponding

to the single large coefficient. In this case, the canonical analysis can be used to determine the relative sensitivity of the predicted response surface to variations in that factor. (See the “Getting Started” section on page 4034 for an example.)

Ridge Analysis

If the estimated surface is found to have a simple optimum well within the range of experimentation, the analysis performed by the preceding two steps may be sufficient. In more complicated situations, further search for the region of optimum response is required. The method of ridge analysis computes the estimated ridge of optimum response for increasing radii from the center of the original design. The ridge analysis answers the following question:

- If there is not a unique optimum of the response surface within the range of experimentation, in which direction should further searching be done in order to locate the optimum?

You can use the RIDGE statement to compute the ridge of maximum or minimum response.

Coding the Factor Variables

For the results of the canonical and ridge analyses to be interpretable, the values of different factor variables should be comparable. This is because the canonical and ridge analyses of the response surface are not invariant with respect to differences in scale and location of the factor variables. The analysis of variance is not affected by these changes. Although the actual predicted surface does not change, its parameterization does. The usual solution to this problem is to code each factor variable so that its minimum in the experiment is -1 and its maximum is 1 and to carry through the analysis with the coded values instead of the original ones. This practice has the added benefit of making 1 a reasonable boundary radius for the ridge analysis since 1 represents approximately the edge of the experimental region. By default, PROC RSREG computes the linear transformation to perform this coding as the data are initially read in, and the canonical and ridge analyses are performed on the model fit to the coded data. The actual form of the coding operation for each value of a variable is

$$\text{coded value} = (\text{original value} - M)/S$$

where M is the average of the highest and lowest values for the variable in the design and S is half their difference.

Missing Values

If an observation has missing data for any of the variables used by the procedure, then that observation is not used in the estimation process. If one or more response variables are missing, but no factor or covariate variables are missing, then predicted values and confidence limits are computed for the output data set, but the residual and Cook's D statistic are missing.

Plotting the Surface

You can generate predicted values for a grid of points with the PREDICT option (see the “Getting Started” section on page 4034 for an example) and then use these values to create a contour plot or a three-dimensional plot of the response surface over a two-dimensional grid. Any two factor variables can be chosen to form the grid for the plot. Several plots can be generated by using different pairs of factor variables.

Searching for Multiple Response Conditions

Suppose you want to find the factor setting that produces responses in a certain region. For example, you have the following data with two factors and three responses:

```
data a;
  input x1 x2 y1 y2 y3;
  datalines;
-1      -1      1.8 1.940  3.6398
-1      1       2.6 1.843  4.9123
1       -1      5.4 1.063  6.0128
1       1       0.7 1.639  2.3629
0       0       8.5 0.134  9.0910
0       0       3.0 0.545  3.7349
0       0       9.8 0.453 10.4412
0       0       4.1 1.117  5.0042
0       0       4.8 1.690  6.6245
0       0       5.9 1.165  6.9420
0       0       7.3 1.013  8.7442
0       0       9.3 1.179 10.2762
1.4142  0       3.9 0.945  5.0245
-1.4142 0       1.7 0.333  2.4041
0       1.4142  3.0 1.869  5.2695
0       -1.4142 5.7 0.099  5.4346
;
```

You want to find the values of $x1$ and $x2$ that maximize $y1$ subject to $y2 < 2$ and $y3 < y2 + y1$. The exact answer is not easy to obtain analytically, but you can obtain a practically feasible solution by checking conditions across a grid of values in the range of interest. First, append a grid of factor values to the observed data, with missing values for the responses.

```
data b;
  set a end=eof;
```

```

output;
if eof then do;
  y1=.;
  y2=.;
  y3=.;
  do x1=-2 to 2 by .1;
    do x2=-2 to 2 by .1;
      output;
    end;
  end;
end;
run;

```

Next, use PROC RSREG to fit a response surface model to the data and to compute predicted values for both the observed data and the grid, putting the predicted values in a data set C.

```

proc rsreg data=b out=c;
  model y1 y2 y3=x1 x2 / predict;
run;

```

Finally, find the subset of predicted values that satisfy the constraints, sort by the unconstrained variable, and display the top five predictions.

```

data d;
  set c;
  if y2<2;
  if y3<y2+y1;

proc sort data=d;
  by descending y1;
run;

data d; set d;
  i = _n_;
proc print;
  where (i <= 5);
run;

```

The final results are displayed in [Figure 63.5](#). They indicate that optimal values of the factors are around 0.3 for x1 and around -0.5 for x2.

Obs	x1	x2	_TYPE_	y1	y2	y3	i
1	0.3	-0.5	PREDICT	6.92570	0.75784	7.60471	1

3	0.3	-0.4	PREDICT	6.91003	0.77870	7.64341	3
4	0.4	-0.6	PREDICT	6.90769	0.73357	7.51836	4
5	0.4	-0.5	PREDICT	6.90540	0.75135	7.56883	5

Figure 63.5. Top Five Predictions

Handling Covariates

Covariate regressors are added to a response surface model because they are believed to account for a sizable yet relatively uninteresting portion of the variation in the data. What the experimenter is really interested in is the response corrected for the effect of the covariates. A common example is the block effect in a block design. In the canonical and ridge analyses of a response surface, which estimate responses at hypothetical levels of the factor variables, the actual value of the predicted response is computed using the average values of the covariates. The estimated response values do optimize the estimated surface of the response corrected for covariates, but true prediction of the response requires actual values for the covariates. You can use the COVAR= option in the MODEL statement to include covariates in the response surface model. [Example 63.2](#) on page 4059 illustrates the use of this option.

Computational Method

Canonical Analysis

For each response variable, the model can be written in the form

$$y_i = \mathbf{x}_i' \mathbf{A} \mathbf{x}_i + \mathbf{b}' \mathbf{x}_i + \mathbf{c}' \mathbf{z}_i + \epsilon_i$$

where

y_i is the i th observation of the response variable.

$\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{ik})'$ are the k factor variables for the i th observation.

$\mathbf{z}_i = (z_{i1}, z_{i2}, \dots, z_{iL})'$ are the L covariates, including the intercept term.

\mathbf{A} is the $k \times k$ symmetrized matrix of quadratic parameters, with diagonal elements equal to the coefficients of the pure quadratic terms in the model and off-diagonal elements equal to half the coefficient of the corresponding cross product.

\mathbf{b} is the $k \times 1$ vector of linear parameters.

\mathbf{c} is the $L \times 1$ vector of covariate parameters, one of which is the intercept.

ϵ_i is the error associated with the i th observation. Tests performed by PROC RSREG assume that errors are independently and normally distributed with mean zero and variance σ^2 .

The parameters in \mathbf{A} , \mathbf{b} , and \mathbf{c} are estimated by least squares. To optimize y with respect to \mathbf{x} , take partial derivatives, set them to zero, and solve:

$$\frac{\partial y}{\partial \mathbf{x}} = 2\mathbf{x}' \mathbf{A} + \mathbf{b}' = \mathbf{0} \implies \mathbf{x} = -\frac{1}{2} \mathbf{A}^{-1} \mathbf{b}$$

You can determine if the solution is a maximum or minimum by looking at the eigenvalues of \mathbf{A} :

<u>If the eigenvalues. . .</u>	<u>then the solution is. . .</u>
are all negative	a maximum
are all positive	a minimum
have mixed signs	a saddle point
contain zeros	in a flat area

Ridge Analysis

The eigenvector for the largest eigenvalue gives the direction of steepest ascent from the stationary point, if positive, or steepest descent, if negative. The eigenvectors corresponding to small or zero eigenvalues point in directions of relative flatness.

The point on the optimum response ridge at a given radius R from the ridge origin is found by optimizing

$$(\mathbf{x}_0 + \mathbf{d})' \mathbf{A}(\mathbf{x}_0 + \mathbf{d}) + \mathbf{b}'(\mathbf{x}_0 + \mathbf{d})$$

over \mathbf{d} satisfying $\mathbf{d}'\mathbf{d} = R^2$, where \mathbf{x}_0 is the $k \times 1$ vector containing the ridge origin and \mathbf{A} and \mathbf{b} are as previously discussed. By the method of Lagrange multipliers, the optimal \mathbf{d} has the form

$$\mathbf{d} = -(\mathbf{A} - \mu\mathbf{I})^{-1}(\mathbf{A}\mathbf{x}_0 + 0.5\mathbf{b})$$

where \mathbf{I} is the $k \times k$ identity matrix and μ is chosen so that $\mathbf{d}'\mathbf{d} = R^2$. There may be several values of μ that satisfy this constraint; the right one depends on which sort of response ridge is of interest. If you are searching for the ridge of maximum response, then the appropriate μ is the unique one that satisfies the constraint and is greater than all the eigenvalues of \mathbf{A} . Similarly, the appropriate μ for the ridge of minimum response satisfies the constraint and is less than all the eigenvalues of \mathbf{A} . (Refer to Myers and Montgomery (1995) for details.)

Output Data Sets

OUT=SAS-data-set

An output data set containing statistics requested with options in the MODEL statement for each observation in the input data set is created whenever the OUT= option is specified in the PROC RSREG statement. The data set contains the following variables.

- the BY variables
- the ID variables
- the WEIGHT variable
- the independent variables in the MODEL statement

- the variable `_TYPE_`, which identifies the observation type in the output data set. `_TYPE_` is a character variable with a length of eight, and it takes on the values 'ACTUAL', 'PREDICT', 'RESIDUAL', 'U95M', 'L95M', 'U95', 'L95', and 'D', corresponding to the options specified.
- the response variables containing special output values identified by the `_TYPE_` variable

All confidence limits use the two-tailed Student's t value.

OUTR=SAS-data-set

An output data set containing the optimum response ridge is created when the `OUTR=` option is specified in the `RIDGE` statement. The data set contains the following variables:

- the current values of the `BY` variables
- a character variable `_DEPVAR_` containing the name of the dependent variable
- a character variable `_TYPE_` identifying the type of ridge being computed, `MINIMUM` or `MAXIMUM`. If both `MAXIMUM` and `MINIMUM` are specified, the data set contains observations for the minimum ridge followed by observations for the maximum ridge.
- a numeric variable `_RADIUS_` giving the distance from the ridge starting point
- the values of the model factors at the estimated optimum point at distance `_RADIUS_` from the ridge starting point
- a numeric variable `_PRED_`, which is the estimated expected value of the dependent variable at the optimum
- a numeric variable `_STDERR_`, which is the standard error of the estimated expected value

Displayed Output

All estimates and hypothesis tests assume that the model is correctly specified and the errors are distributed according to classical statistical assumptions.

The output displayed by `PROC RSREG` includes the following.

Estimation and Analysis of Variance

- The actual form of the coding operation for each value of a variable is

$$\text{coded value} = \frac{1}{S}(\text{original value} - M)$$

where M is the average of the highest and lowest values for the variable in the design and S is half their difference. The `Subtracted off` column contains the M values for this formula for each factor variable, and S is found in the `Divided by` column.

- The summary table for the response variable contains the following information.
 - Response Mean is the mean of the response variable in the sample. When a WEIGHT statement is used, the mean \bar{y} is calculated by

$$\bar{y} = \frac{\sum_i w_i y_i}{\sum_i w_i}$$
 - Root MSE estimates the standard deviation of the response variable and is calculated as the square root of the Total Error mean square.
 - The R-Square value is R^2 , or the coefficient of determination. R^2 measures the proportion of the variation in the response that is attributed to the model rather than to random error.
 - The Coefficient of Variation is 100 times the ratio of the Root MSE to the Response Mean.
- A table analyzing the significance of the terms of the regression is displayed. Terms are brought into the regression in four steps: (1) the Intercept and any covariates in the model, (2) Linear terms like X1 and X2, (3) pure Quadratic terms like X1*X1 or X2*X2, and (4) Crossproduct terms like X1*X2.
 - The Degrees of Freedom should be the same as the number of corresponding parameters unless one or more of the parameters are not estimable.
 - Type I Sum of Squares, also called the sequential sums of squares, measure the reduction in the error sum of squares as sets of terms (Linear, Quadratic, and so forth) are added to the model.
 - R-Square measures the portion of total R^2 contributed as each set of terms (Linear, Quadratic, and so forth) is added to the model.
 - Each F Value tests the null hypothesis that all parameters in the term are zero using the Total Error mean square as the denominator. This item is a test of a Type I hypothesis, containing the usual F test numerator, conditional on the effects of subsequent variables not being in the model.
 - $\text{Pr} > F$ is the significance value or probability of obtaining at least as great an F ratio given that the null hypothesis is true.
- The Total Error Sum of Squares can be partitioned into Lack of Fit and Pure Error. When Lack of Fit is significant, there is variation around the model other than random error (such as cubic effects of the factor variables).
 - The Total Error Mean Square estimates σ^2 , the variance.
 - F Value tests the null hypothesis that the variation is adequately described by random error.
- A table containing the parameter estimates from the model is displayed.
 - The Parameter Estimate column contains the parameter estimates based on the *uncoded* values of the factor variables. If an effect is a linear combination of previous effects, the parameter for the effect is not estimable. When this happens, the degrees of freedom are zero, the parameter estimate is set to zero, and the estimates and tests on other parameters are conditional on this parameter being zero.

- The Standard Error column contains the estimated standard deviations of the parameter estimates based on *uncoded* data.
 - The t Value column contains t values of a test of the null hypothesis that the true parameter is zero when the *uncoded* values of the factor variables are used.
 - $\text{Pr} > |T|$ gives the significance value or probability of a greater absolute t ratio given that the true parameter is zero.
 - The Parameter Estimate from Coded Data column contains the parameter estimates based on the *coded* values of the factor variables. These are the estimates used in the subsequent canonical and ridge analyses.
- The sum of squares are partitioned by the Factors in the model, and an analysis table is displayed. The test on a factor, say X1, is a joint test on all the parameters involving that factor. For example, the test for X1 tests the null hypothesis that the true parameters for X1, X1*X1, and X1*X2 are all zero.

Canonical Analysis

- The Critical Value columns contains the values of the factor variables that correspond to the stationary point of the fitted response surface. The critical values can be at a minimum, maximum, or saddle point.
- The Eigenvalues and Eigenvectors are from the matrix of quadratic parameter estimates based on the coded data. They characterize the shape of the response surface.

Ridge Analysis

- Coded Radius is the distance from the coded version of the associated point to the coded version of the origin of the ridge. The origin is given by the point at radius zero.
- Estimated Response is the estimated value of the response variable at the associated point. The Standard Error of this estimate is also given. This quantity is useful for assessing the relative credibility of the prediction at a given radius. Typically, this standard error increases rapidly as the ridge moves up to and beyond the design perimeter, reflecting the inherent difficulty of making predictions beyond the range of experimentation.
- Uncoded Factor Values are the values of the uncoded factor variables that give the optimum response at this radius from the ridge origin.

ODS Table Names

PROC RSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see [Chapter 14, “Using the Output Delivery System.”](#)

Table 63.1. ODS Tables Produced in PROC RSREG

ODS Table Name	Description	Statement
Coding	Coding coefficients for the independent variables	default
ErrorANOVA	Error analysis of variance	default
FactorANOVA	Factor analysis of variance	default
FitStatistics	Overall statistics for fit	default
ModelANOVA	Model analysis of variance	default
ParameterEstimates	Estimated linear parameters	default
Ridge	Ridge analysis for optimum response	RIDGE
Spectral	Spectral analysis	default
StationaryPoint	Stationary point of response surface	default

Examples

Example 63.1. A Saddle-Surface Response Using Ridge Analysis

Frankel (1961) reports an experiment aimed at maximizing the yield of *mercaptobenzothiazole* (MBT) by varying processing time and temperature. Myers (1976) uses a two-factor model in which the estimated surface does not have a unique optimum. A ridge analysis is used to determine the region in which the optimum lies. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements read the data and invoke PROC RSREG. These statements produce [Output 63.1.1](#) through [Output 63.1.5](#):

```

data d;
  input Time Temp MBT;
  label Time = "Reaction Time (Hours)"
        Temp = "Temperature (Degrees Centigrade)"
        MBT = "Percent Yield Mercaptobenzothiazole";
  datalines;
  4.0  250  83.8
  20.0 250  81.7
  12.0 250  82.4
  12.0 250  82.9
  12.0 220  84.7

Temp*Temp	1	-0.009836	0.004304	-2.29	0.0623	-8.852519

Factor	DF	Sum of Squares	Mean Square	F Value	Pr > F	Label
Time	3	61.290957	20.430319	0.96	0.4704	Reaction Time (Hours)
Temp	3	461.250925	153.750308	7.22	0.0205	Temperature (Degrees Centigrade)

Output 63.1.2 shows that the lack of fit for the model is highly significant. Since the quadratic model does not fit the data very well, firm statements about the underlying process should not be based only on the current analysis. Note from the analysis of variance for the model that the test for the time factor is not significant. If further experimentation is undertaken, it might be best to fix Time at a moderate to high value and to concentrate on the effect of temperature. In the actual experiment discussed here, extra runs were made that confirmed the results of the following analysis.

Output 63.1.3. Canonical Analysis

The RSREG Procedure			
Canonical Analysis of Response Surface Based on Coded Data			
Factor	Critical Value		Label
	Coded	Uncoded	
Time	-0.441758	8.465935	Reaction Time (Hours)
Temp	-0.309976	240.700718	Temperature (Degrees Centigrade)
Predicted value at stationary point: 83.741940			
Eigenvalues	Eigenvectors		
	Time	Temp	
2.528816	0.953223	-0.302267	
-9.996940	0.302267	0.953223	
Stationary point is a saddle point.			

The canonical analysis (Output 63.1.3) indicates that the predicted response surface is shaped like a saddle. The eigenvalue of 2.5 shows that the valley orientation of the saddle is less curved than the hill orientation, with eigenvalue of -9.99. The coefficients of the associated eigenvectors show that the valley is more aligned with Time and the hill with Temp. Because the canonical analysis resulted in a saddle point, the estimated surface does not have a unique optimum.

Output 63.1.4. Ridge Analysis

The RSREG Procedure				
Estimated Ridge of Maximum Response for Variable MBT: Percent Yield Mercaptobenzothiazole				
Coded Radius	Estimated Response	Standard Error	Uncoded Factor Values	
			Time	Temp

However, the ridge analysis in [Output 63.1.4](#) indicates that maximum yields will result from relatively high reaction times and low temperatures. A contour plot of the predicted response surface, shown in [Output 63.1.5](#), confirms this conclusion.

Output 63.1.5. Contour Plot of Predicted Response Surface

The statements that produce this plot follow. Note that contour and three-dimensional plots can be created interactively using SAS/INSIGHT software or the ADX Interface in SAS/QC software. Initial DATA steps create a grid over Time and Temp and combine this grid with the original data, using a variable flag to indicate the grid. Then, PROC RSREG is used to create predictions for the combined data. Finally, PROC GCONTOUR to displays a contour plot of the predictions over just the grid.

```

data b;
  set d;
  flag=1;
  MBT=.;
  do Time=0 to 20 by 1;
    do Temp=220 to 280 by 5;
      output;
    end;
  end;
data c;
  set d b;
proc rsreg data=c out=e noprint;
  model MBT=Time Temp / predict;
  id flag;
run;

```

```

axis1 label=(angle=90) minor=none;
axis2 order=(220 to 280 by 20) minor=none;

proc gcontour data=e(where=(flag=1));
  plot Time*Temp=MBT
       / nlevels=12 vaxis=axis1 haxis=axis2 nolegend autolabel
       llevels=2 2 2 1 1 1 1 1 1 1 1 1 ;
run;

```

Example 63.2. Response Surface Analysis with Covariates

One way of viewing covariates is as extra sources of variation in the dependent variable that may mask the variation due to primary factors. This example demonstrates the use of the COVAR= option in PROC RSREG to fit a response surface model to the dependent variable values corrected for the covariates.

You have a chemical process with a yield that you hypothesize to be dependent on three factors: reaction time, reaction temperature, and reaction pressure. You perform an experiment to measure this dependence. You are willing to include up to 20 runs in your experiment, but you can perform no more than 8 runs on the same day, so the design for the experiment is composed of three blocks. Additionally, you know that the grade of raw material for the reaction has a significant impact on the yield. You have no control over this, but you keep track of it. The following statements create a SAS data set containing the results of the experiment:

```

data Experiment;
  input Day Grade Time Temp Pressure Yield;
  datalines;
1 67      -1      -1      -1           32.98
1 68      -1       1       1           47.04
1 70       1      -1       1           67.11
1 66       1       1      -1           26.94
1 74       0       0       0          103.22
1 68       0       0       0           42.94
2 75      -1      -1       1          122.93
2 69      -1       1      -1           62.97
2 70       1      -1      -1           72.96
2 71       1       1       1           94.93
2 72       0       0       0           93.11
2 74       0       0       0          112.97
3 69       1.633  0       0           78.88
3 67      -1.633  0       0           52.53
3 68       0       1.633  0           68.96
3 71       0      -1.633  0           92.56
3 70       0       0       1.633        88.99
3 72       0       0      -1.633       102.50
3 70       0       0       0           82.84
3 72       0       0       0          103.12
;

```

Your first analysis neglects to take the covariates into account. The following statements use PROC RSREG to fit a response surface to the observed yield, but note that Day and Grade are omitted.

```
proc rsreg data=Experiment;
  model Yield = Time Temp Pressure;
run;
```

The ANOVA results (shown in [Output 63.2.1](#)) indicate that *no* process variable effects are significantly larger than the background noise.

Output 63.2.1. Analysis of Variance Ignoring Covariates

The RSREG Procedure					
Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Linear	3	1880.842426	0.1353	0.67	0.5915
Quadratic	3	2370.438681	0.1706	0.84	0.5023
Crossproduct	3	241.873250	0.0174	0.09	0.9663
Total Model	9	4493.154356	0.3233	0.53	0.8226
Residual	DF	Sum of Squares	Mean Square		
Total Error	10	9405.129724	940.512972		

However, when the yields are adjusted for covariate effects of day and grade of raw material, very strong process variable effects are revealed. The following statements produce the ANOVA results in [Output 63.2.2](#). Note that in order to include the effects of the classification factor Day as covariates, you need to create dummy variables indicating each day separately.

```
data Experiment; set Experiment;
  d1 = (Day = 1);
  d2 = (Day = 2);
  d3 = (Day = 3);
proc rsreg data=Experiment;
  model Yield = d1-d3 Grade Time Temp Pressure / covar=4;
run;
```

Output 63.2.2. Analysis of Variance Including Covariates

The RSREG Procedure					
Regression	DF	Type I Sum of Squares	R-Square	F Value	Pr > F
Covariates	3	13695	0.9854	316957	<.0001
Linear	3	156.524497	0.0113	3622.53	<.0001
Quadratic	3	22.989775	0.0017	532.06	<.0001
Crossproduct	3	23.403614	0.0017	541.64	<.0001
Total Model	12	13898	1.0000	80413.2	<.0001
Residual	DF	Sum of Squares	Mean Square		
Total Error	7	0.100820	0.014403		

The results show very strong effects due to both the covariates and the process variables.

Chapter 64

The SCORE Procedure

Overview

The SCORE procedure multiplies values from two SAS data sets, one containing coefficients (for example, factor-scoring coefficients or regression coefficients) and the other containing raw data to be scored using the coefficients from the first data set. The result of this multiplication is a SAS data set containing linear combinations of the coefficients and the raw data values.

Many statistical procedures output coefficients that PROC SCORE can apply to raw data to produce scores. The new score variable is formed as a linear combination of raw data and scoring coefficients. For each observation in the raw data set, PROC SCORE multiplies the value of a variable in the raw data set by the matching scoring coefficient from the data set of scoring coefficients. This multiplication process is repeated for each variable in the VAR statement. The resulting products are then summed to produce the value of the new score variable. This entire process is repeated for each observation in the raw data set. In other words, PROC SCORE cross multiplies part of one data set with another.

Raw Data Set

The raw data set can contain the original data used to calculate the scoring coefficients, or it can contain an entirely different data set. The raw data set must contain all the variables needed to produce scores. In addition, the scoring coefficients and the variables in the raw data set that are used in scoring must have the same names. See the section “Getting Started” beginning on page 4067.

Scoring Coefficients Data Set

The data set containing scoring coefficients must contain two special variables: the `_TYPE_` variable and the `_NAME_` or `_MODEL_` variable.

- The `_TYPE_` variable identifies the observations that contain scoring coefficients.
- The `_NAME_` or `_MODEL_` variable provides a SAS name for the new score variable.

PROC SCORE first looks for a `_NAME_` variable in the SCORE= input data set. If there is such a variable, the variable’s value is what SCORE uses to name the new score variable. If the SCORE= data set does not have a `_NAME_` variable, then PROC SCORE looks for a `_MODEL_` variable.

For example, PROC FACTOR produces an output data set that contains factor-scoring coefficients. In this output data set, the scoring coefficients are identified by

`_TYPE_='SCORE'`. For `_TYPE_='SCORE'`, the `_NAME_` variable has values of 'Factor1', 'Factor2', and so forth. PROC SCORE gives the new score variables the names Factor1, Factor2, and so forth.

As another example, the REG procedure produces an output data set that contains parameter estimates. In this output data set, the parameter estimates are identified by `_TYPE_='PARMS'`. The `_MODEL_` variable contains the label used in the MODEL statement in PROC REG, or it uses `MODELn` if no label is specified. This label is the name PROC SCORE gives to the new score variable.

Standardization of Raw Data

PROC SCORE automatically standardizes or centers the `DATA=` variables for you, based on information from the original variables and analysis from the `SCORE=` data set.

If the `SCORE=` scoring coefficients data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, then PROC SCORE standardizes the raw data before scoring. For example, this type of `SCORE=` data set can come from PROC PRINCOMP without the COV option.

If the `SCORE=` scoring coefficients data set contains observations with `_TYPE_='MEAN'` but `_TYPE_='STD'` is absent, then PROC SCORE centers the raw data (the means are subtracted) before scoring. For example, this type of `SCORE=` data set can come from PROC PRINCOMP with the COV option.

If the `SCORE=` scoring coefficients data set does not contain observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, or if you use the NOSTD option, then PROC SCORE does not center or standardize the raw data.

If the `SCORE=` scoring coefficients are obtained from observations with `_TYPE_='USCORE'`, then PROC SCORE “standardizes” the raw data using the uncorrected standard deviations identified by `_TYPE_='USTD'`, and the means are not subtracted from the raw data. For example, this type of `SCORE=` data set can come from PROC PRINCOMP with the NOINT option. For more information on `_TYPE_='USCORE'` scoring coefficients in `TYPE=UCORR` or `TYPE=UCOV` output data sets, see [Appendix A, “Special SAS Data Sets.”](#)

You can use PROC SCORE to score the data that were also used to generate the scoring coefficients, although more typically, scoring results are directly obtained from the `OUT=` data set in a procedure that computes scoring coefficients. When scoring new data, it is important to realize that PROC SCORE assumes that the new data have approximately the same scales as the original data. For example, if you specify the COV option with PROC PRINCOMP for the original analysis, the scoring coefficients in the PROC PRINCOMP `OUTSTAT=` data set are not appropriate for standardized data. With the COV option, PROC PRINCOMP will not output `_TYPE_='STD'` observations to the `OUTSTAT=` data set, and PROC SCORE will only subtract the means of the original (not new) variables from the new variables before multiplying. Without the COV option in PROC PRINCOMP, both the original variable means and standard deviations will be in the `OUTSTAT=` data set, and PROC SCORE will

subtract the original variable means from the new variables and divide them by the original variable standard deviations before multiplying.

In general, procedures that output scoring coefficients in their OUTSTAT= data sets provide the necessary information for PROC SCORE to determine the appropriate standardization. However, if you use PROC SCORE with a scoring coefficients data set that you constructed without `_TYPE_='MEAN'` and `_TYPE_='STD'` observations, you might have to do the relevant centering or standardization of the new data first. If you do this, you must use the means and standard deviations of the original variables, that is, the variables that were used to generate the coefficients, not the means and standard deviations of the variables to be scored.

See the section “Getting Started” on page 4067 for further illustration.

Getting Started

The SCORE procedure multiplies the values from two SAS data sets and creates a new data set to contain the results of the multiplication. The variables in the new data set are linear combinations of the variables in the two input data sets. Typically, one of these data sets contains raw data that you want to score, and the other data set contains scoring coefficients.

The following example demonstrates how to use the SCORE procedure to multiply values from two SAS data sets, one containing factor-scoring coefficients and the other containing raw data to be scored using the scoring coefficients.

Suppose you are interested in the performance of three different types of schools: private schools, state-run urban schools, and state-run rural schools. You want to compare the schools’ performances as measured by student grades on standard tests in English, mathematics, and biology. You administer these tests and record the scores for each of the three types of schools.

The following DATA step creates the SAS data set `Schools`. The data are provided by Chaseling (1996).

```

;

```

The data set `Schools` contains the character variable `Type`, which represents the type of school. Valid values are `p` (private schools), `r` (state-run rural schools), and `u` (state-run urban schools).

The three numeric variables in the data set are `English`, `Math`, and `Biology`, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (`@@`) in the `INPUT` statement specifies that observations are input from each line until all values are read.

The following statements invoke the `FACTOR` procedure to compute the data set of factor scoring coefficients. The statements perform a principle components factor analysis using all three numeric variables in the SAS data set `Schools`. The `OUTSTAT=` option requests that `PROC FACTOR` output the factor scores to the data set `Scores`. The `NOPRINT` option suppresses display of the output.

```

proc factor data=Schools score outstat=Scores noprint;
  var english math biology;
run;
proc score data=schools score=Scores out=New;
  var english math biology;
  id type;
run;

```

The SCORE procedure is then invoked using `Schools` as the raw data set to be scored and `Scores` as the scoring data set. The `OUT=` option creates the SAS data set `New` to contain the linear combinations.

The `VAR` statement specifies that the variables `English`, `Math`, and `Biology` are used in computing scores. The `ID` statement copies the variable `Type` from the `Schools` data set to the output data set `New`.

The following statements print the SAS output data set `Scores`, the first two observations from the original data set `Schools`, and the first two observations of the resulting data set `New`.

```
title 'OUTSTAT= Data Set from PROC FACTOR';
proc print data=Scores;
run;
title 'First Two Observations of the DATA= Data Set from PROC SCORE';
proc print data=Schools(obs=2);
run;
title 'First Two Observations of the OUT= Data Set from PROC SCORE';
proc print data=New(obs=2);
run;
```

[Figure 64.1](#) displays the output data set `Scores` produced by the `FACTOR` procedure. The last observation (observation number 11) contains the scoring coefficients (`_TYPE_='SCORE'`). Only one factor has been retained. [Figure 64.1](#) also lists the first two observations of the original SAS data set `Schools` and the first two observations of the output data set `New` from the `SCORE` procedure.

Figure 64.1. Views of the Scores, Schools, and New Data Sets

The score variable `Factor1` in the New data set is named according to the value of the `_NAME_` variable in the Scores data set. The values of the variable `Factor1` are computed as follows: the original data set variables are standardized to a mean of 0 and a variance of 1 because the Scores data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`. These standardized variables are then multiplied by their respective standardized scoring coefficients from the data set Scores. These products are summed over all three variables, and the sum is the value of the new variable `Factor1`. The first two values of the scored variable `Factor1` are obtained as follows:

$$\left(\frac{(52 - 55.525)}{12.949} \times 0.390 \right) + \left(\frac{(55 - 52.325)}{12.356} \times 0.378 \right) + \left(\frac{(45 - 50.350)}{12.239} \times 0.347 \right) = -0.17604$$

$$\left(\frac{(42 - 55.525)}{12.949} \times 0.390 \right) + \left(\frac{(49 - 52.325)}{12.356} \times 0.378 \right) + \left(\frac{(40 - 50.350)}{12.239} \times 0.347 \right) = -0.80294$$

The following statements request that the GCHART procedure produce a horizontal bar chart of the variable `Type`. The length of each bar represents the mean of the variable `Factor1`.

```
proc gchart;
  hbar type/type=mean sumvar=Factor1;
run;
```

Figure 64.2. Bar Chart of School Type

Figure 64.2 displays the mean score of the variable **Factor1** for each of the three school types. For private schools (**Type=p**), the average value of the variable **Factor1** is 0.384, while for state-run schools the average value is much lower. The state-run urban schools (**Type=u**) have the lowest mean value of -0.202, and the state-run rural schools (**Type=r**) have a mean value of -0.183.

Syntax

The following statements are available in the SCORE procedure.

```
PROC SCORE DATA= SAS-data-set < options > ;
  BY variables ;
  ID variables ;
  VAR variables ;
```

The only required statement is the **PROC SCORE** statement. The **BY**, **ID**, and **VAR** statements are described following the **PROC SCORE** statement.

PROC SCORE Statement

PROC SCORE DATA= *SAS-data-set* < options > ;

You can specify the following options in the PROC SCORE statement.

DATA=*SAS-data-set*

names the input SAS data set containing the raw data to score. This specification is required.

NOSTD

suppresses centering and scaling of the raw data. Ordinarily, if PROC SCORE finds `_TYPE_='MEAN'`, `_TYPE_='USCORE'`, `_TYPE_='USTD'`, or `_TYPE_='STD'` observations in the SCORE= data set, the procedure uses these to standardize the raw data before scoring.

OUT=*SAS-data-set*

specifies the name of the SAS data set created by PROC SCORE. If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to “SAS Files” in *SAS Language Reference: Concepts* for more information on permanent SAS data sets.) If the OUT= option is omitted, PROC SCORE still creates an output data set and automatically names it according to the DATA n convention, just as if you omitted a data set name in a DATA statement.

PREDICT

specifies that PROC SCORE should treat coefficients of -1 in the SCORE= data set as 0. In regression applications, the dependent variable is coded with a coefficient of -1 . Applied directly to regression results, PROC SCORE produces negative residuals (see the description of the RESIDUAL option, which follows); the PREDICT option produces predicted values instead.

RESIDUAL

reverses the sign of each score. Applied directly to regression results, PROC SCORE produces negative residuals (PREDICT–ACTUAL); the RESIDUAL option produces positive residuals (ACTUAL–PREDICT) instead.

SCORE=*SAS-data-set*

names the data set containing the scoring coefficients. If you omit the SCORE= option, the most recently created SAS data set is used. This data set must have two special variables: `_TYPE_` and either `_NAME_` or `_MODEL_`.

TYPE=*name* | *'string'*

specifies the observations in the SCORE= data set that contain scoring coefficients. The TYPE= procedure option is unrelated to the data set option that has the same name. PROC SCORE examines the values of the special variable `_TYPE_` in the SCORE= data set. When the value of `_TYPE_` matches `TYPE=name`, the observation in the SCORE= data set is used to score the raw data in the DATA= data set.

If you omit the TYPE= option, scoring coefficients are read from observations with either `_TYPE_='SCORE'` or `_TYPE_='USCORE'`. Because the default for PROC SCORE is TYPE=SCORE, you need not specify the TYPE= option for factor scoring or for computing scores from OUTSTAT= data sets from the CANCORR, CANDISC,

PRINCOMP, or VARCLUS procedure. When you use regression coefficients from PROC REG, specify TYPE=PARMS.

The maximum length of the argument specified in the TYPE= option depends on the length defined by the VALIDVARIABLE= SAS system option. For additional information, refer to *SAS Language Reference: Dictionary*.

Note that the TYPE= option setting is not case-sensitive. For example, the two option settings, TYPE='MyScore' and TYPE='myscore', are equivalent.

BY Statement

BY variables ;

You can specify a BY statement with PROC SCORE to obtain separate scoring for observations in groups defined by the BY variables. You can also specify a BY statement to apply separate groups of scoring coefficients to the entire DATA= data set.

If your SCORE= input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the SCORE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

If the DATA= data set does not contain any of the BY variables, the entire DATA= data set is scored by each BY group of scoring coefficients in the SCORE= data set.

If the DATA= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the DATA= data set as in the SCORE= data set, then PROC SCORE prints an error message and stops.

If all the BY variables appear in the DATA= data set with the same type and length as in the SCORE= data set, then each BY group in the DATA= data set is scored using scoring coefficients from the corresponding BY group in the SCORE= data set. The BY groups in the DATA= data set must be in the same order as in the SCORE= data set. All BY groups in the DATA= data set must also appear in the SCORE= data set. If you do not specify the NOTSORTED option, some BY groups can appear in the SCORE= data set but not in the DATA= data set; such BY groups are not used in computing scores.

ID Statement

ID *variables* ;

The ID statement identifies variables from the DATA= data set to be included in the OUT= data set. If there is no ID statement, all variables from the DATA= data set are included in the OUT= data set. The ID variables can be character or numeric.

VAR Statement

VAR *variables* ;

The VAR statement specifies the variables to be used in computing scores. These variables must be in both the DATA= and SCORE= input data sets and must be numeric. If you do not specify a VAR statement, the procedure uses all numeric variables in the SCORE= data set. You should almost always specify a VAR statement with PROC SCORE because you would rarely use all the numeric variables in your data set to compute scores.

Details

Missing Values

If one of the scoring variables in the DATA= data set has a missing value for an observation, all the scores have missing values for that observation. The exception to this criterion is if the PREDICT option is specified, the variable with a coefficient of -1 can tolerate a missing value and still produce a prediction score. Also, a variable with a coefficient of 0 can tolerate a missing value.

If a scoring coefficient in the SCORE= data set has a missing value for an observation, the coefficient is not used in creating the new score variable for the observation. In other words, missing values of scoring coefficients are treated as zeros. This treatment affects only the observation in which the missing value occurs.

Regression Parameter Estimates from PROC REG

If the SCORE= data set is an OUTEST= data set produced by PROC REG and if you specify TYPE=PARMS, the interpretation of the new score variables depends on the PROC SCORE options chosen and the variables listed in the VAR statement. If the VAR statement contains only the independent variables used in a model in PROC REG, the new score variables give the predicted values. If the VAR statement contains the dependent variables and the independent variables used in a model in PROC REG, the interpretation of the new score variables depends on the PROC SCORE options chosen. If you omit both the PREDICT and the RESIDUAL options, the new score variables give negative residuals (PREDICT–ACTUAL). If you specify the RESIDUAL option, the new score variables give positive residuals (ACTUAL–PREDICT). If you specify the PREDICT option, the new score variables give predicted values.

Unless you specify the NOINT option for PROC REG, the OUTEST= data set contains the variable Intercept. The SCORE procedure uses the intercept value in computing the scores.

Output Data Set

PROC SCORE produces an output data set but displays no output. The output OUT= data set contains the following:

- the ID variables, if any
- all variables from the DATA= data set, if no ID variables are specified
- the BY variables, if any
- the new score variables, named from the `_NAME_` or `_MODEL_` values in the SCORE= data set

Computational Resources

Let

v = number of variables used in computing scores

s = number of new score variables

b = maximum number of new score variables in a BY group

n = number of observations

Memory

The array storage required is approximately $8(4v + (3 + v)b + s)$ bytes. When you do not use BY processing, the array storage required is approximately $8(4v + (4 + v)s)$ bytes.

Time

The time required to construct the scoring matrix is roughly proportional to vs and the time needed to compute the scores is roughly proportional to nvs .

Examples

The following three examples use a subset of the Fitness data set. The complete data set is given in Chapter 61, “The REG Procedure.”

Example 64.1. Factor Scoring Coefficients

This example shows how to use PROC SCORE with factor scoring coefficients. First, the FACTOR procedure produces an output data set containing scoring coefficients in observations identified by `_TYPE_='SCORE'`. These data, together with the original data set `Fitness`, are supplied to PROC SCORE, resulting in a data set containing scores `Factor1` and `Factor2`. These statements produce [Output 64.1.1](#) through [Output 64.1.3](#):

```

/* This data set contains only the first 12 observations */
/* from the full data set used in the chapter on PROC REG. */

19	SCORE	Factor2	0.7760	-0.0667	0.3744	-0.177	-0.0479

Since the PROC SCORE statement does not contain the NOSTD option, the data in the Fitness data set are standardized before scoring. For each variable specified in the VAR statement, the mean and standard deviation are obtained from the FactOut data set. For each observation in the Fitness data set, the variables are then standardized. For example, for observation 1 in the Fitness data set, the variable Age is standardized to $0.5569 = [(44 - 42.4167)/2.8431]$.

After the data in the Fitness data set are standardized, the standardized values of the variables in the VAR statement are multiplied by the matching coefficients in the FactOut data set, and the resulting products are summed. This sum is output as a value of the new score variable.

Output 64.1.3 displays the FScore data set produced by PROC SCORE. This data set contains the variables Age, Weight, Oxygen, RunTime, RestPulse, and RunPulse from the Fitness data set. It also contains Factor1 and Factor2, the two new score variables.

Output 64.1.3. OUT= Data Set from PROC SCORE Reproduced with PROC PRINT

Example 64.2. Regression Parameter Estimates

In this example, PROC REG computes regression parameter estimates for the Fitness data. (See [Example 64.1](#) to create the Fitness data set.) The parameter estimates are output to a data set and used as scoring coefficients. For the first part of this example, PROC SCORE is used to score the Fitness data, which are the same data used in the regression.

In the second part of this example, PROC SCORE is used to score a new data set, Fitness2. For PROC SCORE, the TYPE= specification is PARMS, and the names of the score variables are found in the variable `_MODEL_`, which gets its values from the model label. The following code produces [Output 64.2.1](#) through [Output 64.2.3](#):

```
proc reg data=Fitness outest=RegOut;
  OxyHat: model Oxygen=Age Weight RunTime RunPulse RestPulse;
  title 'REGRESSION SCORING EXAMPLE';
run;

proc print data=RegOut;
  title2 'OUTEST= Data Set from PROC REG';
run;

proc score data=Fitness score=RegOut out=RScoreP type=parms;
  var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreP;
  title2 'Predicted Scores for Regression';
run;

proc score data=Fitness score=RegOut out=RScoreR type=parms;
```

```

var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreR;
  title2 'Negative Residual Scores for Regression';
run;

```

Output 64.2.1 shows the PROC REG output. The column labeled “Parameter Estimates” lists the parameter estimates. These estimates are output to the RegOut data set.

Output 64.2.1. Creating an OUTEST= Data Set with PROC REG

RestPulse	1	-0.17910	0.13005	-1.38	0.2176

Output 64.2.2 lists the RegOut data set. Notice that `_TYPE_='PARMS'` and `_MODEL_='OXYHAT'`, which are from the label in the MODEL statement in PROC REG.

Output 64.2.2. OUTEST= Data Set from PROC REG Reproduced with PROC PRINT

REGRESSION SCORING EXAMPLE						
OUTEST= Data Set from PROC REG						
Obs	_MODEL_	_TYPE_	_DEPVAR_	_RMSE_	Intercept	Age
1	oxyhat	PARMS	Oxygen	2.53970	151.916	-0.63045
Obs	Weight	RunTime	RunPulse	Rest Pulse	Oxygen	
1	-0.10586	-1.75698	-0.22891	-0.17910	-1	

Output 64.2.3 lists the data sets created by PROC SCORE. Since the SCORE= data set does not contain observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set are not standardized before scoring. The SCORE= data set contains the variable `Intercept`, so this intercept value is used in computing the score. To produce the `RScoreP` data set, the VAR statement in PROC SCORE includes only the independent variables from the model in PROC REG. As a result, the `OxyHat` variable contains predicted values. To produce the `RScoreR` data set, the VAR statement in PROC SCORE includes both the dependent variables and the independent variables from the model in PROC REG. As a result, the `OxyHat` variable contains negative residuals (`PREDICT-ACTUAL`). If the RESIDUAL option is specified, the variable `OxyHat` contains positive residuals (`ACTUAL-PREDICT`). If the PREDICT option is specified, the `OxyHat` variable contains predicted values.

Output 64.2.3. Predicted and Residual Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

The second part of this example uses the parameter estimates to score a new data set. The following code produces [Output 64.2.4](#) and [Output 64.2.5](#):

```

/* The FITNESS2 data set contains observations 13-16 from */
/* the FITNESS data set used in EXAMPLE 2 in the PROC REG */
/* chapter. */
data Fitness2;
  input Age Weight Oxygen RunTime RestPulse RunPulse;
  datalines;
45 66.45 44.754 11.12 51 176
47 79.15 47.273 10.60 47 162
54 83.12 51.855 10.33 50 166
49 81.42 49.156 8.95 44 180
;

proc print data=Fitness2;
  title 'REGRESSION SCORING EXAMPLE';

```

```

    title2 'New Raw Data Set to be Scored';
run;

proc score data=Fitness2 score=RegOut out=NewPred type=parms
    nostd predict;
    var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=NewPred;
    title2 'Predicted Scores for Regression';
    title3 'for Additional Data from FITNESS2';
run;

```

Output 64.2.4 lists the Fitness2 data set.

Output 64.2.4. Listing of the Fitness2 Data Set

REGRESSION SCORING EXAMPLE						
New Raw Data Set to be Scored						
Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse
1	45	66.45	44.754	11.12	51	176
2	47	79.15	47.273	10.60	47	162
3	54	83.12	51.855	10.33	50	166
4	49	81.42	49.156	8.95	44	180

PROC SCORE scores the Fitness2 data set using the parameter estimates in the RegOut data set. These parameter estimates result from fitting a regression equation to the Fitness data set. The NOSTD option is specified, so the raw data are not standardized before scoring. (However, the NOSTD option is not necessary here. The SCORE= data set does not contain observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, so standardization is not performed.) The VAR statement contains the dependent variables and the independent variables used in PROC REG. In addition, the PREDICT option is specified. This combination gives predicted values for the new score variable. The name of the new score variable is `OxyHat`, from the value of the `_MODEL_` variable in the SCORE= data set. Output 64.2.5 shows the data set produced by PROC SCORE.

Output 64.2.5. Predicted Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

REGRESSION SCORING EXAMPLE							
Predicted Scores for Regression							
for Additional Data from FITNESS2							
Obs	Age	Weight	Oxygen	Run Time	Rest Pulse	Run Pulse	oxyhat

2	47	79.15	47.273	10.60	47	162	49.7802
3	54	83.12	51.855	10.33	50	166	43.9682
4	49	81.42	49.156	8.95	44	180	47.5949

Example 64.3. Custom Scoring Coefficients

This example uses a specially created custom scoring data set and produces [Output 64.3.1](#). The first scoring coefficient creates a variable that is Age–Weight; the second scoring coefficient evaluates the variable RunPulse–RstPulse; and the third scoring coefficient totals all six variables. Since the scoring coefficients data set (data set A) does not contain any observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set (see [Example 64.1](#)) are not standardized before scoring.

```

data A;
  input _type_ $ _name_ $

Chapter 65

The SIM2D Procedure

Overview

The SIM2D procedure produces a spatial simulation for a Gaussian random field with a specified mean and covariance structure in two dimensions using an LU decomposition technique.

The simulation can be conditional or unconditional. If it is conditional, a set of coordinates and associated field values are read from a SAS data set. The resulting simulation honors these data values.

You can specify the mean structure as a quadratic in the coordinates. You can specify the covariance by naming the form and supplying the associated parameters.

PROC SIM2D can handle anisotropic and nested semivariogram models. Three covariance models are supported: Gaussian, exponential, and spherical. A single nugget effect is also supported.

You can specify the locations of simulation points in a GRID statement or they can be read from a SAS data set. The grid specification is most suitable for a regular grid; the data set specification can handle any irregular pattern of points.

The SIM2D procedure writes the simulated values for each grid point to an output data set. The SIM2D procedure does not produce any displayed output.

Introduction to Spatial Simulation

The purpose of spatial simulation is to produce a set of partial realizations of a spatial random field (SRF) $Z(\mathbf{s}), \mathbf{s} \in D \subset \mathcal{R}^2$ in a way that preserves a specified mean $\mu(\mathbf{s}) = E[Z(\mathbf{s})]$ and covariance structure $C_z(\mathbf{s}_1 - \mathbf{s}_2) = cov(Z(\mathbf{s}_1), Z(\mathbf{s}_2))$.

The realizations are partial in the sense that they occur only at a finite set of locations $(\mathbf{s}_1, \mathbf{s}_2, \dots, \mathbf{s}_n)$. These locations are typically on a regular grid, but they can be arbitrary locations in the plane.

There are a number of different types of spatial simulation and associated computational methods. PROC SIM2D produces simulations for continuous processes in two dimensions. This means that the possible values of the measured quantity $Z(\mathbf{s}_0)$ at location $\mathbf{s}_0 = (x_0, y_0)$ can vary continuously over a certain range.

An additional assumption, needed for computational purposes, is that the spatial random field $Z(\mathbf{s})$ is Gaussian.

Spatial simulation is different from spatial prediction, where the emphasis is on producing a point estimate at a given grid location. In this sense, spatial prediction is local. In contrast, spatial simulation is global; the emphasis is on the entire realization $(Z(\mathbf{s}_1), Z(\mathbf{s}_2), \dots, Z(\mathbf{s}_n))$.

Given the correct mean $\mu(\mathbf{s})$ and covariance structure $C_z(\mathbf{s}_1 - \mathbf{s}_2)$, SRF quantities that are difficult or impossible to calculate in a spatial prediction context can easily be approximated by repeated simulations.

Getting Started

Spatial simulation, just like spatial prediction, requires a model of spatial dependence, usually in terms of the covariance $C_z(h)$. For a given set of spatial data $Z(\mathbf{s}_i)$, $i = 1, \dots, n$, the covariance structure (both the form and parameter values) can be found by the VARIOGRAM procedure. This example uses the coal seam thickness data that is also used in the “Getting Started” section of Chapter 80, “The VARIOGRAM Procedure.”

Preliminary Spatial Data Analysis

In this example, the data consist of coal seam thickness measurements (in feet) taken over an approximately square area. The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

It is instructive to see the locations of the measured points in the area where you want to perform spatial simulations. It is generally desirable to have these locations scattered evenly around the simulation area.

First, the data are input and the sample locations plotted.

Figure 65.2. Surface Plot of Coal Seam Thickness

Figure 65.2 shows the small scale variation typical of spatial data, but there does not appear to be any surface trend. Hence, you can work with the original thickness data rather than residuals from a trend surface fit. In fact, a reasonable approximation of the spatial process generating the coal seam data is given by

$$Z(\mathbf{s}) = \mu + \varepsilon(\mathbf{s})$$

where the $\varepsilon(\mathbf{s})$ is a Gaussian SRF with Gaussian covariance structure

$$C_z(h) = c_0 \exp\left(-\frac{h^2}{a_0^2}\right)$$

Note that the term “Gaussian” is used in two ways in this description. For a set of locations $\mathbf{s}_1, \mathbf{s}_2, \dots, \mathbf{s}_n$, the random vector

$$\mathbf{Z}(\mathbf{s}) = \begin{bmatrix} Z(\mathbf{s}_1) \\ Z(\mathbf{s}_2) \\ \vdots \\ Z(\mathbf{s}_n) \end{bmatrix}$$

has a multivariate Gaussian or normal distribution $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. The (i,j) th element of $\boldsymbol{\Sigma}$ is computed by $C_z(\mathbf{s}_i - \mathbf{s}_j)$, which happens to be a Gaussian functional form. Any functional form for $C_z(\mathbf{h})$ yielding a valid covariance matrix $\boldsymbol{\Sigma}$ can be used. Both the functional form of $C_z(\mathbf{h})$ and the parameter values

$$\mu = 40.14$$

$$c_0 = 7.5$$

$$a_0 = 30.0$$

are visually estimated using PROC VARIOGRAM, a DATA step, and the GPLOT procedure. Refer to the “Getting Started” section beginning on page 4852 in the chapter on the VARIOGRAM procedure for details on how these parameter values are obtained.

The choice of a Gaussian functional form for $C_z(\mathbf{h})$ is simply based on the data, and it is not at all crucial to the simulation. However, it *is* crucial to the simulation method used in PROC SIM2D that $Z(\mathbf{s})$ be a Gaussian SRF. For details, see the section “Computational and Theoretical Details of Spatial Simulation” beginning on page 4106.

Investigating Variability by Simulation

The variability of $Z(\mathbf{s})$, modeled by

$$Z(\mathbf{s}) = \mu + \varepsilon(\mathbf{s})$$

with the Gaussian covariance structure $C_z(\mathbf{h})$ found previously is not obvious from the covariance model form and parameters. The variation around the mean of the surface is relatively small, making it difficult visually to pick up differences in surface plots of simulated realizations. Instead, you investigate variations at selected grid points.

To do this investigation, this example uses PROC SIM2D and specifies the Gaussian model with the parameters found previously. Five thousand simulations (iterations) are performed on two points: the extreme south-west point of the region and a point towards the north-east corner of the region. Because of the irregular nature of these points, a GDATA= data set is produced with the coordinates of the selected points.

Summary statistics are computed for each of these grid points by using a BY statement in PROC UNIVARIATE.

Figure 65.4. Simulation Statistics at Grid Point (XC=75, YC=75)

Syntax

The following statements are available in PROC SIM2D.

```

PROC SIM2D options ;
COORDINATES coordinate-variables ;
GRID grid-options ;
SIMULATE simulate-options ;
MEAN mean-options ;

```

The SIMULATE and MEAN statements are hierarchical; you can specify any number of SIMULATE statements, but you must specify at least one. If you specify a MEAN statement, it refers to the preceding SIMULATE statement. If you do not specify a MEAN statement, a zero mean model is simulated.

You must specify a single COORDINATES statement to identify the x and y coordinate variables in the input data set when you perform a conditional simulation. You must also specify a single GRID statement to specify the grid information.

The following table outlines the options available in PROC SIM2D classified by function.

Table 65.1. Options Available in the SIM2D Procedure

Task	Statement	Option
Data Set Options		
specify input data set	PROC SIM2D	DATA=
specify grid data set	GRID	GDATA=

specify nested angles	SIMULATE	ANGLE=(a_1, \dots, a_k)
specify a minor-major axis ratio for an anisotropic model	SIMULATE	RATIO=
specify nested minor-major axis ratios	SIMULATE	RATIO=(ra_1, \dots, ra_k)

PROC SIM2D Statement

PROC SIM2D *options* ;

You can specify the following options with the PROC SIM2D statement.

DATA=SAS-*data-set*

specifies a SAS data set containing the x and y coordinate variables and the SIMULATE VAR= variables. This data set is required if any of the SIMULATE statements are conditional, that is, if you specify the VAR= option. If none of the SIMULATE statements are conditional then you do not need the DATA= option, and this option is ignored if you specify it.

NARROW

restricts the variables included in the OUTSIM= data set. When you specify the NARROW option, only four variables are included. This option is useful when a large number of simulations are produced. Including only four variables reduces the memory required for the OUTSIM= data set. For details on the variables that are excluded with the NARROW option, see the section “[Output Data Set](#)” on page 4110.

OUTSIM=SAS-*data-set*

specifies a SAS data set to store the simulation values, iteration number, simulate statement label, variable name, and grid location. For details, see the section “[Output Data Set](#)” on page 4110.

COORDINATES Statement

COORDINATES *coordinate-variables* ;

The following two options give the name of the variables in the DATA= data set containing the values of the x and y coordinates of the conditioning data.

Only one COORDINATES statement is allowed, and it is applied to all SIMULATE statements that have a VAR= specification. In other words, it is assumed that all the VAR= variables in all SIMULATE statements have the same x and y coordinates.

You can abbreviate the COORDINATES statement as COORD.

XCOORD=(*variable-name*)

XC=(*variable-name*)

gives the name of the variable containing the x coordinate of the data in the DATA= data set.

YCOORD=(*variable-name*)

YC=(*variable-name*)

gives the name of the variable containing the y coordinate of the data locations in the DATA= data set.

GRID Statement

GRID *grid-options* ;

The following options can be used to specify the grid of spatial locations at which to perform the simulations. A single GRID statement is required and is applied to all SIMULATE statements.

There are two basic methods for specifying the grid. You can specify the x and y coordinates explicitly, or they can be read from a SAS data set. The options for the explicit specification of grid locations are as follows.

X=*number*

X= x_1, \dots, x_m

X= x_1 to x_m

X= x_1 to x_m by δx

specifies the x coordinate of the grid locations.

Y=*number*

Y= y_1, \dots, y_m

Y= y_1 to y_m

Y= y_1 to y_m by δy

specifies the y coordinate of the grid locations.

For example, the following two GRID statements are equivalent:

```
grid x=1,2,3,4,5 y=0,2,4,6,8,10;
grid x=1 to 5 y=0 to 10 by 2;
```

To specify grid locations from a SAS data set, you must provide the name of the data set and the variables containing the values of the x and y coordinates.

GRIDDATA=SAS-*data-set*

GDATA=SAS-*data-set*

specifies a SAS data set containing the x and y grid coordinates.

XCOORD=(*variable-name*)

XC=(*variable-name*)

gives the name of the variable containing the x coordinate of the grid locations in the GRIDDATA= data set.

YCOORD=(*variable-name*)

YC=(*variable-name*)

gives the name of the variable containing the y coordinate of the grid locations in the GRIDDATA= data set.

SIMULATE Statement

SIMULATE *simulate-options* ;

The SIMULATE statement specifies details on the simulation and the covariance model used in the simulation. You can specify the following options with a SIMULATE statement, which can be abbreviated by SIM.

NUMREAL=*number*

NUMR=*number*

NR=*number*

specifies the number of realizations to produce for the spatial process specified by the covariance model. Note that the number of observations in the OUTSIM= data set contributed by a given SIMULATE statement is the product of the NUMREAL= value with the number of grid points. This can cause the OUTSIM= data set to become large even for moderate values of the NUMREAL= option.

VAR= (*variable-name*)

specifies the single numeric variable used as the conditioning variable in the simulation. In other words, the simulation is conditional on the values of the VAR= variable found in the DATA= data set. If you omit the VAR= option, the simulation is *unconditional*. Since multiple SIMULATE statements are allowed, you can perform both unconditional and conditional simulations with a single PROC SIM2D statement.

Covariance Model Specification

There are two ways to specify a semivariogram or covariance model. In the first method, you can specify the required parameters SCALE, RANGE, and FORM, and possibly the optional parameters NUGGET, ANGLE, and RATIO, explicitly in the SIMULATE statement.

In the second method, you can specify an MDATA= data set. This data set contains variables corresponding to the required SCALE, RANGE, and FORM parameters, and, optionally, variables for the NUGGET, ANGLE, and RATIO parameters.

The two methods are exclusive; either you specify all parameters explicitly, or they are all read from the MDATA= data set.

ANGLE=*angle*

ANGLE=(*angle*₁, . . . , *angle*_{*k*})

specifies the angle of the major axis for anisotropic models, measured in degrees clockwise from the N-S axis. In the case of a nested semivariogram model, you can specify an angle for each nesting. The default is ANGLE=0.

FORM=*form_spec*

FORM=(*form_spec*₁, *form_spec*₂, . . . , *form_spec*_{*k*})

specifies the functional form or forms of the semivariogram model, where *form_spec* can take only the values SPHERICAL, EXPONENTIAL, and GAUSSIAN. The two ways of specifying the FORM= parameter allows specification of both nested and nonnested models. The following abbreviations are permitted. For the spherical model, you can specify the *form_spec* as FORM=SPHERICAL, FORM=SPH, or FORM=S. For the exponential model, you can specify the *form_spec* as FORM=EXPONENTIAL, FORM=EXP, or FORM=E. For the Gaussian model, you can specify the *form_spec* as FORM=GAUSSIAN, FORM=GAUSS, or FORM=G.

MDATA=*SAS-data-set*

specifies the input data set that contains parameter values for the covariance or semivariogram model. The MDATA= data set must contain variables named SCALE, RANGE, and FORM, and it can optionally contain the variables NUGGET, ANGLE, and RATIO.

The FORM variables must be character, and they can assume the same values allowed in the explicit FORM= syntax described previously. The RANGE and SCALE variables must be numeric. The optional variables ANGLE, RATIO, and NUGGET must also be numeric if present.

The number of observations present in the MDATA= data set corresponds to the level of nesting of the covariance or semivariogram model. For example, to specify a non-nested model using a spherical covariance, an MDATA= data set might look like the following.

```
data mdl;
  input scale range form $;
  datalines;
  25 10 sph
run;
```

The PROC SIM2D statement to use the MDATA= specification is of the form

```
proc sim2d data=...;
  sim var=.... mdata=mdl;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc sim2d data=...;
  sim var=.... scale=25 range=10 form=sph;
run;
```

The following MDATA= data set is an example of an anisotropic nested model:

```
data md2;
  input scale range form $ nugget angle ratio;
  datalines;
  20 8 S 5 35 .7
  12 3 G 5 0 .8
  4 1 G 5 45 .5
  ;

proc sim2d data=...;
  sim var=.... mdata=md2;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc sim2d data=...;
  sim var=.... scale=(20,12,4) range=(8,3,1) form=(S,G,G)
  angle=(35,0,45) ratio=(.7,.8,.5) nugget=5;
run;
```

This example is somewhat artificial in that it is usually hard to detect different anisotropy directions and ratios for different nestings using an experimental semi-variogram. Note that the NUGGET value is the same for all nestings. This is always the case; the nugget effect is a single additive term for all models. For further details, refer to the section “The Nugget Effect” on page 2051 in [Chapter 37](#), “The KRIGE2D Procedure.”

The SIMULATE statement can be given a label. This is useful for identification in the OUTSIM= data set when multiple SIMULATE statements are specified.

For example,

```
proc sim2d data=...;
  gauss1: sim var=.... form=gauss;
  mean ....;
  gauss2: sim var=.... form=gauss;
  mean ....;
  exp1: sim var=.... form=exp;
  mean ....;
  exp2: sim var=.... form=exp;
  mean ....;
run;
```

In the OUTSIM= data set, the values 'GAUSS1', 'GAUSS2', 'EXP1', and 'EXP2' for the LABEL variable help to identify the realizations corresponding to the four SIMULATE statements. If you do not provide a label for a SIMULATE statement, a default label of SIM n is given, where n is the number of unlabeled SIMULATE statements seen so far.

NUGGET=number

specifies the nugget effect for the model. This effect is due to a discontinuity in the semivariogram as determined by plotting the sample semivariogram (refer to the section “[The Nugget Effect](#)” on page 2051 in the chapter on the KRIGE2D procedure for details). For models without any nugget effect, the NUGGET= option is left out. The default is NUGGET=0.

RANGE=range**RANGE=(range₁, . . . , range_k)**

specifies the range parameter in the semivariogram models. In the case of a nested semivariogram model, you must specify a range for each nesting.

The range parameter is the divisor in the exponent in all supported models. It has the units of distance or distance squared for these models, and it is related to the correlation scale for the underlying spatial process. Refer to the section “[Theoretical Semivariogram Models](#)” beginning on page 2045 in the chapter on the KRIGE2D procedure for details on how the RANGE= values are determined.

RATIO=ratio**RATIO=(ratio₁, . . . , ratio_k)**

specifies the ratio of the length of the minor axis to the length of the major axis for anisotropic models. The value of the RATIO= option must be between 0 and 1. In the case of a nested semivariogram model, you can specify a ratio for each nesting. The default is RATIO=1.

SCALE=scale**SCALE=(scale₁, . . . , scale_k)**

specifies the scale parameter in semivariogram models. In the case of a nested semivariogram model, you must specify a scale for each nesting.

The scale parameter is the multiplicative factor in all supported models; it has the same units as the variance of the VAR= variable. Refer to the section “[Theoretical Semivariogram Models](#)” beginning on page 2045 in the chapter on the KRIGE2D procedure for details on how the SCALE= values are determined.

SEED=seed value

specifies the seed to use for the random number generator. If you omit the SEED= value, the system clock is used.

SINGULAR=number

gives the singularity criteria for solving the set of linear equations involved in the computation of the mean and covariance of the conditional distribution associated with a given SIMULATE statement. The larger the value of the SINGULAR= option, the easier it is for the covariance matrix system to be declared singular. The default is SINGULAR=1E-8. For more details on the use of the SINGULAR= option, see the section “[Computational and Theoretical Details of Spatial Simulation](#)” beginning on page 4106.

MEAN Statement

MEAN *spec*₁,...,*spec*₆ ;

MEAN QDATA=*SAS-data-set* *CONST*=*var*₁ *CX*=*var*₂ *CY*=*var*₃

CXX=*var*₄ *CYY*=*var*₅ *CXY*=*var*₆ ;

MEAN QDATA=*SAS-data-set* ;

A mean function $\mu(s)$ that is a quadratic in the coordinates can be written

$$\mu(s) = \mu(x, y) = \beta_0 + \beta_1x + \beta_2y + \beta_3x^2 + \beta_4y^2 + \beta_5xy$$

The MEAN statement is used to specify the quadratic surface to use as the mean function for the simulated SRF. There are three ways to specify the MEAN statement. The MEAN statement allows the specification of the coefficients β_0, \dots, β_5 either explicitly or through a QDATA= data set.

An example of an explicit specification is

```
mean 1.4 + 2.5*x + 3.6*y + .47*x*x + .58*y*y + .69*x*y;
```

In this example, all terms have a nonzero coefficient. Any term with a zero coefficient is simply left out of the specification. For example,

```
mean 1.4;
```

is a valid quadratic form with all terms having zero coefficients except the constant term.

An equivalent way of specifying the mean function is through the QDATA= data set. For example, the following MEAN statement

```
mean 1.4 + 2.5*x + 3.6*y + .47*x*x + .58*y*y + .69*x*y;
```

can be alternatively specified by the following DATA step and MEAN statement:

```
data q1;
  input c1 c2 c3 c4 c5 c6;
  datalines;
  1.4 2.5 3.6 .47 .58 .69
run;
proc sim2d data=....;
  simulate ...;
  mean qdata=q1 const=c1 cx=c2 cy=c3 cxx=c4
    cyy=c5 cxy=c6;
run;
```

The QDATA= data set specifies the data set containing the coefficients. The parameters CONST=, CX=, CY=, CXX=, CYY=, and CYX= specify the variables in the QDATA= data set that correspond to the constant, linear x, linear y, and so on. For any coefficient not specified in this list, the QDATA= data set is checked for the presence of variables with default names of CONST, CX, CY, CXX, CYY, and CYX. If these variables are present, their values are taken as the corresponding coefficients. Hence, you can rewrite the previous example as

```
data q1;
  input const cx cy cxx cyy cxy;
  datalines;
  1.4 2.5 3.6 .47 .58 .69
  ;
proc sim2d data=....;
  simulate ...;
  mean qdata=q1;
run;
```

If a given coefficient does not appear in the list or in the data set with the default name, a value of zero is assumed.

Details

Computational and Theoretical Details of Spatial Simulation

Introduction

There are a number of approaches to simulating spatial random fields or, more generally, simulating sets of dependent random variables. This includes sequential indicator methods, turning bands, and the Karhunen-Loeve Expansion. Refer to Christakos (1992, Chapter 8) and Duetsch and Journel (1992, Chapter V) for details.

A particularly simple method available for Gaussian spatial random fields is the LU decomposition method. This method is computationally efficient. For a given covariance matrix, the $LU = \mathbf{L}\mathbf{L}^T$ decomposition is computed once, and the simulation proceeds by repeatedly generating a vector of independent $N(0, 1)$ random variables and multiplying by the \mathbf{L} matrix.

One problem with this technique is memory requirements; memory is required to hold the full data and grid covariance matrix in core. While this is especially limiting in the three-dimensional case, you can use PROC SIM2D, which handles only two-dimensional data, for moderately sized simulation problems.

Theoretical Development

It is a simple matter to produce an $N(0, 1)$ random number, and by stacking k $N(0, 1)$ random numbers in a column vector, you can obtain a vector with independent standard normal components $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$. The meaning of the terms *independence* and *randomness* in the context of a deterministic algorithm required for the generation of these numbers is a little subtle; refer to Knuth (1981, Vol. 2, Chapter 3) for details.

Rather than $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$, what is required is the generation of a vector $\mathbf{Z} \sim N_k(\mathbf{0}, \mathbf{C})$, that is,

$$\mathbf{Z} = \begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_k \end{bmatrix}$$

with covariance matrix

$$\mathbf{C} = \begin{pmatrix} C_{11} & C_{12} & \cdots & C_{1k} \\ C_{21} & C_{22} & \cdots & C_{2k} \\ & & \ddots & \\ C_{k1} & C_{k2} & \cdots & C_{kk} \end{pmatrix}$$

If the covariance matrix is symmetric and positive definite, it has a Cholesky root \mathbf{L} such that \mathbf{C} can be factored as

$$\mathbf{C} = \mathbf{L}\mathbf{L}^T$$

where \mathbf{L} is lower triangular. Refer to Ralston and Rabinowitz (1978, Chapter 9, Section 3-3) for details. This vector \mathbf{Z} can be generated by the transformation $\mathbf{Z} = \mathbf{L}\mathbf{W}$. Note that this is where the assumption of a Gaussian SRF is crucial. When $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$, then $\mathbf{Z} = \mathbf{L}\mathbf{W}$ is also Gaussian. The mean of \mathbf{Z} is

$$E(\mathbf{Z}) = \mathbf{L}(E(\mathbf{W})) = \mathbf{0}$$

and the variance is

$$\text{Var}(\mathbf{Z}) = \text{Var}(\mathbf{L}\mathbf{W}) = E(\mathbf{L}\mathbf{W}\mathbf{W}^T\mathbf{L}^T) = \mathbf{L}E(\mathbf{W}\mathbf{W}^T)\mathbf{L}^T = \mathbf{L}\mathbf{L}^T = \mathbf{C}$$

Consider now an SRF $Z(\mathbf{s}), \mathbf{s} \in D \subset \mathcal{R}^2$, with spatial covariance function $C(\mathbf{h})$. Fix locations $\mathbf{s}_1, \mathbf{s}_2, \dots, \mathbf{s}_k$, and let \mathbf{Z} denote the random vector

$$\mathbf{Z} = \begin{bmatrix} Z(\mathbf{s}_1) \\ Z(\mathbf{s}_2) \\ \vdots \\ Z(\mathbf{s}_k) \end{bmatrix}$$

with corresponding covariance matrix

$$\mathbf{C}_z = \begin{pmatrix} C(\mathbf{0}) & C(\mathbf{s}_1 - \mathbf{s}_2) & \cdots & C(\mathbf{s}_1 - \mathbf{s}_k) \\ C(\mathbf{s}_2 - \mathbf{s}_1) & C(\mathbf{0}) & \cdots & C(\mathbf{s}_2 - \mathbf{s}_k) \\ & & \ddots & \\ C(\mathbf{s}_k - \mathbf{s}_1) & C(\mathbf{s}_k - \mathbf{s}_2) & \cdots & C(\mathbf{0}) \end{pmatrix}$$

Since this covariance matrix is symmetric and positive definite, it has a Cholesky root, and the $Z(\mathbf{s}_i), i = 1, \dots, k$ can be simulated as described previously. This is how the SIM2D procedure implements unconditional simulation in the zero mean case. More generally,

$$Z(\mathbf{s}) = \mu(\mathbf{s}) + \varepsilon(\mathbf{s})$$

with $\mu(\mathbf{s})$ being a quadratic form in the coordinates $\mathbf{s} = (x, y)$, and the $\varepsilon(\mathbf{s})$ being an SRF having the same covariance matrix \mathbf{C}_z as previously. In this case, the $\mu(\mathbf{s}_i), i = 1, \dots, k$ is computed once and added to the simulated vector $\varepsilon(\mathbf{s}_i), i = 1, \dots, k$ for each realization.

For a conditional simulation, this distribution of

$$\mathbf{Z} = \begin{bmatrix} Z(\mathbf{s}_1) \\ Z(\mathbf{s}_2) \\ \vdots \\ Z(\mathbf{s}_k) \end{bmatrix}$$

must be conditioned on the observed data. The relevant general result concerning conditional distributions of multivariate normal random variables is the following. Let $\mathbf{X} \sim N_m(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, where

$$\mathbf{X} = \begin{bmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \end{bmatrix}$$

$$\boldsymbol{\mu} = \begin{bmatrix} \boldsymbol{\mu}_1 \\ \boldsymbol{\mu}_2 \end{bmatrix}$$

and

$$\boldsymbol{\Sigma} = \begin{pmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{pmatrix}$$

The subvector \mathbf{X}_1 is $k \times 1$, \mathbf{X}_2 is $n \times 1$, $\boldsymbol{\Sigma}_{11}$ is $k \times k$, $\boldsymbol{\Sigma}_{22}$ is $n \times n$, and $\boldsymbol{\Sigma}_{12} = \boldsymbol{\Sigma}_{21}^T$ is $k \times n$, with $k + n = m$. The full vector \mathbf{X} is partitioned into two subvectors \mathbf{X}_1 and \mathbf{X}_2 , and $\boldsymbol{\Sigma}$ is similarly partitioned into covariances and cross covariances.

With this notation, the distribution of \mathbf{X}_1 conditioned on $\mathbf{X}_2 = \mathbf{x}_2$ is $N_k(\tilde{\boldsymbol{\mu}}, \tilde{\boldsymbol{\Sigma}})$, with

$$\tilde{\boldsymbol{\mu}} = \boldsymbol{\mu}_1 + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}(\mathbf{x}_2 - \boldsymbol{\mu}_2)$$

and

$$\tilde{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$$

Refer to Searle (1971, pp. 46–47) for details. The correspondence with the conditional spatial simulation problem is as follows. Let the coordinates of the observed data points be denoted $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$, with values $\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_n$. Let $\tilde{\mathbf{Z}}$ denote the random vector

$$\tilde{\mathbf{Z}} = \begin{bmatrix} Z(\tilde{s}_1) \\ Z(\tilde{s}_2) \\ \vdots \\ Z(\tilde{s}_n) \end{bmatrix}$$

The random vector $\tilde{\mathbf{Z}}$ corresponds to \mathbf{X}_2 , while \mathbf{Z} corresponds to \mathbf{X}_1 . Then $(\mathbf{Z} | \tilde{\mathbf{Z}} = \tilde{\mathbf{z}}) \sim N_k(\tilde{\boldsymbol{\mu}}, \tilde{\mathbf{C}})$ as in the previous distribution. The matrix

$$\tilde{\mathbf{C}} = \mathbf{C}_{11} - \mathbf{C}_{12}\mathbf{C}_{22}^{-1}\mathbf{C}_{21}$$

is again positive definite, so a Cholesky factorization can be performed.

The dimension n for $\tilde{\mathbf{Z}}$ is simply the number of nonmissing observations for the VAR= variable; the values $\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_n$ are the values of this variable. The coordinates $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$ are also found in the DATA= data set, with the variables corresponding to the x and y coordinates identified in the COORDINATES statement. Note that all VAR= variables use the same set of conditioning coordinates; this fixes the matrix \mathbf{C}_{22} for all simulations.

The dimension k for \mathbf{Z} is the number of grid points specified in the GRID statement. Since there is a single GRID statement, this fixes the matrix \mathbf{C}_{11} for all simulations. Similarly, \mathbf{C}_{12} is fixed.

The Cholesky factorization $\tilde{\mathbf{C}} = \mathbf{L}\mathbf{L}^T$ is computed once, as is the mean correction

$$\tilde{\boldsymbol{\mu}} = \boldsymbol{\mu}_1 + \mathbf{C}_{12}\mathbf{C}_{22}^{-1}(\mathbf{x}_2 - \boldsymbol{\mu}_2)$$

Note that the means $\boldsymbol{\mu}_1$ and $\boldsymbol{\mu}_2$ are computed using the grid coordinates $\mathbf{s}_1, \mathbf{s}_2, \dots, \mathbf{s}_k$, the data coordinates $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$, and the quadratic form specification from the MEAN statement. The simulation is now performed exactly as in the unconditional case. A $k \times 1$ vector of independent standard $N(0, 1)$ random variables is generated and multiplied by \mathbf{L} , and $\tilde{\boldsymbol{\mu}}$ is added to the transformed vector. This is repeated N times, where N is the value specified for the NR= option.

Computational Details

In the computation of $\tilde{\boldsymbol{\mu}}$ and $\boldsymbol{\Sigma}$ described in the previous section, the inverse $\boldsymbol{\Sigma}_{22}^{-1}$ is never actually computed; an equation of the form

$$\boldsymbol{\Sigma}_{22}\mathbf{A} = \mathbf{B}$$

is solved for \mathbf{A} using a modified Gaussian elimination algorithm that takes advantage of the fact that $\boldsymbol{\Sigma}_{22}$ is symmetric with constant diagonal $C_z(0)$ that is larger than all off-diagonal elements. The SINGULAR= option pertains to this algorithm. The value specified for the SINGULAR= option is scaled by $C_z(0)$ before comparison with the pivot element.

Memory Usage

For conditional simulations, the largest matrix held in core at any one time depends on the number of grid points and data points. Using the previous notation, the data-data covariance matrix C_{22} is $n \times n$, where n is the number of nonmissing observations for the VAR= variable in the DATA= data set. The grid-data cross covariance C_{12} is $n \times k$, where k is the number of grid points. The grid-grid covariance C_{11} is $k \times k$. The maximum memory required at any one time for storing these matrices is

$$\max(k(k+1), n(n+1) + 2(n \times k)) \times \text{sizeof}(\text{double})$$

There are additional memory requirements that add to the total memory usage, but usually these matrix calculations dominate, especially when the number of grid points is large.

Output Data Set

The SIM2D procedure produces a single output data set: the OUTSIM=*SAS-data-set*. The OUTSIM= data set contains all the needed information to uniquely identify the simulated values.

The OUTSIM= data set contains the following variables:

- LABEL, which is the label for the current SIMULATE statement
- VARNAME, which is the name of the conditioning variable for the current SIMULATE statement
- _ITER_, which is the iteration number within the current SIMULATE statement
- GXC, which is the x-coordinate for the current grid point
- GYC, which is the y-coordinate for the current grid point
- SVALUE, which is the value of the simulated variable

If you specify the NARROW option in the PROC SIM2D statement, the LABEL and VARNAME variables are not included in the OUTSIM= data set. This option is useful in the case where the number of data points, grid points, and realizations are such that they generate a very large OUTSIM= data set. The size of the OUTSIM= data set is reduced when these variables are not included.

In the case of an unconditional simulation, the VARNAME variable is not included. In the case of mixed conditional and unconditional simulations (that is, when multiple SIMULATE statements are specified and one or more contain a VAR= specification and one or more do *not* contain a VAR= specification), the VARNAME variable is included but is given a missing value for those observations corresponding to an unconditional simulation.

Example

Example 65.1. Simulation

Continuing with the coal seam thickness example from the “Getting Started” section beginning on page 4092, this example asks a more complicated question. This question is economic in nature, and the (approximate) answer requires the use of simulation.

Simulating a Subregion for Economic Feasibility

The coal seam must be of a minimum thickness, called a *cutoff value*, for a mining operation to be profitable. Suppose that, for a subregion of the measured area, the cost of mining is higher than the remaining areas due to the geology of the overburden. This higher cost results in a higher thickness cutoff value for the subregion. Suppose also that it is determined from a detailed cost analysis that at least 60 percent of the subregion must exceed a seam thickness of 39.7 feet for profitability.

How can you use the SRF model (μ and $C_z(\mathbf{s})$) and the measured seam thickness values $Z(\mathbf{s}_i)$, $i = 1, \dots, 75$ to determine, in some approximate way, if at least 60 percent of the subregion exceeds this minimum?

Spatial prediction does not appear to be helpful in answering this question. While it is easy to determine if a predicted value at a location in the subregion is above the 39.7 feet cutoff value, it is not clear how to incorporate the standard error associated with the predicted value. The standard error is what characterizes the stochastic nature of the prediction (and the underlying SRF). It is clear that it must be included in any realistic approach to the problem.

A conditional simulation, on the other hand, seems to be a natural way of obtaining an approximate answer. By simulating the SRF on a sufficiently fine grid in the subregion, you can determine the proportion of grid points in which the mean value over realizations exceeds the 39.7 feet cutoff and compare it with the 60 percent value needed for profitability.

It is desirable in any simulation study that the quantity being estimated (in this case, the proportion exceeding the 39.7 feet cutoff) not depend on the number of simulations performed. For example, suppose that the maximum seam thickness is simulated. It is likely that the maximum value increases as the number of simulations performed increases. Hence, a simulation is not useful for such an estimate. A simulation is useful for determining the *distribution* of the maximum, but there are general theoretical results for such distributions, making such a simulation unnecessary. Refer to Leadbetter, Lindgren, and Rootzen (1983) for details.

In the case of simulating the proportion exceeding the 39.7 feet cutoff, it is expected that this quantity will settle down to a fixed value as the number of realizations increases. At a fixed grid point, the quantity being compared with the cutoff value is the mean over all simulated realizations; this mean value settles down to a fixed number as the number of realizations increases. In the same manner, the proportion of the grid where the mean values exceed the cutoff also becomes constant. This can be tested using PROC SIM2D.

A crucial, nonprovable assumption in applying SRF theory to the coal seam thickness data is that the values $Z(\mathbf{s}_i)$, $i = 1, \dots, 75$ represent a *single* realization from the set of all possible realizations consistent with the SRF model (μ and $C_z(\mathbf{h})$). A conditional simulation repeatedly produces other possible simulated realizations consistent with the model and data. However, the only concern of the mining company is with this single unique realization. It is not concerned with similar coal fields to be mined sometime in the future; it may never see another coal field remotely similar to this one, or it may not be in business in the future.

Hence the proportion found by generating repeated simulated realizations must somehow relate back to the unique realization that is the coal field (seam thickness). This is done by interpreting the proportion found from a simulation to the spatial mean proportion for the unique realization. The term “spatial mean” is simply an appropriate integral over the fixed (but unknown) spatial function $z(\mathbf{s})$. (The SRF is denoted $Z(\mathbf{s})$; a particular realization, a deterministic function of the spatial coordinates, is denoted $z(\mathbf{s})$.)

This interpretation requires an ergodic assumption, which is also needed in the original estimation of $C_z(\mathbf{s})$. Refer to Cressie (1993, pp. 53–58) for a discussion of ergodicity and Gaussian SRFs.

Implementation Using PROC SIM2D

The subregion to be considered is the southeast corner of the field, which is a square region with length 40 distance units (in thousands of feet). PROC SIM2D is run on the entire data set for conditioning, while the simulation grid covers only this subregion. It is convenient to be able to vary the seed, the grid increment, and the number of simulations performed. The following macro implements the computation of the percent area exceeding the cutoff value by using the seed, the grid increment, and the number of simulated realizations as macro arguments.

The data set produced by PROC SIM2D is transposed so that each grid location is a separate variable. The MEANS procedure is then used to average the simulated value at each grid point over all realizations. It is this average that is compared to the cutoff value. The last DATA step does the comparison and determines the percent of the grid locations that exceed this cutoff value and writes the results to the listing file in the form of a report.

The macro is first invoked with a relatively coarse grid (grid increment of 10 distance units) and a small number of realizations (5). The next invocation uses a finer grid and 50 realizations, and the final invocation uses the same grid increment and 500 realizations. Each time, the macro is invoked with a different seed. The simulations indicate that around 87 percent of the subregion exceeds the cutoff value.

The number of grid points in the simulation increases with the square of the decrease in the grid increment, leading to long CPU processing times. Increasing the number of realizations results in a linear increase in processing times. Hence, using as coarse a grid as possible allows more realizations and experimentation with different seeds.

Chapter 66

The STDIZE Procedure

Overview

The STDIZE procedure standardizes one or more numeric variables in a SAS data set by subtracting a location measure and dividing by a scale measure. A variety of location and scale measures are provided, including estimates that are resistant to outliers and clustering. Some of the well-known standardization methods such as mean, median, std, range, Huber's estimate, Tukey's biweight estimate, and Andrew's wave estimate are available in the STDIZE procedure.

In addition, you can multiply each standardized value by a constant and add a constant. Thus, the final output value is

$$result = add + multiply \times \frac{original - location}{scale}$$

where

<i>result</i>	= final output value
<i>add</i>	= constant to add (ADD= option)
<i>multiply</i>	= constant to multiply by (MULT= option)
<i>original</i>	= original input value
<i>location</i>	= location measure
<i>scale</i>	= scale measure

PROC STDIZE can also find quantiles in one pass of the data, a capability that is especially useful for very large data sets. With such data sets, the UNIVARIATE procedure may have high or excessive memory or time requirements.

Getting Started

The following example demonstrates how you can use the STDIZE procedure to obtain location and scale measures of your data.

In the following hypothetical data set, a random sample of grade 12 students is selected from a number of co-educational schools. Each school is classified as one of two types: Urban or Rural. There are 40 observations.

The variables are *id* (student identification), *Type* (type of school attended: 'urban'=urban area and 'rural'=rural area), and *total* (total assessment scores in History, Geometry, and Chemistry).

The following DATA step creates the SAS data set *TotalScores*.

```
data TotalScores;
  title 'High School Scores Data';
  input id Type $ total;
  datalines;
  1      rural      135
  2      rural      125
  3      rural      223
  4      rural      224
  5      rural      133
  6      rural      253
  7      rural      144
  8      rural      193
  9      rural      152
  10     rural      178
  11     rural      120
  12     rural      180
  13     rural      154
  14     rural      184
  15     rural      187
  16     rural      111
  17     rural      190
  18     rural      128
  19     rural      110
  20     rural      217
  21     urban      192
  22     urban      186
  23     urban       64
  24     urban      159
  25     urban      133
  26     urban      163
  27     urban      130
  28     urban      163
  29     urban      189
  30     urban      144
  31     urban      154
  32     urban      198
  33     urban      150
  34     urban      151
  35     urban      152
  36     urban      151
  37     urban      127
  38     urban      167
  39     urban      170
  40     urban      123
  ;
run;
```

Suppose you would now like to standardize the total scores in different types of schools prior to any further analysis. Before standardizing the total scores, you can use the Schematic Plots from PROC UNIVARIATE to summarize the total scores for both types of schools.

```
proc univariate data=TotalScores plot;  
  var total;  
  by Type;  
run;
```

The PLOT option in the PROC UNIVARIATE statement creates the Schematic Plots and several other types of plots. The Schematic Plots display side-by-side box plots for each BY group ([Figure 66.1](#)). The vertical axis represents the total scores, and the horizontal axis displays two box plots: the one on the left is for the rural scores and the one on the right is for the urban scores.

Figure 66.1. Schematic Plots from PROC UNIVARIATE

Inspection reveals that one urban score is a low outlier. Also, if you compare the lengths of two boxplots, there seems to be twice as much dispersion for the rural scores as for the urban scores.

High School Scores Data			
----- Type=urban -----			
The UNIVARIATE Procedure			
Variable: total			
Extreme Observations			
----Lowest----		----Highest---	
Value	Obs	Value	Obs
64	23	170	39
123	40	186	22
127	37	189	29
130	27	192	21
133	25	198	32

Figure 66.2. Table for Extreme Observations When Type=urban

Figure 66.2 displays the table from PROC UNIVARIATE for the lowest and highest five total scores for urban schools. The outlier (Obs = 3), marked in Figure 66.1 by the symbol '0', has a score of 64.

The following statements use the traditional standardization method (METHOD=STD) to compute the location and scale measures:

```
proc stdize data=totalscores method=std pstat;
  title2 'METHOD=STD';
  var total;
  by Type;
run;
```

```

High School Scores Data
METHOD=STD
----- Type=rural -----

The STDIZE Procedure

Location and Scale Measures

Location = mean      Scale = standard deviation

Name      Location      Scale      N
total     167.050000     41.956713     20

High School Scores Data
METHOD=STD
----- Type=urban -----

The STDIZE Procedure

Location and Scale Measures

Location = mean      Scale = standard deviation

Name      Location      Scale      N
total     153.300000     30.066768     20

```

Figure 66.3. Location and Scale Measures Table When METHOD=STD

Figure 66.3 displays the table of location and scale measures from the PROC STDIZE statement. PROC STDIZE uses the mean as the location measure and the standard deviation as the scale measure for standardizing. The PSTAT option displays this table; otherwise, no display is created.

The ratio of the scale of rural scores to the scale of urban scores is approximately 1.4 (41.96/30.07). This ratio is smaller than the dispersion ratio observed in the previous Schematic Plots.

The STDIZE procedure provides several location and scale measures that are resistant to outliers. The following statements invoke three different standardization methods and display the Location and Scale Measures tables:

```

proc stdize data=totalscores method=mad pstat;
  title2 'METHOD=MAD';
  var total;
  by Type;
run;

```

```

proc stdize data=totalscores method=iqr pstat;
  title2 'METHOD=IQR';
  var total;
  by Type;
run;

proc stdize data=totalscores method=abw(4) pstat;
  title2 'METHOD=ABW(4)';
  var total;
  by Type;
run;

```

The results from this analysis are displayed in the following figures.

High School Scores Data METHOD=MAD			
----- Type=rural -----			
The STDIZE Procedure			
Location and Scale Measures			
Location = median		Scale = median abs dev from median	
Name	Location	Scale	N
total	166.000000	32.000000	20
High School Scores Data METHOD=MAD			
----- Type=urban -----			
The STDIZE Procedure			
Location and Scale Measures			
Location = median		Scale = median abs dev from median	
Name	Location	Scale	N
total	153.000000	15.500000	20

Figure 66.4. Location and Scale Measures Table When METHOD=MAD

Figure 66.4 displays the table of location and scale measures when the standardization method is MAD. The location measure is the median, and the scale measure is the median absolute deviation from median. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5) and is close to the dispersion ratio observed in the previous Schematic Plots.

```

High School Scores Data
METHOD=IQR
----- Type=rural -----

The STDIZE Procedure

Location and Scale Measures

Location = median      Scale = interquartile range

Name      Location      Scale      N

METHOD=ABW(4)
----- Type=urban -----

The STDIZE Procedure

Location and Scale Measures

Location = biweight 1-step M-estimate      Scale = biweight A-estimate

Name          Location          Scale          N
total         156.014608          28.615980          20

```

Figure 66.6. Location and Scale Measures Table When METHOD=ABW

Figure 66.6 displays the table of location and scale measures when the standardization method is ABW. The location measure is the biweight 1-step M-estimate, and the scale measure is the biweight A-estimate. Note that the initial estimate for ABW is MAD. The tuning constant (4) of ABW is obtained by the following steps:

1. For rural scores, the location estimate for MAD is 166.0 and the scale estimate for MAD is 32.0. The maximum of the rural scores is 253 (not shown), and the minimum is 110 (not shown). Thus, the tuning constant needs to be 3 so that it does not reject any observation that has a score between 110 to 253.
2. For urban scores, the location estimate for MAD is 153.0 and the scale estimate for MAD is 15.5. The maximum of the rural scores is 198, and the minimum (also an outlier) is 64. Thus, the tuning constant needs to be 4 so that it rejects the outlier (64) but includes the maximum (198) as a normal observation.
3. The maximum of the tuning constants, obtained in steps 1 and 2, is 4.

Refer to Goodall (1983, Chapter 11) for details on the tuning constant. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5). It is also close to the dispersion ratio observed in the previous Schematic Plots.

The preceding analysis shows that METHOD=MAD, METHOD=IQR, and METHOD=ABW all provide better dispersion ratios than does METHOD=STD.

You can recompute the standard deviation after deleting the outlier from the original data set for comparison. The following statements create a DATA set NoOutlier that excludes the outlier from the TotalScores data set and invoke PROC STDIZE with METHOD=STD.

```
data NoOutlier;
  set totalscores;
  if (total = 64) then delete;
run;

proc stdize data=NoOutlier method=std pstat;
  title2 'after removing outlier, METHOD=STD';
  var total;
  by Type;
run;
```

High School Scores Data after removing outlier, METHOD=STD			
----- Type=rural -----			
The STDIZE Procedure			
Location and Scale Measures			
Location = mean		Scale = standard deviation	
Name	Location	Scale	N
total	167.050000	41.956713	20
High School Scores Data after removing outlier, METHOD=STD			
----- Type=urban -----			
The STDIZE Procedure			
Location and Scale Measures			
Location = mean		Scale = standard deviation	
Name	Location	Scale	N
total	158.000000	22.088207	19

Figure 66.7. After Deleting the Outlier, Location and Scale Measures Table When METHOD=STD

Figure 66.7 displays the location and scale measures after deleting the outlier. The lack of resistance of the standard deviation to outliers is clearly illustrated: if you delete the outlier, the sample standard deviation of urban scores changes from 30.07 to 22.09. The new ratio of the scale of rural scores to the scale of urban scores is approximately 1.90 (41.96/22.09).

Syntax

The following statements are available in the STDIZE procedure.

```

PROC STDIZE < options > ;
  BY variables ;
  FREQ variable ;
  LOCATION variables ;
  SCALE variables ;
  VAR variables ;
  WEIGHT variable ;

```

The PROC STDIZE statement is required. The BY, LOCATION, FREQ, VAR, SCALE, and WEIGHT statements are described in alphabetical order following the PROC STDIZE statement.

PROC STDIZE Statement

```

PROC STDIZE < options > ;

```

The PROC STDIZE statement invokes the procedure. You can specify the following options in the PROC STDIZE statement.

Table 66.1. Summary of PROC STDIZE Statement Options

Task	Options	Description
Specify standardization methods	METHOD=	specifies the name of the standardization method
	INITIAL=	specifies the method for computing initial estimates for the A estimates
Unstandardize variables	UNSTD	unstandardizes variables when you also specify the METHOD=IN option
Process missing values	NOMISS	omits observations with any missing values from computation
	MISSING=	specifies the method or a numeric value for replacing missing values
	REPLACE	replaces missing data by zero in the standardized data
	REONLY	replaces missing data by the location measure (does not standardize the data)
Specify data set details	DATA=	specifies the input data set
	OUT=	specifies the output data set
	OUTSTAT=	specifies the output statistic data set
Specify computational settings	VARDEF=	specifies the variances divisor
	NMARKERS=	specifies the number of markers when you also specify PCTLMTD=ONEPASS

Table 66.1. (continued)

Task	Options	Description
Specify percentiles	MULT=	specifies the constant to multiply each value by after standardizing
	ADD=	specifies the constant to add to each value after standardizing and multiplying by the value specified in the MULT= option
	FUZZ=	specifies the relative fuzz factor for writing the output
	PCTLDEF=	specifies the definition of percentiles when you also specify the PCTLMTD=ORD_STAT option
	PCTLMTD=	specifies the method used to estimate percentiles
Normalize scale estimators	PCTLPTS=	writes observations containing percentiles to the data set specified in the OUTSTAT= option
	NORM	normalizes the scale estimator to be consistent for the standard deviation of a normal distribution
Specify output	SNORM	normalizes the scale estimator to have an expectation of approximately 1 for a standard normal distribution
	PSTAT	displays the location and scale measures

These options and their abbreviations are described, in alphabetical order, in the remainder of this section.

ADD= *c*

specifies a constant, *c*, to add to each value after standardizing and multiplying by the value you specify in the MULT= option. The default value is 0.

DATA=SAS-*data-set*

specifies the input data set to be standardized. If you omit the DATA= option, the most recently created data set is used.

FUZZ=*c*

specifies the relative fuzz factor. The default value is 1E-14. For the OUT= data set, the score is computed as follows:

$$\text{if } |\text{Result}| < \text{Scale} \times \text{Fuzz}, \text{ then Result} = 0$$

For the OUTSTAT= data set and the Location and Scale table, the scale and location values are computed as follows:

$$\text{if } \text{Scale} < |\text{Location}| \times \text{Fuzz}, \text{ then Scale} = 0$$

Otherwise,

$$\text{if } |\text{Location}| < \text{Scale} \times \text{Fuzz}, \text{ then Location} = 0$$

INITIAL=method

specifies the method for computing initial estimates for the A estimates (ABW, AWAVE, and AHUBER). The following methods are not allowed: INITIAL=ABW, INITIAL=AHUBER, INITIAL=AWAVE, and INITIAL=IN. The default is INITIAL=MAD.

METHOD=name

specifies the name of the method for computing location and scale measures. Valid values for *name* are as follows: MEAN, MEDIAN, SUM, EUCLEN, USTD, STD, RANGE, MIDRANGE, MAXABS, IQR, MAD, ABW, AHUBER, AWAVE, AGK, SPACING, L, and IN.

For details on these methods, see the descriptions in the “[Standardization Methods](#)” section on page 4136. The default is METHOD=STD.

MISSING= method

MISSING= value

specifies the method (or a numeric value) for replacing missing values. If you omit the MISSING= option, the REPLACE option replaces missing values with the location measure given by the METHOD= option. Specify the MISSING= option when you want to replace missing values with a different value. You can specify any name that is valid in the METHOD= option except the name IN. The corresponding location measure is used to replace missing values.

If a numeric value is given, the value replaces missing values after standardizing the data. However, you can specify the REONLY option with the MISSING= option to suppress standardization for cases in which you want only to replace missing values.

MULT= c

specifies a constant, *c*, by which to multiply each value after standardizing. The default value is 1.

NMARKERS= n

specifies the number of markers used when you specify the one-pass algorithm (PCTLMTD=ONEPASS). The value *n* must be greater than or equal to 5. The default value is 105.

NOMISS

omits observations with missing values for any of the analyzed variables from calculation of the location and scale measures. If you omit the NOMISS option, all nonmissing values are used.

NORM

normalizes the scale estimator to be consistent for the standard deviation of a normal distribution when you specify the option METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING.

OUT=SAS-data-set

specifies the name of the SAS data set created by PROC STDIZE. The output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Note that analyzed variables are those specified in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement. See the section [“Output Data Sets”](#) on page 4141 for more information.

If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to “SAS Files” in *SAS Language Reference: Concepts* for more information on permanent SAS data sets.)

If you omit the OUT= option, PROC STDIZE creates an output data set named according to the DATA n convention.

OUTSTAT=SAS-data-set

specifies the name of the SAS data set containing the location and scale measures and other computed statistics. See the section [“Output Data Sets”](#) on page 4141 for more information.

PCTLDEF= percentiles

specifies which of five definitions is used to calculate percentiles when you specify the option PCTLMTD=ORD_STAT. By default, PCTLDEF=5.

Note that the option PCTLMTD=ONEPASS implies a specification of PCTLDEF=5. See the section [“Computational Methods for the PCTLDEF= Option”](#) on page 4140 for details on the PCTLDEF= option.

PCTLMTD=ORD_STAT**PCTLMTD=ONEPASS | P2**

specifies the method used to estimate percentiles. Specify the PCTLMTD=ORD_STAT option to compute the percentiles by the order statistics method. The PCTLMTD=ONEPASS option modifies an algorithm invented by Jain and Chlamtac (1985). See the [“Computing Quantiles”](#) section on page 4139 for more details on this algorithm.

The PCTLMTD=ONEPASS option modifies an algorithm invented by Jain and Chlamtac (1985). See the [“Computing Quantiles”](#) section on page 4139 for more details on this algorithm.

PCTLPTS= n

writes percentiles to the OUTSTAT= data set. Values of n can be any decimal number between 0 and 100, inclusive.

A requested percentile is identified by the _TYPE_ variable in the OUTSTAT= data set with a value of P n . For example, suppose you specify the option PCTLPTS=10, 30. The corresponding observations in the OUTSTAT= data set that contain the 10th and the 30th percentiles would then have values _TYPE_=P10 and _TYPE_=P30, respectively.

PSTAT

displays the location and scale measures.

REPLACE

replaces missing data with the value 0 in the standardized data (this value corresponds to the location measure before standardizing). To replace missing data by other values, see the preceding description of the MISSING= option. You cannot specify both the REPLACE and REONLY options.

REONLY

replaces missing data only; PROC STDIZE does not standardize the data. Missing values are replaced with the location measure unless you also specify the MISSING=*value* option, in which case missing values are replaced with *value*. You cannot specify both the REPLACE and REONLY options.

SNORM

normalizes the scale estimator to have an expectation of approximately 1 for a standard normal distribution when you specify the METHOD=SPACING option.

UNSTD**UNSTDIZE**

unstandardizes variables when you specify the METHOD=IN(*ds*) option. The location and scale measures, along with constants for addition and multiplication that the unstandardization is based upon, are identified by the `_TYPE_` variable in the *ds* data set.

The *ds* data set must have a `_TYPE_` variable and contain the following two observations: a `_TYPE_`= 'LOCATION' observation and a `_TYPE_`= 'SCALE' observation. The variable `_TYPE_` can also contain the optional observations, 'ADD' and 'MULT'; if these observations are not found in the *ds* data set, the constants specified in the ADD= and MULT= options (or their default values) are used for unstandardization.

See the “[OUTSTAT= Data Set](#)” section on page 4141 for details on the statistics that each value of `_TYPE_` represents. The formula used for unstandardization is as follows: If the final output value from the previous standardization is calculated as

$$result = add + multiply \times \frac{original - location}{scale}$$

$$original = scale \times \frac{result - add}{multiply} + location$$

VARDEF= DF**VARDEF= N****VARDEF= WDF****VARDEF= WEIGHT | WGT**

specifies the divisor to be used in the calculation of variances. By default, VARDEF=DF. The values and associated divisors are as follows.

Value	Divisor	Formula
DF	degrees of freedom	$n - 1$
N	number of observations	n
WDF	sum of weights minus 1	$(\sum_i w_i) - 1$
WEIGHT WGT	sum of weights	$\sum_i w_i$

BY Statement

BY *variables* ;

You can specify a BY statement with PROC STDIZE to obtain separate standardization for observations in groups defined by the BY variables.

If your DATA= input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the STDIZE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

When you specify the option METHOD=IN(*ds*), the following rules are applied to BY-group processing:

- If the *ds* data set does not contain any of the BY variables, the entire DATA= data set is standardized by the location and scale measures (along with the constants for addition and multiplication) in the *ds* data set.
- If the *ds* data set contains some, but not all, of the BY variables or if some BY variables do not have the same type or length in the *ds* data set that they have in the DATA= data set, PROC STDIZE displays an error message and stops.
- If all of the BY variables appear in the *ds* data set with the same type and length as in the DATA= data set, each BY group in the DATA= data set is standardized using the location and scale measures (along with the constants for addition and multiplication) from the corresponding BY group in the *ds* data set. The BY groups in the *ds* data set must be in the same order as they appear in the DATA= data set. All BY groups in the DATA= data set must also appear in the *ds* data set. If you do not specify the NOTSORTED option, some BY groups can appear in the *ds* data set but not in the DATA= data set; such BY groups are not used in standardizing data.

FREQ Statement

FREQ | FREQUENCY *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable name in a FREQ statement. PROC STDIZE treats the data set as if each observation appeared n times, where n is the value of the FREQ variable for the observation. Nonintegral values of the FREQ variable are truncated to the largest integer less than the FREQ value. If the FREQ variable has a value that is less than 1 or is missing, the observation is not used in the analysis.

LOCATION Statement

LOCATION *variables* ;

The LOCATION statement specifies a list of numeric variables that contain location measures in the input data set specified by the METHOD=IN option.

SCALE Statement

SCALE *variables* ;

The SCALE statement specifies the list of numeric variables containing scale measures in the input data set specified by the METHOD=IN option.

VAR Statement

VAR | VARIABLES *variables* ;

The VAR statement lists numeric variables to be standardized. If you omit the VAR statement, all numeric variables not listed in the BY, FREQ, and WEIGHT statements are used.

WEIGHT Statement

WGT | WEIGHT *variable* ;

The WEIGHT statement specifies a numeric variable in the input data set with values that are used to weight each observation. Only one variable can be specified.

The WEIGHT variable values can be nonintegers. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero. The WEIGHT variable applies only when you specify the option METHOD=MEAN, METHOD=SUM, METHOD=EUCLEN, METHOD=USTD, METHOD=STD, METHOD=AGK, or METHOD=L.

PROC STDIZE uses the value of the WEIGHT variable w_i , as follows.

The sample mean and (uncorrected) sample variances are computed as

$$\bar{x}_w = \sum_i w_i x_i / \sum_i w_i$$

$$us_w^2 = \sum_i w_i x_i^2 / d$$

$$s_w^2 = \sum_i w_i (x_i - \bar{x}_w)^2 / d$$

where w_i is the weight value of the i th observation, x_i is the value of the i th observation, and d is the divisor controlled by the VARDEF= option (see the VARDEF= option for details).

PROC STDIZE uses the value of the WEIGHT variable to calculate the following statistics:

MEAN	the weighted mean, \bar{x}_w
SUM	the weighted sum, $\sum_i w_i x_i$
USTD	the weighted uncorrected standard deviation, $\sqrt{us_w^2}$
STD	the weighted standard deviation, $\sqrt{s_w^2}$
EUCLEN	the weighted Euclidean length, computed as the square root of the weighted uncorrected sum of squares:

$$\sqrt{\sum_i w_i x_i^2}$$

AGK	the AGK estimate. This estimate is documented further in the ACECLUS procedure as the METHOD=COUNT option. See the discussion of the WEIGHT statement in Chapter 16, “The ACECLUS Procedure,” for information on how the WEIGHT variable is applied to the AGK estimate.
L	the L_p estimate. This estimate is documented further in the FASTCLUS procedure as the LEAST= option. See the discussion of the WEIGHT statement in Chapter 28, “The FASTCLUS Procedure,” for information on how the WEIGHT variable is used to compute weighted cluster means. Note that the number of clusters is always 1.

Details

Standardization Methods

The following table lists standardization methods and their corresponding location and scale measures available with the METHOD= option.

Table 66.2. Available Standardization Methods

Method	Location	Scale
MEAN	mean	1
MEDIAN	median	1
SUM	0	sum
EUCLEN	0	Euclidean length
USTD	0	standard deviation about origin
STD	mean	standard deviation
RANGE	minimum	range
MIDRANGE	midrange	range/2
MAXABS	0	maximum absolute value
IQR	median	interquartile range
MAD	median	median absolute deviation from median
ABW(<i>c</i>)	biweight 1-step M-estimate	biweight A-estimate
AHUBER(<i>c</i>)	Huber 1-step M-estimate	Huber A-estimate
AWAVE(<i>c</i>)	Wave 1-step M-estimate	Wave A-estimate
AGK(<i>p</i>)	mean	AGK estimate (ACECLUS)
SPACING(<i>p</i>)	mid minimum-spacing	minimum spacing
L(<i>p</i>)	L(<i>p</i>)	L(<i>p</i>)
IN(<i>ds</i>)	read from data set	read from data set

For METHOD=ABW(*c*), METHOD=AHUBER(*c*), or METHOD=AWAVE(*c*), *c* is a positive numeric tuning constant.

For METHOD=AGK(*p*), *p* is a numeric constant giving the proportion of pairs to be included in the estimation of the within-cluster variances.

For METHOD=SPACING(*p*), *p* is a numeric constant giving the proportion of data to be contained in the spacing.

For METHOD=L(*p*), *p* is a numeric constant greater than or equal to 1 specifying the power to which differences are to be raised in computing an L(*p*) or Minkowski metric.

For METHOD=IN(*ds*), *ds* is the name of a SAS data set that meets either one of the following two conditions:

- contains a `_TYPE_` variable. The observation that contains the location measure corresponds to the value `_TYPE_ = 'LOCATION'` and the observation that contains the scale measure corresponds to the value `_TYPE_ = 'SCALE'`. You can also use a data set created by the OUTSTAT= option from another PROC STDIZE statement as the *ds* data set. See the section “[Output Data Sets](#)” on page 4141 for the contents of the OUTSTAT= data set.
- contains the location and scale variables specified by the LOCATION and SCALE statements.

PROC STDIZE reads in the location and scale variables in the *ds* data set by first looking for the `_TYPE_` variable in the *ds* data set. If it finds this variable, PROC

STDIZE continues to search for all variables specified in the VAR statement. If it does not find the `_TYPE_` variable, PROC STDIZE searches for the location variables specified in the LOCATION statement and the scale variables specified in the SCALE statement.

For robust estimators, refer to Goodall (1983) and Iglewicz (1983). The MAD method has the highest breakdown point (50%), but it is somewhat inefficient. The ABW, AHUBER, and AWAVE methods provide a good compromise between breakdown and efficiency. The $L(p)$ location estimates are increasingly robust as p drops from 2 (corresponding to least squares, or mean estimation) to 1 (corresponding to least absolute value, or median estimation). However, the $L(p)$ scale estimates are not robust.

The SPACING method is robust to both outliers and clustering (Jannsen et al. 1995) and is, therefore, a good choice for cluster analysis or nonparametric density estimation. The mid-minimum spacing method estimates the mode for small p . The AGK method is also robust to clustering and more efficient than the SPACING method, but it is not as robust to outliers and takes longer to compute. If you expect g clusters, the argument to `METHOD=SPACING` or `METHOD=AGK` should be $\frac{1}{g}$ or less. The AGK method is less biased than the SPACING method for small samples. As a general guide, it is reasonable to use AGK for samples of size 100 or less and SPACING for samples of size 1000 or more, with the treatment of intermediate sample sizes depending on the available computer resources.

Computation of the Statistics

Formulas for statistics of `METHOD=MEAN`, `METHOD=MEDIAN`, `METHOD=SUM`, `METHOD=USTD`, `METHOD=STD`, `METHOD=RANGE`, and `METHOD=IQR` are given in the chapter on elementary statistics procedures in the *SAS Procedures Guide*.

Note that the computations of median and upper and lower quartiles depend on the `PCTLMTD=` option.

The other statistics listed in Table 66.2, except for `METHOD=IN`, are described as follows:

EUCLEN	Euclidean length. $\sqrt{\sum_{i=1}^n x_i^2}$ where x_i is the i th observation and n is the total number of observations in the sample.
$L(p)$	Minkowski metric. This metric is documented as the <code>LEAST=p</code> option in the PROC FASTCLUS statement of the FASTCLUS procedure (see Chapter 28, “The FASTCLUS Procedure,”). If you specify <code>METHOD=$L(p)$</code> in the PROC STDIZE statement, your results are similar to those obtained from PROC FASTCLUS if you specify the <code>LEAST=p</code> option with <code>MAXCLUS=1</code> (and use the default values of the <code>MAXITER=</code> option). The difference between the two types of calculations concerns the maximum number of iterations. In PROC STDIZE, it is a criteria for convergence on

	all variables; In PROC FASTCLUS, it is a criteria for convergence on a single variable.
	The location and scale measures for $L(p)$ are output to the OUTSEED= data set in PROC FASTCLUS.
MIDRANGE	(maximum + minimum)/2
ABW(c)	Tukey's biweight. Refer to Goodall (1983, pp. 376–378, p. 385) for the biweight 1-step M-estimate. Also refer to Iglewicz (1983, pp. 416–418) for the biweight A-estimate.
AHUBER(c)	Hubers. Refer to Goodall (1983, pp. 371–374) for the Huber 1-step M-estimate. Also refer to Iglewicz (1983, pp. 416–418) for the Huber A-estimate of scale.
AWAVE(c)	Andrews' Wave. Refer to Goodall (1983, p. 376) for the Wave 1-step M-estimate. Also refer to Iglewicz (1983, pp. 416–418) for the Wave A-estimate of scale.
AGK(p)	The noniterative univariate form of the estimator described by Art, Gnanadesikan, and Kettenring (1982). The AGK estimate is documented in the section on the METHOD= option in the PROC ACECLUS statement of the ACECLUS procedure (also see the “Background” section on page 388 in Chapter 16, “The ACECLUS Procedure,”). Specifying METHOD=AGK(p) in the PROC STDIZE statement is the same as specifying METHOD=COUNT and P= p in the PROC ACECLUS statement.
SPACING(p)	The absolute difference between two data values. The minimum spacing for a proportion p is the minimum absolute difference between two data values that contain a proportion p of the data between them. The mid minimum-spacing is the mean of these two data values.

Computing Quantiles

PROC STDIZE offers two methods for computing quantiles: the one-pass approach and the order-statistics approach (like that used in the UNIVARIATE procedure).

The one-pass approach used in PROC STDIZE modifies the P^2 algorithm for histograms proposed by Jain and Chlamtac (1985). The primary difference comes from the movement of markers. The one-pass method allows a marker to move to the right (or left) by more than one position (to the largest possible integer) as long as it does not result in two markers being in the same position. The modification is necessary in order to incorporate the FREQ variable.

You may obtain inaccurate results if you use the one-pass approach to estimate quantiles beyond the quartiles (that is, when you estimate quantiles $< P_{25}$ or $> P_{75}$). A large sample size (10,000 or more) is often required if the tail quantiles (quantiles $\leq P_{10}$ or $\geq P_{90}$) are requested. Note that, for variables with highly skewed or heavy-tailed distributions, tail quantile estimates may be inaccurate.

The order-statistics approach for estimating quantiles is faster than the one-pass method but requires that the entire data set be stored in memory. The accuracy in estimating the quantiles is comparable for both methods when the requested percentiles are between the lower and upper quartiles. The default is PCTLMTD=ORD_STAT if enough memory is available; otherwise, PCTLMTD=ONEPASS.

Computational Methods for the PCTLDEF= Option

You can specify one of five methods for computing quantile statistics when you use the order-statistics approach (PCTLMTD=ORD_STAT); otherwise, the PCTLDEF=5 method is used when you use the one-pass approach (PCTLMTD=ONEPASS).

Let n be the number of nonmissing values for a variable, and let x_1, x_2, \dots, x_n represent the ordered values of the variable. For the t th percentile, let $p = t/100$. In the following definitions numbered 1, 2, 3, and 5, let

$$np = j + g$$

where j is the integer part and g is the fractional part of np . For definition 4, let

$$(n + 1)p = j + g$$

Given the preceding definitions, the t th percentile, y , is defined as follows:

PCTLDEF=1 weighted average at x_{np}

$$y = (1 - g)x_j + gx_{j+1}$$

where x_0 is taken to be x_1

PCTLDEF=2 observation numbered closest to np

$$y = x_i$$

where i is the integer part of $np + 1/2$ if $g \neq 1/2$. If $g = 1/2$, then

$y = x_j$ if j is even, or

$y = x_{j+1}$ if j is odd

PCTLDEF=3 empirical distribution function

$$y = x_j \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

PCTLDEF=4 weighted average aimed at $x_{p(n+1)}$

$$y = (1 - g)x_j + gx_{j+1}$$

where x_{n+1} is taken to be x_n

PCTLDEF=5 empirical distribution function with averaging

$$y = (x_j + x_{j+1})/2 \text{ if } g = 0$$

$$y = x_{j+1} \text{ if } g > 0$$

Missing Values

Missing values can be replaced by the location measure or by any specified constant (see the REPLACE option and the MISSING= option). You can also suppress standardization if you want only to replace missing values (see the REPNLY option).

If you specify the NOMISS option, PROC STDIZE omits observations with any missing values in the analyzed variables from computation of the location and scale measures.

Output Data Sets

OUT= Data Set

The output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Analyzed variables are those listed in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement.

OUTSTAT= Data Set

The new data set contains the following variables:

- the BY variables, if any
- `_TYPE_`, a character variable
- the analyzed variables

Each observation in the new data set contains a type of statistic as indicated by the `_TYPE_` variable. The values of the `_TYPE_` variable are as follows:

`_TYPE_`

LOCATION	location measure of each variable
SCALE	scale measure of each variable
ADD	constant specified in the ADD= option. This value is the same for each variable.
MULT	constant specified in the MULT= option. This value is the same for each variable.
N	total number of nonmissing positive frequencies of each variable
NORM	norm measure of each variable. This observation is produced only when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING.
NObsRead	number of physical records read
NObsUsed	number of physical records used in the analysis
NObsMiss	number of physical records containing missing values

SumFreqsRead	sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations read
SumFreqsUsed	sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations used in the analysis
SumWeightsRead	sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations read
SumWeightsUsed	sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations used in the analysis
P n	percentiles of each variable, as specified by the PCTLPTS= option. The argument n is any real number such that $0 \leq n \leq 100$.

Displayed Output

If you specify the PSTAT option, PROC STDIZE displays the following statistics for each variable:

- the name of the variable, Name
- the location estimate, Location
- the scale estimate, Scale
- the norm estimate, Norm (when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING)
- the total nonmissing positive frequencies, N

ODS Table Names

PROC STDIZE assigns a name to the single table it creates. You can use this name to reference the table when using the Output Delivery System (ODS) to select output or create an output data set. For more information on ODS, see [Chapter 14, “Using the Output Delivery System.”](#)

Table 66.3. ODS Table Produced in PROC STDIZE

ODS Table Name	Description	Option
Statistics	Location and Scale Measures	PSTAT

Examples

Example 66.1. Standardization of Variables in Cluster Analysis

To illustrate the effect of standardization in cluster analysis, this example uses the Fish data set described in the “Getting Started” section of Chapter 28, “The FASTCLUS Procedure.” The numbers are measurements taken on 159 fish caught from the same lake (Laengelmavesi) near Tampere in Finland; this data set is available from the Data Archive of the *Journal of Statistics Education*. The complete data set is displayed in Chapter 67, “The STEPDISC Procedure.”

The species (Bream, Parkki, Pike, Perch, Roach, Smelt, and Whitefish), weight, three different length measurements (measured from the nose of the fish to the beginning of its tail, the notch of its tail, and the end of its tail), height, and width of each fish are recorded. The height and width are recorded as percentages of the third length variable.

Several new variables are created in the Fish data set: Weight3, Height, Width, and logLengthRatio. The weight of a fish indicates its size—a heavier Tuna tends to be larger than a lighter Tuna. To get a one dimensional measure of the size of a fish, take the cubic root of the weight (Weight3). The variables Height, Width, Length1, Length2, and Length3 are rescaled in order to adjust for dimensionality. The logLengthRatio variable measures the tail length.

Because the new variables Weight3–logLengthRatio depend on the variable Weight, observations with missing values for Weight are not added to the data set. Consequently, there are 157 observations in the SAS data set Fish.

Before you perform a cluster analysis on coordinate data, it is necessary to consider scaling or transforming the variables since variables with large variances tend to have a larger effect on the resulting clusters than those with small variances.

This example uses three different approaches to standardize or transform the data prior to the cluster analysis. The first approach uses several standardization methods provided in the STDIZE procedure. However, since standardization is not always appropriate prior to the clustering (refer to Milligan and Cooper, 1987, for a Monte Carlo study on various methods of variable standardization), the second approach performs the cluster analysis with no standardization. The third approach invokes the ACECLUS procedure to transform the data into a within-cluster covariance matrix.

The clustering is performed by the FASTCLUS procedure to find seven clusters. Note that the variables Length2 and Length3 are eliminated from this analysis since they both are significantly and highly correlated with the variable Length1. The correlation coefficients are 0.9958 and 0.9604, respectively. An output data set is created, and the FREQ procedure is invoked to compare the clusters with the species classification.

The DATA step is as follows:

```

proc format;
  value specfmt
    1='Bream'
    2='Roach'
    3='Whitefish'
    4='Parkki'
    5='Perch'
    6='Pike'
    7='Smelt';
data Fish (drop=HtPct WidthPct);
  title 'Fish Measurement Data';
  input Species Weight Length1 Length2 Length3 HtPct
    WidthPct @@;

  if Weight <= 0 or Weight=. then delete;
  Weight3=Weight**(1/3);
  Height=HtPct*Length3/(Weight3*100);
  Width=WidthPct*Length3/(Weight3*100);
  Length1=Length1/Weight3;
  Length2=Length2/Weight3;
  Length3=Length3/Weight3;
  logLengthRatio=log(Length3/Length1);

  format Species specfmt.;
  symbol = put(Species, specfmt2.);
  datalines;
1  242.0 23.2 25.4 30.0 38.4 13.4
1  290.0 24.0 26.3 31.2 40.0 13.8
1  340.0 23.9 26.5 31.1 39.8 15.1

... [155 more records]
;
run;

```

The following macro, Std, standardizes the Fish data. The macro reads a single argument, mtd, which selects the METHOD= specification to be used in PROC STDIZE.

```

/*--- macro for standardization ---*/

%macro Std(mtd);
title2 "Data is standardized by PROC STDIZE with
  METHOD= &mtd";
  proc stdize data=fish out=sdzout method=&mtd;
    var Length1 logLengthRatio Height Width Weight3;
  run;
%mend Std;

```

The following macro, FastFreq, includes a PROC FASTCLUS statement for performing cluster analysis and a PROC FREQ statement for cross-tabulating species with the cluster membership information that is derived from the previous PROC FASTCLUS statement. The macro reads a single argument, ds, which selects the input data set to be used in PROC FASTCLUS.

```

/*--- macro for clustering and cross-tabulating ---*/
/*--- cluster membership with species          ---*/
%macro FastFreq(ds);
    proc fastclus data=&ds out=clust maxclusters=7 maxiter=100 noprint;
        var Length1 logLengthRatio Height Width Weight3;
    run;

    proc freq data=clust;
        tables species*cluster;
    run;
%mend FastFreq;

```

The following analysis, (labeled ‘Approach 1’) includes 18 different methods of standardization followed by clustering. Since there is a large amount of output from this approach, only results from METHOD=STD, METHOD=RANGE, METHOD=AGK(.14), and METHOD=SPACING(.14) are shown. The following statements produce [Output 66.1.1](#) through [Output 66.1.4](#).

```

/*****
/*
/*      Approach 1: data is standardized by PROC STDIZE      */
/*

Total	29	16	10	15	39	4	44	157
	18.47	10.19	6.37	9.55	24.84	2.55	28.03	100.00

Table 66.4 displays a table summarizing each classification results. In this table, the first column represents the standardization method, the second column represents the number of clusters that the 7 species are classified into, and the third column represents the total number of observations that are misclassified.

Table 66.4. Summary of Clustering Results

Method of Standardization	Number of Clusters	Misclassification
MEAN	5	71
MEDIAN	5	71
SUM	6	51
EUCLEN	6	45
USTD	6	45
STD	5	33
RANGE	7	32
MIDRANGE	7	32
MAXABS	7	26
IQR	5	28
MAD	4	35
ABW(5)	6	34
AWAVE(5)	6	29
AGK(.14)	7	28
SPACING(.14)	7	25
L(1)	6	41
L(1.5)	5	33
L(2)	5	33
untransformed	5	71
PROC ACECLUS	5	71

Consider the results displayed in [Output 66.1.1](#). In that analysis, the method of standardization is STD, and the number of clusters and the number of misclassifications are computed as shown in [Table 66.5](#).

Table 66.5. Computations of Numbers of Clusters and Misclassification When Standardization Method Is STD

Species	Cluster Number	Misclassification in Each Species
Bream	6	0
Roach	7	0
Whitefish	7	3
Parkki	5	0
Perch	7	29
Pike	1	0
Smelt	3	1

In [Output 66.1.1](#), the Bream species is classified as cluster 6 since all 34 Bream fish are categorized into cluster 6 with no misclassification. A similar pattern is seen with the Roach, Parkki, Pike, and Smelt species.

For the Whitefish species, two fish are categorized into cluster 2, one fish is categorized into cluster 4, and three fish are categorized into cluster 7. Because the majority of this species is categorized into cluster 7, it is recorded in [Table 66.5](#) as being classified as cluster 7 with 3 misclassifications. A similar pattern is seen with the Perch species: it is classified as cluster 7 with 29 misclassifications.

In summary, when the standardization method is STD, seven species of fish are classified into only 5 clusters and the total number of misclassified observations is 33.

The result of this analysis demonstrates that when variables are standardized by the STDIZE procedure with methods including RANGE, MIDRANGE, MAXABS, AGK(.14), and SPACING(.14), the FASTCLUS procedure produces the correct number of clusters and less misclassification than it does when other standardization methods are used. The SPACING method attains the best result, probably because the variables Length1 and Height both exhibit marked groupings (bimodality) in their distributions.

Chapter 67

The STEPDISC Procedure

Overview

Given a classification variable and several quantitative variables, the STEPDISC procedure performs a stepwise discriminant analysis to select a subset of the quantitative variables for use in discriminating among the classes. The set of variables that make up each class is assumed to be multivariate normal with a common covariance matrix. The STEPDISC procedure can use forward selection, backward elimination, or stepwise selection (Klecka 1980). The STEPDISC procedure is a useful prelude to further analyses using the CANDISC procedure or the DISCRIM procedure.

With PROC STEPDISC, variables are chosen to enter or leave the model according to one of two criteria:

- the significance level of an F -test from an analysis of covariance, where the variables already chosen act as covariates and the variable under consideration is the dependent variable
- the squared partial correlation for predicting the variable under consideration from the CLASS variable, controlling for the effects of the variables already selected for the model

Forward selection begins with no variables in the model. At each step, PROC STEPDISC enters the variable that contributes most to the discriminatory power of the model as measured by Wilks' Lambda, the likelihood ratio criterion. When none of the unselected variables meets the entry criterion, the forward selection process stops.

Backward elimination begins with all variables in the model except those that are linearly dependent on previous variables in the VAR statement. At each step, the variable that contributes least to the discriminatory power of the model as measured by Wilks' Lambda is removed. When all remaining variables meet the criterion to stay in the model, the backward elimination process stops.

Stepwise selection begins, like forward selection, with no variables in the model. At each step, the model is examined. If the variable in the model that contributes least to the discriminatory power of the model as measured by Wilks' lambda fails to meet the criterion to stay, then that variable is removed. Otherwise, the variable not in the model that contributes most to the discriminatory power of the model is entered. When all variables in the model meet the criterion to stay and none of the other variables meet the criterion to enter, the stepwise selection process stops. Stepwise selection is the default method of variable selection.

It is important to realize that, in the selection of variables for entry, only one variable can be entered into the model at each step. The selection process does not take into account the relationships between variables that have not yet been selected. Thus, some important variables could be excluded in the process. Also, Wilks' Lambda may not be the best measure of discriminatory power for your application. However, if you use PROC STEPDISC carefully, in combination with your knowledge of the data and careful cross-validation, it can be a valuable aid in selecting variables for a discrimination model.

As with any stepwise procedure, it is important to remember that, when many significance tests are performed, each at a level of, for example, 5% (0.05), the overall probability of rejecting at least one true null hypothesis is much larger than 5%. If you want to prevent including any variables that do not contribute to the discriminatory power of the model in the population, you should specify a very small significance level. In most applications, all variables considered have some discriminatory power, however small. To choose the model that provides the best discrimination using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size.

Costanza and Afifi (1979) use Monte Carlo studies to compare alternative stopping rules that can be used with the forward selection method in the two-group multivariate normal classification problem. Five different numbers of variables, ranging from 10 to 30, are considered in the studies. The comparison is based on conditional and estimated unconditional probabilities of correct classification. They conclude that the use of a moderate significance level, in the range of 10 percent to 25 percent, often performs better than the use of a much larger or a much smaller significance level.

The significance level and the squared partial correlation criteria select variables in the same order, although they may select different numbers of variables. Increasing the sample size tends to increase the number of variables selected when using significance levels, but it has little effect on the number selected using squared partial correlations.

See Chapter 6, "Introduction to Discriminant Procedures," for more information on discriminant analysis.

Getting Started

The data in this example are measurements on 159 fish caught in Finland's lake Laengelmavesi; this data set is available from the Data Archive of the *Journal of Statistics Education*. For each of the seven species (bream, parkki, pike, perch, roach, smelt, and whitefish), the weight, length, height, and the width of each fish are tallied. Three different length measurements are recorded: from the nose of the fish to the beginning of its tail, from the nose to the notch of its tail, and from the nose to the end of its tail. The height and width are recorded as percentages of the third length variable. PROC STEPDISC will select a subset of the six quantitative variables that may be useful for differentiating between the fish species. This subset is used in conjunction with PROC CANDISC and PROC DISCRIM to develop discrimination models.

The following program creates the data set fish and uses PROC STEPDISC to select a subset of potential discriminator variables. By default, PROC STEPDISC uses stepwise selection on all numeric variables that are not listed in other statements, and the significance levels for a variable to enter the subset and to stay in the subset are set to 0.15.

PROC STEPDISC begins by displaying summary information about the analysis; see [Figure 67.1](#). This information includes the number of observations with nonmissing values, the number of classes in the classification variable (specified by the CLASS statement), the number of quantitative variables under consideration, the significance criteria for variables to enter and to stay in the model, and the method of variable selection being used. The frequency of each class is also displayed.

Fish Measurement Data				
The STEPDISC Procedure				
The Method for Selecting Variables is STEPWISE				
Observations	158	Variable(s) in the Analysis	6	
Class Levels	7	Variable(s) will be Included	0	
		Significance Level to Enter	0.15	
		Significance Level to Stay	0.15

Whitefish	Whitefish	6	6.0000	0.037975

Figure 67.1. Summary Information

For each entry step, the statistics for entry are displayed for all variables not currently selected; see [Figure 67.2](#). The variable selected to enter at this step (if any) is displayed, as well as all the variables currently selected. Next are multivariate statistics that take into account all previously selected variables and the newly entered variable.

Figure 67.5. Step Summary

All the variables in the data set are found to have potential discriminatory power. These variables are used to develop discrimination models in both the CANDISC and DISCRIM procedure chapters.

Syntax

The following statements are available in PROC STEPDISC.

```

PROC STEPDISC < options > ;
  CLASS variable ;

  BY variables ;
  FREQ variable ;
  VAR variables ;
  WEIGHT variable ;

```

The BY, CLASS, FREQ, VAR, and WEIGHT statements are described after the PROC STEPDISC statement.

PROC STEPDISC Statement

```

PROC STEPDISC < options > ;

```

The PROC STEPDISC statement invokes the STEPDISC procedure. The PROC STEPDISC statement has the following options.

Table 67.1. STEPDISC Procedure Options

	PSSCP

Table 67.1. (continued)

Task	Options
	TSSCP
	WSSCP
Miscellaneous	ALL SIMPLE STDMEAN
Suppress Output	SHORT

ALL

activates all of the display options.

BCORR

displays between-class correlations.

BCOV

displays between-class covariances. The between-class covariance matrix equals the between-class SSCP matrix divided by $n(c - 1)/c$, where n is the number of observations and c is the number of classes. The between-class covariances should be interpreted in comparison with the total-sample and within-class covariances, not as formal estimates of population parameters.

BSSCP

displays the between-class SSCP matrix.

DATA=SAS-data-set

specifies the data set to be analyzed. The data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. These specially structured data sets include TYPE=CORR, COV, CSSCP, and SSCP. If the DATA= option is omitted, the procedure uses the most recently created SAS data set.

INCLUDE=n

includes the first n variables in the VAR statement in every model. By default, INCLUDE=0.

MAXSTEP=n

specifies the maximum number of steps. By default, MAXSTEP= two times the number of variables in the VAR statement.

METHOD=BACKWARD | BW**METHOD=FORWARD | FW****METHOD=STEPWISE | SW**

specifies the method used to select the variables in the model. The BACKWARD method specifies backward elimination, FORWARD specifies forward selection, and STEPWISE specifies stepwise selection. By default, METHOD=STEPWISE.

PCORR

displays pooled within-class correlations (partial correlations based on the pooled within-class covariances).

PCOV

displays pooled within-class covariances.

PR2ENTRY= ρ **PR2E= ρ**

specifies the partial R^2 for adding variables in the forward selection mode, where $p \leq 1$.

PR2STAY= ρ **PR2S= ρ**

specifies the partial R^2 for retaining variables in the backward elimination mode, where $p \leq 1$.

PSSCP

displays the pooled within-class corrected SSCP matrix.

SHORT

suppresses the displayed output from each step.

SIMPLE

displays simple descriptive statistics for the total sample and within each class.

SINGULAR= ρ

specifies the singularity criterion for entering variables, where $0 < p < 1$. PROC STEPDISC precludes the entry of a variable if the squared multiple correlation of the variable with the variables already in the model exceeds $1 - p$. With more than one variable already in the model, PROC STEPDISC also excludes a variable if it would cause any of the variables already in the model to have a squared multiple correlation (with the entering variable and the other variables in the model) exceeding $1 - p$. By default, SINGULAR= 1E-8.

SLENTRY= ρ **SLE= ρ**

specifies the significance level for adding variables in the forward selection mode, where $0 \leq p \leq 1$. The default value is 0.15.

SLSTAY= ρ **SLS= ρ**

specifies the significance level for retaining variables in the backward elimination mode, where $0 \leq p \leq 1$. The default value is 0.15.

START= n

specifies that the first n variables in the VAR statement be used to begin the selection process. When you specify METHOD=FORWARD or METHOD=STEPWISE, the default value is 0; when you specify METHOD=BACKWARD, the default value is the number of variables in the VAR statement.

STDMEAN

displays total-sample and pooled within-class standardized class means.

STOP=*n*

specifies the number of variables in the final model. The STEPDISC procedure stops the selection process when a model with *n* variables is found. This option applies only when you specify METHOD=FORWARD or METHOD=BACKWARD. When you specify METHOD=FORWARD, the default value is the number of variables in the VAR statement; when you specify METHOD=BACKWARD, the default value is 0.

TCORR

displays total-sample correlations.

TCOV

displays total-sample covariances.

TSSCP

displays the total-sample corrected SSCP matrix.

WCORR

displays within-class correlations for each class level.

WCOV

displays within-class covariances for each class level.

WSSCP

displays the within-class corrected SSCP matrix for each class level.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC STEPDISC to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the STEPDISC procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS *variable* ;

The values of the CLASS variable define the groups for analysis. Class levels are determined by the formatted values of the CLASS variable. The CLASS variable can be numeric or character. A CLASS statement is required.

FREQ Statement

FREQ *variable* ;

If a variable in the data set represents the frequency of occurrence for the other values in the observation, include the name of the variable in a FREQ statement. The procedure then treats the data set as if each observation appears n times, where n is the value of the FREQ variable for the observation. The total number of observations is considered to be equal to the sum of the FREQ variable when the procedure determines degrees of freedom for significance probabilities.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, the value is truncated to an integer.

VAR Statement

VAR *variables* ;

The VAR statement specifies the quantitative variables eligible for selection. The default is all numeric variables not listed in other statements.

WEIGHT Statement

WEIGHT *variable* ;

To use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the WEIGHT variable are proportional to the reciprocals of the variances. If the value of the WEIGHT variable is missing or is less than zero, then a value of zero for the weight is assumed.

The WEIGHT and FREQ statements have a similar effect except that the WEIGHT statement does not alter the degrees of freedom.

Details

Missing Values

Observations containing missing values are omitted from the analysis.

Input Data Sets

The input data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. For more information on these data sets, see [Appendix A, “Special SAS Data Sets.”](#) The BY variable in these data sets becomes the CLASS variable in PROC STEPDISC. These specially structured data sets include

- TYPE=CORR data sets created by PROC CORR using a BY statement
- TYPE=COV data sets created by PROC PRINCOMP using both the COV option and a BY statement
- TYPE=CSSCP data sets created by PROC CORR using the CSSCP option and a BY statement, where the OUT= data set is assigned TYPE=CSSCP with the TYPE= data set option
- TYPE=SSCP data sets created by PROC REG using both the OUTSSCP= option and a BY statement

When the input data set is TYPE=CORR, TYPE=COV, or TYPE=CSSCP, the STEPDISC procedure reads the number of observations for each class from the observations with `_TYPE_='N'` and the variable means in each class from the observations with `_TYPE_='MEAN'`. The procedure then reads the within-class correlations from the observations with `_TYPE_='CORR'`, the standard deviations from the observations with `_TYPE_='STD'` (data set TYPE=CORR), the within-class covariances from the observations with `_TYPE_='COV'` (data set TYPE=COV), or the within-class corrected sums of squares and crossproducts from the observations with `_TYPE_='CSSCP'` (data set TYPE=CSSCP).

When the data set does not include any observations with `_TYPE_='CORR'` (data set TYPE=CORR), `_TYPE_='COV'` (data set TYPE=COV), or `_TYPE_='CSSCP'` (data set TYPE=CSSCP) for each class, PROC STEPDISC reads the pooled within-class information from the data set. In this case, the STEPDISC procedure reads the pooled within-class correlations from the observations with `_TYPE_='PCORR'`, the pooled within-class standard deviations from the observations with `_TYPE_='PSTD'` (data set TYPE=CORR), the pooled within-class covariances from the observations with `_TYPE_='PCOV'` (data set TYPE=COV), or the pooled within-class corrected SSCP matrix from the observations with `_TYPE_='PSSCP'` (data set TYPE=CSSCP).

When the input data set is TYPE=SSCP, the STEPDISC procedure reads the number of observations for each class from the observations with `_TYPE_='N'`, the sum of weights of observations from the variable INTERCEPT in observations with `_TYPE_='SSCP'` and `_NAME_='INTERCEPT'`, the variable sums

from the `variable=variablenames` in observations with `_TYPE_='SSCP'` and `_NAME_='INTERCEPT'`, and the uncorrected sums of squares and crossproducts from the `variable=variablenames` in observations with `_TYPE_='SSCP'` and `_NAME_=variablenames`.

Computational Resources

In the following discussion, let

- n = number of observations
- c = number of class levels
- v = number of variables in the VAR list
- l = length of the CLASS variable
- t = $v + c - 1$.

Memory Requirements

The amount of memory in bytes for temporary storage needed to process the data is

$$c(4v^2 + 28v + 3l + 4c + 72) + 16v^2 + 92v + 4t^2 + 20t + 4l$$

Additional temporary storage of 72 bytes at each step is also required to store the results.

Time Requirements

The following factors determine the time requirements of a stepwise discriminant analysis.

- The time needed for reading the data and computing covariance matrices is proportional to nv^2 . The STEPDISC procedure must also look up each class level in the list. This is faster if the data are sorted by the CLASS variable. The time for looking up class levels is proportional to a value ranging from n to $n \ln(c)$.
- The time needed for stepwise discriminant analysis is proportional to the number of steps required to select the set of variables in the discrimination model. The number of steps required depends on the data set itself and the selection method and criterion used in the procedure. Each forward or backward step takes time proportional to $(v + c)^2$.

Displayed Output

The STEPDISC procedure displays the following output:

- Class Level Information, including the values of the classification variable, the Frequency of each value, the Weight of each value, and the Proportion of each value in the total sample

Optional output includes

- Within-Class SSCP Matrices for each group
- Pooled Within-Class SSCP Matrix
- Between-Class SSCP Matrix
- Total-Sample SSCP Matrix
- Within-Class Covariance Matrices for each group
- Pooled Within-Class Covariance Matrix
- Between-Class Covariance Matrix, equal to the between-class SSCP matrix divided by $n(c - 1)/c$, where n is the number of observations and c is the number of classes
- Total-Sample Covariance Matrix
- Within-Class Correlation Coefficients and $\text{Pr} > |r|$ to test the hypothesis that the within-class population correlation coefficients are zero
- Pooled Within-Class Correlation Coefficients and $\text{Pr} > |r|$ to test the hypothesis that the partial population correlation coefficients are zero
- Between-Class Correlation Coefficients and $\text{Pr} > |r|$ to test the hypothesis that the between-class population correlation coefficients are zero
- Total-Sample Correlation Coefficients and $\text{Pr} > |r|$ to test the hypothesis that the total population correlation coefficients are zero
- descriptive Simple Statistics including N (the number of observations), Sum, Mean, Variance, and Standard Deviation for the total sample and within each class
- Total-Sample Standardized Class Means, obtained by subtracting the grand mean from each class mean and dividing by the total-sample standard deviation
- Pooled Within-Class Standardized Class Means, obtained by subtracting the grand mean from each class mean and dividing by the pooled within-class standard deviation

At each step, the following statistics are displayed:

- for each variable considered for entry or removal: Partial R-Square, the squared (partial) correlation, the F statistic, and $\text{Pr} > F$, the probability level, from a one-way analysis of covariance

- the minimum Tolerance for entering each variable. A variable is entered only if its tolerance and the tolerances for all variables already in the model are greater than the value specified in the SINGULAR= option. The tolerance for the entering variable is $1 - R^2$ from regressing the entering variable on the other variables already in the model. The tolerance for a variable already in the model is $1 - R^2$ from regressing that variable on the entering variable and the other variables already in the model. With m variables already in the model, for each entering variable, $m + 1$ multiple regressions are performed using the entering variable and each of the m variables already in the model as a dependent variable. These $m + 1$ tolerances are computed for each entering variable, and the minimum tolerance is displayed for each.

The tolerance is computed using the total-sample correlation matrix. It is customary to compute tolerance using the pooled within-class correlation matrix (Jennrich 1977), but it is possible for a variable with excellent discriminatory power to have a high total-sample tolerance and a low pooled within-class tolerance. For example, PROC STEPDISC enters a variable that yields perfect discrimination (that is, produces a canonical correlation of one), but a program using pooled within-class tolerance does not.

- the variable Label, if any
- the name of the variable chosen
- the variables already selected or removed
- Wilks' Lambda and the associated F approximation with degrees of freedom and $\text{Pr} < F$, the associated probability level after the selected variable has been entered or removed. Wilks' lambda is the likelihood ratio statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the "Multivariate Tests" section in [Chapter 2](#), "Introduction to Regression Procedures.") Lambda is close to zero if any two groups are well separated.
- Pillai's Trace and the associated F approximation with degrees of freedom and $\text{Pr} > F$, the associated probability level after the selected variable has been entered or removed. Pillai's trace is a multivariate statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the "Multivariate Tests" section in [Chapter 2](#)).
- Average Squared Canonical Correlation (ASCC). The ASCC is Pillai's trace divided by the number of groups minus 1. The ASCC is close to 1 if all groups are well separated and if all or most directions in the discriminant space show good separation for at least two groups.
- Summary to give statistics associated with the variable chosen at each step. The summary includes the following:
 - Step number
 - Variable Entered or Removed
 - Number In, the number of variables in the model
 - Partial R-Square
 - the F Value for entering or removing the variable

- $\text{Pr} > F$, the probability level for the F statistic
- Wilks' Lambda
- $\text{Pr} < \text{Lambda}$ based on the F approximation to Wilks' Lambda
- Average Squared Canonical Correlation
- $\text{Pr} > \text{ASCC}$ based on the F approximation to Pillai's trace
- the variable Label, if any

ODS Table Names

PROC STEPDISC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, "Using the Output Delivery System."

Table 67.2. ODS Tables Produced in PROC STEPDISC

ODS Table Name	Description	PROC STEPWISE Option
BCorr	Between-class correlations	BCORR
BCov	Between-class covariances	BCOV
BSSCP	Between-class SSCP matrix	BSSCP
Counts	Number of observations, variables, classes, df	default
CovDF	DF for covariance matrices, not printed	any *COV option
Levels	Class level information	default
Messages	Entry/removal messages	default
Multivariate	Multivariate statistics	default
PCorr	Pooled within-class correlations	PCORR
PCov	Pooled within-class covariances	PCOV
PSSCP	Pooled within-class SSCP matrix	PSSCP
PStdMeans	Pooled standardized class means	STDMEAN
SimpleStatistics	Simple statistics	SIMPLE
Steps	Stepwise selection entry/removal	default
Summary	Stepwise selection summary	default
TCorr	Total-sample correlations	TCORR
TCov	Total-sample covariances	TCOV
TSSCP	Total-sample SSCP matrix	TSSCP
TStdMeans	Total standardized class means	STDMEAN
Variables	Variable lists	default
WCorr	Within-class correlations	WCORR
WCov	Within-class covariances	WCOV
WSSCP	Within-class SSCP matrices	WSSCP

Example

Example 67.1. Performing a Stepwise Discriminant Analysis

The iris data published by Fisher (1936) have been widely used for examples in discriminant analysis and cluster analysis. The sepal length, sepal width, petal length, and petal width are measured in millimeters on fifty iris specimens from each of three species: *Iris setosa*, *I. versicolor*, and *I. virginica*.

A stepwise discriminant analysis is performed using stepwise selection.

In the PROC STEPDISC statement, the BSSCP and TSSCP options display the between-class SSCP matrix and the total-sample corrected SSCP matrix. By default, the significance level of an F test from an analysis of covariance is used as the selection criterion. The variable under consideration is the dependent variable, and the variables already chosen act as covariates. The following SAS statements produce [Output 67.1.1](#) through [Output 67.1.8](#):

```

proc stepdisc data=iris bsscp tsscp;
  class Species;
  var SepalLength SepalWidth PetalLength PetalWidth;
run;

```

Output 67.1.1. Iris Data: Summary Information

```

In Step 1, the tolerance is 1.0 for each variable under consideration because no variables have yet entered the model. Variable `PetalLength` is selected because its F statistic, 1180.161, is the largest among all variables.

Output 67.1.3. Iris Data: Stepwise Selection Step 1

Average Squared Canonical Correlation  0.470686
    
```

In Step 2, with variable `PetalLength` already in the model, `PetalLength` is tested for removal before selecting a new variable for entry. Since `PetalLength` meets the criterion to stay, it is used as a covariate in the analysis of covariance for variable selection. Variable `SepalWidth` is selected because its F statistic, 43.035, is the largest among all variables not in the model and its associated tolerance, 0.8164, meets the criterion to enter. The process is repeated in Steps 3 and 4. Variable `PetalWidth` is entered in Step 3, and variable `SepalLength` is entered in Step 4.

Chapter 68

The SURVEYFREQ Procedure

Overview

The SURVEYFREQ procedure produces one-way to n -way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals and proportions, and the corresponding standard errors. PROC SURVEYFREQ computes the variance estimates based on the sample design used to obtain the survey data. The design can be a complex multistage survey design with stratification, clustering, and unequal weighting. PROC SURVEYFREQ also provides design-based tests of independence and association between variables.

PROC SURVEYFREQ uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice. The Taylor expansion method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters or primary sampling units (PSUs) in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate.

Getting Started

The following example shows how you can use PROC SURVEYFREQ to analyze sample survey data. The example uses data from a customer satisfaction survey for a student information system (SIS), a software product that provides modules for student registration, class scheduling, attendance, grade reporting, and other functions.

The software company conducted a survey of school personnel who use the SIS. A probability sample of SIS users was selected from the study population, which included SIS users at middle schools and high schools in the three-state area of Georgia, South Carolina, and North Carolina. The sample design for this survey was a two-stage stratified design. A first-stage sample of schools was selected from the list of schools using the SIS in the three-state area. The list of schools, or the first-stage sampling frame, was stratified by state and by customer status (whether the school was a new user of the system, or a renewal user). Within the first-stage strata, schools were selected with probability proportional to size and with replacement, where the size measure was school enrollment. From each sample school, five staff members were randomly selected to complete the SIS satisfaction questionnaire. These staff members included three teachers, and two administrators or guidance staff members.

The SAS data set `SIS_Survey` contains the survey results, as well as the sample design information needed to analyze the data. This data set includes an observation for each school staff member responding to the survey. The variable `Response` contains the staff member's response on overall satisfaction with the system.

The variable `State` contains the school's state, and the variable `NewUser` contains the school's customer status ('New Customer' or 'Renewal Customer'). These two variables determine the first stage strata from which schools were selected. The variable `School` contains the school identification code and identifies the first-stage sampling units, or clusters. The variable `SamplingWeight` contains the overall sampling weight for each respondent. Overall sampling weights were computed from the selection probabilities at each stage of sampling and were adjusted for nonresponse.

Other variables in the data set `SIS_Survey` include `SchoolType` and `Department`. The variable `SchoolType` identifies the school as a high school or a middle school. The variable `Department` identifies the staff member as a teacher, or an administrator or guidance department member.

The following PROC SURVEYFREQ statements request a one-way table for the variable `Response`.

```

title 'School Information System Survey';
proc surveyfreq data=SIS_Survey;
  tables Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;

```

The PROC SURVEYFREQ statement invokes the procedure and identifies the input data set to be analyzed. The TABLES statement requests a one-way table for the variable `Response`. The table request syntax for PROC SURVEYFREQ is very similar to the PROC FREQ table request syntax. This example shows a request for a single one-way table, but you can also request two-way tables or multiway tables. As in PROC FREQ, you can request more than one table in the same TABLES statement, and you can use multiple TABLES statements in the same invocation of PROC SURVEYFREQ.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information to the procedure, so that the analysis is done according to the sample design used for the survey, and the estimates apply to the study population. The STRATA statement names the variables `State` and `NewUser`, which identify the first-stage strata. Note that the design for this example also includes stratification at the second stage of selection (by type of school personnel), but you specify only the first-stage strata for PROC SURVEYFREQ. The CLUSTER statement identifies `School` as the cluster or first-stage sampling unit. The WEIGHT statement names the sampling weight variable.

Figure 68.1 and Figure 68.2 display the output produced by PROC SURVEYFREQ, which includes the Data Summary table and the one-way Table of Response. The Data Summary table is produced by default unless you specify the NOSUMMARY option. This table shows there are 6 strata, 370 clusters or schools, and 1850 observations or respondents in the SIS_Survey data set. The sum of the sampling weights is approximately 39,000, which estimates the total number of school personnel using the SIS in the study area.

School Information System Survey	
The SURVEYFREQ Procedure	
Data Summary	
Number of Strata	6
Number of Clusters	370
Number of Observations	1850
Sum of Weights	38899.6482

Figure 68.1. SIS_Survey Data Summary

Figure 68.2 displays the one-way table for Response, which provides estimates of the population total (weighted frequency) and the population percentage for each category, or level, of Response. The response level 'Very Unsatisfied' has a frequency of 304, which means that 304 sample respondents fall into this category. It is estimated that 17.17% of all school personnel in the study population fall into this category, and the standard error of this estimate is 1.29%. Note that the estimates apply to the population of all SIS users in the study area, as opposed to describing only the sample of 1850 respondents. The estimate of the total number of school personnel 'Very Unsatisfied' is 6,678, with a standard deviation of 502. The standard errors computed by PROC SURVEYFREQ are based on the multistage stratified design used for the survey. This differs from some of the traditional analysis procedures, which assume the design is simple random sampling from an infinite population.

School Information System Survey					
Table of Response					
Response	Frequency	Weighted Frequency	Std Dev of Wgt Freq	Percent	Std Err of Percent
Very Unsatisfied	304	6678	501.61039	17.1676	1.2872
Unsatisfied	326	6907	495.94101	17.7564	1.2712
Neutral	581	12291	617.20147	31.5965	1.5795
Satisfied	455	9309	572.27868	23.9311	1.4761
Very Satisfied	184	3714	370.66577	9.5483	0.9523
Total	1850	38900	129.85268	100.000	

Figure 68.2. One-Way Table of Response

The following PROC SURVEYFREQ statements request confidence limits for the percentage estimates and a chi-square goodness-of-fit test for the one-way table of Response.

```
proc surveyfreq data=SIS_Survey nosummary;
  tables Response / cl nowt chisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The NOSUMMARY option in the PROC statement suppresses the Data Summary table. In the TABLES statement, the CL option requests confidence limits for the percentages in the one-way table. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square goodness-of-fit test.

Figure 68.3 shows the one-way table of Response, which includes confidence limits for the percentages. The 95% confidence limits for the percentage of users that are 'Very Unsatisfied' are 14.64% and 19.70%. To change the α level of the confidence limits, which equals 5% by default, you can use the ALPHA= option. As for the other estimates and standard errors produced by PROC SURVEYFREQ, these confidence limit computations take into account the complex sample design used for the survey, and the results apply to the entire study population.

School Information System Survey						
The SURVEYFREQ Procedure						
Table of Response						
Response	Frequency	Percent	Std Err of Percent	95% Confidence Limits for Percent		
Very Unsatisfied	304	17.1676	1.2872	14.6364	19.6989	
Unsatisfied	326	17.7564	1.2712	15.2566	20.2562	
Neutral	581	31.5965	1.5795	28.4904	34.7026	
Satisfied	455	23.9311	1.4761	21.0285	26.8338	
Very Satisfied	184	9.5483	0.9523	7.6756	11.4210	
Total	1850	100.000				

Figure 68.3. Confidence Limits for Response Percentages

Figure 68.4 shows the chi-square goodness-of-fit results for the table of **Response**. The null hypothesis for this test is equal proportions for the levels of the one-way table. (To test a null hypothesis of specified proportions instead of equal proportions, you can use the `TESTP=` option to specify null hypothesis proportions.)

The chi-square test invoked by the `CHISQ` option is the Rao-Scott design-adjusted chi-square test, which takes the survey design into account and provides inferences for the entire study population. To produce the Rao-Scott chi-square statistic, `PROC SURVEYFREQ` first computes the usual Pearson chi-square statistic based on the weighted frequencies, and then adjusts this value with a design correction. An F approximation is also provided. For the table of **Response**, the F value is 632.85 with a p -value $< .0001$, which leads to rejection of the null hypothesis of equal proportions for all response levels.

Table of Response	
Rao-Scott Chi-Square Test	
Pearson Chi-Square	5294.7773
Design Correction	2.0916
Rao-Scott Chi-Square	2531.3980
DF	4
Pr > ChiSq	<.0001
F Value	632.8495
Num DF	4
Den DF	1456
Pr > F	<.0001
Sample Size = 1850	

Figure 68.4. Chi-Square Goodness-of-Fit Test for Response

Continuing to analyze the `SIS_Survey` data, the following `PROC SURVEYFREQ` statements request a two-way table for the variables `SchoolType` by `Response`.

```
proc surveyfreq data=SIS_Survey nosummary;
  tables SchoolType * Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The `STRATA`, `CLUSTER` and `WEIGHT` statements do not change from the one-way table example, since the survey design and the input data set are the same. These `SURVEYFREQ` statements request a different table, but specify the same sample design information.

Figure 68.5 shows the two-way table produced. The first variable named in the two-way table request, `SchoolType`, is referred to as the *row variable*, and the second variable named, `Response`, is referred to as the *column variable*. Two-way tables display all column variable levels for each row variable level. So this two-way table lists all levels of the column variable `Response` for each level of the row variable `SchoolType`, 'Middle School' and 'High School'. Also `SchoolType = 'Total'` shows the distribution of `Response` overall for both types of schools. And `Response = 'Total'` provides totals over all levels of response, for each type of school and overall. To suppress these totals, you can use the `NOTOTAL` option.

By default, without any other `TABLES` statement options, a two-way table displays the frequency, weighted frequency and its standard deviation, and percentage and its standard error for each table cell, or combination of row and column variable levels. But there are several options available to customize your table display by adding more information or suppressing some of the default information.

School Information System Survey						
The SURVEYFREQ Procedure						
Table of SchoolType by Response						
SchoolType	Response	Frequency	Weighted Frequency	Std Dev of Wgt Freq	Percent	Std Err of Percent

	Very Satisfied	184	3714	370.66577	9.5483	0.9523
	Total		1850	38900	129.85268	100.000

Figure 68.5. Two-Way Table of SchoolType by Response

The following PROC SURVEYFREQ statements request a two-way table of SchoolType by Response with row percentages, and also request a chi-square test for association between the two variables.

```
proc surveyfreq data=SIS_Survey nosummary;
  tables SchoolType * Response / row nowt chisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The ROW option in the TABLES statement requests row percentages, which display the distribution of Response as a percentage of each level of the row variable SchoolType. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square test of association between SchoolType and Response.

Figure 68.6 displays the two-way table produced. For middle schools, it is estimated that 25.79% of school personnel are satisfied with the school information system, and 12.39% are very satisfied. For high schools, these estimates are 22.67% and 7.61%, respectively.

School Information System Survey						
The SURVEYFREQ Procedure						
Table of SchoolType by Response

Figure 68.7. Chi-Square Test of No Association

Syntax

The following statements are available in PROC SURVEYFREQ.

```
PROC SURVEYFREQ < options > ;
  BY variables ;
  CLUSTER variables ;
  STRATA variables < / option > ;
  TABLES requests < / options > ;
  WEIGHT variable ;
```

The PROC SURVEYFREQ statement invokes the procedure, identifies the data set to be analyzed, and provides sample design information. The PROC SURVEYFREQ statement is required.

The TABLES statement specifies frequency or crosstabulation tables and requests tests and statistics for those tables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The WEIGHT statement names the sampling weight variable. You can use a BY statement with PROC SURVEYFREQ to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYFREQ statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLUSTER, STRATA, TABLES, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYFREQ statement.

PROC SURVEYFREQ Statement

PROC SURVEYFREQ < options > ;

The PROC SURVEYFREQ statement invokes the procedure. In this statement, you identify the data set to be analyzed and specify sample design information. The DATA= option names the input data set to be analyzed. If your analysis includes a finite population correction factor, you can input either the sampling rate or the population total using the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set containing the stratification variables.

You can specify the following options in the PROC SURVEYFREQ statement:

DATA=SAS-data-set

names the SAS data set to be analyzed by PROC SURVEYFREQ. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MISSING

requests that the procedure treat missing values as a valid category for all categorical variables, which include TABLES variables, STRATA variables, and CLUSTER variables. For more information, see the section “Missing Values” on page 4205.

NOSUMMARY

suppresses the display of the Data Summary table, which PROC SURVEYFREQ produces by default. For a description of this table, see the section “Data and Sample Design Summary Table” on page 4225.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the order in which the values of the frequency and crosstabulation table variables are to be reported. The following table shows how PROC SURVEYFREQ interprets values of the ORDER= option:

DATA	orders values according to their order in the input data set.
FORMATTED	orders values by their formatted values. This order is operating-environment dependent. By default, the order is ascending.
FREQ	orders values by descending frequency count. The frequency count of a variable value is its (nonweighted) frequency of occurrence or sample size, and not its weighted frequency.
INTERNAL	orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating-environment dependent.

By default, ORDER=INTERNAL.

PAGE

displays only one table per page. Otherwise, PROC SURVEYFREQ displays multiple tables per page as space permits.

RATE=value | SAS-data-set**R=value | SAS-data-set**

specifies the sampling rate as a nonnegative *value*, or identifies an input data set that gives the stratum sampling rates in a variable named `_RATE_`. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Population Totals and Sampling Rates](#)” on page 4204 for more details.

The sampling rate *value* must be a nonnegative number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

TOTAL=value | SAS-data-set**N=value | SAS-data-set**

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or identifies an input data set that gives the stratum population totals in a variable named `_TOTAL_`. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Population Totals and Sampling Rates](#)” on page 4204 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC SURVEYFREQ to obtain separate analyses on observations in groups defined by the BY variables. The *variables* are one or more variables in the input data set.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, the difference being that in domain analysis the total number of units in the subpopulation is not known with certainty. You should include the domain variable(s) in your TABLES request to obtain domain analysis. See the section “[Domain Analysis](#)” on page 4205 for more details.

If you specify more than one BY statement, the procedure uses only the last BY statement and ignores any previous BY statements.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the FREQ procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLUSTER Statement

CLUSTER *variables* ;

The CLUSTER statement names variables that identify the first-stage clusters, or PSUs, in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a [STRATA](#) statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters or primary sampling units (PSUs) in the CLUSTER statement. See the section “[Specifying the Sample Design](#)” on page 4203 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can either be character or numeric, but the procedure treats them as categorical variables. The formatted values of the CLUSTER variables determine the

CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can use multiple CLUSTER statements to specify CLUSTER variables. The procedure uses variables from all CLUSTER statements to create clusters.

STRATA Statement

STRATA *variables* < / *option* > ;

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “[Specifying the Sample Design](#)” on page 4203 for more information.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a “Stratum Information” table, which lists all strata together with the corresponding values of the STRATA variables. This table provides the number of observations and number of clusters for each stratum, as well as the sampling fraction if you specify the RATE= or the TOTAL= option. See the section “[Stratum Information Table](#)” on page 4225 for more information.

TABLES Statement

TABLES *requests* < / *options* > ;

The TABLES statement requests one-way to *n*-way frequency and crosstabulation tables and statistics for those tables.

If you omit the TABLES statement, PROC SURVEYFREQ generates one-way frequency tables for all data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement.

requests

specify the frequency and crosstabulation tables to produce. A *request* is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an *n*-way

table, where $n > 2$), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and layers of the table.

For two-way tables to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate crosstabulation table for each layer. For example, a specification of $A*B*C*D$ in a TABLES statement produces k tables, where k is the number of different combinations of levels for A and B . Each table lists the levels for D (columns) within each level of C (rows).

You can use multiple TABLES statements in the PROC SURVEYFREQ step. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. For example, the following statements illustrate grouping syntax:

Table 68.1. Grouping Syntax

Request	Equivalent to
tables A*(B C);	tables A*B A*C;
tables (A B)*(C D);	tables A*C B*C A*D B*D;
tables (A B C)*D;	tables A*D B*D C*D;
tables A -- C;	tables A B C;
tables (A -- C)*D;	tables A*D B*D C*D;

The TABLES statement variables are one or more variables from the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC SURVEYFREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a FORMAT statement, PROC SURVEYFREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the ORDER= option. To list the values in ascending order by formatted value, use ORDER=FORMATTED in the PROC SURVEYFREQ statement.

Without Options

If you request a frequency or crosstabulation table without specifying options, PROC SURVEYFREQ produces the following for each table level or cell:

- frequency (sample size)
- weighted frequency (estimated total)
- standard error of weighted frequency
- percentage (estimated proportion)
- standard error of percentage

The table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFREQ option in the TABLES statement. The table also displays the number of observations with missing values. See the section “[One-Way Frequency Tables](#)” on page 4226 and the section “[Crosstabulation Tables](#)” on page 4227 for more information.

Options

The following table lists the options available with the TABLES statement. Descriptions follow in alphabetical order.

Table 68.2. TABLES Statement Options

Option	Description
Control Statistical Analysis	
ALPHA=	sets the level for confidence limits
CHISQ	requests Rao-Scott chi-square test
CHISQ1	requests Rao-Scott modified chi-square test
DDF=	specifies denominator DF for Wald chi-square tests
LRCHISQ	requests Rao-Scott likelihood ratio test
LRCHISQ1	requests Rao-Scott modified likelihood ratio test
TESTP=	specifies null proportions for one-way chi-square tests
WCHISQ	requests Wald chi-square test
WLLCHISQ	requests Wald log-linear chi-square test
Control Additional Table Information	
CL	displays confidence limits for percents
CLWT	displays confidence limits for weighted frequencies
COL	displays column percents and standard errors
CV	displays coefficients of variation for percents
CVWT	displays coefficients of variation for weighted frequencies
DEFF	displays design effects for percents
EXPECTED	displays expected weighted frequencies for two-way tables
ROW	displays row percents and standard errors
VAR	displays variances for percents
VARWT	displays variances for weighted frequencies
WTFREQ	displays weighted frequencies and standard errors when there is no WEIGHT statement
Control Displayed Output	
NOFREQ	suppresses display of frequency counts
NOPERCENT	suppresses display of percents
NOPRINT	suppresses display of tables but displays statistical tests
NOSPARE	suppresses display of zero rows and columns in two-way tables
NOSTD	suppresses display of standard errors for all estimates
NOTOTAL	suppresses display of row and column totals
NOWT	suppresses display of weighted frequencies

You can specify the following options in a TABLES statement:

ALPHA= α

sets the level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

You request confidence limits for percentages with the CL option, and you request confidence limits for weighted frequencies with the CLWT option. See the section “Confidence Limits” on page 4213 for more information.

CHISQ

requests the Rao-Scott chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies. See the section “Rao-Scott Chi-Square Test” on page 4216 for more information.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

The CHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the CHISQ1 option.

CHISQ1

requests the Rao-Scott modified chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “Rao-Scott Chi-Square Test” on page 4216 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the CHISQ option.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

CL

requests confidence limits for the percentages, or proportion estimates, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. See the section “Confidence Limits” on page 4213 for more information.

CLWT

requests confidence limits for the weighted frequencies, or estimated totals, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. See the section “Confidence Limits” on page 4213 for more information.

COL

displays the column percentage, or estimated proportion of the column total, for each cell in a two-way table. The COL option also displays the standard errors of the column percentages. See the section “[Row and Column Proportions](#)” on page 4212 for more information. This option has no effect for one-way tables.

CV

displays the coefficient of variation for each percentage, or proportion estimate, in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 4214 for more information.

CVWT

displays the coefficient of variation for each weighted frequency, or estimated total, in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 4214 for more information.

DDF=*df*

specifies the denominator degrees of freedom for the F -statistics used in the Wald chi-square tests. By default, the denominator degrees of freedom is the number of clusters minus the number of strata. See the section “[Wald Chi-Square Test](#)” on page 4221 and the section “[Wald Log-Linear Chi-Square Test](#)” on page 4223 for more information. You request the Wald chi-square test with the [WCHISQ](#) option, and you request the Wald log-linear chi-square test with the [WLLCHISQ](#) option.

DEFF

displays the design effect for each overall proportion estimate in the crosstabulation table. See the section “[Design Effect](#)” on page 4215 for more information.

EXPECTED

displays expected weighted frequencies for the table cells in a two-way table. The expected frequencies are computed under the null hypothesis that the row and column variables are independent. See the section “[Expected Weighted Frequency](#)” on page 4215 for more information. This option has no effect for one-way tables.

LRCHISQ

requests the Rao-Scott likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 4219 for more information.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the [TESTP=](#) option.

The LRCHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the [LRCHISQ1](#) option.

LRCHISQ1

requests the Rao-Scott modified likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page

4219 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the [LRCHISQ](#) option.

By default for one-way tables, the [LRCHISQ](#) option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the [TESTP=](#) option.

NOFREQ

suppresses the display of cell frequencies in the crosstabulation table. The [NOFREQ](#) option also suppresses the display of row, column, and overall table frequencies.

NOPERCENT

suppresses the display of cell percentages in the crosstabulation table. The [NOPERCENT](#) option also suppresses the display of standard errors of the percentages.

NOPRINT

suppresses the display of frequency and crosstabulation tables but displays all requested statistical tests. Note that this option disables the Output Delivery System (ODS) for the suppressed tables. For more information, see [Chapter 14](#), “Using the Output Delivery System.”

NOSPARSE

suppresses the display of variable levels with zero frequency in two-way tables. By default, the procedure displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row variable levels with zero frequency for the layer. Also by default, the procedure displays all variable levels that occur in the input data set, including those levels with no observations actually used in the analysis due to missing or nonpositive weights or missing values. See the section “[Missing Values](#)” on page 4205 for details.

NOSTD

suppresses the display of all standard errors in the crosstabulation table.

NOTOTAL

suppresses the display of row totals, column totals, and overall totals in the crosstabulation table.

NOWT

suppresses the display of weighted frequencies in the crosstabulation table. The [NOWT](#) option also suppresses the display of standard errors of the weighted frequencies.

ROW

displays the row percentage, or estimated proportion of the row total, for each cell in a two-way table. The [ROW](#) option also displays the standard errors of the row percentages. See the section “[Row and Column Proportions](#)” on page 4212 for more information. This option has no effect for one-way tables.

TESTP=(values)

specifies null hypothesis proportions, or test percentages, for one-way chi-square tests. You can separate *values* with blanks or commas. Specify *values* in probability form as numbers between 0 and 1, where the proportions sum to 1. Or specify *values* in percentage form as numbers between 0 and 100, where the percentages sum to 100. PROC SURVEYFREQ treats the value 1 as the percentage form 1%. The number of TESTP= values must equal the number of variable levels in the one-way table. List these values in the order in which the corresponding variable levels appear in the output.

When you specify the TESTP= option, PROC SURVEYFREQ displays the specified test percentages in the one-way frequency table. The TESTP= option has no effect for two-way tables.

PROC SURVEYFREQ uses the TESTP= values for all one-way chi-square tests you request in the TABLES statement. The available one-way chi-square tests include the Rao-Scott (Pearson) chi-square test and the Rao-Scott likelihood ratio chi-square test and their modified versions, requested by options [CHISQ](#), [CHISQ1](#), [LRCHISQ](#), and [LRCHISQ1](#). See the section “[Rao-Scott Chi-Square Test](#)” on page 4216 and the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 4219 for more details.

VAR

displays the variance estimate for each percentage in the crosstabulation table. See the section “[Proportions](#)” on page 4210 for details.

VARWT

displays the variance estimate for each weighted frequency, or estimated total, in the crosstabulation table. See the section “[Totals](#)” on page 4209 for details.

WCHISQ

requests the Wald chi-square test. See the section “[Wald Chi-Square Test](#)” on page 4221 for more information. By default, the denominator degrees of freedom for the Wald test *F*-statistic is the number of clusters minus the number of strata. Alternatively, you can specify the denominator degrees of freedom with the [DDF=](#) option.

WLLCHISQ

requests the Wald log-linear chi-square test. See the section “[Wald Log-Linear Chi-Square Test](#)” on page 4223 for more information. By default, the denominator degrees of freedom for the Wald test *F*-statistic is the number of clusters minus the number of strata. Alternatively, you can specify the denominator degrees of freedom with the [DDF=](#) option.

WTFREQ

displays the weighted frequencies and their standard errors when you do not specify a WEIGHT statement. PROC SURVEYFREQ displays the weighted frequencies by default when the analysis includes a WEIGHT statement. Without a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1.

WEIGHT Statement

WEIGHT *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “[Missing Values](#)” on page 4205 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

Details

Specifying the Sample Design

PROC SURVEYFREQ produces tables and statistics based on the sample design used to obtain the survey data. The procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. See the section “[Statistical Computations](#)” on page 4206 for details. This method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice.

PROC SURVEYFREQ can be used for single-stage designs or for multistage designs, with or without stratification, and with or without unequal weighting. You provide sample design information with the [STRATA](#), [CLUSTER](#), and [WEIGHT](#) statements, and with the [RATE=](#) or [TOTAL=](#) option in the PROC SURVEYFREQ statement.

When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variance among PSUs. For a multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

Stratification

If your sample design is stratified at the first stage of sampling, use the [STRATA](#) statement to name variables that form the strata. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. If you do not specify a STRATA statement, PROC SURVEYFREQ assumes there is no stratification at the first stage.

Clustering

If your sample design selects clusters at the first stage of sampling, use the [CLUSTER](#) statement to name variables that identify the first-stage clusters, or primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters, or PSUs, in the CLUSTER statement. PROC SURVEYFREQ assumes that each cluster defined by the CLUSTER statement variables represents a PSU in the sample, and that each observation belongs to one PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.

Weighting

If your sample design includes unequal weighting, use the WEIGHT statement to name the variable that contains the sampling weights. If you do not specify a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 4205 for more information.

Population Totals and Sampling Rates

If your analysis needs to include a finite population correction (*fpc*), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option in the PROC SURVEYFREQ statement. (You cannot specify both of these options in the same PROC SURVEYFREQ statement.) If you do not specify one of these options, the procedure does not use the *fpc* when computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the RATE=*value* option or the TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the RATE=SAS-*data-set* option or the TOTAL=SAS-*data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. Furthermore, the BY groups must appear in the same order as in the primary data set. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-*data-set* option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. Alternatively, if you specify the RATE=SAS-*data-set* option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Domain Analysis

PROC SURVEYFREQ provides domain analysis through its multiway table capability. *Domain Analysis* refers to the computation of statistics for subpopulations, or domains, in addition to the computation of statistics for the entire study population. Formation of these domains may be unrelated to the sample design, so the domain sample sizes may actually be random variables. Domain analysis takes into account this variability, using the entire sample when estimating variance for domain estimates. This is also known as subgroup analysis, subpopulation analysis, or subdomain analysis. For more information on domain analysis, refer to Lohr (1999), Cochran (1977), and Fuller et al. (1989).

To request domain analysis with PROC SURVEYFREQ, you should include the domain variable(s) in your TABLES statement request. For example, specifying DOMAIN * A * B in a TABLES statement produces separate two-way tables of A by B for each level of DOMAIN. If your domains are formed by more than one variable, you can specify DomainVariable_1 * DomainVariable_2 * A * B, for example, to obtain two-way tables of A by B for each domain formed by the different combinations of levels for DomainVariable_1 and DomainVariable_2.

Including the domain variables in a TABLES statement request gives a different analysis from that obtained by using a BY statement, which provides completely separate analyses of the BY groups. The BY statement can also be used to analyze the dataset by subgroups, but it is critical to note that this will *not* produce a valid domain analysis. The BY statement is only appropriate when the number of units in each subgroup is known with certainty; when the subgroup sample size is a random variable, include the domain variables in your TABLES statement request.

Missing Values

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYFREQ excludes that observation from the analysis.

An observation is also excluded from the analysis if it has a missing value for any STRATA or CLUSTER variable, unless you specify the MISSING option in the PROC SURVEYFREQ statement. The MISSING option requests that the procedure treat missing values as a valid category for all categorical variables, which include strata variables, cluster variables, and classification or table variables.

Additionally, PROC SURVEYFREQ excludes an observation from a crosstabulation table (and any associated analyses) if that observation has a missing value for any

of the table variables, unless you specify the MISSING option. When the procedure excludes observations with missing values from a table, it displays the total frequency of missing observations below that table. With the MISSING option, the procedure treats the missing values as a valid category and includes them in calculations of percentages and other statistics.

If all values in a stratum are excluded from the analysis of a table as missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the table, which is used to determine the degrees of freedom for confidence limits and tests. Similarly, empty clusters and missing observations are not included in the total counts of clusters and observations used in the analysis of the table.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS summary table that contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the requested table. When there are missing observations, empty strata, or empty clusters for the requested table, then these numbers in the “Table Summary” differ from the total number of observations, strata, and clusters that are present in the input data set and reported in the “Data Summary.” See [Example 68.3](#) on page 4236 for more information on the “Table Summary.”

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. Once data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYFREQ. Refer to Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more details.

Statistical Computations

The SURVEYFREQ procedure uses the Taylor series expansion method to estimate standard errors of estimators of proportions for crosstabulation tables. For sample survey data, the proportion estimator is a ratio estimator formed from estimators of totals. For example, to estimate the proportion in a crosstabulation table cell, the procedure uses the ratio of the estimator of the cell total frequency to the estimator of the overall population total, where these totals are linear statistics computed from the survey data. The Taylor series expansion method obtains a first-order linear approximation for the ratio estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975).

When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variance among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate. For a

multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

In addition to this required sample design information, you also need to specify the sampling weights for a valid analysis, if the weights are not equal. Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse.

For more information on the analysis of sample survey data, refer to Lohr (1999), Särndal, Swenson, and Wretman (1992), Lee, Forthoffer, and Lorimor (1989), Cochran (1977), Kish (1965), and Hansen, Hurwitz, and Madow (1953).

Definitions and Notation

For a stratified clustered sample design, define the following:

$h = 1, 2, \dots, H$ is the stratum number, with a total of H strata

$i = 1, 2, \dots, n_h$ is the cluster number within stratum h ,
with a total of n_h sample clusters from stratum h

$j = 1, 2, \dots, m_{hi}$ is the unit number within cluster i of stratum h ,
with a total of m_{hi} sample units from cluster i of stratum h

$n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample

$f_h =$ first-stage sampling rate for stratum h

$W_{hij} =$ sampling weight of unit j in cluster i of stratum h

The sampling rate f_h is the fraction of first-stage units (PSUs) selected for the sample. You can specify the stratum sampling rates with the `RATE=` option. Or if you specify population totals with the `TOTAL=` option, PROC SURVEYFREQ computes f_h as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section “Population Totals and Sampling Rates” on page 4204 for details. If you do not specify the `RATE=` option or the `TOTAL=` option, then the procedure assumes that the stratum sampling rates f_h are negligible and does not use a finite population correction when computing variances.

This notation is also applicable to other sample designs. For example, for a design without stratification, you can let $H = 1$; for a sample design without clustering, you can let $m_{hi} = 1$ for every h and i , replacing clusters with individual sampling units.

For a two-way table representing the crosstabulation of two variables, define the following, where there are R levels of the row variable and C levels of the column variable:

$r = 1, 2, \dots, R$ is the row number, with a total of R rows

$c = 1, 2, \dots, C$ is the column number, with a total of C columns

N_{rc} = is the population total in row r and column c

$N_{r\cdot} = \sum_{c=1}^C N_{rc}$ is the total in row r

$N_{\cdot c} = \sum_{r=1}^R N_{rc}$ is the total in column c

$N = \sum_{r=1}^R \sum_{c=1}^C N_{rc}$ is the overall total

$P_{rc} = N_{rc} / N$ is the population proportion in row r and column c

$P_{r\cdot} = N_{r\cdot} / N$ is the proportion in row r

$P_{\cdot c} = N_{\cdot c} / N$ is the proportion in column c

$P_{rc}^r = N_{rc} / N_{r\cdot}$ is the row proportion for cell (r, c)

$P_{rc}^c = N_{rc} / N_{\cdot c}$ is the column proportion for cell (r, c)

For a specified observation (identified by stratum, cluster, and unit number within the cluster), define the following to indicate whether or not that observation belongs to cell (r, c) , row r and column c , of the two-way table, for $r = 1, 2, \dots, R$ and $c = 1, 2, \dots, C$:

$$\delta_{hij}(r, c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in cell } (r, c) \\ 0 & \text{otherwise} \end{cases}$$

Similarly, define the following functions to indicate the observation's row classification and the observation's column classification.

$$\delta_{hij}(r) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in row } r \\ 0 & \text{otherwise} \end{cases}$$

$$\delta_{hij}(c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in column } c \\ 0 & \text{otherwise} \end{cases}$$

Totals

PROC SURVEYFREQ estimates population frequency totals for the specified crosstabulation tables, including totals for two-way table cells, rows, columns, and overall totals. The procedure computes the estimate of the total frequency in table cell (r, c) as the weighted frequency sum

$$\widehat{N}_{rc} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}$$

Similarly, PROC SURVEYFREQ computes estimates of the row totals, column totals, and overall totals as

$$\widehat{N}_{r\cdot} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r) W_{hij}$$

$$\widehat{N}_{\cdot c} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(c) W_{hij}$$

$$\widehat{N} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}$$

The estimators of totals are linear sample statistics, and so their variances can be estimated directly, without the Taylor series approximation that is used for proportions. PROC SURVEYFREQ estimates the variance of the total frequency in table cell (r, c) as

$$\widehat{\text{Var}}(\widehat{N}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{N}_{rc})$$

where if $n_h > 1$,

$$\widehat{\text{Var}}_h(\widehat{N}_{rc}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h)^2$$

$$n_{rc}^{hi} = \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}$$

$$\bar{n}_{rc}^h = \sum_{i=1}^{n_h} n_{rc}^{hi} / n_h$$

and if $n_h = 1$,

$$\widehat{\text{Var}}_h(\widehat{N}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard deviation of the total is computed as

$$\text{Std}(\widehat{N}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{N}_{rc})}$$

The variances and standard deviations are computed in a similar manner for row totals, column totals, and overall table totals.

Covariance of Totals

PROC SURVEYFREQ estimates the covariance between total frequency estimates for table cells (r, c) and (a, b) as

$$\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab}) = \sum_{h=1}^H \left(\frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h) (n_{ab}^{hi} - \bar{n}_{ab}^h) \right)$$

The estimated covariance matrix of the table cell totals \widehat{N}_{rc} is an $rc \times rc$ matrix $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$, which contains the pair-wise table cell covariances $\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab})$, for $r = 1, \dots, R$; $c = 1, \dots, C$; $a = 1, \dots, R$; and $b = 1, \dots, C$.

Proportions

PROC SURVEYFREQ computes the estimate of the proportion in table cell (r, c) as the ratio of the estimated total for the table cell to the estimated overall total,

$$\begin{aligned} \widehat{P}_{rc} &= \widehat{N}_{rc} / \widehat{N} \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij} \end{aligned}$$

Using the Taylor series expansion method, PROC SURVEYFREQ estimates the variance of this proportion estimate as

$$\widehat{\text{Var}}(\widehat{P}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc})$$

where if $n_h > 1$,

$$\begin{aligned} \widehat{\text{Var}}_h(\widehat{P}_{rc}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{rc}^{hi} - \bar{e}_{rc}^h)^2 \\ e_{rc}^{hi} &= \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}) W_{hij} \right) / \widehat{N} \\ \bar{e}_{rc}^h &= \sum_{i=1}^{n_h} e_{rc}^{hi} / n_h \end{aligned}$$

and if $n_h = 1$,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard error of the proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc})}$$

Similarly, the estimate of the proportion in row r is

$$\widehat{P}_{r.} = \widehat{N}_{rc} / \widehat{N}$$

And its variance estimate is

$$\widehat{\text{Var}}(\widehat{P}_{r.}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{r.})$$

where if $n_h > 1$,

$$\begin{aligned} \widehat{\text{Var}}_h(\widehat{P}_{r.}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{r.}^{hi} - \bar{e}_{r.}^h)^2 \\ e_{r.}^{hi} &= \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r) - \widehat{P}_{r.}) W_{hij} \right) / \widehat{N} \\ \bar{e}_{r.}^h &= \sum_{i=1}^{n_h} e_{r.}^{hi} / n_h \end{aligned}$$

and if $n_h = 1$,

$$\widehat{\text{Var}}_h(\widehat{P}_{r.}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard error of the proportion in row r is computed as

$$\text{StdErr}(\widehat{P}_{r.}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{r.})}$$

Computations for the proportion in column c are done in the same way.

Row and Column Proportions

PROC SURVEYFREQ computes the estimate of the row proportion for table cell (r, c) as the ratio of the estimated total for the table cell to the estimated total for row r ,

$$\begin{aligned}\widehat{P}_{rc}^r &= \widehat{N}_{rc} / \widehat{N}_r \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r) W_{hij}\end{aligned}$$

Again using the Taylor series expansion method, PROC SURVEYFREQ estimates the variance of this row proportion estimate as

$$\widehat{\text{Var}}(\widehat{P}_{rc}^r) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc}^r)$$

where if $n_h > 1$,

$$\begin{aligned}\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{rc}^{hi} - \bar{g}_{rc}^h)^2 \\ g_{rc}^{hi} &= \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}^r \delta_{hij}(r)) W_{hij} \right) / \widehat{N}_r \\ \bar{g}_{rc}^h &= \sum_{i=1}^{n_h} g_{rc}^{hi} / n_h\end{aligned}$$

and if $n_h = 1$,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard error of the row proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}^r) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc}^r)}$$

Similarly, PROC SURVEYFREQ estimates the column proportion for table cell (r, c) as the ratio of the estimated total for the table cell to the estimated total for column c ,

$$\begin{aligned}\widehat{P}_{rc}^c &= \widehat{N}_{rc} / \widehat{N}_{.c} \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(c) W_{hij}\end{aligned}$$

The variance estimate for the column proportion is computed as described above for the row proportion, but with

$$g_{rc}^{hi} = \left(\sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \hat{P}_{rc}^c \delta_{hij}(c)) W_{hij} \right) / \hat{N}_{.c}$$

Confidence Limits

If you specify the **CL** option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the proportions in the frequency and crosstabulation tables. The confidence coefficient is determined according to the value of the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

For the proportion in table cell (r, c) , the confidence limits are computed as

$$\hat{P}_{rc} \pm t_{df, \alpha/2} \cdot \text{StdErr}(\hat{P}_{rc})$$

where \hat{P}_{rc} is the estimate of the proportion in table cell (r, c) , $\text{StdErr}(\hat{P}_{rc})$ is the standard error of the estimate, and $t_{df, \alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the t distribution with df degrees of freedom calculated as described in the “**Degrees of Freedom**” section on page 4214. The confidence limits for row proportions and column proportions are computed similarly to the confidence limits for table cell proportions.

If you specify the **CLWT** option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the weighted frequencies, or totals, in the crosstabulation tables.

For the total in table cell (r, c) , the confidence limits are computed as

$$\hat{N}_{rc} \pm t_{df, \alpha/2} \cdot \text{StdErr}(\hat{N}_{rc})$$

where \hat{N}_{rc} is the estimate of the total frequency in table cell (r, c) , $\text{StdErr}(\hat{N}_{rc})$ is the standard error of the estimate, and $t_{df, \alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the t distribution with df degrees of freedom calculated as described in the “**Degrees of Freedom**” section on page 4214. The confidence limits for row totals, column totals, and the overall total are computed similarly to the confidence limits for table cell totals.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS summary table that contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, this table also contains the degrees of freedom df and the value of $t_{df, \alpha/2}$ used to compute the confidence limits. See [Example 68.3](#) on page 4236 for more information on the table summary.

Degrees of Freedom

To compute confidence limits for proportions and totals, PROC SURVEYFREQ uses the $100(1-\alpha/2)$ percentile from the t distribution with df degrees of freedom. PROC SURVEYFREQ calculates the degrees of freedom for t as the number of clusters minus the number of strata. If there are no clusters, then df equals the number of observations minus the number of strata. If the design is not stratified, then df equals the number of clusters minus one. If missing values or missing weights are present in the data, the number of strata, the number of observations, and the number of clusters are counted based on the observations in nonempty strata. See the section “Missing Values” on page 4205 for details.

For the Wald F statistics, PROC SURVEYFREQ also calculates the denominator degrees of freedom as the number of clusters minus the number of strata. Alternatively you can specify the denominator degrees of freedom for these tests with the `DDF=` option in the TABLES statement. See the section “Wald Chi-Square Test” on page 4221 and the section “Wald Log-Linear Chi-Square Test” on page 4223 for details.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS summary table that contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits or chi-square tests, this table also contains the degrees of freedom df . See Example 68.3 on page 4236 for more information on the table summary.

Coefficient of Variation

If you specify the `CV` option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the proportion estimates in the frequency and crosstabulation tables. The coefficient of variation is the ratio of the standard error to the estimate.

For the proportion in table cell (r, c) , the coefficient of variation is computed as

$$CV(\hat{P}_{rc}) = \text{StdErr}(\hat{P}_{rc}) / \hat{P}_{rc}$$

where \hat{P}_{rc} is the estimate of the proportion in table cell (r, c) , and $\text{StdErr}(\hat{P}_{rc})$ is the standard error of the estimate. The coefficients of variation for row proportions and column proportions are computed similarly.

If you specify the `CVWT` option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the weighted frequencies, or estimated totals, in the crosstabulation tables. For the total in table cell (r, c) , the coefficient of variation is computed as

$$CV(\hat{N}_{rc}) = \text{StdErr}(\hat{N}_{rc}) / \hat{N}_{rc}$$

where \hat{N}_{rc} is the estimate of the total in table cell (r, c) , and $\text{StdErr}(\hat{N}_{rc})$ is the standard error of the estimate. The coefficients of variation for row totals, column totals, and the overall total are computed similarly.

Design Effect

If you specify the **DEFF** option in the TABLES statement, PROC SURVEYFREQ computes design effects for the overall proportion estimates in the frequency and crosstabulation tables. The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. Refer to Lohr (1999) and Kish (1965).

The design effect for the proportion in table cell (r, c) is computed as

$$\begin{aligned} \text{DEFF}(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \widehat{\text{Var}}_{\text{SRS}}(\hat{P}_{rc}) \\ &= \widehat{\text{Var}}(\hat{P}_{rc}) / \left\{ (1-f) \hat{P}_{rc} (1-\hat{P}_{rc}) / (n-1) \right\} \end{aligned}$$

where \hat{P}_{rc} is the estimate of the proportion in table cell (r, c) , $\widehat{\text{Var}}(\hat{P}_{rc})$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample.

PROC SURVEYFREQ determines the value of f , the overall sampling fraction, based on the **RATE=** and **TOTAL=** options. If you do not specify either of these options, then PROC SURVEYFREQ assumes the value of f is negligible and does not use a finite population correction in the analysis, as described in the section “Population Totals and Sampling Rates” on page 4204. If you specify **RATE=value**, then PROC SURVEYFREQ uses this value for the overall sampling fraction f . If you specify **TOTAL=value**, then PROC SURVEYFREQ computes f as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates with the **RATE=SAS-data-set** option, then PROC SURVEYFREQ computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total, and computes f as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the **TOTAL=SAS-data-set** option, then PROC SURVEYFREQ sums these totals to compute the overall total. The overall sampling fraction f is then computed as the ratio of the number of sample PSUs to the overall total.

Expected Weighted Frequency

If you specify the **EXPECTED** option in the TABLES statement, PROC SURVEYFREQ displays expected weighted frequencies for the table cells in two-way tables. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent, as

$$E_{rc} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}$$

where $\hat{N}_{r.}$ is the estimated total for row r , $\hat{N}_{.c}$ is the estimated total for column c , and \hat{N} is the estimated overall total. Equivalently,

$$E_{rc} = \hat{P}_{r.} \hat{P}_{.c} \hat{N}$$

These expected values are used in the design-based chi-square tests of independence, as described in “[Rao-Scott Chi-Square Test](#)” and the section “[Wald Chi-Square Test](#)” on page 4221.

Rao-Scott Chi-Square Test

The Rao-Scott chi-square test is a design-adjusted version of the Pearson chi-square test, which involves differences between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables, the Rao-Scott chi-square tests the null hypothesis of equal proportions, or you can specify null proportions for one-way tables with the `TESTP=` option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott chi-square test with the `CHISQ` option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified chi-square test, with the `CHISQ1` option.

Refer to Lohr (1999), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987) for details on design-adjusted chi-square tests.

Two-Way Tables

The Rao-Scott chi-square statistic is computed from the Pearson chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom. An F approximation is also given.

The Rao-Scott chi-square is computed as

$$Q_{RS} = Q_P / D$$

where D is the design correction described in the “[Design Correction for Two-Way Tables](#)” section on page 4217, and Q_P is the Pearson chi-square based on the estimated totals.

$$Q_P = \sum_r \sum_c (\hat{N}_{rc} - E_{rc})^2 / E_{rc}$$

where \hat{N}_{rc} is the estimated total for table cell (r, c) , and E_{rc} is the expected total for cell (r, c) under the null hypothesis of no association,

$$E_{rc} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}$$

Under the null hypothesis of no association, the Rao-Scott chi-square Q_{RS} approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom. A better approximation may be obtained by the F statistic

$$F = Q_{RS} / (R - 1)(C - 1)$$

which has an F distribution with $(R - 1)(C - 1)$ and $(R - 1)(C - 1)\kappa$ degrees of freedom under the null hypothesis, where κ equals the number of clusters minus the number of strata, as described in the section “[Degrees of Freedom](#)” on page 4214.

Design Correction for Two-Way Tables

If you specify the CHISQ option, the design correction is computed from the estimated proportions, as

$$D = \left\{ \sum_r \sum_c (1 - \hat{P}_{rc}) \text{DEFF}(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_{r.}) \text{DEFF}(\hat{P}_{r.}) - \sum_c (1 - \hat{P}_{.c}) \text{DEFF}(\hat{P}_{.c}) \right\} / (R - 1)(C - 1)$$

where

$$\begin{aligned} \text{DEFF}(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \text{Var}_{\text{SRS}}(\hat{P}_{rc}) \\ &= \widehat{\text{Var}}(\hat{P}_{rc}) / \left\{ (1 - f) \hat{P}_{rc} (1 - \hat{P}_{rc}) / (n - 1) \right\} \end{aligned}$$

as described in the section “[Design Effect](#)” on page 4215. \hat{P}_{rc} is the estimate of the proportion in table cell (r, c) , $\widehat{\text{Var}}(\hat{P}_{rc})$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample. $\text{DEFF}(\hat{P}_{r.})$, the design effect for the estimate of the proportion in row r , and $\text{DEFF}(\hat{P}_{.c})$, the design effect for the estimate of the proportion in row c , are computed similarly.

If you specify the CHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions, computed as the product of the corresponding estimated row and cell proportions.

$$D_0 = \left\{ \sum_r \sum_c (1 - P_{rc}^0) \text{DEFF}_0(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_{r.}) \text{DEFF}(\hat{P}_{r.}) - \sum_c (1 - \hat{P}_{.c}) \text{DEFF}(\hat{P}_{.c}) \right\} / (R - 1)(C - 1)$$

where

$$P_{rc}^0 = \hat{P}_{r.} \cdot \hat{P}_{.c}$$

and

$$\begin{aligned} \text{DEFF}_0(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \text{Var}_{\text{SRS}}(P_{rc}^0) \\ &= \widehat{\text{Var}}(\hat{P}_{rc}) / \left\{ (1 - f) P_{rc}^0 (1 - P_{rc}^0) / (n - 1) \right\} \end{aligned}$$

One-Way Tables

For one-way tables, the Rao-Scott chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the `TESTP=` option, PROC SURVEYFREQ computes the goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott chi-square statistic approximately follows a chi-square distribution with $(C - 1)$ degrees of freedom for a table with C levels. PROC SURVEYFREQ also computes an F statistic that may provide a better approximation.

The Rao-Scott chi-square is computed as

$$Q_{RS} = Q_P / D$$

where D is the design correction described in the section “[Design Correction for One-Way Tables](#)” on page 4219, and Q_P is the Pearson chi-square based on the estimated totals,

$$Q_P = \sum_c (\hat{N}_c - E_c)^2 / E_c$$

where E_c is the expected total for level c under the null hypothesis. For the null hypothesis of equal proportions,

$$E_c = \hat{N} / C$$

For specified null proportions,

$$E_c = \hat{N} \cdot P_c^0$$

where P_c^0 is the null proportion for level c .

Under the null hypothesis, the one-way Rao-Scott chi-square Q_{RS} approximately follows a chi-square distribution with $(C - 1)$ degrees of freedom. A better approximation may be obtained by the F statistic

$$F = Q_{RS} / (C - 1)$$

which has an F distribution with $(C - 1)$ and $(C - 1)\kappa$ degrees of freedom under the null hypothesis, where κ equals the number of clusters minus the number of strata, as described in the section “[Degrees of Freedom](#)” on page 4214.

Design Correction for One-Way Tables

If you specify the CHISQ option, the design correction is computed from the estimated proportions, as

$$D = \sum_c (1 - \hat{P}_c) \text{DEFF}(\hat{P}_c) / (C - 1)$$

where

$$\text{DEFF}(\hat{P}_c) = \widehat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) \hat{P}_c (1 - \hat{P}_c) / (n - 1) \right\}$$

\hat{P}_c is the proportion estimate for table level c , $\widehat{\text{Var}}(\hat{P}_c)$ is the variance of the estimate, f is the overall sampling fraction, and n is the number of observations in the sample.

If you specify the CHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis proportions – either equal proportions for all levels, or the proportions you specify with the TESTP= option.

$$D_0 = \sum_c (1 - P_c^0) \text{DEFF}_0(\hat{P}_c) / (C - 1)$$

where

$$\text{DEFF}_0(\hat{P}_c) = \widehat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) P_c^0 (1 - P_c^0) / (n - 1) \right\}$$

and $P_c^0 = 1/C$ for equal proportions, or P_c^0 takes the value specified with the TESTP= option.

Rao-Scott Likelihood Ratio Chi-Square Test

The Rao-Scott likelihood ratio chi-square test is a design-adjusted version of the likelihood ratio test, which involves ratios between observed and expected frequencies and tests the null hypothesis of no association between the row and column variables in a two-way table. For a one-way tables the null hypothesis is equal proportions for the table levels, or you can specify other null proportions with the TESTP= option. Refer to Lohr (1999), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987).

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott likelihood ratio test with the LRCHISQ option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified likelihood ratio test, with the LRCHISQ1 option.

Two-Way Tables

The Rao-Scott likelihood ratio statistic is computed from the likelihood ratio chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association, this statistic approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom. An F approximation is also given.

The Rao-Scott likelihood ratio chi-square is computed as

$$G_{RS}^2 = G^2 / D$$

where G^2 is the likelihood ratio chi-square based on the estimated totals, and D is the design correction.

$$G^2 = 2 \sum_r \sum_c \hat{N}_{rc} \ln \left(\hat{N}_{rc} / E_{rc} \right)$$

where \hat{N}_{rc} is the estimated total for table cell (r, c) , and E_{rc} is the expected total for cell (r, c) under the null hypothesis of no association,

$$E_{rc} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}$$

The Rao-Scott likelihood ratio chi-square uses the same design correction D as the Rao-Scott (Pearson) chi-square uses, which is described in the section “[Design Correction for Two-Way Tables](#)” on page 4217. If you specify the [LRCHISQ](#) option, the design correction is computed from the estimated proportions. If you specify the [LRCHISQ1](#) option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions, computed as the product of the corresponding estimated row and column proportions.

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square G_{RS}^2 approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom. A better approximation may be obtained by the F statistic

$$F = G_{RS}^2 / (R - 1)(C - 1)$$

which has an F distribution with $(R - 1)(C - 1)$ and $(R - 1)(C - 1)\kappa$ degrees of freedom under the null hypothesis, where κ equals the number of clusters minus the number of strata, as described in the section “[Degrees of Freedom](#)” on page 4214.

One-Way Tables

For one-way tables, the Rao-Scott likelihood ratio chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the [TESTP=](#) option, PROC SURVEYFREQ computes the goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott likelihood ratio statistic approximately follows a chi-square distribution with $(C - 1)$ degrees of freedom for a table with C levels. An F approximation is also given.

The Rao-Scott likelihood ratio chi-square is computed as

$$G_{RS}^2 = G^2 / D$$

where G^2 is the likelihood ratio chi-square based on the estimated totals, and D is the design correction.

$$G^2 = 2 \sum_c \hat{N}_c \ln(\hat{N}_c / E_c)$$

where E_c is the expected total for level c under the null hypothesis. For the null hypothesis of equal proportions,

$$E_c = \hat{N} / C$$

For specified null proportions P_c^0 ,

$$E_c = \hat{N} \cdot P_c^0$$

The Rao-Scott likelihood ratio chi-square uses the same design correction D as the Rao-Scott (Pearson) chi-square uses, which is described in the section “[Design Correction for One-Way Tables](#)” on page 4219. If you specify the LRCHISQ option, the design correction is computed from the estimated proportions. If you specify the LRCHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions.

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square G_{RS}^2 approximately follows a chi-square distribution with $(C - 1)$ degrees of freedom. A better approximation may be obtained by the F statistic

$$F = G_{RS}^2 / (C - 1)$$

which has an F distribution with $(C - 1)$ and $(C - 1)\kappa$ degrees of freedom under the null hypothesis, where κ equals the number of clusters minus the number of strata, as described in the section “[Degrees of Freedom](#)” on page 4214.

Wald Chi-Square Test

PROC SURVEYFREQ provides two Wald chi-square tests for independence of the row and column variables in two-way tables: a Wald chi-square test based on the difference between observed and expected weighted cell frequencies, and a Wald log-linear chi-square test based on the log odds ratio. These statistics test for independence of the row and column variables in two-way tables, taking into account the complex survey design. Refer to Bedrick (1983), Koch, Freeman, and Freeman (1975), and Wald (1943) for information on Wald statistics and their applications to categorical data analysis.

For these two tests, PROC SURVEYFREQ computes the generalized Wald chi-square statistic, the corresponding Wald F statistic, and also an adjusted Wald F statistic for tables larger than 2×2 . Under the null hypothesis of independence, the Wald chi-square statistic approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom for very large samples. However, it has been shown that this test may perform poorly in terms of actual significance level and power, especially for tables with a large number of cells or for samples with a relatively small number of clusters. Refer to Thomas and Rao (1984 and 1985) and Lohr (1999) for more

information. Refer to Felligi (1980) and Hidioglou, Fuller, and Hickman (1980) for information on the adjusted Wald F statistic. Thomas and Rao (1984) found that the adjusted Wald F statistic provides a more stable test than the chi-square statistic, although its power may be low when the number of sample clusters is not large. Refer also to Korn and Graubard (1990) and Thomas, Singh, and Roberts (1996).

If you specify the **WCHISQ** option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence in the two-way table based on the differences between the observed (weighted) cell frequencies and the expected frequencies.

Under the null hypothesis of independence of the row and column variables, the expected cell frequencies are computed as

$$E_{rc} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}$$

where $\hat{N}_{r.}$ is the estimated total for row r , $\hat{N}_{.c}$ is the estimated total for column c , and \hat{N} is the estimated overall total, as described in the section “[Expected Weighted Frequency](#)” on page 4215. And the null hypothesis that the population weighted frequencies equal the expected frequencies is

$$H_0: Y_{rc} - E_{rc} = 0$$

for all $r = 1, \dots, (R - 1)$ and $c = 1, \dots, (C - 1)$. This null hypothesis can be stated equivalently in terms of cell proportions, with the expected cell proportions computed as the products of the marginal row and column proportions.

The generalized Wald chi-square statistic is computed as

$$Q_{\text{Wald}} = \hat{\mathbf{Y}}' (\mathbf{H} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{H}')^{-1} \hat{\mathbf{Y}}$$

where $\hat{\mathbf{Y}}$ is the $(R - 1)(C - 1)$ array of the differences between the observed and expected weighted frequencies ($\hat{N}_{rc} - E_{rc}$), and $(\mathbf{H} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{H}')$ estimates the variance of $\hat{\mathbf{Y}}$.

$\hat{\mathbf{V}}(\hat{\mathbf{N}})$ is the covariance matrix of the estimates \hat{N}_{rc} , and its computation is described in the section “[Covariance of Totals](#)” on page 4210.

\mathbf{H} is an $(R - 1)(C - 1)$ by RC matrix containing the partial derivatives of the elements of $\hat{\mathbf{Y}}$ with respect to the elements of $\hat{\mathbf{N}}$. The elements of \mathbf{H} are computed as follows, where a denotes a row different from row r , and b denotes a column different from column c .

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{rc} = 1 - \left(\hat{N}_{r.} + \hat{N}_{.c} - \hat{N}_{.c} \hat{N}_{r.} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{ac} = - \left(\hat{N}_{r.} - \hat{N}_{r.} \hat{N}_{.c} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{N}_{rb} = - \left(\hat{N}_{.c} - \hat{N}_{r.} \hat{N}_{.c} / \hat{N} \right) / \hat{N}$$

$$\partial \hat{Y}_{rc} / \partial \hat{Y}_{ab} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}^2$$

Under the null hypothesis of independence, the statistic Q_{Wald} approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom for very large samples.

PROC SURVEYFREQ computes the Wald F statistic as

$$F_{\text{Wald}} = Q_{\text{Wald}} / (R - 1)(C - 1)$$

Under the null hypothesis of independence, F_{Wald} approximately follows an F distribution with $(R - 1)(C - 1)$ numerator degrees of freedom. By default, PROC SURVEYFREQ computes the denominator degrees of freedom as the number of clusters minus the number of strata, as described in the section “[Degrees of Freedom](#)” on page 4214. Alternatively, you can specify the denominator degrees of freedom with the `DDF=` option in the TABLES statement.

For tables larger than 2×2 , PROC SURVEYFREQ also computes the adjusted Wald F statistic

$$F_{\text{Adj Wald}} = \frac{s - k + 1}{k s} Q_{\text{Wald}}$$

where $k = (R - 1)(C - 1)$, and s is the number of clusters minus the number of strata. Alternatively, you can specify the value of s with the `DDF=` option in the TABLES statement. Note that for 2×2 tables, $k = (R - 1)(C - 1) = 1$, so the the adjusted Wald F statistic equals the (unadjusted) Wald F statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, $F_{\text{Adj Wald}}$ approximately follows an F distribution with k numerator degrees of freedom and $(s - k + 1)$ denominator degrees of freedom.

Wald Log-Linear Chi-Square Test

If you specify the `WLLCHISQ` option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence based on the log odds ratios. See the section “[Wald Chi-Square Test](#)” on page 4221 for more information on Wald tests.

For a two-way table of R rows and C columns, the Wald log-linear test is based on the $(R - 1)(C - 1)$ array of

$$\hat{Y}_{rc} = \log \hat{N}_{rc} - \log \hat{N}_{rC} - \log \hat{N}_{Rc} + \log \hat{N}_{RC}$$

where \hat{N}_{rc} is the estimated total for table cell (r, c) . The null hypothesis of independence between the row and column variables is $H_0: Y_{rc} = 0$ for all $r = 1, \dots, (R - 1)$ and $c = 1, \dots, (C - 1)$. This null hypothesis can be stated equivalently in terms of cell proportions.

The generalized Wald log-linear chi-square statistic is computed as

$$Q_{\text{Wald LL}} = \hat{\mathbf{Y}}' \hat{\mathbf{V}}(\hat{\mathbf{Y}})^{-1} \hat{\mathbf{Y}}$$

where $\hat{\mathbf{Y}}$ is the $(R-1)(C-1)$ array of the \hat{Y}_{rc} , and $\hat{\mathbf{V}}(\hat{\mathbf{Y}})$ estimates the variance of $\hat{\mathbf{Y}}$.

$$\hat{\mathbf{V}}(\hat{\mathbf{Y}}) = \mathbf{A} \mathbf{D}^{-1} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{D}^{-1} \mathbf{A}'$$

where $\hat{\mathbf{V}}(\hat{\mathbf{N}})$ is the covariance matrix of the estimates \hat{N}_{rc} , as described in the section “Covariance of Totals” on page 4210, \mathbf{D} is a diagonal matrix with the estimated totals \hat{N}_{rc} on the diagonal, and \mathbf{A} is the $(R-1)(C-1)$ by $RC \times RC$ linear contrast matrix.

Under the null hypothesis of independence, the statistic $Q_{\text{Wald LL}}$ approximately follows a chi-square distribution with $(R-1)(C-1)$ degrees of freedom for very large samples.

PROC SURVEYFREQ computes the Wald log-linear F statistic as

$$F_{\text{Wald LL}} = Q_{\text{Wald LL}} / (R-1)(C-1)$$

Under the null hypothesis of independence, $F_{\text{Wald LL}}$ approximately follows an F distribution with $(R-1)(C-1)$ numerator degrees of freedom. By default, PROC SURVEYFREQ computes the denominator degrees of freedom as the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214. Alternatively, you can specify the denominator degrees of freedom with the `DDF=` option in the TABLES statement.

For tables larger than 2×2 , PROC SURVEYFREQ also computes the adjusted Wald log-linear F statistic

$$F_{\text{Adj Wald LL}} = \frac{s - k + 1}{k s} Q_{\text{Wald LL}}$$

where $k = (R-1)(C-1)$, and s is the number of clusters minus the number of strata. Alternatively, you can specify the value of s with the `DDF=` option in the TABLES statement. Note that for 2×2 tables, $k = (R-1)(C-1) = 1$, so the adjusted Wald F statistic equals the (unadjusted) Wald F statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, $F_{\text{Adj Wald LL}}$ approximately follows an F distribution with k numerator degrees of freedom and $(s - k + 1)$ denominator degrees of freedom.

Displayed Output

Data and Sample Design Summary Table

The “Data Summary” table provides information on the input data set and the sample design. PROC SURVEYFREQ displays this table unless you specify the **NOSUMMARY** option in the PROC SURVEYFREQ statement.

The “Data Summary” table displays the total number of valid observations. To be considered *valid*, an observation must have a nonmissing, positive **WEIGHT** value if you specify a **WEIGHT** statement. If you do not specify the **MISSING** option, a valid observation must also have nonmissing values for all **STRATA** and **CLUSTER** variables. The number of valid observations may differ from the the number of nonmissing observations for an individual analysis variable, which the procedure displays in the frequency or crosstabulation tables. See the section “**Missing Values**” on page 4205 for more information.

PROC SURVEYFREQ displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a **STRATA** statement
- Number of Clusters, if you specify a **CLUSTER** statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a **WEIGHT** statement

Stratum Information Table

If you specify the **LIST** option in the **STRATA** statement, PROC SURVEYFREQ displays a “Stratum Information” table. This table provides the following information for each stratum.

- Stratum Index, which is a sequential stratum identification number
- **STRATA** variable(s), which lists the levels of **STRATA** variables for the stratum
- Number of Observations, which is the number of valid observations in the stratum
- Population Total for the stratum, if you specify the **TOTAL=** option
- Sampling Rate for the stratum, if you specify the **TOTAL=** option or the **RATE=** option. If you specify the **TOTAL=** option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a **CLUSTER** statement

One-Way Frequency Tables

PROC SURVEYFREQ displays one-way frequency tables for all one-way table requests in the TABLES statements, unless you specify the NOPRINT option in the TABLES statement. A one-way table shows the sample frequency distribution of a single variable, and provides estimates for its population distribution in terms of totals and proportions. For each level of the variable, PROC SURVEYFREQ displays the following information in the one-way table:

- Frequency count, giving the number of sample observations for the level
- Weighted Frequency total, estimating the total population frequency for the level
- Standard Deviation of Weighted Frequency
- Percent, estimating the population proportion for the level
- Standard Error of Percent

The one-way table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFREQ option in the TABLES statement.

The one-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the NOFREQ option in the TABLES statement. Also, the NOWT option suppresses the weighted frequencies and their standard deviations. The NOPERCENT option suppresses the percentages and their standard errors. The NOSTD option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The NOTOTAL option suppresses the total row of the one-way table.

PROC SURVEYFREQ optionally displays the following information for a one-way table:

- Variance of Weighted Frequency, if you specify the VARWT option
- Confidence Limits for Weighted Frequency, if you specify the CLWT option
- Coefficient of Variation for Weighted Frequency, if you specify the CVWT option
- Test Percent, if you specify the TESTP= option
- Variance of Percent, if you specify the VAR option
- Confidence Limits for Percent, if you specify the CL option
- Coefficient of Variation for Percent, if you specify the CV option
- Design Effect for Percent, if you specify the DEFF option

Crosstabulation Tables

PROC SURVEYFREQ displays all multiway table requests in the **TABLES** statements, unless you specify the **NOPRINT** option in the **TABLES** statement. For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables form one layer. PROC SURVEYFREQ produces a separate two-way crosstabulation table for each layer.

For each layer, the crosstabulation table displays the row and column variable names and values (or levels). Each two-way table lists levels of the column variable within each level of the row variable.

By default, the procedure displays all levels of the column variable within each level of the row variables, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row levels with zero frequency for that layer. You can suppress the display of zero frequency levels by specifying the **NOSPARSE** option.

For each combination of variable levels, or table cell, the two-way table displays the following information:

- Frequency, giving the number of observations that have the indicated values of the two variables
- Weighted Frequency total, estimating the total population frequency for the table cell
- Standard Deviation of Weighted Frequency
- Percent, estimating the population proportion for the table cell
- Standard Error of Percent

The two-way table displays weighted frequencies if your analysis includes a **WEIGHT** statement, or if you specify the **WTFREQ** option in the **TABLES** statement.

The two-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the **NOFREQ** option in the **TABLES** statement. Also, the **NOWT** option suppresses the weighted frequencies and their standard deviations. The **NOPERCENT** option suppresses the percentages and their standard errors. The **NOSTD** option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The **NOTOTAL** option suppresses the row totals and column totals.

PROC SURVEYFREQ optionally displays the following information for a two-way table:

- Expected Weighted Frequency, if you specify the **EXPECTED** option
- Variance of Weighted Frequency, if you specify the **VARWT** option
- Confidence Limits for Weighted Frequency, if you specify the **CLWT** option
- Coefficient of Variation for Weighted Frequency, if you specify the **CVWT** option
- Variance of Percent, if you specify the **VAR** option
- Confidence Limits for Percent, if you specify the **CL** option
- Coefficient of Variation for Percent, if you specify the **CV** option
- Design Effect for Percent, if you specify the **DEFF** option
- Row Percent, estimating the cell's proportion of the population total for that cell's row, if you specify the **ROW** option
- Standard Error of Row Percent, if you specify the **ROW** option
- Variance of Row Percent, if you specify the **VAR** option and the **ROW** option
- Confidence Limits for Row Percent, if you specify the **CL** option and the **ROW** option
- Coefficient of Variation for Row Percent, if you specify the **CV** option and the **ROW** option
- Column Percent, estimating the cell's proportion of the population total for that cell's column, if you specify the **COL** option
- Standard Error of Column Percent, if you specify the **COL** option
- Variance of Column Percent, if you specify the **VAR** option and the **COL** option
- Confidence Limits for Column Percent, if you specify the **CL** option and the **COL** option
- Coefficient of Variation for Column Percent, if you specify the **CV** option and the **COL** option

If you specify the **ROW** option, the **NOPERCENT** option suppresses the row percentages and their standard errors. The **NOSTD** option suppresses the standard errors of the row percentages. Similarly, if you specify the **COL** option, the **NOPERCENT** option suppresses the column percentages and their standard errors. The **NOSTD** option suppresses the standard errors of the column percentages.

Statistical Tests

If you specify the **CHISQ** option for the Rao-Scott chi-square test, the **CHISQ1** option for the modified test, the **LRCHISQ** option for the Rao-Scott likelihood ratio chi-square test, or the **LRCHISQ1** option for the modified test, PROC SURVEYFREQ displays the following information:

- Pearson Chi-Square, if you specify the **CHISQ** or **CHISQ1** option
- Likelihood Ratio Chi-Square, if you specify the **LRCHISQ** or **LRCHISQ1** option
- Design Correction
- Rao-Scott Chi-Square, if you specify the **CHISQ** or **CHISQ1** option
- Rao-Scott Likelihood Ratio Chi-Square, if you specify the **LRCHISQ** or **LRCHISQ1** option
- DF, the degrees of freedom for the chi-square test
- Pr > ChiSq, the p -value for the chi-square test
- F Value
- Num DF, the numerator degrees of freedom for F
- Den DF, the denominator degrees of freedom for F
- Pr > F, the p -value for the F test

If you specify the **WCHISQ** option for the Wald chi-square test or the **WLLCHISQ** option for the Wald log-linear chi-square test, PROC SURVEYFREQ displays the following information:

- Wald Chi-Square, if you specify the **WCHISQ** option
- Wald Log-Linear Chi-Square, if you specify the **WLLCHISQ** option
- F Value
- Num DF, the numerator degrees of freedom for F
- Den DF, the denominator degrees of freedom for F
- Pr > F, the p -value for the F test
- Adjusted F Value, for tables larger than 2×2
- Num DF, the numerator degrees of freedom for Adjusted F
- Den DF, the denominator degrees of freedom for Adjusted F
- Pr > Adj F, the p -value for the Adjusted F test

ODS Table Names

PROC SURVEYFREQ assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 68.3. ODS Tables Produced in PROC SURVEYFREQ

ODS Table Name	Description	Statement	Option
ChiSq	Chi-square test	TABLES	CHISQ
ChiSq1	Modified chi-square test	TABLES	CHISQ1
CrossTabs	Crosstabulation table	TABLES	(<i>n</i> -way table request, <i>n</i> > 1)
LRChiSq	Likelihood ratio test	TABLES	LRCHISQ
LRChiSq1	Modified likelihood ratio test	TABLES	LRCHISQ1
OneWay	One-way frequency table	PROC or TABLES	(with no TABLES stmt) (one-way table request)
StrataInfo	Stratum information	STRATA	LIST
Summary	Data summary	PROC	default
TableSummary	Table summary (not displayed)	TABLES	default
WChiSq	Wald chi-square test	TABLES	WCHISQ
WLLChiSq	Wald log-linear chi-square test	TABLES	WLLCHISQ

Examples

Example 68.1. Two-Way Tables

This example uses the `SIS_Survey` data set from the section “Getting Started” on page 4185. The data set contains results from a customer satisfaction survey for a student information system (SIS).

The following PROC SURVEYFREQ statements request a two-way table for the variables `Department` by `Response` and customize the crosstabulation table display.

```
proc surveyfreq data=SIS_Survey;
  tables Department * Response /
         cv deff nowt nostd nototal;
  strata State NewUser / list;
  cluster School;
  weight SamplingWeight;
run;
```

The TABLES statement requests a two-way table of `Department` by `Response`. The CV option requests coefficients of variation for the percentage estimates. The DEFF option requests design effects for the percentage estimates. The NOWT option suppresses display of the weighted frequencies, and the NOSTD option suppresses display of standard errors for the estimates. The NOTOTAL option suppresses the row totals, column totals, and overall totals.

The WCHISQ option requests a Wald chi-square test of association between the variables `Department` and `Response`.

The `STRATA`, `CLUSTER`, and `WEIGHT` statements provide sample design information to the procedure, so that the analysis will be done according to the sample design used for the survey. The `STRATA` statement names the variables `State` and `NewUser`, which identify the first-stage strata. The `LIST` option in the `STRATA` statement requests a Stratum Information table. The `CLUSTER` statement identifies `School` as the cluster or first-stage sampling unit. The `WEIGHT` statement names the sampling weight variable.

[Output 68.1.1](#) displays the Data Summary and Stratum Information tables produced by `PROC SURVEYFREQ`. The Stratum Information table lists the six strata in the survey and shows the number of clusters, or schools, and the number of observations in each stratum.

Output 68.1.1. Data Summary and Stratum Information

School Information System Survey				
The SURVEYFREQ Procedure				
Data Summary				
Number of Strata				6
Number of Clusters				370
Number of Observations				1850
Sum of Weights				38899.6482
Stratum Information				
Stratum Index	State	NewUser	Number of Obs	Number of Clusters
1	GA	Renewal Customer	315	63
2	GA	New Customer	355	71
3	NC	Renewal Customer	280	56
4	NC	New Customer	420	84
5	SC	Renewal Customer	210	42
6	SC	New Customer	270	54

Output 68.1.2 displays the two-way table of Department by Response. According to the TABLES statement options specified, this two-way table includes coefficients of variation and design effects for the percentage estimates, and it does not show the weighted frequencies or the standard errors of the estimates.

Output 68.1.2. Two-Way Table of Department by Response

School Information System Survey						
The SURVEYFREQ Procedure						
Table of Department by Response						
Department	Response	Frequency	Percent	CV for Percent	Design Effect	
Faculty	Very Unsatisfied	209	13.4987	0.0865	2.1586	
	Unsatisfied	203	13.0710	0.0868	2.0962	
	Neutral	346	22.4127	0.0629	2.1157	
	Satisfied	254	16.2006	0.0806	2.3232

Admin/Guidance	Very Unsatisfied	95	3.6690	0.1277	1.1477	
	Unsatisfied	123	4.6854	0.1060	1.0211	
	Neutral	235	9.1838	0.0700	0.9166	
	Satisfied	201	7.7305	0.0756	0.8848	
	Very Satisfied	86	3.3016	0.1252	0.9892	

The following PROC SURVEYFREQ statements request a two-way table of Department by Response that includes row percentages, and also a Wald chi-square test of association between the two table variables.

```
proc surveyfreq data=SIS_Survey nosummary;
  tables Department * Response /
    row nowt wchisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

Output 68.1.3 displays the two-way table. The row percentages show the distribution of Response for Department = 'Faculty' and for Department = 'Admin/Guidance'.

Output 68.1.3. Table of Department by Response with Row Percentages

School Information System Survey						
The SURVEYFREQ Procedure						
Table of Department by Response						
Department	Response	Frequency	Percent	Std Err of Percent	Row Percent	Std Err of Row Percent
Faculty	Very Unsatisfied	209	13.4987	1.1675	18.8979	1.6326
	Unsatisfied	203	13.0710	1.1350	18.2992	1.5897
	Neutral	346	22.4127	1.4106	31.3773	1.9705
	Satisfied	254	16.2006	1.3061	22.6805	1.8287
	Very Satisfied	98	6.2467	0.8506	8.7452	1.1918
	Total	1110	71.4297	0.1468	100.000	
Admin/Guidance	Very Unsatisfied	95	3.6690	0.4684	12.8419	1.6374
	Unsatisfied	123	4.6854	0.4966	16.3995	1.7446
	Neutral	235	9.1838	0.6430	32.1447	2.2300
	Satisfied	201	7.7305	0.5842	27.0579	2.0406
	Very Satisfied	86	3.3016	0.4133	11.5560	1.4466
	Total	740	28.5703	0.1468	100.000	
Total	Very Unsatisfied	304	17.1676	1.2872		
	Unsatisfied	326	17.7564	1.2712		
	Neutral	581	31.5965	1.5795		
	Satisfied	455	23.9311	1.4761		
	Very Satisfied	184	9.5483	0.9523		
	Total	1850	100.000			

Output 68.1.4 displays the Wald chi-square test for association between Department and Response. The Wald chi-square is 11.44, and the corresponding adjusted F value is 2.84 with a p -value of .0243. This indicates a significant association between department (faculty or admin/guidance) and satisfaction with the student information system.

Output 68.1.4. Wald Chi-Square Test

Table of Department by Response	
Wald Chi-Square Test	
Chi-Square	11.4454
F Value	2.8613
Num DF	4
Den DF	364
Pr > F	0.0234
Adj F Value	2.8378
Num DF	4
Den DF	361
Pr > Adj F	0.0243
Sample Size = 1850	

Example 68.2. Multiway Tables

Continuing to use the `SIS_Survey` data set from the section “Getting Started” on page 4185, this example shows how to produce multiway tables. The following PROC SURVEYFREQ statements request a table of Department by SchoolType by Response for the student information system survey.

```
proc surveyfreq data=SIS_Survey;
  tables Department * SchoolType * Response
         SchoolType * Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The TABLES statement requests a multiway table with SchoolType as the row variable, Response as the column variable, and Department as the layer variable. This request produces a separate two-way table of SchoolType by Response for each level of the variable Department. The TABLES statement also requests a two-way table of SchoolType by Response, which totals the multiway table over both levels of Department. As in the previous examples, the STRATA, CLUSTER, and WEIGHT statements provide sample design information, so that the analysis will be done according to the design used for this survey.

[Output 68.2.1](#) displays the multiway table produced by PROC SURVEYFREQ, which includes a table of SchoolType by Response for Department = 'Faculty' and for Department = 'Admin/Guidance'.

Output 68.2.1. Multiway Table of Department by SchoolType by Response

School Information System Survey						
The SURVEYFREQ Procedure						
Table of SchoolType by Response

Example 68.3. Output Data Sets

PROC SURVEYFREQ uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. Using ODS, you can create a SAS data set from any piece of PROC SURVEYFREQ output. For more information on ODS, see [Chapter 14](#), “Using the Output Delivery System.”

When selecting tables for ODS output data set, you reference tables by their ODS table names. Each table created by PROC SURVEYFREQ is assigned a name, and the section “[ODS Table Names](#)” on page 4230 lists the table names.

To save the one-way table of Response from [Figure 68.3](#) in an output data set, use an ODS OUTPUT statement as follows:

```
proc surveyfreq data=SIS_Survey;
  tables Response / cl nowt;
  ods output OneWay=ResponseTable;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

[Output 68.3.1](#) displays the output data set ResponseTable, which contains the one-way table of Response. This data set has six observations, and each of these observations corresponds to a row of the one-way table. The first five observations correspond to the five levels of Response, as they are ordered in the display, and the last observation corresponds to the overall total, which is the last row of the table. The data set ResponseTable includes a variable corresponding to each column of the one-way table. For example, the variable Percent contains the percentage estimates, and the variables LowerCL and UpperCL contain the lower and upper confidence limits for the percentage estimates.

Output 68.3.1. ResponseTable Output Data Set

Obs	Table	Response	Frequency	Percent	StdErr	LowerCL	UpperCL
1	Table Response	Very Unsatisfied	304	17.1676	1.2872	14.6364	19.6989
2	Table Response	Unsatisfied	326	17.7564	1.2712	15.2566	20.2562
3	Table Response	Neutral	581	31.5965	1.5795	28.4904	34.7026
4	Table Response	Satisfied	455	23.9311	1.4761	21.0285	26.8338
5	Table Response	Very Satisfied	184	9.5483	0.9523	7.6756	11.4210
6	Table Response	.	1850	100.000	—	—	—

PROC SURVEYFREQ also creates a table summary that is not displayed. Some of the information in this table is similar to that contained in the “Data Summary” table, but the table summary describes data used to analyze the specified table, while the data summary describes the entire input data set. Due to missing values, for example, the number of observations (or strata or clusters) used to analyze a particular table may differ from the number of observations (or strata or clusters) reported for the input data set in the “Data Summary” table. See the section “[Missing Values](#)” on page

4205 for more details. If you request confidence limits, the “Table Summary” table also contains the degrees of freedom and the t -value used to compute the confidence limits.

The following statements store the nondisplayed “Table Summary” table in the output data set ResponseSummary.

```
proc surveyfreq data=SIS_Survey;
  tables Response / cl nowt;
  ods output TableSummary=ResponseSummary;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

Output 68.3.2 displays the output data set ResponseSummary.

Output 68.3.2. ResponseSummary Output Data Set

Obs	Table	Number of Observations	Number of Strata	Number of Clusters	Degrees of Freedom	t Percentile
1	Table Response	1850	6	370	364	1.966503

Chapter 69

The SURVEYLOGISTIC Procedure

Overview

Categorical responses arise extensively in survey research. Common examples of responses include

- binary: e.g., attended graduate school or not
- ordinal: e.g., mild, moderate, and severe pain
- nominal: e.g., ABC, NBC, CBS, FOX TV network viewed at a certain hour

Logistic regression analysis is often used to investigate the relationship between such discrete responses and a set of explanatory variables. See Binder (1981, 1983), Roberts, Rao, and Kumar (1987), Skinner, Holt, and Smith (1989), Morel (1989), and Lehtonen and Pahkinen (1995) for papers that describe logistic regression for sample survey data.

For binary response models, the response of a sampling unit can take a specified value or not (for example, attended graduate school or not). Suppose \mathbf{x} is a row vector of explanatory variables and π is the response probability to be modeled. The linear logistic model has the form

$$\text{logit}(\pi) \equiv \log\left(\frac{\pi}{1-\pi}\right) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

where α is the intercept parameter and $\boldsymbol{\beta}$ is the vector of slope parameters.

The logistic model shares a common feature with the more general class of generalized linear models, namely, that a function $g = g(\mu)$ of the expected value, μ , of the response variable is assumed to be linearly related to the explanatory variables. Since μ implicitly depends on the stochastic behavior of the response, and since the explanatory variables are assumed to be fixed, the function g provides the link between the random (stochastic) component and the systematic (deterministic) component of the response variable. For this reason, Nelder and Wedderburn (1972) refer to $g(\cdot)$ as a link function. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4). Other link functions that are widely used in practice are the probit function and the complementary log-log function. The SURVEYLOGISTIC procedure enables you to choose one of these link functions, resulting in fitting a broad class of binary response models of the form

$$g(\pi) = \alpha + \mathbf{x}\boldsymbol{\beta}$$

For ordinal response models, the response Y of an individual or an experimental unit may be restricted to one of a usually small number of ordinal values, denoted for convenience by $1, \dots, D, D + 1$ ($D \geq 1$). For example, the pain severity can be classified into three response categories as 1=mild, 2=moderate, and 3=severe. The SURVEYLOGISTIC procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$g(\Pr(Y \leq d | \mathbf{x})) = \alpha_d + \mathbf{x}\boldsymbol{\beta}, \quad 1 \leq d \leq D$$

where $\alpha_1, \dots, \alpha_k$ are k intercept parameters and $\boldsymbol{\beta}$ is the vector of slope parameters. This model has been considered by many researchers. Aitchison and Silvey (1957) and Ashford (1959) employ a probit scale and provide a maximum likelihood analysis; Walker and Duncan (1967) and Cox and Snell (1989) discuss the use of the log-odds scale. For the log-odds scale, the cumulative logit model is often referred to as the *proportional odds* model.

For nominal response logistic models, where the $D + 1$ possible responses have no natural ordering, the logit model can also be extended to a *generalized logit* model, which has the form

$$\log \left(\frac{\Pr(Y = i | \mathbf{x})}{\Pr(Y = D + 1 | \mathbf{x})} \right) = \alpha_i + \boldsymbol{\beta}'_i \mathbf{x}, \quad i = 1, \dots, D$$

where the $\alpha_1, \dots, \alpha_D$ are D intercept parameters, and the $\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_D$ are D vectors of parameters. These models were introduced by McFadden (1974) as the *discrete choice* model, and they are also known as *multinomial* models.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by the method of maximum likelihood. For statistical inferences, PROC SURVEYLOGISTIC incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The maximum likelihood estimation is carried out with either the Fisher-scoring algorithm or the Newton-Raphson algorithm. You can specify starting values for the parameter estimates. The logit link function in the ordinal logistic regression models can be replaced by the probit function or the complementary log-log function.

Odds ratio estimates are displayed along with parameter estimates. You can also specify the change in the explanatory variables for which odds ratio estimates are desired. Variances of the regression parameters and odds ratios are computed using the Taylor expansion approximation; see Binder (1983).

The SURVEYLOGISTIC procedure enables you to specify categorical variables (also known as CLASS variables) as explanatory variables. It also enables you to specify interaction terms in the same way as in the LOGISTIC procedure.

Like many procedures in SAS/STAT software that allow the specification of CLASS variables, the SURVEYLOGISTIC procedure provides a **CONTRAST** statement

for specifying customized hypothesis tests concerning the model parameters. The CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful for obtaining odds ratio estimates for various levels of the CLASS variables.

Getting Started

The SURVEYLOGISTIC procedure is similar to the LOGISTIC procedure and other regression procedures in the SAS System. Please refer to [Chapter 42, “The LOGISTIC Procedure,”](#) for general information about how to perform logistic regression using SAS. PROC SURVEYLOGISTIC is designed to handle sample survey data, and thus it incorporates the sampling design information into the analysis.

The following example illustrates how to use PROC SURVEYLOGISTIC to perform logistic regression for sample survey data.

In the customer satisfaction survey example in the “Getting Started” section on page 4422 of [Chapter 72, “The SURVEYSELECT Procedure,”](#) an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company’s current subscribers from four states: Alabama (AL), Florida (FL), Georgia (GA), and South Carolina (SC). The company plans to select a sample of customers from this population, interview the selected customers and ask their opinions on customer service, and then make inferences about the entire population of subscribers from the sample data. A stratified sample is selected using the probability proportional to size (PPS) method. The sample design divides the customers into strata depending on their types (‘Old’ or ‘New’) of their states (AL, FL, GA, SC). There are eight strata in all. Within each stratum, customers are selected and interviewed using the PPS with replacement method, where the size variable is Usage. The stratified PPS sample contains 192 customers. The data are stored in the SAS data set `SampleStrata`. [Figure 69.1](#) displays the first 10 observations of this data set.

Customer Satisfaction Survey Stratified PPS Sampling (First 10 Observations)						
Obs	State	Type	Customer ID	Rating	Usage	Sampling Weight
1	AL	New	2178037	Unsatisfied	23.53	14.7473
2	AL	New	75375074	Unsatisfied	99.11	3.5012
3	AL	New	116722913	Satisfied	31.11	11.1546
4	AL	New	133059995	Neutral	52.70	19.7542
5	AL	New	216784622	Satisfied	8.86	39.1613
6	AL	New	225046040	Neutral	8.32	41.6960
7	AL	New	238463776	Satisfied	4.63	74.9483
8	AL	New	255918199	Unsatisfied	10.05	34.5405
9	AL	New	395767821	Extremely Unsatisfied	33.14	10.4719
10	AL	New	409095328	Satisfied	10.67	32.5295

Figure 69.1. Stratified PPS Sample (First 10 Observations)

In the SAS data set `SampleSRS`, the variable `CustomerID` uniquely identifies each

customer. The variable **State** contains the state of the customer's address. The variable **Type** equals 'Old' if the customer has subscribed to the service for more than one year; otherwise, the variable **Type** equals 'New'. The variable **Usage** contains the customer's average monthly service usage, in hours. The variable **Rating** contains the customer's responses to the survey. The sample design uses an unequal probability sampling method, with the sampling weights stored in the variable **SamplingWeight**.

The following SAS statements fit a cumulative logistic model between the satisfaction levels and the Internet usage using the stratified PPS sample.

```

title 'Customer Satisfaction Survey';
proc surveylogistic data=SampleStrata;
strata state type/list;
model Rating (order=internal) = Usage;
weight SamplingWeight;
run;

```

The PROC statement invokes the SURVEYLOGISTIC procedure. The STRATA statement specifies the stratification variables **State** and **Type** that are used in the sample design. The LIST option requests a summary of the stratification. In the MODEL statement, **Rating** is the response variable and **Usage** is the explanatory variable. The ORDER=internal is used for the response variable **Rating** to ask the procedure to order the response levels using the internal numerical value (1-5) instead of the formatted character value. The WEIGHT statement specifies the variable **SamplingWeight** that contains the sampling weights.

The results of this analysis are shown in the following tables.

Customer Satisfaction Survey		
The SURVEYLOGISTIC Procedure		
Model Information		
Data Set	WORK.SAMPLESTRATA	
Response Variable	Rating	
Number of Response Levels	5	
Stratum Variables	State	
	Type	
Number of Strata	8	
Weight Variable	SamplingWeight	Sampling Weight
Model	Cumulative Logit	
Optimization Technique	Fisher's Scoring	
Variance Adjustment	Degrees of Freedom (DF)	

Figure 69.2. Stratified PPS Sample, Model Information

PROC SURVEYLOGISTIC first lists the following model fitting information and sample design information in [Figure 69.2](#):

- The link function is the logit of the cumulative of the lower response categories.

- The Fisher Scoring optimization technique is used to obtain the maximum likelihood estimates for the regression coefficients.
- The response variable is **Rating**, which has five response levels.
- The stratification variables are **State** and **Type**.
- There are eight strata in the sample.
- The weight variable is **SamplingWeight**.
- The [variance adjustment method](#) used for the regression coefficients is the default degrees of freedom adjustment.

Customer Satisfaction Survey	
Number of Observations Read	192
Number of Observations Used	192
Sum of Weights Read	13262.74
Sum of Weights Used	13262.74

Figure 69.3. Stratified PPS Sample, Number of Observations

Figure 69.3 lists the number of observations in the data set and the number of observations used in the analysis. Since no missing value presents in this example, observations in the entire data set are used in the analysis. The sums of weights are also reported in this table.

Customer Satisfaction Survey			
Response Profile			
Ordered Value	Rating	Total Frequency	Total Weight
1	Extremely Unsatisfied	52	2067.1092
2	Unsatisfied	47	2148.7127
3	Neutral	47	3649.4869
4	Satisfied	38	2533.5379
5	Extremely Satisfied	8	2863.8888

Probabilities modeled are cumulated over the lower Ordered Values.

Figure 69.4. Stratified PPS Sample, Response Profile

The “Response Profile” table in Figure 69.4 lists the five response levels, their ordered values, and their total frequencies and total weights for each category. Due to the `ORDER=internal` option for the response variable **Rating**, the category “Extremely Unsatisfied” has the Ordered Value 1, the category “Unsatisfied” has the Ordered Value 2, and so on.

Customer Satisfaction Survey			
Stratum Information			
Stratum Index	State	Type	N Obs
1	AL	New	22
2		Old	24
3	FL	New	25
4		Old	22
5	GA	New	25
6		Old	25
7	SC	New	24
8		Old	25

Figure 69.5. Stratified PPS Sample, Stratification Summary

Figure 69.5 displays the output of the stratification summary. There are a total of eight strata, and each stratum is defined by the customer types within each state. The table also shows the number of customers within each stratum.

Customer Satisfaction Survey		
Score Test for the Proportional Odds Assumption		
Chi-Square	DF	Pr > ChiSq
3692.2558	3	<.0001

Figure 69.6. Stratified PPS Sample, Testing the Proportional Odds Assumption

Figure 69.6 shows the chi-square test for testing the proportional odds assumption. The test is highly significant, which indicates that the cumulative logit model may not adequately fit the data.

Customer Satisfaction Survey		
Model Convergence Status		
Convergence criterion (GCONV=1E-8) satisfied.		
Model Fit Statistics		
Criterion	Intercept Only	Intercept and Covariates
AIC	42099.954	41378.851
SC	42112.984	41395.139
-2 Log L	42091.954	41368.851

Figure 69.7. Stratified PPS Sample, Model Fitting Information

Figure 69.7 shows the iteration algorithm converged to obtain the MLE for this example. The “Model Fit Statistics” table contains the Akaike Information Criterion (AIC), the Schwarz Criterion (SC), and the negative of twice the log likelihood (-2 Log L) for the intercept-only model and the fitted model. AIC and SC can be used to compare different models, and the ones with smaller values are preferred.

Customer Satisfaction Survey			
Testing Global Null Hypothesis: BETA=0			
Test	Chi-Square	DF	Pr > ChiSq
Likelihood Ratio	723.1023	1	<.0001
Score	465.4939	1	<.0001
Wald	4.5212	1	0.0335

Figure 69.8. Stratified PPS Sample, Testing Global Null Hypothesis

The table “Testing Global Null Hypothesis: BETA=0” in Figure 69.8 shows the likelihood ratio test, the efficient score test, and the Wald test for testing the significance of the explanatory variable (Usage). All tests are significant.

Customer Satisfaction Survey						
Analysis of Maximum Likelihood Estimates						
Parameter	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq	
Intercept Extremely Unsatisfied	1	-2.0168	0.3988	25.5769	<.0001	
Intercept Unsatisfied	1	-1.0527	0.3543	8.8292	0.0030	
Intercept Neutral	1	0.1334	0.4189	0.1015	0.7501

Syntax

The following statements are available in PROC SURVEYLOGISTIC:

```

PROC SURVEYLOGISTIC < options >;
  BY variables ;
  CLASS variable <(v-options)> <variable <(v-options)>... >
    < /v-options >;
  CLUSTER variables ;
  CONTRAST 'label' effect values <,... effect values>< /options >;
  FREQ variable ;
  MODEL events/trials = < effects >< / options >;
  MODEL variable < (variable_options) > = < effects >< / options >;
  STRATA variables < / options >;
  < label: > TEST equation1 < , ... , < equationk >>< /option >;
  UNITS independent1 = list1 < ... independentk = listk >< /option >;
  WEIGHT variable </ option >;

```

The PROC SURVEYLOGISTIC and MODEL statements are required. The CLASS, CLUSTER, STRATA, and CONTRAST statements can appear multiple times. You should only use one MODEL statement and one WEIGHT statement. The CLASS statement (if used) must precede the MODEL statement, and the CONTRAST statement (if used) must follow the MODEL statement.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC SURVEYLOGISTIC statement. The remaining statements are covered in alphabetical order.

PROC SURVEYLOGISTIC Statement

```

PROC SURVEYLOGISTIC < options >;

```

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure and optionally identifies input data sets and controls the ordering of the response levels.

ALPHA= α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=SAS-data-set

names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

INEST= *SAS-data-set*

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section “[INEST= Data Set](#)” on page 4280 for more information.

MISSING

requests that the procedure treat missing values as a valid category for all categorical variables, which include classification variables in the model, strata variables, and cluster variables.

NAMELEN=*n*

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

NOSORT

suppresses the internal sorting process to shorten the computation time if the data set is presorted by the STRATA and CLUSTER variables. By default, the procedure sorts the data by the STRATA variables if you use the STRATA statement; then the procedure sorts the data by the CLUSTER variables within strata. If your data are already stored by the order of STRATA and CLUSTER variables, then you can specify this option to omit this sorting process to reduce the usage of computing resources, especially when your data set is very large. However, if you specify this NOSORT option while your data is not presorted by STRATA and CLUSTER variables, then any changes in these variables creates a new stratum or cluster.

RATE=*value* | *SAS-data-set***R=***value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction (fpc) for variance estimation when the sample design is without replacement. If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of primary sampling units (PSUs) selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4280 for more details.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC will convert that number to a proportion. The procedure treats the value 1 as 100%.

If you do not specify the [TOTAL=](#) option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

TOTAL=*value* | *SAS-data-set*

N=*value* | *SAS-data-set*

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or names an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4280 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC SURVEYLOGISTIC to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty.

When a BY statement appears, the procedure expects the input data sets to be sorted in the order of the BY variables. The *variables* are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Use the BY statement options NOTSORTED or DESCENDING in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLASS Statement

```
CLASS variable <(v-options)> <variable <(v-options)>... >
      < / v-options >;
```

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *v-options* for the CLASS statement by placing them after a slash (/). Global *v-options* are applied to all the variables specified in the CLASS statement. However, individual CLASS variable *v-options* override the global *v-options*.

CPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is $32 - \min(32, \max(2, f))$, where *f* is the formatted length of the CLASS variable.

DESCENDING

DESC

reverses the sorting order of the classification variable.

LPREFIX= *n*

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

ORDER=DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SURVEYLOGISTIC interprets values of the ORDER= option.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter

on the SORT procedure in the *SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

PARAM=keyword

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=EFFECT. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used.

EFFECT	specifies effect coding
GLM	specifies less-than-full-rank, reference cell coding; this option can only be used as a global option
ORDINAL	specifies the cumulative parameterization for an ordinal CLASS variable.
POLYNOMIAL	
POLY	specifies polynomial coding
REFERENCE	
REF	specifies reference cell coding
ORTHEFFECT	orthogonalizes PARAM=EFFECT
ORTHORDINAL	
ORTHOTERM	orthogonalizes PARAM=ORDINAL
ORTHPOLY	orthogonalizes PARAM=POLYNOMIAL
ORTHREF	orthogonalizes PARAM=REFERENCE

The EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for the EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

REF='level' | keyword

specifies the reference level for PARAM=EFFECT or PARAM=REFERENCE. For an individual (but not a global) variable REF= *option*, you can specify the *level* of the variable to use as the reference level. For a global or individual variable REF= *option*, you can use one of the following *keywords*. The default is REF=LAST.

FIRST	designates the first ordered level as reference
LAST	designates the last ordered level as reference

CLUSTER Statement

CLUSTER | **CLUSTERS** *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section “[Primary Sampling Units \(PSUs\)](#)” on page 4281 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses all variables from all CLUSTER statements to create clusters.

CONTRAST Statement

CONTRAST *'label'* *row-description* <,..., *row-description*>< / *options* >;

where a *row-description* is: *effect values* <,...*effect values*>

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC LOGISTIC and PROC GLM, depending on the coding schemes used with any classification variables involved.

The CONTRAST statement enables you to specify a matrix, \mathbf{L} , for testing the hypothesis $\mathbf{L}\boldsymbol{\theta} = \mathbf{0}$, where $\boldsymbol{\theta}$ is the parameter vector. You must be familiar with the details of the model parameterization that PROC SURVEYLOGISTIC uses (for more information, see the PARAM= option in the section “[CLASS Statement](#)” on page 4253). Optionally, the CONTRAST statement enables you to estimate each row, $l'_i\boldsymbol{\theta}$, of $\mathbf{L}\boldsymbol{\theta}$ and test the hypothesis $l'_i\boldsymbol{\theta} = 0$. Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The following parameters are specified in the CONTRAST statement:

label identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.

- effect* identifies an effect that appears in the MODEL statement. The name INTERCEPT can be used as an effect when one or more intercepts are included in the model. You do not need to include all effects that are included in the MODEL statement.
- values* are constants that are elements of the **L** matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of **L** are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the **L** matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by default or by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded CLASS variable A has four levels. Then there are three parameters ($\alpha_1, \alpha_2, \alpha_3$) representing the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of A, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form $\mathbf{L}\boldsymbol{\theta} = \mathbf{0}$, is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements are constructed similarly. For example,

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
                    A 0 1 0,
                    A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying PARAM=GLM in the CLASS statement), each row is checked for estimability. If PROC SURVEYLOGISTIC finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC SURVEYLOGISTIC handles missing level combinations of classification variables in the same manner as PROC LOGISTIC. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the **L** matrix in your CONTRAST statement. If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the LOGISTIC procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A*B. If you specify a CONTRAST statement involving A alone, the **L** matrix contains nonzero terms for both A and A*B, since A*B contains A.

The degrees of freedom is the number of linearly independent constraints implied by the CONTRAST statement, that is, the rank of **L**.

You can specify the following options after a slash (/).

ALPHA= α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

E

requests that the **L** matrix be displayed.

ESTIMATE=keyword

requests that each individual contrast (that is, each row, $l'_i\beta$, of $L\beta$) or exponentiated contrast ($e^{l'_i\beta}$) be estimated and tested. PROC SURVEYLOGISTIC displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast ($e^{l'_i\beta}$), or both, by specifying one of the following *keywords*:

PARM	specifies that the contrast itself be estimated
EXP	specifies that the exponentiated contrast be estimated
BOTH	specifies that both the contrast and the exponentiated contrast be estimated

SINGULAR = number

tunes the estimability check. This option is ignored when the full-rank parameterization is used. If v is a vector, define $ABS(v)$ to be the largest absolute value of the elements of v . For a row vector l' of the contrast matrix L , define c to be equal to $ABS(l)$ if $ABS(l)$ is greater than 0; otherwise, c equals 1. If $ABS(l' - l'T)$ is greater than $c * number$, then l is declared nonestimable. The T matrix is the Hermite form matrix $I_0^- I_0$, where I_0^- represents a generalized inverse of the information matrix I_0 of the null model. The value for *number* must be between 0 and 1; the default value is 1E-4.

FREQ Statement

FREQ *variable* ;

The *variable* in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC SURVEYLOGISTIC treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1.

If you use the *events/trials* syntax in the MODEL statement, the FREQ statement is disallowed because the event and trial variables represent the frequencies in the data set.

MODEL Statement

MODEL *events/trials*= < *effects* >< / *options* >;

MODEL *variable* < (*variable_options*) >= < *effects* >< /*options* >;

The MODEL statement names the response variable and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section “Specification of Effects” on page 1784 of Chapter 32, “The GLM Procedure,”

for more information. If you omit the explanatory variables, the procedure fits an intercept-only model. [Model options](#) can be specified after a slash (/).

Two forms of the MODEL statement can be specified. The first form, referred to as *single-trial* syntax, is applicable to binary, ordinal, and nominal response data. The second form, referred to as *events/trials* syntax, is restricted to the case of binary response data. The *single-trial* syntax is used when each observation in the DATA= data set contains information on only a single trial, for instance, a single subject in an experiment. When each observation contains information on multiple binary-response trials, such as the counts of the number of subjects observed and the number responding, then *events/trials* syntax can be used.

In the *events/trials* syntax, you specify two variables that contain count data for a binomial experiment. These two variables are separated by a slash. The value of the first variable, *events*, is the number of positive responses (or events). The value of the second variable, *trials*, is the number of trials. The values of both *events* and (*trials*–*events*) must be nonnegative and the value of *trials* must be positive for the response to be valid.

In the *single-trial* syntax, you specify one variable (on the left side of the equal sign) as the response variable. This variable can be character or numeric. [Options](#) specific to the response variable can be specified immediately after the response variable with a pair of parentheses around them.

For both forms of the MODEL statement, explanatory *effects* follow the equal sign. Variables can be either continuous or classification variables. Classification variables can be character or numeric, and they must be declared in the CLASS statement. When an effect is a classification variable, the procedure enters a set of coded columns into the design matrix instead of directly entering a single column containing the values of the variable.

Response Variable Options

You specify the following options by enclosing them in a pair of parentheses after the response variable.

DESCENDING | DESC

reverses the order of response categories. If both the DESCENDING and [ORDER=](#) options are specified, PROC SURVEYLOGISTIC orders the response categories according to the ORDER= option and then reverses that order. See the [“Response Level Ordering”](#) section on page 4269 for more detail.

EVENT='category' | keyword

specifies the event category for the binary response model. PROC SURVEYLOGISTIC models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted if a format is applied) of the event category in quotes or you can specify one of the following keywords. The default is EVENT=FIRST.

FIRST	designates the first ordered category as the event
LAST	designates the last ordered category as the event

One of the most common sets of response levels is {0,1}, with 1 representing the event for which the probability is to be modeled. Consider the example where *Y* takes the values 1 and 0 for event and nonevent, respectively, and *Exposure* is the explanatory variable. To specify the value 1 as the event category, use the model statement

```
model Y(event='1') = Exposure;
```

ORDER= DATA | FORMATTED | FREQ | INTERNAL

specifies the sorting order for the levels of the response variable. By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows the interpretation of the ORDER= values.

Value of ORDER=	Levels Sorted By
DATA	order of appearance in the input data set
FORMATTED	external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	descending frequency count; levels with the most observations come first in the order
INTERNAL	unformatted value

For more information on sorting order, see the chapter on the SORT procedure in the *SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

REFERENCE='category' | keyword

REF='category' | keyword

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each nonreference category is contrasted with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes or you can specify one of the following keywords. The default is REF=LAST.

FIRST designates the first ordered category as the reference

LAST designates the last ordered category as the reference

Model Options

Model options can be specified after a slash (/). Table 69.1 summarizes the options available in the MODEL statement.

Table 69.1. Model Statement Options

Option	Description
Model Specification Options	
LINK=	Specifies link function
NOINT	Suppresses intercept(s)
OFFSET=	Specifies offset variable
Convergence Criterion Options	
ABSFCNV=	Specifies absolute function convergence criterion
FCONV=	Specifies relative function convergence criterion
GCONV=	Specifies relative gradient convergence criterion
XCONV=	Specifies relative parameter convergence criterion
MAXITER=	Specifies maximum number of iterations
NOCHECK	Suppresses checking for infinite parameters
RIDGING=	Specifies technique used to improve the log-likelihood function when its value is worse than that of the previous step
SINGULAR=	Specifies tolerance for testing singularity
TECHNIQUE=	Specifies iterative algorithm for maximization
Options for Adjustment to Variance Estimation	
VADJUST=	Choose variance estimation adjustment method
Options for Confidence Intervals	
ALPHA=	Specifies α for the $100(1 - \alpha)\%$ confidence intervals
CLPARM	Computes confidence intervals for parameters
CLODDS	Computes confidence intervals for odds ratios
Options for Display of Details	
CORRB	Displays correlation matrix
COVB	Displays covariance matrix
EXPB	Displays exponentiated values of estimates
ITPRINT	Displays iteration history
NODUMMYPRINT	Suppresses “Class Level Information” table
PARMLABEL	Displays parameter labels
RSQUARE	Displays generalized R^2
STB	Displays standardized estimates

The following list describes these options.

ABSFCNV=value

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations,

$$|l^{(i)} - l^{(i-1)}| < value$$

where $l^{(i)}$ is the value of the log-likelihood function at iteration i . See the section “Convergence Criteria” on page 4277.

ALPHA= α

sets the level of significance α for $100(1 - \alpha)\%$ confidence intervals for regression parameters or odds ratios. The value α must be between 0 and 1. By default, α is equal to the value of the ALPHA= option in the PROC SURVEYLOGISTIC statement, or $\alpha = 0.05$ if the option is not specified. This option has no effect unless confidence limits for the parameters or odds ratios are requested.

CLODDS

requests confidence intervals for the odds ratios. Computation of these confidence intervals is based on individual Wald tests. The confidence coefficient can be specified with the ALPHA= option. See the “Wald Confidence Intervals for Parameters” section on page 4288 for more information.

CLPARM

requests confidence intervals for the parameters. Computation of these confidence intervals is based on the individual Wald tests. The confidence coefficient can be specified with the ALPHA= option. See the “Wald Confidence Intervals for Parameters” section on page 4288 for more information.

CORRB

displays the correlation matrix of the parameter estimates.

COVB

displays the covariance matrix of the parameter estimates.

EXPB**EXPEST**

displays the exponentiated values ($e^{\hat{\theta}_i}$) of the parameter estimates $\hat{\theta}_i$ in the “Analysis of Maximum Likelihood Estimates” table for the logit model. These exponentiated values are the estimated odds ratios for the parameters corresponding to the continuous explanatory variables.

FCONV=*value*

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations,

$$\frac{|l^{(i)} - l^{(i-1)}|}{|l^{(i-1)}| + 1\text{E-}6} < \textit{value}$$

where $l^{(i)}$ is the value of the log-likelihood at iteration i . See the section “Convergence Criteria” on page 4277.

GCONV=*value*

specifies the relative gradient convergence criterion. Convergence requires that the normalized prediction function reduction is small,

$$\frac{\mathbf{g}^{(i)\prime} \mathbf{I}^{(i)} \mathbf{g}^{(i)}}{|l^{(i)}| + 1\text{E-}6} < \textit{value}$$

where $l^{(i)}$ is the value of the log-likelihood function, $\mathbf{g}^{(i)}$ is the gradient vector, and $\mathbf{I}^{(i)}$ the (expected) information matrix. All of these functions are evaluated at iteration

i. This is the default convergence criterion, and the default value is $1E-8$. See the section [“Convergence Criteria”](#) on page 4277.

ITPRINT

displays the iteration history of the maximum-likelihood model fitting. The ITPRINT option also displays the last evaluation of the gradient vector and the final change in the -2 Log Likelihood.

LINK=keyword

L=keyword

specifies the link function linking the response probabilities to the linear predictors. You can specify one of the following keywords. The default is LINK=LOGIT.

CLOGLOG	the complementary log-log function. PROC SURVEYLOGISTIC fits the binary complementary log-log model for binary response and fits the cumulative complementary log-log model when there are more than two response categories. Aliases: CCLOGLOG, CCLL, CUMCLOGLOG.
GLOGIT	the generalized logit function. PROC SURVEYLOGISTIC fits the generalized logit model where each nonreference category is contrasted with the reference category. You can use the response variable option REF= to specify the reference category.
LOGIT	the cumulative logit function. PROC SURVEYLOGISTIC fits the binary logit model when there are two response categories and fits the cumulative logit model when there are more than two response categories. Aliases: CLOGIT, CUMLOGIT.
PROBIT	the inverse standard normal distribution function. PROC SURVEYLOGISTIC fits the binary probit model when there are two response categories and fits the cumulative probit model when there are more than two response categories. Aliases: NORMIT, CPROBIT, CUMPROBIT.

See the section [“Link Functions and the Corresponding Distributions”](#) on page 4273 for details.

MAXITER=*n*

specifies the maximum number of iterations to perform. By default, MAXITER=25. If convergence is not attained in *n* iterations, the displayed output created by the procedure contain results that are based on the last maximum likelihood iteration.

NOCHECK

disables the checking process to determine whether maximum likelihood estimates of the regression parameters exist. If you are sure that the estimates are finite, this option can reduce the execution time if the estimation takes more than eight iterations. For more information, see the [“Existence of Maximum Likelihood Estimates”](#) section on page 4277.

NODUMMYPRINT**NODESIGNPRINT****NODP**

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

NOINT

suppresses the intercept for the binary response model or the first intercept for the ordinal response model.

OFFSET= *name*

names the offset variable. The regression coefficient for this variable will be fixed at 1.

PARMLABEL

displays the labels of the parameters in the “Analysis of Maximum Likelihood Estimates” table.

RIDGING=ABSOLUTE | RELATIVE | NONE

specifies the technique used to improve the log-likelihood function when its value in the current iteration is less than that in the previous iteration. If you specify the RIDGING=ABSOLUTE option, the diagonal elements of the negative (expected) Hessian are inflated by adding the ridge value. If you specify the RIDGING=RELATIVE option, the diagonal elements are inflated by a factor of 1 plus the ridge value. If you specify the RIDGING=NONE option, the crude line search method of taking half a step is used instead of ridging. By default, RIDGING=RELATIVE.

RSQUARE**RSQ**

requests a generalized R^2 measure for the fitted model. For more information, see the “[Generalized Coefficient of Determination](#)” section on page 4280.

SINGULAR=*value*

specifies the tolerance for testing the singularity of the Hessian matrix (Newton-Raphson algorithm) or the expected value of the Hessian matrix (Fisher-scoring algorithm). The Hessian matrix is the matrix of second partial derivatives of the log likelihood. The test requires that a pivot for sweeping this matrix be at least this number times a norm of the matrix. Values of the SINGULAR= option must be numeric. By default, SINGULAR=1E-12.

STB

displays the standardized estimates for the parameters for the continuous explanatory variables in the “Analysis of Maximum Likelihood Estimates” table. The standardized estimate of θ_i is given by $\hat{\theta}_i/(s/s_i)$, where s_i is the total sample standard deviation for the i th explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{Logistic} \\ 1 & \text{Normal} \\ \pi/\sqrt{6} & \text{Extreme-value} \end{cases}$$

For the intercept parameters and parameters associated with a CLASS variable, the standardized estimates are set to missing.

TECHNIQUE=FISHER | NEWTON

TECH=FISHER | NEWTON

specifies the optimization technique for estimating the regression parameters. NEWTON (or NR) is the Newton-Raphson algorithm and FISHER (or FS) is the Fisher-scoring algorithm. Both techniques yield the same estimates, but the estimated covariance matrices are slightly different except for the case when the LOGIT link is specified for binary response data. The default is TECHNIQUE=FISHER. See the section “[Iterative Algorithms for Model-Fitting](#)” on page 4275 for details.

VADJUST=DF | MOREL | NONE < (Morel-options) >

VARADJ=DF | MOREL | NONE < (Morel-options) >

VARADJUST=DF | MOREL | NONE < (Morel-options) >

specifies an [adjustment to the variance estimation](#) (on page 4286) for the regression coefficients.

By default, PROC SURVEYLOGISTIC uses the degrees of freedom adjustment VADJUST=DF.

You can specify the VADJUST=MOREL option for the variance adjustment proposed by Morel (1989).

If you do not wish to use any variance adjustment, you can specify the VADJUST=NONE option.

You can specify the following *Morel-options* within parentheses after the VADJUST=MOREL option.

ADJBOUND= ϕ

sets the upper bound coefficient ϕ in the variance adjustment. This upper bound must be positive. By default, the procedure use $\phi = 0.5$. See the section “[Adjustments to the Variance Estimation](#)” on page 4286 for more details on how this upper bound is used in the variance estimation.

DEFFBOUND= δ

sets the lower bound of the estimated design effect in the variance adjustment. This lower bound must be positive. By default, the procedure use $\delta = 1$. See the section “[Adjustments to the Variance Estimation](#)” on page 4286 for more details on how this lower bound is used in the variance estimation.

XCONV=*value*

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations,

$$\max_j |\delta_j^{(i)}| < \text{value}$$

where

$$\delta_j^{(i)} = \begin{cases} \theta_j^{(i)} - \theta_j^{(i-1)} & |\theta_j^{(i-1)}| < 0.01 \\ \frac{\theta_j^{(i)} - \theta_j^{(i-1)}}{\theta_j^{(i-1)}} & \text{otherwise} \end{cases}$$

and $\theta_j^{(i)}$ is the estimate of the j th parameter at iteration i . See the section “[Iterative Algorithms for Model-Fitting](#)” on page 4275.

STRATA Statement

STRATA | **STRATUM** *variables* < /option > ;

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4280 for more information.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *SAS Procedures Guide*.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a “Stratum Information” table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section “[Displayed Output](#)” on page 4292 for more details.

TEST Statement

< label: > **TEST** *equation1* < , . . . , < *equationk* > > < /option > ;

The TEST statement tests linear hypotheses about the regression coefficients. The Wald test is used to jointly test the null hypotheses ($H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$) specified in a single TEST statement. When $\mathbf{c} = \mathbf{0}$ you should specify a **CONTRAST** statement instead.

Each *equation* specifies a linear hypothesis (a row of the \mathbf{L} matrix and the corresponding element of the \mathbf{c} vector); multiple *equations* are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an *equation* is as follows:

term < \pm *term* . . . > < = \pm *term* < \pm *term* . . . > >

where *term* is a parameter of the model, or a constant, or a constant times a parameter. For a binary response model, the intercept parameter is named INTERCEPT;

for an ordinal response model, the intercept parameters are named INTERCEPT, INTERCEPT2, INTERCEPT3, and so on. When no equal sign appears, the expression is set to 0. The following code illustrates possible uses of the TEST statement:

```
proc surveylogistic;
  model y= a1 a2 a3 a4;
  test1: test intercept + .5 * a2 = 0;
  test2: test intercept + .5 * a2;
  test3: test a1=a2=a3;
  test4: test a1=a2, a2=a3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

You can specify the following option in the TEST statement after a slash(/).

PRINT

displays intermediate calculations in the testing of the null hypothesis $H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$. This includes $\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}'$ bordered by $(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$ and $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}$ bordered by $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$, where $\hat{\boldsymbol{\theta}}$ is the maximum likelihood estimator of $\boldsymbol{\theta}$ and $\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})$ is the estimated covariance matrix of $\hat{\boldsymbol{\theta}}$.

For more information, see the “Testing Linear Hypotheses about the Regression Coefficients” section on page 4288.

UNITS Statement

UNITS *independent1 = list1 < ... independentk = listk >< /option >* ;

The UNITS statement enables you to specify units of change for the continuous explanatory variables so that customized odds ratios can be estimated. An estimate of the corresponding odds ratio is produced for each unit of change specified for an explanatory variable. The UNITS statement is ignored for CLASS variables. If the CLODDS option is specified in the MODEL statement, the corresponding confidence limits for the odds ratios are also displayed.

The term *independent* is the name of an explanatory variable and *list* represents a list of units of change, separated by spaces, that are of interest for that variable. Each unit of change in a list has one of the following forms:

- *number*
- SD or –SD
- *number* * SD

where *number* is any nonzero number, and SD is the sample standard deviation of the corresponding independent variable. For example, $X = -2$ requests an odds ratio that represents the change in the odds when the variable X is decreased by two units.

$X = 2*SD$ requests an estimate of the change in the odds when X is increased by two sample standard deviations.

You can specify the following option in the UNITS statement after a slash(/).

DEFAULT= *list*

gives a list of units of change for all explanatory variables that are not specified in the UNITS statement. Each unit of change can be in any of the forms described previously. If the DEFAULT= option is not specified, PROC SURVEYLOGISTIC does not produce customized odds ratio estimates for any explanatory variable that is not listed in the UNITS statement.

For more information, see the “[Odds Ratio Estimation](#)” section on page 4288.

WEIGHT Statement

WEIGHT *variable* < / *option* >;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYLOGISTIC assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

Details

Missing Values

Any observation with missing values for the response, offset, or explanatory variables is excluded from the analysis. The estimated linear predictor, its standard error estimate, the fitted probabilities, and their confidence limits are not computed for any observation with missing offset or explanatory variable values.

An observation is also excluded if it has a missing value for any STRATA or CLUSTER variable, unless the MISSING option is used in the PROC SURVEYLOGISTIC statement.

Missing values in your survey data (such as nonresponse) can compromise the quality of your results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*.

If the missing data are missing at random, then PROC SURVEYLOGISTIC produces unbiased results when it excludes observations with missing values. However, if the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then excluding nonrespondents from the analysis may result in biased estimates that do not accurately represent the survey population.

When the missing data are not missing at random, you should use imputation to replace missing values with acceptable values and use sampling weight adjustments

to compensate for nonresponse before you use PROC SURVEYLOGISTIC. Refer to Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more information.

Model Specification

Response Level Ordering

Response level ordering is important because, by default, PROC SURVEYLOGISTIC models the probabilities of response levels with lower *Ordered Value*. Ordered Values, displayed in the “Response Profile” table, are assigned to response levels in ascending sorted order. That is, the lowest response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so on. For example, if your response variable Y takes values in $\{1, \dots, D + 1\}$, then the functions of the response probabilities modeled with the cumulative model are

$$\text{logit}(\Pr(Y \leq i|\mathbf{x})), i = 1, \dots, D$$

and for the generalized logit model they are

$$\log\left(\frac{\Pr(Y = i|\mathbf{x})}{\Pr(Y = D + 1|\mathbf{x})}\right), i = 1, \dots, D$$

where the highest Ordered Value $Y = D + 1$ is the reference level. You can change these default functions by specifying the `EVENT=`, the `REF=`, the `DESCENDING`, or the `ORDER=` response variable options in the MODEL statement.

For binary response data with event and nonevent categories, the procedure models the function

$$\text{logit}(\pi) = \log\left(\frac{\pi}{1 - \pi}\right)$$

where π is the probability of the response level assigned Ordered Value 1 in the “Response Profiles” table. Since

$$\text{logit}(\pi) = -\text{logit}(1 - \pi)$$

the effect of reversing the order of the two response levels is to change the signs of α and β in the model $\text{logit}(\pi) = \alpha + \beta'x$.

If your event category has a higher Ordered Value than the nonevent category, the procedure models the nonevent probability. You can use response variable options to model the event probability. For example, suppose the binary response variable Y

takes the values 1 and 0 for event and nonevent, respectively, and **Exposure** is the explanatory variable. By default, the procedure assigns Ordered Value 1 to response level $Y=0$, and Ordered Value 2 to response level $Y=1$. Therefore, the procedure models the probability of the nonevent (Ordered Value=1) category. To model the event probability, you can do the following:

- explicitly state which response level is to be modeled using the response variable option **EVENT=** in the MODEL statement,

```
model Y(event='1') = Exposure;
```

- specify the response variable option **DESCENDING** in the MODEL statement,

```
model Y(descending)=Exposure;
```

- specify the response variable option **REF=** in the MODEL statement as the nonevent category for the response variable. This option is most useful when you are fitting a generalized logit model.

```
model Y(ref='0') = Exposure;
```

- assign a format to **Y** such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, $Y=1$ is assigned formatted value 'event' and $Y=0$ is assigned formatted value 'nonevent'. Since **ORDER=FORMATTED** by default, Ordered Value 1 is assigned to response level $Y=1$ so the procedure models the event.

```
proc format;
  value Disease 1='event' 0='nonevent';
run;
proc surveylogistic;
  format Y Disease.;
  model Y=Exposure;
run;
```

CLASS Variable Parameterization

Consider a model with one CLASS variable **A** with four levels, 1, 2, 5, and 7. Details of the possible choices for the **PARAM=** option follow.

EFFECT Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of -1 . For instance, if the reference level is 7 (**REF=7**), the design matrix columns for **A** are as follows.

Effect Coding			
A	Design Matrix		
	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	-1	-1	-1

Parameter estimates of CLASS main effects using the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

GLM

As in PROC GLM, four columns are created to indicate group membership. The design matrix columns for A are as follows.

GLM Coding				
A	Design Matrix			
	A1	A2	A5	A7
1	1	0	0	0
2	0	1	0	0
5	0	0	1	0
7	0	0	0	1

Parameter estimates of CLASS main effects using the GLM coding scheme estimate the difference in the effects of each level compared to the last level.

ORDINAL

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

Ordinal Coding			
A	Design Matrix		
	A2	A5	A7
1	0	0	0
2	1	0	0
5	1	1	0
7	1	1	1

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects using the ORDINAL coding scheme estimate the effect on the response as the ordinal factor is set to each succeeding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

POLYNOMIAL

POLY

Three columns are created. The first represents the linear term (x), the second represents the quadratic term (x^2), and the third represents the cubic term (x^3), where x is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sorting order. The design matrix columns for A are as follows.

Polynomial Coding			
A	Design Matrix		
	APOLY1	APOLY2	APOLY3
1	1	1	1
2	2	4	8
5	5	25	125
7	7	49	343

REFERENCE

REF Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

Reference Coding			
A	Design Matrix		
	A1	A2	A5
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects using the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

ORTHEFFECT The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

Orthogonal Effect Coding			
A	Design Matrix		
	AOEFF1	AOEFF2	AOEFF3
1	1.41421	-0.81650	-0.57735
2	0.00000	1.63299	-0.57735
5	0.00000	0.00000	1.73205
7	-1.41421	-0.81649	-0.57735

ORTHORDINAL

ORTHOTHERM The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

Orthogonal Ordinal Coding			
	Design Matrix		
A	AOORD1	AOORD2	AOORD3
1	-1.73205	0.00000	0.00000
2	0.57735	-1.63299	0.00000
5	0.57735	0.81650	-1.41421
7	0.57735	0.81650	1.41421

ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

Orthogonal Polynomial Coding			
	Design Matrix		
A	AOPOLY1	AOPOLY2	AOPOLY5
1	-1.153	0.907	-0.921
2	-0.734	-0.540	1.473
5	0.524	-1.370	-0.921
7	1.363	1.004	0.368

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

Orthogonal Reference Coding			
	Design Matrix		
A	AOREF1	AOREF2	AOREF3
1	1.73205	0.00000	0.00000
2	-0.57735	1.63299	0.00000
5	-0.57735	-0.81650	1.41421
7	-0.57735	-0.81650	-1.41421

Link Functions and the Corresponding Distributions

Four link functions are available in the SURVEYLOGISTIC procedure. The logit function is the default. To specify a different link function, use the LINK= option in the MODEL statement. The link functions and the corresponding distributions are as follows:

- The logit function

$$g(\pi) = \log\left(\frac{\pi}{1 - \pi}\right)$$

is the inverse of the cumulative logistic distribution function, which is

$$F(x) = \frac{1}{1 + e^{-x}}$$

- The probit (or normit) function

$$g(\pi) = \Phi^{-1}(\pi)$$

is the inverse of the cumulative standard normal distribution function, which is

$$F(x) = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{1}{2}z^2} dz$$

Traditionally, the probit function includes an additive constant 5, but throughout PROC SURVEYLOGISTIC, the terms probit and normit are used interchangeably, defined as $g(p)$ above.

- The complementary log-log function

$$g(\pi) = \log(-\log(1 - \pi))$$

is the inverse of the cumulative extreme-value function (also called the Gompertz distribution), which is

$$F(x) = 1 - e^{-e^x}$$

- The generalized logit function extends the binary logit link to a vector of levels $(\pi_1, \dots, \pi_{k+1})$ by contrasting each level with a fixed level

$$g(\pi_i) = \log\left(\frac{\pi_i}{\pi_{k+1}}\right) \quad i = 1, \dots, k$$

The variances of the normal, logistic, and extreme-value distributions are not the same. Their respective means and variances are

Distribution	Mean	Variance
Normal	0	1
Logistic	0	$\pi^2/3$
Extreme-value	$-\gamma$	$\pi^2/6$

where γ is the Euler constant. In comparing parameter estimates using different link functions, you need to take into account the different scalings of the corresponding distributions and, for the complementary log-log function, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates using the logit link function should be about $\pi/\sqrt{3} \approx 1.8$ larger than the estimates from the probit link function.

Model Fitting

Determining Observations for Likelihood Contributions

If you use *events/trials* syntax, each observation is split into two observations. One has the response value 1 with a frequency equal to the frequency of the original observation (which is 1 if the *FREQ* statement is not used) times the value of the *events* variable. The other observation has the response value 2 and a frequency equal to the frequency of the original observation times the value of (*trials* – *events*). These two observations have the same explanatory variable values and the same *FREQ* and *WEIGHT* values as the original observation.

For either *single-trial* or *events/trials* syntax, let j index all observations. In other words, for *single-trial* syntax, j indexes the actual observations. And, for *events/trials* syntax, j indexes the observations after splitting (as described previously). If your data set has 30 observations and you use *single-trial* syntax, j has values from 1 to 30; if you use *events/trials* syntax, j has values from 1 to 60.

Suppose the response variable in a cumulative response model can take on the ordered values $1, \dots, k, k+1$ where k is an integer ≥ 1 . The likelihood for the j th observation with ordered response value y_j and explanatory variables vector (row vectors) \mathbf{x}_j is given by

$$L_j = \begin{cases} F(\alpha_1 + \mathbf{x}_j\boldsymbol{\beta}) & y_j = 1 \\ F(\alpha_i + \mathbf{x}_j\boldsymbol{\beta}) - F(\alpha_{i-1} + \mathbf{x}_j\boldsymbol{\beta}) & 1 < y_j = i \leq k \\ 1 - F(\alpha_k + \mathbf{x}_j\boldsymbol{\beta}) & y_j = k + 1 \end{cases}$$

where $F(\cdot)$ is the logistic, normal, or extreme-value distribution function, $\alpha_1, \dots, \alpha_k$ are ordered intercept parameters, and $\boldsymbol{\beta}$ is the slope parameter vector.

For the generalized logit model, letting the $k + 1$ st level be the reference level, the intercepts $\alpha_1, \dots, \alpha_k$ are unordered and the slope vector $\boldsymbol{\beta}_i$ varies with each logit. The likelihood for the j th observation with ordered response value y_j and explanatory variables vector \mathbf{x}_j (row vectors) is given by

$$L_j = \Pr(Y = y_j | \mathbf{x}_j) = \begin{cases} \frac{e^{\alpha_i + \mathbf{x}_j\boldsymbol{\beta}_i}}{1 + \sum_{i=1}^k e^{\alpha_i + \mathbf{x}_j\boldsymbol{\beta}_i}} & 1 \leq y_j = i \leq k \\ \frac{1}{1 + \sum_{i=1}^k e^{\alpha_i + \mathbf{x}_j\boldsymbol{\beta}_i}} & y_j = k + 1 \end{cases}$$

Iterative Algorithms for Model-Fitting

Two iterative maximum likelihood algorithms are available in PROC SURVEYLOGISTIC to obtain the maximum likelihood estimate $\hat{\boldsymbol{\theta}}$ of the model parameter $\boldsymbol{\theta}$. The default is the Fisher-scoring method, which is equivalent to fitting by iteratively reweighted least squares. The alternative algorithm is the

Newton-Raphson method. Both algorithms give the same parameter estimates; The covariance matrix of $\hat{\boldsymbol{\theta}}$ is estimated in the section “Variance Estimation for Sample Survey Data” on page 4282. For a generalized logit model, only the Newton-Raphson technique is available. You can use the `TECHNIQUE=` option to select a fitting algorithm.

Iteratively Reweighted Least-Squares Algorithm (Fisher Scoring)

Let Y be the response variable which takes values $1, \dots, k, k+1$ ($k \geq 1$). Let j index all observations and Y_j be the value of response for the j th observation. Consider the multinomial variable $\mathbf{Z}_j = (Z_{1j}, \dots, Z_{kj})'$ such that

$$Z_{ij} = \begin{cases} 1 & \text{if } Y_j = i \\ 0 & \text{otherwise} \end{cases}$$

and $Z_{(k+1)j} = 1 - \sum_{i=1}^k Z_{ij}$. With π_{ij} denoting the probability that the j th observation has response value i , the expected value of \mathbf{Z}_j is $\boldsymbol{\pi}_j = (\pi_{1j}, \dots, \pi_{kj})'$, and $\pi_{(k+1)j} = 1 - \sum_{i=1}^k \pi_{ij}$. The covariance matrix of \mathbf{Z}_j is \mathbf{V}_j , which is the covariance matrix of a multinomial random variable for one trial with parameter vector $\boldsymbol{\pi}_j$. Let $\boldsymbol{\theta}$ be the vector of regression parameters; for example, $\boldsymbol{\theta} = (\alpha_1, \dots, \alpha_k, \boldsymbol{\beta})'$ for cumulative logit model. Let \mathbf{D}_j be the matrix of partial derivatives of $\boldsymbol{\pi}_j$ with respect to $\boldsymbol{\theta}$. The estimating equation for the regression parameters is

$$\sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j) = \mathbf{0}$$

where $\mathbf{W}_j = w_j f_j \mathbf{V}_j^{-1}$, w_j and f_j are the `WEIGHT` and `FREQ` values of the j th observation.

With a starting value of $\boldsymbol{\theta}^{(0)}$, the maximum likelihood estimate of $\boldsymbol{\theta}$ is obtained iteratively as

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + \left(\sum_j \mathbf{D}'_j \mathbf{W}_j \mathbf{D}_j \right)^{-1} \sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j)$$

where \mathbf{D}_j , \mathbf{W}_j , and $\boldsymbol{\pi}_j$ are evaluated at the i th iteration $\boldsymbol{\theta}^{(i)}$. The expression after the plus sign is the step size. If the log-likelihood evaluated at $\boldsymbol{\theta}^{(i+1)}$ is less than that evaluated at $\boldsymbol{\theta}^{(i)}$, then $\boldsymbol{\theta}^{(i+1)}$ is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained, that is, until $\boldsymbol{\theta}^{(i+1)}$ is sufficiently close to $\boldsymbol{\theta}^{(i)}$. Then the maximum likelihood estimate of $\boldsymbol{\theta}$ is $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$.

By default, starting values are zero for the slope parameters, and for the intercept parameters, starting values are the observed cumulative logits (that is, logits of the observed cumulative proportions of response). Alternatively, the starting values may be specified with the `INEST=` option.

Newton-Raphson Algorithm

Let

$$\mathbf{g} = \sum_j w_j f_j \frac{\partial l_j}{\partial \boldsymbol{\theta}}$$

$$\mathbf{H} = \sum_j -w_j f_j \frac{\partial^2 l_j}{\partial \boldsymbol{\theta}^2}$$

be the gradient vector and the Hessian matrix, where $l_j = \log L_j$ is the log likelihood for the j th observation. With a starting value of $\boldsymbol{\theta}^{(0)}$, the maximum likelihood estimate $\hat{\boldsymbol{\theta}}$ of $\boldsymbol{\theta}$ is obtained iteratively until convergence is obtained:

$$\boldsymbol{\theta}^{(i+1)} = \boldsymbol{\theta}^{(i)} + \mathbf{H}^{-1} \mathbf{g}$$

where \mathbf{H} and \mathbf{g} are evaluated at the i th iteration $\boldsymbol{\theta}^{(i)}$. If the log likelihood evaluated at $\boldsymbol{\theta}^{(i+1)}$ is less than that evaluated at $\boldsymbol{\theta}^{(i)}$, then $\boldsymbol{\theta}^{(i+1)}$ is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained, that is, until $\boldsymbol{\theta}^{(i+1)}$ is sufficiently close to $\boldsymbol{\theta}^{(i)}$. Then the maximum likelihood estimate of $\boldsymbol{\theta}$ is $\hat{\boldsymbol{\theta}} = \boldsymbol{\theta}^{(i+1)}$.

Convergence Criteria

Four convergence criteria are allowed, namely, **ABSFCONV=**, **FCONV=**, **GCONV=**, and **XCONV=**. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is **GCONV=1E-8**.

Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The existence, finiteness, and uniqueness of maximum likelihood estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986).

Consider a binary response model. Let Y_j be the response of the i th subject and let \mathbf{x}_j be the vector of explanatory variables (including the constant 1 associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations: complete separation, quasi-complete separation, and overlap.

Complete Separation

There is a complete separation of data points if there exists a vector \mathbf{b} that correctly allocates all observations to their response groups; that is,

$$\begin{cases} \mathbf{b}'\mathbf{x}_j > 0 & Y_j = 1 \\ \mathbf{b}'\mathbf{x}_j < 0 & Y_j = 2 \end{cases}$$

This configuration gives nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the log likelihood diminishes to zero, and the dispersion matrix becomes unbounded.

Quasi-Complete Separation The data are not completely separable but there is a vector \mathbf{b} such that

$$\begin{cases} \mathbf{b}'\mathbf{x}_j \geq 0 & Y_j = 1 \\ \mathbf{b}'\mathbf{x}_j \leq 0 & Y_j = 2 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

Overlap If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the maximum likelihood estimates exist and are unique.

Complete separation and quasi-complete separation are problems typically encountered with small data sets. Although complete separation can occur with any type of data, quasi-complete separation is not likely with truly continuous explanatory variables.

The SURVEYLOGISTIC procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution giving complete separation, if such a solution exists. In maximizing the log likelihood, there is no checking for complete or quasi-complete separation if convergence is attained in eight or fewer iterations. Subsequent to the eighth iteration, the probability of the observed response is computed for each observation. If the probability of the observed response is one for all observations, there is a complete separation of data points and the iteration process is stopped. If the complete separation of data has not been determined and an observation is identified to have an extremely large probability (≥ 0.95) of the observed response, there are two possible situations. First, there is overlap in the data set, and the observation is an atypical observation of its own group. The iterative process, if allowed to continue, will stop when a maximum is reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observations vectors (all explanatory variables standardized to zero mean and unit variance) exceeds 5,000, quasi-complete separation is declared and the iterative process is stopped. If either complete separation or quasi-complete separation is detected, a warning message is displayed in the procedure output.

Checking for quasi-complete separation is less foolproof than checking for complete separation. The NOCHECK option in the MODEL statement turns off the process of checking for infinite parameter estimates. In cases of complete or quasi-complete separation, turning off the checking process typically results in the procedure failing to converge.

Model Fitting Statistics

Suppose the model contains s explanatory effects. For the j th observation, let $\hat{\pi}_j$ be the estimated probability of the observed response. The three criteria displayed by the SURVEYLOGISTIC procedure are calculated as follows:

- -2 Log Likelihood:

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \log(\hat{\pi}_j)$$

where w_j and f_j are the weight and frequency values of the j th observation. For binary response models using *events/trials* syntax, this is equivalent to

$$-2 \text{ Log L} = -2 \sum_j w_j f_j \{r_j \log(\hat{\pi}_j) + (n_j - r_j) \log(1 - \hat{\pi}_j)\}$$

where r_j is the number of events, n_j is the number of trials, and $\hat{\pi}_j$ is the estimated event probability.

- Akaike Information Criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

where p is the number of parameters in the model. For cumulative response models, $p = k + s$ where k is the total number of response levels minus one, and s is the number of explanatory effects. For the generalized logit model, $p = k(s + 1)$.

- Schwarz Criterion:

$$\text{SC} = -2 \text{ Log L} + p \log\left(\sum_j f_j\right)$$

where p is as defined previously.

The -2 Log Likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero) and the procedure produces a p -value for this statistic. The AIC and SC statistics give two different ways of adjusting the -2 Log Likelihood statistic for the number of terms in the model and the number of observations used.

Generalized Coefficient of Determination

Cox and Snell (1989, pp. 208–209) propose the following generalization of the coefficient of determination to a more general linear model:

$$R^2 = 1 - \left\{ \frac{L(\mathbf{0})}{L(\hat{\boldsymbol{\theta}})} \right\}^{\frac{2}{n}}$$

where $L(\mathbf{0})$ is the likelihood of the intercept-only model, $L(\hat{\boldsymbol{\theta}})$ is the likelihood of the specified model, and n is the sample size. The quantity R^2 achieves a maximum of less than 1 for discrete models, where the maximum is given by

$$R_{\max}^2 = 1 - \{L(\mathbf{0})\}^{\frac{2}{n}}$$

Nagelkerke (1991) proposes the following adjusted coefficient, which can achieve a maximum value of 1:

$$\tilde{R}^2 = \frac{R^2}{R_{\max}^2}$$

Properties and interpretation of R^2 and \tilde{R}^2 are provided in Nagelkerke (1991). In the “Testing Global Null Hypothesis: BETA=0” table, R^2 is labeled as “RSquare” and \tilde{R}^2 is labeled as “Max-rescaled RSquare.” Use the [RSQUARE](#) option to request R^2 and \tilde{R}^2 .

INEST= Data Set

You can specify starting values for the iterative algorithm in the INEST= data set.

The INEST= data set contains one observation for each BY group. The INEST= data set must contain the intercept variables (named Intercept for binary response models and Intercept, Intercept2, Intercept3, and so forth, for ordinal response models) and all explanatory variables in the MODEL statement. If BY processing is used, the INEST= data set should also include the BY variables, and there must be one observation for each BY group. If the INEST= data set also contains the `_TYPE_` variable, only observations with `_TYPE_` value 'PARMS' are used as starting values.

Survey Design Information

Specification of Population Totals and Sampling Rates

Variance estimates in survey samples involve a finite population correction (*fpc*) for sampling without replacement. For small sampling fractions or sampling with replacement, it is appropriate to ignore this correction (Cochran 1977; Kish 1965), and PROC SURVEYLOGISTIC does so by default. If your analysis requires an *fpc*, specify the sampling fraction using either the RATE= option or the TOTAL= option on the PROC SURVEYLOGISTIC statement. If you do not specify one of these options, the procedure does not use the *fpc* when computing variance estimates.

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of *primary sampling units* (PSUs) in the sample to the total number of PSUs in the study population. If you are using the TOTAL= option for a multistage design, you should specify the total number of PSUs in the study population. See the section “Primary Sampling Units (PSUs)” on page 4281 for more details.

For a nonstratified sample design, or for a stratified sample design for which all the strata have the same sampling rate or population total, you should specify the rate or total as the value of the RATE=*value* option or the TOTAL=*value* option. If your sample design is stratified with different sampling rates or population totals in the strata, then you should use the RATE=SAS-*data-set* option or the TOTAL=SAS-*data-set* option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement, as well as all the variables in the BY statement if any of these statements are specified. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-*data-set* option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. If you specify the RATE=SAS-*data-set* option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be positive numbers. You can specify *value* as a number between 0 and 1; or you can specify *value* in percentage form as a number between 1 and 100, in which case PROC SURVEYLOGISTIC will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=*value* option, this *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or *primary sampling units* (PSUs), in your sample design, the procedure estimates the variance based on the variation among PSUs. Use the CLUSTER statement to identify the first-stage clusters in your design. PROC SURVEYLOGISTIC assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.

Variance Estimation for Sample Survey Data

Due to the variability of characteristics among items in the population, researchers apply scientific sample designs in the sample selection process to reduce the risk of a distorted view of the population, and they make inferences about the population based on the information from the sample survey data. In order to make statistically valid inferences for the population, they must incorporate the sample design in the data analysis.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data using the maximum likelihood method. In the variance estimation, the procedure incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself. See Binder (1981, 1983), Roberts, Rao, and Kumar (1987), Skinner, Holt, and Smith (1989), Morel (1989), and Lehtonen and Pahkinen (1995) for papers that describe logistic regression for sample survey data. When there are clusters, or primary sampling units (PSUs), in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For t tests of the estimates, the degrees of freedom equals the number of clusters minus the number of strata in the sample design. Statistical analyses, such as hypothesis tests and confident limits, will depend on these variance estimates.

Notation

Let Y be the response variable with categories $1, 2, \dots, D, D + 1$. The p covariates are denoted by a p -dimension row vector \mathbf{x} .

For a stratified clustered sample design, each observation is represented by a row vector,

$$(w_{hij}, \mathbf{y}'_{hij}, y_{hij(D+1)}, \mathbf{x}_{hij})$$

where

- $h = 1, 2, \dots, H$ is the stratum number with a total of H strata
- $i = 1, 2, \dots, n_h$ is the cluster number within stratum h , with a total of n_h clusters
- $j = 1, 2, \dots, m_{hi}$ is the unit number within cluster i of stratum h , with a total of m_{hi} units
- w_{hij} denotes the sampling weight
- \mathbf{y}_{hij} is a D -dimensional column vector whose elements are indicator variables for the first D categories for variable Y . If the response of the j th member of the i th cluster in stratum h falls in category d , the d th row of the vector is one, and the remaining elements of the vector are zero, where $d = 1, 2, \dots, D$

- $y_{hij(D+1)}$ is the indicator variable for the $(D + 1)$ category of variable Y
- \mathbf{x}_{hij} denotes the k -dimensional row vector of explanatory variables for the j th member of the i th cluster in stratum h . If there is an intercept, then $x_{hij1} \equiv 1$.
- $\tilde{n} = \sum_{h=1}^H n_h$ is the total number of clusters in the entire sample
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ is the total sample size

The following notations are also used in the following sections:

- f_h denotes the sampling rate for stratum h
- $\boldsymbol{\pi}_{hij}$ is the expected vector of the response variable

$$\begin{aligned}\boldsymbol{\pi}_{hij} &= E(\mathbf{y}_{hij} | \mathbf{x}_{hij}) \\ &= (\pi_{hij1}, \pi_{hij2}, \dots, \pi_{hijD})' \\ \pi_{hij(D+1)} &= E(y_{hij(D+1)} | \mathbf{x}_{hij})\end{aligned}$$

Note that $\pi_{hij(D+1)} = 1 - \mathbf{1}'\boldsymbol{\pi}_{hij}$ where $\mathbf{1}$ is a D -dimensional column vector whose elements are 1.

Likelihood Function

Let $\mathbf{f}(\cdot)$ be a link function such that

$$\boldsymbol{\pi} = \mathbf{f}(\mathbf{x}, \boldsymbol{\theta})$$

where $\boldsymbol{\theta}$ is a p -dimensional column vector for regression coefficients. The pseudo log likelihood is

$$l(\boldsymbol{\theta}) = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \left((\log(\boldsymbol{\pi}_{hij}))' \mathbf{y}_{hij} + \log(\pi_{hij(D+1)}) y_{hij(D+1)} \right)$$

Denote the maximum likelihood estimator as $\hat{\boldsymbol{\theta}}$, which is a solution to the estimating equations:

$$\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \mathbf{D}'_{hij} \left(\text{diag}(\boldsymbol{\pi}_{hij}) - \boldsymbol{\pi}_{hij} \boldsymbol{\pi}'_{hij} \right)^{-1} (\mathbf{y}_{hij} - \boldsymbol{\pi}_{hij}) = \mathbf{0}$$

where \mathbf{D}_{hij} is the matrix of partial derivatives of the link function f with respect to $\boldsymbol{\theta}$.

To obtain the maximum likelihood estimator $\hat{\boldsymbol{\theta}}$, the procedure uses iterations with a starting value $\boldsymbol{\theta}^{(0)}$ for $\boldsymbol{\theta}$. See the section “[Iterative Algorithms for Model-Fitting](#)” on page 4275 for detail.

Generalized Logistic Model

Formulation of the generalized logit models for nominal response variables can be found in Agresti (1990). Without loss of generality, let the last category, $D + 1$, be the reference category for the response variable Y . The link function for the generalized logistic model is defined as

$$\pi_{hijd} = \frac{e^{\mathbf{x}_{hij}\boldsymbol{\beta}_d}}{1 + \sum_{r=1}^D e^{\mathbf{x}_{hij}\boldsymbol{\beta}_r}}$$

and the model parameters are:

$$\begin{aligned}\boldsymbol{\beta}_d &= (\beta_{d1}, \beta_{d2}, \dots, \beta_{dk})' \\ \boldsymbol{\theta} &= (\boldsymbol{\beta}'_1, \boldsymbol{\beta}'_2, \dots, \boldsymbol{\beta}'_D)'\end{aligned}$$

for $d = 1, 2, \dots, D$.

Cumulative Logit Model

Details of the cumulative logit model (or proportional odds model) can be found in McCullagh and Nelder (1989). Denote the cumulative sum of the expected proportions for the first d categories of variable Y by

$$F_{hijd} = \sum_{r=1}^d \pi_{hijr}$$

for $d = 1, 2, \dots, D$. Then the link function for the proportional odds model is

$$\log\left(\frac{F_{hijd}}{1 - F_{hijd}}\right) = \alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta}$$

with the model parameters:

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k) \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

Complementary log-log Model

Use the notations in the previous section, the link function for the complementary log-log is

$$\log(-\log(1 - F_{hijd})) = \alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta}$$

with the model parameters:

$$\begin{aligned}\boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k) \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')'\end{aligned}$$

Probit Model

Another commonly used model for ordinal responses is the probit model with the link function

$$F_{hijd} = \Phi(\alpha_d + \mathbf{x}_{hij}\boldsymbol{\beta})$$

where

$$\Phi(z_0) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{z_0} e^{-\frac{1}{2}z^2} dz$$

is the cumulative distribution function of the standard normal distribution. The model parameters are:

$$\begin{aligned} \boldsymbol{\beta} &= (\beta_1, \beta_2, \dots, \beta_k)' \\ \boldsymbol{\alpha} &= (\alpha_1, \alpha_2, \dots, \alpha_D)', \quad \alpha_1 < \alpha_2 < \dots < \alpha_D \\ \boldsymbol{\theta} &= (\boldsymbol{\alpha}', \boldsymbol{\beta}')' \end{aligned}$$

Estimated Variances

Using Taylor approximation, the estimated covariance matrix of $\hat{\boldsymbol{\theta}}$ is

$$\widehat{V}(\hat{\boldsymbol{\theta}}) = \widehat{\mathbf{Q}}^{-1} \widehat{\mathbf{G}} \widehat{\mathbf{Q}}^{-1}$$

where

$$\begin{aligned} \widehat{\mathbf{Q}} &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \widehat{\mathbf{D}}_{hij} (\text{diag}(\widehat{\boldsymbol{\pi}}_{hij}) - \widehat{\boldsymbol{\pi}}_{hij} \widehat{\boldsymbol{\pi}}_{hij}')^{-1} \widehat{\mathbf{D}}_{hij}' \\ \widehat{\mathbf{G}} &= \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})(\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' \\ \mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} w_{hij} \widehat{\mathbf{D}}_{hij} (\text{diag}(\widehat{\boldsymbol{\pi}}_{hij}) - \widehat{\boldsymbol{\pi}}_{hij} \widehat{\boldsymbol{\pi}}_{hij}')^{-1} (\mathbf{y}_{hij} - \widehat{\boldsymbol{\pi}}_{hij}) \\ \bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot} \end{aligned}$$

If you use the Newton-Raphson algorithm by using the `TECHNIQUE=NEWTON` option in the `MODEL` statement, the matrix $\widehat{\mathbf{Q}}$ is replaced by the negative (expected) Hessian matrix,

The matrices of partial derivatives $\widehat{\mathbf{D}}_{hij}$ and the response probabilities $\widehat{\boldsymbol{\pi}}_{hij}$ are evaluated at $\hat{\boldsymbol{\theta}}$.

Adjustments to the Variance Estimation

The factor $(n - 1)/(n - p)$ in the computation of the matrix $\widehat{\mathbf{G}}$ should reduce the small sample bias associated with using the estimated function to calculate deviations (Morel 1989; Hidioglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which p parameter are estimated. By default, the procedure will use this adjustment in variance estimation. It is equivalent to specify the **VADJUST=DF option** in the MODEL statement. If you do not wish to use this multiplier in the variance estimation, you can specify the **VADJUST=NONE option** in the MODEL statement to suppress this factor.

In addition, you can specify the **VADJUST=MOREL option** to compute a further adjustment to the variance estimator for the regression coefficients $\hat{\boldsymbol{\theta}}$, introduced by Morel (1989):

$$\widehat{\mathbf{V}}(\hat{\boldsymbol{\theta}}) = \widehat{\mathbf{Q}}^{-1} \widehat{\mathbf{G}} \widehat{\mathbf{Q}}^{-1} + \kappa \lambda \widehat{\mathbf{Q}}^{-1}$$

where for given nonnegative constants δ and ϕ ,

$$\begin{aligned} \kappa &= \max\left(\delta, p^{-1} \text{tr}\left(\widehat{\mathbf{Q}}^{-1} \widehat{\mathbf{G}}\right)\right) \\ \lambda &= \min\left(\phi, \frac{p}{\tilde{n} - p}\right) \end{aligned}$$

The adjustment $\kappa \lambda \widehat{\mathbf{Q}}^{-1}$ will

- reduce the small sample bias reflected in inflated Type 1 error rates
- guarantee a positive definite estimated covariance matrix provided that $\widehat{\mathbf{Q}}^{-1}$ exists
- be close to zero when the sample size becomes large

In this adjustment, κ is an estimate of the design effect, which has been bounded below by the positive constant δ . You can use **DEFFBOUND= δ** in the **VADJUST=MOREL option** in the MODEL statement to specify this lower bound; by default, the procedure uses $\delta = 1$. The factor λ converges to zero when the sample size becomes large, and λ has an upper bound ϕ . You can use **ADJBOUND= ϕ** in the **VADJUST=MOREL option** in the MODEL statement to specify this upper bound; by default, the procedure uses $\phi = 0.5$.

Hypothesis Testing and Estimation

Score Statistics and Tests

To understand the general form of the score statistics, let $\mathbf{g}(\boldsymbol{\theta})$ be the vector of first partial derivatives of the log likelihood with respect to the parameter vector $\boldsymbol{\theta}$, and let $\mathbf{g}(\boldsymbol{\theta})$ be the matrix of second partial derivatives of the log likelihood with respect to $\boldsymbol{\theta}$. That is, $\mathbf{g}(\boldsymbol{\theta})$ is the gradient vector, and $\mathbf{H}(\boldsymbol{\theta})$ is the Hessian matrix. Let $\mathbf{I}(\boldsymbol{\theta})$ be either $-\mathbf{H}(\boldsymbol{\theta})$ or the expected value of $-\mathbf{H}(\boldsymbol{\theta})$. Consider a null hypothesis H_0 . Let $\hat{\boldsymbol{\theta}}_0$ be the MLE of $\boldsymbol{\theta}$ under H_0 . The chi-square score statistic for testing H_0 is defined by

$$\mathbf{g}'(\hat{\boldsymbol{\theta}}_0)\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}}_0)\mathbf{g}(\hat{\boldsymbol{\theta}}_0)$$

and it has an asymptotic χ^2 distribution with r degrees of freedom under H_0 , where r is the number of restrictions imposed on $\boldsymbol{\theta}$ by H_0 .

Testing the Parallel Lines Assumption

For an ordinal response, PROC SURVEYLOGISTIC performs a test of the parallel lines assumption. In the displayed output, this test is labeled “Score Test for the Equal Slopes Assumption” when the LINK= option is NORMIT or CLOGLOG. When LINK=LOGIT, the test is labeled as “Score Test for the Proportional Odds Assumption” in the output. This section describes the methods used to calculate the test.

For this test the number of response levels, $D + 1$, is assumed to be strictly greater than 2. Let Y be the response variable taking values $1, \dots, D, D + 1$. Suppose there are k explanatory variables. Consider the general cumulative model without making the parallel lines assumption

$$g(\Pr(Y \leq d | \mathbf{x})) = (1, \mathbf{x})\boldsymbol{\theta}_d, \quad 1 \leq d \leq D$$

where $g(\cdot)$ is the link function, and $\boldsymbol{\theta}_d = (\alpha_d, \beta_{d1}, \dots, \beta_{dk})'$ is a vector of unknown parameters consisting of an intercept α_d and k slope parameters $\beta_{k1}, \dots, \beta_{kd}$. The parameter vector for this general cumulative model is

$$\boldsymbol{\theta} = (\boldsymbol{\theta}'_1, \dots, \boldsymbol{\theta}'_D)'$$

Under the null hypothesis of parallelism $H_0: \beta_{1i} = \beta_{2i} = \dots = \beta_{Di}, 1 \leq i \leq k$, there is a single common slope parameter for each of the s explanatory variables. Let β_1, \dots, β_k be the common slope parameters. Let $\hat{\alpha}_1, \dots, \hat{\alpha}_D$ and $\hat{\beta}_1, \dots, \hat{\beta}_D$ be the MLEs of the intercept parameters and the common slope parameters. Then, under H_0 , the MLE of $\boldsymbol{\theta}$ is

$$\hat{\boldsymbol{\theta}}_0 = (\hat{\boldsymbol{\theta}}'_1, \dots, \hat{\boldsymbol{\theta}}'_D)' \quad \text{with} \quad \hat{\boldsymbol{\theta}}_d = (\hat{\alpha}_d, \hat{\beta}_1, \dots, \hat{\beta}_k)' \quad 1 \leq d \leq D$$

and the chi-squared score statistic $\mathbf{g}'(\hat{\boldsymbol{\theta}}_0)\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}}_0)\mathbf{g}(\hat{\boldsymbol{\theta}}_0)$ has an asymptotic chi-square distribution with $k(D-1)$ degrees of freedom. This tests the parallel lines assumption by testing the equality of separate slope parameters simultaneously for all explanatory variables.

Wald Confidence Intervals for Parameters

Wald confidence intervals are sometimes called the normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The $100(1-\alpha)\%$ Wald confidence interval for θ_j is given by

$$\hat{\theta}_j \pm z_{1-\alpha/2}\hat{\sigma}_j$$

where z_p is the 100 p th percentile of the standard normal distribution, $\hat{\theta}_j$ is the maximum likelihood estimate of θ_j , and $\hat{\sigma}_j$ is the standard error estimate of $\hat{\theta}_j$ in the section “Variance Estimation for Sample Survey Data” on page 4282.

Testing Linear Hypotheses about the Regression Coefficients

Linear hypotheses for $\boldsymbol{\theta}$ are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\theta} = \mathbf{c}$$

where \mathbf{L} is a matrix of coefficients for the linear hypotheses, and \mathbf{c} is a vector of constants. The vector of regression coefficients $\boldsymbol{\theta}$ includes slope parameters as well as intercept parameters. The Wald chi-square statistic for testing H_0 is computed as

$$\chi_W^2 = (\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})'[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\theta}} - \mathbf{c})$$

where $\hat{\mathbf{V}}(\hat{\boldsymbol{\theta}})$ is the estimated covariance matrix in the section “Variance Estimation for Sample Survey Data” on page 4282. Under H_0 , χ_W^2 has an asymptotic chi-square distribution with r degrees of freedom, where r is the rank of \mathbf{L} .

Odds Ratio Estimation

Consider a dichotomous response variable with outcomes *event* and *nonevent*. Consider a dichotomous risk factor variable X that takes the value 1 if the risk factor is present and 0 if the risk factor is absent. According to the logistic model, the log odds function, $g(X)$, is given by

$$g(X) \equiv \log\left(\frac{\Pr(\text{event} | X)}{\Pr(\text{nonevent} | X)}\right) = \beta_0 + \beta_1 X$$

The odds ratio ψ is defined as the ratio of the odds for those with the risk factor ($X = 1$) to the odds for those without the risk factor ($X = 0$). The log of the odds ratio is given by

$$\log(\psi) \equiv \log(\psi(X = 1, X = 0)) = g(X = 1) - g(X = 0) = \beta_1$$

The parameter, β_1 , associated with X represents the change in the log odds from $X = 0$ to $X = 1$. So, the odds ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The odds ratio indicates how the odds of *event* change as you change X from 0 to 1. For instance, $\psi = 2$ means that the odds of an event when $X = 1$ are twice the odds of an event when $X = 0$.

Suppose the values of the dichotomous risk factor are coded as constants a and b instead of 0 and 1. The odds when $X = a$ become $\exp(\beta_0 + a\beta_1)$, and the odds when $X = b$ become $\exp(\beta_0 + b\beta_1)$. The odds ratio corresponding to an increase in X from a to b is

$$\psi = \exp[(b - a)\beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c$$

Note that for any a and b such that $c = b - a = 1$, $\psi = \exp(\beta_1)$. So the odds ratio can be interpreted as the change in the odds for any increase of one unit in the corresponding risk factor. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight may be too small to be considered important, while a change of 10 pounds may be more meaningful. The odds ratio for a change in X from a to b is estimated by raising the odds ratio estimate for a unit change in X to the power of $c = b - a$ as shown previously.

For a polytomous risk factor, the computation of odds ratios depends on how the risk factor is parameterized. For illustration, suppose that **Race** is a risk factor with four categories: White, Black, Hispanic, and Other.

For the effect parameterization scheme (PARAM=EFFECT) with White as the reference group, the design variables for **Race** are as follows.

Race	Design Variables		
	X_1	X_2	X_3
Black	1	0	0
Hispanic	0	1	0
Other	0	0	1
White	-1	-1	-1

The log odds for Black is

$$\begin{aligned} g(\text{Black}) &= \beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) \\ &= \beta_0 + \beta_1 \end{aligned}$$

The log odds for White is

$$\begin{aligned} g(\text{White}) &= \beta_0 + \beta_1(X_1 = -1) + \beta_2(X_2 = -1) + \beta_3(X_3 = -1) \\ &= \beta_0 - \beta_1 - \beta_2 - \beta_3 \end{aligned}$$

Therefore, the log odds ratio of Black versus White becomes

$$\begin{aligned}\log(\psi(\text{Black}, \text{White})) &= g(\text{Black}) - g(\text{White}) \\ &= 2\beta_1 + \beta_2 + \beta_3\end{aligned}$$

For the reference cell parameterization scheme (PARAM=REF) with White as the reference cell, the design variables for race are as follows.

Race	Design Variables		
	X_1	X_2	X_3
Black	1	0	0
Hispanic	0	1	0
Other	0	0	1
White	0	0	0

The log odds ratio of Black versus White is given by

$$\begin{aligned}\log(\psi(\text{Black}, \text{White})) &= g(\text{Black}) - g(\text{White}) \\ &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) - \\ &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) \\ &= \beta_1\end{aligned}$$

For the GLM parameterization scheme (PARAM=GLM), the design variables are as follows.

Race	Design Variables			
	X_1	X_2	X_3	X_4
Black	1	0	0	0
Hispanic	0	1	0	0
Other	0	0	1	0
White	0	0	0	1

The log odds ratio of Black versus White is

$$\begin{aligned}\log(\psi(\text{Black}, \text{White})) &= g(\text{Black}) - g(\text{White}) \\ &= (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0)) - \\ &\quad (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) \\ &= \beta_1 - \beta_4\end{aligned}$$

Consider the hypothetical example of heart disease among race in Hosmer and Lemeshow (2000, p. 51). The entries in the following contingency table represent counts.

Disease Status	Race			
	White	Black	Hispanic	Other
Present	5	20	15	10
Absent	20	10	10	10

The computation of odds ratio of Black versus White for various parameterization schemes is tabulated in the following table.

Odds Ratio of Heart Disease Comparing Black to White					
PARAM	Parameter Estimates				Odds Ratio Estimation
	$\hat{\beta}_1$	$\hat{\beta}_2$	$\hat{\beta}_3$	$\hat{\beta}_4$	
EFFECT	0.7651	0.4774	0.0719		$\exp(2 \times 0.7651 + 0.4774 + 0.0719) = 8$
REF	2.0794	1.7917	1.3863		$\exp(2.0794) = 8$
GLM	2.0794	1.7917	1.3863	0.0000	$\exp(2.0794) = 8$

Since the log odds ratio ($\log(\psi)$) is a linear function of the parameters, the Wald confidence interval for $\log(\psi)$ can be derived from the parameter estimates and the estimated covariance matrix. Confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence intervals for the log odds ratios. In the displayed output of PROC SURVEYLOGISTIC, the “Odds Ratio Estimates” table contains the odds ratio estimates and the corresponding 95% Wald confidence intervals computed using the covariance matrix in the section “[Variance Estimation for Sample Survey Data](#)” on page 4282. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

To customize odds ratios for specific units of change for a continuous risk factor, you can use the [UNITS](#) statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized odds ratios are given in a separate table. Let (L_j, U_j) be a confidence interval for $\log(\psi)$. The corresponding lower and upper confidence limits for the customized odds ratio $\exp(c\beta_j)$ are $\exp(cL_j)$ and $\exp(cU_j)$, respectively (for $c > 0$), or $\exp(cU_j)$ and $\exp(cL_j)$, respectively (for $c < 0$). You use the [CLODDS=](#) option to request the confidence intervals for the odds ratios.

For a generalized logit model, odds ratios are computed similarly, except D odds ratios are computed for each effect, corresponding to the D logits in the model.

Rank Correlation of Observed Responses and Predicted Probabilities

The predicted mean score of an observation is the sum of the Ordered Values (shown in the Response Profile table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted mean score = $\sum_{d=1}^{D+1} (d-1)\hat{\pi}_d$, where $D+1$ is the number of response levels and $\hat{\pi}_d$ is the predicted probability of the d th (ordered) response.

A pair of observations with different observed responses is said to be *concordant* if the observation with the lower ordered response value has a lower predicted mean score than the observation with the higher ordered response value. If the observation with the lower ordered response value has a higher predicted mean score than the observation with the higher ordered response value, then the pair is *discordant*. If the pair is neither concordant nor discordant, it is a *tie*. Enumeration of the total numbers of concordant and discordant pairs is carried out by categorizing the predicted mean score into intervals of length $D/500$ and accumulating the corresponding frequencies of observations.

Let N be the sum of observation frequencies in the data. Suppose there is a total of t pairs with different responses, n_c of them are concordant, n_d of them are discordant, and $t - n_c - n_d$ of them are tied. PROC SURVEYLOGISTIC computes the following four indices of rank correlation for assessing the predictive ability of a model:

$$c = (n_c + 0.5(t - n_c - n_d))/t$$

$$\text{Somers' } D = (n_c - n_d)/t$$

$$\text{Goodman-Kruskal Gamma} = (n_c - n_d)/(n_c + n_d)$$

$$\text{Kendall's Tau-}a = (n_c - n_d)/(0.5N(N - 1))$$

Note that c also gives an estimate of the area under the receiver operating characteristic (ROC) curve when the response is binary (Hanley and McNeil 1982).

For binary responses, the predicted mean score is equal to the predicted probability for Ordered Value 2. As such, the preceding definition of concordance is consistent with the definition used in previous releases for the binary response model.

Output

Displayed Output

The displayed output of the SURVEYLOGISTIC procedure includes the following:

- name of the input Data Set
- name and label of the Response Variable if the *single-trial* syntax is used
- number of Response Levels
- name of the Events Variable if the *events/trials* syntax is used
- name of the Trials Variable if the *events/trials* syntax is used
- Number of Observations read from the input data set

- Number of Observations used in the analysis
- name of the Frequency Variable if the `FREQ` statement is specified
- Sum of Frequencies of all the observations read from the input data set
- Sum of Frequencies of all the observations used in the analysis
- name of the Weight Variable if the `WEIGHT` statement is specified
- Sum of Weights of all the observations read from the input data set
- Sum of Weights of all the observations used in the analysis
- name of the Offset Variable if the `OFFSET=` option is specified
- name(s) of the stratification variable(s) if the `STRATA` statement is specified
- total number of strata if the `STRATA` statement is specified
- name(s) of the cluster variable(s) if the `CLUSTER` statement is specified
- total number of clusters if the `CLUSTER` statement is specified
- Sum of Weights of all the observations used in the analysis
- Link Function
- variance adjustment method
- parameters used in the `VADJUST=MOREL` option if this option is specified
- “Response Profile” table, which gives, for each response level, the ordered value (an integer between one and the number of response levels, inclusive); the value of the response variable if the *single-trial* syntax is used or the values “EVENT” and “NO EVENT” if the *events/trials* syntax is used; the count or frequency; and the sum of weights if the `WEIGHT` statement is specified
- “Class Level Information” table, which gives the level and the design variables for each `CLASS` explanatory variable
- “Maximum Likelihood Iterative Phase” table, which gives the iteration number, the step size (in the scale of 1.0, .5, .25, and so on) or the ridge value, -2 log likelihood, and parameter estimates for each iteration. Also displayed are the last evaluation of the gradient vector and the last change in the -2 log likelihood. You need to use the `ITPRINT` option in the `MODEL` statement to obtain this table
- score test result for testing the parallel lines assumption, if an ordinal response model is fitted. If `LINK=CLOGLOG` or `LINK=PROBIT`, this test is labeled “Score Test for the Parallel Slopes Assumption.” The proportion odds assumption is a special case of the parallel lines assumption when `LINK=LOGIT`. In this case, the test is labeled “Score Test for the Proportional Odds Assumption”
- “Model Fit Statistics” and “Testing Global Null Hypothesis: `BETA=0`” tables, which give the various criteria (-2 Log L, AIC, SC) based on the likelihood for fitting a model with intercepts only and for fitting a model with intercepts and explanatory variables. If you specify the `NOINT` option, these statistics are calculated without considering the intercept parameters. The third column of the table gives the chi-square statistics and *p*-values for the -2 Log L statistic and for the Score statistic. These test the joint effect of the explanatory

variables included in the model. The Score criterion is always missing for the models identified by the first two columns of the table. Note also that the first two rows of the Chi-Square column are always missing, since tests cannot be performed for AIC and SC

- generalized R^2 measures for the fitted model if you specify the RSQUARE option in the MODEL statement
- “Type III Analysis of Effects” table if the model contains an effect involving a CLASS variable. This table gives the Wald Chi-square statistic, the degrees of freedom, and the p -value for each effect in the model
- “Analysis of Maximum Likelihood Estimates” table, which includes
 - maximum likelihood estimate of the parameter
 - estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
 - Wald chi-square statistic, computed by squaring the ratio of the parameter estimate divided by its standard error estimate
 - p -value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
 - standardized estimate for the slope parameter, given by $\hat{\beta}_i/(s/s_i)$, where s_i is the total sample standard deviation for the i th explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{Logistic} \\ 1 & \text{Normal} \\ \pi/\sqrt{6} & \text{Extreme-value} \end{cases}$$

You need to specify the STB option in the MODEL statement to obtain these estimates. Standardized estimates of the intercept parameters are set to missing.

- value of $(e^{\hat{\beta}_i})$ for each slope parameter β_i if you specify the EXPB option in the MODEL statement. For continuous variables, this is equivalent to the estimated odds ratio for a 1 unit change.
 - label of the variable (if space permits) if you specify the PARMLABEL option in the MODEL statement. Due to constraints on the line size, the variable label may be suppressed in order to display the table in one panel. Use the SAS system option LINESIZE= to specify a larger line size to accommodate variable labels. A shorter line size can break the table into two panels allowing labels to be displayed.
- “Odds Ratio Estimates” table, which contains the odds ratio estimates and the corresponding 95% Wald confidence intervals. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.
 - measures of association between predicted probabilities and observed responses, which include a breakdown of the number of pairs with different responses, and four rank correlation indexes: Somers’ D , Goodman-Kruskal Gamma, and Kendall’s Tau- a , and c

- confidence intervals for all the parameters if you use the CLPARM option in the MODEL statement
- confidence intervals for all the odds ratios if you use the CLODDS option in the MODEL statement
- “Analysis of Effects not in the Model” table, which gives the score chi-square statistic for testing the significance of each variable not in the model after adjusting for the variables already in the model, and the p -value of the chi-square statistic with respect to a chi-square distribution with one degree of freedom. You specify the DETAILS option in the MODEL statement to obtain this table.
- estimated covariance matrix of the parameter estimates if you use the COVB option in the MODEL statement
- estimated correlation matrix of the parameter estimates if you use the CORRB option in the MODEL statement
- “Linear Hypothesis Testing” table, which gives the result of the Wald test for each TEST statement (if specified)

ODS Table Names

PROC SURVEYLOGISTIC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see [Chapter 14, “Using the Output Delivery System.”](#)

Table 69.2. ODS Tables Produced in PROC SURVEYLOGISTIC

ODS Table Name	Description	Statement	Option
ClassLevelInfo	CLASS variable levels and design variables	MODEL	default (with CLASS vars)
CLOdds	Wald’s confidence limits for odds ratios	MODEL	CLODDS
CLparmWald	Wald’s confidence limits for parameters	MODEL	CLPARM
ContrastCoeff	L matrix from CONTRAST	CONTRAST	E
ContrastEstimate	Estimates from CONTRAST	CONTRAST	ESTIMATE=
ContrastTest	Wald test for CONTRAST	CONTRAST	default
ConvergenceStatus	Convergence status	MODEL	default
CorrB	Estimated correlation matrix of parameter estimators	MODEL	CORRB
CovB	Estimated covariance matrix of parameter estimators	MODEL	COVB
CumulativeModelTest	Test of the cumulative model assumption	MODEL	(ordinal response)
DesignSummary	Design summary	STRATA CLUSTER	default
FitStatistics	Model fit statistics	MODEL	default
GlobalTests	Test for global null hypothesis	MODEL	default
IterHistory	Iteration history	MODEL	ITPRINT

Table 69.2. (continued)

ODS Table Name	Description	Statement	Option
LastGradient	Last evaluation of gradient	MODEL	ITPRINT
LogLikeChange	Final change in the log likelihood	MODEL	ITPRINT
ModelInfo	Model information	PROC	default
NObs	Number of observations	PROC	default
OddsRatios	Odds ratios	MODEL	default
ParameterEstimates	Maximum likelihood estimates of model parameters	MODEL	default
RSquare	R-square	MODEL	RSQUARE
ResponseProfile	Response profile	PROC	default
SimpleStatistics	Summary statistics for explanatory variables	PROC	SIMPLE
StrataInfo	Stratum information	STRATA	LIST
TestPrint1	$\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}'$ and $\mathbf{Lb-c}$	TEST	PRINT
TestPrint2	$\text{Ginv}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')$ and $\text{Ginv}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')(\mathbf{Lb-c})$	TEST	PRINT
TestStmts	Linear hypotheses testing results	TEST	default
TypeIII	Type III tests of effects	MODEL	default (with CLASS variables)

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

Examples

Example 69.1. Logistic Regression with Different Link Functions for Stratified Cluster Sampling

A market research firm conducts a survey among undergraduate students at a certain university to evaluate three new Web designs for a commercial Web site targeting undergraduate students at the university.

The sample design is a stratified sample where strata are students' classes. Within each class, 300 students are randomly selected using simple random sampling without replacement. The total number of students in each class in the fall semester of 2001 is shown in the following table:

Class	Enrollment
1 - Freshman	3,734
2 - Sophomore	3,565
3 - Junior	3,903
4 - Senior	4,196

This total enrollment information is saved in the SAS data set `Enrollment` using the following SAS statements:

```
proc format ;
  value Class 1='Freshman' 2='Sophomore'
              3='Junior'   4='Senior';
run;
data Enrollment;
  format Class Class.;
  input Class _TOTAL_;
datalines;
1 3734
2 3565
3 3903
4 4196
;
```

In the data set `Enrollment`, the variable `_TOTAL_` contains the enrollment figures for all classes. They are also the population size for each stratum in this example.

Each student selected in the sample evaluates one randomly selected Web design using the following scale:

1	dislike very much
2	dislike
3	neutral
4	like
5	like very much

The survey results are collected and shown in the following table, with the three different Web designs coded as A, B, and C.

		Evaluation of New Web Designs				
		Rating Counts				
Strata	Design	1	2	3	4	5
Freshman	A	10	34	35	16	15
	B	5	6	24	30	25
	C	11	14	20	34	21
Sophomore	A	19	12	26	18	25
	B	10	18	32	23	26
	C	15	22	34	9	20
Junior	A	8	21	23	26	22
	B	1	4	15	33	47
	C	16	19	30	23	12
Senior	A	11	14	24	33	18
	B	8	15	25	30	22
	C	2	34	30	18	16

The survey results are stored in a SAS data set `WebSurvey` using the following SAS statements.

```
proc format ;
  value Design 1='A' 2='B' 3='C';
  value Rating 1='dislike very much'
              2='dislike'
              3='neutral'
              4='like'
              5='like very much';
run;
data WebSurvey;
  format Class Class. Design Design. Rating Rating. ;
  do Class=1 to 4;
    do Design=1 to 3;
      do Rating=1 to 5;
        input Count @@;
        output;
      end;
    end;
  end;
datalines;
10 34 35 16 15   8 21 23 26 22   5 10 24 30 21
 1 14 25 23 37  11 14 20 34 21  16 19 30 23 12
19 12 26 18 25  11 14 24 33 18  10 18 32 23 17
 8 15 35 30 12  15 22 34  9 20   2 34 30 18 16
;
data WebSurvey; set WebSurvey;
  if Class=1 then Weight=3734/300;
  if Class=2 then Weight=3565/300;
  if Class=3 then Weight=3903/300;
  if Class=4 then Weight=4196/300;
```

The data set `WebSurvey` contains the variables `Class`, `Design`, `Rating`, `Count`, and `Weight`. The variable `class` is the stratum variable, with four strata: freshman, sophomore, junior, and senior. The variable `Design` specifies the three new Web designs: A, B, and C. The variable `Rating` contains students' evaluations for the new Web designs. The variable `counts` gives the frequency with which each Web design received each rating within each stratum. The variable `weight` contains the sampling weights, which are the reciprocals of selection probabilities in this example.

Output 69.1.1. Web Design Survey Sample (First 20 Observation)

Obs	Class	Design	Rating	Count	Weight
1	Freshman	A	dislike very much	10	12.4467
2	Freshman	A	dislike	34	12.4467
3	Freshman	A	neutral	35	12.4467
4	Freshman	A	like	16	12.4467
5	Freshman	A	like very much	15	12.4467
6	Freshman	B	dislike very much	8	12.4467
7	Freshman	B	dislike	21	12.4467
8	Freshman	B	neutral	23	12.4467
9	Freshman	B	like	26	12.4467
10	Freshman	B	like very much	22	12.4467
11	Freshman	C	dislike very much	5	12.4467
12	Freshman	C	dislike	10	12.4467
13	Freshman	C	neutral	24	12.4467
14	Freshman	C	like	30	12.4467
15	Freshman	C	like very much	21	12.4467
16	Sophomore	A	dislike very much	1	11.8833
17	Sophomore	A	dislike	14	11.8833
18	Sophomore	A	neutral	25	11.8833
19	Sophomore	A	like	23	11.8833
20	Sophomore	A	like very much	37	11.8833

Output 69.1.1 shows the first 20 observations of the data set.

The following SAS statements perform the logistic regression.

```
proc surveylogistic data=WebSurvey total=Enrollment;
  stratum Class;
  freq Count;
  class Design;
  model Rating (order=internal) = design ;
  weight Weight;
run;
```

The PROC statement invokes PROC SURVEYLOGISTIC. The TOTAL= option specifies the data set Enrollment, which contains the population totals in the strata. The population totals are used to calculate the finite population correction factor in the variance estimates. The response variable Rating is in the ordinal scale. A cumulative logit model is used to investigate the responses to the Web designs. In the MODEL statement, rating is the response variable, and Design is the effect in the regression model. The ORDER=INTERNAL option is used for the response variable Rating to sort the ordinal response levels of Rating by its internal (numerical) values rather than by the formatted values (e.g., “like very much”). Because the sample design involves stratified simple random sampling, the STRATA statement is used to specify the stratification variable Class. The WEIGHT statement specifies the variable Weight for sampling weights.

Output 69.1.2. Web Design Survey, Model Information

The SURVEYLOGISTIC Procedure			
Model Information			
Data Set		WORK.WEBSURVEY	
Response Variable		Rating	
Number of Response Levels		5	
Frequency Variable		Count	
Stratum Variable		Class	
Number of Strata		4	
Weight Variable		Weight	
Model		Cumulative Logit	
Optimization Technique		Fisher's Scoring	
Variance Adjustment		Degrees of Freedom (DF)	
Finite Population Correction		Used	

Response Profile			
Ordered Value	Rating	Total Frequency	Total Weight
1	dislike very much	116	1489.0733
2	dislike	227	2933.0433
3	neutral	338	4363.3767
4	like	283	3606.8067
5	like very much	236	3005.7000

Probabilities modeled are cumulated over the lower Ordered Values.

The sample and analysis summary is shown in [Output 69.1.2](#). There are five response levels for the Rating with 'dislike very much' as the lowest ordered value. The regression model is modeling lower cumulative probabilities using logit as the link function. Because the TOTAL= option is used, the finite population correction is included in the variance estimation. The sampling weight is also used in the analysis.

Output 69.1.3. Web Design Survey, Testing the Proportional Odds Assumption

Score Test for the Proportional Odds Assumption		
Chi-Square	DF	Pr > ChiSq
98.1957	6	<.0001

In [Output 69.1.3](#), the score chi-square for testing the proportional odds assumption is 98.1957, which is highly significant. This indicates that the cumulative logit model may not adequately fit the data.

An alternative model is to use the generalized logit model with the LINK=GLOGIT option as shown in the following SAS statements:

```
proc surveylogistic data=WebSurvey total=Enrollment;
  stratum Class;
```

```

freq Count;
class Design;
model Rating (ref='neutral') = Design /link=glogit;
weight Weight;
run;

```

The REF='neutral' option is used for the response variable Rating to indicate that all other response levels are referenced to the level 'neutral.' The option LINK=GLOGIT option requests the procedure to fit a generalized logit model.

Output 69.1.4. Web Design Survey, Model Information

The SURVEYLOGISTIC Procedure			
Model Information			
Data Set		WORK.WEBSURVEY	
Response Variable		Rating	
Number of Response Levels		5	
Frequency Variable		Count	
Stratum Variable		Class	
Number of Strata		4	
Weight Variable		Weight	
Model		Generalized Logit	
Optimization Technique		Fisher's Scoring	
Variance Adjustment		Degrees of Freedom (DF)	
Finite Population Correction		Used	
Response Profile			
Ordered Value	Rating	Total Frequency	Total Weight
1	dislike	227	2933.0433
2	dislike very much	116	1489.0733
3	like	283	3606.8067
4	like very much	236	3005.7000
5	neutral	338	4363.3767
Logits modeled use Rating='neutral' as the reference category.			

The summary of the analysis is shown in [Output 69.1.4](#), which indicates that the generalized logit model is used in the analysis.

Output 69.1.5. Web Design Survey, Class Level Information

Class Level Information			
Class	Value	Design Variables	
Design	A	1	0
	B	0	1
	C	-1	-1

Output 69.1.5 shows the parameterization for the main effect Design.

Output 69.1.6. Web Design Survey, Parameter and Odds Ratio Estimates

Analysis of Maximum Likelihood Estimates						
Parameter	Rating	DF	Estimate	Standard Error	Wald Chi-Square	Pr > ChiSq
Intercept	dislike	1	-0.3964	0.0832	22.7100	<.0001
Intercept	dislike very much	1	-1.0826	0.1045	107.3889	<.0001
Intercept	like	1	-0.1892	0.0780	5.8888	0.0152
Intercept	like very much	1	-0.3767	0.0824	20.9223	<.0001
Design A	dislike	1	-0.0942	0.1166	0.6518	0.4195
Design A	dislike very much	1	-0.0647	0.1469	0.1940	0.6596
Design A	like	1	-0.1370	0.1104	1.5400	0.2146
Design A	like very much	1	0.0446	0.1130	0.1555	0.6933
Design B	dislike	1	0.0391	0.1201	0.1057	0.7451
Design B	dislike very much	1	0.2721	0.1448	3.5294	0.0603
Design B	like	1	0.1669	0.1102	2.2954	0.1298
Design B	like very much	1	0.1420	0.1174	1.4641	0.2263

Odds Ratio Estimates				
Effect	Rating	Point Estimate	95% Wald Confidence Limits	
Design A vs C	dislike	0.861	0.583	1.272
Design A vs C	dislike very much	1.153	0.692	1.923
Design A vs C	like	0.899	0.618	1.306
Design A vs C	like very much	1.260	0.851	1.865
Design B vs C	dislike	0.984	0.659	1.471
Design B vs C	dislike very much	1.615	0.975	2.675
Design B vs C	like	1.218	0.838	1.768
Design B vs C	like very much	1.389	0.925	2.086

The parameter and odds ratio estimates are shown in Output 69.1.6. For each odds ratio estimate, its 95% confidence limits shown in the table contain the value 1.0. Therefore, no conclusion can be made based on this survey about which Web design is preferred.

Example 69.2. The Household Component of the Medical Expenditure Panel Survey (MEPS)

The Household Component of the Medical Expenditure Panel Survey (MEPS-HC) is designed to produce national and regional estimates of the health care use, expenditures, sources of payment, and insurance coverage of the U.S. civilian non-institutionalized population (MEPS Fact Sheet, 2001). The sample design of the survey includes stratification, clustering, multiple stages of selection, and disproportionate sampling. Furthermore, the MEPS sampling weights reflect adjustments for survey nonresponse and adjustments to population control totals from the Current Population Survey (Computing Standard Errors for MEPS Estimates, 2003).

In this example, the 1999 full-year consolidated data file HC-038 (PUF Data Files, 2002) from the MEPS is used to investigate the relationship between med-

ical insurance coverage and the demographic variables. The data can be downloaded directly from the Agency for Healthcare Research and Quality (AHRQ) Web site (<http://www.meps.ahrq.gov/Puf/PufDetail.asp?ID=93>) in either ASCII format or SAS transport format. The Web site includes a detailed description of the data as well as the SAS program code used to access and to format it.

For this example, the SAS transport format data file for HC-038 is downloaded to 'C:H38.ssp' on a Windows-based PC. The instructions on the Web site lead to the following SAS statements for creating a SAS data set named MEPS, which contains only the sample design variables and other variables necessary for this analysis.

```
proc format;
  value racex
    -9 = 'NOT ASCERTAINED'
    -8 = 'DK'
    -7 = 'REFUSED'
    -1 = 'INAPPLICABLE'
    1 = 'AMERICAN INDIAN'
    2 = 'ALEUT, ESKIMO'
    3 = 'ASIAN OR PACIFIC ISLANDER'
    4 = 'BLACK'
    5 = 'WHITE'
    91 = 'OTHER'
  ;
  value sex
    -9 = 'NOT ASCERTAINED'
    -8 = 'DK'
    -7 = 'REFUSED'
    -1 = 'INAPPLICABLE'
    1 = 'MALE'
    2 = 'FEMALE'
  ;
  value povcat9h
    1 = 'NEGATIVE OR POOR'
    2 = 'NEAR POOR'
    3 = 'LOW INCOME'
    4 = 'MIDDLE INCOME'
    5 = 'HIGH INCOME'
  ;
  value inscov9f
    1 = 'ANY PRIVATE'
    2 = 'PUBLIC ONLY'
    3 = 'UNINSURED'
  ;
run;

libname puflib 'C:';
filename in1 'C:H38.ssp';
proc xcopy in=in1 out=puflib import;
run;

data meps; set puflib.H38;
  label racex= sex= inscov99= povcat99=
    varstr99= varpsu99= perwt99f= totexp99=;
```

```

format racex racex. sex sex.
      povcat99 povcat9h. inscov99 inscov9f.;
keep inscov99 sex racex povcat99 varstr99
      varpsu99 perwt99f totexp99;
run;

```

There are a total of 24,618 observations in this SAS data set. Each observation corresponds to a person in the survey. The stratification variable is VARSTR99, which identifies the 143 strata in the sample. The variable VARPSU99 identifies the 460 PSUs in the sample. The sampling weights are stored in the variable PERWT99F. The response variable is the health insurance coverage indicator variable, INSCOV99, which has three values:

- 1 the person had any private insurance coverage any time during 1999
- 2 the person had only public insurance coverage during 1999
- 3 the person was uninsured during all of 1999

The demographic variables include gender (SEX), race (RACEX), and family income level as a percent of the poverty line (POVCAT99). The variable RACEX has five categories:

- 1 American Indian
- 2 Aleut, Eskimo
- 3 Asian or Pacific Islander
- 4 Black
- 5 White

The variable POVCAT99 is constructed by dividing family income by the applicable poverty line (based on family size and composition), with the resulting percentages grouped into five categories:

- 1 negative or poor (less than 100%)
- 2 near poor (100% to less than 125%)
- 3 low income (125% to less than 200%)
- 4 middle income (200% to less than 400%)
- 5 high income (greater than or equal to 400%)

The data set also contains the total health care expenditure in 1999, TOTEXP99, which is used as a covariate in the analysis.

Output 69.2.1. 1999 Full-year MEPS (First 30 Observations)

Output 69.2.1 displays the first 30 observations of this data set.

The following SAS statements fit a generalized logit model for the 1999 full-year consolidated MEPS data.

```
proc surveylogistic data=meps;
  stratum VARSTR99;
  cluster VARPSU99;
  weight PERWT99F;
  class SEX RACEX POV99;
  model INSCOV99 = TOTEXP99 SEX RACEX POV99 / link=glogit;
run;
```

The STRATUM statement specifies the stratification variable VARSTR99. The CLUSTER statement specifies the PSU variable VARPSU99. The WEIGHT statement specifies the sample weight variable PERWT99F. The demographic variables

SEX, RACEX, and POVCAT99 are listed in the CLASS statement to indicate that they are categorical independent variables in the MODEL statement. In the MODEL statement, the response variable is INSCOV99, and the independent variables are TOTEXP99 along with the selected demographic variables. The LINK= option requests the procedure to fit the generalized logit model because the response variable INSCOV99 has nominal responses.

The results of this analysis are shown in the following tables.

Output 69.2.2. MEPS, Model Information

The SURVEYLOGISTIC Procedure	
Model Information	
Data Set	WORK.MEPS
Response Variable	INSCOV99
Number of Response Levels	3
Stratum Variable	VARSTR99
Number of Strata	143
Cluster Variable	VARPSU99
Number of Clusters	460
Weight Variable	PERWT99F
Model	Generalized Logit
Optimization Technique	Fisher's Scoring
Variance Adjustment	Degrees of Freedom (DF)

PROC SURVEYLOGISTIC lists the model fitting information and sample design information in [Output 69.2.2](#):

Output 69.2.3. MEPS, Number of Observations

Number of Observations Read	24618
Number of Observations Used	23565
Sum of Weights Read	2.7641E8
Sum of Weights Used	2.7641E8

[Output 69.2.3](#) displays the number of observations and the total of sampling weights both in the data set and used in the analysis. Only the observations with positive person-level weight are used in the analysis. Therefore, 1,053 observations with zero person-level weights were deleted.

Output 69.2.4. MEPS, Response Profile

Response Profile			
Ordered Value	INSCOV99	Total Frequency	Total Weight
1	ANY PRIVATE	16130	204403997
2	PUBLIC ONLY	4241	41809572
3	UNINSURED	3194	30197198

Logits modeled use INSCOV99='UNINSURED' as the reference category.

Output 69.2.4 lists the three insurance coverage levels for the response variable INSCOV99. The “UNINSURED” category is used as the reference category in the model.

Output 69.2.5. MEPS, Classification Levels

Class Level Information					
Class	Value	Design Variables			
SEX	FEMALE	1			
	MALE	-1			
RACEX	ALEUT, ESKIMO	1	0	0	0
	AMERICAN INDIAN	0	1	0	0
	ASIAN OR PACIFIC ISLANDER	0	0	1	0
	BLACK	0	0	0	1
	WHITE	-1	-1	-1	-1
POVCAT99	HIGH INCOME	1	0	0	0
	LOW INCOME	0	1	0	0
	MIDDLE INCOME	0	0	1	0
	NEAR POOR	0	0	0	1
	NEGATIVE OR POOR	-1	-1	-1	-1

Output 69.2.5 shows the parameterization in the regression model for each categorical independent variable.

Output 69.2.6. MEPS, Parameter Estimates

Chapter 70

The SURVEYMEANS Procedure

Overview

The SURVEYMEANS procedure produces estimates of survey population means and totals from sample survey data. The procedure also produces variance estimates, confidence limits, and other descriptive statistics. When computing these estimates, the procedure takes into account the sample design used to select the survey sample. The sample design can be a complex survey sample design with stratification, clustering, and unequal weighting.

PROC SURVEYMEANS uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters, or primary sampling units (PSUs), in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate.

PROC SURVEYMEANS uses the Output Delivery System (ODS) to place results in output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality.

Getting Started

This section demonstrates how you can use the SURVEYMEANS procedure to produce descriptive statistics from sample survey data. For a complete description of PROC SURVEYMEANS, please refer to the [“Syntax”](#) section on page 4322. The [“Examples”](#) section on page 4350 provides more complicated examples to illustrate the applications of PROC SURVEYMEANS.

Simple Random Sampling

This example illustrates how you can use PROC SURVEYMEANS to estimate population means and proportions from sample survey data. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on average, and what percentage of students spend at least \$10 weekly for ice cream.

To answer these questions, 40 students were selected from the entire student population using simple random sampling (SRS). Selection by simple random sampling means that all students have an equal chance of being selected, and no student can be selected more than once. Each student selected for the sample was asked how much

he spends for ice cream per week, on average. The SAS data set named `IceCream` saves the responses of the 40 students:

```
data IceCream;
  input Grade Spending @@;
  if (Spending < 10) then Group='less';
  else Group='more';
  datalines;
7 7 7 7 8 12 9 10 7 1 7 10 7 3 8 20 8 19 7 2
7 2 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 8
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 10 8 13 7 2 9 6 9 11 7 2 7 9
;
```

The variable `Grade` contains a student's grade. The variable `Spending` contains a student's response on how much he spends per week for ice cream, in dollars. The variable `Group` is created to indicate whether a student spends at least \$10 weekly for ice cream: `Group='more'` if a student spends at least \$10, or `Group='less'` if a student spends less than \$10.

You can use PROC SURVEYMEANS to produce estimates for the entire student population, based on this random sample of 40 students:

```
title1 'Analysis of Ice Cream Spending';
title2 'Simple Random Sample Design';
proc surveymeans data=IceCream total=4000;
  var Spending Group;
run;
```

The PROC SURVEYMEANS statement invokes the procedure. The `TOTAL=4000` option specifies the total number of students in the study population, or school. The procedure uses this total to adjust variance estimates for the effects of sampling from a finite population. The `VAR` statement names the variables to analyze, `Spending` and `Group`.

Figure 70.1 displays the results from this analysis. There are a total of 40 observations used in the analysis. The "Class Level Information" table lists the two levels of the variable `Group`. This variable is a character variable, and so PROC SURVEYMEANS provides a categorical analysis for it, estimating the relative frequency or proportion for each level. If you want a categorical analysis for a numeric variable, you can name that variable in the `CLASS` statement.

```

```

Figure 70.1. Analysis of Ice Cream Spending, Simple Random Sample Design

The “Statistics” table displays the estimates for each analysis variable. By default, PROC SURVEYMEANS displays the number of observations, the estimate of the mean, its standard error, and 95% confidence limits for the mean. You can obtain other statistics by specifying the corresponding statistic-keywords in the PROC SURVEYMEANS statement.

The estimate of the average weekly ice cream expense is \$8.75 for students in this school. The standard error of this estimate is \$0.85, and the 95% confidence interval for weekly ice cream expense is from \$7.04 to \$10.46.

The analysis variable Group is a character variable, and so PROC SURVEYMEANS analyzes it as categorical, estimating the relative frequency or proportion for each level or category. These estimates are displayed in the Mean column of the “Statistics” table. It is estimated that 57.5% of all students spend less than \$10 weekly on ice cream, while 42.5% of the students spend at least \$10 weekly. The standard error of each estimate is 7.9%.

Stratified Sampling

Suppose that the sample of students described in the previous section was actually selected using stratified random sampling. In stratified sampling, the study population is divided into nonoverlapping strata, and samples are selected from each stratum independently.

The list of students in this junior high school was stratified by grade, yielding three strata: grades 7, 8, and 9. A simple random sample of students was selected from each grade. [Table 70.1](#) shows the total number of students in each grade.

Table 70.1. Number of Students by Grade

Grade	Number of Students
7	1,824
8	1,025
9	1,151
Total	4,000

To analyze this stratified sample, you need to provide the population totals for each stratum to PROC SURVEYMEANS. The SAS data set named `StudentTotals` contains the information from [Table 70.1](#):

```
data StudentTotals;
    input Grade _total_ ; datalines;
    7 1824
    8 1025
    9 1151
    ;
```

The variable `Grade` is the stratum identification variable, and the variable `_TOTAL_` contains the total number of students for each stratum. PROC SURVEYMEANS requires you to use the variable name `_TOTAL_` for the stratum population totals.

The procedure uses the stratum population totals to adjust variance estimates for the effects of sampling from a finite population. If you do not provide population totals or sampling rates, then the procedure assumes that the proportion of the population in the sample is very small, and the computation does not involve a finite population correction.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information in order to produce an unbiased mean estimator. In this example, the appropriate sampling weights are reciprocals of the probabilities of selection. You can use the following data step to create the sampling weights:

```
data IceCream;
    set IceCream;
    if Grade=7 then Prob=20/1824;
    if Grade=8 then Prob=9/1025;
    if Grade=9 then Prob=11/1151;
    Weight=1/Prob;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following SAS statements perform the stratified analysis of the survey data:

```

title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
  stratum Grade / list;
  var Spending Group;
  weight Weight;
run;

```

The PROC SURVEYMEANS statement invokes the procedure. The DATA= option names the SAS data set `IceCream` as the input data set to be analyzed. The TOTAL= option names the data set `StudentTotals` as the input data set containing the stratum population totals. Comparing this to the analysis in the “[Simple Random Sampling](#)” section on page 4315, notice that the TOTAL=`StudentTotals` option is used here instead of the TOTAL=`4000` option. In this stratified sample design, the population totals are different for different strata, and so you need to provide them to PROC SURVEYMEANS in a SAS data set.

The STRATA statement identifies the stratification variable `Grade`. The LIST option in the STRATA statement requests that the procedure display stratum information. The WEIGHT statement tells the procedure that the variable `Weight` contains the sampling weights.

```

Stratum Index	Grade	Population Total	Sampling Rate	N Obs	Variable	Level	N
1	7	1824	1.10%	20	Spending Group	less	17
						more	3
2	8	1025	0.88%	9	Spending Group	less	0
						more	9
3	9	1151	0.96%	11	Spending Group	less	6
						more	5

Figure 70.3. Stratum Information

Figure 70.3 displays information for each stratum. The table displays a Stratum Index and the values of the STRATA variable. The Stratum Index identifies each stratum by a sequentially assigned number. For each stratum, the table gives the population total (total number of students), the sampling rate, and the sample size. The stratum sampling rate is the ratio of the number of students in the sample to the number of students in the population for that stratum. The table also lists each analysis variable and the number of stratum observations for that variable. For categorical variables, the table lists each level and the number of sample observations in that level.

Variable	Level	Upper 95% CL for Mean
Spending Group		10.218825
	less	0.662932
	more	0.573823

Figure 70.4. Analysis of Ice Cream Spending, Stratified SRS Design

Figure 70.4 shows that

- the estimate of average weekly ice cream expense is \$9.14 for students in this school, with a standard error of \$0.53, and a 95% confidence interval from \$8.06 to \$10.22.
- an estimate of 54.5% of all students spend less than \$10 weekly on ice cream, and 45.5% spend more, with a standard error of 5.8%.

Output Data Set

PROC SURVEYMEANS uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information on ODS, see [Chapter 14](#), “Using the Output Delivery System.”

For example, to save the “Statistics” table shown in [Figure 70.4](#) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```

title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
  stratum Grade / list;
  var Spending Group;
  weight Weight;
  ods output Statistics=MyStat;
run;

```

The statement

```
ods output Statistics=MyStat;
```

requests that the “Statistics” table that appears in [Figure 70.4](#) be placed in a SAS data set named MyStat.

The PRINT procedure displays observations of the data set MyStat:

```

proc print data=MyStat;
run;

```

[Figure 70.5](#) displays the data set MyStat.

Figure 70.5. The Data Set MyStat

The section “ODS Table Names” on page 4349 gives the complete list of the tables produced by PROC SURVEYMEANS.

Syntax

The following statements are available in PROC SURVEYMEANS.

```

PROC SURVEYMEANS < options > < statistic-keywords > ;
  BY variables ;
  CLASS variables ;
  CLUSTER variables ;
  DOMAIN variables < variable*variable
                        variable*variable*variable ... > ;
  RATIO < 'label' > variables / variables ;
  STRATA variables < / option > ;
  VAR variables ;
  WEIGHT variable ;

```

The PROC SURVEYMEANS statement invokes the procedure. It optionally names the input data sets and specifies statistics for the procedure to compute. The PROC SURVEYMEANS statement is required.

The VAR statement identifies the variables to be analyzed. The CLASS statement identifies those numeric variables that are to be analyzed as categorical variables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The DOMAIN statement lists the variables that define domains for subpopulation analysis. The RATIO statement requests ratio analysis for means or proportions of analysis variables. The WEIGHT statement names the sampling

weight variable. You can use a BY statement with PROC SURVEYMEANS to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYMEANS statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLASS, CLUSTER, DOMAIN, RATIO, STRATA, VAR, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYMEANS statement.

PROC SURVEYMEANS Statement

PROC SURVEYMEANS < options > < statistic-keywords > ;

The PROC SURVEYMEANS statement invokes the procedure. In this statement, you identify the data set to be analyzed and specify sample design information. The DATA= option names the input data set to be analyzed. If your analysis includes a finite population correction factor, you can input either the sampling rate or the population total using the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set containing the stratification variables.

In the PROC SURVEYMEANS statement, you also can use [statistic-keywords](#) to specify statistics for the procedure to compute. Available statistics include the population mean and population total, together with their variance estimates and confidence limits. You can also request data set summary information and sample design information.

You can specify the following options in the PROC SURVEYMEANS statement:

ALPHA= α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=SAS-data-set

specifies the SAS data set to be analyzed by PROC SURVEYMEANS. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MISSING

requests that the procedure treat missing values as a valid category for all categorical variables, which include categorical analysis variables, strata variables, cluster variables, and domain variables.

ORDER=DATA | FORMATTED | INTERNAL

specifies the order in which the values of the categorical variables are to be reported. The following shows how PROC SURVEYMEANS interprets values of the ORDER= option:

DATA orders values according to their order in the input data set.

FORMATTED	orders values by their formatted values. This order is operating environment dependent. By default, the order is ascending.
INTERNAL	orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating environment dependent.

By default, ORDER=FORMATTED.

The ORDER= option applies to all the categorical variables. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

RATE=*value* | SAS-data-set

R=*value* | SAS-data-set

specifies the sampling rate as a nonnegative *value*, or names an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4334 for more details.

The sampling rate *value* must be a nonnegative number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYMEANS will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

STACKING

requests the procedure to produce the output data sets using a stacking table structure, which was the default in releases prior to Version 9. The new default is to produce a rectangular table structure in the output data sets.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo

When you use the ODS statement to create SAS data sets for these tables in the output, the data set structure can be either stacking or rectangular. A rectangular structure creates one observation for each analysis variable in the data set. However, if you use the STACKING option in Version 9, the procedure creates only one observation in the output data set for all analysis variables. The following example shows these two structures in output data sets.

```

data new;
  input sex$ x;
  datalines;
M 12
F 5
M 13
F 23
F 11
;

proc surveymeans data=new mean;
  ods output statistics=rectangle;
run;

proc print data=rectangle;
run;

proc surveymeans data=new mean stacking;
  ods output statistics=stacking;
run;

proc print data=stacking;
run;

```

Figure 70.6 shows the rectangular structure of the output data set for the statistics table.

rectangle structure in the output data set				
OBS	Var Name	Var Level	Mean	StdErr
1	x		12.800000	2.905168
2	sex	F	0.600000	0.244949
3	sex	M	0.400000	0.244949

Figure 70.6. Rectangular Structure in the Output Data Set

Figure 70.7 shows the stacking structure of the output data set for the statistics table.

stacking structure in the output data set					
OBS	x	x_Mean	x_StdErr	sex_F	sex_F_Mean
1	x	12.800000	2.905168	sex=F	0.600000
OBS	sex_F_StdErr	sex_M	sex_M_Mean	sex_M_StdErr	
1	0.244949	sex=M	0.400000	0.244949	

Figure 70.7. Stacking Structure in the Output Data Set

TOTAL=*value* | SAS-data-set

N=*value* | SAS-data-set

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or names an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4334 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

statistic-keywords

specifies the statistics for the procedure to compute. If you do not specify any statistic-keywords, PROC SURVEYMEANS computes the NOBS, MEAN, STDERR, and CLM statistics by default.

The statistics produced depend on the type of the analysis variable. If you name a numeric variable in the CLASS statement, then the procedure analyzes that variable as a categorical variable. The procedure always analyzes character variables as categorical. See the section “[CLASS Statement](#)” on page 4329 for more information.

PROC SURVEYMEANS computes MIN, MAX, and RANGE for numeric variables but not for categorical variables. For numeric variables, the keyword MEAN produces the mean, but for categorical variables it produces the proportion in each category or level. Also for categorical variables, the keyword NOBS produces the number of observations for each variable level, and the keyword NMISS produces the number of missing observations for each level. If you request the keyword NCLUSTER for a categorical variable, PROC SURVEYMEANS displays for each level the number of clusters with observations in that level. PROC SURVEYMEANS computes SUMWGT in the same way for both categorical and numeric variables, as the sum of the weights over all nonmissing observations.

PROC SURVEYMEANS performs univariate analysis, analyzing each variable separately. Thus the number of nonmissing and missing observations may not be the same for all analysis variables. See the section “Missing Values” on page 4333 for more information.

If you use the keyword RATIO without the keyword MEAN, the keyword MEAN is implied.

Other available statistics computed for a ratio are N, NCLU, SUMWGT, RATIO, STDERR, DF, T, PROBT, and CLM, as listed below. If no statistics are requested, the procedure will compute the ratio and its standard error by default for a RATIO statement.

The valid statistic-keywords are as follows:

ALL	all statistics listed
CLM	100(1 – α)% two-sided confidence limits for the MEAN, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
CLSUM	100(1 – α)% two-sided confidence limits for the SUM, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
CV	coefficient of variation for MEAN
CVSUM	coefficient of variation for SUM
DF	degrees of freedom for the <i>t</i> test
LCLM	100(1 – α)% one-sided lower confidence limit of the MEAN, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
LCLMSUM	100(1 – α)% one-sided lower confidence limit of the SUM, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
MAX	maximum value
MEAN	mean for a numeric variable, or the proportion in each category for a categorical variable
MIN	minimum value
NCLUSTER	number of clusters
NMISS	number of missing observations
NOBS	number of nonmissing observations
RANGE	range, MAX–MIN
RATIO	ratio of means or proportions
STD	standard deviation of the SUM. When you request SUM, the procedure computes STD by default.
STDERR	standard error of the MEAN or RATIO. When you request MEAN or RATIO, the procedure computes STDERR by default.

SUM	weighted sum, $\sum w_i y_i$, or estimated population total when the appropriate sampling weights are used
SUMWGT	sum of the weights, $\sum w_i$
T	t -value and its corresponding p -value with DF degrees of freedom for $H_0 : \theta = 0$ where θ is the population mean or the population ratio
UCLM	100(1 - α)% one-sided upper confidence limit of the MEAN, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
UCLMSUM	100(1 - α)% one-sided upper confidence limit of the SUM, where α is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$
VAR	variance of the MEAN or RATIO
VARSUM	variance of the SUM

See the section “[Statistical Computations](#)” on page 4336 for details on how PROC SURVEYMEANS computes these statistics.

BY Statement

BY variables ;

You can specify a BY statement with PROC SURVEYMEANS to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis.

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. The *variables* are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Use the BY statement options NOTSORTED or DESCENDING in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS | CLASSES *variables* ;

The CLASS statement names variables to be analyzed as categorical variables. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. PROC SURVEYMEANS always analyzes character variables as categorical. If you want categorical analysis for a numeric variable, you must include that variable in the CLASS statement.

The CLASS *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLASS variables determine the categorical variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can use multiple CLASS statements to specify categorical variables.

When you specify class variables, you may use the SAS system option SUMSIZE= to limit (or to specify) the amount of memory that is available for data analysis. Refer to the chapter on SAS System options in *SAS Language Reference: Dictionary* for a description of the SUMSIZE= option.

CLUSTER Statement

CLUSTER | CLUSTERS *variables* ;

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section “[Primary Sampling Units \(PSUs\)](#)” on page 4335 for more information.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

DOMAIN Statement

DOMAIN | SUBGROUP *variables* < *variable*variable*
*variable*variable*variable* ... > ;

The DOMAIN statement requests analysis for subpopulations, or domains, in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains may be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “[Domain Statistics](#)” on page 4342 for more details.

A domain variable can be either character or numeric. However, the procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*), then every possible combination of levels of the variables determines a domain. The procedure performs a descriptive analysis within each domain defined by the domain variables.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

RATIO Statement

RATIO < '*label*' > *variables* / *variables* ;

The RATIO statement requests ratio analysis for means or proportions of analysis variables. A ratio statement names the variables whose means will be used as numerators or denominators in a ratio. Variables appearing before the slash (/), called *numerator variables*, are used for numerators. Variables appearing after the slash (/), called *denominator variables*, are used for denominators. These *variables* can be any number of analysis variables, either continuous or categorical, in the input data set.

You can optionally specify a label for each RATIO statement to identify the ratios in the output. Labels must be enclosed in single quotes.

If a RATIO statement does not have any numerator variable or denominator variable specified, the RATIO statement will be ignored.

A numerator or denominator variable must be an analysis variable. That is, if there is a VAR statement, then a numerator or denominator variable must appear in the VAR

statement. If there is no VAR statement, a numerator or denominator variable must be on the default analysis variable list (see the section “VAR Statement” on page 4332). If a numerator or denominator variable is not an analysis variable, it is ignored.

The computation of ratios depends on whether the numerator and denominator variables are continuous or categorical.

For continuous variables, ratios are calculated with the mean of the variables. For example, for continuous variables X, Y, Z, and T, the following RATIO statement requests the procedure to analyze the ratios \bar{x}/\bar{z} , \bar{x}/\bar{t} , \bar{y}/\bar{z} , and \bar{y}/\bar{t} :

```
ratio x y / z t;
```

If a continuous variable appears as both a numerator and a denominator variable, the ratio of this variable itself is ignored.

For categorical variables, ratios are calculated with the proportions for the categories of a categorical variable. For example, if categorical variable Gender has values “Male” and “Female,” with proportions $p_m = \text{Pr}(\text{Gender}=\text{“Male”})$ and $p_f = \text{Pr}(\text{Gender}=\text{“Female”})$, and Y is a continuous variable, then the following RATIO statement requests the procedure to analyze the ratios p_m/p_f , p_f/p_m , \bar{y}/p_m , and \bar{y}/p_f :

```
ratio Gender y / Gender;
```

If a categorical variable appears as both a numerator and a denominator variable, then the ratios of the proportions for all categories are computed, except the ratio of each category with itself.

You may have more than one RATIO statement. Each RATIO statement produces ratios independently using its own numerator and denominator variables. Each RATIO statement also produces its own ratio analysis table.

Available statistics for a ratio are

- N, number of observations used to compute the ratio
- NCLU, number of clusters
- SUMWGT, sum of weights
- RATIO, ratio
- STDERR, standard error of ratio
- VAR, variance of ratio
- T, t -value of ratio
- PROBT, p -value of t
- DF, degrees of freedom of t
- CLM, two-sided confidence limits of ratio
- UCLM, one-sided upper confidence limit of ratio

- LCLM, one-sided lower confidence limit of ratio

The procedure will calculate these statistics based on the [statistic-keywords](#) described on page 4326 which you specified in the PROC statement. If a statistic-keyword is not appropriate for RATIO statement, that statistic-keyword is ignored. If no valid statistics are requested for a RATIO statement, the procedure will compute the ratio and its standard error by default.

Note that ratios within a domain are currently not available.

When calculating the means or proportions for the numerator and denominator variables in a ratio, an observation is excluded if it has a missing value in either the continuous numerator variable or the denominator variable. An observation with missing values is also excluded for the categorical numerator or denominator variables, unless the MISSING option is used.

STRATA Statement

STRATA | STRATUM *variables* < / *option* > ;

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section [“Specification of Population Totals and Sampling Rates”](#) on page 4334 for more information.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *SAS Procedures Guide*.

You can specify the following option in the STRATA statement after a slash (/):

LIST

displays a “Stratum Information” table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section [“Displayed Output”](#) on page 4345 for more details.

VAR Statement

VAR *variables* ;

The VAR statement names the variables to be analyzed.

If you want a categorical analysis for a numeric variable, you must also name that variable in the CLASS statement. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. Character variables are always analyzed as categorical variables. See the section [“CLASS Statement”](#) on page 4329 for more information.

If you do not specify a VAR statement, then PROC SURVEYMEANS analyzes all variables in the DATA= input data set, except those named in the BY, CLUSTER, STRATA, and WEIGHT statements.

WEIGHT Statement

WEIGHT | WGT *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYMEANS assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

Details

Missing Values

When computing statistics for an analysis variable, PROC SURVEYMEANS omits observations with missing values for that variable. The procedure bases statistics for each variable only on observations that have nonmissing values for that variable. If you specify the [MISSING option](#) described on page 4323 in the PROC SURVEYMEANS statement, the procedure treats missing values of a categorical variable as a valid category.

An observation is also excluded if it has a missing value for any STRATA or CLUSTER variable, unless the MISSING option is used.

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYMEANS excludes that observation from the analysis.

The procedure performs univariate analysis and analyzes each VAR variable separately. Thus, the number of missing observations may be different for different variables. You can specify the keyword NMIS in the PROC SURVEYMEANS statement to display the number of missing values for each analysis variable in the “Statistics” table.

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a complete respondent, and an observation with missing values is called an incomplete respondent. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then the survey estimates will be biased and will not accurately represent the survey population. A variety of techniques in sample design and survey operations can reduce nonresponse. Once data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYMEANS. Refer to Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more details.

PROC SURVEYMEANS assumes that missing data are missing at random, because the patterns of missing data are unknown. Therefore, PROC SURVEYMEANS excludes those observations with missing values.

If there is evidence indicating that the missing data are not at random, for example, if complete respondents are different from incomplete respondents for your study, you can use the DOMAIN statement to compute the descriptive statistics among complete respondents from your survey data without imputation on incomplete respondents. See [Example 70.4](#) on page 4358.

If missing values result in empty strata in the sample, then they will have an impact on the statistical computation, which uses the total number of strata. If all the observations in a stratum have missing weights or missing values for the current analysis variable, this stratum is an *empty stratum*. For example,

```
data new;
  input stratum y z w;
  datalines;
1 . 13 40
1 2 9 .
1 . 5 25
2 5 10 20
2 8 60 15
;
proc surveymeans df mean nobis nmiss;
  strata stratum;
  var y z;
  weight w;
run;
```

You analyze variable Y and Z, with weight variable W and stratum variable STRATUM. For variable Y, all observations have missing values or missing weights in STRATUM=1, therefore, the analysis for variable Y uses only observations in STRATUM=2. Thus, for variable Y, STRATUM=1 is an empty stratum and STRATUM=2 is a non-empty stratum. Note, however, that STRATUM=1 is a non-empty stratum for variable Z.

If your sample design contains stratification, PROC SURVEYMEANS analyzes only the data in non-empty strata. Therefore, the total number of strata for an analysis variable means the total number of *non-empty* strata. In this example, the total number of strata for Y and Z is one and two, respectively.

Survey Data Analysis

Specification of Population Totals and Sampling Rates

If your analysis should include a finite population correction (*fpc*), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option. (You cannot specify both of these options in the same PROC SURVEYMEANS statement.) If you do not specify one of these options, the procedure does not use the *fpc* when computing variance estimates. For fairly small

sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the `RATE=` option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the `TOTAL=` option for a multistage design, you should input the total number of PSUs in the study population. See the section “[Primary Sampling Units \(PSUs\)](#)” on page 4335 for more details. For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the `RATE=value` option or the `TOTAL=value` option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the `RATE=SAS-data-set` option or the `TOTAL=SAS-data-set` option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the `DATA=` option.

The secondary data set must contain all the stratification variables listed in the `STRATA` statement and all the variables in the `BY` statement. If there are formats associated with the `STRATA` variables and the `BY` variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the `TOTAL=SAS-data-set` option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. Or if you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and `PROC SURVEYMEANS` will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs. See the section “[Variance and Standard Error of the Mean](#)” on page 4338 and the section “[Variance and Standard Deviation of the Total](#)” on page 4341. You can use the `CLUSTER` statement to identify the first stage clusters in your design. `PROC SURVEYMEANS` assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a `CLUSTER` statement, the procedure treats each observation as a PSU.

Domain Analysis

It is common practice to compute statistics for subpopulations, or domains, in addition to computing statistics for the entire study population. Analysis for domains using the entire sample is called *domain analysis* (subgroup analysis, subpopulation analysis, subdomain analysis). The formation of these subpopulations of interest may be unrelated to the sample design. Therefore, the sample sizes for the subpopulations may actually be random variables.

In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement. Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. For more detailed information about domain analysis, refer to Kish (1965).

Statistical Computations

The SURVEYMEANS procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For t tests of the estimates, the degrees of freedom equals the number of clusters minus the number of strata in the sample design.

For a multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse. In such surveys, the appropriate sampling weights must be used to obtain valid estimates for the study population.

For more information on the analysis of sample survey data, refer to Lee, Forthoffer, and Lorimor (1989), Cochran (1977), Kish (1965), and Hansen, Hurwitz, and Madow (1953).

Definition and Notation

For a stratified clustered sample design, together with the sampling weights, the sample can be represented by an $n \times (P + 1)$ matrix

$$\begin{aligned} (\mathbf{w}, \mathbf{Y}) &= (w_{hij}, \mathbf{y}_{hij}) \\ &= \left(w_{hij}, y_{hij}^{(1)}, y_{hij}^{(2)}, \dots, y_{hij}^{(P)} \right) \end{aligned}$$

where

- $h = 1, 2, \dots, H$ is the stratum number, with a total of H strata
- $i = 1, 2, \dots, n_h$ is the cluster number within stratum h , with a total of n_h clusters
- $j = 1, 2, \dots, m_{hi}$ is the unit number within cluster i of stratum h , with a total of m_{hi} units
- $p = 1, 2, \dots, P$ is the analysis variable number, with a total of P variables
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample
- w_{hij} denotes the sampling weight for observation j in cluster i of stratum h
- $y_{hij} = (y_{hij}^{(1)}, y_{hij}^{(2)}, \dots, y_{hij}^{(P)})$ are the observed values of the analysis variables for observation j in cluster i of stratum h , including both the values of numerical variables and the values of indicator variables for levels of categorical variables.

For a categorical variable C , let l denote the number of levels of C , and denote the level values as c_1, c_2, \dots, c_l . Then there are l indicator variables associated with these levels. That is, for level $C = c_k$ ($k = 1, 2, \dots, l$), a $y^{(q)}$ ($q \in \{1, 2, \dots, P\}$) contains the values of the indicator variable for the category $C = c_k$, with the value of observation j in cluster i of stratum h :

$$y_{hij}^{(q)} = I_{\{C=c_k\}}(h, i, j) = \begin{cases} 1 & \text{if } C_{hij} = c_k \\ 0 & \text{otherwise} \end{cases}$$

Therefore, the total number of analysis variables, P , is the total number of numerical variables plus the total number of levels of all categorical variables.

Also, f_h denotes the sampling rate for stratum h . You can use the TOTAL= option or the RATE= option to input population totals or sampling rates. See the section “[Specification of Population Totals and Sampling Rates](#)” on page 4334 for details. If you input stratum totals, PROC SURVEYMEANS computes f_h as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYMEANS uses these values directly for f_h . If you do not specify the TOTAL= option or the RATE= option, then the procedure assumes that the stratum sampling rates f_h are negligible, and a finite population correction is not used when computing variances.

This notation is also applicable to other sample designs. For example, for a sample design without stratification, you can let $H = 1$; for a sample design without clusters, you can let $m_{hi} = 1$ for every h and i .

Mean

When you specify the keyword MEAN, the procedure computes the estimate of the mean (mean per element) from the survey data. Also, the procedure computes the mean by default if you do not specify any [statistic-keywords](#) in the PROC SURVEYMEANS statement.

PROC SURVEYMEANS computes the estimate of the mean as

$$\widehat{Y} = \left(\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right) / w_{...}$$

where

$$w_{...} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}$$

is the sum of the weights over all observations in the sample.

Variance and Standard Error of the Mean

When you specify the keyword STDERR, the procedure computes the standard error of the mean. Also, the procedure computes the standard error by default if you specify the keyword MEAN, or if you do not specify any [statistic-keywords](#) in the PROC SURVEYMEANS statement. The keyword VAR requests the variance of the mean.

PROC SURVEYMEANS uses the Taylor series expansion theory to estimate the variance of the mean \widehat{Y} . The procedure computes the estimated variance as

$$\widehat{V}(\widehat{Y}) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y})$$

where if $n_h > 1$,

$$\begin{aligned} \widehat{V}_h(\widehat{Y}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{hi\cdot} - \bar{e}_{h\cdot\cdot})^2 \\ e_{hi\cdot} &= \left(\sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - \widehat{Y}) \right) / w_{...} \\ \bar{e}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} e_{hi\cdot} \right) / n_h \end{aligned}$$

and if $n_h = 1$,

$$\widehat{V}_h(\widehat{Y}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard error of the mean is the square root of the estimated variance.

$$\text{StdErr}(\widehat{Y}) = \sqrt{\widehat{V}(\widehat{Y})}$$

Ratio

When you use a RATIO statement, the procedure produces statistics requested by the statistics-keywords in the PROC SURVEYMEANS statement.

Suppose that you want to calculate the ratio of variable *Y* over variable *X*. Let x_{hij} be the value of variable *X* for the *j*th member in cluster *i* in the *h*th stratum.

The ratio of *Y* over *X* is

$$\widehat{R} = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}}$$

PROC SURVEYMEANS uses the Taylor series expansion method to estimate the variance of the ratio \widehat{R} as

$$\widehat{V}(\widehat{R}) = \sum_{h=1}^H \widehat{V}_h(\widehat{R})$$

where if $n_h > 1$,

$$\begin{aligned} \widehat{V}_h(\widehat{R}) &= \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (g_{hi\cdot} - \bar{g}_{h\cdot\cdot})^2 \\ g_{hi\cdot} &= \frac{\sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - x_{hij}\widehat{R})}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}} \\ \bar{g}_{h\cdot\cdot} &= \left(\sum_{i=1}^{n_h} g_{hi\cdot} \right) / n_h \end{aligned}$$

and if $n_h = 1$,

$$\widehat{V}_h(\widehat{R}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard error of the ratio is the square root of the estimated variance.

$$\text{StdErr}(\widehat{R}) = \sqrt{\widehat{V}(\widehat{R})}$$

***t* Test for the Mean**

If you specify the keyword T, PROC SURVEYMEANS computes the *t*-value for testing that the population mean equals zero, $H_0 : \bar{Y} = 0$. The test statistic equals

$$t(\widehat{Y}) = \widehat{Y} / \text{StdErr}(\widehat{Y})$$

The two-sided *p*-value for this test is

$$\text{Prob}(|T| > |t(\widehat{Y})|)$$

where T is a random variable with the t distribution with df degrees of freedom.

PROC SURVEYMEANS calculates the degrees of freedom for the t test as the number of clusters minus the number of strata. If there are no clusters, then df equals the number of observations minus the number of strata. If the design is not stratified, then df equals the number of clusters minus one. The procedure displays df for the t test if you specify the keyword DF in the PROC SURVEYMEANS statement.

If missing values or missing weights are present in your data, the number of strata, the number of observations, and the number of clusters are counted based on the observations in non-empty strata. See the section “[Missing Values](#)” on page 4333 for details. For degrees of freedom in domain analysis, see the section “[Domain Statistics](#)” on page 4342.

Confidence Limits for the Mean

If you specify the keyword CLM, the procedure computes two-sided confidence limits for the mean. Also, the procedure includes the confidence limits by default if you do not specify any [statistic-keywords](#) in the PROC SURVEYMEANS statement.

The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\hat{Y} \pm \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha/2}$$

where \hat{Y} is the estimate of the mean, $\text{StdErr}(\hat{Y})$ is the standard error of the mean, and $t_{df, \alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the t distribution with df calculated as described in the section “[t Test for the Mean](#)” on page 4339.

If you specify the keyword UCLM, the procedure computes the one-sided upper $100(1 - \alpha)$ confidence limit for the mean:

$$\hat{Y} + \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}$$

If you specify the keyword LCLM, the procedure computes the one-sided lower $100(1 - \alpha)$ confidence limit for the mean:

$$\hat{Y} - \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}$$

Coefficient of Variation

If you specify the keyword CV, PROC SURVEYMEANS computes the coefficient of variation, which is the ratio of the standard error of the mean to the estimated mean.

$$cv(\bar{Y}) = \text{StdErr}(\hat{Y}) / \hat{Y}$$

If you specify the keyword CVSUM, PROC SURVEYMEANS computes the coefficient of variation for the estimated total, which is the ratio of the standard deviation of the sum to the estimated total.

$$cv(Y) = \text{Std}(\hat{Y}) / \hat{Y}$$

Proportions

If you specify the keyword MEAN for a categorical variable, PROC SURVEYMEANS estimates the proportion, or relative frequency, for each level of the categorical variable. If you do not specify any [statistic-keywords](#) in the PROC SURVEYMEANS statement, the procedure estimates the proportions for levels of the categorical variables, together with their standard errors and confidence limits.

The procedure estimates the proportion in level c_k for variable C as

$$\hat{p} = \frac{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}^{(q)}}{\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}}$$

where $y_{hij}^{(q)}$ is the value of the indicator function for level $C = c_k$, defined in the section [“Definition and Notation”](#) on page 4336, and $y_{hij}^{(q)}$ equals 1 if the observed value of variable C equals c_k , and $y_{hij}^{(q)}$ equals 0 otherwise. Since the proportion estimator is actually an estimator of the mean for an indicator variable, the procedure computes its variance and standard error according to the method outlined in the section [“Variance and Standard Error of the Mean”](#) on page 4338. Similarly, the procedure computes confidence limits for proportions as described in the section [“Confidence Limits for the Mean”](#) on page 4340.

Total

If you specify the keyword SUM, the procedure computes the estimate of the population total from the survey data. The estimate of the total is the weighted sum over the sample.

$$\hat{Y} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}$$

For a categorical variable level, \hat{Y} estimates its total frequency in the population.

Variance and Standard Deviation of the Total

When you specify the keyword STD or the keyword SUM, the procedure estimates the standard deviation of the total. The keyword VARSUM requests the variance of the total.

PROC SURVEYMEANS estimates the variance of the total as

$$\widehat{V}(\hat{Y}) = \sum_{h=1}^H \widehat{V}_h(\hat{Y})$$

where if $n_h > 1$,

$$\widehat{V}_h(\hat{Y}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (y_{hi\cdot} - \bar{y}_{h\cdot\cdot})^2$$

$$y_{hi\cdot} = \sum_{j=1}^{n_{hi}} w_{hij} y_{hij}$$

$$\bar{y}_{h\cdot\cdot} = \left(\sum_{i=1}^{n_h} y_{hi\cdot} \right) / n_h$$

and if $n_h = 1$,

$$\widehat{V}_h(\widehat{Y}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

The standard deviation of the total equals

$$\text{Std}(\widehat{Y}) = \sqrt{\widehat{V}(\widehat{Y})}$$

Confidence Limits of a Total

If you specify the keyword CLSUM, the procedure computes confidence limits for the total. The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

$$\widehat{Y} \pm \text{Std}(\widehat{Y}) \cdot t_{df, \alpha/2}$$

where \widehat{Y} is the estimate of the total, $\text{Std}(\widehat{Y})$ is the estimated standard deviation, and $t_{df, \alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the t distribution with df calculated as described in the section “[t Test for the Mean](#)” on page 4339.

If you specify the keyword UCLSUM, the procedure computes the one-sided upper $100(1 - \alpha)$ confidence limit for the sum:

$$\widehat{Y} + \text{Std}(\widehat{Y}) \cdot t_{df, \alpha}$$

If you specify the keyword LCLSUM, the procedure computes the one-sided lower $100(1 - \alpha)$ confidence limit for the sum:

$$\widehat{Y} - \text{Std}(\widehat{Y}) \cdot t_{df, \alpha}$$

Domain Statistics

When you use a DOMAIN statement to request a domain analysis, the procedure computes the requested statistics for each domain.

For a domain D , let I_D be the corresponding indicator variable:

$$I_D(h, i, j) = \begin{cases} 1 & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

Let

$$z_{hij} = y_{hij} I_D(h, i, j) = \begin{cases} y_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

The requested statistics for variable y in domain D are computed based on the values of z .

Domain Mean The estimated mean of y in the domain D is

$$\widehat{Y}_D = \left(\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} z_{hij} \right) / v_{\dots}$$

where

$$v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}$$

$$v_{\dots} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij}$$

The variance of \widehat{Y}_D is estimated by

$$\widehat{V}(\widehat{Y}_D) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y}_D)$$

where if $n_h > 1$,

$$\widehat{V}_h(\widehat{Y}_D) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (r_{hi\cdot} - \bar{r}_{h\cdot})^2$$

$$r_{hi\cdot} = \left(\sum_{j=1}^{m_{hi}} v_{hij} (z_{hij} - \widehat{Y}_D) \right) / v_{\dots}$$

$$\bar{r}_{h\cdot} = \left(\sum_{i=1}^{n_h} r_{hi\cdot} \right) / n_h$$

and if $n_h = 1$,

$$\widehat{V}_h(\widehat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

Domain Total The estimated total in domain D is

$$\widehat{Y}_D = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} v_{hij} z_{hij}$$

and its estimated variance is

$$\widehat{V}(\widehat{Y}_D) = \sum_{h=1}^H \widehat{V}_h(\widehat{Y}_D)$$

where if $n_h > 1$,

$$\widehat{V}_h(\widehat{Y}_D) = \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (z_{hi\cdot} - \bar{z}_{h\cdot\cdot})^2$$

$$z_{hi\cdot} = \sum_{j=1}^{m_{hi}} v_{hij} z_{hij}$$

$$\bar{z}_{h\cdot\cdot} = \left(\sum_{i=1}^{n_h} z_{hi\cdot} \right) / n_h$$

and if $n_h = 1$,

$$\widehat{V}_h(\widehat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}$$

Degrees of Freedom For domain analysis, PROC SURVEYMEANS computes the degrees of freedom for t tests as the number of clusters in the non-empty strata minus the number of non-empty strata. When the sample design has no clusters, the degrees of freedom equals the number of observations in non-empty strata minus the number of non-empty strata. As discussed in the section “[Missing Values](#)” on page 4333, missing values and missing weights can result in empty strata. In domain analysis, an empty stratum can also occur when the stratum contains no observations in the specified domain. If no observations in a whole stratum belong to a domain, then this stratum is called an empty stratum for that domain.

For example,

```
data new;
  input str clu y w d;
  datalines;
1 1 . 40 9
1 2 2 . 9
1 3 . 25 9
2 4 5 20 9
2 5 8 15 9
3 6 5 30 7
3 7 9 89 7
3 8 6 23 7
;
proc surveymeans df nobs nclu nmiss;
  strata str;
  cluster clu;
  var y;
  weight w;
  domain d;
run;
```

Table 70.2. Calculations of *df* for Y

	Domain D=7	Domain D=9
Non Empty Strata	STR=3	STR=2
Clusters Used in the Analysis	CLU=6, CLU=7, and CLU=8	CLU=4 and CLU=5
<i>df</i>	$3 - 1 = 2$	$2 - 1 = 1$

Although there are three strata in the data set, STR=1 is an empty stratum for variable Y because of missing values and missing weights. In addition, no observations in stratum STR=3 belong to domain D=9. Therefore, STR=3 becomes an empty stratum as well for variable Y in domain D=9. As a result, the total number of non-empty strata for domain D=9 is one. The non-empty stratum for domain D=9 and variable Y is stratum STR=2. The total number of clusters for domain D=9 is two, which belong to stratum STR=2. Thus, for variable Y in domain D=9, the degrees of freedom for the *t* tests of the domain mean is $df = 2 - 1 = 1$. Similarly, for domain D=7, strata STR=1 and STR=2 are both empty strata, so the total number of strata is one (STR=3), and the total number of clusters is three (CLU=6, CLU=7, and CLU=8). Table 70.2 illustrates how domains affect the total number of clusters and total number of strata in the *df* calculation. Figure 70.8 shows the *df* computed by the procedure.

Output

Output Data Sets

Output data sets from PROC SURVEYMEANS are produced using ODS (Output Delivery System). ODS encompasses more than just the production of output data sets. For example, you can use ODS to manipulate the format of your output, the headers and titles of the tables, and the order of the columns in a table. For a more detailed description on using ODS, see Chapter 14, “Using the Output Delivery System.”

Displayed Output

By default PROC SURVEYMEANS displays a “Data Summary” table and a “Statistics” table. If you specify CLASS variables, or if you specify any character variables in the VAR statement, then the procedure displays a “Class Level Information” table. If you specify the LIST option in the STRATA statement, then the procedure displays a “Stratum Information” table. If you have a DOMAIN statement,

the procedure displays a “Domain Analysis” table. If you have a RATIO statement, the procedure displays a “Ratio Analysis” table.

Data and Sample Design Summary

The “Data Summary” table provides information on the input data set and the sample design. This table displays the total number of valid observations, where an observation is considered *valid* if it has nonmissing values for all procedure variables other than the analysis variables; that is, for all specified STRATA, CLUSTER, and WEIGHT variables. This number may differ from the number of nonmissing observations for an individual analysis variable, which the procedure displays in the “Statistics” table. See the section “Missing Values” on page 4333 for more information.

PROC SURVEYMEANS displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a STRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT statement

Class Level Information

If you use a CLASS statement to name classification variables for categorical analysis, or if you list any character variables in the VAR statement, then PROC SURVEYMEANS displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

Stratum Information

If you specify the LIST option in the STRATA statement, PROC SURVEYMEANS displays a “Stratum Information” table. This table displays the number of valid observations in each stratum, as well as the number of nonmissing stratum observations for each analysis variable. The “Stratum Information” table provides the following for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum

- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- N Obs, which is the number of valid observations
- Variable, which lists each analysis variable name
- Levels, which identifies each level for categorical variables
- N, which is the number of nonmissing observations for the analysis variable
- Clusters, which is the number of clusters, if you specify a CLUSTER statement

Statistics

The “Statistics” table displays all of the statistics that you request with [statistic-keywords](#) described on page 4326 in the PROC SURVEYMEANS statement. If you do not specify any statistic-keywords, then by default this table displays the following information for each analysis variable: the sample size, the mean, the standard error of the mean, and the confidence limits for the mean. The “Statistics” table may contain the following information for each analysis variable, depending on which statistic-keywords you request:

- Variable name
- Level, which identifies each level for categorical variables
- N, which is the number of nonmissing observations
- N Miss, which is the number of missing observations
- Minimum
- Maximum
- Range
- Number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the t test
- Mean
- Std Error of Mean, which is the standard error of the mean
- Var of Mean, which is the variance of the mean
- t Value, for testing H_0 : population MEAN = 0
- $\text{Pr} > |t|$, which is the two-sided p -value for the t test
- $100(1 - \alpha)\%$ CL for Mean, which are two-sided confidence limits for the mean
- $100(1 - \alpha)\%$ Upper CL for Mean, which are one-sided upper confidence limits for the mean
- $100(1 - \alpha)\%$ Lower CL for Mean, which are one-sided lower confidence limits for the mean

- Coeff of Variation, which is the coefficients of variation for the mean and the sum
- Sum
- Std Dev, which is the standard deviation of the sum
- Var of Sum, which is the variance of the sum
- $100(1 - \alpha)\%$ CL for Sum, which are two-sided confidence limits for the sum
- $100(1 - \alpha)\%$ Upper CL for Sum, which are one-sided upper confidence limits for the sum
- $100(1 - \alpha)\%$ Lower CL for Sum, which are one-sided lower confidence limits for the Sum

Domain Analysis

If you use a DOMAIN statement, the procedure displays statistics in each domain in a “Domain Analysis” table. A “Domain Analysis” table contains all the columns in the “Statistics” table, plus columns of domain variable values.

Note that depending on how you define the domains with domain variables, the procedure may produce more than one “Domain Analysis” table. For example, in the following DOMAIN statement

```
domain A B*C*D A*C C;
```

you use four definitions to define domains:

- A: all the levels of A
- C: all the levels of C
- A*C: all the interactive levels of A and C
- B*C*D: all the interactive levels of B, C, and D

The procedure displays four “Domain Analysis” tables, one for each domain definition. However, if you use ODS output statement to create an output data set for domain analysis, the output data set contains a variable `Domain` whose values are these domain definitions.

Ratio Analysis

The “Ratio Analysis” table displays all of the statistics that you request with [statistic-keywords in the PROC statement](#) described on page 4326. If you do not specify any statistic-keywords, then by default this table displays the ratio and its standard error. The “Ratio Analysis” table may contain the following information for each ratio, depending on which statistic-keywords you request:

- Numerator, which identifies the numerator variable of the ratio
- Denominator, which identifies the denominator variable of the ratio

- N, which is the number of observations used in the ratio analysis
- number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the t test
- Ratio
- Std Error of Ratio, which is the standard error of the ratio
- Var of Ratio, which is the variance of the ratio
- t Value, for testing $H_0 : \text{population RATIO} = 0$
- $\Pr > |t|$, which is the two-sided p -value for the t test
- $100(1 - \alpha)\%$ CL for Ratio, which are two-sided confidence limits for the Ratio
- Upper $100(1 - \alpha)\%$ CL for Ratio, which are one-sided upper confidence limits for the Ratio
- Lower $100(1 - \alpha)\%$ CL for Ratio, which are one-sided lower confidence limits for the Ratio

When you use the ODS output statement to create an output data set, if you use labels for your RATIO statement, these labels are saved in a variable Ratio Statement in the output data set.

ODS Table Names

PROC SURVEYMEANS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 70.3. ODS Tables Produced in PROC SURVEYMEANS

ODS Table Name	Description	Statement	Option
ClassVarInfo	Class level information	CLASS	default
Domain	Statistics in domains	DOMAIN	default
Ratio	Statistics for ratios	RATIO	default
Statistics	Statistics	PROC	default
StrataInfo	Stratum information	STRATA	LIST
Summary	Data summary	PROC	default

For example, the following statements create an output data set named MyStrata, which contains the “StrataInfo” table, and an output data set named MyStat, which contains the “Statistics” table for the ice cream study discussed in the section “Stratified Sampling” on page 4318:

```

title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
  strata Grade / list;

```

```

var Spending Group;
weight Weight;
ods output StrataInfo = MyStrata
           Statistics = MyStat;
run;

```

Examples

The “Getting Started” section on page 4315 contains examples of analyzing data from simple random sampling and stratified simple random sample designs. This section provides more examples that illustrate how to use PROC SURVEYMEANS.

Example 70.1. Stratified Cluster Sample Design

Consider the example in the section “Stratified Sampling” on page 4318. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on the average, and what percentage of students spend at least \$10 weekly for ice cream.

The example in the section “Stratified Sampling” on page 4318 assumes that the sample of students was selected using a stratified simple random sample design. This example shows analysis based on a more complex sample design.

Suppose that every student belongs to a study group and that study groups are formed within each grade level. Each study group contains between two and four students. [Table 70.4](#) shows the total number of study groups for each grade.

Table 70.4. Study Groups and Students by Grade

Grade	Number of Study Groups	Number of Students
7	608	1,824
8	252	1,025
9	403	1,151
Total	617	4,000

It is quicker and more convenient to collect data from students in the same study group than to collect data from students individually. Therefore, this study uses a stratified clustered sample design. The primary sampling units, or clusters, are study groups. The list of all study groups in the school is stratified by grade level. From each grade level, a sample of study groups is randomly selected, and all students in each selected study group are interviewed. The sample consists of eight study groups from the 7th grade, three groups from the 8th grade, and five groups from the 9th grade.

The SAS data set named `IceCreamStudy` saves the responses of the selected students:

```

data IceCreamStudy;
  input Grade StudyGroup Spending @@;
  if (Spending < 10) then Group='less';
  else Group='more';

```

```

      datalines;
7  34  7      7  34  7      7 412  4      9  27 14
7  34  2      9 230 15      9  27 15      7 501  2
9 230  8      9 230  7      7 501  3      8  59 20
7 403  4      7 403 11      8  59 13      8  59 17
8 143 12      8 143 16      8  59 18      9 235  9
8 143 10      9 312  8      9 235  6      9 235 11
9 312 10      7 321  6      8 156 19      8 156 14
7 321  3      7 321 12      7 489  2      7 489  9
7  78  1      7  78 10      7 489  2      7 156  1
7  78  6      7 412  6      7 156  2      9 301  8
;

```

In the data set `IceCreamStudy`, the variable `Grade` contain a student's grade. The variable `StudyGroup` identifies a student's study group. It is possible for students from different grades to have the same study group number because study groups are sequentially numbered within each grade. The variable `Spending` contains a student's response to how much he spends per week for ice cream, in dollars. The variable `GROUP` indicates whether a student spends at least \$10 weekly for ice cream. It is not necessary to store the data in order of grade and study group.

The SAS data set `StudyGroup` is created to provide PROC SURVEYMEANS with the sample design information shown in [Table 70.4](#):

```

data StudyGroups;
  input Grade _total_; datalines;
7 608
8 252
9 403
;

```

The variable `Grade` identifies the strata, and the variable `_TOTAL_` contains the total number of study groups in each stratum. As discussed in the section “[Specification of Population Totals and Sampling Rates](#)” on page 4334, the population totals stored in the variable `_TOTAL_` should be expressed in terms of the primary sampling units (PSUs), which are study groups in this example. Therefore, the variable `_TOTAL_` contains the total number of study groups for each grade, rather than the total number of students.

In order to obtain unbiased estimates, you create sampling weights using the following SAS statements:

```

data IceCreamStudy;
  set IceCreamStudy;
  if Grade=7 then Prob=8/608;
  if Grade=8 then Prob=3/252;
  if Grade=9 then Prob=5/403;
  Weight=1/Prob;

```

The sampling weights are the reciprocals of the probabilities of selections. The variable `Weight` contains the sampling weights. Because the sampling design is

clustered, and all students from each selected cluster are interviewed, the sampling weights equal the inverse of the cluster (or study group) selection probabilities.

The following SAS statements perform the analysis for this sample design:

```

title1 'Analysis of Ice Cream Spending';
title2 'Stratified Clustered Sample Design';
proc surveymeans data=IceCreamStudy total=StudyGroups;
  strata Grade / list;
  cluster StudyGroup;
  var Spending Group;
  weight Weight;
run;

```

Output 70.1.1. Data Summary and Class Information

Analysis of Ice Cream Spending Stratified Clustered Sample Design		
The SURVEYMEANS Procedure		
Data Summary		
Number of Strata		3
Number of Clusters		16
Number of Observations		40
Sum of Weights		3162.6
Class Level Information		
Class		
Variable	Levels	Values
Group	2	less more

Output 70.1.1 provides information on the sample design and the input data set. There are 3 strata in the sample design, and the sample contains 16 clusters and 40 observations. The variable `Group` has two levels, 'less' and 'more'.

Output 70.1.2. Stratum Information

```

-----

```

Output 70.1.2 displays information for each stratum. Since the primary sampling units in this design are study groups, the population totals shown in Output 70.1.2 are the total numbers of study groups for each stratum or grade. This differs from Figure 70.3 on page 4320, which provides the population totals in terms of students since students were the primary sampling units for that design. Output 70.1.2 also displays the number of clusters for each stratum and analysis variable.

Output 70.1.3. Statistics

Analysis of Ice Cream Spending Stratified Clustered Sample Design					
The SURVEYMEANS Procedure					
Statistics					
Variable	Level	N	Mean	Std Error of Mean	Lower 95% CL for Mean
Spending Group		40	8.923860	0.650859	7.517764
	less	23	0.561437	0.056368	0.439661
	more	17	0.438563	0.056368	0.316787

Statistics		
Variable	Level	Upper 95% CL for Mean
Spending Group		10.329957
	less	0.683213
	more	0.560339

Output 70.1.3 displays the estimates of the average weekly ice cream expense and the percentage of students spending at least \$10 weekly for ice cream.

Example 70.2. Domain Analysis

Suppose that you are studying profiles of the 800 top-performing companies to provide information on their impact on the economy. You are also interested in the company profiles within each market type. A sample of 66 companies is selected with unequal probability across market types. However, market type is not included in the sample design. Thus, the number of companies within each market type is a random variable in your sample. To obtain statistics within each market type, you should use domain analysis. The data of the 66 companies are saved in the following data set:

```

data Company;
  length Type $14;
  input Type$ Asset Sale Value Profit Employee Weight;
  datalines;

For each company in your sample,

- the variable `Type` identifies the type of market for the company.
- the variable `Asset` contains the company's assets in millions of dollars.
- the variable `Sale` contains sales in millions of dollars.
- the variable `Value` contains the market value of the company in millions of dollars.
- the variable `Profit` contains the profit in millions of dollars.
- the variable `Employee` stores the number of employees in thousands.
- the variable `Weight` contains the sampling weight.

The following SAS statements use PROC SURVEYMEANS to perform the domain analysis, estimating means and other statistics for the overall population and also for the subpopulations (or domain) defined by market type. The DOMAIN statement specifies `Type` as the domain variable:

```

title1 'Top Companies Profile Study';
proc surveymeans data=Company total=800 mean sum;
  var Asset Sale Value Profit Employee;
  weight Weight;
  domain Type;
run;

```

Output 70.2.1. Company Profile Study

Top Companies Profile Study				
The SURVEYMEANS Procedure				
Data Summary				
	Number of Observations		66	
	Sum of Weights		799.8	
Statistics				
Variable	Mean	Std Error of Mean	Sum	Std Dev
Asset	6523.488510	720.557075	5217486	1073829
Sale	4215.995799	839.132506	3371953	847885
Value	2145.935121	342.531720	1716319	359609

Example 70.3. Ratio Analysis

Suppose you are interested in the profit per employee and the sale per employee among the 800 top-performing companies in the data in the previous example. The following SAS statements illustrate how you can use PROC SURVEYMEANS to estimate these ratios:

```

title1 'Ratio Analysis in Top Companies Profile Study';
proc surveymeans data=Company total=800 ratio;
  var Profit Sale Employee;
  weight Weight;
  ratio Profit Sale / Employee;
run;

```

The RATIO statement requests the ratio of the profit and the sale to the number of employees.

Output 70.3.1. Estimate Ratios

Ratio Analysis in Top Companies Profile Study			
The SURVEYMEANS Procedure			
Ratio Analysis			
Numerator	Denominator	Ratio	Std Err
Sale	Employee	114.332497	20.502742
Profit	Employee	5.119698	1.058939

Output 70.3.1 shows the estimated ratios and their standard errors. Because the profit and the sale figures are in millions of dollars, and the employee numbers in thousands, the profit per employee is estimated as \$5,120 with a standard error of \$1,059, and the sale per employee is \$114,333 with a standard error of \$20,503.

Example 70.4. Analyzing Survey Data with Missing Values

As described in the section “Missing Values” on page 4333, the SURVEYMEANS procedure excludes an observation from the analysis if it has a missing value for the analysis variable or a nonpositive value for the WEIGHT variable.

However, if there is evidence indicating that the nonrespondents are different from the respondents for your study, you can use the DOMAIN statement to compute descriptive statistics among respondents from your survey data without imputation for nonrespondents. Note that although the variance estimation for respondents takes into account the assumption that the study population consists of distinct groups of respondents and nonrespondents, the degrees of freedom will not adjust for the nonrespondents because they are deleted from the computation. As a result, there are fewer degrees of freedom and wider confidence limits in comparison to counting

those nonrespondents for degrees of freedom. When the sample size and the number of respondents are large, the difference maybe ignored.

Consider the ice cream example in the section “Stratified Sampling” on page 4318. Suppose that some of the students failed to provide the amounts spent on ice cream, as shown in the following data set IceCream:

```

data IceCream;
  input Grade Spending @@; datalines;
7 7 7 7 8 . 9 10 7 . 7 10 7 3 8 20 8 19 7 2
7 . 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 .
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 . 8 13 7 . 9 . 9 11 7 2 7 9
;
data StudentTotals;
  input Grade _total_; datalines;
7 1824
8 1025
9 1151
;

```

Considering the possibility that those students who didn’t respond spend differently than those students who did respond, you can create an indicator variable to identify the respondents and non-respondents with the following SAS DATA step statements:

```

data IceCream;
  set IceCream;
  if Spending=. then Indicator='Nonrespondent';
  else do;
    Indicator='Respondent';
    if (Spending < 10) then Group='less';
    else Group='more';
  end;
  if Grade=7 then Prob=20/1824;
  if Grade=8 then Prob=9/1025;
  if Grade=9 then Prob=11/1151;
  Weight=1/Prob;

```

The variable Indicator identifies a student in the data set as either a respondent or a nonrespondent. The variable Group specifies whether a student spent more than \$10 among the respondents.

The following SAS statements produce the desired analysis:

```

title1 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCream total=StudentTotals mean sum;
  strata Grade / list;
  var Spending Group;
  weight Weight;
  domain Indicator;
run;

```

Output 70.4.1. Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

```

Analysis of Ice Cream Spending

The SURVEYMEANS Procedure

Chapter 71

The SURVEYREG Procedure

Overview

The SURVEYREG procedure performs regression analysis for sample survey data. This procedure can handle complex survey sample designs, including designs with stratification, clustering, and unequal weighting. The procedure fits linear models for survey data and computes regression coefficients and their variance-covariance matrix. The procedure also provides significance tests for the model effects and for any specified estimable linear functions of the model parameters. Using the regression model, the procedure can compute predicted values for the sample survey data.

PROC SURVEYREG computes the regression coefficient estimators by generalized least-squares estimation using element-wise regression. The procedure assumes that the regression coefficients are the same across strata and primary sampling units (PSUs). To estimate the variance-covariance matrix for the regression coefficients, PROC SURVEYREG uses the Taylor expansion theory for estimating sampling errors of estimators based on complex sample designs (Woodruff 1971; Fuller 1975; Särndal, Swenson, and Wretman 1992, Chapter 5 and Chapter 13). This method obtains a linear approximation for the estimator and then uses the variance estimator for this approximation to estimate the variance of the estimator itself.

PROC SURVEYREG uses the ODS (Output Delivery System) to place results in output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality.

Getting Started

This section demonstrates how you can use PROC SURVEYREG to perform a regression analysis for sample survey data. For a complete description of the usage of PROC SURVEYREG, see the section “[Syntax](#)” on page 4373. The “[Examples](#)” section on page 4395 provides more detailed examples that illustrate the applications of PROC SURVEYREG.

Simple Random Sampling

Suppose that, in a junior high school, there are a total of 4,000 students in grades 7, 8, and 9. You want to know how household income and the number of children in a household affect students’ average weekly spending for ice cream.

In order to answer this question, you draw a sample using simple random sampling from the student population in the junior high school. You randomly select 40 students and ask them their average weekly expenditure for ice cream, their household income, and the number of children in their household. The answers from the 40 students are saved as a SAS data set:

```

data IceCream;
  input Grade Spending Income Kids @@;
  datalines;
7 7 39 2 7 7 38 1 8 12 47 1
9 10 47 4 7 1 34 4 7 10 43 2
7 3 44 4 8 20 60 3 8 19 57 4
7 2 35 2 7 2 36 1 9 15 51 1
8 16 53 1 7 6 37 4 7 6 41 2
7 6 39 2 9 15 50 4 8 17 57 3
8 14 46 2 9 8 41 2 9 8 41 1
9 7 47 3 7 3 39 3 7 12 50 2
7 4 43 4 9 14 46 3 8 18 58 4
9 9 44 3 7 2 37 1 7 1 37 2
7 4 44 2 7 11 42 2 9 8 41 2
8 10 42 2 8 13 46 1 7 2 40 3
9 6 45 1 9 11 45 4 7 2 36 1
7 9 46 1
;

```

In the data set `IceCream`, the variable `Grade` indicates a student's grade. The variable `Spending` contains the dollar amount of each student's average weekly spending for ice cream. The variable `Income` specifies the household income, in thousands of dollars. The variable `Kids` indicates how many children are in a student's family.

The following PROC SURVEYREG statements request a regression analysis:

```

title1 'Ice Cream Spending Analysis';
title2 'Simple Random Sample Design';
proc surveyreg data=IceCream total=4000;
  class Kids;
  model Spending = Income Kids / solution anova;
run;

```

The PROC SURVEYREG statement invokes the procedure. The `TOTAL=4000` option specifies the total in the population from which the sample is drawn. The `CLASS` statement requests that the procedure use the variable `Kids` as a classification variable in the analysis. The `MODEL` statement describes the linear model that you want to fit, with `Spending` as the dependent variable and `Income` and `Kids` as the independent variables. The `SOLUTION` option in the `MODEL` statement requests that the procedure output the regression coefficient estimates. The `ANOVA` option requests that the procedure output the ANOVA table.

```

Ice Cream Spending Analysis

Regression Analysis for Dependent Variable Spending

Tests of Model Effects

Effect      Num DF      F Value      Pr > F
Model              4      119.15      <.0001
Intercept          1      153.32      <.0001
Income             1      324.45      <.0001
Kids               3         0.92      0.4385

NOTE: The denominator degrees of freedom for the F tests is 39.

```

Figure 71.2. Testing Effects in the Regression

Figure 71.2 displays the ANOVA table for the regression and the tests for model

effects. The effect `Income` is significant in the linear regression model, while the effect `Kids` is not significant at the 5% level.

Ice Cream Spending Analysis				
Simple Random Sample Design				
The SURVEYREG Procedure				
Regression Analysis for Dependent Variable Spending				
Estimated Regression Coefficients				
Parameter	Estimate	Standard Error	t Value	Pr > t
Intercept	-26.084677	2.46720403	-10.57	<.0001
Income	0.775330	0.04304415	18.01	<.0001
Kids 1	0.897655	1.12352876	0.80	0.4292
Kids 2	1.494032	1.24705263	1.20	0.2381
Kids 3	-0.513181	1.33454891	-0.38	0.7027
Kids 4	0.000000	0.00000000	.	.

NOTE: The denominator degrees of freedom for the t tests is 39.
Matrix X'X is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Figure 71.3. Regression Coefficients

The regression coefficient estimates and their standard errors and associated t tests are displayed in Figure 71.3.

Stratified Sampling

Suppose that the previous student sample is actually drawn using a stratified sample design. The strata are grades in the junior high school: 7, 8, and 9. Within strata, simple random samples are selected. Table 71.1 provides the number of students in each grade.

Table 71.1. Students in Grades

Grade	Number of Students
7	1,824
8	1,025
9	1,151
Total	4,000

In order to analyze this sample using PROC SURVEYREG, you need to input the stratification information by creating a SAS data set with the information in Table 71.1. The following SAS statements create such a data set called `StudentTotals`:

```
data StudentTotals;
  input Grade _TOTAL_;
  datalines;
7 1824
```

```

8 1025
9 1151
;

```

The variable `Grade` is the stratification variable, and the variable `_TOTAL_` contains the total numbers of students in each stratum in the survey population. PROC SURVEYREG requires you to use the keyword `_TOTAL_` as the name of the variable that contains the population total information.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information. For this example, the appropriate sampling weights are the reciprocals of the probabilities of selection. You can use the following data step to create the sampling weights:

```

data IceCream;
  set IceCream;
  if Grade=7 then Prob=20/1824;
  if Grade=8 then Prob=9/1025;
  if Grade=9 then Prob=11/1151;
  Weight=1/Prob;

```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following statements demonstrate how you can fit a linear model while incorporating the sample design information (stratification):

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution anova;
  weight Weight;
run;

```

Comparing these statements to those in the section “[Simple Random Sampling](#)” on page 4365, you can see how the `TOTAL=StudentTotals` option replaces the previous `TOTAL=4000` option.

The STRATA statement specifies the stratification variable `Grade`. The LIST option in the STRATA statement requests that the stratification information be included in the output. The WEIGHT statement specifies the weight variable.

```

Kids 4         0.000000     0.00000000     .         .

```

NOTE: The denominator degrees of freedom for the t tests is 37.
Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

Figure 71.7. Regression Coefficients

The regression coefficient estimates for the stratified sample, along with their standard errors and associated t tests, are displayed in [Figure 71.7](#).

You can request other statistics and tests using PROC SURVEYREG. You can also analyze data from a more complex sample design. The remainder of this chapter provides more detailed information.

Output Data Set

PROC SURVEYREG uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

For example, to save the “ParameterEstimates” table (Figure 71.7) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```

title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution;
  weight Weight;
  ods output ParameterEstimates = MyParmEst;
run;

```

The statement

```
ods output ParameterEstimates = MyParmEst;
```

requests that the “ParameterEstimates” table that appears in Figure 71.7 be placed in a SAS data set named MyParmEst.

The PRINT procedure displays observations of the data set MyParmEst:

```

proc print data=MyParmEst;
run;

```

Figure 71.8 displays the observations in the data set MyParmEst.

Ice Cream Spending Analysis Stratified Simple Random Sample Design						
OBS	Parameter	Estimate	StdErr	DenDF	tValue	Probt
1	Intercept	-26.086882	2.44108058	37	-10.69	<.0001

5	Kids 3	-0.526817	1.32748011	37	-0.40	0.6938
6	Kids 4	0.000000	0.00000000	37	.	.

Figure 71.8. The Data Set MyParmEst

The section “ODS Table Names” on page 4394 gives the complete list of the tables produced by PROC SURVEYREG.

Syntax

The following statements are available in PROC SURVEYREG:

```

PROC SURVEYREG < options > ;
  BY variables ;
  CLASS variables ;
  CLUSTER variables ;
  CONTRAST 'label' effect values
    < ... effect values > < / options > ;
  ESTIMATE 'label' effect values
    < ... effect values > < / options > ;
  MODEL dependent = < effects > < / options > ;
  STRATA variables < / options > ;
  WEIGHT variable ;

```

The PROC SURVEYREG and MODEL statements are required. If your model contains classification effects, you must list the classification variables in a CLASS statement, and the CLASS statement must precede the MODEL statement. If you use a CONTRAST statement or an ESTIMATE statement, the MODEL statement must precede the CONTRAST or ESTIMATE statement.

The CLASS, CLUSTER, STRATA, CONTRAST, and ESTIMATE statements can appear multiple times. You should only use one MODEL statement and one WEIGHT statement.

PROC SURVEYREG Statement

```

PROC SURVEYREG < options >;

```

The PROC SURVEYREG statement invokes the procedure. You can specify the following options in the PROC SURVEYREG statement:

ALPHA= α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

DATA=SAS-data-set

specifies the SAS data set to be analyzed by PROC SURVEYREG. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

RATE=*value* | *SAS-data-set***R=***value* | *SAS-data-set*

specifies the sampling rate as a non-negative *value*, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a non-negative *value* for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section [Specification of Population Totals and Sampling Rates](#) on page 4382 for more details.

The *value* in the RATE= option or the values of `_RATE_` in the secondary data set must be non-negative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYREG will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

TOTAL=*value* | *SAS-data-set***N=***value* | *SAS-data-set*

specifies the total number of primary sampling units in the study population as a positive *value*, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section [Specification of Population Totals and Sampling Rates](#) on page 4382 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

TRUNCATE

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of the CLASS, STRATA, and CLUSTER variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.

BY Statement

BY *variables* ;

You can specify a BY statement with PROC SURVEYREG to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. For more information on subpopulation analysis for sample survey data, refer to Cochran (1977).

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the SURVEYREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

CLASS Statement

CLASS | **CLASSES** *variables* ;

The CLASS statement specifies the classification variables to be used in the model. Typical class variables are TREATMENT, GENDER, RACE, GROUP, and REPLICATION. If you specify the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Concepts*. By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. In releases prior to Version 9, class levels were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this

previous behavior you can use the [TRUNCATE](#) option in the PROC SURVEYREG statement.

You can use multiple CLASS statements to specify classification variables.

CLUSTER Statement

CLUSTER | **CLUSTERS** *variables* ;

The CLUSTER statement specifies variables that identify clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*. By default, clusters are determined from the entire formatted values of the CLUSTER variables. Note that this represents a slight change from previous releases in the way in which clusters are determined. In releases prior to Version 9, clusters were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the [TRUNCATE](#) option in the PROC SURVEYREG statement.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

CONTRAST Statement

CONTRAST *'label' effect values* < / *options* > ;

CONTRAST *'label' effect values* < ... *effect values* > < / *options* > ;

The CONTRAST statement provides custom hypothesis tests for linear combinations of the regression parameters $H_0: \mathbf{L}\beta = 0$, where \mathbf{L} is the vector or matrix you specify and β is the vector of regression parameters. Thus, to use this feature, you must be familiar with the details of the model parameterization used by PROC SURVEYREG. For information on the parameterization, see the section “Parameterization of PROC GLM Models” on page 1787 in Chapter 32, “The GLM Procedure.”

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or a special notation using variable names and operators. For more details on how to specify an effect, see the section “Specification of Effects” on page 1784 in Chapter 32, “The GLM Procedure.”

For each CONTRAST statement, PROC SURVEYREG computes Wald’s F test. The procedure displays this value with the degrees of freedom, and identifies it with the

contrast label. The numerator degrees of freedom for Wald's F test equals $\text{rank}(\mathbf{L})$. The denominator degrees of freedom equals the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can use the DF= option in the MODEL statement to specify the denominator degrees of freedom.

You can specify any number of CONTRAST statements, but they must appear after the MODEL statement.

In the CONTRAST statement,

<i>label</i>	identifies the contrast in the output. A label is required for every contrast specified. Labels must be enclosed in single quotes.
<i>effect</i>	identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
<i>values</i>	are constants that are elements of \mathbf{L} associated with the effect.

You can specify the following options in the CONTRAST statement after a slash (/):

E

displays the entire coefficient \mathbf{L} vector or matrix.

NOFILL

requests no filling in higher-order effects. When you specify only certain portions of \mathbf{L} , by default PROC SURVEYREG constructs the remaining elements from the context. (For more information, see the section “Specification of ESTIMATE Expressions” on page 1801 in Chapter 32, “The GLM Procedure.”)

When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector or matrix \mathbf{L} as it is defined in the CONTRAST statement.

SINGULAR=value

specifies the sensitivity for checking estimability. If \mathbf{v} is a vector, define $\text{ABS}(\mathbf{v})$ to be the largest absolute value of the elements of \mathbf{v} . Say \mathbf{H} is the $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ matrix, and C is $\text{ABS}(\mathbf{L})$ except for elements of \mathbf{L} that equal 0, and then C is 1. If $\text{ABS}(\mathbf{L} - \mathbf{LH}) > C \cdot \text{value}$, then \mathbf{L} is declared nonestimable. The SINGULAR=value must be between 0 and 1, and the default is 10^{-4} .

As stated previously, the CONTRAST statement enables you to perform hypothesis tests $H_0: \mathbf{L}\boldsymbol{\beta} = 0$.

If the \mathbf{L} matrix contains more than one contrast, then you can separate the rows of the \mathbf{L} matrix with commas. For example, for the model

```
proc surveyreg;
  class A B;
  model Y=A B;
run;
```

with A at 5 levels and B at 2 levels, the parameter vector is

$$(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \alpha_4 \ \alpha_5 \ \beta_1 \ \beta_2)$$

To test the hypothesis that the pooled A linear and A quadratic effect is zero, you can use the following **L** matrix:

$$\mathbf{L} = \begin{bmatrix} 0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\ 0 & 2 & -1 & -2 & -1 & 2 & 0 & 0 \end{bmatrix}$$

The corresponding CONTRAST statement is

```
contrast 'A Linear & Quadratic'
  a -2 -1 0 1 2,
  a 2 -1 -2 -1 2;
```

ESTIMATE Statement

ESTIMATE *'label' effect values* < / options > ;

ESTIMATE *'label' effect values* < ... *effect values* > < / options > ;

You can use an ESTIMATE statement to estimate a linear function of the regression parameters by multiplying a row vector **L** by the parameter estimate vector $\hat{\beta}$.

Each term in the MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with a special notation using variable names and operators. For more details on how to specify an effect, see the section “Specification of Effects” on page 1784 in Chapter 32, “The GLM Procedure.”

PROC SURVEYREG checks the linear function for estimability. (See the [SINGULAR= option](#) described on page 4379).

The procedure displays the estimate $\mathbf{L}\hat{\beta}$ along with its standard error and *t* test. If you specify the CLPARM option in the MODEL statement, PROC SURVEYREG also displays confidence limits for the linear function. By default, the degrees of freedom for the *t* test equals the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can specify the degrees of freedom with the DF= option in the MODEL statement.

You can specify any number of ESTIMATE statements, but they must appear after the MODEL statement.

In the ESTIMATE statement,

label identifies the linear function **L** in the output. A label is required for every function specified. Labels must be enclosed in single quotes.

effect identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.

values values are constants that are elements of the vector **L** associated with the effect. For example, the following code forms an estimate that is the difference between the parameters estimated for the first and second levels of the CLASS variable A.

```
estimate 'A1 vs A2' A 1 -1;
```

You can specify the following options in the ESTIMATE statement after a slash (/):

DIVISOR=*value*

specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integers. For example, you can use

```
estimate '1/3(A1+A2) - 2/3A3' a 1 1 -2 / divisor=3;
```

instead of

```
estimate '1/3(A1+A2) - 2/3A3' a 0.33333 0.33333 -0.66667;
```

E

displays the entire coefficient vector **L**.

NOFILL

requests no filling in higher-order effects. When you specify only certain portions of the vector **L**, by default PROC SURVEYREG constructs the remaining elements from the context. (See the section “[Specification of ESTIMATE Expressions](#)” on page 1801 in [Chapter 32, “The GLM Procedure.”](#)) When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector **L** as it is defined in the ESTIMATE statement.

SINGULAR=*value*

specifies the sensitivity for checking estimability. If **v** is a vector, define $ABS(\mathbf{v})$ to be the largest absolute value of the elements of **v**. Say **H** is the $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ matrix, and **C** is $ABS(\mathbf{L})$ except for elements of **L** that equal 0, and then **C** is 1. If $ABS(\mathbf{L} - \mathbf{LH}) > C \times value$, then **L** is declared nonestimable. The SINGULAR=*value* must be between 0 and 1, and the default is 10^{-4} .

MODEL Statement

```
MODEL dependent = < effects > < / options >;
```

The MODEL statement specifies the dependent (response) variable and the independent (regressor) variables or effects. Each term in a MODEL statement, called an *effect*, is a variable or a combination of variables. You can specify an effect with a variable name or with special notation using variable names and operators. For more information on how to specify an effect, see the section “[Specification of Effects](#)” on page 1784 in [Chapter 32, “The GLM Procedure.”](#) The dependent variable must be numeric. Only one MODEL statement is allowed for each PROC SURVEYREG

statement. If you specify more than one MODEL statement, the procedure uses the first model and ignores the rest.

You can specify the following options in the MODEL statement after a slash (/):

ADJRSQ

requests the procedure to compute the adjusted multiple R-square.

ANOVA

requests the ANOVA table to be produced in the output. By default, the ANOVA table will not be printed in the output.

CLPARM

requests confidence limits for the parameter estimates. The SURVEYREG procedure determines the confidence coefficient using the ALPHA= option, which by default equals 0.05 and produces 95% confidence bounds. The CLPARM option also requests confidence limits for all the estimable linear functions of regression parameters in the ESTIMATE statements.

Note that when there is a CLASS statement, you need to use the SOLUTION option with the CLPARM option to obtain the parameter estimates and their confidence limits.

COVB

displays the estimated covariance matrix of the estimated regression estimates.

DEFF

displays design effects for the regression coefficient estimates.

DF=value

specifies the denominator degrees of freedom for the F tests and the degrees of freedom for the t tests. The default is the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of actual strata. The number of actual strata equals the number of strata in the data before collapsing minus the number of strata collapsed plus 1. See the section “Stratum Collapse” on page 4388 for details on “collapsing of strata.”

I

INVERSE

displays the inverse or the generalized inverse of the $X'X$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $X'WX$ matrix, where W is the diagonal matrix constructed from WEIGHT variable values.

NOINT

omits the intercept from the model.

SOLUTION

displays a solution to the normal equations, which are the parameter estimates. The SOLUTION option is useful only when you use a CLASS statement. If you do not specify a CLASS statement, PROC SURVEYREG displays parameter estimates by default. But if you specify a CLASS statement, PROC SURVEYREG does not display parameter estimates unless you also specify the SOLUTION option.

VADJUST=DF | NONE**VARADJ=DF | NONE****VARADJUST=DF | NONE**

specifies if you want to use degrees of freedom adjustment $(n - 1)/(n - p)$ in the computation of the matrix **G** for the [variance estimation](#) on page 4385. If you do not specify the VADJUST= option, by default, PROC SURVEYREG uses the degrees of freedom adjustment, that is equivalent to the VARADJ=DF option. If you do not wish to use this variance adjustment, you can specify the VADJUST=NONE option.

X**XPX**

displays the $X'X$ matrix, or the $X'WX$ matrix when there is a WEIGHT variable, where **W** is the diagonal matrix constructed from WEIGHT variable values. The X option also displays the crossproducts vector $X'y$, or $X'Wy$.

STRATA Statement

STRATA | STRATUM *variables* < / options > ;

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section [“Specification of Population Totals and Sampling Rates”](#) on page 4382 for more information.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric. By default, strata are determined from the entire formatted values of the STRATA variables. Note that this represents a slight change from previous releases in the way in which strata are determined. In releases prior to Version 9, strata were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the [TRUNCATE](#) option in the PROC SURVEYREG statement.

Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide*.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following options in the STRATA statement after a slash (/):

LIST

displays a “Stratum Information” table, which includes values of the STRATA variables, and the number of observations, number of clusters, population total, and sampling rate for each stratum. This table also displays stratum collapse information.

NOCOLLAPSE

prevents the procedure from collapsing, or combining, strata that have only one sampling unit. By default, the procedure [collapses](#) strata that contain only one sampling unit. See the section [“Stratum Collapse”](#) on page 4388 for details.

WEIGHT Statement

WEIGHT | **WGT** *variable* ;

The WEIGHT statement specifies the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYREG assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

Details

Missing Values

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYREG excludes that observation from the analysis. An observation is also excluded if it has a missing value for any STRATA variable, CLUSTER variable, dependent variable, or any variable used in the independent effects. The analysis includes all observations in the data set that have nonmissing values for all these design and analysis variables.

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. Once data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYREG. Refer to Cochran (1977) for more details.

Survey Design Information

Specification of Population Totals and Sampling Rates

If your analysis should include a finite population correction (*fpc*), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option. You cannot specify both of these options in the same PROC SURVEYREG statement. If you do not specify one of these options, the procedure does not use the *fpc* when computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the `RATE=value` option or the `TOTAL=value` option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the `RATE=SAS-data-set` option or the `TOTAL=SAS-data-set` option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the `DATA=` option.

The secondary data set must contain all the stratification variables listed in the `STRATA` statement and all the variables in the `BY` statement. If there are formats associated with the `STRATA` variables and the `BY` variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the `TOTAL=SAS-data-set` option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. Or if you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates.

The secondary data set must contain all `BY` and `STRATA` groups that occur in the primary data set. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option, or the values of `_RATE_` in the secondary data set, must be non-negative numbers. You can specify a sampling rate as a number between 0 and 1. Or you can specify a sampling rate in percentage form as a number between 1 and 100, and PROC SURVEYREG will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

Primary Sampling Units (PSUs)

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs. For more information, see the section “[Variance Estimation](#)” on page 4385. You can use the `CLUSTER` statement to identify the first stage clusters in your design. PROC SURVEYREG assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a `CLUSTER` statement, the procedure treats each observation as a PSU.

Computational Details

Notation

For a stratified clustered sample design, observations are represented by an $n \times (p+2)$ matrix

$$(\mathbf{w}, \mathbf{y}, \mathbf{X}) = (w_{hij}, y_{hij}, \mathbf{x}_{hij})$$

where

- w denotes the sampling weight vector
- y denotes the dependent variable
- \mathbf{X} denotes the design matrix. (When an effect contains only classification variables, the columns of \mathbf{X} corresponding to this effect contain only 0s and 1s; no reparameterization is made.)
- $h = 1, 2, \dots, H$ is the stratum number with a total of H strata
- $i = 1, 2, \dots, n_h$ is the cluster number within stratum h , with a total of n_h clusters
- $j = 1, 2, \dots, m_{hi}$ is the unit number within cluster i of stratum h , with a total of m_{hi} units
- p is the total number of parameters (including an intercept if the INTERCEPT effect is included in the MODEL statement)
- $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample

Also, f_h denotes the sampling rate for stratum h . You can use the TOTAL= option or the RATE= option to input population totals or sampling rates. See the section “Specification of Population Totals and Sampling Rates” on page 4382 for details. If you input stratum totals, PROC SURVEYREG computes f_h as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYREG uses these values directly for f_h . If you do not specify the TOTAL= option or the RATE= option, then the procedure assumes that the stratum sampling rates f_h are negligible, and a finite population correction is not used when computing variances.

Regression Coefficients

PROC SURVEYREG solves the normal equations $\mathbf{X}'\mathbf{W}\mathbf{X}\boldsymbol{\beta} = \mathbf{X}'\mathbf{W}\mathbf{y}$ using a modified sweep routine that produces a generalized (g2) inverse $(\mathbf{X}'\mathbf{W}\mathbf{X})^-$ and a solution (Pringle and Raynor 1971)

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^- \mathbf{X}'\mathbf{W}\mathbf{y}$$

where \mathbf{W} is the diagonal matrix constructed from WEIGHT variable values.

For models with class variables, there are more design matrix columns than there are degrees of freedom (DF) for the effect. Thus, there are linear dependencies among the columns. In this case, the parameters are not estimable; there is an infinite number of

least-squares solutions. PROC SURVEYREG uses a generalized (g2) inverse to obtain values for the estimates. The solution values are not displayed unless you specify the SOLUTION option in the MODEL statement. The solution has the characteristic that estimates are 0 whenever the design column for that parameter is a linear combination of previous columns. (Strictly termed, the solution values should not be called estimates.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Variance Estimation

PROC SURVEYREG uses the Taylor series expansion theory to estimate the covariance-variance matrix of the estimated regression coefficients (Fuller 1975). Let

$$\mathbf{r} = \mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

where the (h, i, j) th element is r_{hij} . Compute $1 \times p$ row vectors

$$\begin{aligned} \mathbf{e}_{hij} &= w_{hij} r_{hij} \mathbf{x}_{hij} \\ \mathbf{e}_{hi\cdot} &= \sum_{j=1}^{m_{hi}} \mathbf{e}_{hij} \\ \bar{\mathbf{e}}_{h\cdot\cdot} &= \frac{1}{n_h} \sum_{i=1}^{n_h} \mathbf{e}_{hi\cdot} \end{aligned}$$

and calculate the $p \times p$ matrix

$$\mathbf{G} = \frac{n-1}{n-p} \sum_{h=1}^H \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})' (\mathbf{e}_{hi\cdot} - \bar{\mathbf{e}}_{h\cdot\cdot})$$

PROC SURVEYREG computes the covariance matrix of $\boldsymbol{\beta}$ as

$$\hat{\mathbf{V}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{G} (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}$$

The factor $(n-1)/(n-p)$ in the computation of the matrix $\hat{\mathbf{G}}$ should reduce the small sample bias associated with using the estimated function to calculate deviations (Hidioglou *et al.* (1980)). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which p parameter are estimated. By default, the procedure will use this adjustment in the variance estimation. It is equivalent to specify the [VADJUST=DF option](#) in the MODEL statement. If you do not wish to use this multiplier in the variance estimation, you can specify the [VADJUST=NONE option](#) in the MODEL statement to suppress this factor.

Degrees of Freedom

PROC SURVEYREG produces tests for the significance of model effects, regression parameters, estimable functions specified in the [ESTIMATE](#) statement, and contrasts specified in the [CONTRAST](#) statement. It computes all these tests taking into account the sample design. The degrees of freedom for these tests differ from the degrees of freedom for the ANOVA table, which does not consider the sample design.

Denominator Degrees of Freedom

The denominator DF refers to the denominator degrees of freedom for F tests and to the degrees of freedom for t tests in the analysis. By default, the denominator DF equals the number of clusters minus the actual number of strata. If there are no clusters, the denominator DF equals the number of observations minus the actual number of strata. The *actual number of strata* equals

- one, if there is no STRATA statement
- the number of strata in the sample, if there is a STRATA statement but the procedure does not collapse any strata
- the number of strata in the sample after collapsing, if there is a STRATA statement and the procedure collapses strata that have only one sampling unit

Alternatively, you can specify the denominator DF using the `DF=` option on page 4380 in the MODEL statement.

Numerator Degrees of Freedom

The numerator DF refers to the numerator degrees of freedom for the Wald F statistic associated with an effect or with a contrast. The procedure computes the Wald F statistic for an effect as a Type III test; that is, the test has the following properties:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.

See the section “[Testing Effects](#)” on page 4386 for more information. The numerator DF for the Wald F statistic for a contrast is the rank of the \mathbf{L} matrix that defines the contrast.

Testing Effects

For each effect in the model, PROC SURVEYREG computes an \mathbf{L} matrix such that every element of $\mathbf{L}\boldsymbol{\beta}$ is estimable; the \mathbf{L} matrix has the maximum possible rank associated with the effect. To test the effect, the procedure uses the Wald F statistic for the hypothesis $H_0: \mathbf{L}\boldsymbol{\beta} = 0$. The Wald F statistic equals

$$F_{\text{Wald}} = \frac{(\mathbf{L}\hat{\boldsymbol{\beta}})'(\mathbf{L}'\hat{\mathbf{V}}\mathbf{L})^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

with numerator degrees of freedom equal to $\text{rank}(\mathbf{L})$ and denominator degrees of freedom equal to the number of clusters minus the number of strata (unless you have specified the denominator degrees of freedom with the `DF=` option in the MODEL statement; see the section “[Denominator Degrees of Freedom](#)” on page 4386). It is possible that the \mathbf{L} matrix cannot be constructed for an effect, in which case that effect is not testable. For more information on how the matrix \mathbf{L} is constructed, see the discussion in [Chapter 11](#), “The Four Types of Estimable Functions.”

Analysis of Variance (ANOVA)

PROC SURVEYREG produces an analysis of variance table for the model specified in the **MODEL** statement. This table is identical to the one produced by the GLM procedure for the model. PROC SURVEYREG computes ANOVA table entries using the sampling weights, but not the sample design information on stratification and clustering.

The degrees of freedom (DF) displayed in the ANOVA table are the same as those in the ANOVA table produced by PROC GLM. The Total DF is the total degrees of freedom used to obtain the regression coefficient estimates. The Total DF equals the total number of observations minus 1 if the model includes an intercept. If the model does not include an intercept, the Total DF equals the total number of observations. The Model DF equals the degrees of freedom for the effects in the MODEL statement, not including the intercept. The Error DF equals the total DF minus the model DF.

Multiple R-square

PROC SURVEYREG computes a multiple R-square for the weighted regression as

$$R^2 = 1 - \frac{SS_{\text{error}}}{SS_{\text{total}}}$$

where SS_{error} is the error sum of squares in the ANOVA table

$$SS_{\text{error}} = \mathbf{r}'\mathbf{W}\mathbf{r}$$

and SS_{total} is the total sum of squares

$$SS_{\text{total}} = \begin{cases} \mathbf{y}'\mathbf{W}\mathbf{y} & \text{if no intercept} \\ \mathbf{y}'\mathbf{W}\mathbf{y} - \left(\sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right)^2 / w_{\dots} & \text{otherwise} \end{cases}$$

where w_{\dots} is the sum of the sampling weights over all observations.

Adjusted R-square

If you specify the option ADJRSQ in the MODEL statement, PROC SURVEYREG computes an multiple R-square adjusted as the weighted regression as

$$\text{ADJRSQ} = \begin{cases} 1 - \frac{n(1 - R^2)}{n - p} & \text{if no intercept} \\ 1 - \frac{(n - 1)(1 - R^2)}{n - p} & \text{otherwise} \end{cases}$$

where R^2 is the multiple R-square.

Root Mean Square Errors

PROC SURVEYREG computes the square root of mean square errors as

$$\sqrt{\text{MSE}} = \sqrt{n \text{ SS}_{\text{error}} / (n - p) w_{\dots}}$$

where w_{\dots} is the sum of the sampling weights over all observations.

Design Effect

If you specify the DEFF option in the MODEL statement, PROC SURVEYREG calculates the design effects for the regression coefficients. The design effect of an estimate is the ratio of the actual variance to the variance computed under the assumption of simple random sampling.

$$\text{DEFF} = \frac{\text{Variance under the Sample Design}}{\text{Variance under Simple Random Sampling}}$$

Refer to Kish (1965, p. 258). PROC SURVEYREG computes the numerator as described in the section “[Variance Estimation](#)” on page 4385. And the denominator is computed under the assumption that the sample design is simple random sampling, with no stratification and no clustering.

To compute the variance under the assumption of simple random sampling, PROC SURVEYREG calculates the sampling rate as follows. If you specify both sampling weights and sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is calculated as

$$f_{\text{SRS}} = n / w_{\dots}$$

where n is the sample size and w_{\dots} (the sum of the weights over all observations) estimates the population size. If the sum of the weights is less than the sample size, f_{SRS} is set to zero. If you specify sampling rates for the analysis but not sampling weights, then PROC SURVEYREG computes the sampling rate under simple random sampling as the average of the stratum sampling rates.

$$f_{\text{SRS}} = \frac{1}{H} \sum_{h=1}^H f_h$$

If you do not specify sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is assumed to be zero.

$$f_{\text{SRS}} = 0$$

Stratum Collapse

If there is only one sampling unit in a stratum, then PROC SURVEYREG cannot estimate the variance for this stratum. To estimate stratum variances, by default the procedure collapses, or combines, those strata that contain only one sampling unit. If you specify the [NOCOLLAPSE](#) option in the STRATA statement, PROC SURVEYREG

does not collapse strata and uses a variance estimate of 0 for any stratum that contains only one sampling unit.

If you do not specify the NOCOLLAPSE option, PROC SURVEYREG collapses strata according to the following rules. If there are multiple strata that each contain only one sampling unit, then the procedure collapses, or combines, all these strata into a new pooled stratum. If there is only one stratum with a single sampling unit, then PROC SURVEYREG collapses that stratum with the preceding stratum, where strata are ordered by the STRATA variable values. If the stratum with one sampling unit is the first stratum, then the procedure combines it with the following stratum.

If you specify stratum sampling rates using the RATE=SAS-data-set option, PROC SURVEYREG computes the sampling rate for the new pooled stratum as the weighted average of the sampling rates for the collapsed strata. See the section “Computational Details” on page 4384 for details. If the specified sampling rate equals 0 for any of the collapsed strata, then the pooled stratum is assigned a sampling rate of 0. If you specify stratum totals using the TOTAL=SAS-data-set option, PROC SURVEYREG combines the totals for the collapsed strata to compute the sampling rate for the new pooled stratum.

Sampling Rate of the Pooled Stratum from Collapse

Assuming that PROC SURVEYREG collapses single-unit strata h_1, h_2, \dots, h_c into the pooled stratum, the procedure calculates the sampling rate for the pooled stratum as

$$f_{\text{Pooled Stratum}} = \begin{cases} 0 & \text{if any of } f_{h_l} = 0 \text{ where } l = 1, 2, \dots, c \\ \left(\sum_{l=1}^c n_{h_l} f_{h_l}^{-1} \right)^{-1} \sum_{l=1}^c n_{h_l} & \text{otherwise} \end{cases}$$

Contrasts

You can use the CONTRAST statement to perform custom hypothesis tests. If the hypothesis is testable in the univariate case, the Wald F statistic for $H_0 : \mathbf{L}\boldsymbol{\beta} = 0$ is computed as

$$F_{\text{Wald}} = \frac{(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})'(\mathbf{L}_{\text{Full}}'\hat{\mathbf{V}}\mathbf{L}_{\text{Full}})^{-1}(\mathbf{L}_{\text{Full}}\hat{\boldsymbol{\beta}})}{\text{rank}(\mathbf{L})}$$

where \mathbf{L} is the contrast vector or matrix you specify, $\boldsymbol{\beta}$ is the vector of regression parameters, $\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\mathbf{W}\mathbf{Y}$, $\hat{\mathbf{V}}$ is the estimated covariance matrix of $\hat{\boldsymbol{\beta}}$, $\text{rank}(\mathbf{L})$ is the rank of \mathbf{L} , and \mathbf{L}_{Full} is a matrix such that

- \mathbf{L}_{Full} has the same number of columns as \mathbf{L}
- \mathbf{L}_{Full} has full row rank
- the rank of \mathbf{L}_{Full} equals the rank of the \mathbf{L} matrix
- all rows of \mathbf{L}_{Full} are estimable functions
- the Wald F statistic computed using the \mathbf{L}_{Full} matrix is equivalent to the Wald F statistic computed using the \mathbf{L} matrix with any row deleted that is a linear combination of previous rows

If \mathbf{L} is a full-rank matrix, and all rows of \mathbf{L} are estimable functions, then \mathbf{L}_{Full} is the same as \mathbf{L} . It is possible that \mathbf{L}_{Full} matrix cannot be constructed for contrasts in a CONTRAST statement, in which case the contrasts are not testable.

Output

Displayed Output

The SURVEYREG procedure produces the following output.

Data Summary

By default, PROC SURVEYREG displays the following information in the “Data Summary” table:
